CASTRAMETATION.

CASTRAMETATION is, in its strict and limited sense, the art of tracing out and disposing of, advantageously and regularly, the different parts of a camp on the ground. But taken in its more indefinite and unlimited acceptation, it extends to and is connected with all the ordinary operations of the campaign, as well as the conducting and management of sieges. Under the first of these considerations, an able officer, in choosing situations for the encampment of his troops, will endeavour to derive advantages from every situation, of which the variety is almost endless and indefinite, that nature presents to his view, as plains, mountains, passes, hollow ways, ponds, marshes, rivers, particularly such as are navigable and commodious for the transportation of stores and provisions, rivulets fit for forming inundations, woods convenient for making abattes and furnishing abundance of palisades and fire-wood; positions advantageously situated for works, for commanding and keeping open his communications with those tracts or districts of country from which he draws his supplies of forage and provisions; for covering and protecting his convoys; for securing a sufficiency of ground commodious for drawing up his troops on in order of battle, if necessary, and for their facile and expeditious performance of all the requisite movements without disorder or confusion even in the face of the enemy; and posts well calculated for bridling the enemy's operations, and checking his inroads into his country, whilst they facilitate his incursions into the enemy's. He should not only be capable of discerning these advantages, but should also be able to turn them immediately to account without suffering the opportunity of profiting by them to escape him. And under the last of these considerations, when the besieging army is unavoidably so encamp'd, as is indeed oftener the case than otherwise, that the different parts of it are separated from one another by rivers, great or small, ravines, or other obstacles and obstructions, he should know how to open and esta-

lish such communications between them, in the most expeditious manner, as will render their co operations, in either covering, forwarding, and protecting the different branches of the approaches, or in checking and curbing the sallies of the besieged, as convenient, easy, and efficient as possible. He should not only be able to discern, almost immediately, the positions in the environs of the place most advantageously situated for facilitating these purposes, but ought to occupy them whether they be a little too near to or too far from the enemy's works, taking care to keep the rear of his camp (the form or figure of which he must change or vary from what is customary, but, at the same time, *secundum artem* to make it suit his situation and circumstances) out of the reach of their cannon. He should know how to determine without loss of time the precise distance from the works of the place he invests, necessary for the safety and security of his camp against annoyance from them, that he may avoid the unnecessary labour, delay, and trouble of throwing up too extensive lines of circumvallation. He should carefully guard against his camp's being looked into by commanding ground near any part of it in front, on either flank, or in the rear. For it is better to occupy such eminences with good redoubts or to make the lines themselves communicate with them, than to leave the camp exposed to danger or molestation. And in the disposition or arrangement of the line of circumvallation for its defence, he ought to avail himself of heights, rivers, ravines, steep banks, and slopes, dikes, ditches, pits, walls, buildings, fences, abattes, thickets, &c. and, in short, every thing that can be embraced by it, and from which any additional strength or advantage can be derived to it.

In every country its quarter-master general ought to be a man of the most extensive military knowledge and information, as ruinous consequences may result from his being a person of a different description. And the officers under him ought also to be men of the first intelligence. They

ought not only to understand how to trace out ground for troops to encamp in the usual or customary manner, but they ought also to be so far conversant in geometry and in the doctrine of ratios or relations, as to be able without confining themselves to the rules prescribed by any writer on castrametation, none of which are applicable to every situation, with promptitude and readiness to vary the form of an encampment in such a manner as to make it suit the circumstances they are placed in, preserving, at the same time, in the different parts of it order, regularity, and due proportion. They should possess knowledge enough to enable them to discern immediately which of two positions, apparently in other respects alike advantageous for an encampment, is capable of being secured and defended with the least trouble and difficulty. They ought to understand the principles of fortification, and particularly of irregular construction, without which the *camp d'artillerie* cannot be carried to much perfection. And they should, in short, be well acquainted with the doctrine of positions and the combinations of attack and defence, which, united, form the sublime part of war.

Every nation, or tribe of people, even the most savage and uncivilized, has had a particular mode of encamping. But by whom a regular method of forming an encampment was first introduced, cannot with certainty be determined. A little knowledge, however, of geometry, was necessary for tracing out a camp regularly; it is more than probable, that regular castrametation was first made use of in Egypt. The great numbers of people assembled together, and employed in digging the immense canals, and other prodigious public works in that country, must have been encamped, as they could not return home daily. The Israelites, before they left Egypt, must have been often and long encamped, and, of course, after the manner of the Egyptians. Moses gives us no account of the way in which they encamped, either in Etham, or near Pi Hahiroth, in front of Baal-zephon, before he carried them across the Red Sea. But in the second chapter of the book of Numbers he delivers a general one of what he was commanded to observe in regard both to their castrametation and order of march. They were ordered to pitch their tents, every man by his own camp, and by his own standard, throughout their several halts.

These, who were under the standard of Judah, viz. the tribes of Judah, Issachar, and Zebulun, to the amount of 186,400 fighting men, formed the east side of the camp, towards the rising of the sun. These, on descending, were to be first pitched, or led the van, and were commanded by Nahshon, Nethanel, and Uthai.

Those under the standard of Reuben, viz. the tribes of Reuben, Simeon, and Gad, amounting to 151,450 warriors, formed the south side of the camp. These, on ascending, were to be second pitched, and were commanded by Shizur, Shammuel, and Ishmai.

Those under the standard of Ephraim, viz. the tribes of Ephraim, Manasseh, and Benjamin, amounting to 128,100 combatants, formed the west side, and were commanded by Ephraim, Gamaliel, and Abidan. These, however, on a march, did not follow immediately those that formed the front side of the camp, but the Levites, who with the tabernacle followed the warriors under the standard of Reuben.

Those under the standard of Dan, viz. the tribes of Dan, Asher, and Naphtali, to the number of 157,600 fighting men, formed the north side, and were commanded by Aniezer, Pagiel, and Ahira. These, on a march, brought up the rear.

In the middle of that immense encampment, the Levites, to the number of 22,000, encamped with the tabernacle of the congregation at the fourth side of the camp, with Moses and Aaron and his sons in front of it, towards the east.

It is probable, nay almost evident, that this huge camp was a square, or nearly so. For although the number of fighting men that pitched their tents under the standard of Judah, on the east side of the camp, amounted to 186,400, exceeding the number of those who encamped towards the west, or on the opposite side of the camp, under the standard of Ephraim, by 7,200, yet the number of warriors encamped on the north side of the camp, under the standard of Dan, amounting to 157,600, exceeded the number of those encamped on the south side, under the standard of Reuben, by 6,150 only. Now had they encamped in the same manner as we must necessarily suppose they did, and with the same depth in each front or side, their camp would have been a trapezium, having its sides to one another as the numbers 186,400, 157,600, 151,450, 128,100. This, however, would have been a very awkward and inconvenient figure for it: but by making the depth of the encampment on the east side to that on the north side, as 186 to 157, and the depth of it on the west and south sides respectively as 108 and 131 to 107, they might easily have made their camp a square. And it is more than probable, that it was a perfect square when the ground allowed of it, for Moses was made in all the knowledge and learning of the Egyptians, and they were sufficiently acquainted with geometry to know that of all rectilinear figures with the same perimeter, the square contains the greatest area.

Moses neither tells us how their tents were arranged, nor whether they furnished their camp with an intrenchment. That fanciful French writer, however, M. de Folard, in his "Traité de l'Attaque et de la Défense des Places des Anciens," article third, roundly asserts, that Moses always intrenched his camps. In speaking of lines of circumvallation and countervallation, he uses the following words: "On ignore que des Egyptiens, des Juifs, des Assyriens, ou des Médes, l'en eût servi le premier. Je pen herois plutôt pour les premiers que pour les autres, parce que je les crois plus anciens. Moïse se ret enva toujours dans les camps. L'écriture ne dit pas qu'il eût le premier, qui se soit servi de ces sortes de precautions; et lorsqu'il le parle de l'invincible des villes on ne voit rien, qui puisse marquer ou faire conjecturer que c'eût pour la première fois."

Moses tells us, that the Israelites, on quitting their camp, moved in four large bodies, of three tribes each, with the Levites and the tabernacle of the congregation between the second and third of these divisions.

The Romans also, on quitting their camp, marched in five principal bodies or divisions, for the extraordinary ones led the van; next after them marched the allies of the right wing, who were followed by the baggage of both; after them marched the first of the two Roman legions, with its own baggage behind it; then followed the second legion with both its own baggage behind it, and that of the allies of the left wing, who closed the rear. The cavalry marched sometimes in the rear of the respective bodies to whom they belonged, and sometimes on the flanks of the bodies of burden loaded with the baggage, keeping them together, and covering them from wind. When any attack was expected to be made upon the rear, the extraordinaries of the allies were placed there, instead of leading the van. The two legions and the two wings of the allies changed their places daily on a march, which the four principal bodies of the Israelites do not appear to have done, that they might

might enjoy by turns the advantage of arriving first at water and forage. When they were threatened with any immediate danger, and were marching through an open country, they advanced in three parallel lines behind one another, with the baggage of each line in its front.

Before the end of a march, and the approach of the army to the place of encampment, a tribune, accompanied by some centurions, advanced to examine and survey the ground, to determine the situation of the campular tent, and on which side of it the legions could be most conveniently encamped.

As to the castrametation of the Romans, according to Polybius, and during the commonwealth, see the article CAMP. The French Encyclopedists, following Justin Lipsius, chiefly make it nearly an equilateral quadrangle or square; but Polybius makes it a perfect square.

As to the castrametation of the Greeks, we understand from Polybius that they had no invariable, fixed, or determinate method of encamping. Xenophon, in treating of the Lacedæmonian republic, delivers Lycurgus's sentiments respecting castrametation, and informs us, that that lawgiver regarding the four angles of a quadrangle, or square, as useless, enjoined the circular form for a camp, unless it were secured by a mountain, or had its rear covered by a wall or river. His words are these: "Ἐρω δὲ καὶ ἢ στρατοπέδουεσθαι ποιεῖται χρῆσιμὸν ἀνεκέρως διὰ μὲν γὰρ τὴν γῆναιαν πρὸ τετραγώνου ἀχρηστοῦν εἶναι, κενὸν στρατοπέδουεσθαι, εἰ μὴ ὄρος ἀσφαλὲς ἴη, ἢ πτερυγὸς, ἢ ποταμὸν ὀπισθεν ἔχουιν."

Even this mode of castrametation, delivered by Lycurgus, was not fixed or determinate, but might vary with the circumstances of ground and situations; and we have the authority of Polybius for asserting, that the Greeks in general, when they encamped, considered chiefly the natural strength of the position they chose for that purpose, and accommodated to it the admeasurements and disposition of the different parts of their camp, partly from anxiety to avoid the labour of throwing up an intrenchment round it, and partly from the persuasion that works raised by art are less secure than those that are made by nature. In compliance with what the nature of the ground demanded, they were accordingly obliged not only to give their camp occasionally every kind of figure, but also to vary the positions and dimensions of its several parts, as the place for each was favourable or otherwise. Hence, this judicious historian tells us, arose that great inconvenience, namely, that the Grecian soldier never knew either his own place in the camp, or that of the body to which he belonged. On the other hand, he says, the Romans willingly submitted to the toil of throwing up an intrenchment, and to other painful labours, for the sake of the advantage they found in employing a method of castrametation that was never changed, and which rendered all the parts of the camp familiar to the army.

The Romans also, on their marches, cheerfully underwent much greater fatigue for the security of their camps than the Greeks were willing to submit to, each soldier frequently carrying three or four palisades for the intrenchment. This was a labour, Polybius tells us, which in the discipline of the Grecian armies was regarded as impracticable; whereas the Romans performed it without much difficulty. The Greeks, he says, on their marches, were hardly able to support the toil of moving along their own bodies. But the Romans, after slinging their shields with the leathern braces behind their shoulders, took their javelins in their hands, and were at the same time able to carry the palisades. They also discovered more judgment both in the choice and shape of their palisades than the Greeks, whose aversion from labour

and fatigue must have frequently left their camps in a state of great infcurity.

Besides the account given by Polybius of the Roman method of encamping, there is a description of their castrametation, given on a mutilated ferol or label by Hyginus, who appears to have been a camp and land measurer in the time of Trajan and Hadrian, when the empire was in its highest pitch of glory, as Trajan had extended it beyond the Tigris on one side, and beyond the Danube on the other. Hygi us's fragment was first published in 1605, but in a form so defective and mutilated, as to be hardly intelligible. In 1662, it was published at Amsterdam, with a very curious, learned, and elaborate commentary on it by Rhabodus Hermannus Schelius.

In the time of Marius, the military affairs of the Romans without doubt underwent a considerable change, which probably affected their ancient system of castrametation, but to what extent it is impossible to determine. But the alterations then introduced gradually occasioned a great departure from their former rules and regulations. It is no wonder then that their castrametation, according to Hyginus, differs so materially as it does from that of Polybius. Though the empire of the Romans was at its utmost extent, and existed in full force and vigour, their language was on the decline, and its purity in a great measure lost. The legions, by residing long in the conquered countries, adopted by degrees the barbarisms of the natives, and became familiar to their manners and customs. The attaching of large bodies of mercenaries to them gave rise to a different establishment, both for their national and auxiliary troops; in the latter of whom they could not always place so much confidence as formerly, and occasioned the creation of many new officers and appointments, which rendered a new method of castrametation necessary. Hence, this writer makes use of terms that are not to be found in any other author, and seem to have been unknown in the time of Polybius. The ferol or label containing his rules of castrametation is entitled "Hygini Gromatici de Castrametatione Liber."

He informs us, that a complete army consisted of three legions, with their supplementa, or auxiliaries, making use of this number for the purpose of exemplifying or illustrating his castrametation, and observing at the same time that the largest army was composed of no more than five or six such legions. He tells us, that every camp, as often as circumstances will permit, should be one half longer than it is broad, or have its length to its breadth in the ratio of three to two. Such a camp he calls *castra tertiata*. He accordingly makes the length of a camp for three legions equal to 2,400 Roman feet, and its breadth equal to 1,600 feet. General Roy, however, says that the particular measures as given by him do not correspond exactly with these general dimensions, and makes the sum of them, as he has collected them from the original, give the length of the camp equal to 2,310 feet only, and the breadth equal to 1,620 feet, the one falling short of 2,400 feet by 90, and the other exceeding 1,600 by 20.

When the camp was longer in proportion to its breadth, than in the ratio of three to two, it was called *castra classica*, because a general sounding of all the martial instruments together became necessary, as the buccinum or bugle-horn sounded in front of the prætorium could not then be distinctly heard at the distant parts of the camp.

Hyginus divides the length of his camp into three unequal parts. By streets extending across the whole breadth of it. The first of these, lying in front of the prætorium, he calls the *prætentura*. The second, lying between the principal

street and the quintan street, and in the middle of which stands the prætorium, he calls the *latera prætorii*; and to the third, situated beyond the quintan street and behind the prætorium, he gives the name of *retentura*.

The principal street, according to him, was 60 feet broad, and had the middle of it before the centre of the prætorium distinguished by the name of *groma*, from the cross-staff, or some similar instrument, which was used for tracing out the right angles of the camp. And those employed in this business, or in making allotments of lands in the conquered countries for the veterans, were probably called *gromatici*. The prætorian street, leading from the *groma* perpendicularly to the principal street, is also 60 feet wide. The breadth of the quintan street is 30 feet as well as that of the sagular street, which runs quite along the four sides of the camp, dividing the interior part of it from the exterior, or that which lies between the said street and the intrenchment. But when an army consisted of five or six legions, the breadth of each of these streets was equal to 40 feet. The interval between the tents on the outside of the sagular street, and the intrenchment making part of the exterior division of the camp, is every where 60 feet wide. This camp commonly had only four gates, viz. the right and left principal gates, the decuman gate, and the prætorian gate. Hyginus says, that the decuman gate received its name from the tenth cohort of the legion's being encamped near it. General Roy, however, places this gate differently from Hyginus, and differs also from Schellus in several particulars in regard to the interior divisions and arrangement of the camp.

It was the practice of the Romans during the commonwealth to place their own legions in the centre, both in the camp and when drawn up in order of battle. Hyginus, however, places the most of the legionary troops in the exterior part of the camp without the sagular street, and nearest to the rampart, for the defence of which they were more to be depended on than the mercenaries, in whom they did not confide so much as they formerly used to do in their socii or allies. He alleges that the foreign troops, by being kept thus within, or surrounded by the Roman legions, were more easily rendered obedient and attentive to their duty. They certainly had it less in their power to desert, or carry intelligence to the enemy, than they would had they been encamped next to the intrenchment. The form of his camp null in a great measure have depended on the proportion which the number of the legionary troops bore to that of the mercenaries, or auxiliaries, since when the last was but small, the Roman cohorts could encamp with a greater depth and less extended front, leaving more space between

the sagular street and the rampart; and when it was great, with a smaller depth and a more extended front, leaving less space between the said street and the rampart.

Hyginus tells us, that a complete century of foot consisted of eighty men, and that one tent held eight men. When all the men of a century then were off duty, they would have required ten tents. But as part of each century was always on duty, they pitched only eight tents, leaving thereby sufficient room for that of the centurion. For every tent a space of 12 feet in length was allowed. The length of the ground then occupied by the men of the century and the centurion was equal to 120 feet. The breadth of the space allowed for each tent was equal to 10 feet. Five feet more were allotted for the arms, and nine for the bat-horses, or beasts of burden. The whole breadth therefore of the hemistrigium, or half-friga, amounted to 24 feet; and the length of it was what Hyginus terms *intabulino*. Another hemistrigium lying contiguous to this, but in an order reversed, that the horses might front those in the other, and feed at the same manger, made a breadth of 48 feet for one friga, to which, if a width of 12 feet along the whole length of the space occupied by it for a street, between it and the next friga be added, we get 60 feet. The whole space then, including the said street of 12 feet wide, allotted for one friga, or two hemistrigium, consisting of two centuries or 160 men, contained 120 multiplied by 60 feet, or 7200 square feet. And a cohort, which consisted of six centuries, occupied of course 21,600 square feet. For the Hyginian camp of a Roman army, composed of three legions, with their supplementa or auxiliaries, consisting of 42,626 men, see *Plate of Castrametation*, figs. 1, 2, 3.

It is evident that in the Hyginian camp the same number of troops occupied a much smaller space than they did in the Polybian camp. The Roman armies under their emperors were more impatient of labour and fatigue than they were under the commonwealth, which led to the shortening of the length of the intrenchment and the crowding of as many men as possible into a given space. They also got into the practice of employing a much greater proportion of cavalry to their number of infantry than they did before their government became imperial. And the cavalry were commonly exempted from working on the intrenchments. These and other causes made them depart gradually from their ancient system of castrametation, as described by Polybius, and make their camps sometimes rectangular, sometimes triangular, sometimes circular, sometimes oval, and, to avoid labour, give it different forms to suit the circumstances of advantageous ground, and the necessity of their situation.

CASTRAMENTATION.

Distribution of the troops in the Hyginian camp, containing three legions,
with their supplements, or auxiliaries.

In the Prætentura, or Front Division of the Camp.	Legi- onary foot.	Auxili- ary or other foot.	Total infan- try.	Horse.	Total.	Gener- al-tot- al.
Ten legionary cohorts of 480 each, placed without the sagular street	4,800					
Three legionary cohorts of the same number within that street	1,440					
One first cohort of the legion double in number to the ordinary cohorts	560		7,700			
The vexillarii of one legion attached to and encamped with this cohort	500				10,000	
Marines of Misenum		500				
Marines of Ravenna		800				
Attached to the hospital for the men, the veterinarium for the horses, including artificers and labourers of all sorts		1,000	2,300			15,216
Exploratores, or scouts				200		
Moorish horse				600		
Pannonian veredaries				800		
Four ala milliariae, or wings of horse, of 1000 each, from which, deducting 96 supernumerary horses belonging to the officers, there remain 904 for the effective establishment of each ala				3,616	5,216	
In the Prætorian, or Central Division of the Camp.						
Six legionary cohorts of 480 each, without the sagular street	2,880					
Two first cohorts of the legions within the sagular street, on the right and left, each consisting of 960 men	1,920		5,800			
The vexillarii of these two legions, encamped with their respective first cohorts, at 500 each	1,000				8,720	
Four prætorian cohorts, reckoned only at the establishment of the ordinary legionary cohorts, 480 each		1,920				
The primipilarii and evocati, who encamped with them, might amount to		1,000	2,920			11,750
Five quingenarian ala of 500 each, from which deducting 64 supernumerary horses, belonging to the officers, and their establishment is reduced to 436 horsemen in each ala					2,180	
Prætorian horse				400		
Singular, or select horse				450	3,030	
In the Retentura, or Rear Division of the Camp.						
Eight legionary cohorts of 480 each, without the sagular street	3,840		3,840			
Three milliarian cohorts of foot of 960 each		2,880				
Three quingenarian cohorts of foot of 480 each		1,440				
Two milliarian pedestrian equestrian cohorts, each consisting of 760 and 240 horse		1,520		480		
Four quingenarian pedestrian equestrian cohorts, each consisting of 380 foot and 120 horse		1,520		480		
Statores				200		15,660
Auxilia nationum						
{ Palmyreni		500				
{ Daci		700				
{ Getæ		900				
{ Cantabri		700				
{ Britones		500				
	17,340	16,080	33,420	9,206	26,066	42,626

N. B. Hyginus does not give the number of the cohorts imperatoris, or chief attendants on the emperor; neither are we told how many cohorts there were of the regulares, (riders or drivers), which, when they were to go out to assault the enemy, used to encamp in the prætoriana near the prætorians; but when detached to longer duty, were placed in the ænatoria, or rear division of the camp.

Though general Roy makes the division or distinction between the different cohorts, Hyginus does not mention any.

Hyginus places 24 of the prætoriana cohorts composed three legions, without the regular troops, in the exterior part of the encampment.

General Roy thinks that Hyginus by the *signa* meant the front of the cohort, and by *retia* its depth. If regard to the rows of tents he derives from Schellius, who makes them run parallel to the signal street, whereas he places them perpendicularly to it. He says that the width of the camp with a regular street was every where equal to 1260 feet; that the length of the prætoriana within the same street was equal to 720 feet; that the distance across the prætoriana from the principal to the quintan street, was also equal to 720 feet; but that the distance across the *tentura* was only equal to 480 feet, or two thirds of the distance of either of the other two parts. See §§s. 1, 2, and 3.

Of modern Campmetation.

The invention of gunpowder and the application of it to military purposes, have necessarily rendered modern campmetation very different from that of any nation among the ancients. The principal object of Europeans in forming their encampments is the convenience or facility of drawing up their troops at the heads of them. Hence it follows that we should encamp them in such a manner as to be able with expedition and without confusion, to assemble and parade them in the very disposition which is regarded as the best for fighting in the situation we happen to be in. The order of battle therefore should determine and regulate the order of encampment. Consequently, the place of each regiment in the line of battle should be at the head of its own encampment, and the extent of the line of battle from the right to the left of the camp should be equal to the front of the troops formed in line of battle, with the same intervals in the one as in the other. The front or principal line of the camp is commonly directed or laid out in such a manner as to face or look towards the enemy.

It being once admitted that camps should be encamped in the order in which they ought to fight, it is a difficult matter to deliver general rules for the advancement and the tracing of camps.

A camp does not always furnish a position, though a position occupied necessarily supports a camp.

The dispositions and the orders of battle unavoidably vary with the nature of the ground and situations. The arrangement of the troops in their companies or companies accordingly. The order of battle also frequently depends on the views and intentions, genius and capacity of the general, and on his fertility in stratagems and resources. That wonderful man and extraordinary general, Annibal, the son of the no less celebrated Amilcar Barca, made use of a different order of battle and arrangement of his troops in almost every engagement with the Romans. Whenever the ground and weather admitted of his employing stratagem against his enemies, he was sure to profit by it, as at Trebia and the Trasymene lake. And when he found no circumstances of ground, situation, or weather, that he could convert to his advantage, he changed the disposition of his troops and his order of battle, as at Cannæ.

Were there but one fixed and determinate order of battle, or method of arranging troops for action, there need be but one invariable rule of encamping, or method of campmetation. But nature delights in variety. Ground is infinitely various and diversified; and fire arms are by no means suited to all this diversity, or to the different circumstances and incidents of time. Before the discovery of gunpowder, the Roman arms, order of battle, and manner of fighting, were adapted to all times and to all sorts of ground, and were calculated for combatting the enemy with a select body, and for presenting a front to the enemy by a single row of men, from whatever quarter they might be suddenly attacked. The Macedonian phalanx, on the other hand, from which our manner of forming troops in files is manifestly derived, was adapted to only one time and place, and to one kind or determinate manner of action. It was sluggish and tardy in its movements, and its whole strength, like that of our infantry, consisted in its retaining an unbroken and entire body, or in the conjoint action of those who composed it. Whenever they were obliged to engage the Romans individually, they were sure to be defeated and destroyed. The phalanx could neither move over uneven and interrupted ground, nor engage on it without breaking and leaving intervals or openings for the troops engaged with it in close action, and furnished with arms and armour, alike calculated for single and joint combat, to rush in and attack those separated and broken parts, both on their flanks and in the rear. The phalanx, therefore, never engaged the Romans on ground uneven and irregular, without being defeated, and meeting its destruction. Of this, the battle of Cynosephale was a remarkable instance. The phalanx also, like our infantry, was not well adapted either to defensive or offensive operations in the dark, or during the time of night; whereas, the Roman arms and mode of fighting were alike suited both to day and night. The Macedonian phalanx, like a modern army in close action, when its fire becomes useless, required ground that was level, plain, naked, and free from every obstacle, such as fences, ditches, lanes, walls, woods, thickets, breaks, obliquities, brows of hills, channels of rivers and rivulets, &c. The troops in it lost all their strength and capacity of fighting when they engaged either in separate companies, or man with man. A Roman soldier, on the other hand, when once armed and ready for service, was equally fitted for combat in any time and in any place, or upon any appearance of an enemy, however sudden or unexpected, and always preserved the same power and the same capability of action, whether he engaged with the whole army, or only with a part of it, whether in a separate company or with a small number. Mankind in attempting to present themselves in closed and interrupted countries as they would be constantly breaking and getting into disorder whenever it met with the least barrier, retreat, resistance, or opposition. A few thousand active men, armed each with the Roman gladius and a light shield, would find very quiet, nay, almost constant opportunities of closing advantageously with the separated or broken parts of such a penetrating body of an enemy, and of occasioning a dreadful carnage among them with very little loss or injury to themselves. Were the infantry to fire on their closing with them, the broke would only increase their confusion and facilitate their retreat. If they attempted to defend themselves either individually or in separate and small bodies they would certainly perish. They would therefore be reduced to the alternative of either surrendering themselves prisoners without resistance, or of throwing away their arms, and running as fast as their legs could carry them;

CASTRAMETATION.

them; for they could not carry their muskets along with them and retire with half the celerity that troops armed in the other way could follow them. Were there any reason for apprehending an invasion of this country, ten thousand active men armed in this manner would be of more use for the purposes of defence than sixty thousand of either sharpshooters, or common infantry. But custom and prejudice, and perhaps ignorance too of the proper mode of defending it, may possibly prevent the adoption of such a measure. As to cavalry, it is manifest that they can be of but little use in either attacking or defending it, since there are but few situations in it where they could be brought to act with advantage and effect.

As the men in the phalanx had shields, or bucklers, as well as spears, the width or breadth of a file in it was equal to three feet. A Roman soldier standing under arms alone occupied three feet, but in order of battle he necessarily occupied six feet, in order to have the free use of his large shield on his left arm, and the gladius in his right hand in action.

Though the arrangement of troops in a camp must vary with the nature of the ground, it is customary to suppose for each corps of an army such a fixed or determinate order of battle as can be made use of on a plain or level ground. Such an order serves for forming the tableau, delineation, picture, or description of the force of the army, and for regulating the order of service in regard both to the superior officers, and the troops that they command.

The number of men that forms a battalion varies in different countries of Europe, and has varied at different times. The space necessary for constituting the breadth of a file also varies: some make it equal only to 22 inches, but others, perhaps with better reason, allow two feet for it, as the three ranks are thereby less confined in their fringes.

Troops are divided not only by battalions and squadrons, but also by regiments and brigades.

An army generally consists of infantry, cavalry, and artillery, and may be called or denominated the union or junction of the battalions, squadrons, and artillery. The formation or arrangement of these three corps constitutes the order of battle. And this name or appellation for the said arrangement comes from the principal design or intention of making it, which is always to give battle.

The number of lines, on which an army ought to engage, is not at all fixed or determined; for the ground, the disposition of the enemy, the number of troops, &c. may render material changes or alterations necessary. It is a point, indeed, that no determination can be come to, which will suit every circumstance of ground or situation.

An army, however, when drawn up in order of battle, is generally ranged in two lines with a corps of reserve behind them, and consisting like them of battalions and squadrons, to succour those parts that may be hard pressed and in danger of yielding or giving way. This corps is stronger or weaker as occasion requires. For the most part the infantry is posted in the centres of these lines, and the cavalry on the wings. The ground, however, makes it necessary sometimes to place the cavalry in the centre and the infantry on the wings, and sometimes part of the infantry on the flanks of the position, and the greatest part of the cavalry on one wing with the remainder of it behind the infantry. The common practice of posting the cavalry on the wings of the infantry, and in a line with it, seems to be in various respects improper and injudicious. It cannot advance quicker than the infantry without leaving its flanks of both uncovered and exposed. It cannot in such a position either protect the infantry or receive protection from it. Disposed

of in this manner it therefore renders the movements of the whole slow and tardy. It is usually alleged that the cavalry is posted on the wings of the infantry in order to cover its flanks. This, however, is a very bad reason, for cavalry cannot form a flank for itself, but infantry may. The arrangement of our different species of troops, and the forming of them in files after the manner of the phalanx, excludes every idea of quickness or celerity, which is the very life and soul of military manœuvres, and alone can render them successful.

It is generally a maxim in the order of battle to place the second line 900 feet at least, or 1000 feet behind the first, to prevent the enemy's balls or shot from reaching it. This distance may, and most probably will change during the course and progress of an engagement. Attention, however, should be paid to it in placing the troops in order of battle.

It is customary to place fewer battalions and squadrons in the second line than in the first, when the first is full, in order that the first, if routed or thrown into confusion, may have sufficient intervals to pass through for the purpose of recovering from their disorder, and regaining regularity and order.

All the infantry of Europe commonly fight *en lignes pleines*, or in continuous lines, without any intervals between the battalions, but such as are necessary for the guns, for each of which about 20 feet are usually allowed. When intervals are admitted between regiments that consist each of more than one battalion, or between brigades, an additional allowance of 40 feet is generally made.

Sometimes hussars and dragoons are placed out of the line to cover the flanks of the cavalry. This, however, is for the most part a bad and injudicious disposition; for cavalry never can be so disposed of as to afford an effectual cover and protection to the flanks of cavalry, though infantry may. They are said to be out of the line, because they ought to be posted a little behind the lines. All troops indeed, or bodies detached for any service, are said to be *hors de ligne*, or out of the line.

In the camp, the same distance or interval of 20 feet for each piece of artillery is allowed between the battalions, or ought to be, as in order of battle; and when the divisions are admitted between regiments, or brigades, 40 feet more are allowed.

The situation of the park of artillery is not precisely fixed or ascertained. It is customary, however, to place it for the most part either behind the centre of the second line of infantry at the distance of about 1000 feet from the same, and in a line with the reserve; or behind the reserve, at the same distance of about 1000 feet. On other occasions, as circumstances make it advisable, or necessary, it is placed towards the centre at a greater or less distance from the first line of infantry. For the form of a park of artillery, see *Plate, Castrametation, fig. 4.*

When an army then encamps in three lines, and the park of artillery is in a line with the reserve, the depth of the camp cannot well be less than from 2500 to 2750 feet; and when the park of artillery is about 1000 feet behind the reserve, the depth of the camp must be from about 3500 to 3750 feet.

The depth of the tents of a battalion depends on the manner in which the companies composing it are encamped, whether by a whole company, a half-company, or a quarter-company, in each row of tents perpendicular to the front of the encampment. But, including the tents of the officers, sutlers, and servants, the depth is usually about 200 feet, and that of a squadron is about 400 feet.

The front or necessary houses, of the first line, are usually about 200 feet beyond the *front de l'embarras* or *front* of the lines, which determines the extent or length of the camp, and on which are placed the colours and standards of the troops that occupy it: and those of the second line are commonly about 150 feet behind the officers' tents. There ought to be nothing, however, in front of the camp that can in the smallest respect interfere with the movements and the formation of the troops in order of battle.

The intervals between squadrons of cavalry are different in different countries. And their depth, when encamped, will, of course, be influenced by that of the camp, which, itself, is not regulated but by certain rules and arrangements founded on custom or usage.

If n be supposed to represent the number of men in a battalion, d , the number of men in a file, and b , the breadth or width of the file, the front of the battalion will be generally expressed by $\frac{n \times b}{d}$. Thus, if $b = 2$ feet, and $d = 3$, the

front of the battalion in feet will be equal to $\frac{2n}{3}$, which, when $n = 600$, gives 400 feet for the front of the battalion; when n is $= 800$, or the battalion is 800 strong, gives 533 $\frac{1}{3}$ feet for its front; and when n is $= 900$, or the battalion is 900 strong, gives 600 feet for its front; and so on. But if the width of the file be supposed equal only to 22 inches, or $\frac{11}{3}$ feet, and d be equal to 3, the front of the battalion

will be expressed by $\frac{11 \times n}{18}$ feet. And if, in this case, n be $= 600$, or the battalion 600 strong, its front will be equal to $\frac{11 \times 600}{18}$ feet $= \frac{1100}{3}$ feet $= 366$ feet 8 inches. If the battalion be 800 strong, its front, in this case, will be equal to $\frac{4400}{9}$ feet $= 488 \frac{2}{3}$ feet; and if it be 900 strong, its front will be $= 550$ feet; and so on. And whatever is the length of its front in order of battle, the same ought to be the front of its encampment, when the ground and circumstances will permit.

If d be supposed equal to 2, or the files to be only two men deep, which is as deep, perhaps, as they ever should be, when it is intended that all the men should fire without hurting or wounding one another, the length of the front of a battalion in each of the foregoing supposed cases will be just one-third greater. When the number of men in it is given, the length of its front will be as the breadth of the file directly, and the depth of the same in number of men inversely. When the number of men in it and the breadth of the file are given, the length of its front will be inversely as d , the depth of the file. And when both the breadth of the file, and its depth in men are given, the length of the front of the battalion will be directly as the number of men in it.

The breadth or width of a file of cavalry is generally equal to three feet. The Macedonians allowed three feet of their measure for the width of a file in their phalanx, when drawn up in order of battle; and the Romans allowed also three feet of their measure to a soldier when standing under arms, but six feet to him when in order of battle. If n then be supposed to denote the number of men in a squadron of cavalry, and d , as before, the depth of the file in men, its front will be expressed generally in feet, by $\frac{3n}{d}$, which, when $d = 3$, is simply equal to n . Hence, then, it appears, that the front of a squadron, drawn up three deep, is equal to as many feet as there are men in it, and that its

front, when it is drawn up only two deep, is equal to half as many more feet as there are men in it.

The width of the large streets in a camp depends also, in a great measure, on the mode of encamping the companies. For, if f denote the front, l , the length of a tent, n , the number of the rows of tents, r , the width of each of the small streets, m , their number, q , the number of the large streets, and v , the variable width of one of them, we shall have $v = \frac{f - ln - mr}{q}$.

The camp maxims most commonly delivered are the following:

To give the camp the same length of front that the troops occupy, when drawn up in order of battle, whatever be the width or depth of the file.

To make the troops encamp by battalions and squadrons, except the royal artillery, who usually encamp on the right and left of their parts, whereforever it is placed, with the train horses in the rear of the same.

To place the broad-waggons in the rear of the camp, and as near as possible, for the convenience of distributing the bread easily.

That the commander in chief should encamp in the centre of his army, or, at least, at such a convenient distance from it, that a speedy and easy communication may be kept up at all times between head-quarters and every part of the camp.

To pay particular attention to the convenience of winter fuel and storage, and to cleanliness, for the preservation of health among the troops.

The highest and most important branch of castrametation, however, consists in the choice of situations proper for encampments and for engagements. The doctrine of positions, indeed, and the combinations of attack and defence, form the sublime part of war. And in illustrating this subject, we conceive we cannot do better than adopt the concise observations of marshall Saxe, who, in point of natural endowments, genius, and talents as a commander, as well as of military information, acquired by experience, study, and reflection, was certainly inferior to no general that has appeared in modern times.

Of situations proper for the encampment of armies, and for engagements.

It is the part of an able general, to derive advantages from every different situation which nature presents to him; from plains, mountains, hollow ways, ponds, rivers, woods, and an infinite number of other particulars, all which are capable of rendering great services, when they are converted to proper purposes: but although they make so material an alteration, both in situation and circumstance, wherever they happen to be, yet, as such advantages are frequently overlooked, till the opportunity of profiting by them is lost, it may not be unreasonable to enter into some detail upon the subject.

Let us then, in the first place, suppose a piece of ground divided by a rivulet, and a chain of ponds. See *Plate, Castrametation*, n. fig. 5 and 6. AA represents the army marching up to attack BB, whose infantry is at first drawn up in one line to cover the ponds: but, as soon as the enemy arrives within reach, my infantry in the front of these ponds, (says the marshall,) marches back by the intervals or banks between them, to form a second line; and my cavalry is at the same time advanced upon the right, to keep in awe the enemy's left wing, which movement alone is sufficient to disconcert him: if he attempts to attack this cavalry, it is to repulse the intervals between the ponds, which are guarded by bodies of infantry, that are posted immediately behind them.

This

This manœuvre will have so long engaged the enemy's attention upon his left, that he will not have sufficient time to change his disposition, or to reinforce his right; because the moment my cavalry is arrived upon my right, I attack all that part of the enemy's line that lies between me and the rivulet, which very probably I shall throw into confusion. His right wing being thus defeated, the rest of his army will be assaulted in front and rear by my two wings of cavalry, and in flank by all my infantry. If he inclines in the least to the right, in order to present a front to my infantry, he will thereby expose his left flank to the troops which I have posted upon my right, and upon the intervals between the ponds; under these circumstances, therefore, it will be impossible for him to make any movement, without being thrown into confusion.

According to this disposition, I suppose the enemy's army to consist of double the strength of mine: and although it may be imagined, that the cavalry upon my right is in danger of being cut to pieces, yet the more the attention of the enemy is taken up with an object in his front, the more he will be entangled in the snare that is laid before him; for I shall thereby be furnished with a better opportunity of falling upon his rear; after which my cavalry will be more than commonly unfortunate, if it be not able to make good its retreat by the intervals between the ponds, where the enemy will certainly not dare to pursue it.

Fig. 7, represents the two armies in another situation, where AA is to attack BB: C, C, C, are three strong redoubts thrown up at the distance of three hundred paces in the front of BB, furnished each with two battalions, and every thing else that may be necessary for their defence: D represents some detached cavalry: E, E, are two flanking batteries: F, F, two battalions posted in two redoubts to cover the batteries. I suppose the enemy's army AA to be twice as powerful in numbers as BB; nevertheless, in what manner is he to attack me in this disposition? It is impossible for him to march up in line of battle, without being broken and disordered, till he has first rendered himself master of my redoubts; in attempting to do which, he will be exposed to a severe flanking fire from my two battalions; and to pass the redoubts, and leave them in his rear, will be impracticable: if then he resolves to attack them by detachments, I shall in like manner make others to maintain them; in which I must have considerably the advantage, on account of the damage that he will unavoidably sustain from my cannon: if he advances with his whole army against them, I give the signal for my cavalry, which is concealed behind the wood, to move up at full speed, and fall upon his rear; at which time I also march up, and charge him in front; being, therefore, at once embarrassed by the redoubts, thrown into some disorder, and attacked in rear, there is all the appearance of my obtaining an easy victory.

This is an excellent disposition, where you can be certain that the enemy is either inclined, or obliged to attack you; for one cannot possibly be too careful in avoiding every step that may correspond with any hopes or expectations of his. This is a maxim in war never to be departed from, but in extraordinary cases, where no fixed rules can be given. A good opportunity for engaging should never be neglected, merely because the situation may happen not to be strictly agreeable to your fancy; for you must form your disposition according as you find it, and decline the attack altogether, unless you can make it with advantage; by which I mean, unless your flanks are well covered; unless you can engage a small part of his army with a large part of yours; can amuse, or keep a check upon him, by the means of any

small river, marsh, or other obstacle that may lie between you; supported by circumstances of which nature, you can attack him with confidence, although considerably inferior in numbers, because you will risk nothing, and may obtain a great deal.

Suppose, for instance, his army, BB, to be divided by a river, in the manner represented in fig. 8, and that I am to attack him with AA in that situation; I shall, therefore, make the following disposition for it. With my right wing I shall keep in awe his left, and with my left try all efforts to defeat his right: according to appearances, I shall be able to pierce him in the part marked C, upon the bank of the river; for it is but reasonable to suppose, that the strong must overpower the weak; in consequence of which advantage, as the communication between the two divisions of his army will be thereby cut off, and the left, in which his principal strength consisted, be no longer able to sustain the right, he must be rendered incapable of maintaining his ground; and, finding himself exposed both in front and flank, will undoubtedly retire.—Let us proceed to another example.

A is the enemy's army which I am to attack with B: the rivulet between us is supposed to be every where fordable; and the encampment of A to be made upon its banks, as is usually the custom in such situations, as well on account of the protection which it naturally affords, as for the convenience of the water: the enemy being in this disposition, I arrive towards the evening, and encamp with B on the opposite side. As he will not be inclined to trust to the uncertain event of an immediate engagement, he will undoubtedly, therefore, not pass the rivulet, or quit the advantage of his post, to attack me in the night-time; on the other hand, I rather imagine that he will be altogether taken up in providing for the defence of it: on my side, I shall only leave one weak line opposite to him, and marching all night with the remainder, gain the position, C. I have nothing to fear from the enemy, in making this movement; for he will certainly not venture to pass the rivulet, or to leave his post unguarded, on bare surmise or conjecture only. The day arriving he discovers me upon his left flank, as well as in front; after which it will be impossible for him to make any disposition, or to form any order of battle, without being thrown into confusion; for I shall fall upon him before he can have sufficient time to finish it: but his attention will principally be taken up, in sustaining his post upon the rivulet, which I shall attack at the same time, with the troops that were left on the opposite side for that purpose: he will detach some brigades to oppose me upon the left, which, arriving *en detail*, and having to engage with a large body, drawn up in good order, will easily be repulsed; inasmuch that he will be in a manner totally defeated, before he can be even able to persuade himself, that the real attack was made on this side; and, after having thus at length discovered his mistake, he will cease to be in any kind of capacity to remedy it.

Fig. 9, represents another situation, in which the enemy's army, AAA, is supposed to be formed in separate bodies, and extended to a considerable distance along a large river, in order to cover a province, as is frequently the case. AAA is, therefore, to defend the river, and BBB is the offensive army, endeavouring to pass it; and extended in like manner upon the opposite borders. These large rivers have generally plains on both sides, bounded by mountains, out of which issue small ones, or rivulets, that are sometimes of a considerable size, and that discharge themselves into the greater: by the means, therefore, of such a rivulet, one must endeavour to build a bridge, unknown to the enemy; for

in this lies the great difficulty of passing all rivers; after having then prepared your bridge all along the rivulet, you are to throw it over that part of the river marked C, where you are to force your passage; in which, I take it for granted, you will be able to succeed, especially if you make at the same time two false attacks at the places marked D and E: the enemy will not dare to vacate any of his posts, neither will the general officer, situated in different quarters, execute any orders they may receive to that effect; for as, at this time, they will be engaged themselves, and as each will suppose it to be the real attack, they will from thence be induced, not unreasonably, to suppose, that their commander in chief had not been informed of it: during all this time the grand effort is making at the centre between the rivulet and the mountain, marked F. The first step to be taken after the passage, is to possess yourself of the eminences; by which means you divide the enemy, and having cut off his communications, he can hardly hope to time his arrival afterwards so well, as to be able to attack you on both sides at once; and although he even does, he will, nevertheless, be easily demolished: the circumstance of your being possessed of these advantages, without having suffered any loss in the obtaining of them, will add to his confusion; for, notwithstanding your passage should be disputed, yet the opposition you meet with can never be considerable enough to permit it; especially when you have used proper precautions, and made your disposition with judgment. After you have once taken post, and erected your bridge, for which four hours are a sufficient space of time, and as much more will be required for the passage of 10,000 men, you may allow the enemy twenty-four hours to penetrate into your real design, and twenty-four more to assemble either half of his army, at the place in which he has attacked you: but even this will be rendered impracticable, because I suppose you to be effectually covered, after you have passed, by the rivulet on the one side, and by the mountain on the other.

All the large rivers that I have seen produce a great variety of situations where passages of this kind may be executed; and smaller ones afford likewise the same; but they are seldom quite so commodious, because the pains and mountains which surround them are usually not so advantageous, nor the rivulets so considerable. In short, by discernment one may reap advantages from a thousand different sorts of situations; and a commander void of that cannot possibly be expected to do any great things, even with the most numerous armies.

The marshall concludes these remarks on the choice of situations for encampments and engagements with the following observations upon the battle of Malplaquet. If, instead of posting the French troops in bad entrenchments, the three woods over-against the hollow ground had been only cut down, and three or four redoubts thrown up in it, supported by a few bridges, I am of opinion (he says) that things would have taken a different turn: for, had the allies attacked them, they must have lost an infinite number of men, without ever being able to carry them. It is the property of the French nation to attack: but when a general is unwilling to depend altogether upon the exact discipline of troops, and upon that great order which, according to the present system, is always necessary to be observed in actions, he ought, by throwing up redoubts, to introduce the method of engaging *en detail*, and of attacking by brigades; in which he might certainly succeed very well. The first shock of the French is scarcely to be resisted; nevertheless it is the part of a general to be able, by the prudence of his disposition, to renew it: and no means can facilitate this so much as redoubts; for you can always

force the troops to follow them, and to oppose the enemy. Nothing can be more certain, therefore, or tend to dispirit him to that great degree, because he will be afraid, at every attack, of being exposed in flank: while, on the other hand, your own troops become thereby encouraged; for they are convinced that your reinforcements are sure, and that the enemy will not dare to pursue them beyond the redoubts. It is upon such a occasion that you might be able to reap the grand advantages from their vigour and impetuosity: but to post them behind entrenched works, is, in a manner, to occasion their defeat; or, at least, to deprive them of the means by which they might have conquered. That would have been the case of the French at Malplaquet, if marshall Villars had taken the same part of his army, and attacked the one half of that of the allies, which had been so imprudent, as to form a disposition in which it was totally separated from the other by a wood, without having any communication at the same time made between them: the flanks and rear, moreover, of the French army would have been uncovered, and you may be seen in the situation of it, represented in fig. 10.

There is more address required in making bad dispositions than may at first be imagined; provided they be such as are intentional, and so formed as to admit of being instantaneously converted into good ones. Nothing can so offend an enemy more, who has perhaps been anticipating a victory, than a stratagem of this kind; for he perceives your weakness, and draws up his army in the order in which he expects to benefit the most from it; but the attack is no sooner begun, than he discovers the imposition. I must repeat it, therefore, that nothing can possibly disconcert an enemy so much, or plunge him into errors so dangerous; for, if he does not change his disposition, he will infallibly be defeated; and the alternative, in the presence of his adversary, will be attended with the faire fatal consequences.

If the marshall had abandoned his entrenchment at the approach of the allies, and made his disposition in the manner represented in fig. 11, it appears to me that he would have succeeded much better.

CASTRATING *a book*, among *Book-sellers*, is the taking out of some leaf, sheet, or the like, which renders it imperfect, and unfit for sale. The word is also applied to the taking away of particular passages, on account of their obscenity, too great freedom with respect to government, &c.

CASTRATING is also used among *Gardeners*, in speaking of melons and cucumbers; where it signifies the same with PRUNING or PINCHING of other plants.

CASTRATION, in *Surgery*, from *castrum*, "quia castrum facit;" the operation of rendering any animal incapable of generating, by the excision of the testicles in male subjects, and of the ovaries in females. This operation is commonly named GELDING and SPAYING among farriers, who are in the constant practice of thus mutilating various brutes for domestic uses, &c. Even several of the watery tribe of animals have sometimes been castrated, for the purpose of rendering them more fat and luscious for the table of epicures!

This operation has been performed by the Turks, Persians, Egyptians, and Hebrews, time immemorial, especially upon their slaves, from motives of jealousy: nor was it unknown to the Greeks and Romans, as appears from the writings of certain ancient medical and fatical authors; and, even to the present day, the Italians are so barbarous as to castrate great numbers of male children, with a view to preserve their shrill voice for singing! See EUNUCH.

The effect on the physical constitution of a man is the same, whether the testicles be injured by contusion, so as to break down their natural texture; whether the spermatic vessels be obliterated, still leaving the testis entire; or, whether

ther those organs be wholly removed by excision. In any of these cases, the offence was regarded as so atrocious, by the old laws of England, as to amount to felony; "et lequitur aliquando poena capitalis, aliquando perpetuum exilium, cum omnium bonorum ademptione;" (Baft. fol. 144.); and this, says Judge Blackstone, although the crime of *mayhem* was committed upon the highest provocation: (Comment. vol. iv. b. iv. c. 15.) See МАУНТ. But, we presume, the law cannot affect regular-bred Surgeons who perform the operation, only with a view to the good of their patients; notwithstanding, a different opinion has been held by certain writers, who affirm, "that it is penal in Physicians and Surgeons to castrate even with consent of the party;" (See Encyclop. Brit. vol. v. p. 250, edit. ult.) It becomes, however, a dubious and nice point, on some occasions, to decide upon the necessity and probable advantages of castrating a man.

We shall here say nothing of the corresponding more cruel mutilation in women, as it is very properly exploded from surgical practice: and although we are told by Athenæus, Helychius, Suidas, Galen, Aristotle, and others, that the female ovaries (formerly called testicles) have been actually retrenched by some barbarians, it is doubtful whether most of the cases alluded to did not rather consist in padlocking, or INFIBULATION; which Cornelius Celsus describes, as having been exercised also on boys. But, for a more detailed history of the origin and extension of this practice, as an act of policy or refinement, we refer to vol. i. of M. Dujardin's Hist. de la Chirurgie, Introd. pp. 36-44, 4to. Paris, 1774; and to M. Mahon's posthumous work, entitled "Médecine Légale et Police Médicale," 8vo. vol. ii. Paris, 1801. We now shall offer a few remarks on this operation, as it concerns the practical surgeon.

Castration is advisable in any case, where the life of a person is considerably endangered by a change of structure and loss of function in the testicle; as well as in many other cases, where the removal of an indurated and greatly enlarged testis would materially contribute to the relief or accommodation of a patient. It can very rarely be requisite to extirpate a testicle for the existence merely of an abscess, or for varicose vessels of the spermatic chord; though this operation has been sometimes resorted to, under such circumstances. But, when it has been resolved on as proper to be done, the following are the most approved modes of operating:

After having shaved the hair from the affected side of the scrotum and pubes, the patient is placed upon a table of a proper height, with his head and shoulders somewhat elevated, his legs and thighs at some distance from each other, and his knees a little bent; and in this posture he must be secured by two assistants. Or, as Mr. Murinna advises, the patient may be placed upon a high and strong chair, whilst the operator sits upon a low one, or kneels down before him. The skin of the anterior surface of the scrotum is then drawn into a fold, in such a manner, that the incision by which this fold is to be separated, shall reach from the top to the bottom of the scrotum. The operator holds this fold at one end with the fingers of his left hand, whilst an assistant holds it at the other, and cuts it at once completely through with a bistoury. Mr. Theden draws the fold of the scrotum, with the aid of an assistant, as tight as the skin will admit; after which he thrusts his bistoury through this fold, with its edge turned upwards and the back directed towards the diseased testicle: he then raises the knife upwards, and thus cuts through the whole fold of the skin in the quickest manner, whereby he thinks the patient is spared a great deal of pain.

This incision may be so long, that its upper extremity shall reach above the abdominal ring, whilst the lower extremity terminates an inch higher than the base of the scrotum. Should the incision be found too small, it must immediately be enlarged either at its upper or lower extremity, as it ought to extend over the whole tumor, in order that the tunica vaginalis may also be cut through in the same direction. Although it is desirable that this incision should be made precisely in the middle of the fold, this is in some rare cases impracticable, on account of the distended blood vessels being situated there, the division of which would produce a violent hæmorrhage, when another place must be chosen for making the incision. But should these vessels occupy a very large extent, we are obliged to cut them through, in which case the bleeding arteries must be secured or compressed by an assistant, whilst the operator is making his second incision.

The lips of the wound are now drawn asunder at both sides, to the distance of some inches from each other, or the operator dissects them away from the tunica vaginalis, in order that he may gain more room. When there is any fluid contained in the tunica vaginalis, this must be divided from top to bottom, with the same knife, as in the hydrocele. If we now find the diseased testicle for the greater part detached, we lay hold of it with the left hand, separate it here wherever it is attached, and divide its stronger posterior adhesion, with the scalpel, in such a manner as at the same time to separate all the diseased substance that may be found there; after which the spermatic cord is separated above from all its adhesions, and the whole of the cellular substance dissected away from it. The spermatic cord being thus laid bare, the operator accurately examines it, and if it be in its natural condition, he immediately ties it very firmly, (with many strong waxed threads, twisted together), an inch above the diseased part, and then cuts off the testicle half an inch below the ligature. After this, the spermatic cord will be immediately retracted towards the abdominal ring, in which situation it must be kept without stretching it, and consequently the ligature, the end of which is fastened over the ossa pubes by means of adhesive plaster, must not be drawn tight, but held loose. By this means, and by the application of a little lint under the end of the spermatic cord that has been cut, it is prevented from having too much stress laid upon it, as well as from forming its adhesion too low.

In most cases, however, it might be advisable to detach the spermatic cord from above down to the place where it is intended to divide it, and not so disengage the testicle till after the cord has been tied. For the excision of the testicle is always combined with some degree of pain and spasm of the spermatic cord, which may be avoided by tying and dividing the spermatic cord, before we cut out the testicle.

Mr. Theden having (he says) observed various nervous affections, such as spasms and epileptic symptoms, to supervene upon the tight application of ligatures, adopted the *Tamponade*, the advantage of which he maintains upon the following grounds: After some hours the artery contracts so strongly that no hæmorrhage is any longer to be apprehended; the pain and irritation of the spermatic cord is avoided; a swelling of the spermatic cord, and a congection of fluids in the cellular substance situated on the outside of the peritonæum, and at the back, which may frequently give rise to fatal consequences, never take place when this method is adopted, as they do when ligatures are employed. He performs the operation in the following manner: he first lays a piece of agaric, equal in size to the circumference of the spermatic cord, upon its divided extremity, and over that

that a larger, which he presses chiefly upon that part where the spermatic artery lies, and then pulls them, with a very gentle pressure, towards the abdominal ring, so as not to occasion the smallest pain to the patient. He then applies close to the divided spermatic cord several bunches of seraped lint, covers all the wounded parts with the same substance, wets the whole with his arquebuse diluted with water, and again directs the assistant to place his finger upon the spermatic cord. Finally, he covers the whole of the dressings with compresses, which are also wetted with the arquebuse. For security's sake, he directs the spermatic cord to be kept constantly gently compressed, for the space of twenty-four hours, by assistants who relieve each other.

Mr. Le Blanc also believes, that the fatal consequences, which so frequently follow castration, generally depend upon the too great tightness with which the spermatic cord is tied. On this account, he directs that the ligatures should be drawn only moderately tight, and instead of drawing them tight, to apply again, and secure it upon the part for several hours, by a gentle pressure with the hand.

Mr. Warner stops the hæmorrhage after castration, by applying gentle pressure to the vessels, by means of his thumb and fore-finger, with which he lays hold of the vessel for the space of several minutes; he has also found the application of a small piece of linen to the orifice of the vessels, to answer his purpose without occasioning the slightest degree of pain.

But though the tamponade has been also used by other practitioners with success, it is, however, justly considered by the greater part as not perfectly safe. For reasons, which, though well known, are however very important, Mr. Marshall condemns it in the strongest terms, and recommends tying as the safest remedy; but the method according to which he performs this operation, has something peculiar to itself, which will scarcely come into general use. He considers the prevention of the retraction of the spermatic cord into the abdominal ring, as the principal cause of all the troublesome symptoms. He therefore always separates the spermatic cord as high as the abdominal ring, loosening both it and the testicle from all its adhesions with the neighbouring parts, by means of his finger or a sharp instrument. He then divides the spermatic cord, an inch below the abdominal ring, and ties it, applying under the string, which consists of four waxed threads, two small compresses, in order to prevent its cutting the parts; besides which, he considers it to be very useful, to push the spermatic cord into the abdominal ring, which consequently cannot be done without making an incision into the ring.

Mr. Loder concludes from his experience, that the spermatic cord may be tied, without there being reason to apprehend dangerous consequences, provided we use the precaution first to separate it from the neighbouring parts to which it adheres, and tie it, with a broad ligature, gradually, and not tighter than is necessary. For this purpose, he uses a ligature, consisting of five or six strong threads, which he applies loose round the spermatic cord, after having separated both that and the testicle completely from all the surrounding cellular substance; he then draws the spermatic cord gently forward, cuts it through with a pair of scissors, and gradually tightens the ligature till the hæmorrhage ceases, upon which he makes a second knot, and cuts off the ends of the ligature so as still to leave some inches of the threads hanging out of the wound. For the sake of greater security, he applies, besides this ligature, sometimes another narrower one in a similar manner.

Mr. Murrina, however, is of a contrary opinion. The ligature, which with him is formed of three strong waxed

threads, he introduces at the proper place under the exposed spermatic cord, and fastens it anteriorly, with a double knot, in such a manner, as to draw the whole string as tight as possible, in order that all the parts included in the ligature may be, in a manner, crushed. The double knot he further secures by a single one, in order that it may not get loose. This violent method of tying, he says, at first produces exquisite pain; but that is only momentary, and afterwards nothing of it is felt. By this means almost all the violent symptoms, which generally succeed the operation, may be avoided, and the cure will be greatly accelerated. Only when the ligature has not been drawn sufficiently tight, or when, in consequence of the spermatic cord being much loaded with fat, or not sufficiently detached from the cellular substance, it again becomes loose before the nerve has been destroyed, the pain, and sometimes also the hæmorrhage, returns, which is frequently followed by nervous affections.

In order to prevent such accidents, he always applies a second similar ligature loose round the first, fastening the ends of the string, with a palfir, upon the patient's belly, in order that in case of necessity, particularly if a hæmorrhage should occur, they may be immediately used. When the patient, after the application of the ligatures, still feels pain in the spermatic cord, extending to the abdominal ring, the surgeon may conclude, that the ligatures have been applied too loose, or at least that the nerve has not been completely destroyed. In this case, he must renew the ligature, by applying a second string at the same place, and in order to prevent hæmorrhage and all the other symptoms, he should continue to tighten it, till the pain entirely remits. Mr. Richter entirely concurs in this opinion, and appeals to experience in proof of the assertion, that a ligature drawn perfectly tight produces far less violent symptoms, than one which is only moderately tight, and merely irritates, instead of altogether suppressing the vital actions. Mr. Pearson, of the Lock hospital, whose instructions will be hereafter introduced, is of the same opinion.

The method of stopping the hæmorrhage employed by Mr. Sibold, is done without including the nerve in the ligature, whereby he thinks all the dangerous symptoms may be obviated; as the stopping of the hæmorrhage is the only purpose for which the ligature is applied. He draws the spermatic artery forwards, with Bromfield's tenaculum, and ties it, without including any other part of the spermatic cord in the ligature, and without giving the least pain to the patient by the operation. Applying the ligature round the whole spermatic cord, he entirely condemns, and expresses his surprize that surgeons, notwithstanding all the dangerous consequences that have been found to arise from it, still hesitate to tie the spermatic artery quite separate from all the surrounding parts; an operation, which has not only always succeeded with him, but has likewise been always performed with great facility.

But after the excision of the testicle and the application of the ligature, should some other artery, besides the spermatic, either in the internal or external coats of the scrotum, bleed profusely, it is proper either to draw it forward with a needle and tie it also, or when this cannot be done, to apply pressure and styptic remedies.

When the scrotum is perfectly sound, or when we are sure that all the indurated parts have been entirely removed from it, we ought, as Mr. Fearon advises, to endeavour to effect the healing of the wound by the first intention; for which purpose the divided parts must be gently drawn together, in order to bring the lips of the wound in as accurate contact as possible, in which situation they must be

secured by means of adhesive plaster; or, as Mr. Loder advises, two futures may be applied, and between these long slips of adhesive plaster.

In other cases the wound is to be filled up with dry lint, and the lips of the wound drawn somewhat nearer together by means of long slips of adhesive plaster, which are covered with a pledget spread with ointment; over this is laid, a thick, soft and dry compress, and the whole is secured with the T bandage. After the dressings have been applied, the patient is put in bed, where he should lie with his feet constantly stretched out. Mr. Schmucker directs us to lay the patient, after the operation, in a horizontal posture upon mattresses stuffed with horse hair, in order that the divided portion of the spermatic cord may always keep the same position, and not contract when the knees have first been drawn upwards, and are afterwards extended. This horizontal position which is adopted by most practitioners, Mr. Murlinna conceives to be inconvenient, and therefore places the patient on his back, with his head and shoulders somewhat elevated, and his thighs moderately bent.

The lint, that has been introduced into the wound, must be suffered to remain there, till it spontaneously separates in consequence of suppuration, which generally happens on the fourth or fifth day; till which period the renewal of the dressings must also be deferred.

After every thing that can easily be separated has been extracted out of the wound, it must be carefully cleansed of the blood and matter, again loosely filled up with dry lint, and we must continue to draw the lips of the wound gently together, by means of adhesive plaster, without however exciting pain. Afterwards the dressings are to be renewed daily, or should the suppuration be very copious, twice a day, till a complete cure is obtained. The upper part of the wound, in which the spermatic cord is situated, must not be suffered entirely to close till the ligature has been drawn out; however, we must here also endeavour to prevent too violent a suppuration. After the ligature has been drawn out, the small wound must be cicatrized by the application of dry dressings and gentle pressure.

Upon this subject Mr. Pearson has offered some judicious observations. He says, "1. It is seldom necessary to remove any part of the serotum when the disease has not arrived at the ulcerated state. I have never seen the mere bulk of the part form a valid objection against leaving the whole of the integuments; for the serotum will generally contract within very moderate dimensions. But where the skin adheres to the testicle; where it has undergone a morbid alteration; or when the person has formerly been punctured several times for a hydrocele; the integuments will be found in such an indurated state, that it will be generally prudent to remove the altered and callous parts. However, the removal even of a considerable portion of the diseased serotum will not necessarily prevent us from healing the wound by the first intention; for the skin of this part dilates so readily, that the lips of the wound can be easily detained in contact by employing a few ligatures.

"2. Of all the methods that have been devised for the suppression of hæmorrhage, the application of a ligature round the bleeding vessel is the least painful, and the most certain; and in the operation of which we are now speaking, it is the easiest and most expeditious method, to tie the whole spermatic cord. It has frequently been delivered as the opinion of very respectable surgeons, that the most dangerous consequences are to be apprehended, from including the spermatic cord in the ligature. Some have forbidden us to include the cremaster muscle; others have advised the separation of the nerve; and some have only di-

rected us to avoid the *vas deferens*. Heister and other eminent surgeons, have declared the separation of the nerve from the blood-vessels, to be both unnecessary and impracticable; and they who advise such a practice, are charged with being ignorant of anatomy. It is however probable, that in Mr. Bromfield's method of securing the spermatic artery, the nerve may be generally avoided. I think this mode of proceeding is not entirely free from objection; for as the cord is divided at the beginning of the operation, it must be trusted to the fingers of the assistant till the diseased testicle be removed from the serotum; but it has more than once happened, that the cord has retracted, so as to escape from the fingers of the assistant; and the operator has consequently found great difficulty in securing the vessels under such unfavourable circumstances. Mr. Pott has directed us to tie the spermatic cord, after the operator has separated the *vas deferens* from the blood-vessels with his finger and thumb. When the spermatic cord is in a natural state, there will be little difficulty, or loss of time, in complying with this direction; but where it has been for some time diseased, the cellular membrane loses its mobility, so that the several parts are not easily separable: in such cases, it is of consequence to know whether the separation of the *vas deferens* be a part of the operation, which cannot be omitted without danger to the patient. It is the result of my experience hitherto, that no danger nor inconvenience whatever will ensue from including the *vas deferens* in the ligature: I am farther of opinion, that by following a contrary rule, the operation is made more complex, without being rendered either less painful or hazardous: and in this opinion I am supported by the authority of the most respectable writers on surgery.

"Some practitioners have thought it advisable to interpose a piece of lint, or some other soft substance between the ligature and the spermatic cord; and this was probably devised, either to prevent the waxed silk from cutting the vessels; or by thus increasing the lateral pressure, to render it unnecessary to draw the ligature so tight as to give much pain. When the spermatic artery is perfectly free from disease, and the cord is small and flexible, a very small degree of pressure, thus applied, will no doubt be sufficient to prevent a hæmorrhage. But where the spermatic artery is much enlarged, and the cord has become unnaturally dense and elastic, a very gentle pressure will be insufficient to close the bleeding vessels: and if the ligature be drawn very tight, we shall in a great measure forego the advantages that were proposed. Among the reasons that have been offered against including the whole spermatic cord in the ligature, it has been urged: 1st. That the patient always suffers exquisite pain when the cord is tied; and 2dly. That severe inflammation, great disorder of the contents of the abdomen, and even alarming convulsions, are among the symptoms that supervene to this mode of treatment. I do not pretend to deny, that violent pain, and sometimes dangerous consequences have attended the usual way of tying the spermatic cord; but I would beg leave to suggest, that these consequences may probably depend less upon including the whole cord in the ligature, than upon tying it too gently. If we merely proposed to restrain the hæmorrhage from the divided spermatic artery, a very moderate degree of pressure would be sufficient; but as a nerve, a muscle, &c. are also to be included, there ought to be the farther intention of intercepting all communication between the brain and the part below the ligature: if a sufficient force be exerted to produce this effect, the vitality, and consequently the sensibility of that portion of the cord will be quickly destroyed. I therefore always draw the knot as tight as possible; and al-

though

though the patient may complain at the moment, yet the pain very soon goes off; so that in no one instance where this method was followed, have I ever known the least subsequent inconvenience. All imperfect and partial pressure must necessarily be followed by the alarming symptoms which different practitioners have recorded. It would therefore be much better not to tie the cord at all, than to fail of drawing the ligature to such a degree of tightness, as immediately to kill the included part; and this additional reason for the observation may likewise be subjoined, that when the knot is left comparatively loose, the separation will not be completed as soon, as when the life of the parts that are compressed by it is instantly destroyed. When the cord is found at any time to dense and elastic, that the ligature applied in the usual way, proves insufficient to restrain the hemorrhage, we are advised to carry a needle with a double ligature through the middle of the cord, and tie it on both sides; this method will certainly be effectual, but the operator ought to be careful not to puncture the artery, when he passes the needle into the spermatic cord." See Pearson on Cancerous Complaints, p. 71. &c.

In most cases that require castration, the testicle is not only entirely diseased, but also so large as to fill the whole tunica vaginalis, which is itself either partly, or entirely diseased, or has only formed close adhesions with the testicle in various parts. This may generally be discovered before the operation, both by the eye and the touch, from the size, the weight, and especially the hardness of this part. When the tumor has besides a rugged surface, and occasions pain, we are enabled to distinguish the nature of the disease with still greater certainty; namely, that there is little or no water contained in the tunica vaginalis, and that this is for the greater part adhering to the testis, and diseased. In this case, after having divided the external integuments, and sufficiently laid bare the tumor, an incision, several inches in length, should be made into the tunica vaginalis, below the abdominal ring and over the spermatic cord, the fluid that may be contained in it discharged, the spermatic cord detached as much as possible from all its connection with the surrounding parts, and if it be free from disease, tied in the manner above-mentioned. The whole tunica vaginalis, with the diseased testicle, is then to be cut out of the cellular substance of the scrotum, after which the whole mass under the ligature is cut away with the scalpel.

Only it is necessary, in performing this operation, that we should take care not to injure either the septum scroti or the ferotum itself. In order that this accident may be avoided, we must draw the tunica vaginalis tight, by means of a double tenaculum, and direct the assistant to draw tight the external skin, in order that we may be able to cut as much as possible within the cellular substance. When, as happens in some rare cases, the tumor has formed adhesions with the ferotum, we must separate it with the scalpel, but not cut through the ferotum, as the indurated parts of the skin may be healed and preserved during the suppuration. In the still rarer case, when the tunica vaginalis adheres not only to the testicle, but also to the external skin, on its whole anterior side, in such a manner as to render it impossible to draw the skin into a fold; we must divide the external skin, by a perpendicular incision, lay bare the tunica vaginalis, and then perform its excision, as well as that of the testicle, after the manner above described.

Should the spermatic cord be indurated or diseased, which may readily be discovered by the sight and touch, it must be tied an inch above the diseased part. But should the cord be diseased as high up as the abdominal ring, it must

also be laid bare higher, the abdominal ring itself enlarged, the spermatic cord drawn tight, separated from all its connection with the parts in the abdominal ring, and tied as tight as possible above the diseased part in order to prevent the subsequent renewal of the disease, and effect a radical cure. As it is not to be expected that the disease will extend higher than the abdominal ring, we may also tie the cord, with hopes of a successful event, even though it should be diseased as high up as the abdominal ring.

This indurated and diseased state of the spermatic cord may also probably be discovered before we undertake the operation, as the larger size of the tumor, the manner in which it has been produced, and the length of time during which it has continued, will direct our attention to it. When therefore we find the tumor to extend into the abdominal ring, and that it is preternaturally hard and painful to the touch, without the patient's having previously been affected either with an oedema or interstinal hernia; the spermatic cord is in all probability diseased. As even in this case the operation has sometimes been successfully performed, and the patient's life preserved, by widening the abdominal ring, separating the spermatic cord, and then tying it; the surgeon ought also in such a case, provided the other circumstances be favourable, to perform that operation.

CASTRATION, in Rural Economy. See GELDING and SPAYING.

CASTRATION is a term which has been sometimes used by the older physicians to signify the correcting of violent medicines, especially purgatives. See CORRECTION and CORRECTORS.

CASTRATION also denotes the art of retrenching, or cutting away any part of a thing from its whole.

CASTRATO, *Ital.* a male singer, with a soprano or female voice, occasioned by a cruel act, which needs no further explanation than what is given under the article CASTRATION, which see. It is a delicate and difficult subject to discuss. The custom in the East has prevailed from the highest antiquity. The chamberlains of the Egyptian kings, in the time of the Pharaohs, were eunuchs; and in the East the practice of emasculation has long been general on the guardians of females in the harem of the great. Italy is the only country, perhaps, on the globe where the inhuman custom has prevailed of gratifying the auricular sense at the expense of humanity. The Italians pretend to have very severe laws against this inhuman practice; but evirati have been employed in the pontifical chapel to sing the soprano, or treble parts, ever since the establishment of the opera, in the beginning of the 17th century; till which period the treble parts were sung by Spaniards in falset, which see. The favour and fortune which some of the castrati have obtained by their voice, taste, and talents in singing, have stimulated fordid and unnatural parents to have their children mutilated in expectation of their aggrandizement, though the horrid operation does not give or improve a voice, but only preserves it from change at the time of puberty; and as not one boy in a 100 has a fine voice, though all boys have a shrill and effeminate voice previous to manhood; yet of all the unhappy children thus mangled, the number is very small of those who have voices fit for the theatre. And even when there is a voice, the want of genius, diligence, figure, and intelligence, will prevent their ever acquiring the favour or the pity of the public; and though they merit the utmost commiseration for the inhumanity of their barbarous parents, they are always treated with scorn and derision by the gross and vulgar part of society. See ΕΥΚΡΕΜ; where we shall

shall resume the subject, and detail the history and life of councils from the most remote antiquity to the establishment of the musical drama in Italy.

CASTREDE d'Alva, in *Geography*, a town of Portugal, in the province of Tras los Montes, on the Duero; 4 leagues S.E. of Elpadoacta.

CASTREL, or rather **KESTRIL**, in *Ornithology*, *falco tinnunculus* of Linnæus, which see.

CASTRENSIS, *Marli*. See *CAMP Dijeyses*.

CASTRENSIANI, or **CASTRENSES**, in *Antiquity*, an order of servants in the Greek emperor's household, to whom belonged the care and service of what related to his table and cloathing. They were thus called either on account of their attending the emperor, when in camp, or because they observed a sort of camp-discipline in the court; or rather because they were considered as soldiers, were paid as such, and had the privileges belonging to the military body.—The castrensiæ were also called "castrenses ministri," and "militæriani."

To this order belonged the bakers, butlers, waiters, fulcers, tilters, &c. They had a head, or superior, who was called "comes castrensis," which was a palatine dignity under the chamberlain.

CASTRES, in *Geography*, a city of France, and principal place of a district, in the department of the Tarn; before the revolution, the see of a bishop, suffragan of Alby. In the reign of Lewis XIII. the inhabitants were chiefly Protestants, and formed within themselves a kind of republic; but since that time the walls have been demolished, and the place laid open. It is a town of good trade, containing 15,380 inhabitants; those of the canton amount to 17,266: the territory comprehends 142½ kilometres, and 7 communes. Turquoise stones have been found in its neighbourhood. It is distant 34 miles from Toulouse. N. lat. 43° 40'. E. long. 2°.—Also, a town of France, in the department of the Gironde, and district of Cadillac; 10 miles S.E. of Bon leaux.

CASTREZZATO, a town of Italy, in the Bressian; 11 miles W. of Brescia.

CASTRI, a town of European Turkey, in Livadia, built on the site of the ancient Delphos, but has little remains of its former splendour. It contains about 200 houses, and the inhabitants are miserably poor; 14 miles N.W. of Livadia.

CASTRIES, a town of France, in the department of the Hérault, and chief place of a canton, in the district of Montpellier; 2 leagues N.E. of Montpellier. The place contains 560, and the canton 4934 inhabitants: the territory includes 105 kilometres, and 20 communes.

CASTRIES, *Bay of*, so called by Perouse, is situated in the North Pacific ocean, at the top of a gulf about 200 leagues from the strait of Sangaar, on the coast of Tartary; it affords deep water, and a safe commodious anchorage. N. lat. 51° 32'. E. long. 142° 28'. In this bay the furthest winds are more steady, more constant, and more oblique than in the seas of China, from which they proceed; because, being confined between two lands, their greatest variation cannot exceed two points to the eastward or westward. With a fresh breeze the sea rises to an alarming and dangerous height. The bay of Calicut alone, says Perouse, of all those we visited on the coast of Tartary, deserves that name. It affords a secure asylum against bad weather, and it would even be possible to winter there. The bottom is muddy, and shoals gradually from 12 to 5 fathoms, in approaching the shore, from which the breakers extend to three cables' length, so that it is very difficult to land, even in a boat, when the tide is low. No sea abounds more with

weeds and different species of fuci; and among the weeds vast quantities of salmon are caught, to the number of 2000 in a day, which are found in a rivulet that discharges itself at the top of the bay. The inhabitants of this coast are described as a very worthy and hospitable people. Their chief subsistence is salmon, prepared on the fire with a small grain, which is their most valued food. This grain is brought to them from the country of the Manchous, who dwell seven or eight days' journey from them, up the river Segalien, and who have a direct communication with the Chinese. Besides this grain they also bring from their country nankeens, both which they probably receive in exchange for oil, dried fish, and perhaps for some skins of bears or elks, which, together with dogs and squirrels, were the only quadrupeds whose exuvie were observed. The Tartar village of the Orotchys, for to a nation of this name they belong, was composed of four huts, strongly built of the trunks of fir-trees throughout their length, and properly notched to fit each other at the corners. A frame supported the roof, which was composed of the bark of trees, and the fire was situated in the middle, under an aperture sufficiently large to give vent to the smoke. These four huts were inhabited by four different families, who seemed to live in the closest union, and the most perfect mutual confidence. Such were the inviolable fidelity of these people and their respect for property, that the French navigators left in the middle of their huts, and under the seal of their probity, their bags full of manufactures, beads, iron utensils, and, in short, all the articles exchanged with them; nor was their confidence in any instance abused. Each hut was surmounted by a place for drying salmon, which was exposed by the women, to whom the operation is committed, on poles to the heat of the sun, after having been smoked two or three days round the fire in the middle of their houses. The people of this bay, as well as those of Segalien, wear on their thumbs a thick ring of lead or bone, against which they cut in stripping the salmon with a sharp knife, worn by each of them at his waist. Their village stood on a neck of low and marshy land, exposed to the north, and appeared uninhabitable during the winter. But on the opposite side of the gulf, on a more elevated spot open to the south, and near a wood, was another village, consisting of eight huts, larger and better constructed than the former. Above these, and near them, were subterraneous houses, like those of Kamtschatka, described in the 3d volume of Cook's last voyage. They were large enough to contain, during the rigour of winter, the inhabitants of eight huts. At one extremity of this village were several tombs, better constructed, and equally extensive with the houses; each of which contained four or five biers, properly formed and adorned with Chinese manufactures. Bows, arrows, nets, and, in general, the most valuable articles, were suspended within these monuments, of which the wooden doors were secured by a bar supported at each extremity. Their houses were also filled with their effects in the same manner. Their clothes, furs, snow-shoes, bows and arrows, and pikes, remained in this deserted village, which they inhabit only during the winter. They pass the summer on the other side of the gulf. In their interment of the dead, they proportion the expence of their mausolea to their respective wealth. Whilst a relative kind of magnificence is manifested in the monuments of the more affluent, those of the poorer class are exposed on a bier, which is placed on a stage supported by stakes four feet high. All have their bows, their arrows, their nets, and some pieces of cloth round their tombs, and we may well conceive, from the veneration which these people pay to their ancestors, that it would be deemed sacrilege to rob their tombs.

These

These people, like the inhabitants of Segalieu, seem to acknowledge no chief, and to submit to no government. Nevertheless, the gentleness of their manners, and their respect for old age, may give this apparent anarchy a character of mildness. We never witnessed, say the French navigators, the slightest quarrel; and their mutual affection and parental tenderness afforded an interesting spectacle. However, these people are filthy and offensive to a disgusting degree; and there is not, perhaps, a race of persons more feebly constituted, and whose countenance is more inconsistent with all our ideas of beauty. Their average height is under 4 feet 10 inches, French measure; their form is slender, and their voice weak and shrill, like that of children. They have prominent cheek-bones, and small blue eyes in diagonal directions. Their mouth is large, nose flat, short chin, almost without beard, and skin olive, varnished, as it were, with oil and smoke. They let their hair grow, and braid it in tresses, somewhat in the European manner. That of the women falls loose upon their shoulders, and they have the same call of countenance with the men. It would not be easy to distinguish them, if it were not for a slight difference in their dress, and in their leaving their necks entirely open. All the cares of the female sex are limited to cutting and sewing their clothes, disposing the fish for drying, and nursing their children, whom they suckle till they are three or four years old. Females seem to be much respected in this part of the globe. The men never conclude any bargain without the consent of their wives. The silver ear-rings and copper jewels which adorned their dresses, are entirely reserved for women and little girls. The men and little boys are dressed in jackets of nankeen, dog's skin, and fish skin, in the form of carters' frocks. If these extend below the knees, they wear no drawers; otherwise they have such as are used by the Chinese, and which extend to the calf of the leg. They have all boots of seal skin, which they reserve for winter; and they wear at all times, and at all ages, a leathern girdle, to which are suspended a knife and sheath, a flint, steel, a little bag for tobacco, and a pipe. The women are covered with a large nankeen gown, or one of salmon-skin, which they have the art of tanning, and of rendering extremely flexible. This dress extends to the ancle, and is sometimes adorned with a fringe of small copper ornaments, which make a noise like little bells. As to their religion, they seem to have neither temple nor priests; but they appear to have some idols of rough sculpture, suspended from the roofs of their cottages. These images, however, may only serve as memorials of some child devoured by the bears, or some hunter whom these animals may have wounded. They are represented as a people whose delicacy and refinement of manners indicate a degree of civilization, not exceeded by any who have neither flocks nor agriculture. Dogs are their most valuable property. These they harness to little sledges, very light, and extremely well made, and exactly similar to those of Kamtschatka. These dogs are of the wolf kind; and though small in size, are very strong, docile, and gentle, and seem to possess the character of their masters; while those of Port des Français, which are much smaller and of the same breed, are wild and ferocious. The bay of Calixie abounds with islands; the soil of which consists of lava and other volcanic substances. Among the latter, the eruption of which appeared more ancient, were discovered various crystallizations; but no craters of volcanoes could be perceived. Vegetation in the month of July was nearly such as it is in the environs of Paris in the middle of May. Strawberries and raspberries were still in bloom; gooseberries began to redden,

and celery and water-creffes were very scarce. Several fine foliated oyster-shells of a vinous and black colour, were found strongly attached to the rock, and separated from it with difficulty; and their valves were so thin that it was very difficult to preserve them entire. With the dredge were taken up some shells of a fine colour, some peccines, small mussels of the common kind, and some varieties of the cockle. Several species of birds, such as pullets, wild ducks, cormorants, plover, white and black wag-tails, and a small blue fly-catcher, were thinly scattered. The beach and the woods echo with the croaking of ravens, and afford refuge to bald eagles and other birds of prey. The martin and sand-martin alone appeared to be in their natural climate. The earth seems to continue in a frozen state throughout the summer, as the water taken into the ship was only $1\frac{1}{2}$ above the freezing point, and that of the streams never above four degrees. The mercury, however, was constantly at 55° , even in the open air. The momentary heat penetrates but a little way; it only quickens vegetation, which begins and ends in the short interval of three months, and infinitely multiplies gnats, musktoes, and other troublesome insects. No plants are cultivated by the natives; and yet they are fond of vegetable substances. The grain of the Manchoux, which is probably a small shelled millet, is their greatest luxury. They gather with great care some spontaneous roots, which they dry for their winter provision; among others the yellow lily, or saranna, which is a species of onion. They are unaccustomed to the use of the shuttle, and are only dressed in the most ordinary of the Chinese manufactures, or the exuvie of some terrestrial animals and seals. Voyage of La Pérouse, vol. II Engl. Transl.

CASTRIMONIUM, in *Ancient Geography*, a small town of Italy, in Campania, rendered municipal by a law of Sylla.

CASTRIOT, GEORGE, in *Biography*. See SCANDERBEG. CASTRO, PIETRO DI, an eminent painter of those subjects that are comprehended under the denomination of still life, such as vases, shells, musical instruments, gems, vessels of gold, silver, and crystal, books, and rich bracelets. He was well acquainted with all the true principles of perspective, and the chiaro-scuro; and none of his contemporaries were superior to him in transparency and truth. His colouring was peculiarly excellent, and he manifested peculiar judgment in grouping a variety of objects, so as to give union and harmony to the whole. This artist died in 1663. Pilkington.

CASTRO, ALPHONSO DE, a Franciscan friar, was a native of Zamora, in Spain, celebrated as a preacher, and much esteemed by the emperor Charles V. and his son, Philip II. He accompanied the latter into England, when he came hither to marry queen Mary. His principal residence was in the Low Countries; and though nominated to the archbishopric of Compostella, he never took possession of it, but died at Brussels in 1558, at the age of 63 years. As a writer he is principally known by his work "Against Heresies," consisting of 14 books, partly historical and partly polemical. An enlarged edition of this work by Feuudent, a Franciscan, was published at Paris, in 1570. Castro was also the author of a commentary on the 12 minor prophets and of several homilies. Du Pin's *Eccle. Hist.*

CASTRO, JOHN DE, an eminent Portuguese commander, was born at Lisbon, in 1500, and first served at Tangier. He then accompanied Stephen de Gama to the Straits of the Red Sea, which he accurately described. On his return to Portugal, he was appointed to the command of a squadron for guarding the coast; and he soon afterwards attended

Charles

Charles V. in his expedition to Tunis. He strengthened the fortifications of Din, the siege of which the Turks, after great loss, had been obliged to abandon; and then took a number of towns: but in 1548, he expired in the arms of St. Francis Xavier, after having been very recently advanced to the viceroyalty of the Indies. His description of all the coasts from Goa to Din is preserved in the Jesuits' college, at Evora. His life was written in Portuguese by Hyacinth Freyre d'Andrada, and has been translated into Latin.

CASTRO, PAUL DE, a celebrated lawyer of the 15th century, was born at the place from which he took his name, in the kingdom of Naples, and received his education in part from Christopher da Castiglione. From an obscure original, he rose, by assiduous application, to several stations of eminence, and distinguished himself as a professor of jurisprudence at Avignon, Florence, Sienna, Bologna, and Padua. At the latter place, where he was teacher of the law for 45 years, he died about the year 1436. His reputation was such, that it was proverbially said, "If there had been no Bartolus, Paul would have held his place;" and Cujacius said, "He who has not Paul de Castro, let him sell his coat, and buy him." His works are principally commentaries on the code and digest, and have been printed at Venice, Frankfurt, and other places. Gen. Biog.

CASTRO, in *Geography*, a town of Spain in Arragon; 10 miles N.E. of Balbastro.

CASTRO, a strong town of South America, in the island of Chiloe near the coast of Cullu, in the South Pacific ocean; 180 miles S. of Baldivia, and subject to Spain. S. lat. 43°. W. long. 82°.

CASTRO, anciently called *Mitylene*, a sea-port town of the island of Metelin, and the capital, situate on the north-east coast, facing the gulf of Adramiti, with two harbours, one of which is capable of receiving large vessels. It was formerly a place distinguished by its grandeur and magnificence, of which some vestiges still remain. It has two castles, one ancient and another modern, each of which is furnished with a Turkish garrison and commander. The inhabitants are chiefly Greeks, among whom are some Armenians; the former have four churches and a metropolitan. The chief trade is ship-building. It is 30 miles S.W. of Adramiti N. lat. 39° 14'. E. long. 26° 29'.

CASTRO, a duchy of Italy, in the state of the church, bounded on the north by the Orvietan, on the east by the Patrimonio, on the south by the fee, and on the west by the Siennese; 25 miles long, and from 8 to 13 wide. The duchy of Castro, together with the earldom of Ronciglione, was conferred by Pope Paul III. on his natural son, Peter Aloysius Farnese, who afterwards became duke of Parma and Placentia; it was mortgaged by one of his descendants to the Monte di Pietà at Rome; but upon his paying neither principal nor interest, it was sequestered by Pope Urban VIII. and in the year 1661 was annexed to the papal dominions. The town of Castro, from which it derives its name, which was formerly a bishop's see, was demolished by Pope Innocent X. and the see removed to Acquapendente, because the inhabitants had murdered a bishop whom he had sent to them.

CASTRO, a town of Naples, in the province of Otranto, the see of a bishop, suffragan of Otranto; which has been frequently plundered by the Corsairs; four miles S.S.W. of Otranto.

CASTRO DE CALDULAS, a town of Spain, in the province of Galicia; 9 leagues N.E. of Orense.

CASTRO DAYRO, a town of Portugal, in the province of Beira; 5 leagues S.S.W. of Lamego.

CASTRO GIOVANNI, a town of Sicily, in the valley of Noto; 63 miles S.W. of Melazzo.

CASTRO DE GORS, a town of Portugal in the province of Beira; three leagues N.W. of Vico.

CASTRO NOVA, a town of Sicily, in the valley of Mazzara, containing about 4000 inhabitants; 20 miles S.E. of Palermo.

CASTRO NUOVO, a town of Venetian Dalmatia, built by a king of Bosnia, defended towards the sea by inaccessible rocks, and towards the land by a citadel and castle.

CASTRO DE REY, a town of Spain, in the province of Galicia; 5 leagues S. of Mondonedo.

CASTRO DEL RIO, a town of Spain, in the province of Cordova; 5 leagues from Cordova.

CASTRO TRIONTO, a town of Naples, in the province of Calabria Citra; 11 miles E. of Rossano.

CASTRO VERDE, a town of Portugal, in the province of Alentejo; 1½ leagues N.E. of Ourique.

CASTRO VICENTE, a town of Portugal, in the province of Tras los Montes; 6 leagues E. of Mirandola.

CASTRO VILLORA, a town of Naples in the province of Calabria Citra; 6 miles W. of Castellano.

CASTRO VIRREYNO, a jurisdiction of South America, in the country of Peru, and in the diocese of Guamanga, W. of the city of Guamanga; and extending in some parts above 30 leagues, with such a variety of temperatures, that it produces every kind of grain and fruits. The heaths, which are its coldest parts, are frequented by a kind of sheep, called Vicuina, whose wool is the most considerable article of its commerce. Its town of the same name is 125 miles S.E. of Lima. S. lat. 12° 50'. W. long. 74° 45'.

CASTROMARIM, a town of Portugal, on the Guadiana, four leagues E.N.E. of Tavira. It surrounds a hill on which is an old ruinous castle, no longer fortified. The houses are small, and the place poor and mean, but far more lively than Villa-real. Near Castromarim immediately rise mountains of the chain that divides Algarvia from Alentejo, which gradually become high as you advance northwards; they consist of argillaceous slate, and a sand stone, which has a very strong resemblance to the grey round stones found in the Hartz mountains in Germany, called "Grauwache."

CASTROP, a town of Germany, in the circle of Westphalia, and county of Mark, containing one church for Roman Catholics, and two for protestants of different persuasions; 27 miles S.S.W. of Munster.

CASTROPOL, a town of Spain, in the province of Asturias, on the borders of Galicia; 14 miles N.E. of Mondonedo.

CASTROREALE, a town of Sicily, in the valley of Demona, containing about 8000 inhabitants; 15 miles W. of Messina.

CASTROSAROS, a town of European Turkey, in the province of Romania; 44 miles W. of Gallipoli.

CASTROZARPA, in *Ancient Geography*, a town of Thrace, fortified by the emperor Justinian.

CASTRUCCI, PIETRO, in *Biography*, a native of Rome, a scholar of Corelli, and an eminent performer on the violin, arrived in England in 1715, with the earl of Burlington, when he returned from his travels. This violinist, an enthusiast, and more than half mad, is represented in one of Hogarth's prints as the *enraged musician*; the painter having sufficient *poliff-nerie*, previous to making the drawing, to have his house beset by all the noisy instruments he could collect together, whose clamorous performance brought him to the window in all the agonies of auricular torture.

On his arrival, Corbet, who had hitherto led the opera

band, was superseded for *Castrucci*, who was appointed leader. In 1731, a concert was advertised at Hickford's room, for the benefit of signor *Castrucci*, *first violin of the opera*, who was to play the first and eighth concerto of his master, the famous Corelli, and several pieces of his own composition, particularly a solo, in which he engaged to execute "twenty-four notes with one bow." This advertisement was burlesqued, the next day, and a solo promised by the *last violin of Goodman's Fields playhouse*, in which he would perform "twenty-five notes with one bow."

In 1732 Handel composed, in his opera of *Seftimes*, an *Aria parlante, cwor di madre*, on purpose to display the talents of *Castrucci* in the accompaniment; and from this period to the year 1737, he seems to have led at all concerts; giving way only to the two boys, Cleg and Dubourg, in the solos, in which, from their youth as well as talents, they were highly favoured by the public. This year *Castrucci*, in advertising a benefit concert, styles himself *first violin of the opera*; promising a particular concerto, with an echo, adding, that "as he has for the space of so many years had the honour to serve the English nobility, he hopes they will favour him this last time, being to return the ensuing summer to Rome, his native city."

About the year 1737, poor *Castrucci*, Hogarth's *enraged musician*, was superseded at the opera, in favour of *Felting*, for whom he had such an antipathy, that in his next loud intervals, he instantly lost his temper, if not his reason, on hearing it pronounced. It was a common and irritating practice with some of his young waggish acquaintance, who had no respect for age and talents, to address him in conversation by the name of Mr. *Felting*, as if by mistake,—“I beg your pardon,—Mr. *Castrucci* I mean;” which put him in as great a rage as Hogarth's street musicians could do on May-day.

After his dismissal from the opera, oppressed with years, infirmities, and poverty, he was obliged to supplicate for a benefit at the opera-house, which on the merit of his past services was, with due benevolence, granted him at the age of 80, when he performed a solo for the last time, and died soon after.

He was a voluminous composer for his own instrument. Two books of solos, and 12 concertos for violins, though never much known, seem to have more fire and variety than most violin music of his time, till Verucini, still more inflamed, surpassed him in genius, hand, knowledge, and capacity.

He had a brother, *Prospero Castrucci*, who for several years led at the Cattle concert, and played concertos with his brother, *a parti equali*; but the high inferior to *Pietro*, he was not devoid of merit.

CASTRUM, in *Ancient Geography*, a term which, in combination with others, gives name to several fortified places; of which some were towns, and others were fortresses. They are too numerous, and not of sufficient importance, to be here recited.

CASTRUM Doloris, in *Medical Writers*, denotes a catafalco, or lofty tomb of state, erected in honour of some person of eminence, usually in the church where his body is interred; and decorated with arms, emblems, lights, and the like.

Ecclesiastical writers speak of a ceremony of consecrating a *castrum doloris*; the edifice was to be made to represent the body of the deceased, and the priest and deacon were to take their posts, and say the prayers after the same manner as if the corpse were actually present.

CASTRUP, in *Geography*, a town of Germany, in the

circle of Westphalia, and bishopric of Munster; 5 miles S.S.E. of Cloppenburg.

CASTS. See CAST, CASTING, and *Impressions from MEDALS*.

CASTULO, or CASTULUM, in *Ancient Geography*, *Cazulna*, a considerable town of Spain, towards the eastern part of Bætica, belonging to the *Orontici*. It had the title of “*Conventus*” when the Romans made themselves masters of the country, but before that time the Carthaginians had contended for the possession of it with those to whom it naturally belonged. It was the native place of Imilia, the wife of Hannibal. This town was situated in a mountainous country; and some have derived its name from “*Castlon*,” an oriental term, signifying the noise of a fall of water; and we learn from Strabo, that there were rocks near the place which gave rise to the river that passed to Castulo. The town itself, placed on a mountain, or at least very near it, seems to have some relation, by its name and situation, to Parnassus, famous for its fountain “*Catalia*,” and hence some have been led to imagine that it was founded by the Phœceans, to whom belonged, in Greece, the fountains of Callatia and Parnassus. *Silvius Italicus* has not omitted this allusion. Julius Cæsar, having purchased the lands in the territory of Castulo, established a colony in it. There were desiles in the vicinity of Castulo, mentioned by Livy, and called “*Saltus Castellensis*.”

CASU COSMILLI, in *Law*, a writ of entry, where a tenant by courtesy, or for life, aliens in fee or in tail, or for another's life: it takes its name hence, that authority being given by stat. West. 2. 13 Edw. I. c. 24. to the clerks in chancery to make new forms, as often as any new case should arise, not under any of the old forms; they framed this writ to the likeness of the other called *Casu provisorio*.

CASU PROVISORIO, a writ of entry, given by the statute of Gloucester, 6 Edw. I. c. 7. in case where a tenant in dower aliens in fee, or for term of life, in tail: and lies for him in reversion against the alienee.

CASUAL, something that happens fortuitously, or without any design, or measures taken to bring it to pass.

CASUAL *de ab*. See *DEODANN*.

CASUAL *ex Cor*, in *Law*, a nominal descendant in reversion, and who continues such until appearance by or for the tenant in possession. Blackst. Comm. vol. iii. p. 202.

CASUAL *revertens*, are those which arise from forfeitures, confiscations, deaths, attainders, &c.

CASUAL *de offi*, a denomination given by some to what is more frequently called casuality. See *CASUIR*.

Adm. Ombler, chancellor of the university of Tubingen, has published a system of *casus theologici*, containing the solution of dubious questions, and cases of conscience. Theologia Casualis, 6 vols. 4to. Tubing. 1782.

CASUALTY, in the *Tin Mines*, a word used to denote the earth and stony matter which is, by washing in the stamping-mills, &c. separated from the tin ore, before it is dried and goes to the crushing mill.

CASUARI, in *Ancient Geography*, a people of Upper Germany, according to Ptolemy, who dwelt near the *Suevi*.

CASUARIA, a place of Gaul, in the division called the “*Greek Alps*,” which was situated at a small distance to the right of Icara.

CASUARINA, in *Botany*, (said by Ventenot to be so called from a fancied likeness of its branches to the feathers of the cassowary. Fork. Gen. 52. Thunb. Nov. Gen. Pl. 53. Linn. Jan. Suppl. p. 62. Schreb. Gen. 1105. Jeff. p. 412. Vent. vol. iii. p. 576. Gært. 508. Vilao, Lat. Encyc. Pösc. Nov.

Nouv. Dict. Clafs and order, *monœcia monandria*. Nat. ord. *confineæ*. Juff. Vent.

Gen. Ch. Male. *Cal. common*; catkin filiform, imbricated; feales fomewhat membranous, whorled, lanceolate-awl-shaped, connate at the bafe, ciliated, one-flowered. *Calyx proper* two-valved; valves acute, equal, boat-shaped, fhorter than the feales of the catkin. *Cor.* none. *Stam.* one, capillary, longer than the feale. Female. *Cal. common* ovate-cylindrical; feales ovate, acute, keeled, ciliated. *Calyx proper* two-valved, longer than the feales of the catkin, permaucit. *Cor.* none. *Pyl.* germ egg-shaped, compressed; lyle filiform, long, bifid; fligmas two. *Peric.* ftrobile almolt globular, composed of the enlarged, aggregate calyces, each containing a fingle feed. *Seeds* winged, compressed. Gart. and Vent.

Efl. Ch. Calyx common, a catkin; calyx proper, two-valved. Style bifid. Pericarp a ftrobile.

Sp. 1. *C. equififolia*, Linn. Fil. Supp. Thunb. Nov. Gen. p. 53. Forfl. Gen. tab. 52. Lam. Encyc. Illuf. pl. 746. fig. 1. Mart. Mill. (C. littorea, Rumph. Amb. vol. iii. p. 86. tab. 57.) "Monoicous; whorls of flamens approximating." Thunb. "Little branches irregularly difpofed, crowded; catkins thickened towards the top." Lam. A large, fpreading, lofty tree. *Branches* greyifh or brown, knotty, and tubercled on their lower part, furnifhed on their upper part with numerous branches, which are fet close together, almolt falcifculated, very flender, jointed, and regularly channelled, refembling the ramifications of the horfe-tails: (equifeta).

Male catkins about an inch long, terminal, ftraight, linear-cylindrical. *Strobiles* about the fize of a walnut, woody, lateral, below the flender branches; peduncles two or three lines long. A native of Madagafcar and the Eaft Indies. 2. *C. nodiflora*, Thunb. Mart. Gart. (C. verticillata, Lam. Encyc.) "Whorls of flamens remote." Thunb. "Little branches whorled, loofe; catkins attenuated towards the top." Lam. A large tree, with a lefs denfe head than the preceding. *Branches* more diftant; upper ones three or four together, in diftinct whorls. *Male catkins* not more than long, cylindrical, jointed, whitifh; filaments not more than a line and a half longer than the feales. Lam. *Strobile* nearly globular, echinate, peduncled. *Scales of the catkin*, when ripe, much thickened, of a corklike fubftance, retufe, white, in pairs, fet fo close together as to appear one body, handfomely tefellated, in quadrangular figures; valves of the calyx elongated, coriaceous, concave. Gart. A native of the Eaft Indies and New Caledonia. 3. *C. ftricta*, Hort. Kew. 320. Mart. "Dioicous; little branches erect; feales of the ftrobiles marred, fmoothifh; male-fleaths multifid, fmooth." A native of New South Wales, flowering in November and December. 4. *C. torulofa*, Hort. Kew. 320. Mart. "Dioicous; little branches fcedid; feales of the ftrobiles villous, roughened with tubercles; male-fleaths quadrifid." A native of New South Wales, introduced by fir Jofeph Banks in 1772. 5. *C. africana*, Lour. Cochin. 549. Mart. "Little branches filiform, fwelling at the tip, and fporiferous; ftrobiles roundifh, axillary." A native of the fandry ealt coaft of Africa.

CASUENTINUM, or CASENTINUM, in *Ancient Geography*, a burgh of Italy, in Umbria, according to Pliny.

CASUENUM, BASIENUM, a river of Italy, marked by M. d'Anville's map in Lucania, which difcharged itfelf into the gulf of Tarentum. Alaric, king of the Goths, was buried in the bed of this river.

CASUHATI, in *Geography*, a high chain of mountains, in South America, part of a triangle, one fide of which extends to the Andes, and another to the ftraits of Magellan.

CASUIST, a perfon who professes to refolve cafes of confcience. Efcobar has made a collection of the opinions of all the casuifts before him.

To casuiftry belongs the decision of all difficulties arifing about what a man may confcientioufly do, or not do; what is fin, or not fin; what things a man is obliged to do in order to difcharge his duty, and what he may let alone without breach of it.

M. le Poire, preceptor of Lewis XIII. called the books of the casuifts the art of quibbling with God; which does not feem far from the truth; by reafon of the multitudes of diftinctions and fubtilties with which they abound.

CASULÆ CARIANENSIS, in *Ancient Geography*, an epifcopal fee of Africa, in the Byfaccne territory.

CASURGIS, a town placed by Ptolemy in Germania Major, fuppofed to be the prefent Caurzim, in Bohemia.

CASUS AMISSIONIS, in *Scots Law*. In actions proving the tenor of obligations inextinguifhable by the debtor's retiring or cancelling them, it is neceffary for the purfuer, before he is allowed a proof of the tenor, to confedeed upon fuch a "Casus amiffionis," or accident by which the writing was deftroyed, as fhews it was loft while in the writer's poffeffion.

CASWELL, in *Geography*, a county of America, in the diftrict of Hillborough and ftate of North Carolina, containing 10,096 inhabitants, of whom 2,736 are flaves. The chief town is Leeburg.

CASYRUS, or CHASIRUS, in *Ancient Geography*, a mountain of Afia, in Saffiana; near which Pliny places the town of Solftres.

CASYSTES, a port of Afia Minor, in Ionia, placed by Strabo at the foot of mount Corica.

CAT, CLAUDE NICHOLAS LE, in *Biography*, was born at Blerencourt, in Picardy, September 6, 1700. His father, Claude Le Cat, who was a furgeon of eminence, would have educated him to his bufinefs, but finding him difpofed to theological ftudies, he encouraged him in that purfuit, and he performed the duties of an ecclefiaftic feveral years. Being well verfed in geometry, he, for a time, employed himfelf in acquiring a knowledge of military architecture, and made fome drawings in that line which gained him credit; but his friends not approving that project, and requiring him to fix on the object he now purpofed following, he determined on ftudying medicine, fome knowledge in which he had acquired early, under the tuition of his father. He was now fent to Paris, and as he was of an ardent difpofition, he foon, by his intefe application to his ftudies, attracted the notice of the profeffors. Though anatomy was the part to which he feemed particularly attached, yet he foon fhewed himfelf to be no mean proficient in furgery, and medicine, infomuch, that in the year 1729, M. Treffan, archbifhop of Rouen, appointed him his phyfician and furgeon, though he did not take his degree of doctör in medicine, until the year 1732, when that honour was conferred upon him at Rheims. He had the preceding year been chofen furgeon major to the Hotel Dieu, at Rouen. For this honour, and for the attachment his countrymen conftantly fhewed him, he was not ungrateful. In the year 1733, having now completed his ftudies, he went and refided among them, and in the fame year he began his courfe of lectures in anatomy and furgery, which foon became fo numerous attended, that the rooms in which they had been accluftomed to be given would not contain the concourfe of pupils, who required admiffion. He therefore propofed building a theatre for the lectures, and founding a college, or fchool for the ftudy of anatomy and furgery,

which he had the pleasure of seeing carried into execution. He also formed a literary society, which was afterwards erected into a royal academy, to which, as one of the most zealous and active members, he was appointed secretary, which post he held to the time of his death. In 1759, an addition of 2000 livres was made to his salary as principal surgeon to the Hotel Dieu, and in January, 1762, the king gave him letters of nobility. In the mean while he had made himself known to most of the philosophical, and medical societies in Europe, by his communications on the subjects of anatomy and surgery; he was also a frequent correspondent with the editors of the Journal des Savans, Mercure de France, and other literary and medical journals. The subjects of his dissertations were sometimes such as rather showed his ingenuity than his judgment, and tended more to amuse than to improve the mind; as, of the nature and properties of the nervous fluid, on the causes of the colour of the skin in negroes, &c. Many of them, however, were of a higher kind, and in the opinion of Haller, whom he occasionally opposed, and who was therefore, perhaps, no just appreciator of his merits, he made some improvements both in anatomy, and surgery. But the same versatility of disposition, which made it difficult for him to fix on a profession, might prevent his being a correct experimenter, to which an almost unwearied attention is necessary. He died in full possession of the esteem and veneration of his fellow citizens, August 22, 1768. Of his works, which are numerous, Haller has given complete lists, with occasional remarks, in his *Eib. Anat. & Chirurg.* The following are the titles of some of the principal of them. "Traité des Sens, Rouen, 1740. 8vo. avec figures." It has been several times reprinted. Haller finds fault of the figures faulty. "Recueil de Pièces concernant l'Operation de la Taille." Rouen, 1752, 8vo. Some of the plates in this work are also engraved by Haller. He also wrote on solvents of the stone, on the causes of the menfes. "La Theorie de l'Onie, Supplement à cette Article du Traité des Sens." Paris 1767, 8vo. the most finished, Haller says, of his works. *Eloq. D. A. Hist.*

CAT, in *Geography*, a lake of North America. N. lat. 52° 30'. W. long. 91° 40'.

CAT Islands, or *Guanabani*, one of the Bahama islands. It was the first land discovered by Columbus, to which he gave the name of St. Salvador, Oct. 11, 1492. It lies on a particular bay to the east of the great Bahama bank, from which it is parted by a narrow channel called Exuma Sound. N. lat. 24° 30'. W. long. 74° 30'.—Also, an island near the gulf of Mexico, and the coast of West Florida. N. lat. 6° 0'. W. long. 89°.

CAT, in *Sea Language*, denotes a ship formed on the Norwegian model, used by the northern nations of Europe, and sometimes employed in the English coal trade. It has three masts and a bowsprit, rigged like an English ship; having, however, pole-masts, and to top gallant masts. The mizen is with a gaff. These vessels usually carry from four to six hundred tons.

CAT, in a *Ship*. See CAT-heads.

CAT the anchor. See ANCHOR and CATTING.

CAT, in *Zoology*. See FELIS *Catus*, the common cat, and its varieties.—CAT *Mexican*. See FELIS *Pardalis*.—TIGER-CAT, *Mexican*. See FELIS *Mexicana*.—TIGER-CAT, *Bergal*. See FELIS *Bengalensis*.—TIGER-CAT, *Casse*. See FELIS *Caspensis*.

CAT bird, or CAT-fly-catcher, in *Ornithology*, MUSCICAPA *Carolinensis*, which see.

CAT's ear, in *Botany*, see HYPOCHÆRIS.

CAT's eye, in *Mineralogy*, a siliceous gem, called by the Latins, *oculus cati*, and sometimes *onyxopalis*, as having white zones or rings like the onyx, and belonging to the division of chatoyant stones, or such as vary their colour according to the position of the light and the eye of the observer, which M. Chaptal confidrs as varieties of the opal. Near the middle it has a point, from which proceed, in a circle, greenish traces of a very lively colour. Its colour is generally of a greenish or yellowish grey, or light, or dark-yellowish brown, or reddish brown, or striped with these colours; and in certain positions, particularly when polished, emitting a silvery or yellowish moveable effulgence. Klaproth mentions two varieties of this mineral; the one whitish or yellow, from Ceylon, which says Kirwan, is found in blunt or rounded fragments; its lustre 2, and transparency, 3.2; its fracture imperfectly conchoidal, sometimes approaching to the splintery; fragments, 3; hardness, 10; sp. gr. from 2.56 to 2.60. Klaproth says, that the species from Ceylon had 2.66 of specific gravity; and was found to contain of silica 95 per cent. of alumine 1½, of lime 1½, and of oxyd of iron ½. The other species is reddish, and is produced from the Malabar coal. This, or alroites, says Klaproth, was composed of 54½ per cent. of silica, 2 of alumine, 1½ of lime, and ¼ of oxyd of iron. Its specific gravity was 2.625. This is the sun-stone of the Turks, called *güne he*. The best of these stones are very scarce. One of them, an inch in diameter, was in the cabinet of the dukes of Tuscany. See ASTERIA and CHALCEDONY.

CAT-fish, in *Ichthyology*; several of the shark tribe are known by this title. The lesser cat-fish, *Catulus minor*, and *Squalus catulus* of Linnæus, is called also the lesser dog-fish.—Great cat-fish of Edwards, *Catulus maximus* of Willoughby and Ray, is the Linnæan *Squalus felinus*. See SQUALUS.

CAT-gut, a denomination given to small strings for fiddles, and other instruments, made of the intestines of sheep or lambs dried and twisted, either singly, or several together. These are sometimes coloured red, sometimes blue, but are commonly left whitish or brownish, the natural colour of the gut. They are used also by watch-makers, cutlers, turners, and other artificers. Great quantities are imported into England, and other northern countries, from Lyons and Italy.

CAT-harpings, in *Sea Language*, are small ropes running in little blocks from one side of the shrouds to the other, near the deck; their use is to force the shrouds, and to make them tight, for the greater security of the masts, and to afford room for drawing the yards in more obliquely, to trim the sails for a side-wind, when they are said to be close haul'd.

CAT-heads, two strong short beams of timber, which project almost horizontally over the ship's bows, on each side of the bowsprit, being like two radii which extend from a centre, taken in the direction of the bowsprit. That part of the cat-head, which rests upon the fore-castle, is securely bolted to the beams; the other part projects like a crane, as above described, and carries in its extremity two or three small wheels, or sheaves of brass, or strong wood, about which a rope, called the *cat fall*, passes, and communicates with the cat-block, which also contains three sheaves. The machine formed by this combination of pulleys is called the *cat*, which serves to pull the anchor up to the cat-head, without tearing the ship's sides with its flukes. The cat-head serves also to suspend the anchor clear of the bow, when it is necessary to let it go; it is supported by a sort of knee which is generally ornamented with sculpture. The cat-block is fitted with a large and strong hook, which catches

catches the ring of the anchor when it is to be drawn up.

CAT's head, in *Mineralogy*, a denomination given to a fort of waste stony lumps, not inflammable, found in coalmine. In these there are frequently impressions of ferns. Phil. Trans. N^o 360, p. 970.

CAT-holes, two small holes above the gun-room ports, to bring in a cable or hawser through them to the capitan, when it becomes necessary to heave the ship a-tern.

CAT-mint, in *Botany*. See **CATMINT**.

CAT of Mountain, in *Zoology*. See **CATUS pardus**.

CAT's paw, a light air of wind perceived at a distance in a calm, by the impression made on the surface of the sea, which it sweeps very lightly and then decays.

CAT-salt, a name given by our salt-workers to a very beautifully granulated kind of common salt. It is formed out of the bitter or leach brine, which runs from the salt when taken out of the pan. When they draw out the common salt from the boiling-pans they put it into long wooden troughs, with holes bored at the bottom for the brine to drain out; under these troughs are placed vessels to receive this brine, and across them are placed certain small sticks, to which the cat-salt affixes itself in very large and beautiful crystals. This salt contains some portion of the bitter purgig salt, and is very sharp and pungent, and is white when powdered, though pellucid in the mass. It is used by some for the table, but the greatest part of what is made of it is used by the manufacturers of hard soap.

CAT-silver, and **CAT gold**, names given to certain fossil substances, usually called also *glimmer*, and in Latin, *mica*. They are various species of the *bractearia*, or foliaceous talcs, in final sponges. The fragments of mica, denominated as above, according to their colour, are employed as a sand for drying ink upon paper. See **MICA**.

CAT's-tail-grass, in *Botany*, different species of *Pbleum*; which see.

CATABANES, in *Ancient Geography*, a people of Arabia Deserta, who inhabited the parts between the town of Pelusium and the Red Sea, according to Pliny.

CATABANI, a people placed by Pliny in Arabia Felix, towards the strait of the Arabian gulf.

CATABAPTIST, a person averle from baptism; particularly from that of infants.

The word is compounded of the preposition *κατα*, which, in composition, signifies *against*, and *βαπτω*, I *wash*. See **ANABAPTISTS** and **BAPTISTS**.

CATABASION, in the *Greek Church*, a place under the altar, wherein the relics are kept. The word is formed from *καταβασω*, I *descend*; because they went down into it.

CATABATHMOS, or **CATABATHMUS**, in *Ancient Geography*, a valley below the steep declivity of a mountain, whence its name, from *καταβασω*, to descend, on account of the precipitation of its descent; extending to Egypt, over-against the spot where stood the temple of Jupiter Ammon, and separating Egypt from Cyrenaica. It is also called "Cato Sappires;" and the Arab pilgrims, who pass through it in their way to Mecca, denominate it in their language, "Hefachbir," or the ruined places. Steph. Byz. makes it a place of Lybia, between Ammon and Paratonium, and Pliny reckons 86 miles from this last place to Catabathmos. Ptolemy mentions two places under this appellation; one the greater Catabathmos, which he makes a sea-port of Lybia; and the other, the lesser Catabathmos, which he says was a mountain

CATABAW, in *Geography*, a river of North America,

otherwise called *Wateroe*, which unites with the Canga-ree, and forms the Santee, 5 miles N. of Amelia, in South Carolina.

CATABAWS, a small tribe of Indians who possess one town, called Catabaw, situated on the river of the same name, on the boundary line between N. and S. Carolina, and containing about 450 inhabitants, of whom about 150 are fighting men. These are the only tribe which resides in the flat; the proprietary government having granted them 144,000 acres of land. They are a remnant of a formidable nation, the bravest and the most generous enemy the Six Nations had; but they have degenerated since they have been surrounded by the whites. N. lat. 35° 8'. W. long. 85° 54'.

CATABEDA, in *Ancient Geography*, a river of India on the other side of the Ganges, according to Ptolemy. M. d'Anville marks the mouth of this river at the bottom of the gulf of the Ganges, to the east of the principal mouth of this river.

CATABIBAZON, in *Astronomy*, the moon's descending node; called also *DRAGON'S tail*.

CATABITANUS, in *Ancient Geography*, an episcopal see of Africa, in Mauritania Cæariensis.

CATABOLUM, or **CATABULUM**, a place of Cilicia, so called in Antonine's Itinerary, and marked in the route from Tyana to Alexandria, between Cægæ and Baizæ; supposed to be the place called *Castabala*.

CATABULENSES, in the *Middle Ages*, a sort of ministers, or servants of the empire, appointed to conduct the public carriage from one *catabulum*, or stage, to another. The catabulenes appear also to have had the charge of conveying the public corn to and from the mills; whence in the Theodosian code they are joined with bakers.

CATABULUM, a kind of stable, or building, wherein beasts, especially of burden and carriage, were kept for the public service. The ancient Christians were sometimes condemned to serve in the catabula, that is, to work at the cleaning of them, attending the beasts, &c.

CATACAUSTIC CURVES, in the *Higher Geometry*, the species of *CAUSTIC curves* formed by *reflexion*. See **CAUSTIC curves**.

CATACECAUMENE, in *Ancient Geography*, a country of Asia Minor, occupied in common by the Lydians and Mysians, according to Strabo. Steph. Byz. who assigns to this country the town of Ephesus says, that it produced no trees except the vine, and that the wine derived its name from it. Vitruvius also mentions the hills of Asia Minor in Myia under this appellation.—Also, an island situated in the Arabian gulf, mentioned by Ptolemy and Steph. Byz.

CATACHRESIS, in *Rhetoric*, a figure whereby an improper word is used instead of a proper one.

The word is formed from *καταχρησμαι*, *abuse*, I *abuse*; of *κατα*, *against*, or *contrary to*; and *χρησμι*, I *use*.

The catachresis occurs, when for want of a word proper to express a thought, we use, or rather abuse, a word that comes somewhat near it: as when we call a person who has killed his mother, father, or prince, *parricide*; which word, in propriety, is only applicable to him who has murdered his father: and *vir gregis ipse caper*, is also a catachresis. Carachresis signifies in general any harsh trope, though it is most commonly found in metaphors; and is principally used by poets, who make choice of it for novelty, or to enforce expression, where the proper word does not seem strong enough. As when Milton, (*Parad. Lost*, p. 4. v. 268.)

268.) in describing the angel Raphael's descent from heaven, says, he

"Sails between worlds and worlds;"

where the novelty of the word enlivens the image more than if he had said, flies. This trope, however, is sometimes found in the gravell authors, and even in the sacred writings. Thus, we read of the "blood of the grape;" and Solomon, (Prov. xxx. 15.) says, "the horse-leech hath two daughters." In all these instances the trope is a metaphor: but when St. John says in the Revelation, (ch. i. 12.) "I turned to see the voice that spake to me;" it is here a metonymy of the adjunct; the word voice being put for the person who uttered it. St. Matthew, (ch. xxvi. 6.) mentions "Simon the leper;" not that he was then a leper, but had been so, and was cured; which is a synecdoche of the part. And when a criminal is said "to have had his reward," that is, his punishment, it is an irony. Ward's Oratory, vol. ii. p. 23.

CATACLASIS, from *κατακλαω*, *I distort*, in Surgery, denotes a disorder of the eye, wherein the eye-lid is inverted by a convulsion of the muscles that close it; called also *campylon*.

CATACLYSMUS, from *κατακλυω*, *I deluge*, a Greek name for a deluge, or inundation of waters.

CATACOMBS, in *Antiquity*. This word, derived from the Greek *κατα* and *κομβος*, a hollow or cavity, is used to denote grottoes or subterraneous excavations for the burial of the dead.

These are monuments of great curiosity, and considerable both in size and number. Of the remarkable excavations existing, there are various kinds. Some are temples, like those of India, in the mountains of Ellora; some have been originally executed for the purposes of sepulture; others have owed their origin to the operations of quarrying for building materials, and have been subsequently converted to other purposes: of this nature are the catacombs of Rome, and the quarries, or *Latomie* of Syracuse, which served for public prisons.

The religious ideas of various nations led them to honour the dead with extraordinary solicitude, and tombs and mausoleums are among the most eminent remains of antiquity; where rocks afforded a convenient opportunity, it was an idea at once natural, and of peculiar propriety, to excavate in these silent retreats the habitations of the dead.

In Egypt the honours paid to the dead partook of the nature of a religious homage. By the process of embalming they endeavoured to preserve the body from the common laws of nature, by which every substance is decomposed, and returns to its original elements. They also provided magnificent and durable habitations for the dead, proud tombs, the astonishment of all succeeding nations, which have not preferred but buried the memory of their founders. But by a singular fatality, the well adapted punishment of pride, the extraordinary precautions by which it seemed in a manner to triumph over death, have only led to a more humiliating disappointment. The splendour of the tomb has but attracted the violence of rapine; the sarcophagus has been violated; and while other bodies have quietly returned to their native dust in the bosom of their mother earth, the Egyptian, converted to a mummy, has been preserved only to the insults of curiosity, or avarice, or barbarism.

The date of the construction of not one of these monuments is known; indeed, most of them must have been executed progressively during a considerable time: it is, therefore, impossible to follow any chronological order in describing them: we shall, however, begin with those of Egypt,

which, while they are in many respects the finest and most remarkable, are, in all probability, more ancient than any European instances.

The catacombs of Alexandria begin at the place where the ruins of the old city terminate, and extend along the sea-shore for a considerable distance. They consist in general of long galleries, with apartments on each side, excavated in the rock: in the side of these rooms there are three tiers of holes, or niches, in which the bodies were deposited; but they have been all violated, and nothing is found in them at present. The galleries sometimes run parallel to one another, and sometimes cross at right angles; others are carried one above the other, according to the situation of the ground. Many have been washed away by the sea, and others are rendered inaccessible by the drifting sand. The apartments in general but little exceed the length of a man, but some which were probably the tombs of considerable persons, may, according to Dr. Pococke, "be reckoned among the finest that have been discovered, being beautiful rooms cut out of the rock, and niches in many of them, so as to deposit the bodies in, adorned with a sort of Doric pillars on each side." Norden gives a section of the finest of these, vol. i. page 16, which is an apartment of a circular form, and terminated by a dome. There are four doors opposite one another, ornamented with pillars and an entablature, and pediments terminated with a cressent. One of these doorways serves as the entrance to the apartment, the other three lead to large square recesses, each of which contains a kind of chest or sarcophagus of the substance of the rock, and sufficiently large to contain a body. From the style of the decorations observed in this subterranean chamber, one would be led to date its construction much later than the generality of the catacombs.

Near the pyramids of Saecara, which are at a short distance from Cairo on the opposite side of the Nile, there is a descent to a circular plain which has a rising in the middle. Bones and skulls are scattered over this spot, under which are the catacombs of the mummies, extending about half a mile, the whole country being a rocky soil, covered over with sand five or six feet deep. At some distance from these are the catacombs of the birds.

The catacombs of the mummies are entered by various wells about four feet wide, and 20 or 30 feet deep, cut through the rock, the upper part being sand, which is often moved by the wind and fills up the cavity. Some of these wells Dr. Pococke observed to be cased with unburnt bricks at the top as far as the depth of the sand, which from the size he imagined to be very ancient. The wells have holes on each side to descend by, but too much worn away to be of any use. Having descended the well, a passage succeeds, about 50 feet long, and five feet wide, which leads to another gallery of the same size, and about six feet high. On one side of this gallery there are apartments with platforms about two feet high, on which it is probable the mummies were laid during part of the process of preparation, and on the other side there are narrow cells just big enough to receive a large coffin. To this gallery there succeeds one much narrower, with niches on each side, which seem designed to set coffins in upright. From these passages there are cut oblong square apartments, which are full of the remains of mummies, and probably here the inferior persons of a family were deposited, piled up on one another, as we may suppose the heads of the family were set upright in the niches, which appear to have been walled up as well as all the other apartments.

This is the description given by Pococke of the catacomb which he examined; and it seems likely that the rest resembled

fembled this. These must have been the tombs of the common people.

The catacombs of the birds are similar to those last described, but more magnificent. These sepulchres were opened while the French were in possession of Egypt, and more than five hundred mummies of the ibis discovered.

Sint is a large well-peopled town, apparently built on the site of the ancient Lycopolis, or the city of the wolf. No antiquities are found in this town; but the Lybian chain of mountains at the foot of which it stands, exhibits proofs of the ancient proximity of some grand and flourishing city. These rocks are about half a league from Sint, and are excavated by a vast number of tombs of various dimensions, and decorated with more or less magnificence. Denon has given a view and plan of one of the largest of these catacombs. The outer porch is a large vaulted excavation, with a doorway leading into the interior of the tomb, which consists of several chambers one within the other, of various sizes and perfect regularity. All the inner porches are covered with a profusion of hieroglyphics, and the most delicate and elegant ornaments. M. Denon observes, that "if one of these excavations was a single operation, as the uniform regularity of the plan of each would seem to indicate, it must be an immense labour to construct a tomb; but we may suppose that such a one when once finished, would serve for ever for the sepulture of a whole family, or even race, and that some religious worship was regularly paid to the dead; else where would have been the use of such finished ornaments, of inscriptions never read, and of a ruinous, secret, and buried splendour? At different periods, or annual festivals, or when some new inhabitant was added to the tomb, funeral rites were doubtless performed, in which the pomp of ceremony might vie with the magnificence of the place; which is the more probable, as the richness of decoration in the interior part forms a most striking contrast with the outer walls, which are only the rough native rock. I found one of these caves with a single saloon, in which were an innumerable quantity of graves cut in the rock in regular order: they had been ransacked in order to procure the mummies, and I found several fragments of their contents, such as linen, hands, feet, and loose bones."

Besides these principal grottoes, there is such a countless number of smaller excavations, that the whole rock is cavernous, and reounds under the foot.

At Gebel Silsilis, on the banks of the Nile, between Et-fu and Ombois, the site of the principal quarries of Egypt, there are various chapels consisting of porticos with columns and entablatures, covered with hieroglyphics, all cut out of the solid rock, and likewise a large number of tombs also hollowed out of the mountain. These tombs are very curious, though they are disfigured with trenches and rubbish.

In several of these tombs small private chambers are found, many of which contain large seated figures; these chambers are adorned with hieroglyphics traced on the rock, and terminated with coloured stucco representing constantly offerings of bread, fruit, liquors, fowls, &c. The ceilings, also stuccoed, are ornamented with painted scrolls in an exquisite taste; the floor is inlaid with a number of tombs of the same dimensions and forms as are given to the cases of mummies, and equal in number to the sculptured figures: those that represent men have small square beards with a head-dress hanging behind over the shoulders: the women have the same dresses, but falling down in front over their naked necks. These latter are commonly represented with one arm passing within the arm of the figure beside them; and the other holding a lotus flower, a plant

of Acheron, the emblem of death. Some of these sepulchral chambers contain but a single figure, and may probably be the tombs of men who have died in celibacy. Others contain three or more figures, and seem to be family monuments.

At Montfalut there are also quarries, the grottoes of which still remain: they resemble those of Sint, and seem to have served as tombs to the ancient Egyptians, and as places of retreat to the first solitaries.

The catacombs of Thebes are, among all these monuments, the most extraordinary and magnificent; their consist of the Necropolis or city of the dead, on the west bank of the Nile, which was the common burial place of the inhabitants, and the tomb of the kings.

The Necropolis of Thebes is situated on the north-west of this city, on a step of the lower part of the Lybian chain, an arid and desolate spot, which seems to be devoted by nature to silence and death. The rock cut down on an inclined plane presents three sides of a square, in which double galleries have been excavated, and behind them sepulchral caves. These excavations are almost innumerable, and occupy a space of nearly a mile and a half square. At present they afford a lodging to the inhabitants of Kurnu and their numerous flocks, who, strong in these retreats, maintained themselves against the French in their late invasion of Egypt with singular obstinacy, and were only reduced by a regular siege. M. Denon, who accompanied this expedition, has given a lively and interesting description, which we shall transcribe.

"I now began my researches accompanied by some volunteers. I examined the grottoes which we had taken by assault: they were constructed without magnificence, consisting of a regular double gallery supported by pillars, behind which was a row of chambers often double, and tolerably regular. If we had not observed tombs, and even some remains of mummies, we might be tempted to believe that these were the dwellings of the primitive inhabitants of Egypt, or rather that after having first served for this purpose, these subterranean caves had become the abode of the dead, and had at last been restored by the people of Kurnu to their original destination.

In proportion as the height of these grottoes increases, they become more richly decorated, and I was soon convinced by the magnificence both of the paintings and sculptures, and of the subjects which they represented, that I was among the tombs of great men or heroes. The sculpture in all is incomparably more laboured, and higher finished than any that I had seen in the temples; and I stood in astonishment at the high perfection of the art, and its singular destiny to be fixed in places devoted to silence and obscurity. In the working of these galleries, beds of a very fine grained calcareous clay have occasionally been crossed, and here the lines of the hieroglyphics have been cut with a firmness of touch, and a precision, of which marble offers but few examples; the figures have an elegance and correctness of contour, of which I never thought Egyptian sculpture susceptible. Here too I could judge of the style of this people in subjects which were neither hieroglyphic nor historical, nor scientific; for there were representations of small scenes taken from nature, in which the stiff profile outlines, so common with the Egyptian artists, were exchanged for supple and natural attitudes: groups of persons were given in perspective, and cut in deeper relief than I should have supposed any thing but metal could have been worked. One cannot help being struck with the little analogy which the greater number of these subjects have with the spot wherein they are immured; it requires the presence

of mummies to persuade one's self that these excavations are tombs. I have found here bas-reliefs representing games, such as rowing, dancing; and asses taught to play tricks and to rear on their hind legs, which are sculptured with all the nature and simplicity which B. Flin has shown in representing the stone animals on the canvas.

The plan of these excavations is not less singular; there are some which are five feet and computed, that one would take them for labyrinths or subterranean temples. After passing the apartments so formed in the elegant style that I have just described, we entered long and gloomy galleries, which wind backwards and forwards in numerous angles, and seem to occupy a great extent of ground; they are melancholy, repulsive, and without any decoration; but from time to time open into other chambers covered with hieroglyphics, and branch out into narrow paths that lead to deep perpendicular pits, in which we descended by resting our arms against the sides and fixing our feet into steps that are cut in the rock. At the bottom of these pits we found other adorned chambers, and lower still a new series of perpendicular pits and horizontal chambers, and at last ascending a long flight of steps, we arrived at an open space which we found to be on a level with the chambers that we first entered."

M. Denon made many researches among these tombs, in hopes of finding one that had not been ransacked, that he might light upon an unrisen mummy and find out the manner in which they were laid within the tombs, a secret which the inhabitants obstinately concealed, as the situation of their village had given them almost an exclusive trade in this singular article of commerce. During their search, M. Denon and his companions arrived at a narrow hole, before which were scattered numerous fragments of mummies. After some hesitation, they proceeded, and having crawled along near a hundred paces over a heap of dead and half-decayed bodies, the vault became loftier, more spacious, and decorated with a considerable degree of care. They now found that this tomb had already been searched, that those who first entered it not having torches, had used bushes to give them light, and that these had fit fire to the linen and resin of the mummies which had caused such a combustion as to split some of the stones, melt the gums and resins, and blacken all the sides of the cave. They could observe however, that this vault had been intended for the burial-place of two comely female persons, whose figures were sculptured in relief seven feet in height, holding each other by the hand. Above their heads was a bas-relief representing two dogs in a leash lying on a altar; and two figures kneeling, had the appearance of worshippers, which makes it probable that two friends were buried here who were unwilling to part even in death. Besides this, there were lateral chambers unornamented and filled with corpses that had been embalmed with more or less care, shewing that though the tombs had been constructed and decorated by persons of consequence, they received not only the corpses of the founders, but of their children, friends, relations, and perhaps all the servants of their house. M. Denon found several bodies lying on the ground swathed up but without any coffin, and others that were not swathed; and observed various particulars concerning these.

The sepulchres of the kings of Thebes are mentioned by Diodorus Siculus as wonderful works, and such as could never be exceeded by any thing afterwards executed in this kind. He says that 47 of them were mentioned in their history, that only 17 remained to the time of Ptolemy Lagus; and adds, that most of them were destroyed in his time. It seems probable that most of these sepulchres were built and not excavated in the rock, as it is not easy to de-

stroy such sort of monuments. Strabo, however, says, that above the Memnonium were the sepulchres of the kings of Thebes, in grottoes cut out of the rock, being about 40 in number, wonderfully executed and worthy to be seen. In these, he says, were obelisks with inscriptions on them fitting forth the riches, power, and empire of these kings as far as Scythia, Bactria, India, and Ionia, their great revenues, and their armies consisting of a million of men.

The magnificent catacombs, called the tombs of the kings, lie to the north-west of Thebes, at some distance in the desert. Having passed the Necropolis, the traveller enters a narrow and rugged valley flanked with perpendicular rocks, and ascending a narrow steep passage about 10 feet high, which seems to have been broken down through the rock, the ancient passage being probably from the Memnonium under the hills, he comes to a kind of amphitheatre about 100 yards wide, which is called Dab-Bi-Melut, that is, the gate or court of the king; being the sepulchres of the kings of Thebes. In this court there are figures of about 18 excavations, but only nine can be entered; the hills on each side are high steep rocks, and the whole plain is covered with rough stones that seem to have rolled from them.

The grottoes present externally no other ornaments than a door in a simple square frame, with an oval in the centre of the upper part, on which are inscribed the hieroglyphic figures of a beetle, a man with a hawk's head, and beyond the circle two figures on their knees in the act of adoration. Having passed the first gate, long arched galleries are discovered of about 12 feet wide, and 20 in height, cauld with stucco sculptured and painted; the vaults, of an elegant elliptical figure, are covered with innumerable hieroglyphics, disposed with so much taste, that notwithstanding the singular grotesqueness of the forms and the total absence of demi-tint or aerial perspective, the ceilings make an agreeable whole, a rich and harmonious association of colours. Four or five of these galleries, one within the other, generally lead to a spacious room containing the sarcophagus of the king, composed of a single block of granite about 12 feet long by 3 in breadth, ornamented with hieroglyphics both within and without; they are square at one end, and rounded at the other, like the splendid sarcophagus deposited in the British Museum, and supposed by Dr. Clarke, to have contained the body of Alexander. They are covered by a lid of the same material, and of enormous thickness, fluctuating with a groove; but neither this precaution, nor these vast blocks of stone, brought from such a distance with such immense labour, have been able to preserve the relics of the sovereigns from the attempts of avarice; all the tombs are violated. The figure of the king appears to have been sculptured and painted at full length on the lid of each sarcophagus.

The paintings found in these sepulchres are among the most curious and interesting remains of Egyptian art, and in wonderful preservation, the colours being as fresh as when first executed. Some of these figures were copied by Bruce; and Denon who in a short visit observed every thing with the eye of an artist, has published a most valuable collection which have all the appearance of spirited and characteristic resemblances. We shall extract part of his relation. "I discovered some little chambers, on the walls of which were represented all kinds of arms, such as panoplies, coats of mail, tigers' skins, bows, arrows, quivers, pikes, javelins, sabres, helmets, and whips; in another was a collection of household utensils, such as caskets, chests of drawers, chairs, sofas, and beds, all of exquisite forms, and such as might well grace the apartments of modern luxury. As these were probably accurate representations of the objects them-

elves, it is almost a proof that the ancient Egyptians employed for their furniture Indian woods carved and gilt, which they covered with embroidery. Besides these, were represented various smaller articles, as vases, coffee-pots, ewers with their basons, a tea-pot, and basket. Another chamber was consecrated to agriculture, in which were represented all its various instruments, a sledge similar to those in use at present, a man sowing grain by the side of a canal, from the borders of which the inundation is beginning to retire, a field of corn reaped with a sickle, fields of rice with men watching them. In a fourth chamber was a figure clothed in white playing on a richly ornamented harp with eleven strings." M. Denon also observed figures with the heads cut off, which represented black men while their executioners were coloured red. (Pococke and Denon).

Quitting Egypt, the European examples of catacombs come next to be described, and we shall begin with those of Rome, which though by no means the most considerable for size or beauty, are, however, the most generally known.

The catacombs of Rome are a vast collection of subterranean labyrinths, excavated sometimes in stone or tufa, but more commonly in beds of puzzolana, which run sometimes to 80 feet below the surface of the earth. Thus it seems probable, that these excavations were originally dug for the purpose of procuring this useful substance, and afterwards appropriated as a burial place. In many places the sinking of the earth has suddenly afforded an entrance to new caverns, but similar accidents have filled up others, so that the extent of this subterranean city is unknown. The principal entrances are those of San. Sebastiano, San. Lorenzo, and Porta Porrese. These galleries are in general three or four feet wide, and six or seven in height. Some, however, are so low that it is necessary to stoop greatly to pass along them. There is no masonry or vault, the earth supports itself. In the two sides of these alleys, the sarcophagi containing dead bodies were placed length-ways, in recesses three or four tiers over one another, and closed with very thick tiles, or sometimes slabs of marble, cemented in a manner which would be very difficult to imitate at present. Some tombs are placed on the floor. There are also found a large number of urns containing bones, which, upon access of air, are reduced to powder. Sometimes, though rarely, the name of the deceased is found on the tile or urn, and frequently a palm is seen painted or engraved, with the cypher X. P. These are supposed to be the graves of the early Christians, and their contents are regarded by the Romans as sacred relics. The sarcophagi are for the most part quite plain, and the little sculpture, painting, or ornament, that has been found in the catacombs, is of the lower ages of the empire, and very indifferent. Almost all the galleries and chambers which have been discovered resemble one another, differing only in size. It is said that one may travel 20 miles in them; but many parts are shut up to prevent people from losing themselves in these gloomy labyrinths.

The catacombs of Naples are much larger and finer than those last described. These caverns do not extend under the city like those of Rome; they are situated in a mountain to the north of Naples, and dug one over the other partly in a stone used for building, and partly in beds of compacted puzzolana. There are three tiers of galleries, but earthquakes have closed the greater part.

From the entrance of the catacombs a straight street, 18 feet wide, and about 14 in height to the top of the vault, continues to a considerable length. It then becomes irregular, and seems to have been pierced at random in the mountain, as well as several other streets of various dimensions, with which it communicates on all sides. These ca-

terns resemble, in their distribution, the excavations of a stone quarry with various large chambers, in which piers have been left to support the ceiling. Among these subterranean halls, there are some which may have served as chapels, with altars of rough stone, and some fresco paintings, representing the virgin and saints, which seem to be of the 10th century.

The walls on both sides, through their whole length, are pierced with an infinite number of recesses; there are in some places five, six, and even seven rows one above the other. These cavities are large enough to receive a human body horizontally, but not a sarcophagus: they are of various sizes, and seem to have been calculated for the individual tenant. When the body was deposited in these recesses, they were closed with a long, flat stone, or with brick-work well cemented. In some places there were niches in which the bodies were placed upright; these were perhaps the sepulchres of particular families. Some of the tombs are ornamented with Mosaic paintings of the lower ages; and there were found marble monuments with Greek and Latin inscriptions, but these have been sawed to form the pavement of the church della Sanita. All the niches have been opened and the remains removed.

There are also considerable catacombs at Civita Turclino, near Carreto.

Sicily possesses many monuments of this kind; so that the ancient greatness of Catania, Palermo, Agrigentum, and Syracuse, is attested by extraordinary excavations. The catacombs of Syracuse are the most ample and magnificent of any in Europe. These form a kind of subterranean town, with its greater and smaller streets, squares, and places, all cut in the rock on several levels, and evidently originally destined for a place of sepulture, differing in that respect from the other remarkable excavations of that town, the Latomie and Dionysius's ear, which were at first stone quarries, while the catacombs are not at all adapted for that purpose, their entrances being neither spacious nor convenient.

The catacombs are entered from the church of St. John, one of the oldest Christian churches in Sicily. They consist of various streets crossing one another in many directions, and are hewn with great care and regularity. The principal street continues to a very great distance, but its whole length cannot be estimated, as the sinking of the ground has filled it up in one part. On each side the walls are occupied by large tombs incrusting in the rock. At stated distances large excavations branch off, which sometimes contain near 60 coffins hollowed out of the rock. In other places there are private sepulchral chambers with doors which appear formerly to have been fastened with locks; in the middle of these chambers there are large insulated tombs, doubtless intended for the heads of families. The interfections of the streets form large openings, and there are various considerable circular halls with domes, and pierced at top with an opening to the outer air; these halls are stuccoed, and there are tombs placed symmetrically in them of the same kind as those in the streets.

In exploring these caverns, the traveller is surprised to find himself returned to the same spot whence he set out, but upon a lower story. Though it is only possible to visit a part of these vast excavations, the extent of what is seen excites the utmost admiration of the energetic industry of the nation that could construct such noble sepulchres. They are undoubtedly the greatest monument of the ancient Syracusans. The only ornaments found in these catacombs, have been added at a later period, and consist of some indifferent Greek paintings of the last age of the empire, executed upon a stucco applied to the rock. Among the coffins of all sizes which are excavated in the floors of the sepulchral

polebral chambers, there are some so small as to be fit for nothing but the reception of a cat or lap-dog.

The edifices of Syracuse have not the usual appearance of those of Naples and Rome, but a mysterious tranquillity prevails in them perfectly adapted to the sanctuaries of repose. Voyage Pittoresque de Naples & Sicile. Swinburn's Travels.

The excavations of Malta are remarkable for the smallness of their dimensions, and their perfect preservation. Even in a white stone and perfectly dry, they appear like works of yesterday. The galleries are so narrow that only one person can pass at a time, rarely distributed and vaulted. At certain distances sepulchral chambers occur; the principal of these is decorated with two fluted columns. The tombs are regularly placed in square recesses, and ornamented with pediments. Small niches, apparently to receive lamps, are distributed in various places. No vestiges remain of inscriptions, sculpture, or painting. Voyage Pittoresque de Naples & Sicile.

CATACOUSTICS, from $\kappa\alpha\tau\alpha$ and $\alpha\kappa\omega\upsilon\sigma$, *I hear*, called also CATAPROUSTICS, the science of reflected sounds or echoes. See ACOUSTICS. Catacoustics is to acoustics what catoptrics is to optics.

CATACOUSTICS, in *Military Languages*, are *écoutes*, or small galleries from distance to distance in front of the glacis of a fortified place, all of which communicate with a gallery, that is carried parallel to the covert-way. The besieged make use of them in going to meet the enemy's miners and interrupt their progress.

CATADA, in *Ancient Geography*, now the *Miliana*, a river of Africa, which discharges itself into the Mediterranean, nearly S. of Carthage, and at a small distance from Rhades or Ades, forming the bay of Tunis. About a mile from it is the noted hot-bath called Hammam Leef, much resorted to by the inhabitants of Tunis.

CATADERBIS, a lake of Asia, in Susiana, abounding with fish, the mouth of which at the sea was nearly closed by the small isle Margastana, 500 stadia from the mouth of the river Arsis, according to the journal of the navigation of Nearchus. It is mentioned by Arrian.

CATIOPTRICAL *telescope*, the same with *reflecting telescope*, which see.

CATADRÆ, in *Ancient Geography*, a people of Ethiopia, near Egypt. Ptolemy says that they occupied the parts that lie S. of mount Garbate.

CATADROMUS, from $\kappa\alpha\tau\alpha$ and $\delta\rho\omicron\mu\omicron\varsigma$, *I run*, in *Antiquity*, a stretched sloping rope in the theatres, down which the funambuli walked to shew their skill.

Some have taken the word to signify the hippodrome, or *decurforium*, wherein the Roman knights used to exercise themselves in running and fighting on horse-back.

But the most natural meaning is that of a rope, fastened at one end to the top of the theatre, and at the other to the bottom, to walk or run down, with the highest glory of the ancient *sebenubates*, or *funambuli*. Elephants were also taught to run down the catadromus. Suetonius speaks of the exploit of a Roman knight, who passed down the catadromus mounted on an elephant's back, in Ner. cap. xi. p. 5.

CATADUPA, in *Hydrography*, a cataract, or water-fall. See CATARACT.

The word comes from $\kappa\alpha\tau\alpha$, downwards, and $\delta\alpha\pi\tau\omicron\varsigma$, to make a noise by falling.

The appellation catadupa seems to have been peculiarly given to a place in Æthiopia joining on Egypt, where the Nile, which here first assumes that name, rushed down a steep rock into the subjacent plain, with a noise so impetuous, that the inhabitants are said to have lost all sense of

hearing. Plin. Hist. Nat. lib. v. cap. 9. Ammian. Marc. lib. xxii. cap. 34, &c. Senec. Nat. Quæst. lib. iv. cap. 7.

CATADUPI, $\kappa\alpha\tau\alpha\delta\upsilon\pi\iota$, in *Ancient Geography*, an appellation given by the ancients to the inhabitants about the cataracts of the Nile. The catadupi are represented as all deaf; being made so by the continual din of the falling waters.

CATÆA, or CATTÆA, an island of the Persian gulf, on the coast of Carmania, according to the journal of the navigation of Nearchus; in whose time it was inhabited, and consecrated to divinites, whom he describes under the names of Mercury and Venus. It extended from the west-south-west to the east-north-east, and was distant about two or three leagues from the continent. Piny calls it *Apbrocissus*, which see.

CATÆONIUM *Promontorium*, a promontory of Africa, placed by Ptolemy in Marmarica.

CATAPALCO, an Italian term literally signifying *sea-flood*. It is chiefly used for a decoration of architecture, sculpture, and painting; raised on a timber scaffold, to shew a coffin, or tomb, in a funeral solemnity.

CATAGELI, in *Ancient Geography*, a town of Sicily, according to the scholiast of Aristophanes.

CATAGMATICS, in the *Materia Medica*, medicines proper to unite broken bones; by promoting the formation of a callus. The word comes from $\kappa\alpha\tau\alpha$, against, and $\alpha\gamma\mu\mu\alpha$, *I break*. Put as this is a power which is not certainly known to exist in any medicine whatever, the term, says Dr. Cullen, is falsely employed. See CONSOLIDATION.

CATAGOGION, $\kappa\alpha\tau\alpha\gamma\omicron\gamma\omicron\iota\omicron\upsilon$, a heathen festival at Ephesus, celebrated on the twenty-second of January, in which the devotees ran about the streets dressed in divers exotic and unseemly manners, with huge cudgels in their hands, and carrying with them the images of their gods; in which guise they ravished the women they met with, abused, and often killed the men, and committed many other disorders, to which the religion of the day gave a sanction. Du-Cange.

CATAGRAPHIA, $\kappa\alpha\tau\alpha\gamma\rho\alpha\phi\iota\alpha$, in *Antiquity*, denote oblique figures, or views of men's faces; answering to what the moderns call *PROFILES*. Catagrapha are said to be the invention of Simon Cleonæus, who first taught painters to vary the looks of their figures, and sometimes direct them upwards, sometimes downwards, and sometimes sideways, or backwards. Plin. Hist. Nat. lib. xxxv. cap. 8. cum Not. Hardouin.

CATALAUNI, or CATALAUNUM, in *Ancient Geography*, now *Chalens sur Marne*, a town of Gaul, in Belgica Secunda; called also "Duro-Catalauni," in the Itinerary of Antonine. It was before this place that the emperor Aurelian vanquished Tetricus, the president of Aquitania, who had been proclaimed emperor by the troops, according to Vopiscus and Eutropius.

CATALECTIC, a term in poetry, derived from $\kappa\alpha\tau\alpha$ and $\lambda\epsilon\gamma\omicron\varsigma$, *I end*. The ancients called *catalectic verses* those which wanted either feet or syllables, in opposition to *acatalecticis*, which are complete verses, wanting nothing.

CATALEPSY, in *Medicine*, $\kappa\alpha\tau\alpha\lambda\epsilon\psi\iota\varsigma$, *apprehensio, occupatio*, from $\kappa\alpha\tau\alpha\lambda\epsilon\psi\iota\sigma\theta\epsilon\iota\sigma$, to be seized or possessed, a disease in which the senses and the power of voluntary motion are suddenly suspended, the body and limbs of the patient remaining unmoved in the situation in which they happen to be at the moment of the attack, and readily receiving and retaining any other position, which is communicated to them by external force.

With respect to the nature of this singular disease, which is aptly enough compared by Van Swieten to that condition of the body, which was produced, according to the fictions

visions of the poets, by the sight of Medusa's head, much difference of opinion has existed among physicians, and various denominations have been given to it. By the ancient writers it does not appear to have been accurately distinguished from other soporose diseases. According to Galen, those affected with it were originally called *καταχουσι*, and the disease itself *catachoe* or *catochus*; but the catochus of Galen bears a greater resemblance to apoplexy or tetanus, and the term, perhaps, included the catalepsy, together with these diseases. Cælius Aurelianus, who considers the catalepsy as bearing an affinity chiefly to lethargy and apoplexy, has enumerated the fynonims, which his predecessors had employed to designate it. By Praxagoras and others it was included, he says, with the comatose affections, under the general terms, coma, lethargy, &c. By others some prominent symptom was assumed as a name for the disease, implying that its nature or affinity with other diseases was not understood; thus it was called *αναθηα* by Antigenes, from the loss of hearing which accompanied it, and *αφονια* by Diocles, from the loss of voice;—circumstances by which, however, it is obvious, it could not be distinguished from *syncope*, epilepsy, and many dissimilar disorders. Aesculapius first denominated it catalepsy; but he has not left any distinct description of the disease, such as it is now considered. (See Cæli Aureliani, de Tard. Passion. lib. ii. cap. 5.)

It is not quite clear whether Celsus was acquainted with the catalepsy, or not. The learned Van Swieten is of opinion, and in this he is followed by Morgagni, that this disease is meant by Celsus, when he speaks of persons, as it were, thunderstruck, *attoniti*. (De Medicin. lib. iii. cap. 26.) for although he confounds the disorder of the *attoniti* with the apoplexy of the Greeks, yet he describes it as a rare disease; while in the subsequent chapter he speaks of apoplexy again, as a palsy of the whole body, and a common disease; meaning the complaint commonly understood by that term. (See Van Swieten. Com. § 1007.) In short, the accounts to be collected from the ancient writers respecting the catalepsy are confused and imperfect, and appear to refer to various lethargic or comatose affections; and even to some spasmodic diseases, such as tetanus. Nor do we find all difference of opinion done away, if we descend to the more modern records of medicine; in which several histories are related under the title of cataleptic affections, which obviously belong to other genera of disease. This confusion, together with the extreme rarity of the true disease, and the wonderful histories of cataleptics, which have been detailed by authors, have induced some physicians of eminence, (and among these Dr. Cullen must be particularly mentioned,) to doubt of the existence of such a disease. In his Synopsis of Nosology, Dr. Cullen has mentioned this complaint as a species of apoplexy, under the title of *Apoplexia Cataleptica*; having believed that the cases of catalepsy described by authors were either varieties of apoplexy, or altogether feigned. He had seen no instance of cataleptic symptoms, but what was obviously a deception. The number of well authenticated examples on record, however, in which no cause of an attempt to deceive apparently existed, and which are related by physicians of character and sagacity, render the existence of catalepsy indubitable. Its symptoms are the following:

The patient is suddenly seized, sometimes after feeling a head ach, or stiffness of the neck, or exhibiting obvious signs of torpor of the mind or body, but generally without any previous symptom, with a rigidity of all the limbs; or in other words, the senses and the power of voluntary motion are suddenly suspended, so that the patient remains fixed in the

posture in which he happens to be at the moment of seizure, if he is sitting, he continues to sit; if standing, he remains upright; and if occupied in any mechanical employment, or under the influence of any passion of the mind, he continues in the attitude peculiar to his work, and the countenance retains the expression characteristic of the mental condition, "Sic manus erecta non delabitur; faciei musculi ad risum, ad æctum compositi, risum vel æctum constant expriment." Yet such is the state of equal, though involuntary action in the antagonit muscles, that the limbs are said commonly to retain any position into which they are put by external force. During the paroxysm the sensations are in general suspended; the patient neither receives any impression from external objects, nor retains any recollection of what happened during the fit. The vital functions continue to be performed, but more feebly; the pulse and respiration are regular, but the former is smaller than in health; the colour of the countenance usually undergoes little or no change. After a duration, which is various in different instances, commonly after a few minutes, sometimes after the lapse of a few hours, and occasionally, though rarely, after a continuance of three or four days, the paroxysm suddenly declines. The patient awakes as it were from sleep, generally with deep sighing, and all the functions of the body are restored.

The congeries of symptoms just enumerated constitutes what has been called by systematic writers, the perfect paroxysm, *catalepsis vera*, in which the abolition of the senses, both internal and external, is complete. But more frequently the loss of sense is only partial; and in some instances the senses all remain undiminished, while the voluntary motions are altogether suspended; so that, although the patient is conscious of every thing that is passing around him, he is unable to speak or move, or in any way to make known his feelings or wishes. An interesting example of this kind is on record, (see Duncan's Med. Comment. vol. x. p. 242.) in which a female lay in complete possession of her mental faculties, but deprived of the power of moving a muscle of the body. She was in the distressing condition of finding herself given up by the attendants as dead, of being laid out, with her toes tied together, and her chin tied up, and of hearing certain arrangements for her funeral talked of, yet she was unable to make the slightest sign of her possession of sense, feeling, and life. In other cases there is a certain degree of sense and consciousness during the fit, and of recollection of the circumstances of it afterwards; and the limbs, if bent, do not retain firmly the position into which they are moved, but return gradually to their original position. Some patients are able to move one hand or limb, while the others remain rigid; and some, though apparently lifeless in all other respects, yet retain the power of swallowing whatever is put into their mouths. These are said to be examples of *imperfect* or *spurious* catalepsy. See Sauvages's Nosol. Method. cl. vi. ord. 5. Vogel de Morb. Cognosc. et Curand. § 572. Burser. Inlitt. Med. Pract. tom. iii. cap. 5.

There is also another variety of the spurious catalepsy, which is described by the title of *Ectasis*, by some writers, in the paroxysm of which the imagination of the patient has pictured dreams of an extraordinary nature, which left a vivid impression upon the memory; and after the termination of the fit, she (for it appears to have happened generally with females,) has related accounts of surprising celestial visions, with which she had been favoured during the trance. Many of the histories of trances which are on record, are, however, beyond a doubt, altogether fabulous; and in many instances they have been pure deceptions, feigned with a

view of furthering some political or religious design, or of serving some private purpose;—deceptions such as were practised by diviners of old, and as have been resorted to by fanatics in all ages. Sometimes these *ecstasies* have been among the extravagancies of maniacs.

The particular condition of the body, or of the nervous system, which constitutes the cataleptic state, has been attempted to be explained in various ways. Dr. Cullen considered it as depending upon the same condition of the brain, by which the modification of palsy and apoplexy are produced, and there are some cases on record, which accord with this opinion. Such are two cases related by Henry ab Heers, (Observat. Med. Obs. 3.) which are obviously of an apoplectic nature. One of the patients was a Capuchin friar, who was attacked with the fit, when standing, and remained in an upright posture. The fit went slowly off, but he was seized a second time, and died. Vogel believes that the source of the cataleptic symptoms is rather to be traced to the stomach or abdomen than to the head, which seems to imply a notion that they were of an hysterical nature. The speculations of Boerhaave, Home, and others, respecting the interruption, superabundance, or quiescence of the *nervous fluid* in the voluntary muscles of the patient, merit little attention: they are either altogether gratuitous, or consist of a mere flatement of the facts in other and more ambiguous terms. We know very little in regard to the connection of many of the irregular actions of the nervous system, with the physical condition of the nerves, or of their common source, the brain: and we must content ourselves, for practical purposes, with endeavouring to trace, in the case of uncommon diseases, some analogy with those more common affections, with the treatment of which we are already acquainted.

Epilepsy appears to assume occasionally a cataleptic form; i. e. the paroxysms, which were in the beginning epileptic, become ultimately cataleptic; or vice versa; or the two forms alternate with each other. In those cases in which the patients have died *apoplectic*, the apoplexy must be considered as partaking of the nature of epilepsy, or, perhaps, ensuing to the epileptic state; for the symptoms of catalepsy, as they generally appear, are incompatible with the condition of pure apoplexy. In the latter, the nervous communication from the brain to the muscles is lost, and the limbs are consequently deprived of all power of action; in the catalepsy, on the contrary, a considerable degree of action exists in all the antagonist muscles, at the same time, and in an equal degree, so as to retain the limbs in any position in which they may be placed. The pulse, it may be also added, continues its usual beats, and is smaller than in health; and the complexion of the countenance is unaltered: nor do any of the ill effects of apoplexy remain after the termination of the paroxysm. In by far the most numerous well-authenticated instances on record, catalepsy obviously bears the closest analogy to, or rather appears to be a modification of, hysteria. This conclusion will be drawn, whether we consider the nature of the symptoms, the sex and constitution of the patient, the occasional complication and conversion of the disease, or the remedies which have been successfully employed in its cure.

As a proof of the intimate connection of the cataleptic with the hysterical paroxysm, we shall relate an account of one described by Dr. Jebb, which is similar to several others that have been recorded. The young lady, who was the subject of the disorder, was seized with the fit, when Dr. Jebb was announced on his first visit. "She was employed," he says, "in netting, and was passing the needle through the mesh; in which position she immediately became rigid, exhibiting, in a very pleasing form, a figure of death-like sleep,

beyond the power of art to imitate, or the imagination to conceive. Her forehead was serene, her features perfectly composed. The paleness of her colour, her breathing at a distance being only scarcely perceptible, operated in rendering the similitude to marble more exact and striking. The position of her fingers, hands, and arms, was altered with difficulty; but preserved every form of flexure they acquired: nor were the muscles of the neck exempted from this law; her head maintaining every situation in which the hand could place it, as firmly as her limbs.

"Upon gently raising the eye-lids, they immediately closed with a degree of spasm. The iris contracted upon the approach of a candle, as in a state of vigilance; the eye-ball itself was slightly agitated with a tremulous motion, not discernible when the eye-lid had descended.

"About half an hour after my arrival, the rigidity of her limbs and statue-like appearance being yet unaltered, she sung three plaintive songs, in a tone of voice so elegantly expressive, and with such affecting modulation, as evidently pointed out how much the most powerful passion of the mind was concerned in the production of her disorder, as indeed her history confirmed. In a few minutes afterwards she sighed deeply, and the spasm in her limbs was immediately relaxed. She complained that she could not open her eyes, her hands grew cold, a general tremor followed; but in a few seconds, recovering entirely her recollection and powers of motion, she entered into a detail of her symptoms, and the history of her complaints. After she had discoursed for some time with apparent calmness, the universal spasm suddenly returned. Her features now assumed a different form, denoting a mind strongly impressed with anxiety and apprehension. At times she uttered short and vehement exclamations, in a piercing tone of voice, expressive of the passions that agitated her mind; her hands being strongly locked in each other, and all her muscles, those subservient to speech excepted, being affected with the same rigidity as before." (See Select Cases of Paralysis of the Lower Extrem. by Dr. Jebb, Appendix.) These paroxysms obviously participate of the character of hysteria. The appearances, indeed, are not common; but the varying forms of hysterical diseases are a subject of general observation. Sydenham long ago remarked, that "a day would scarce suffice to enumerate all the symptoms of hysterical complaints, so various they are, and so contrary to one another, that Proteus did not assume more shapes, nor the chameleon a greater variety of colours."

A very large proportion of the decided cases of catalepsy, which have been distinctly recorded, occurred in the female sex, or in hypochondriacal constitutions. Sauvages has related the histories of several cataleptic patients, all of whom were females, and of hysterical habits; and several modern and well authenticated examples are of the same nature. (Saw. loc. cit. Jebb, loc. cit. Hist. Acad. Roy. de Sciences, Paris, 1738, &c. British Magazine, 1800. Edin. Med. & Surg. Journ. vol. i. p. 61, 1805. Mem. Roy. Acad. Scien. of Sweden, 1778.) The last reference is to the case of a melancholic or hypochondriacal man, in whom the catalepsy was accompanied with *trismus*, or locked jaw. Instances are related by other authors in which the catalepsy was joined, or alternated, as well with melancholy, somnambulism, convulsions, &c. as with proper hysterical symptoms; or readily passed into these maladies.

The remote or occasional causes of catalepsy are various. In the majority of instances they appear to have been the same, which, in constitutions naturally pre-disposed to diseases of mobility, excite all the varieties of hysterical and other nervous symptoms; such are all circumstances which powerfully

powerfully influence the mind, or debilitate the body, and thus induce a degree of morbid sensibility and irritability throughout the system. Hence, among the more frequent causes of catalepsy enumerated by authors, are grief, terror, anxiety, love, intense studies, indigestion, cold, strong liquors, acute fevers, &c. Where the disease has been a modification of epilepsy or of apoplexy, if this ever happen, the causes were such as produce other forms of those complaints. See EPILEPSY, &c.

If we consider the nature of the cataleptic disease, in its more common form of *catalepsys hysterica*, it will be obvious by what means the cure is to be attempted. In the various cases which are recorded, it has been often successfully treated by the same remedies to which other nervous and spasmodic diseases commonly yield. Where it occurs in florid and plethoric habits, as hysteria occasionally does, bleeding from the arm or the jugular vein has been practised with advantage, especially during the paroxysm; this, however, is very rarely requisite. Gentle laxatives have been found useful; and in this, probably, as in other nervous complaints, the regular evacuation of the bowels is of the utmost importance. The whole tribe of stimulants and tonics have been resorted to, especially in the modern instances, the former with a view of counteracting the inordinate actions of the nervous system, and the latter in order to restore the strength, and obviate the morbid irritability of the patient. In the fit, opium, ether, volatile alkali, and various fetid antispasmodics, have been administered; errhines have been applied to the nostrils; narcotic or acrid and stimulating glysters injected into the bowels; and friction with mustard, or strong spirits, also employed on the limbs, and surface of the body. In the intervals between the paroxysms, bitter medicines have been given, the cold bath has been prescribed, and exercise in various ways resorted to successfully in different instances. The principle, in short, upon which the disease has been treated, appears to be the same with that upon which all other diseases of nervous mobility have been successfully combated. If the lethargic, apoplectic, or epileptic disorders assume the cataleptic form, which must be determined by the concomitant circumstances, the remedies adapted to the cure of these disorders respectively will of course be indicated.

Before we conclude this article, we cannot forbear to mention an extraordinary account of a woman, labouring under *catalepsys hysterica*, which has been lately published by an old and most respectable physician, Dr. Petetin, of Lyons, president of the Medical Society of that place. The title of his work is "Électricité Animale, prouvée par la découverte des phénomènes physiques et moraux de la catalepsie hystérique, &c." The case which is here related occurred some years ago, and another similar one now exists at Lyons. The history, we must acknowledge, excites our scepticism, but, on the other hand, the respectability of Dr. Petetin, supported by a letter, which we have perused, from a young physician of character at Lyons, who went to see the patient, doubting of all he had heard, but returned fully convinced of its truth, is entitled to attention. In these cases, it is affirmed, that *the senses were transferred to the pit of the stomach, and to the ends of the fingers and toes*; i. e. that the patients, in a state of insensibility to all external impressions upon the proper organs of sense, were, nevertheless, capable of hearing, seeing, smelling, and tasting whatever was approached to the pit of the stomach, or to the ends of the fingers and toes. Dr. Petetin attributes these extraordinary phenomena to the influence of animal electricity or galvanism; and affirms, that if the objects were not applied to the pit of the stomach, but made to communicate with it

by an electric conductor, the sensations were still excited; but that if the communication were interrupted, as by a piece of silk, or other non-conductor, the effect was altogether prevented. The patients are said to have answered questions proposed to the pit of the stomach, to have told the hour by a watch placed there, to have tasted food, and smelt the fragrance of apricots touching the part, &c. &c. Dr. Petetin concludes that hysterical catalepsy should be thus defined: "Abolition réelle des sens, et apparente de la connoissance et du mouvement, avec transport, des premiers ou de quelques-uns d'entre eux dans l'épigastre, à l'extrémité des doigts et des orteils; et pour l'ordinaire disposition de la part des membres à recevoir et à conserver les attitudes qu'on leur donne," p. 140.

The physician whose letter on the subject we have perused, observes, that Dr. Petetin's pamphlet has been and is still considered by many "comme une folie, comme le rêve d'une imagination exaltée;" but he avers, that it is nevertheless true. "I can assure you," he concludes, "that I have observed this cataleptic patient with the most scrupulous attention; that my experiments have been made with every caution, not for the purpose of publication, but solely with a view of satisfying myself as to the reality of a disease of which I had long doubted; and that the result has been a perfect conviction that all I have seen is true. If it be not, my senses have strangely deceived me." Until we obtain farther evidence upon the subject, we leave our readers to balance these authorities against the extraordinary nature of the facts which they promulgate.

CATALINA HARBOUR, in *Geography*, a bay on the east coast of Newfoundland. N. lat. 48° 38'. W. long. 53° 45'.

CATALIS *captis nomine distributionis*, in *Law*, an ancient writ that lay where a house was within a borough, for rent issuing out of the same; and which warranted the taking of doors, windows, &c. by way of distress for rent. Old Nat. Brev. 66. This writ is now obsolete.

CATALIS *reddendis*, an ancient writ which lay, where goods, being delivered to persons to keep till a certain day, are not, upon demand, delivered on that day. It may be otherwise called a "writ of detinue," and corresponds to "actio depositi" in the civil law. Reg. Orig. 139. Old Nat. Brev. 63.

CATALOGUE, a list or enumeration of the names of several books, men, or other things; disposed according to a certain order.

George Willer, sometimes improperly called Viller, and Walter, a bookseller at Augsberg, who frequented the Franckfort fairs, first adopted the plan of causing to be printed for every fair a catalogue of all the new books, in which the size and the names of the printers were marked. Le Mire, better known under the name of Miræus, a catholic clergyman, who was born in 1598, and died in 1640, in his work "De Scriptoribus ecclesiasticis seculi xvi." printed in the "Bibliotheca Ecclesiastica" of Fabricius, Hamb. 1718, fol. informs us, that catalogues were first printed in the year 1554; but Labbe (Bibliotheca Bibliothecarum, Lips. 1682, 2mo. p. 112.), Reimann (Einleitung in die *Historiam Litterariam*, l. p. 203.), and Heumann (Conspectus Reip. Liter. c. vi. § 2. p. 316.), who took their information from Le Mire, erroneously make the year to be 1564, which error is copied by Fabricius. Willer's catalogues were printed till the year 1593 by Nicol. Bassaus, printer at Franckfort. Other booksellers, however, must soon have published catalogues of the like kind, though that of Willer continued a long time to be the principal. Among the many curious and rare articles in the library of professor Baldinger, there

is a collection of old catalogues, the earliest of which are the following: *Catalogue novum nundinarum autumnalium*, Francof. ad Mœn. anno 1586, celebratarum. Plerique apud Joan. Georg. Portenbachium et Th. Lutz. bibliopolam Auguttanum venales habentur; *A catalogue of all the new books*—printed at Franckfort, by Peter Schmid. This catalogue was published by booksellers of Augsburg; but not by Willer, of whom we have, *Catalogus novus nundinarum autumnalium*, Francof. ad Mœn. anno 1587.—Plerique in ædibus Georgii Willeri, bibliopote Auguttani, venales habentur. *A catalogue of almost all the books which have been published between last Easter and the present September fairs*. Franckfort on the Mayn, printed by Nicolas Bassæus. In all these catalogues, printed in 4to. and not paged, the following order is observed. The Latin books occupy the first place, beginning with the Protestant theological works, probably because Willer was a Lutheran; then the Catholic; and after these the books of jurisprudence, medicine, philosophy, poetry, and music. The second place is assigned to German books, which are arranged in the same manner. The last Easter catalogue of Willer, that is found in Baldinger's library, is dated 1597, with the following title: "Plerique libri in ædibus Eliæ et Georgii Willeri, fratrum bibliopolarum Auguttanorum, habentur;" printed by Bassæus at Franckfort. In 1604, the general Easter catalogue was printed with a permission from government, as appears by the following title: "Catalogus univèrsalis pro nundinis Francof. de anno 1604;" Francof. permisso superiorum excudebat Joh. Saur. After this the Leipzig booksellers began not only to reprint the Franckfort catalogues, but to enlarge them with many books which had not been brought to the fairs in that city. Accordingly Baldinger's library has "Catalogus univèrsalis pro nundinis Francofurtensibus vernalisibus de anno 1600;" printed at Leipzig by Abraham Lamberg. An imperial privilege appears, for the first time, in the Franckfort September catalogue of 1616; "cum gratia et privilegio specialis S. Caf. Maj. Prostat apud J. Krugerum Auguttanum." Some imperial permissions, however, may be of an earlier date. Reimann (ubi supra) says, that, after Willer's death, the catalogue was published by the Leipzig bookseller, Henning Grolfe, and by his son and grandson. The council of Franckfort caused several regulations to be issued respecting catalogues; of which an account may be seen in "D'Orth's Treatise on the Imperial Fairs at Franckfort." After the business of bookfelling was drawn from Franckfort to Leipzig, occasioned principally by the restrictions to which it was subjected at the former place by the censors, no more catalogues were printed there; and the shops in Book-street were gradually converted into taverns. See BOOKSELLER.

In perusing these old catalogues, the sudden and great increase of books may well excite astonishment; and when we reflect that a great, perhaps the greater, part of them no longer exist, this perishableness of human labours will produce the same sensations with those which arise in the mind when we read in a church-yard the names and titles of persons long since mouldered into dust. In the 16th century there were few libraries; and these, which did not contain many books, were in monasteries, and consisted principally of theological, philosophical, and historical works, with a few, however, on jurisprudence and medicine; while those which treated of agriculture, manufactures, and trade, were thought unworthy of the notice of the learned, and of being preserved in large collections. The number of these works was, nevertheless, far from being inconsiderable; and, at any rate, many of them would have been of great use, as they would have served to illustrate the instructive history of the arts. Catalogues which might have occasioned inquiries

after books that may be still somewhere preserved, have suffered the fate of tombstones, which, being wasted and crumbled to pieces by the destroying hand of time, become no longer legible. A complete series of them is no where to be found. The loss, however, might in some measure be supplied by two works, that are now exceedingly scarce; viz. those of Clefs and Draudius; who, by the desire of some booksellers, collected together, as Georg did at a later period, all the catalogues published at the different fairs, in different years. The work of Clefs has the following title: "Unius sæculi ejusque virorum litteratorum monumentis tum florentissimi, tum fertilissimi, ab anno 1500 ad 1602 nundinarum autumnalium inclusive, elenchus consummatissimus—desumptus partim ex singulis nundinarum catalogis, partim ex bibliothecis;" first published in 1592. The work of Draudius, printed in several 4to. volumes, for the first time in 1611, and afterwards in 1625, is much larger, more complete, and more methodical. The first part is entitled "Bibliotheca classica, five catalogus officialis, in quo singul' singularum facultatum ac professionum libri, qui in quavis fere lingua extant—recensentur; usque ad annum 1624 inclusive;" auctore G. Draudio, Francof. 1625. This contains Latin works on theology, jurisprudence, medicine, history, geography, and politics. The second part is entitled, "Bibliotheca classica, five catalogus officialis, in quo philosophici artiumque adco humaniorum, poetici etiam et musici libri, usque ad annum 1624 continentur." This part contains Latin books, with an index of all the authors that are mentioned. A small volume, without an index, is entitled, "Bibliotheca exotica, five catalogus officialis librorum peregrinis linguis usulibus scriptorum;" and a third part, containing an index of the authors, is called "Bibliotheca librorum Germanico-rum classica," 1625. This work of Draudius, though it mentions many books which were never printed, and though many titles, names, and dates are given incorrectly, well deserves the attention of those who wish to acquaint themselves with the history of literature; and it was undoubtedly of use to Haller, when he composed his Bibliotheca. See on this subject Beckmann's Hill. of Inventions. vol. iii.

Catalogues of books are digested in different manners; some according to the order of the times when the books were printed, as that of Maittaire; others according to their form and size, as the common booksellers' catalogues; others according to the alphabetical order of the authors' names, as Hyde's catalogue of the Bodlian library; others according to the alphabetical order of matters or subjects which are called real or classical catalogues, as those of Lipenius and Draudius; lastly, others are digested in a mixed method, partaking of several of the former, as de Seine's catalogue of cardinal Stufius's library, which is first divided according to the subjects or sciences, and afterwards the books in each are recited alphabetically.

The most applauded of all catalogues is that of Thuanus's library, in which are united the advantages of all the rest. It was first drawn up by the two Puteani in the alphabetical order, then digested according to the sciences and subjects, by Jhu. Bullialdus, and published by F. Quesnel at Paris in 1679, and reprinted, though incorrectly, at Hamburg in 1704. The books are here ranged with justice under their several sciences and subjects, regard being still had to the nation, sect, age, &c. of every writer. Add, that only the best and choicest books in every subject are found here, and the most valuable editions. Yet the catalogue of M. le Tellier, archbishop of Rheims's library, made by M. Clement, is not inferior to any published in our age, either on account of the number and choice of the books or the method of its disposition.

One advantage, peculiar to this catalogue, is the multitude of anonymous or pseudonymous authors detected in it, scarcely to be met with elsewhere. Some even prefer it to Thuanus's catalogue, as containing a greater variety of classes and books on particular subjects. Bibliotheca Thuanae, Par. 1679, 8vo. 2 vols. and Hamb. 1704, fol. and 8vo.

The conditions required in a catalogue are, that it indicate at the same time the order of the authors and of the matters, the form of the book, the number of volumes, the chronological order of the editions, the language in which it is written, and its place in the library; so that all these circumstances may appear at once, in the shortest, clearest, and exactest manner possible. In this view, all the catalogues yet made will be found to be defective.

An anonymous French writer has hid down a new plan of a catalogue, which shall unite all the advantages, and avoid all the inconveniences of the rest. Lett. à l'Abbé ***; sur un Nouveau Projet de Catalogue de Bibliothéque. Par 1712.

The Jesuits of Antwerp have given us a catalogue of the popes; which makes what they call their *Propyleum*.

CATALOGUE of the stars, is a list of the fixed stars, disposed according to some order in their several constellations; with the longitudes, latitudes, right ascensions, &c. of each.

Catalogues of the stars have been usually restricted to two forms; in the first and most ancient, the stars were classed in their respective constellations; in the latter, they followed one another, in a continued series, according to their right ascensions, or the order in which they transit the meridian. All the catalogues, from the most ancient to that of Flamsteed inclusively, were of the first of these forms; but most of those which have been since constructed are of the latter form, as being much more convenient for the greatest variety of useful purposes. Another catalogue of a third kind has been lately formed, in which the stars are disposed in classes according to zones, or their degrees of polar distance.

The first who undertook to reduce the fixed stars into a catalogue, was Hipparchus Rhodius, about one hundred and twenty-eight years before Christ; in which he made use of the observations of Timocharis and Aristyllus, for about 180 years before him. Pliny informs us (N. H. lib. ii. c. 26) that he, upon the appearance of a new star, began to doubt whether there might not be changes among the fixed stars, and therefore made a catalogue of them, setting down the place and magnitude of each star, so that if, in future time, any new stars should appear, or any of those already observed by him should increase or be diminished in magnitude, or should totally disappear, such changes might be known to succeeding ages. Ptolemy retained Hipparchus's catalogue, containing 1022 stars, with some few alterations; though he himself made many observations, with a view to a new catalogue, A. D. 140. Ptolemy tells us, that he added 2° 40' to the longitudes of Hipparchus, in order to reduce them, from the beginning of the 128th year B. C. (the epoch for which Hipparchus had given them), to the beginning of the year 137 after Christ, or the first of Antoninus Pius. This allowance is after the rate of one degree in 100 years, the quantity of the precession which was found by Hipparchus, from comparing his own observations of Spica Virginis with those which had been made of the same star by Timocharis, about 140 years before; and hence it is manifest that Ptolemy depended on no observations made by himself in this business, but rested wholly on such as had been made

by those two excellent astronomers, three centuries before his time. If he had made any observations himself, he must have found that the quantity which he allowed was too small, by a whole degree at the least; the true quantity of the precession for 265 years (the difference of the epochs being 5° 42' 22.6"). To compare his tables, therefore, with the present, we must still increase his numbers by 1° 2' 22", and then allow for the precession from that time to this. This catalogue, as we have it in Ptolemy, contains 1026 stars, in 47 constellations; but, according to Pliny (N. H. c. 41) it contained 1600 stars, in 72 constellations. This author, however, is so subject to error, that little attention has been paid to what he says on the subject; and it has generally been concluded that the catalogue never contained more stars than are to be found in Ptolemy; especially as none of the copies, which the Arabs have let us, contain more. About the year of Christ 882, Albatgeui, a Syrian, brought down this catalogue to his time.

The most ancient catalogue which the Chinese now have was made in the year of Christ 1050. The Arabians are the first who, after Ptolemy, observed the stars, and noted down their places. The learned Dr. Hyde mentions several of their catalogues; and he published the most considerable of them, with a Latin translation and notes, at Oxford in 1665. This catalogue was made by Ulugh Beigh, a prince of Tartary, and grandson of the famous Tamerlane, from his own observations at Samarcand; it contains the places of 1022, or according to some, 1116 stars, adapted to the beginning of the 841st year of the Hegira, or the year 1437 after Christ. The third person who made a catalogue of the stars from his own observations was Tycho Brahe; who determined the places of 777 stars, for the year 1600. His "Progymnasmatra," published in 1610, contained only this number, and his "Opera omnia," printed in 1648, contain no more. However the places of 223 more stars had then been deduced from his own observations by Kepler, and published with those of the former 777, at the end of the Rodolphine tables, in 1627. The places of the stars, in this catalogue, are adjusted to the end of the year 1600. Kepler added to the 1000 stars observed by Tycho those of Ptolemy's catalogue, which he had omitted, together with those of the new southern constellations, from other authors; so that his whole catalogue amounts to above 1160; their places being computed for the year 1600. About the same time with Tycho, William, landgrave of Hesse, with the aid of his mathematicians, Christopher Rothmannus and Justus Byrgius, determined the places of 400 fixed stars, by his own observations, with their places rectified for the year 1593; which Hevelius prefers to those of Tycho. This catalogue was first published by Willebrord Snellius in 1618, and is said to have contained the places of 400 stars; but the copy of it which we have in the third volume of Flamsteed's "Historia Cœlestis," contains no more than 378. Ricciolus, in his "Astronomia Reformata," determined the places of 101 stars for the year 1700, from his own observations; for the rest he followed Tycho's catalogue, altering it where he thought fit. In the year 1667, Dr. Halley, in the island of St. Helena, observed 350 southern stars, not visible in our horizon. The same labour was also repeated by F. Noel in 1710, who published a new catalogue of the same stars constructed for the year 1687.

In 1603, John Bayer, in his "Uranometria," published a catalogue of 1160 stars, at Augsburg in Germany; and here the situations of the stars, with respect to the constellation in which they are placed, are expressed in words; but their longitudes and latitudes are exhibited by means of maps, in which the figures of the constellations are drawn, and their stars put down in their proper places, and of their respective

appetite and desire. The chief difference, however, of the publications consists in the authors having marked every star with a letter: the brightest or biggest star in each constellation being always denoted by the first letter in the Greek alphabet; the next in degree of brightness, by the second; and so the same through 25, and so on; and when the stars in any constellation exceed the number of letters in that alphabet, the stars remaining are marked by Roman letters; the relative brightness of the stars being still expressed by the order of the letters. By these means, we are enabled not only to refer to every star in the heavens, with great readiness and precision, but to express, likewise, its relative brightness to other stars in the same constellation; and, in some degree, its magnitude also. This invention is so useful, that Flamsteed has, in his catalogue, adopted Bayer's letters, as far as they go; Senex has also done the same upon his globes of the largest size, and also upon his planetariums; and it is followed by most astronomers since his time. Bayer cannot be supposed to have formed this catalogue from his own observations. The places of such stars as are visible in Europe were taken from the catalogues of Ptolemy and Tycho Brahe; and with respect to those which are about the fourth pole, he tells us, that they are partly taken from the observations of Americo Vesputius, partly from those of Andrew Corsalis, and partly from those of Peter de Medina; and that Peter Theodore, a most useful manner, first formed them into constellations, and published them. In 1677, John Hevelius of Dantzic, published his "Machina Cœlestis," which, among other curious and valuable articles, contained a catalogue of the fixed stars. This work is very rare; as the greatest part of the impression was burned with his observatory and instruments, on the 26th of September, 1679. The catalogue is said to have contained the places of 1888 stars, of which 1553 were observed by himself; but as it stands in the "Historia Cœlestis," of Flamsteed (1725), it contains only 1520 stars. Their places are rectified to the end of the year 1660. The most complete catalogue that ever was given from the labours of one man is the Britannic catalogue, deduced from the observations of the Rev. John Flamsteed, the first royal astronomer at Greenwich; who for many years devoted himself wholly to that business. As there was nothing wanting either in the observer or the apparatus, we may consider this as a perfect work, so far as it extends. It is, however, to be regretted that the impression did not pass through his own hands; that now extant was published by authority, but without the author's consent. We have two editions of this catalogue; the first in 1712, which is generally called Dr. Halley's edition, because he was employed as the editor by prince George of Denmark, at whose expense it was printed. This edition contains only 2680 stars: owing, possibly, to its having been published without the consent, and, it is apprehended, contrary to the wishes of Mr. Flamsteed, who might not, on that account, contribute all the materials for it, which he could have done. It is, however, more correct in some instances, than that which was published in 1725, by Mr. Flamsteed's executors, in pursuance of his will; but this latter contains the places of 2934 stars, and is that to which astronomers generally refer. The stars in both are adapted to the beginning of the year 1690. They are distinguished into seven degrees of magnitude (of which those of the 7th degree are telescopic) in their proper constellations. To the last is added Mr. Sharp's catalogue of the southern stars not visible in our hemisphere, adapted to the year 1726. See vol. iii. of the "Historia Cœlestis," in which are printed the catalogues of Ptolemy, Ulugh

Brigh, Tycho, the prince of Hesse, and Hevelius; together with an account of each of them in the "Prolegomena." In 1782, M. B. de member of the Royal Academy of Sciences at Berlin, published a very extensive catalogue of the fixed stars, collected from the observations of Flamsteed, Bradley, Hevelius, Tobias Mayer, De la Caille, Messier, La Moirre, D'Arquier, and other astronomers; in which the places of the stars, amounting in number to 5658, are given for the beginning of the year 1780. This catalogue, which is a very valuable work, though there is reason to apprehend that the last star is inserted more than once, is accompanied by a celestial atlas, or set of maps of the constellations, engraved in a very delicate and beautiful manner.

In all the catalogues already enumerated, the stars are classed in constellations. In the following catalogues they succeed each other according to the order in which they transit the meridian, without any regard to the constellation to which they belong; the name of the star's situation in it. The first catalogue of the stars, as we conceive, that was printed in this form, or in the order of their right ascensions, is that of M. de la Caille, given at the beginning of his Ephemerides, for the 10 years between 1755 and 1765, and printed in 1755. It contains the right ascensions and declinations of 307 stars, adapted to the beginning of the year 1750. In 1757, he published his "Astronomiæ Fundamenta," in which is a catalogue of the right ascensions and declinations of 398 stars, adapted likewise to the beginning of 1750. In 1763, the year immediately succeeding that of his death, the "Cælum Australe Stelliferum" of the same author was published; and this contains a catalogue of the places of 1942 stars, all situated to the southward of the tropic of Capricorn, and observed by the same indefatigable astronomer while he was at the Cape of Good Hope in 1751 and 1752. The places of these are given for the beginning of the year 1750. In the same year, the Ephemerides for the 10 years between 1765 and 1775 were published; in the introduction to which the places of 515 zodiacal stars are given, all deduced from his own observations. The stars in this catalogue are rectified to the beginning of the year 1765. The nautical almanac for 1773 contains a catalogue of 380 stars, in right ascension, declination, longitude, and latitude, derived from the observations of the late Rev. Dr. Bradley, and adjusted to the beginning of the year 1760. It has been since, viz. in 1798, republished with corrections by Dr. Hornsby, in the first volume of Bradley's observations. These make but a small part of what might have been deduced from the labours of that great man, if his representatives had not withheld the rest from the public. Mr. Wollaston, (ubi infra) informs us, that Dr. Bradley had the whole British catalogue calculated to the year 1744; and that traces may be observed in it of his having examined almost every star in it. He adds, from satisfactory information, that Dr. Bradley observed the British catalogue twice through: first with the old instruments of the royal observatory, previous to 1750, and afterwards with the new ones. The 380 stars above-mentioned were carefully rectified for the year 1790 by Mr. G. Gilpin. For a brief account of the state of Dr. Bradley's papers, see the article BRADLEY. In 1775, a thin volume, containing several papers of the late celebrated Tobias Mayer, of Gottingen, was published, under the title of "Opera Inedita;" and among the rest, a catalogue of the right ascension and declination of 698 stars, which may be occulted by the moon and planets. It is adapted to the beginning of the year 1756; and, from the known

skill and accuracy of its author, is much valued. At the end of the first volume of "Astronomical Observations made at the Royal Observatory at Greenwich," published in 1776, Dr. Maskelyne, the present astronomer royal, has given a catalogue of the places of 34 principal stars, in right ascension and north polar distance, adapted to the beginning of the year 1770; and which, being the result of several years' repeated observations, made with the utmost care, and the best instruments, may be presumed to be exceedingly accurate. In 1776, a work was published at Berlin, entitled "Receuil de Tables Astronomiques," in which is contained a very large catalogue of stars from Hevelius, Flamsteed, M. de la Caille, and Dr. Bradley, with their latitudes and longitudes, for the beginning of 1800; with a catalogue of the southern stars of M. de la Caille, of double stars, of changeable stars, and of nebulous stars: a work very useful for the practical astronomer. To these may be added Dr. Herschel's catalogue of double stars, printed in the Philosophical Transactions for 1782 and 1783; M. Messier's nebulae and clusters of stars, published in the "Connoissance des Temps" for 1784; and Dr. Herschel's catalogue of the same kind, given in the Philosophical Transactions for 1786. In 1789, Mr. Francis Wollaston published in folio a "Specimen of a general astronomical Catalogue, arranged in Zones of north-polar Distance, and adapted to January 1, 1790." In forming this catalogue, Mr. Wollaston has not made any use of those which precede Flamsteed, except in a small part that of Hevelius; but all the stars in the British catalogue of 1725 are inserted, as well as those which are in the three latter catalogues of M. de la Caille, those of Dr. Bradley in the Nautical Almanac for 1773, of M. Mayer, of Dr. Maskelyne, the double stars of Dr. Herschel, M. Messier's nebulae, and all those of Dr. Herschel, excepting his 2d and 3d classes, that is, all those which are capable of being discerned with any telescopes inferior to his own. This work contains five distinct catalogues; viz. Dr. Maskelyne's new catalogue of 36 principal fixed stars; a general catalogue of all the stars, in zones of north-polar distance; an index to the general catalogue; a catalogue of all the stars in the order in which they pass the meridian; and a catalogue of zodiacal stars, in longitude and latitude.

The first catalogue contains the right ascensions in time, the annual precession of right ascension in time, and the annual proper motion, both in time and in degrees, for each star, and also the zone to which it belongs in the second catalogue. These circumstances are deduced from a multitude of observations, recently made, with the utmost care and circumspection, by the astronomer royal, for the purpose of determining, when compared with his former settlement of the same stars in 1770, whether those stars have any motion of their own, and what it is. That the *fixed* stars, as they are usually called, have a proper motion of their own, has long been suspected; and it was supposed that it had even been detected in Arcturus: but this motion is certainly so small, that no observations, made before Dr. Bradley's time, were sufficient to exhibit it; and the basis of twenty years, which our present ingenious and indefatigable astronomer royal has yet been able to obtain, seems much too short to determine it with any great degree of accuracy, even in the present improved state of astronomical instruments. The observations, however, sufficiently indicate such a motion in all the stars, and one which is pretty considerable in Arcturus.

The second catalogue, or that in zones, as its disposition is entirely new, will require some explanation. All the stars which are situated within 10 degrees of the north pole are

collected together, and inserted in a catalogue by themselves, according to the order in which they pass the meridian; and this is called the first zone. The second zone contains all the stars which are situated at a greater distance from the north pole than 10 degrees, and at a less distance than 15 degrees, disposed in the same manner. The third zone contains all the stars which are distant between 15 and 20 degrees from the north pole: but hence, till the author comes within 20 degrees of the fourth pole, the zones are but one degree in breadth, that is, the fourth zone contains all the stars which are at the distance of more than 20 degrees from the north pole, and less than 21 degrees, disposed in the order in which they pass the meridian, and so on. The stars which are at a less distance from the fourth pole than 20 degrees, are disposed, like those which are at the same distance from the north pole, into two zones, each 5 degrees broad, and into one which is 10 degrees broad: so that the whole number of the stars is distributed into 146 distinct catalogues, or zones; and in each of these the stars follow one another in the order in which they pass the meridian.

Each of these catalogues employs nine columns: the first contains the right ascension of the stars, in degrees, for the 1st of January 1790; the second, the precession of right ascension, in the same measure; the third, their right ascensions in time; and the fourth, the precession in time. The fifth contains the star's distance from the north pole; the sixth, its precession in north-polar distance. In the seventh, the magnitude is expressed; the eighth contains the number, name, or character of the star, together with the name of the observer by whom its position was ascertained; and the ninth column contains short notes, intended to call the attention of observers to certain circumstances there mentioned, in order that they may either be disproved or verified by future observations. Where the situation of a star has been given by different observers, as is the case in most, each of their situations is given, reduced to the same time, (January the 1st, 1790,) and set down in the order in which their observations were made. By these means, it is readily seen how far different observers agree with each other, and wherein they disagree.

Mr. Wollaston's reason for thinking that a catalogue of the fixed stars would be more useful in this form than in any other, is stated in the Phil. Trans. vol. lxxiv. p. 181, and vol. lxxv. p. 346; where the author proposes frequent examinations of the heavens, as the means of detecting any alterations which may happen among the fixed stars. In this business, every astronomer was invited to take a part, and to examine a certain number of zones, (each one degree in breadth,) with a telescope of a large field, mounted on a polar axis, and furnished with a system of wires in its focus. This telescope being directed to the proper parallel of declination, and fixed there, the business of the observer would be, to take the transits of all the stars which passed the field of the telescope, at the several wires in its focus; which were so disposed as to give both the difference of right ascension and declination between them; and for such a purpose, this catalogue is evidently well adapted.

The third catalogue is called, an index to the stars in the British catalogue, referring to the zone of north-polar distance, in which each star is to be found. This catalogue contains only the stars in the British catalogue of 1725, arranged in constellations; and the stars in each constellation follow one another in the same order as in that catalogue; but the constellations are disposed alphabetically. The catalogue employs three columns: the first containing the number of the star, as it stands in the British catalogue; the se-

cond, Bayer's letter of reference, where the star has one; and the third, the number of the zone to which the star belongs in the second catalogue, reckoning from the north pole; but the reader must take care that he is not misled with regard to the import of this last column: the author does not mean, by the number there put down, the number of the zones as they stand in his catalogue, but the number of the zones in which it would have been, if every one of his zones had been no more than one degree in breadth; so that his first zone, (as described above) is to be considered as containing 10 of the zones in the second catalogue; and the second and third zones must be considered as each containing five.

The fourth catalogue contains the stars of the British catalogue, of de la Caille's southern catalogue, and about eighty stars from Hevelius's catalogue, which were omitted by Flamsteed, all arranged in one continued series, according to the order in which they pass the meridian. This catalogue employs four columns: the first containing the star's right ascension in time, for the 1st of January 1790, put down to the nearest second; the second, the star's distance from the north pole, for the same time; the third, the magnitude of the star; and the fourth, the number, name, or character of the star, and the constellation in which it is placed.

The fifth catalogue gives the longitudes and latitudes of such stars as are situated within nine degrees of the ecliptic, arranged in the order of their longitudes. It contains all the stars which are to be found within these limits, in the catalogues of Flamsteed, Bradley, Mayer, and the small catalogue of de la Caille, at page 258 of his "Astronomiæ Fundamenta." This catalogue employs five columns: the longitude of the star, reduced to the beginning of 1790, stands in the first column; the second contains the latitudes of such stars as are on the north side of the ecliptic; and the third gives the latitudes of such as are on the south side of it. The fourth column exhibits the magnitude of the star; and the fifth, the number, name, or character of it, and the name of the observer who assigned its situation. Where any star has been observed by two or more persons, the result of each of their observations, (reduced to the same epocha,) is inserted, in the order in which their observations were made.

In 1792, Dr. Francisco de Zach published at Gotha, "Tabulæ Motuum Solis;" to which is annexed a new catalogue of the principal fixed stars from his own observations, made in the years 1787, 1788, 1789, 1790. This catalogue contains the right ascension and declination, with the magnitudes and annual variations in right ascension of 381 principal stars, adapted to the beginning of the year 1800. The catalogues of the places of Dr. Bradley's 389 fixed stars, adapted to the beginning of the year 1700; of those of M. de la Caille's 515 zodiacal stars, adapted to the beginning of the year 1763; of the same author's 107 principal stars in the heavens, adapted to the year 1750; of Zach's 381 principal fixed stars, adapted to the beginning of the year 1800; of the same author's declinations of 102 principal fixed stars, with their annual variations, adapted to the beginning of the year 1800; and of Mayer's 992 principal fixed stars, adapted to the year 1790; are published by professor Vince in the 2d volume of his Astronomy. M. de la Lande has published a new catalogue of more than 12,000 stars in the volumes of the "Connoissance des Temps," from the year 7 (1799) to the year 12. Almost all these are stars which had not been before observed. M. C. Vidal has lately communicated to the lycæum of Toulouse a catalogue of 888 austral stars, from the 5th to the

7th magnitude inclusively. Every star has been observed three times, and all are reduced to a mean position, regard being had to the effect of refraction, the aberration of light, and the rotation of the earth's axis. The mean position of all these stars has been calculated to a common period, viz. Jan. 1, 1798; the equation and precession of the equinoxes being previously allowed for. The place of M. Vidal's observation was Mirapexis; a situation admirably suited to his purpose, by the serenity of its atmosphere and the excellence of the instruments with which its observatory is furnished, and commanding nearly six degrees of the heavens southwards more than Paris. On this account C. Lalande, and his nephew C. François Lalande, in their grand work of completing a catalogue of 48,000 stars, have engaged M. Vidal to form a catalogue of the austral stars, which he has executed with great success and admirable precision. From the history of astronomy for 1800, by Jerome de Lalande, it appears that M. F. Lalande has terminated the labour, commenced August 5, 1789, and determined the places of 50,000 stars from the pole to two or three degrees below the tropic of Capricorn. The examination of the heavens is still vigorously prosecuted by the European astronomers, conformably to the plan and wishes of Mr. Wollaston; and from the industry and accuracy with which their observations are conducted, we may expect the happiest result with regard to our knowledge of the stars and other celestial bodies.

CATALOGUES of the *Books of the Old and New Testament, in Biblical History.* See BIBLE, CANON, and TESTAMENT.

CATALONGAY, in *Botany*, the name given by some authors to the plant which produces the *fabæ sanctæ Ignatii*, or St. Ignatius's beans of the shops.

CATALONIA, in *Geography*, a province of Spain, bounded on the north by France, from which it is separated by the Pyrenées, on the east and south-east by the Mediterranean, on the south-west by the province of Valencia, and on the west by Arragon. Its form is nearly that of a triangle; the base towards the Mediterranean being about 160 miles in length, the side towards France 120, and that towards Arragon 140 miles. Catalonia, towards the shores of the Mediterranean, has many convenient sea-ports; the inland country is in general mountainous, particularly in the northern part towards France, but interperled with a variety of spacious plains and fertile valleys. The mountains are covered with large forests of tall trees, such as the oak, the ever-green oak, the beech, the pine, the fir, the chestnut, and many others, besides cork trees, shrubs, and medicinal plants. The soil is rendered productive by the industry of the inhabitants, so that Catalonia is reckoned one of the best cultivated provinces in Spain; and it yields a plentiful supply of corn, wine, oil, flax, hemp, liquorice, and almost every kind of fruit. Brandy, wine, nuts, almonds, raisins, and cork are shipped at different places on the coast, for the merchants who reside in Barcelona. The wines are Mataro, Villanova, Sitges, Valls, and Granatché. The price varies according to the season; but when it is highest, we may reckon Mataro at 16 dollars, or 48s., the hogthead, including the Spanish duties; Villanova, 15 dollars; Granatché, 40. All these are red. The following white wines are, Sitges, 54; Valls, 20 dollars; but the common price is 12½ dollars per hogthead for both the Mataro and Villanova. When brandy is dearest, it is sold, duty free, at 57 dollars, or 8l. 11s. the four cargas or pipe of 124 gallons English, Hollands proof, or rs. 4½d. per gallon; but it is sometimes sold at 10d. Catalonia furnishes 35,000 pipes of brandy, and 2000 of wine, besides

50,000 bags of nuts, containing three bushels each, at 20s. the bag. Of the above about 4000 pipes of brandy, and some silk, go to Guernsey and Alderney, and the rest to France, all to be smuggled into England. The merchants also export wrought silks, printed cottons, woollen goods, small arms, and spice; on the last article, however, is a contraband. Their imports are, corn, fish, woollen goods, hardware, and oil of vitriol. The articles prohibited are, beer, cyder, lead, hose, haberdashery, muslins, and cottons; but of the two last, immense quantities are smuggled into this province. The mountainous districts have quarries of marble of all colours, crystal, alabaster, amethysts, and lapis lazuli. Gold dust has been found among the sands of one or two of its rivers; and here are mines of antimony, copper, lead, tin, iron, silver, one of gold, alum, vitriol, and salt, and many of coal. On the eastern coast they likewise fish for coral. Provisions of every kind are excellent. The climate is mild in the plains, the cold on the mountains is supportable, and the air is pure. It is neither so hot as Andalusia, nor so cold as Asturias, and the northern part of Spain; being sheltered on the north by the Pyrenees, and on the east by the sea. This temperature, joined to the many streams and rivers with which the country abounds, renders it very fertile and delightful. The inhabitants are hardy, courageous, industrious, active, vigorous, and good soldiers, but apt to be discontented. The miquelets are a sort of soldiers, whose province it is to guard the passes of the mountains and to protect travellers; but they are often extortionate in their demands of recompence.

In Catalonia, as in France, with which this province was formerly connected, accounts are kept in livres, sols, and deniers; 12 deniers making a sol, and 20 sols a livre. But in reckoning by the money of the province, nominal and real, there is great perplexity. If we reckon the peso or current dollar at 3s. sterling, the hard dollar will be four, the current pistole 12; and the pistole of gold, 15s. See COINS. As to the measures in Catalonia, 12 cortans make one quarter, which is two bushels, English measure. Sixteen cortans make a carga of wine or brandy, which is about 30 gallons English, and is reckoned to be 12 arrobas. 100 quarteres are reckoned equal to 128 fanegas.

In estimating the weights of this province, eight ounces make a marc, being $\frac{1}{5}$ heavier than in Castile; 12 ounces make a pound; 20 pounds one arroba; four arrobas one quintal, which is 93 pounds English, or 91 pounds Castilian; 125 pounds make 112 pounds English.

In the beginning of the last century they reckoned in Catalonia 101,86 houses, and only 371,499 inhabitants; but the province had then been ravaged by civil war. In 1768 the bishops, in their account of the population, made the following return: viz. men, 189,53; women, 192,763; boys, 3,1379; girls, 229,16; clergy, regular and secular, 12,235; in all, one million and thirty thousand two hundred and forty-five. Since that time the population has not decreased; and yet, in the returns to government, A. D. 1787, the number of inhabitants is stated at only 801,602. Of these 69,83 are under vows, and 1266 are knights. These accounts, so different from one another, without any assignable cause of deficiency in the latter, shew, that, notwithstanding the most vigilant attention on the part of government, they always fall short of the actual population, because it is the interest of every family, parish, and district, to conceal their numbers, in order to avoid the capitation tax. Catalonia enjoys the privilege of exemption from the taxes called alcavala, cientos, and millones; in lieu of which the inhabitants pay 10 per cent. on all rents, belonging to individuals or communities, and on the supposed gains of

merchants and mechanics. They are subject also to some other charges on labour and manufacture, and on cattle. The whole amount of the taxes collected in Catalonia was, A. D. 1721, 481,867l. sterling. But as the revenue of Spain is more than doubled since that period, if we allow the same increase for Catalonia, we may state the revenue arising from this province at little less than a million sterling; which, according to the computed population, is 20s. annually for each person; whereas, taking the whole peninsula together, the Spaniards pay no more than 10s. each per annum. Considering the rapid circulation of money in this province, and the universal affluence resulting from it, with the peculiar advantages and resources of the Catalans, this contribution, though relatively heavy, is comparatively light; for being freed from the stagnating influence of the alcavala, cientos, and millones, they enjoy a decided superiority over provinces which have never claimed the same indulgence. Unfettered by these impolitic restraints, and permitted to set their own value on their commodities exposed to sale; their industry is free, and not like that of less-favoured provinces, crippled in all its operations. In addition to these immunities, the great number of troops, quartered in Catalonia, not only gives to the farmers and manufacturers a ready market for their commodities, but contributes much to maintain good order in the province. For near two centuries previous to the accession of the present family, Catalonia was infested with banditti, who, by robbing and plundering passengers, interrupted the safe and easy communication of the cities with each other, and prevented, in a great measure, the interior commerce of the country. But Philip II. stationed a considerable detachment of his troops in this doubtful part of his dominions; and these not only restored good order, but revived commerce by a quick and certain demand for all the productions of industry. Besides, the popular prejudice in Catalonia is favourable to commerce; for here artists and manufacturers are as much honoured and respected as in other provinces they are despised. In consequence of this their trade is brisk; the vessels employed to carry it on are more than 1000; and government can always depend upon 18000 seamen, who are registered and always ready to obey the summons in cases of emergency. Moreover, what contributes most to the wealth and prosperity of Catalonia is the power, which gentlemen of landed property have over their estates to grant a particular species of lease, called "Establiment by Emfiteutic contracts." By this kind of contract, the great proprietor, inheriting more land than he can cultivate to profit, has power to grant any given quantity for a term of years, either absolute or conditional, either for lives or in perpetuity, always reserving a quit rent, like our copy-holds, with a relief on every succession, a fine on the alienation of the land, and other seigniorial rights dependent on the custom of the district, such as tithes, mills, public-houses, the obligation to plough his land, to furnish him with teams, and to pay hearth-money, with other contributions, by way of commutation for ancient stipulated services. The tenure in Catalonia is evidently feudal. All property in land is traced up to the king, and is held by knights' service from the crown, subject to relief, to fines, and to escheat. Under the royal grant, the great lords claim, not merely tithes of all lands not being freehold, with quit-rents and fines, mills, and public-houses, but the right of appointing magistrates and receiving tolls on the passage of cattle over their estates. To the power retained by them of making emfiteutic contracts has with reason been attributed the cultivation of such waste lands as are susceptible of tillage, and the consequent increase of population. Industry has been promoted, new families have

been called into existence, and many, rescued from poverty and wretchedness, are now maintained in comfortable affluence. Nevertheless by the culpable inattention of great proprietors, both to the general good and to their private benefit, they leave their lands uncultivated; and, therefore, even in Catalonia, according to the government returns, more than 300 villages have been deserted. See on this subject, Townsend's Spain, vol. iii.

The province of Catalonia has been usually divided into 15 vicueries, or jurisdictions, besides the two which are in Roussillon and which belong to the French; viz. Tortosa, Monblanc, Tarragona, Villa Franca de Panades, Barcelona, Gerona, which includes that of Ampurdan, all which lie along the sea-coast; Campredon, Puicerda, with the county of Cardagna, both which lie near the Pyrenean mountains; Balaguer, Lerida, Agramont, Tarrega, Cervera, Maurela, and Vique. Some have divided this principality into Old and New Catalonia, including in the former the country between the Pyrenees, which runs along the river Llobregat eastward to the sea; and towards the west the tract from this river to the borders of Valencia and Arragon. The principal towns of this province are Barcelona, the capital, Tortosa, Tarragona, Gerona, Monblanc, Lerida, and Villa Franca de Panades. The chief rivers are the Segre, the Llobregat, the Cervera, and the Ebro.

Catalonia has been reckoned one of the most populous provinces in Spain; and contains one archbishopric, seven bishoprics, 28 large abbeys, one principality, 2 duchies, 5 marquises, 17 earldoms, 14 vicounties, and a great number of baronies.

When the Moors had overrun the greater part of Spain, and began their attacks on this province, the Catalonians made an effort to secure their freedom, and applied to Charles Martel of France for assistance; by whom, as well as by his son Pepin, they were aided in their wars against the Moors. On the death of Zaro, governor of Barcelona, who had agreed to pay tribute to Charles the Great, Bernard, grandson to Charles, was made earl and governor of Catalonia; on his decease, Godfrey, or Wiford, the son of his colleague in the government of this province, as well as of Provence and Languedoc that were annexed to it, was created governor of Barcelona, and in 884 hereditary count of Barcelona, which was to continue to him and his heirs for ever, with the restriction, that they should remain vassals to the king of France. In 1137, Don Raymond V., count of Barcelona, marrying Petronilla, the daughter of Don Ramiro, the monk, and heirs of Arragon, united Catalonia to the crown of Arragon, but without any incorporation of territories; and in 1182 it shook off all dependency on France. Catalonia continued united to Arragon till the year 1640, when it submitted to France. In 1652, the king of Spain recovered Barcelona and some other places; and by the treaty of the Pyrenees in 1659 he saw himself again master of all Catalonia. In 1705, the whole principality submitted to the archduke of Austria, and adhered firmly to his cause, inasmuch that, though in the year 1713, he was obliged to evacuate Catalonia, Majorca, and Yvica, yet the inhabitants of Barcelona determined to maintain their privileges or die in the attempt; however, in the year 1714, Barcelona was obliged to surrender at discretion, and the whole county was reduced to the subjection of Philip V. who abolished all those valuable privileges, which they had so often asserted with a successful impudency.

Among the ancient inhabitants of this province we may reckon the Castellani, from whom some have imagined that it derived its name; others trace its etymology to the Cat-

lani, an ancient people in Gaul; but others, with greater probability, trace the origin of the appellation to the following circumstance. Upon the decline of the Roman empire, the Alani seized the left part of this province, of which they were, in some measure, dispossessed by the Goths; and at length, mixing together and becoming one people, they came to be called Gothalani, and their country Gothalanonia, which, by degrees, was softened into Catalonia.

CATALPA, in *Botany*, the Indian name of a North American plant, referred by Linnæus to the genus *ignonina*, (see *BIGNONIA catalpa*); but as the plants included in this genus differ considerably from each other, it has been divided by Jussieu and Ventenat into four, *jacaranda*, *catalpa*, *tecoma*, and *ignonina*. Of *catalpa*, the French naturalists give the following character. *Cal.* two-lobed. *Cor.* bell-shaped; tube distended; border four-lobed, unequal. *Stam.* two, fertile, three, barren. *Stigma* bilamellate. *Capsule* resembling a silique, long, cylindrical, two-valved; partition opposite to the valves. *Seeds* with a membranous appendage at the tip and base. Trees, with simple, ternate, whorled leaves and panicle flowers. Jussieu refers to it, *ignonina catalpa* of Linnæus, and *ignonina longissima* of Jacquin.

CATALS, *Cetalla*, denote good or chaste's.

CATAMANA, in *Ancient Geography*, a town of Asia, in Syria, situate, according to Ptolemy, in Comagena.

CATAMARAN, or CATIMORAN, in *Sea Language*, is also called Balza, or Balsa, for an account of which see the article BOAT.

CATAMENIA, from *κατα* and *μην*, *month*, in *Medicine*, women's monthly purgations, called also *menfes*, which see.

CATAMITE, a boy kept for fodomitical practices.

CATANA, in *Ancient Geography*, a town of Sicily, on the eastern coast of the island, in a gulf of the same name. Thucydides says, that this city was founded seven years after Syracuse, by the Chalcidians, from Naxos. Strabo also mentions it, and says, that it was repaired by Augustus, and became a Roman colony. Pliny and Ptolemy give it this title. Strabo reports that this city lost its first inhabitants; but that Hiero, tyrant of Syracuse, placed others in it, and changed its name into that of *Ætna*; assuming the glory of being its founder. It fell bore this name; when Dionysius, to revenge himself for the succours which it had given to the revolted inhabitants of Syracuse, levelled its walls, and bestowed its territory on the Campanians; and immediately after the decease of Hiero, the Catanese expelled those whom he had established there, and demolished the tomb of the tyrant, and the city regained its ancient name. It fell into the hands of the Romans among their earliest acquisitions in Sicily, and became the residence of a prætor. To make it worthy of such an honour, it was adorned with sumptuous buildings, and every convenience was procured to supply the natural and artificial wants of life. It was destroyed by Pompey's son, but restored, with superior magnificence, by Augustus. The reign of Decius is famous, in the history of this city, for the martyrdom of its patroness, St. Agatha, whose intercession is implored on every emergency. She is justly believed, says Swinburne, to have preserved Catania from being overwhelmed by torrents of lava, or shaken to pieces by earthquakes; yet its ancient edifices are covered by repeated streams of volcanic matter, and almost every edifice, even her own church, has been thrown to the ground. In the reign of William the Good, 20,000 Catanians, with their pastor at their head, were deluged before the sacred veil could be properly placed to check the flames. In the 17th century Catania was twice demolished. Cicero, speaking of the riches and beauty of this city, adds, that it had a temple dedicated to

Ceres,

Ceres, in which was preserved an image of this goddess; but that only women were allowed admission, and that it was guarded by young females. See CATANIA.

CATANADROMI, in *Ichthyography*, a term of the fame signification with the more common word *anadromi*, the distinctive term of a set of fishes, which at times leave the fresh water for the salt, and afterwards return to the fresh water again. See ANADROMOUS.

CATANANCHE, in *Botany*, (Gr. *κατανανχη*, violence, so called, according to Dioscorides, because it was superstitiously used as a philtre, or love-charm by the women of Theffaly.) Linn. Gen. 920. Schreb. 1250. Juss. p. 171. Vent. vol. ii. p. 492. Gært. 905. *Catanance*, Tourn. 271. *Cupidone*, Lam. Encyc. Bolc. Nouv. Diët. *Candia lion's foot*. Clafs and order, *Lyngensia polygamia equalis*, Linn. *Cichoraceae*, Juss. Vent.

Gen. Ch. *Cal.* common, imbricate, top-shaped; scales numerous, loose, egg-shaped, acute, concave, scarios, shining, permanent. *Cer.* common, uniform; florets all with lamens and a piskil, numerous, ligulate, linear, truncated, five-toothed. *Stam.* filaments five, capillary, very short; anthers forming a hollow cylinder. *Pist.* germ oblong; style filiform, the length of the lamens; stigma biind, reflexed. *Peric.* the permanent calyx. *Seeds* solitary, egg-top-shaped, crowned with a five-leaved, chaffy, awned pappus or calyale. *Recep.* chaffy.

Eff. Ch. Receptacle chaffy. Calyx imbricate. Pappus confiding of five chaffy awned leaves.

Sp. 1. *C. caerulea*, Linn. Sp. Pl. 1. Willd. 1. Mart. 1. Lam. Encyc. 1. Illust. Pl. 658. fig. 1. (Chondrilla, Bauh. Pin. 130. 6. Barr. Ic. 1134. Rai. Hist. 257.)

"Calyx-scales all egg-shaped, mucronate, coloured in the middle." Lam. "Leaves villous, linear, a little pinnatifid at the base." Willd. *Root* perrenial. *Root-leaves* numerous, long, narrow, with two pair of long, linear teeth, lying flat on the ground. *Stems* about two feet high, slender, pubescent; furnished with small, generally entire leaves, or rather transparent scales growing nearer together as they approach the summit. *Flowers* terminal, blue, large, on long peduncles. A native of the South of Europe, flowering from June to October. 2. *C. aspitosa*, Willd. 2. Desf. Atl. ii. p. 238. tab. 217. "Inferior calyx-scales egg-shaped, acute, leaves linear, rather fleshy, slightly toothed at the tip." Willd. *Root* annual. *Flowers* yellow. 3. *C. lutea*, Linn. Sp. Pl. 2. Willd. 3. Mart. 2. Encyc. Illust. Pl. 658. fig. 2. Gært. tab. 157. fig. 5. "Interior (not inferior, as in Linnæus,) calyx-scales lanceolate." Lam. "Leaves lanceolate, toothed, three-nerved." Willd. *Root* annual. *Stems* two or three, a foot and a half high. *Flowers* small, yellow, on slender peduncles. A native of Italy and the Levant.

Propagation and Culture. The first species may be propagated by slips planted in pots filled with light sandy soil, or in warm borders, under the shelter of walls, pales, or hedges. But it succeeds better when raised from seeds sown in March, in a border of good warm earth, and afterwards transplanted into pots or borders where it is to remain for flowering. The third species may also be readily raised from seeds; but, as it has little beauty, it is not often kept in gardens. Mill.

CATANANCHE *græca*, Linn. Willd. Mart. Lam. See SCORZONERA *elongata*.

CATANDUANES, or CANTUADANES, in *Geography*, a province of the island of LUÇON or Manila, confiding of a small island to the most south-easterly part of LUÇON; its southern point being almost parallel with Suiran. Its shape is triangular, about 30 leagues in compass, and 10 in length.

As it is exposed to the north wind, it is always stormy; and it lies so near the Emtfoadero, or mouth of the channel of St. Bernardin, that some pilots milking it, and apprehending that they were entering the mouth of the strait, have found themselves among dangerous flats, which encompass the island about a musket-shot from the shore, and suffered shipwreck. This island abounds in rice, oil of palms, cocoas, honey, and wax. It has several rivers that are dangerous to crofs, in the channel of which is found gold, brought down from the mountains by the floods. The largest of these is called Catandangan, and by the Spaniards Catanduanes, whence the island took its name. The chief employment of the natives is the carrying of wood, and the making of light boats, which they sell at Mindora, Caleleya, Balayan, and other places. They first make one very large, without any deck, and not nailed, but sewed together with Indian canes, and then others less and less, one within another, and thus they transport them 100 leagues. The people paint themselves; they are warlike, and excellent sailors; and if a boat be overtaken, they leap into the water and immediately turn it. Apprehending such accidents, they carry their provisions in their hollow canes closely stopped, and tied to the sides of the boats. Their habit is only a waistcoat, which reaches down to the knees. The women are of a masculine size, and apply themselves as much as the men to tillage and fishing. They are modestly clad in a coat or jerkin, and a long mantle. Their hair is tied on the crown of the head, forming a knot like a rose. On the forehead they wear a plate of gold two fingers' broad, lined with taffeta; in their ears three gold pendants. On their ancles they have rings, which make a tinkling noise as they move.

CATANGIUS SINUS, in *Ancient Geography*, a gulf of Asia Minor, in the Thracian Bosphorus.

CATANHEDE, in *Geography*, a town of Portugal, in the province of Beira.

CATANI, in *Ancient Geography*, a people of Asia, in the vicinity of the Caspian Sea, according to Pliny.

CATANIA, or CATANEA, the ancient *Catana*, a town of Sicily, in the valley of Noto, near the foot of mount Ætna. This city has frequently suffered in ancient and modern times, from the eruptions of this mountain. See ÆTNA and CATANA. The materials of which the modern city is built are such as might be expected in a volcanised country, where stones of any other than a volcanic nature are not to be found but at a considerable distance. The edifices, both public and private, and even the walls of the city, are principally of lava; which has furnished materials not only for the modern Catania, but also for the more ancient city, which was entirely destroyed by an earthquake in the year 1693; at least its ruins, when dug up, have all been found to consist of lava. Those who have taken a view of the surface of the territory of Catania have every where met with immense accumulations of lava; among which the most conspicuous are the remains of that torrent which, bursting from one of the sides of Ætna in 1669, inundated a space 14 miles in length, and nearly four in breadth, rose over the walls of Catania, burying under it a part of the city, and at length precipitated itself into the sea. The prince of Biscaris has employed great labour and expence in digging down to the ruins. We descended, says Mr. Swinburne, into baths, sepulchres, an amphitheatre, and a theatre, all much injured by the catastrophes that have befallen them. They were erected on old beds of lava, and even built with square pieces of the same substance, which in no instance appears to have been siled by the contact of new lavas. The sciarra, or stones of cold lava,

lava, have constantly proved as strong a barrier against the flowing torrent of fire, as any other stone could have been, though some authors are of opinion, that the hot matter would melt the old masonry, and incorporate with it. Nothing less than the fertility of its territory could have inspired the inhabitants with the courage, or rather the obstinacy, to build and rebuild in a situation which derives no advantage from the sea; which is without a river and without fortifications; exposed to all sorts of natural misfortunes, and continually threatened with the dreadful calamities which have already proved so destructive. And yet in the course of the last century it has revived with great splendour, and when all the houses are finished, it will be a very handsome city. In the progress of its improvement it has acquired more the features of a metropolis and royal residence than Palermo. Its principal streets are long, straight, and wide, and well paved with lava; but they are so disposed, that in the middle of the day this burning town is totally without shade, and almost impassable. If its wealthy inhabitants had possessed a greater degree of taste; if, instead of huge palaces, and large churches of an obsolete and fanciful architecture, the buildings had been erected in a simple and noble style, Catania might have been one of the most magnificent cities in the kingdom of Naples. The market-place, however, is not without beauty; it is a square cut off at the angles, and decorated with arches supported by marble columns. In the centre of the great square formed by the town-hall, seminary, and cathedral, are two antique fragments, very happily grouped; they consist in a part of an Egyptian obelisk of granite, with hieroglyphic characters; placed on the back of an elephant formed of lava, the ancient symbol of Catania. The cathedral erected by the abbot Angerius in 1094, and endowed by earl Roger with the territories of Catania and Ætusa, has suffered so much by earthquakes, that little of the original structure remains, and the modern parts live hardly any thing, except their materials, to recommend them. The other religious edifices of the city are profusely ornamented, but in a bad taste. The Benedictine convent of St. Nicholas is the largest belonging to that or any other religious order. Every part has been rebuilt since the earthquake of 1693. The church is a noble fabric, though it has many defects in the design and execution; and is accounted the largest in Sicily. The organ, constructed by a Neapolitan priest, is much esteemed by connoisseurs in musical instruments. The tones of all sorts of wind and stringed instruments are imitated by it with the most perfect illusion. One wing of the monastery is appropriated to a considerable museum of antiquity and natural history. This museum is magnificent, and amidst a variety of trifling objects it contains some utensils in bronze, of as perfect purity and beauty as those of the cabinet of Pottier, earthen vases of a most elegant form, and very curious lamps. The prince of Biscari, to whom the modern Catania is indebted for many of its improvements, has also formed a very magnificent museum. His collection consists of specimens of the most curious subjects in antiquity which Catania and Sicily produce; such as the remains of architecture, mosaic ornaments, Roman and Grecian materials for building; sculpture, among which, a single colossal Torso, found at Catania, may be ranked with the most beautiful pieces of antiquity; a collection of earthen vases, peculiarly valuable for the number, the forms, and preservation of the figures represented on them; another of antique bronzes; the natural history of marine productions, plants, shells, and fishes; and the productions of the earth, such as minerals, vegetables, volcanic matters, marbles, precious stones, and animals:—the whole arranged in an order which exhibits science,

taste, and industry. You see likewise in this museum a series of arms, armour, and singular colliques. In this city there is also a third museum, the possessor and founder of which is the chevalier Giomi; the valuable contents of which are enumerated by Spallanzani. One of the greatest curiosities at Catania is the Villa Sciarra, belonging to the prince of Biscari. Upon the black impenetrable surface of the lava, which issued from Ætusa in 1669, this prince has laid the plan of a garden, built houses, planted trees in soil brought hither from other places, and formed two large ponds of fresh water, supplied by springs that ooze through the lava. The pools of the Villa are stocked with fish and water-fowl, and are preserved from the fury of the neighbouring sea by a strong pier, which is the only separation between the salt and fresh water.

The number of public edifices that are crowded together in so small a space, has left little room for the houses of individuals; and from this circumstance it has been inferred, that Catania has been embellished at different periods, or that the private houses were extremely small in comparison with the public buildings; or that the ancient city was more ornamented than extensive, and, consequently, more rich than populous. The modern town is somewhat of the same kind. Although its population be estimated at 20 or 30,000, and by the Catanians themselves at double this number, yet nothing is seen in the streets but convents, churches, and palaces, separated by a few private houses. Catania is the see of a bishop, suffragan of Monreal, whose revenues are very considerable; 20000 sterling per annum being derived, as it is said, from the sale of snow collected on mount Ætusa. This city has also an university, the only one in the island, and the nursery of all the lawyers. N. lat. 37° 30'. E. long. 15° 19'. Swinburne's Travels, vol. iv. Brydone's Travels, vol. i. Spallanzani's Travels, vol. i. De Non's Travels.

CATANIDIS PROMONTORIUM, in *Ancient Geography*, a promontory of Asia Minor, in the vicinity of the ile of Lesbos, towards the Arginusæ Islands, according to Diodorus Siculus.

CATANII, a people of Arabia Deserta.

CATANITÆ, a people placed by Ptolemy in Arabia Felix.

CATANZARO, in *Geography*, a town of Naples, in the province of Calabria Ultra, the seat of a governor and tribunal of justice, the see of a bishop, suffragan of Reggio. It is situate on a mountain, and has manufactures of silk velvets and cottons. This town was built in 963 by order of the emperor Nicephorus Phocas, as a post of strength against the Saracens, to which its situation on an eminence, in the pass between the mountains and sea, adapted it. In 1573 it attained to the dignity of capital, formerly the right of Reggio. It contains 12,000 inhabitants, who live by the law, and the sale of corn, silk, and oil. The college of the late Jesuits is a handsome building, and possesses a good statue of St. Ignatius, by Farfeca, and a very fine picture representing St. Bruno distributing bread to the poor; 9 miles N.E. of Squillace. N. lat. 38° 58'. E. long. 18° 00'.

CATAO, a town of Asia, in Thibet; 15 miles W.S.W. of Y slojia.

CATAONIA, in *Ancient Geography*, a province of Asia, in Armenia Minor, between Taurus and Antitus us. Strabo places this province in Cappadocia, because Armenia Minor once made a part of Cappadocia; and he says that Artaxates I. king of Cappadocia, joined Cataonia to Cappadocia. It is situated to the north of Cilicia Campestris, and traversed from the N.E. to the S.W. by the Sarus. The two principal towns were Tariana and Comana Cappadocica. The

Pyramus had its source in the mountains of the eastern part.

CATAPAN, or **CATIPAN**, a name the later Greeks, about the twelfth century, gave the governor of their dominions in Italy.

Ughelius and others say, catapan was the same with *capitaneus*; formed from it by metathesis, or transposition; others derive it from *κατα, juxta*, and *πασι, omne*; in which sense, catapan was a governor-general, or magistrate, who had the direction of all: others will have it derived from *κατα πατριάρχου*, that is, *next after the emperor*. In which sense, catapan was a second ruler, *secundus dominus*. Ducas derives it from *καπετανος, capitain*; which the Greeks applied to every governor, and even every man of quality.

CATAPELTA, an instrument of punishment, in use among the ancients. It consisted of a kind of press, composed of planks, between which the criminal was crushed to death.

CATAPELTÆ, in *Ancient Writers*, more frequently written *catapulta*, which see.

CATAPHONICS, in *Music*, synonymous with *catavocals*, which see.

CATAPHORA, in a theme of the heavens, an appellation given to the houses falling from the third, sixth, ninth, and twelfth angles. In which sense the word stands opposed to *anaphora*.

CATAPHORA, in *Medicine*, a term formerly used to denote a variety of lethargy, or *coma*, with which it may be considered as nearly synonymous. It signified a lesser degree of sopor than the term *CARUS* (which see), or a lesser approach to the state of complete apoplexy. But these distinctions are now discarded as useless, since the nature, causes, and treatment of all must be similar; they are not different diseases, but only different degrees of the same disease. Sauvages defines the cataphora, "Status somolentus facile excitabilis, sine febre, delirio, et oblivione." *Nofol. Meth. clafs. vi. ord. v.*

CATAPHRACTA, from *κατα, & φρασσα, I fortify*, or *arm*, in the *Ancient Military Art*, a cuirass, or heavy defensive armour, composed of sheets or links of iron, so curiously fastened and arranged on strong cloth or leather, like plumes, that they preserved the same appearance in all motions, and left no part of the body exposed. It was formerly used sometimes both by infantry and cavalry, and when by the latter, it was generally made to cover the horse as well as his rider. It was anciently used by the Persians, Sarmatians, and others. It was frequently made to cover only the breast. The Romans adopted it early for their foot, and, according to Vegetius, retained the use of it till the time of Gratian, when the Roman discipline becoming greatly relaxed, and military exercises with laborious duty being chiefly discontinued, their foot thought the cataphracta, as well as the helmet, too great a load for them to carry, and therefore threw both aside. But he tells us, that by thus leaving their breasts and heads exposed and unprotected, they were, when fighting against the Goths, frequently destroyed by the multitude of the archers of those barbarians. And he very emphatically observes, that whilst they declined military fatigue, and the trouble of carrying armour sufficient for their protection, they were in a most disgraceful manner killed like sheep. Hence it would appear, that the Romans were overcome chiefly by the bow, after they laid aside their defensive armour. His words are the following: "Licet exemplo Gotthorum et Alanorum, Hunnorumque equitum arma protercent pedites tamen constat esse nudatos. Ab urbe enim condita usque ad tempus

D. Gratiani, et cataphractis et galeis nudiebatur pedestris exercitus. Sed cum campellis exercitatio, interveniente negligentia deliquaque cessaret, gravia videri arma ceperunt, quæ raro utique milites inducant. Itaque ab imperatore postulant, primo cataphractas, deinde cassides deponere; sic detectis pectoribus et capitibus, congressi contra Gothos milites nostri, multitudo sagittariorum saepe delati sunt; nec post tot clades, quæ usque ad tantum urbium occidia pervenerunt, cuiquam curæ fuit, vel cataphractas vel galeas pedestribus reddere. Ita fit, ut non de pugna, sed de fuga cogitent, qui in acie nudi exponuntur ad vulnera. Quid enim pedes sagittarii sine cataphracta, sine galea, qui cum arcu seutum tenere non potest, faciat? Quid ipsi draconarii atque signiferi, qui sinistra manu hastas gubernant, in prælio facient, quorum et capita nuda esse consilii, et pectora? Sed gravis pediti lorica videtur, et galea fortasse, raro mediantem arma raro traçant. Cæterum quotidianus usus non laborat, etiam si onerosa gessaverit. Sed illi qui laborem in portandis veteribus munimentis armorum, ferre non possunt, detectis corporibus et vulnera sustinere coguntur et mortes; et, quod est gravius (sic et turpius) aut capi, aut certe fuga rempublicam proderet. Sic dum exercitum laboremque declinant, cum maximo dedecore trucidantur ut prædes." In this passage Vegetius ascribes the success of the Goths against the Romans without their defensive armour chiefly to the great multitude of their archers. Even in the defence of modern fortifications there are situations in which we are convinced the bow and the arrow would have greatly the advantage of the musket and bayonet, as in culminated galleries, in the counter-scarps of ditches, &c. where musketry soon becomes useless on account of the smoke. And were it necessary to defend such a very inclosed county as this, many occurrences might arise, in which a certain number of good archers might be of more real use for the purposes of defence than thrice the number of our best musketry. Tacitus, *Hist. lib. i. cap. 79*. Veget. de Re Mil. lib. i. cap. 20.

CATAPHRACTA, among *Surgeons*, denotes a bandage of the thorax; thus denominated from its resemblance to a Roman breast-plate, called *cataphracta*. See **BANDAGE**.

CATAPHRACTÆ NAVES, vessels armed and covered in fight, so that they could not be easily damaged by the enemy. They were covered over with boards or planks, on which the soldiers were placed to defend them: the rows sitting underneath, thus screened from the enemies' weapons.

CATAPHRACTI, or **CATAPHRACTARII**, persons secured with cataphractæ. The term, however, is most commonly employed to denote an ancient species of cuirassiers, or horsemen, covered completely, as well as their horses, with such armour as is described in the article *Cataphracta*, which see. The Persians made use of such cavalry; after them the Greeks; and then the Latins. Antiochus had 3000 of them when he marched against Scipio Asiaticus. And as the Romans copied after the Greeks, notwithstanding their hatred of them, in things they thought useful and advantageous, there is every reason to suppose that they borrowed from them that institution. The same meaning is ascribed to the term *Crapellarii*.

CATAPHRACTUS, in *Zoology*. See **DASYPUS**.

CATAPHRACTUS *Pogge*, in *Ichthyology*. See **COTTUS Cataphractus**.

CATAPHRYGIANS, in *Ecclesiastical History*, a sect in the second century, so called as being of the country of Phrygia. They were orthodox in every thing, setting aside this, that they took Montanus for a prophet, and Pifcilla and

and Maximilla for true prophetesses, to be consulted in every thing relating to religion; as supposing the Holy Spirit had abandoned the church. See MONTANIST.

CATAPLASM, in *Surgery*, a poultice, or external application of a pulpy consistence, more or less composed of substances possessing a medicinal quality, and thence denominated antiseptic, emollient, escharotic, anodyne, astringent, stimulating, maturing, repellent, &c. Cataplasms have their name from *καταπλασμα, ilisma*, to spread or besmeare; and are therefore always supposed to be somewhat coherent or tenacious.

They usually consist of farinaceous ingredients or mucilaginous vegetable matters, which are mingled with gums, balsams, resins, eggs, honey, &c. and softened by the addition of vinegar, water, or milk, and generally applied warm. Ignorance and caprice, however, have introduced a vast farrago of substances into compositions of this class; but judicious and experienced surgeons have limited them very considerably, and much simplified the form of their cataplasms.

The practitioner who keeps in mind the particular object he has in view, whether to communicate heat, cold, moisture, or some peculiar medicinal virtue, will not be at a loss to find appropriate materials for his purpose; in the *Pharmacopœa Chirurgica* of Mr. Houlston are contained many formulæ of this nature, adapted to various occasions.

CATAPOTIA, from *καταπινω*, *I swallow*, dry medicines, in a form fit to be swallowed whole; or otherwise called *pills*.

CATAPPA, in *Botany*, Rumph. *Cœrt.* See **TERMINALIA**.

CATAPTELEA, in *Ancient Geography*, a town of Asia Minor, in Bithynia, seated on the Euxine sea.

CATAPULTA, from *κατα* and *πυλται*, in *Ancient Military Language*. Much diversity of opinion has existed among modern writers, in regard to the *catapulta* and *ballista*; some representing the former as having been employed to throw stones and bullets, and the latter to throw arrows, darts, javelins, pointed poles, &c.; others reversing these applications of them; whilst some contend that each of them was made use of for both purposes. The chevalier de Folard, whom many of the French writers have followed on this subject, in his "Traité de l'Attaque et de la Défense des Places des Anciens," speaks of these machines in the following words.

"Polybe dit formellement par tout, où il parle de ces deux machines (la baliste et la catapulte) que la baliste jettoit des dards, et la catapulte des pierres."

"La catapulte, comme la baliste, avoit différens noms. Les Grecs l'ont appelée d'une façon, et les Romains d'une autre, chaque nation comme il lui a plu. César l'appelle tantôt catapulte, tantôt *onager*, onagre. Les Grecs de la moyenne antiquité appellent tantôt l'un tantôt l'autre, jamais machine n'a souffert tant de différens noms. J'er pourrois compter une douzaine tout au moins, qui ont eourn toutes les nations. Je consens qu'on les adopte tous, mais du moins doit-on se faire entendre dans la description de la machine: car le nom n'y fait rien, et ne change rien à la chose, des que nous en concevons la structure et le principe du mouvement."

"Le scorpion ne fut jamais la catapulte, comme une infinité de commentateurs l'ont cru; ce n'étoit qui la baliste: car quel rapport peut avoir la catapulte avec cet animal?"

"Végèce dit qu'on nommoit autrefois scorpion, ce que de son tems on appelloit *manuballiste*; c'est l'arbalète dont on commença à se servir du tems de nos pères, et que nous avons abandonnée depuis l'invention de nos fusils, ou de nos mousquets, quoique cette arme, toute prevention à part, fut inimitable plus meurtrière et plus avantageuse, que ne le sont nos

fusils, ses coups plus certains et plus affreux, et sa force au moins égale. Végèce prouve assez, que le scorpion étoit la baliste des anciens. Cela se voit dans César en plusieurs endroits de ses commentaires, car il emploie indifféremment ces deux termes pour signifier la même machine; mais il distingue toujours celleci de la catapulte: *Cæsar in castris*, dit Hirtius, *scorpionum catapultarum magnam vim habebat.*"

"Avant que d'entrer dans l'explication de notre catapulte, ou pour mieux dire de celle des anciens, je crois, que le lecteur ne sera pas fâché de voir ici celle d'Ammien Macellin, Liv. xliii. en éclaircissant ce que nous paroit obscur et embarrassé dans le texte de cet historien. Cette hardiesse nous doit être permise, lorsqu'elle ne va pas au delà des bornes raisonnables." This translation follows.

"La catapulte est composée de deux poutres courbes, dit cet historien, qui se joignent à leurs extrémités par deux traversans. Aux deux cotés et vers le milieu de leur courbure, on pratique deux trous arrondi oppozés l'un à l'autre, et larges à proportion du poids qu'on veut jeter; c'est dans ces deux trous que l'on fait passer un cordage tressé en plusieurs tours qui passent dessus et dessous deux chevilles de fer qui partent de cette espèce d'écheveau de cordes. Au milieu de ce cordage filé et partagé par les deux chevilles de fer, on introduit à leur centre le bout d'une pièce de bois ou bras fait en manière d'axe de charrrette. Lorsqu'il est question de s'en servir, l'on entortille et l'on bande les cordes également des deux cotés; et de plus que la force du bandage et des cordes entortillées ne lâche, on tient fixes les deux chevilles par un arrêt: alors on baïsse le bras par le bout d'en haut par le moien d'un moulinet, et ce bout est retenu par une détente; on met alors la pierre à l'extrémité de ce bras qui forme un cuilleron (bowl of a spoon). Un homme lâche alors la détente d'un coup de maillet, et fait partir le bras qui pousse la pierre d'une force extraordinaire, parce qu'il va donner et choquer dans le plus fort de son mouvement contre un montant, au milieu duquel il y a un coussinet rampli de paille hachée."

And he compliments those, who have written before him on the subject, in the following manner.

"S'il nous est permis de dire librement ce que nous pensons, ceux qui nous ont donné de la catapulte, entre autres Lipsé, Choul, Fabretti, Perrault, n'ont rien produit que d'imaginaire."

We so far agree in opinion with Folard that the real and original use of the *catapulta* was to throw stones, and that of the *ballista* to throw darts. &c. But we cannot help observing, that he misquotes Polybius in asserting that that historian constantly makes this distinction between these two machines whenever he mentions them. For at the siege of Thebes in Phthiotis by Philip, where he makes Polybius say there were 150 catapultæ and 25 ballistæ, that writer does not mention ballistæ at all. His words are these. "Στραχηλιται δὲ καταπιληται μὲν καὶ τοὶ περὶ τὸ κέντρον περὶ τὸ κέντρον καὶ τὸ ἄνω καὶ τὸ κάτω, προσήλθαι τῶν θύραων." That is, 150 catapultæ and 25 stone-throwing machines being collected or brought together, i. e. (Philip) advanced towards Thebes. Now the *ἀνω* καὶ τὸ *κάτω*, as distinguished from the *catapulta*, was not the ballistæ, but the *onager*, which threw stones by means of a wooden stilus, pole, or beam, and a chain or a sling suspended at the end thereof for receiving the stones. This machine might have been so constructed as to throw stones of any size. The *καὶ τοὶ τῶν θύραων*, and the multitude of projectiles, which Mr. Hampton has translated, "darts discharged without intermission," might lead an incautious reader to suppose that there were ballistæ there, from which stones were thrown. But this could not have been the case

even according to his own translation of the Greek words denoting the machines, of which there were 25 distinguished from the 150 catapultæ, and which he expressly calls machines for throwing stones. Folard's assertion, then, on this point is altogether unfounded.

In like manner the words "αὐτὴ τῶν βολιθίων βαλλίστρα" and there were three places, stations, or batteries, for stone-throwers, used by Polybius, when speaking of the siege of Echinus by Philip, are without any reason translated by Caufabon "et erant ibi tres statioes idonee locandis ballistis," and by Mr. Hampton, "and in three (trenches) there were three batteries of ballistæ."

Folard also roundly and unscrupulously asserts that Julius Cæsar calls the same machine sometimes *catapulta* and sometimes *onager*. The truth, however, is, that Cæsar does not make any mention at all of the *onager*. But his authority may be confided as decisive in regard to the use that was made both of the ballistæ and the catapultæ, and the distinction, in this respect, between the two machines. He mentions the ballistæ only once, viz. in the 160th chap. or section of his second book. "De Bello civili," when speaking of the siege of Marcellis, by his lieutenant, C. Trebonius. His words are these. "Sed tanti erant antiquitus in oppido omnium rerum ad bellum apparatus, tantaque multitudo tormentorum, ut eorum vim nulla contextæ viminibus viminè sustinere possent. Asseres enim pedum xiii cupidibus præfixi, acque hi maximis ballistis nati per quatuor ordines erant disjunctantur." From this passage it is evident that even the largest ballistæ were employed to throw long pointed poles, &c. and such like missiles. Of the catapultæ he also makes mention only once, when he does in these words; "aut saxa ex catapultis latericium disferent," which clearly shews, that the catapultæ were in contradistinction to the ballistæ employed for throwing stones.

Vegetius does not mention the catapultæ; but he expressly tells us, that the scorpions were called *manuballistæ*, or *hand-ballistæ*, in his time. They were so called, no doubt, from such a machine's being manageable by one person. And, besides him, Vitruvius informs us, that the scorpion and *onager* were different machines, though it appears from Ammianus Marcellinus, that the name of scorpion was also given to the *onager*.

Folard taking it for granted, that the catapultæ and the *onager* were the same machine with different names, has translated as above a passage on the *onager* in the twenty-third book of that author in such a manner as to make it but this supposition. What he calls his *catapultæ* is neither the catapultæ nor the *onager* of the ancients. It has a large wooden stiel, pole, or beam, with a handle or spoon at the end of it for holding a stone. This stiel every time it is let loose and throws a stone, strikes violently against the cross-beam at the top, and must soon shatter either it or itself in pieces, and so shake the other parts of the machine as to render the whole useless. It has no sling or funda, which that writer expressly says the *onager* had, in these words. "Summatice ejus (Alii hie temonis) unci ferri copulantur. e quibus pendet lupæ vel ferrea funda." It is only necessary indeed to turn to the passage in A. Marcellinus to be satisfied, that the chevalier has translated it very erroneously.

The following extract respecting the frame of the machine is from Heron's *Ctesibion Tclestiva*.

"Duo ligna accipiuntur quadrata et equalia, quæ quatuor diapedimatis, id est, *transversariis*, itidem equalibus connectuntur, ex quibus duo in extremitatibus cardines habeant, qui in ligna quadrata immissi in exteriorem partem pertingant, ita ut in ipsorum eminentiarum foraminibus cuneoli adacti p gma totum fortissime contineant. Extremitatibus vero quadratorum lignorum fuculæ, quæ transversum motum

habeant, aptentur, in quibus sint foramina, per quæ rectè trajiciantur, five ad extremitates, five in medio, per quos verferunt. Superant autem quadrata lignea ipsa diapedmata ad superiorem partem." This author represents it as a machine of the cross-bow kind with two straight arms, one end of each of which is fastened in the upright cordage and the other ends are joined by a cord or some other substance, answering the same purpose as the string of a bow.

The catapultæ was certainly of the large cross-bow kind, and when used acted like a peilet bow. The frame was rectangular and consisted of two beams placed longitudinally, and connected together with cross beams. On or near the middle of each of the side pieces there was an upright post erected. These two posts were mortised, or let into a strong cross-beam at top, parallel to, and directly below which there was also a cross beam for upright cordage, which was flamed both above and below by means of crows put into the holes of the circular iron capitals, which had long iron cross pieces, smooth at top, to prevent their chafing the frame, of which there were two sets or coils separate and distinct from each other, equally distant from the centres of the said cross beams, and passing through the upper one, and either round pieces of iron fastened to the beam below, or cross pieces of iron in moveable capitals as in the beam above. The two arms forming the bow lay horizontally. The inner ends of them were inserted in the upright cordage; and the outer ends were united by a bow-string which was drawn back by a windlass or capstan at the hinder end of the machine. When the cord or other substance forming the bow-string was drawn sufficiently back, it was held by a catch and iron pin, from which, when the machine was going to be discharged, it was disengaged by the stroke of a hammer or mallet. Under the bow there was a table or platform on a foot of universal joint, by which it was elevated in front when necessary and also moved a little to the right or left between the upright cordage.

There is now at Gibraltar a catapult, which was constructed at the desire of the late Lord Heathfield under the direction of that very eminent military antiquarian, the present General Melville. It was for throwing stones a very little way over the edge of the rock in a particular place, where the Spaniards used to resort to the foot of it, and where shells thrown from mortars could not injure or annoy them. See the drawing of the said machine. *Artillery, Plate II.*

The catapultæ and ballistæ were both of them machines of the cross-bow kind and resembled each other in their general construction and moving powers, but were differently mounted for the different purposes to which they were applied or made use of. With the bow-string of the catapultæ there was connected a sort of pouch or net-work for receiving the stones or bullets, that were to be thrown by it; and the table under it was plain or smooth; whereas in the ballistæ, the table had a groove or channel in it, for the arrows, darts, poles, &c. that were to be propelled or thrown forward. Their general resemblance, however, or similarity of construction, was probably the cause of their being often confounded with each other even by some of the later Roman authors.

CATAPULTA, in the *Materia Medica*. See EUPHORBIA *Lathyrus*.

CATÁQU NSIS, in *Ancient Geography*, an episcopal see of Africa, in Numidia.

CATARA, in *Geography*, a town of Arabia; 76 miles S.E. of El Calif.

CATARA, in *Ancient Geography*, an episcopal town of Asia Minor, in Lycia.

CATARABON, a river of Upper Germany, which, according

ording to the interpreters of Ptolemy, directed its course towards Dacia.

CATARACT, in *Hydrography*, a fall or precipice in the channel, or bed of a river, caused by rocks, or other obstacles, stopping the course of its stream: from whence the water falls with an increased noise and impetuosity. The word comes from *καταπίπτω*, *I tumble down with violence*; compounded of *κατα*, *down*, and *πίπτω*, *deject*, *I throw down*. Such are the cataracts of the Nile, the Danube, Rhine, &c.

Of the various cataracts of the Nile, two of the most remarkable are formed by the fall of the water between two mountains; which descends with such rapidity and noise, that the inhabitants within the sound of them are said to be all deaf. Mr. Bruce (*Travels in Abyssinia*, vol. iii. p. 43) particularly describes the cataract of the Nile near the village of Alata on the borders of the kingdom of Begemder, S.E. of the lake Tzana or Dembea. The Nile, he says, is here confined between two rocks, and runs in a deep trough, with great roaring and impetuous velocity. The height of this cataract has been somewhat exaggerated by the missionaries who report the fall to be about fifty feet: but Bruce states it at about forty feet. The river, increased by rains, when he observed it, fell in one sheet of water, without any interval, above half an English mile in breadth, with a force and noise that were truly terrible, and which stunned him and for a time made him perfectly dizzy. A thick smoke, or haze, covered the fall all around, and hung over the course of the stream both above and below, marking its track though the water was not seen. For an account of the cataract of Syene; See SYENE. For the cataract of Assar; See ASSAR.

The most extraordinary cataract of the Rhine is that near Schaffhausen, the height of which is estimated by Mr. Coxe at only 50 feet: but M. Ramond, his elegant French translator, observes, that the quantity of water, which varies according to the season, has some influence upon the height, and a considerable effect upon the aspects of this fall. Those who have seen it at the periods when the snows dissolve will admit the exactness of that description, which this ingenious traveller thinks exaggerated, and only true of remote times. M. Ramond has been assured that the height of the cataract, in these circumstances, is not less than 80 feet. About three or four Italian miles east of Terni in Italy, there is a famous waterfall in the river Velino, near the place where it flows out of the Lago delle Marmore. The mountain on which it takes its course before its fall is very high, and environed on both sides by much higher mountains. The shelving of the river's bed, as soon as it comes out of the lake, causes a very rapid stream, that collects itself into three successive cascades, the last and loftiest of which seems to be 200 feet high. The noise of this cataract cannot be heard without astonishment; and from the bottom a white mist rises and fills the air to a considerable height. When the river clears itself of the rocks, between which these cascades are formed, it falls into the Nera about 100 paces distant. The grand water-fall is called the "Cascata delle Marmore." In the Wologda, in Muscovy, there are two cataracts near *Ladoga*, which see. The Zaïre, an African river in Congo, commences with a large cataract, which falls from the top of a mountain. In Japan, which is very mountainous, many rivulets form by their junction considerable rivers, in which are large and surprising cataracts. The most remarkable is that of the lake Togitz, or Pacone, which, being surrounded on all sides by high mountains, has no outlet for its waters excepting three different apertures, from which they fall down in cataracts, with a dreadful violence and noise; thence the three streams, reuniting, run down with a prodigious impetuosity, by a nar-

row channel through a deep valley, over rocks and precipices into the sea. The greatest natural curiosities of the known world are the cataracts of Lower Canada, at the distance of 13 miles from the town of Niagara." Mr. Weld, in his "Travels through Lower Canada (vol. ii.) has presented to his readers four engraved views of these falls, taken from different points of observation. The most stupendous of these is that on the north-western or British side of the Niagara river, commonly called the "Great or Horse-shoe Fall," from its bearing some resemblance to the shape of a horse-shoe. The height of this is only 142 feet, whereas the two others (the river being divided by islands into three distinct collateral falls) are each 160 feet high: but to its inferior height it is principally indebted for its grandeur; the precipice, and of course the bed of the river above it, being so much lower at one side than at the other, by far the greater part of the water of the river finds its way to the low side, and rushes down with greater velocity at that side than it does at the other, as the rapids above the precipice are strongest there. From the centre of the Horse-shoe Fall, arises a prodigious cloud or mist, that may be seen at the distance of several miles, and that exhibits, when the sun shines above it, a beautiful rainbow. The extent of this fall, ascertained by the eye, is estimated at no less than 600 yards in circumference. The island which separates it from the next fall is supposed to be about 250 yards wide; the second fall is about 5 yards wide; the next island about 30 yards; and the third, commonly called the "Fort Schloper Fall," from its being situated towards the side of the river on which that fort stands, is computed at the same measure with the large island. The whole extent of the precipice, therefore, including the islands, is, according to these estimates, 1335 yards. Some have supposed, that the line of the falls altogether exceeds an English mile. The quantity of water, carried down the falls, is prodigious; being found by a moderate calculation to be 670,250 tons per minute. The Fort Schloper Fall is skirted at bottom by milk-white foam, which ascends in thick volumes from the rocks; but it is not seen to rise above the fall like a cloud of smoke, as is the case at the Horse-shoe Fall; nevertheless, the spray is so considerable that it descends on the opposite side of the river like rain. Below these falls the whirlpools and commotions of the waters are so tremendous, as to render navigation impracticable for six miles; and immediately above them the river is much narrower than it is higher up. The river, however, runs evenly, and is navigable with safety for batteaux as far as Fort Chippeway, which is about three miles above the falls, but upon a nearer access the waters are so much agitated, that, unless a boat keep in the middle of the river and is dextrously managed, it must be dashed to pieces; however, with such management it may pass down to an island which divides the river at the falls. Since the falls of Niagara were first discovered, they have very much receded, on account of the disjuncture of the rocks which form the precipice. Within the memory of many of the present inhabitants of the country, the falls have receded several yards. It is not an improbable conjecture, that they were originally situated at Queenstown. Tradition reports that the great fall, instead of having been in the form of a horse-shoe, once projected in the middle; but for a century past it has remained nearly in the present form. The falls of Niagara are much less difficult of access now than they were some years ago. The most favourable season for visiting them is about the middle of September; for then the woods are seen in all their glory, beautifully variegated with the rich tints of autumn, and the spectator is not then annoyed with vermin. In the summer season you meet with

rattle.

C A T A R A C T.

rattle-snakes at every step, and musquitoes swarm so thickly in the air, that, to use a common phrase of the country, you might cut them with a knife. The cold nights in the beginning of September effectually banish these noxious insects. In the province of New York, three leagues from Albany, there is a cataract of 50 feet perpendicular height, the vapour of which, like that of the falls of Niagara, gives rise to a rainbow. For an account of other cataracts in America; See *ANTHONY'S Falls, CHAUDIERE, COHOZ, and MONTMORENCY*. On the Highlands of Scotland, as well as other mountainous countries, there are several falls; but the grandest cascade is that in the river Fyres. This cataract pours down its waters from a height not much less than 500 feet; but it is broken in its progress through the different stages of the rocks. "At the last stage but one," says Mr. Lettice in his "Tour through various Parts of Scotland," "where the freedom of its passage was arched by a narrow channel in a cleft of the precipice, it grew furious and foaming from the obstruction, till at length delivered it issued forth on a broad surface of a rock just below, and in one vast and voluminous sheet tumbled into the profound gulf, with a momentum that shook the glen, and filled the circumambient space with a continual spray."

"Now rolling down the steep again

Headlong, impetuous; see it pour!

The rocks and nodding groves rebellow to the roar."

In the vicinity of the lakes of Cumberland there are several considerable cataracts or cascades; that called "Sour-milk Force," near the bottom of Buttermere lake, is supposed to fall upwards of 300 yards. These cataracts are also rivalled by a remarkable fall of the Tees, on the west of the county of Durham, over which is a bridge suspended by chains, seldom passed but by the adventurous miners; and in this connection we might mention Afsarath Force in Yorkshire.

The principality of Wales abounds with falls of water, cascades, or cataracts, as they may be severally called, which afford amusement to the curious traveller. In the vale of Neath, the scenery of which is very romantic, there are several cascades, that are worthy of notice; but those of the river Hefsey claim particular attention. In the most considerable of these, near the junction of the rivers Hefsey and Melta, a broad sheet of water projects over an abrupt ledge of rock to the depth of 50 feet. Four others occur within an eighth part of a mile from the first. The principal of these is about 25 feet in height, and the smallest about ten. These four are all seen at once; but a bend of the river prevents a view of the great cascade. If the five were visible at one point of view, they would nearly rival the great fall of the Mynach in Cardiganshire, below the Devil's bridge; for though they would still be very inferior in point of height, the Hefsey is much broader than the Mynach, and in that respect would have the advantage with regard to grandeur. At a small distance the brink of a precipice discloses the great fall of the river Melta, which is broader than that of the Hefsey, and 70 feet high. This projects as suddenly as the others, and, carrying a larger body of water, with greater violence. It is, therefore, more awful and tremendous, but unaccompanied with those circumstances of variety and beauty which adorn and enliven its rival cataract. In the vicinity of Neath, at a place called Melin court, there is a magnificent fall of the Cleddough from the height of 80 feet. With the exception of the Mynach fall, this is the largest in South Wales, and unrivalled in its accompaniments, considered as an enclosed scene. The cascade at Ilavod in Cardiganshire, which has a continued fall of about 100 feet, is an interesting object in the scenery of that spot, which has been fo-

justly celebrated on account of the improvements introduced and still carried on by Thomas Johns, esq. its proprietor.

The fall of the Mynach, at the Devil's bridge, has already been mentioned. This stream forms its furious passage through masses and fragments of opposing rocks, hollowing out deep cavities, which are filled with unfathomed waters, and which contribute to increase the gloom of a recess, impervious to sunshine. The depth, from the present bridge to the head of the river, is 114 feet. This cascade comprehends four different falls, each of which is received into a deep and agitated pool at the bottom, but so diminished to the eye of the observer as to melt the four into one continued cascade. The first fall takes place about 40 yards south-west of the bridge, where the river is confined to narrow limits by the rocks; it is carried about six feet over the ridge, and projected into a basin at the depth of 18 feet. Its next leap is 60 feet, and the third is again diminished to 20, when it encounters rocks of prodigious size, through which it struggles to the edge of the largest cataract, and pours in one unbroken torrent down a precipice of 110 feet. The river, therefore, falls 208 perpendicular feet, without allowing for the declivity of the three pools. If we add to this 114 feet, the perpendicular depth from the bridge to the junction of the Mynach and Rydoll is 322 feet or upwards. At a small distance, in a recess seldom frequented, is the fall of the Rydoll. The most remarkable cataracts in North Wales are the following: In Merionethshire, at Dol y-Melynlyn, near Llanelltyd, is "Rhaiadr-du," or the black cataract, which is a double fall of about 60 feet high, where the water foams with a thundering noise down some black rocks, giving to the scene a singular appearance; which is increased by being covered in many places with a pure white lichen. The torrent falls into a small deep basin, from whence it dashes itself along its rugged channel. About one mile from this is another cataract, called "Rhaiadr-a-Mawddach," situated in a river of that name, where the stream forces itself down a rock, about 60 feet high, in which the stream is three times broken in its fall to the basin round which the rocks and trees form a kind of amphitheatre. Near the latter is "Pifyll y Cain," which is by far the highest and most magnificent of the three: it consists of a narrow stream, which rushes down a vast rock of the height at least of 150 feet, whose horizontal strata run into irregular steps through its whole breadth, forming a mural front; but its picturesque beauty is much injured by its regularity. The immense fragments of broken rocks, scattered round in every direction at the foot of the fall, communicate a pleasing effect, which is farther heightened by the agreeable tints of oaks and beech foliage, and, upon the whole, possesses much local beauty and romantic scenery. The most remarkable cataract in Wales is that called "Pifyll-Rhaiadr," in the extremity of the vale that lies about four miles from the village of Llanrhaeadr yn Mochant, on the borders of the counties of Montgomery and Denbigh. This cataract is formed by the river Rhaeadr, which falls from almost a perpendicular crag 210 feet high, and passes foaming through a natural arch or open basin, between two prominent sides, into a small basin at the bottom; whence it rolls over small rocks, through a woody vale, into the Severn or Tanad, a branch of the former. Some have estimated its whole height at 240 feet. The upper part of the cataract, when the sun shines upon it, is visible to a great distance; while its silvery appearance gives a degree of singularity to many of the views. Dr. Worthington, formerly vicar of Llanrhaeadr, erected a small room near the foot of the rock, for the use of visitors, who bring their own refreshments with them: this is frequently praised for its convenience and great utility in these sequestered and

deary region. Melkin's Scenery, &c. of South Wales, 4to. 1804. Evans's Cambrian Itinerary, 8vo. 1801.

Strabo calls that a cataract which we call a cataract; and what we call a cataract, the ancients usually called a *staphylis*. Hippocrates has an express dissertation on "De staphylis nudi cataractis supra & subteritatis," where he uses the word in a new sense; signifying, by cataract, any violent motion of the elements.

Cataract, from *καταρσσειν*, double to *καταρσσειν*, in *Staphylis*, is a lens, opacity, or entire loss of light, produced by an opacity (I do not say behind the pupil, which interrupts the transmission of the light, and is visible through the aperture of the iris. The loss of this opacity is usually in the crystalline lens, and its capsule; it generally arises and increases by slow degrees; sometimes it suddenly appears in a very high degree. At first an impression is made upon the organ, as if all the objects it perceives were enveloped in a mist, which gradually grows thicker, and at length entirely conceals them: at the same time the opacity behind the pupil increases by the same degrees. See Eye and Vision.

According to the different seats of the cataract, it is distinguished into several species. When the opacity exists in the crystalline lens alone, it is termed *crystalline*; when in the capsule alone, *membranous*, or *capsular*, in which case it may occupy the whole capsule, or only the anterior or posterior membrane. Sometimes both the capsule and the lens are opaque, when it is called a *mixed cataract*. Sometimes there is a preternatural accumulation of Morgagni's fluid, which becomes milk-white and opaque. All these species refer to the crystalline lens, or its capsule, and are therefore comprehended under the term of the *genus cataract*; but when the opacity is seated in other parts of the eye, it is termed the *spurious cataract*, which is divided into four species. The first species is, when pus or some other opaque substance is collected in the anterior chamber of the eye into a mass, which stops up the pupil, or fixes itself upon the anterior membrane of the capsule of the lens. In the second species, the hyaloid membrane becomes opaque. In the third species, a brown membrane is found in the eye, which lies upon the anterior part of the capsule, and is termed *choroid cataract*; by those who consider it as an elongation of the choroid membrane; though it is probably produced only by the pigmentum. The fourth species is that which occurs with infants who are born with a clouded pupil: this is named by some *cataracta pupillaris*; but it would more properly be called *juvencula congenita*.

In the crystalline cataract, the lens is sometimes converted into a fluid which resembles milk or pus, or thin jelly. Sometimes its capsule likewise becomes opaque and thickened, and separates itself from the neighbouring parts in such a manner, that, when extracted, it appears like a round case filled with milk. In this case the capsule now and then is detached spontaneously from the vitreous humour, so that the cataract becomes perfectly moveable in the eye, and trembles upon the slightest motion of the eye, or of the substance behind the pupil. Sometimes the lens preserves its natural consistence, excepting that its surface becomes soft and pulpy; sometimes it is firm, like horn or bone, and the harder it becomes the thinner and smaller it is. In this case, the cataract has generally an ash, yellow, or brownish colour. Sometimes the crystalline lens has the consistence of a thick jelly, coagulated milk, or low-milk of clec. Not unfrequently the lens partakes at the same time of all these different degrees of consistence.

In the capsular cataract, the lens generally becomes also opaque; the posterior membrane of the capsule is rarely, but most frequently the anterior alone, opaque. When the

opacity behind the pupil appears white and shining; when white and shining points or streaks are observed at it; when the opacity is as great at the circumference as at the middle, and no black ring is seen around the circumference; when the opacity arises suddenly; or when only a portion of the pupil becomes opaque, we may suspect the cataract to have its seat in the capsule. When the opacity, attended with these phenomena, appears to be behind the pupil, and to be very ill, or gradually fitted in the anterior chamber of the capsule; but when it is far behind the pupil, and seems to be connected, probably has its seat in the posterior membrane of the capsule. In the treatment, extracting and partial cataract the capsule is always opaque.

The secondary cataract is a capsular opacity, produced after the operation of extracting or destroying the lens has been performed; and commonly arises from the capsule, which has been left behind the first operation, and being afterwards opaque, and depriving the pupil at a later period of light. Sometimes the opacity which occurs after the operation, proceeds from portions of the lens remaining behind; and when it occurs after the operation of depuration, it either proceeds from the lens having risen again to its original situation. Sometimes also the light may be lost long after the operation has been performed, in consequence of the capsule, which has been left behind, becoming opaque.

The concreted cataract is always of the capsular kind, either situ or within it; an opacity of the crystalline lens, and in this the capsule has a way formed preternatural adhesions with the surrounding parts. These adhesions may be produced in a threefold manner. The capsule adheres either solely to the lens, or it is formed adhesions at its posterior part with the hyaloid membrane, or at its anterior part with the iris. The cataract, which is produced merely by a preternatural accumulation of the fluid of Morgagni, is rare; as in this case the capsule and the lens are generally at the same time both opaque, though in some cases the accumulation of the liquid is the sole cause of the loss of vision, the lens as well as its capsule being transparent. The different species of spurious cataract are upon the whole but rarely observed.

Besides these principal species of cataract, which require particular attention in the operation, there are also other varieties which demand less attention. To these belong, for example, the diversities of the colour of the cataract which sometimes is milky, sometimes of a pearl colour, ash-grey, brown, yellow, greenish, nay, even black. It was formerly also imagined, that the crystalline lens, in the progress of its becoming opaque, was first softened to a certain degree, and then again gradually hardened. In its soft state it was termed *soft*, and after it had acquired a certain degree of hardness it was called *mature*. In conformity with this theory, a recent cataract was always supposed to be soft, and one of long standing hard; but this opinion has been proved to be late to be without foundation. When the opacity does not occupy the whole pupil, but only half, or a portion of it, it is termed *partial*. Sometimes one only observes a white opaque streak behind the pupil. All these partial opacities have their seat in the capsule of the crystalline lens.

More important is the *complicated cataract*, and it may be combined with all other diseases of the eye, which are partly easy to be discovered, and partly do not impede the cure of the cataract; the *amaurosis* excepted, which not only frustrates the intention of the operation for the cataract, but frequently is also difficult to be discovered. Nevertheless, the knowledge of this latter complication is particularly necessary with respect to the pregnant; for although amaurosis

rofs presents no obstacle to the operation for the cataract, the patient cannot, however, expect to have his sight restored by that alone. See *GUTTA SERENA*.

With respect to the causes of the cataract, it is either a local complaint, or a consequence of some constitutional disease of the body. To the causes of cataract belong—external violence, wounds, bruises, concussion, the action of fire, acrid vapours, inflammations, metallasts of morbid matter, various diseases of the eye, and too much exertion of the organ, immoderate indulgence in venereal pleasures, excessive drinking; also arthritic, serophulous, scorbutic, and venereal acrimony, hereditary disposition, and age; and in the latter cases the operation is less likely to be productive of benefit than in the first. Finally, there also occurs a congenital cataract, which is commonly fluid; but in other respects equally curable with any other species of cataract. The disease may occur in every constitution, under every mode of living, and at every period of life; but it is more frequent in persons advanced in years, than in young people. When from any cause, internal or external, a cataract is produced in one of the eyes, it generally comes on gradually, within a longer or a shorter period, in the other eye also; in many cases, however, the other eye remains free from disease during the patient's life.

The cure of the cataract depends almost entirely upon surgical assistance: though it has in some cases been known to have been cured, without any operation, merely by internal remedies, or even spontaneously; viz. when the cataract evidently proceeds from internal causes, which can be removed by medicines; for example, when it is of an arthritic, venereal, serophulous, &c. origin, and when the cataract depends entirely upon the opacity of the capsule. The crystalline cataract can hardly be cured by internal remedies; though it is probable that the milky may in some cases be dissolved.

When the cataract proceeds from internal causes, such as a venereal, arthritic, &c. taint, such remedies are to be employed as counteract these causes; and when no internal cause can be detected, and the cataract seems to be of a local nature, such remedies are to be employed as are thought to possess a dissolvent power. Mercury has most frequently been employed with success; perhaps because a venereal taint is one of the most frequent internal causes of cataract. A complete opacity behind the pupil, proceeding from an arthritic taint, has been cured, within the space of four weeks, by the internal exhibition of *vin. antim.* and *aconitum*, and the external application of *decoct. cort. mez.* Cataracts, probably those of a serophulous origin, have been cured by means of Peruvian bark and cicuta. In one instance a cataract was cured during the administration of an ointment for the itch, when a plicoric eruption made its appearance.

Amongst the resolvent remedies, those which stand best recommended by the test of experience are mercury, various antimonial preparations, volatile alkali, æther, and extr. hyoscyam. alb. Electricity has also been used with success. Fresh milpeds, emetics, artificial ulcers, and various evacuant stercutatories, combined with mercury, are likewise generally recommended.

The operation, which in the majority of cases is the only remedy remaining for us to try, is not always admissible, or its success is more or less to be expected. The surgeon must examine the case before him with great attention, in order that he may form a proper prognosis; but even under the most favourable circumstances, he ought not to promise his patient any thing with certainty, as even under such circumstances the operation sometimes fails of success.

The operation is altogether inadmissible when the patient

is an infant; when he has long been troubled with obstinate and frequent head-ach, when his face is of a red copper-like colour, his eyes inflamed, painful, and unable to bear the light, and have long continued in this condition; when the patient is actually affected with rheumatic or arthritic symptoms; when he is disturbed with cough; when the diseased eye is preternaturally large and dropical, or preternaturally small and atropic; and when the cataract has formed a complete adhesion with the iris at all points. When an eye is affected with cataract, we ought never to operate, as long as the patient is not almost entirely deprived of sight in that eye, unless it should be rendered necessary by some peculiarly urgent symptoms. It is likewise commonly inadvisable to perform the operation when the patient is blind only in one eye, and the other possesses its perfect powers of vision.

The operation is attended with difficulty, or its event is doubtful, when the patient, without any symptoms of amaurosis, distinguishes light from darkness in an indistinct manner, or not at all: when the cataract arises from external causes, such as a bruise, a blow, or mere y a violent inflammation; when the first appearance of the cataract has been attended with violent head-ach and ophthalmia; when it is membranous, or adhering at any point; when the patient is of a cachectic habit, and the cataract has arisen from some external cause which could only be alleviated, but not entirely removed, before the operation.

Mr. Stoll never undertook the extraction of the lens, with persons who were affected with rheumatic or arthritic pains, who laboured under head-ach, or hemicrania, who were affected with pains in the temples and eyes, with frequent erysipelas, or obstinate cough, or eruptions in the face, or where the teeth and gums were in a very diseased condition, or where the cornea in either of the eyes began to grow opaque, or were dilated, and varicose vessels passed through the eye; as in these cases it generally had unfortunate consequences, the faculty of vision being either weakened, or entirely destroyed, after the operation.

We may expect that the operation will prove successful, when the patient is in other respects perfectly healthy; when the cataract has not been produced by some permanent internal cause; when the patient can perfectly distinguish between light and darkness; when during the commencement of the disease the patient has not been affected with frequent head achs and inflammations of the eyes; when the motion and form of the pupil are perfectly in their natural state; when the cataract is situated at the proper distance behind the pupil, and the eye is in other respects entirely sound and without blemish. But great as the advantages are which this operation produces, it is still always necessary that the want of the crystalline lens should be supplied to the patient by the use of a convex cataract glass; as there are few who are able, after the operation has been performed, to read without the aid of such a glass. See *OPTICS*.

The tedious and careful preparations which surgeons make in order to prevent the inflammation which is apprehended from the operation, are not only unnecessary, but also very prejudicial. All that the surgeon can do with otherwise healthy patients consists in the following means:

1. He must endeavour to diminish and shorten the anxiety and dread of the patient by every possible method; he must not delay the operation long; and even though its success should seem to him to be doubtful, he should endeavour to inspire his patient with hope; he should also endeavour to amuse his mind as much as possible, and prevent his thoughts from dwelling upon the operation; he should remove every thing that may give too great an air of solemnity to the operation, and not inform his patient long before hand of the hour fixed upon for the purpose; when the patient is timorous,

rons, he ought to take, half an hour before the operation, 15 or 20 drops of laudanum in a little wine; and, finally, the operation should be performed without as y unnecessary preparation and parade.

2. Only when the patient is very plethoric, and used to blood-letting, a vein may be opened.

3. For two or three days before the operation, the patient should use a less nourishing diet than usual, and carefully avoid whatever can produce irritation, costiveness, or disturbance in the prime viæ. The patient should particularly avoid all the occasional causes of rheumatic and catarrhal affections.

4. When there is cause to suspect an accumulation of feculent matter in the alimentary canal, a gentle purgative is indeed necessary; and, unless it should be contra-indicated by particular circumstances, some mercurial preparation of this kind is far preferable to the common purgative salts.

But when the patient is troubled with any complaints which might influence the success of the operation, these must be removed, as far as may be done, by means of remedies adapted to their nature and causes. No particular season of the year is exclusively favourable to the operation, all that is required being that the patient should be kept in a moderate temperature, which may be imparted to the atmosphere about him at any season. But when the patient is rheumatic or gouty, the summer is the most favourable season for the operation.

In this operation, much depends upon the convenient position both of the surgeon and patient. The surgeon, when he operates, must sit upon a high, and the patient upon a low chair, so that the head of the latter may be placed opposite to the shoulders of the former. The legs of the patient must be stretched out under the chair upon which the surgeon sits, and the head of the former must be quite close to the breast of the latter. In order to render his hand more steady, the surgeon must place one foot upon the frame of the chair upon which the patient sits, rest the elbow of the arm with which he operates upon his knee, and press his hand close to the cheek of the patient.

The surgeon ought to sit near to one of the windows of the chamber, and direct the curtains to be drawn before the others. The patient should sit in such a situation that the light may fall obliquely over his nose into his eye. The chair upon which the patient sits should have a high perpendicular back, against which his head should rest perfectly close, in order that he may not be able to start back with it during the operation.

The eye upon which the operation is not performed, ought, especially if the patient is able to see with it, to be covered with a fillet. An assistant, who stands behind the patient, lays one of his hands, for example the right, if the operation is performed on the left eye, under the chin of the patient, and raises it a little upwards, so that the face of the patient is directed somewhat upwards, and presses his head to the back of the chair, or if he sits upon one that has no back, or only a low one, to his own breast. The assistant applies his other hand to the patient's forehead, and draws the superior eyelid upwards with the fore and middle fingers of the same hand. The inferior eyelid the operator himself draws downwards with the fore and middle finger of the hand with which he does not operate.

When the line of separation between the patient's two eyelids is not sufficiently long, when the patient is very restless, and the dexterity of the assistant cannot be depended upon, it will be best to let the superior eyelid be drawn upwards by means of a broad silver hook. This hook may be formed most conveniently of a double flexible silver wire. Some also draw the inferior eyelid downwards by means of

a double hook, applying the superior hook to the eyelid and suspending a moderately heavy weight to the inferior.

Mr. Barth has lately proposed a method of operating, adapted for skilful operators, according to which he omits all the preparations hitherto mentioned. He uses no chair either for the operator or the patient, neither does he employ an assistant, nor make use of any hook. He directs the patient to lean standing against the wall of the chamber, in such a position that the light may fall obliquely upon the eye on which he is to operate. He then performs the operation in the following manner. After having placed the four fingers of his right hand (supposing the operation to be performed upon the left eye) upon the anterior part of the hairy scalp of the same side of the head, he draws the upper eyelid as much as he can upwards with the thumb of the same hand; he then places the thumb of his left hand upon the lower eyelid, draws it downwards as much as possible, and presses it with the sufficient degree of force upon the inferior margin of the socket; immediately after having done this, he pushes the point of the fore finger of his left hand under the thumb of his right, fixed in the position above-mentioned, as far as the upper eyelid, which he raises still higher up with the finger, and presses it as much as is necessary to the bottom of the socket, more or less outwards or inwards, in proportion to the necessity there is for presenting the ball of the eye. All this is done to the external parts of the eye, without touching the ball. The eyelids being secured in this manner, he orders the patient, as usual, to direct his eye in the proper position, and touches the cornea repeatedly with the flat of his lancet, at the same time giving the patient to understand that he is not about to operate. By this means he induces the patient (who generally is most restless with his head and eyes at the time when the first puncture is made, not on account of the pain which it occasions, but from fear of the danger in which he thinks his eye is), to remain quiet whilst this puncture is made, thinking the operator is still only examining the parts. But in order to keep him equally quiet whilst he proceeds to make the incision, he endeavours to throw him into a state of stupefaction by suddenly menacing him with impending danger. Having thus made the first puncture, he endeavours, with deliberate speed, to push his lancet towards the point at which it is again to be brought out, in such a manner as not to suffer the ball of the eye to slide too far towards the internal canthus, and to render the incision of a just length; though, as is well known, it ought rather to be too long than short. When he has once got hold of the cornea by bringing out the point of his lancet at the proper spot, and the eye remains in its proper situation, he continues the incision till he has completed it. But when the ball of the eye has rolled farther in any direction than it should, he brings it, as he has it now in his command, into the position necessary for completing the incision. But when he cannot reach the point for the outward puncture, without the cornea being some where in a great measure concealed, he is generally able, by a rapid and experienced comparative observation of the direction of the lancet, and the still visible cornea, to arrive at this point, blindfold as it were, and to complete the incision without damaging either the angle of the eye or the iris. For, entirely to withdraw the lancet (especially for those operators who are not able immediately to find again the entrance and exit-puncture, and to complete the incision without injury to the iris), is always a last, though a melancholy, alternative; which, particularly where it renders it necessary to defer the completion of the operation to another day, frequently disappoints the practitioner of the reputation which he hoped to acquire by it.

C A T A R A C T.

Messrs. Arneman and Conradi also deviate from the common practice, in letting the patient sit during the operation, whilst they perform it standing; as they conceive this posture to be the best and most convenient for the operator. In this manner, Mr. Conradi says he can adapt his own height to that of the patient more accurately and conveniently; and by pressing his arm to the patient's side, and his hand to the cheek of the patient, his hand loses nothing of its steadiness.

The operation for the cataract is performed either by *depression* or *extraction*. In the first, the operator presses the opaque lens out of its natural situation down to the bottom of the eye-ball, so that it may no longer be opposite to the pupil, and consequently no more obstruct the admission of the rays of light into the eye. In the second, he entirely extracts the lens through an artificial orifice in the membranes of the eye. Each of these methods has its peculiar advantages and disadvantages: some consider the one, and some the other, to deserve the preference. The method by depression is indubitably preferable in all cases in which dangerous symptoms are to be apprehended from the extraction of the lens; as when there is cause to fear a violent inflammation; when the patient is very timorous, and the eye very restless; when the cornea is very flat, and the pupil very irritable, so as to contract with unusual force; and when not only the lens but the capsule also is opaque. Depression is likewise said to be preferable when mercurial remedies have been previously employed. In cases of cataract proceeding from rheumatic metastases, it has been advised always to employ the method of depression. Moreover its greatest advantage consists in the circumstance, that even though it should not have succeeded, it may be repeated without danger, without proving an impediment to the operation of extraction being performed, even though various attempts at depression have proved unsuccessful; whilst, on the contrary, when the operation of extraction has been performed, without restoring the sight of the patient, there remains very little hope that he will ever recover it.

For performing the operation of depression, needles particularly prepared for the purpose, and provided with handles, are necessary. These needles are made of different forms, the principal of which are the round and the two-edged; of these the latter deserve in all cases the preference. Before the needle is introduced into the eye, it should be dipped in oil, or else moistened with saliva. It must be held, like a pen, between the thumb, fore and middle fingers, quite close to the foremost end of the handle. The hand must be applied close to the side of the patient's face, which generally renders the eye restless for a moment, in which case we must take care not to frighten the patient still more by repeated injunctions to keep his eye quiet; but rather let the patient alone for some moments, till his eye again becomes quiet, which it generally does in a very short time. As soon as the eye remains quiet in a position convenient for the operation, the needle is thrust quickly, but cautiously, into the eye, namely into the albuginea, at the external angle of the eye; a line from the margin of the transparent cornea, and rather more than a line under the centre. When a two-edged needle is used, it is thrust forward in such a manner, that one of its flat sides is directed upwards and the other downwards, and one of its sharp edges anteriorly, and the other posteriorly. But lest the point of the needle should hit upon the lens, and push it, if hard, into the internal cartilage, the needle must never be pushed through in a perfectly straight direction, but always directed somewhat towards the posterior part of the eye, so as to bring its point behind the lens, in such a manner that it cannot be seen beyond the pupil.

As soon as the needle has been thrust through the membranes of the eye, the operator flops for a moment, till the eye has again become quiet; he then gradually turns the needle, at the same time thrusting it deeper into the eye, in such a manner, that now one of its edges is turned upwards and the other downwards. He pushes the needle obliquely backwards, and so deep into the eye, as to bring its point behind the crystalline lens, and a little beyond its centre. As soon as the needle has been pushed in far enough, the surgeon raises its point, and applies it to the upper margin of the crystalline lens, so that one of the flat sides is directed upwards and the other downwards, lying upon the crystalline lens; and in making these turns he is directed by the black stroke on the handle of his needle. He now presses the lens downwards and backwards, but by no means right perpendicularly. During this operation, he observes the opaque substance sinking down behind the pupil, and the needle following it. It is, however, to be always kept in mind, that the point of the needle cannot be raised within the eye, except by depressing its external handle, and vice versa.

When the surgeon has depressed the lens to a sufficient depth, he waits a moment before he again raises the needle. After having raised it as high as the middle of the pupil, he likewise waits for a few moments, before he draws it out of the eye, in order to see whether the lens again follows the needle; should that be the case, he repeats the operation of depression. Should it not follow the needle, he withdraws this instrument slowly out of the eye, in the same manner as he had introduced it, namely with one of its flat sides directed upwards and the other downwards.

Sometimes the lens penetrates forwards into the pupil, as often as it is pressed upon with the needle, in spite of all the pains that may be taken to push it backwards and downwards. In this case, our best method will be, immediately to determine upon another mode of operating which shall be mentioned hereafter. When the requisite caution is not used, the lens sometimes passes through the pupil into the anterior chamber of the eye, in which case it must be extracted. All the methods that have been proposed for drawing back the lens through the pupil, and afterwards depressing it, are inadmissible. Sometimes the lens, after it has been depressed, constantly rises up again with the point of the needle; and in these cases it is to be presumed that the point of the needle may sometimes have been pushed into the lens, so as always to raise it up again when it is elevated. This may probably occur most easily, when the needle has not been pushed far enough into the eye; and when it does occur, the lens will always be observed to rise together with the point of the needle. In order to obviate this trifling difficulty, nothing more is necessary than to draw the needle a little out of the eye, and then repeat the operation.

Mr. Willburg has endeavoured to improve the operation of depressing the cataract, so that the lens may easily be loosened, and depressed without lacerating it, its rising up again prevented, or at least rendered a rare occurrence, and its being injured by the point of the needle, as much as possible guarded against. He directs us rather to turn round than depress the lens, so as to direct its anterior surface upwards, but its posterior straight downwards, and its inferior margin outwards. For this purpose, the point of the needle, after having been introduced into the eye in the above-mentioned manner, is to be raised, moved round the superior margin of the lens, and applied, with one of its flat sides directed towards the iris, and the other towards the lens, to the anterior surface of the crystalline lens, a little above the centre; upon which the whole lens must be pushed gently
backwards

backwards; in order to loosen it from its adhesions; and then the needle is to be applied a little higher and nearer to the superior margin of the lens, and the upper part of the lens pressed downwards and backwards; and in this manner the whole lens is to be laid at the bottom of the eye in a horizontal direction. In operating according to this method, we may also use the round needle instead of the two-edged one; only when that is done, we must not insert it so near to the edge of the transparent cornea as we do the first, but at two lines distance at least. In order that the point of the needle may be able to follow the superior margin of the lens backwards into the eye, during the operation. Or, it may be still more advantageously to introduce the needle as usual at the distance of a line from the margin of the transparent cornea, in order to prevent its point from injuring the iris, by being pushed over and before the lens; and then turning over the superior part of the lens, to push the needle gradually deeper into the eye, that its point may follow the upper part of the lens backward into the eye.

The surgeon should operate upon the patient's left eye with his right, and upon his right eye with his left hand; since all the proposals that have been made for operating upon the right eye with the right hand, as for example by the operator's standing behind the patient, or using a crossed needle, tend rather to render the operation more difficult than to facilitate it. At farthest it is possible to operate with the common cataract needle upon the right eye, over the patient's nose, and consequently with the right hand, provided that during the operation the eye be turned a good deal outwards; unless the patient's eyes were very deep seated and his nose very large. However, the power of operating with the left hand also is easily obtained by a little practice.

After the operation, particularly during the first days, but also for some time longer, the patient should constantly observe two rules; namely, to avoid all violent and quick motion, or concussions of the head and body, and he must be cautious never to place his head in a low dependent position, and least of all to bend it forwards. Coughing and blowing of the nose are said to hinder the depression of the lens, and must consequently be avoided also after the operation. Vomiting, which is frequently a sympathetic consequence of the operation, must be prevented by the use of opiates. It is not necessary that the patient should constantly lie up on his back; but he may either walk, sit, or lie down; however, whenever he changes his posture, he ought always to do it gradually and cautiously.

The membranous cataract which proceeds from an opacity of the capsule of the crystalline lens, which is first discovered before entering the operation, requires the common method of operating, as in this; especially when the crystalline lens is turned down, its capsule is always depressed together with it. This happens uniformly, so that we may assume it as a rule, whenever the capsule is opaque, always to prefer the turning down of the lens to every other method of operating. Should the capsule in some instances, even break while we are depressing the lens, and that be entirely depressed together with the lens, it may be pushed down afterwards by itself. A two-edged needle is, in such cases, always to be preferred to a round one, as it lays better hold of the capsule.

The *secondary cataract* seldom occurs after the operation of depression, and when it does take place, we ought not to be too hasty in undertaking a second operation, as it frequently disappears spontaneously, in a gradual manner, and sometimes yields to internal remedies. The *secondary cataract* is either in consequence of an inflammation of the capsule, in which case it generally comes on soon after the

operation, and is attended with violent inflammation of the whole ball of the eye, and sometimes disappears together with that inflammation; or, if it still remains behind, yields to the operation of vesicatories, and the internal use of dissolvent remedies, especially antimonials, camphor, cicuta, volatile alkali, &c.: or, it is an effect of the continued arthritic, venereal, or ferocious humors which caused the first opacity; and then it generally comes on late, nay, even three years after the operation; being sometimes attended with inflammation of the eye, and at other times not. In this case, the internal medicine is adapted to the particular cause of the case, are now and then of use.

When the remedies produce no advantage, the surgeon may attempt a second method of operating, in which he must depress the opaque capsule; but when this cannot be done, because of its nature, in order to procure an access for the rays of light to enter the eye, for which purpose the two-edged needle is a more convenient instrument than the round one. The same operation is also necessary in the various species of spurious cataract, especially in the opacity of the crystalline membrane; only, in this case we are not to attempt to depress the membrane, but rather to lacerate and perforate it, in order to form an aperture through which the rays of light may enter.

The *general cataract* is attended with more or less difficulty in the operation, according to its different species. The first species, namely, when the capsule adheres to the lens, is attended with no difficulty at all; nay, we do not even discover it while we are depressing the lens.

In the second species, when the capsule adheres to the hyaloid membrane, every thing depends upon separating the capsule from the substance of the vitreous humour, which is performed by moving the needle several times behind the lens, upwards as far as the superior margin of the lens, and downwards to its inferior margin. By this means it is evident that the separation may be effected, especially if we use a two-edged needle, and direct one of its edges upwards and the other downwards, whilst we are performing the operation.

When, in the third species, the whole anterior surface of the cataract adheres to the iris, we ought rather to omit the operation, as it will scarcely be possible to effect the separation; and should it be possible, it might become ineffectual, in consequence of the inflammation that is to be apprehended. But when the cataract adheres to the iris at one or a few points only, the operation probably may prove successful; but in this case, it will be best not merely to move the needle up and down behind the lens, according to Warr's method, but also to apply it alternately to the superior and inferior margin of the lens, and alternately to raise and depress it, in order to loosen its preternatural adhesions. Should this manner not be sufficient, all that is left for us to do, is to pass the needle round the superior margin of the lens into the posterior chamber of the eye, and then to press it down, with a view to separate the adhesion of these parts.

In the *partial cataract* we may also operate with the needle. As in most cases we immediately destroy the membrane at the centre of the capsule, it will be the best method immediately to lay open the anterior membrane of the capsule with it, and to suffer the dissolved lens to flow into the aqueous humour. We must, however, not merely puncture the crystalline membrane, but also, by moving the needle upwards, downwards, and laterally, form a considerable aperture; not; and if not entirely, yet in a great measure to lacerate and destroy it, which may likewise be most conveniently performed with a two-edged needle.

The milky or gelatinous substance which has found its way out of the capsule into the aqueous humour, generally

renders this turbid, but in general it gradually becomes again clear. However, when there is so large a quantity of the milky fluid as to render the aqueous humour altogether opaque, it seems to be most advisable to evacuate the watery fluid, together with whatever remains of the opaque substance, by an aperture in the cornea. If we know with certainty before-hand, that the cataract is of a fluid consistence, we may, with a view of entirely avoiding the lesion of the vitreous humour behind the cataract, and shortening the operation, thrust the needle at once into the eye, in such a manner as to make it penetrate straight into the capsule, and then perforate its anterior membrane in the manner before-mentioned. Nay, it has been advised in this case, even to thrust the needle through the transparent cornea and pupil, to open the anterior membrane of the capsule, and let out the fluid.

When the soft cheesy cataract has some degree of consistence, and the capsule is not very thin or easily lacerated, the lens passes downwards to the bottom of the eye together with its capsule, and the operation may be easily and successfully completed according to the ordinary method; though, on account of the greater violence done to the vitreous humour, its event is always doubtful. When the cataract is very soft and the capsule thin, the needle is generally soon seen behind the pupil, in the middle of the lens; and in this case it will be best, as in the fluid cataract, when the needle is seen in the capsule, to perforate the anterior membrane of the capsule with its point, to enlarge the orifice sufficiently to procure a free passage for the aqueous humour into the capsule, in order that it may dissolve the lens, and then to roll the needle round between the fingers, in order to break the lens into several small pieces, and thereby to promote its dissolution and complete absorption. If we see before-hand, with certainty, that the cataract is soft, we ought, in order to prevent the lesion of the vitreous humour, rather immediately to thrust the needle through in such a manner as to make it penetrate into the capsule, and then destroy the lens and open the capsule. Should we, however, observe, after some time has elapsed, that there remain behind more solid portions of the lens, which do not seem likely to be dissolved, we have it still in our power to open the cornea and extract them.

The hæmorrhage which occurs either during or after the operation, arises perhaps from injuring a vessel in the tunica conjunctiva or the choroid membrane, or else from a lesion of the iris or ciliary processes. The hæmorrhage from the conjunctiva may sometimes be prevented by rubbing the eye, at the external canthus, with the finger, before we introduce the needle. This hæmorrhage is, nevertheless, of little consequence, and generally ceases gradually, even when it excites a spreading ecchymosis. The hæmorrhage from the choroid membrane is, indeed, most easily excited by a two-edged needle, but it is then also least to be dreaded, as the blood is always discharged externally through the small incision in the scleroticæ. Moreover, a hæmorrhage will seldom occur, even though we use a two-edged needle, provided we introduce it according to the method above directed, namely, with one of its flat sides directed upwards and the other downwards. Though, when the round needle is used, a hæmorrhage more rarely occurs; yet, should it occur, it is also more dangerous, as the blood cannot be discharged externally through the small puncture that has been made with the needle. However, a small quantity of extravasated blood is soon re-absorbed under the use of general remedies. When the bleeding proceeds from the iris or ciliary processes, the blood generally penetrates immediately into the anterior and posterior chamber of the eye, and in parts

a red tinge, more or less deep, to the aqueous humour. Should the hæmorrhage (which, indeed, rarely happens,) be very profuse and of long continuance, as may be known from the deep, opaque, and continually augmenting redness of the aqueous humour, we ought to draw the needle as soon as possible out of the eye, open the transparent cornea, and let out the aqueous humour together with the extravasated blood. When the hæmorrhage is slight, it is no impediment to the operation, and the extravasation soon disappears under the use of antiphlogistic remedies, though we should always be very attentive to check the violent inflammation which may supervene. The small puncture in the membranes of the eye generally heals up without any difficulty; and when, as sometimes happens, a little fungous excrecence arises, this commonly yields soon to the application of astringent remedies.

Of extracting the cataract.

The operation by *extraction* requires the same preparation and position both of the patient, surgeon, and assistant, as have already been directed for the operation of depression; the prognosis also depends upon the same circumstances; but with regard to this operation, the following particulars are to be observed. In patients, whose eyes are situated very deep in the head, and the division of the eye-lids is very short, the operation is always attended with some difficulty; whilst, on the contrary, it is always easier in proportion as the eye-lids are more open and the ball of the eye more prominent. In persons whose cornea is uncommonly convex, and consequently the anterior chamber of the eye large, the operation is particularly easy and secure; whilst, on the contrary, with those persons whose cornea is flat, it is always attended with the danger of injuring the iris. When the eye is very restless, it is likewise difficult and dangerous; and in children it is sometimes entirely impracticable.

Whatever the consistence of the cataract may be, it may always be extracted, though this can be done most easily when it is firm. The fluid cataract generally discharges itself as soon as the capsule is opened, but frequently a portion of opaque mucus remains behind, which must be extracted separately. The work for extracting is the soft or cheesy cataract, which either is protruded at once and entire, in which case, as it is generally very large, it distends the pupil to a great degree, and requires a strong and continued pressure to be made upon the eye; or it breaks, and must be extracted piecemeal. When the pupil is wide, open, and moveable, we may, *caeteris paribus*, expect an easy and successful operation. When it is very small, but yet moveable, it does not, indeed, hinder the operation, but it renders the passage of the lens difficult. Also, when it is small and immovable, the operation may still be performed, provided it does not at the same time adhere to the lens. When it does not dilate itself during the operation, it perhaps admits of being widened with the lancet. When the pupil is large and immovable, provided this does not proceed from anæsthesia, there can be no objection against the operation.

With a view to render the operation as accurate as possible, several means have been proposed for fixing the eye in an immovable position. La Faye's method of fixing the eye, by means of the middle finger of the hand with which the inferior eyelid is drawn downwards; Beranger's double hook, and the small forceps which Le Cat employed for laying hold of the conjunctiva; are rough expedients, by which the eye is very much irritated and inflamed. A better mode is Pamart's spike, to which Casseamata gave the form of an S, whereby the assistant is enabled to lay the hand in which he holds the instrument upon the cheek of the patient, and moderate the pressure which it gives to the eye. But

as, with this construction of the instrument, four hands must always be applied to the cheek of the patient, which is very inconvenient both to him and to the operator, this spike has been fixed to a thimble or ring, which is put upon the middle finger of the hand with which the lower eyelid is drawn downwards. Even this instrument, however, is still defective: Mr. Demours has lately proposed another, which has great advantages over all that had before been invented. It represents a thimble, with a wide opening before and behind, which when put upon the finger, covers only both sides of it, leaving the back and inside of the finger entirely bare. From the superior central point a small hook proceeds, first perpendicularly upwards, and then horizontally sideways. The advantages of this instrument are, that the finger which draws down the lower eyelid also applies the hook, and consequently no more fingers are required than in the ordinary operation. As the finger is applied close to the patient's cheek, the operator has it in his power to moderate the degree of pressure with which the hook is introduced into the eye more than he can with other instruments of this kind. And, finally, the inner side of the finger, which touches the lid and ball of the eye is bare, and consequently lies flat upon the eyelid. It likewise always remains in the operator's option, after he has applied the instrument to his finger, whether to introduce the hook or not, as he may think proper. The hook must be inserted at the same place at which Pamart's spike is usually inserted; namely, as Mr. Gleize advises, into the conjunctiva at the side of the superior margin of the cornea in the inner angle of the eye.

However, all these, and several other instruments of the same kind, as perfect and well adapted to this purpose as they may appear, are in most cases productive of far more injury and inconvenience than benefit; and it likewise always is a difficult task for the surgeon to operate at one and the same time with both hands, and pay the necessary attention to each. In fact these instruments are in most cases really superfluous. For the voluntary as well as the involuntary motion of the eye may be checked by other and gentler means, some of which have already been mentioned. In order entirely to obviate the necessity of fixing the eye, for performing the operation for the cataract, Mr. Mina visits his patient twice a day for some time before he undertakes the operation, and places himself with his lancet in his hand before him, just as if he was about to operate. He directs him to turn his eyes in various directions, and endeavours to render him so practised in doing this as to be able to obey him without being terrified. In the space of 12 or 14 days the eye becomes so easy and obedient, as never to require any instrument for fixing it during the operation.

As to the position of the patient and operator, the same applies here that has been said in speaking of the operation of couching, and in the same manner also are the eyelids to be opened and secured. The operator holds his lancet like a writing pen, and presses the hand in which he holds it as close as possible to the patient's cheek. As soon as the eye is in a position convenient for the operation, the lancet must be thrust in suddenly, in the same manner as the needle. The incision into the cornea through which the lens is to be extracted, must be semicircular; beginning rather above the centre of the cornea towards the external angle of the eye, and extending through its lower half as far as its middle towards the inner canthus, at all points a quarter of a line from the albuginea, and separating the lower half of the conjunctiva in such a manner as to form a flap of the form of a crescent. In order to form this incision, the lancet is introduced with its edge downwards and its back upwards, at the external canthus of the eye, a quarter of a line from the albuginea, into

the transparent cornea; it is then thrust, in the direction of the transverse diameter of the cornea, through the anterior chamber, in such a manner that its point comes out again from the cornea, in the inner angle of the eye, at the same distance from the albuginea. This incision forms an orifice which is full as large as the transverse diameter of the cornea, that is, as large as it ought and can be; it is no where opposite to the pupil, and, consequently, if it should have a cicatrix, vision will not thereby be impeded. When we can foresee with certainty that the cataract is hard and small, or fluid or very soft, and consequently that no large orifice will be necessary for its extraction, we may introduce the lancet and bring it out again at the distance of half a line from the margin of the cornea, and thereby greatly diminish the danger of injuring the iris. When the cornea is very flat, its distance from the iris very small, and consequently the anterior chamber of the eye also very small, there is great danger of injuring the iris; on which account the operator is necessitated, in making his incision into the cornea, to keep as far as possible from the iris. When, on the contrary, the cataract is very large, the surgeon must rather be careful to make the incision sufficiently large, than attend too much to the possibility of injuring the iris.

In making this incision, we are particularly to attend to the rule, that the aqueous humour must not be suffered to flow out till after the incision into the cornea has been completed. With the view to prevent this occurrence, only one instrument must be used for the operation, and the lancet or knife with which the incision into the cornea is made, must possess the following properties: the blade, from the point towards the handle, must increase, not abruptly, but gradually and regularly, both in breadth and thickness, in order that as it penetrates deeper into the cornea and the anterior chamber of the eye, the wound of the cornea may not only be gradually lengthened, but at the same time also so accurately filled up as entirely to prevent the aqueous humour from issuing through it; moreover, the blade must be at its widest part as broad as the half of the cornea, that is, three lines. We must be particularly attentive not to suffer the instrument to lose these dimensions in sharpening it. The blade of the lancet must be from $1\frac{1}{2}$ to 2 inches in length, for were it longer, the surgeon would not be able to apply the hand in which he holds it close to the cheek of the patient, at the beginning of the operation. The handle must be so long, that when the instrument is held like a pen, it can be firmly upon the back of the hand. Both sides of the blade must be slightly convex, partly in order that the blade may have the requisite degree of strength, and partly that it may accurately fill up the wound of the cornea. When the sides of the blade are flat, the aqueous humour always issues out along them. The back of the lancet must be blunt, but by no means thick and broad; it must also be rectilinear, not curved and bending.

The operator holding the knife in the manner already described, and applying his hand to the cheek of the patient, thrusts in the point of the instrument, as soon as the eye is directed straight forwards, but at the same time a little upwards and outwards. The lancet is first directed straight forwards, with its point towards the iris, so as to form a right angle with that part of the cornea into which it is inserted. As soon as the point of the lancet has arrived at the chamber of the eye (of which, however, the operator ought to be perfectly certain, for if it has not, he pushes the point between the lamellæ of the cornea in turning the lancet), he changes the direction of the lancet, so as to turn its point directly towards that place in the cornea at which it is to be brought out again at the internal angle of the eye. In this

direction the lancet is thrust *slowly*, and without turning it any more, straight through the anterior chamber of the eye. The lancet, after it has once been pushed into the eye, must on no account be retracted, though ever so little, as this can never be done without letting out the aqueous humour. It must always be thrust with an uninterrupted course through the anterior chamber of the eye. The knife must be put into the cornea in such a manner that its back is directed a little towards the iris, and its edge from off it. Should the operator by mistake have thrust in the lancet in a faulty direction, this must immediately be corrected before he proceeds to push it farther. Only he must take care not to turn the lancet too suddenly, or else the aqueous humour will certainly flow out too soon; he should therefore rectify the direction of his lancet gradually, whilst he is thrusting it deeper into the eye.

Though all these rules should be observed, the incision sometimes happens to be too small, which is owing either to the motion of the eye towards the inner canthus, or to the iris coming before the edge of the lancet. The latter very embarrassing circumstance may be prevented, by removing all unnecessary pressure or irritation from the eye, according to the rules before mentioned, by thrusting in the lancet at a proper distance from the margin of the cornea, and by preventing the too early discharge of the aqueous humour. Should the iris nevertheless come to be situated opposite to the point of the lancet, it must not be retracted, as this would occasion a discharge of the aqueous humour, and a still greater protrusion of the iris; but it ought also not to be thrust in further, as in that case the iris would be injured. If the surgeon is not able, in this case, to bring the point of his lancet over the iris, by moving it a little forwards towards the cornea, his best method will be, to press the lancet straight downwards, without moving it either forwards or backwards, and in this manner to complete only half of the incision, that is, to make an incision resembling only a quarter of a circle, and afterwards to enlarge this with the scissors.

When the iris comes under the edge of the lancet, the back of it should be turned strongly towards the iris, and the edge forwards towards the cornea, in order to remove the edge from the iris, and complete the incision. In this case, indeed, the incision never goes so far downwards as it ought; however, it may afterwards be enlarged if it be too short, and we may still hope that it will not leave behind any opaque cicatrix, which would certainly be some impediment to vision.

If, after the lancet has been thrust through the anterior chamber, the eye should turn towards the inner canthus, the incision cannot be completed in the proper manner; in which case one of three expedients may be adopted. As soon as the operator perceives that the eye begins to turn, he may immediately apply the instrument for fixing it; or he may endeavour to draw back the eye from the canthus with the lancet inserted in it, and then complete the incision; or he may desist from the attempt to complete the incision with the lancet, press the lancet straight downwards, so as to separate only a quarter of the cornea, and afterwards enlarge the incision with the scissors.

The incision in the cornea may be too small in three different ways. It may either be only a quarter of a circle, with its beginning externally at the middle, and its termination downwards at the middle of the cornea; or the incision may approach more or less towards a rectilinear direction, that is, with its middle too far distant from the lower margin and too near to the pupil; or, finally, the termination of the incision at the inner angle, though in the middle of the cor-

nea, may be too far from its margin, and too near to the pupil. In the first case, which is the most favourable, the enlargement is performed by a double incision, that is, by an incision first in a horizontal direction, and afterwards directed obliquely upwards and outwards. The two latter cases are most embarrassing. In the second case, to bring the incision as near as possible to its proper length and form, its two ends must be lengthened straight upwards. In the third case, the best practice is to enlarge the inner end of the wound obliquely upwards. When the incision is so misshapen that it is impracticable to enlarge it, the best method will be to desist from the operation for the present, and after having suffered the wound to heal, to repeat it again in some days time. In each of these cases the wound may best be enlarged with the scissors, the handle of which ought to be short, in order that the surgeon may apply the hand in which he holds them close to the cheek of the patient. Their points should be smooth and round, in order to avoid injuring the iris, when they are introduced into the anterior chamber of the eye.

As soon as the incision into the cornea has been completed, the capsule must be opened by means of some cutting instrument, for which purpose La Faye's *Cystitome* seems to be very well adapted. The blade, as well as the sheath in which it is concealed, must be thin and narrow, in order that they may be easily introduced into the pupil without injuring the iris. Two rings are attached to the two sides of the instrument. In using it the fore-finger is put into one and the middle finger into the other ring, whilst the thumb is applied below to the knob, and in this manner it may be held steady and secure. It is held in the right hand, which is applied to the patient's cheek; the flap of the cornea is raised by means of the sheath, introduced into the pupil, upon which the blade is repeatedly pushed out of the sheath, and whilst this is done, the instrument is moved backwards, and forwards, upwards and downwards. This being done, the blade is suffered to draw back completely into the sheath, and the cystitome is withdrawn from the eye. Only we must take care, in applying this instrument, not to press it too forcibly against the lens. In order that the blade may be prevented from being thrust too far out of the sheath, a director is adapted to it, which enables the operator, by screwing it higher or lower, to determine with accuracy how far the blade can be protruded out of the sheath.

However, as this part of the operation, even though we use the instrument just described, is always attended with much difficulty and danger, Mr. Siegerist has invented a new instrument for performing it. This is a knife with a straight back, and with a blade gradually increasing in breadth, both of the sides of which are gently convex; but which differs from all others in this circumstance, that its point terminates in a thin two-edged needle, full half an inch in length, and of equal thickness and breadth from its point to the blade of the knife. At the place where the needle terminates, and the blade of the instrument begins, it is very sharp, and does not form an abrupt angle, but the needle gradually extends and loses itself in the blade; in this construction be not observed, the instrument cannot be pushed forwards without much difficulty, after it has penetrated into the cornea as far as the abovementioned point.

This knife is thrust, according to the ordinary method, through the cornea, into the anterior chamber of the eye, till its point is opposite to the pupil, the point is then pressed down into the pupil, and the capsule opened, after which the knife is drawn back a little, the point again raised out of the pupil, and then the incision in the cornea completed according to the usual method. Thus, with the same instrument, and with the same operation, both the cornea and the

C A T A R A C T.

capsule are opened, and the operator is spared the trouble and danger of having to open the capsule with another instrument and by another operation, after having completed the incision in the cornea. Only in case the crystalline membrane is opaque, or the pupil contracts strongly during the passage of the knife through it, or when any obstacle prevents the capsule from being opened during the incision of the cornea, it will be advisable to defer the opening of it till after the incision has been completed.

As soon as the crystalline membrane is cut through, the lens is protruded into the pupil, and dilates it forcibly, and by a small pressure with the finger, applied to the lower part of the ball of the eye, it is forced through the pupil and out of the eye. We must, however, take great care to apply this pressure in a gradual manner, otherwise as the lens is suddenly forced out of the eye, it dilates the pupil so suddenly as to lacerate or render it paralytic; in the latter case the pupil loses its power of motion, or its form is changed, and both are generally attended with injury to the sense of vision. Hence much depends upon our moderating the pressure applied to the eye, and increasing it in a gentle and gradual manner.

It is a very embarrassing circumstance, when, after the incision has been made into the cornea, the pupil is violently contracted, and does not dilate, even though a strong pressure is applied to the eye. As in this case we can seldom obtain our purpose by using force, which indeed it will not be advisable to attempt; our best method will be to close the patient's eyelids for some moments, as the pupil sometimes dilates spontaneously after a short time, or upon the application of gentle pressure. Should it still remain obstinately contracted, we may apply externally to the eyelids a cataplasm with saffron, camphor, milk, fol. cicut. hyoscyam. alb. capit. papav. alb. or extr. belladonn.; but if the contraction still continues after several hours have elapsed, and cannot be removed by the application of moderate pressure, it will be better either to depress the lens, or to enlarge the pupil at both sides by two small cuts with the scissors than to incur a greater danger by applying more violent pressure to the eye.

Whilst we are pressing the lens out of the eye, it may not be amiss to darken the chamber a little; but as soon as it has been extracted, it ought to be as light as possible, in order that we may be able accurately to examine whether the pupil be completely clean, as sometimes some opaque substance remains behind, which, if not extracted, will subsequently be more or less an impediment to vision. Whilst we are making this examination, the light should fall obliquely upon the eye, lest the reflection from the pupil might prevent the surgeon from observing any opaque substance that may exist there, particularly as even after the most careful examination some opaque substance may still remain undiscovered in the eye.

Any thing of this kind that may be found still remaining in the eye, must be extracted by means of David's spoon. This spoon must be first carved, every where smooth and even, and made either of gold or silver. When the spoon is introduced, a slight pressure must be applied to the eye, below the cornea (but with great caution, for fear lest the vitreous humour should be protruded) in order to dilate the pupil and facilitate the introduction of the instrument. During its introduction in the concave side of the spoon must be directed forwards towards the cornea, and the convexity backwards towards the capsule. When we have brought the opaque substance into the hollow of the curette, we should let the anterior and superior margin of the instrument

slide downwards, along the internal surface of the cornea, and out of the eye. Sometimes it is not necessary that the spoon should be introduced into the eye; as, by gently stroking the cornea with the convex side of the curette from above downwards, and at the same time applying a gentle pressure with the fingers below the cornea, all the remaining opaque particles may be brought out of the eye without irritation. This operation must, however, be performed with great care, lest a prolapsus of the vitreous humour should be produced.

When the eye is so restless that the spoon cannot be introduced without injuring the internal parts of the eye; when repeated experiments to lay hold of and extract the remaining opaque particles with the spoon have miscarried; when the spoon has already been introduced several times, and the extraction has generally been attended with irritation and difficulty, and only a very small quantity of opaque matter remains behind; it is better to suffer what is still left of the cataract to continue in the eye, than by repeated introductions of the curette, to expose the patient to the danger of a violent inflammation and even total loss of his eye; especially as such remaining particles have repeatedly been known to be absorbed and disappear gradually, which might perhaps also be promoted by the use of discutient remedies.

In consequence of various faults that may be committed both by the surgeon and the assistant during the performance of the operation, especially by an incautious application of pressure to the eye, the vitreous humour may be protruded, and the cataract, or part of it, remain behind. Moreover the cystic cataract, the passage of which through the pupil is generally attended with difficulty, and requires a long continued and pretty forcible pressure, generally flies suddenly through the pupil; and, if the operator be not very much upon his guard, the vitreous humour comes after it. Sometimes also this happens without any particular occasional cause, in which case the vitreous humour is generally found to be preternaturally thin and dissolved. It is also frequently protruded, when the capsule of the crystalline lens has not been opened by means of a cutting instrument, but burst by the accidental or intentional pressure of the finger. And even after the operation has been completed, we cannot be secure against this accident, as it sometimes occurs, from various causes, several hours, nay even days, after the operation. Many methods have indeed been proposed for preventing this occurrence, but they are all inadequate, as most depends upon shunning the occasional causes, which for the greater part are of that nature that they may very well be avoided. When the eye is in a spasmodic state after the operation, quieting and sedative remedies should be applied to the eye, and also exhibited internally; during the first days after the operation, the patient should be directed not to open his eyes without necessity, and should it be necessary for him to open them, to do it as cautiously as possible; and finally, during the first nights after the operation, he ought to have some person to attend him, in order to prevent him from rubbing, or in any way pressing his eyes.

But though the greatest skill and caution should be employed, we are not always secure against this accident; however it is frequently unattended with any bad consequence, nay even sometimes it is productive of advantage, and may commonly be soon removed. Moreover the loss of a small portion of the vitreous humour is generally restored in the space of a few days; nay, instances have even been known in which half of it has been lost, and yet the eye has after some time recovered its natural size, and the patient his perfect

sense of vision. Some indeed recommend immediately to cut off the part of the vitreous humour that is protruded during the operation, with the scissors, near to the cornea; but this practice is very much to be reprehended: on the contrary our best method will be, as soon as we see it protruded, immediately to let the patient shut his eyes, and without minding the protrusion, to bind up the eye. The wound of the cornea gradually contracts, and separates the protruded portion of the vitreous humour, as if by means of a ligature. The wound of the cornea, at the place where it has been kept open longer than elsewhere by the protruded portion of the vitreous humour, generally remains for some time opaque, white, thick and misshapen; but these irregularities generally disappear sooner or later under the external use of a lotion containing vitriolized zinc, or acetated cress.

When the vitreous humour is not protruded till after the operation, and the eye has been bandaged, it is frequently not discovered till the eye is again opened, on the 5th or 10th day. But it is seldom of any consequence that we are able to discover the protrusion earlier, since even though we should discover it, we can do nothing to remedy it, but must leave the whole to nature.

When the cataract has formed such extensive adhesions with the iris, that the patient cannot distinguish light from darkness; when the cataract is situated immediately behind the pupil; and this is angular, preternaturally small, and quite immovable, the probability of the operation not succeeding is so great, that we had better not undertake it. But when the patient's eye is still sensible to the impression of light at one side or the other; when the cataract on that side is not quite close to the pupil, and the pupil has still some degree of mobility at this point; and while it moves becomes oblique, angular and wrinkled; the adhesion of the cataract with the iris is not so considerable as to deprive us of all hopes of succeeding with the operation: only in giving our prognosis we must not forget the difficulties with which it is likely to be attended.

In order to separate the cataract from the iris, we introduce a flat probe, pretty much curved towards the point, into the anterior chamber of the eye, between the cataract and the iris; and then endeavour, partly by turning the probe round its axis, and partly by pressing it against the cataract, so as to push it back from the iris, to separate these two parts at the points where they adhere.

The adhesion of the lens with its capsule cannot be discovered before the operation; and should it ever be discovered, it would be impossible to separate the parts. Sometimes the lens is protruded, together with its capsule, upon the application of slight pressure, and then this species of cataract requires no particularity of operation.—The third species of the adhering cataract, in which the lens has formed adhesions not only with its capsule, but also with the hyaloid membrane, may be suspected to exist; if, after the incision into the cornea has been judiciously made, and we are convinced that the capsule has been properly opened by means of La Faye's *Cylliome*, the lens shews no disposition to be protruded upon pressure applied first gently and gradually increased, even though the pupil be dilatible, and presents no obstacle to the passage of the lens.

The best method of separating this species of cataract is, to introduce a round cataract-needle through the pupil into the posterior chamber of the eye, and giving it a rotatory motion with the fingers, to push it into the centre of the lens; then to move the lens by means of the needle, at first gently, but, by degrees, somewhat more firmly, in every direction, upwards and downwards, right and left; after which the needle is again to be withdrawn from the eye,

and the eye pressed with the finger, in the usual manner, to promote the passage of the lens through the pupil. Frequently the lens protrudes readily; and when it does not, the former manoeuvre is to be repeated; and should it still remain immovable, it will be advisable to desist from the operation.

When, in the *membranous* cataract, the anterior membrane of the capsule is opaque, no deviation from the ordinary mode of operating is required; or, if any, it is only that in opening the capsule, the crystalline membrane should be cut a little more open than usual. As soon as this has been done, the lens falls into the pupil, and must be extracted whether it be opaque or not. When, after the extraction of the crystalline lens, the orifice in the opaque membrane of the capsule is not sufficiently large, and its opaque edges can be distinctly seen in the pupil, we may, perhaps, attempt to seize and extract them by means of a very small forceps. If we know with certainty before the operation, that the anterior membrane is opaque, we may also, after opening the cornea, introduce a small pair of forceps into the pupil, lay hold of and extract the anterior membrane of the capsule with it, and then press out the lens.

When, after the lens has been extracted, the pupil remains equally opaque, and this opacity is situated farther behind the pupil than before; when the preternatural colour of the pupil is not exactly the same after the operation as it was before; when the opacity resembles a convex surface anteriorly; or when the crystalline lens that has been extracted is transparent, and the pupil remains still equally opaque as it was before the operation, there is reason to believe, that the posterior membrane of the capsule, or the hyaloid membrane, is opaque: only we must be well assured that the opacity of the pupil does not proceed from any thick mucus remaining behind in the capsule. In this case it will probably be the best practice, to perforate the posterior membrane of the capsule, with the *cyllitome* or some other instrument, repeatedly, and as completely as possible; at the same time gently pressing the finger upon the eye below the cornea, in order to bring the opaque membrane nearer to the pupil, to dilate the pupil, to expose the greater part of the opaque membrane, and thus to be able to make a larger orifice in it. When, in performing this operation, the vitreous humour protrudes, it is not only advantageous, but some surgeons think it is even advisable to promote this protrusion by a gentle and cautious pressure upon the eye.

The *secondary cataract*, which takes place soon after the operation, sometimes within a few days, always supervenes during a violent inflammation, and frequently also disappears together with it. Every thing which tends to prevent the inflammation of the eye after the operation, as also what tends most powerfully to remove it after it has come on, tends equally to prevent and remove the secondary cataract. As long as the eye still appears red, there is always ground to hope that the secondary cataract will disappear, together with the inflammation, under the use of cold faturnine lotions, and other antiphlogistic remedies. And should it even remain behind after the inflammation, we may still hope that it will gradually vanish, with the use of internal discutient means, especially sulph. aurat. antimon. mercury, cicuta, &c. But when the secondary cataract comes on later, frequently months or even years after the operation, it is an effect of some internal cause; and this cause, which is generally of an arthritic kind, then requires remedies particularly adapted to counteract it. When these means produce no benefit, the cornea might be opened a second time, and the opaque capsule extracted the more easily and successfully, as in this case there has been no previous inflammation; and,

consequently,

consequently, adhesions of the capsule with the neighbouring part are not so much to be apprehended as in the former case.

As the symptoms of the membranous cataract are frequently very uncertain, and as the opacity of the posterior membrane of the capsule cannot possibly be discovered before the operation, if the lens be likewise opaque; and, consequently, however favourable the circumstances may appear, the event of the operation is always precarious; the best practice will be always to extract the capsule at the same time with the lens. For this purpose, nothing more is necessary than to omit the opening of the capsule, and after the incision into the cornea has been made, immediately to press out gradually both lens and capsule by a cautious application of pressure. Sometimes the capsule, after having been entirely protruded, together with the lens, out of the orifice in the cornea, still remains adhering a little to the vitreous humour. In this case, it must be carefully separated by means of Daviel's spoon, and at the same time we must be cautious not to draw forwards the vitreous humour. But though this operation may frequently be performed with great facility and success, it is, nevertheless, often combined with so many difficulties, that it will scarcely be generally adopted.

The iris always protrudes more or less forwards during the operation, approaching nearer to the cornea; and sometimes it becomes distinctly convex. The more this takes place, the greater is the danger of injuring the iris, for sometimes, in spite of all the caution that may be used, it gets before the point and under the edge of the instrument, especially when part of the aqueous humour is lost. When the latter circumstance is observed to take place, the edge of the lancet must immediately be turned a little upwards, and thus the incision completed; which, in this case, does not become altogether of the form of a crescent, but, however, is generally still sufficiently large for the extraction of the lens. When the iris gets before the point of a knife, the point need only to be inclined a little outwards towards the cornea, in order to remove it from the iris, and as soon as this is done, it may be pushed a little farther forwards, but afterwards again moved downwards, and thrust completely through in the common direction. When this cannot well be accomplished, the lancet ought to be pressed straight downwards, without pushing it forwards, and thus half of the incision completed, which may afterwards be finished with the scissors. Otherwise, the lesion of the iris is seldom attended with very bad consequences, as experience has shewn that it may be injured in various ways without producing violent inflammation.

Of the symptoms particularly to be apprehended after the operation, inflammation is the chief, on which account it will be far more safe for us to endeavour to prevent it, than to rely upon the remedies usually recommended for discussing it. In order to prevent it, the following rules are principally to be observed, besides those preparatory to the operation:

As soon as the lens has been got out of the eye, and the pupil is clean, the eye must be dressed, and all attempts, particularly repeated ones, to investigate the power of vision which the eye has acquired, are to be wholly omitted. Should the flap that has been cut out of the cornea be reverted, it must be reduced by means of Daviel's spoon into its natural situation, so as to make it sit close at every point. When any part, for example the lower part of the iris, projects a little out of the wound, it must be gently pressed back by means of Daviel's spoon, in order that the lips of the wound may sit close together. But when the eye is suffered to close, the upper eye-lid must first be permitted to fall down as low as possible, in order that it may

cover the whole cornea, before we allow the lower eye-lid to rise upwards; for otherwise the latter sometimes gets under the flap of the cornea and produces violent irritation.

The dressings ought properly not to press the eye in the smallest degree, nor leave any access for the air or light to the eye. For this purpose, a very thin compress is applied, which must be long, and broad enough to reach at the bottom, as far as the cheek, at the side, as far as the nose, and at the superior extremity to the eye-brows. This compress is generally secured by means of the monocular bandage. When we have no other end in view in applying the dressings, than to close the eye, the upper eye-lid may be fastened to the lower by means of two narrow slips of adhesive plaster. Besides these, we may also, with a view to keep the rays of light from the eye, apply an eye-bandage that occasions but little pressure, and which consists of a roller to which a compress is attached, to hang down loose over the eye upon which the operation has been performed.

The patient may choose his posture as he finds most convenient, after the operation; that is, he may either lie down in bed, or sit upon the chair: only he must avoid all concussion or violent motion of the head and body, and not suffer his head to fall forwards. But it is indispensably necessary, during the first nights after the operation, that the patient should have some person to watch beside him, in order to prevent his lying in his sleep upon the wounded eye, or applying his hands to it either to rub or press it.

When the patient experiences no disagreeable sensation at all in his eye after the operation, it will be best to abstain entirely from the use of external remedies, and merely to apply dry bandages. If, on the contrary, he experiences various symptoms that require attention, some external applications are, indeed, necessary, but they ought always to be adapted to the particular state of the eye; consequently, they are not to be exclusively emollient, as some recommend, or spirituous, as is recommended by others. The same applies also to the use of internal remedies, the choice of which is likewise to be directed according to the peculiar state of the symptoms that supervene upon the operation; and consequently, none can be recommended indiscriminately.

When no troublesome symptoms are observed, and the patient feels himself in all respects well, no internal remedies are required; and all that can and ought to be done, with a view to prevent inflammation and other symptoms, is to recommend repose to the patient, to remove all accidental causes or irritation, to direct a strictly antiphlogistic regimen, and daily to administer one or two gently opening injections.

The wound of the cornea generally unites within the space of 48 hours, during which the aqueous humour flows out. Should this discharge continue longer, we may suppose some preternatural cause of it to exist in the eye, and examine it in order to find it out. When the aqueous humour ceases to be discharged at the proper time, and the patient experiences no pain or other troublesome symptom about his eye, the eye ought not to be opened before the eighth day; at farthest, it may be opened on the tenth day, even though no bad symptoms be present; and afterwards it must be opened daily, and gradually accustomated to the air and light.

However it is not always in our power, by the observance of these general rules, to prevent the inflammation and other troublesome symptoms; and it is always necessary to pay the greatest attention to the particular state of the patient. Sometimes he experiences, soon after the operation, tension, and spasms; sometimes he is very languid and debilitated; sometimes he is depressed and low-spirited without any apparent cause; sometimes he is affected with great anxiety or vomiting, or colic pains, or obstruction and

an inflated state of the abdominal viscera; and sometimes he is attacked with spasmodic horrors. Whilst these spasmodic symptoms continue, most patients complain that the eye is very restless, and moves backwards and forwards. Some imagine they see light or other appearances before the eye upon which the operation has been performed, notwithstanding that it is covered with the bandages. Sometimes the eyelids open themselves against the will of the patient. In this spasmodic state, external and internal sedative and antispasmodic remedies are necessary; such as warm pediluvia, warm fomentations applied to the abdomen, frequent emollient injections: internally, a mixture of antimonial wine and tincture of opium, or extract of hyoscyamus, &c. When the eye is very restless, we may apply to it a thin-spread, warm cataplasm of bread-crumbs, elder-flowers, saffron, &c. or frequently moisten the compress with a decoction of capit. papav. alb. and flor. malv. &c.

Sometimes, (especially when the eye has suffered much during the operation,) it becomes painful immediately after the operation, and at the same time the pulse is irritated, full, quick, the patient restless, heated, &c. in which case we must endeavour to moderate the violence of the impending inflammation by immediately letting blood, and by administering nitrous remedies, cooling laxatives, glysters, &c. Sometimes there appear symptoms indicative of an effusion of bile, such as a foul tongue, a bitter, disagreeable taste in the mouth, a sense of pain and weight in the forehead, vertigo, &c. in which case the irritating bile must be timely evacuated by means of purgatives and emetics, in order to prevent fever and inflammation.

Should an inflammation of the eye come on in spite of all the caution that we may use to prevent it, it is to be treated according to the manner directed under the article OPTHALMIA. When, after the inflammation has been removed, a languid redness remains for a long time in the eye, whilst the sense of vision is weak, and the cornea dull, and tears are discharged from the eye, these symptoms may be owing to the application of the bandages having been too long continued: and in this case the eye must be opened and washed with fresh water. Sometimes at the end of the inflammation an acrid watery fluid flows out of the eye, which keeps it for a long time red, painful, and inordinately sensible to the light.

Sometimes, in the cataract, the vessels of the retina and choroidea are varicose, in which case, shortly after the operation, a hæmorrhage may supervene, which is profuse, but generally ceases spontaneously; however, in these cases the operation is seldom successful. Sometimes a small vesicle full of water, which is transparent, very tense, and sensible, projects out of the wound of the cornea, some days after the operation; this can only be cut off with the scissors close to the cornea: but sometimes the vesicle returns again.

When the edges, especially the superior edges, of the wound of the cornea become white, thick, and soft, or actually suppurate in a small degree, the external application of saturnine remedies is to be recommended. When the cornea is dim after the operation, white vitriol may be employed.

The patient must be very cautious in making use of his new-restored sense of vision, as the eye is not able immediately to support the action of a strong light. At first, therefore, it will be proper to let him have his eye open for only one hour in the morning and evening, or till he feels that it becomes fatigued, irritable, or even painful. After some days the patient may be suffered to remain during the whole day, with his eyes open, in not too light a chamber; and when at length

he goes into the open air, he should for some time have his eyes covered with a piece of black crape.

Finally, we ought to mention the method which Mr. Conradi has proposed, for performing the operation of couching in a similar manner, which is grounded upon the gradual dissolution of the cataract. According to his method, we are to introduce into the cornea a small, lancet-like, cataract-needle, (in the same manner as the knife in the operation of extraction, only at a little greater distance from the iris); then to bring its point into the pupil and open the capsule, after which the needle is to be withdrawn, and slight bandages applied to the eye for two or three days, as in that space of time the small wound of the cornea in general disappears entirely. After this, we are to await the gradual dissolution of the lens. The needle used for this purpose needs not be quite so long as Richter's cataract knife, and not more than $1\frac{1}{2}$ or two lines in breadth. It ought not to be thicker than is necessary in order to render the blade sufficiently strong, and it ought to be two-edged throughout half of its length.

The advantages of this method of operating are said to consist in the following circumstances: it is much more easily performed than the others; the very small and insignificant wound of the cornea produces none of the troublesome symptoms that are to be apprehended partly during, and partly after, the extraction and depression of the lens. Should the cataract not be dissolved within eight or twelve weeks, any other operation may still be performed upon it equally well as if the former puncture had never been made. Bernsteins Handbuch für Wundärzte, Leip. 1799.

As this article would be extended to a disproportionate length, if we were to subjoin all the observations which relate to *cataract*, it is our design to offer some further remarks, (chiefly including the practice of English surgeons,) under the two heads COUCHING and EXTRACTING; to which we therefore refer our readers.

CATARACTA, in *Ancient Geography*, a town of Italy, in the country of the Samnites, according to Diodorus Siculus, who says that it was taken by the Romans.

CATARACTA, in *Ornithology*; *catarractes*, Gen. s; *catarractæ*, Aldr. &c.; synonymous names among old naturalists for the *Skua gull*; *LARUS catarractes*, which see.

CATARACTE, in *Military Language*, signifies a wooden grate, lattice, or portullice, made in the form of a harrow, with several pieces of timber laid lengthwise and crosswise, and strongly fastened together, armed with iron spikes. It is let down by means of a moulinet or roller, to which it is suspended by a rope, to cover any breach or opening that is made by a petard or otherwise. It is not so good, however, for this purpose as an *orgue*, which is composed of several long and thick pieces of timber that are armed with iron at the bottom, are about six inches apart from one another, and are in like manner suspended perpendicularly by a rope, but have no cross pieces except those that are fastened across them near the top to keep them steady, and in their respective places. For the cataract may be prevented from coming down by setting a piece of wood upright in one of the grooves, made in the door-case or gate for it to slide in, or by placing a piece of wood upright, or nearly so, against the gate, or by putting a *chevalet* under it.

The cataract goes also by the name of *herse* or harrow, and sometimes under the denomination of *farrazine*. Both the besiegers and besieged, for want of chevaux de frise to throw into the ways or roads where cavalry must pass, and on the breaches where the infantry enter, make use of them occasionally

from the rear, and interrupt the march both of cavalry and infantry.

CATARACTUS, in *Antient Geography*, a river, so called from its impetuosity, which seems to have been the same with the Mativas. Quatuor Curtius, l. iii. ch. 1. §. 7. Herodot. l. vi. c. 16.

CATARACTONIUM, CATARRACTONIUM, or CATARACTO, a town of the isle of Albion, placed by Ptolemy in the country of the Brigantes. In the second route of Antonine's itinerary it is placed between Lavatris (Bowes) and Harum (Aldbrough); and, without doubt, is the present Cattarick near Richmond, in Yorkshire.

CATARACTUM, a river in the island of Crete.

CATARI, a people placed by Ptolemy in Pannonia.

CATARIA, *floribus inversis*, in *Botany*, Hall. Gott. 344. See *HYSSOPUS laphanthus*.

CATARIA *foliis cordatis*, Hall. helv. 245.—Herba. Dod. pempt. 69. See *NEPETA cataria*.

CATARIA *Hispanica*, Tourn. Jult. 252. See *NEPETA vitacea* & *nila*.

CATARIA *Montana*, Buxb. Cent. See *DRACOCEPHALUM Sibiricum*.

CATARINGA, in *Geography*, a town of the island of Borneo, on a river of the same name.

CATARRH, in *Medicine*, *defluxus, distillatio*, from *καταρρα, deflusus, I flow down*, a disease which consists principally in an unusual discharge of mucus from the membranes lining the nose, throat, or *bronchie* (the branches of the *trachea* or windpipe, leading to the air-cells of the lungs), accompanied generally with fever. From its well known and universal cause, except when epidemic, the disease is commonly denominated a *cold*.

The attack of catarrh is usually marked by a sense of fullness about the nose and forehead, and of a straitening of the passage of the nostrils, which is either accompanied, or soon followed, by a discharge of a thin, watery, and somewhat acrid fluid, from the Schneiderian membrane lining those passages. There are also a dull pain and a sense of weight in the head, from which the Roman physicians gave these symptoms the appellation of *gravado*. Hippocrates, probably from the heat and acrimony of the discharge, described them under the term of *coryza*, which has been deduced from *καρρα, caput*, and *ζω, bullia*. Sometimes cold shiverings, or a sense of chilliness, are among the first symptoms. The eyes are frequently slightly inflamed, with some degree of stiffness in their motion, and an increased and acrimonious secretion from the lachrymal glands. There is a frequent disposition to sneeze from the irritation of the nostrils, and the voice becomes more obtuse in consequence of the impediment to the passage of the air through them. The discharge gradually becomes more copious and thicker, sometimes assuming an appearance similar to that of *pus*; and, after a course of some days, gradually diminishes and disappears. In the mean time a sense of roughness is felt in the throat, and a troublesome irritation about the *glottis* or entrance of the wind-pipe, which excites a dry and slight cough; some pains are felt about the chest, but especially under the sternum; the neck, back, and limbs are also sometimes affected with pains resembling those of rheumatism; there is a sense of general lassitude; the pulse is quickened, especially towards evening; the appetite fails, and some degree of thirst arises, and the palate is depraved. In a short time the febrile symptoms abate, generally after a free perspiration; an excretion of mucus, at first thin and in small quantity, gradually becoming more thick and copious, attends the cough,

which becomes less frequent and less laborious, until all the symptoms disappear.

The disease, it is obvious, consists in an inflammation of the membrane which lines the nose and the passages to the lungs; the thickening of the membrane, by which the passages become straitened, being produced by the increased flow of blood to the vessels, which also gives rise to the increase of the mucous secretion. The ancients imagined that this discharge proceeded from the head, and was determined to the membrane of the different passages by circumstances; hence the name of the disease, which, both among the Greeks and Romans, signified *defluxio*; and hence Celsus thus begins his account of the different forms of the disease: “*Distillat autem humor de capite interdum in nares, quod lene est; interdum in fauces, quod pejus est; interdum etiam in pulmonem, quod pessimum est.*” Lib. iv. cap. 4.

The mode of operation of cold on the body, when it gives rise to catarrh, has been variously explained by different writers. It has been most generally said to consist in a suppression of the perspiration, by which the matter that should have been thrown off by the cutaneous vessels is carried back, and determined upon the membranes, subject to this inflammation. This has been particularly stated by Dr. Cullen, upon his favourite notion of a balance of circulation between the external and internal parts, especially between the lungs and the skin. But this mechanical account of the fact is somewhat unsatisfactory. The matter of perspiration, and the mucus produced in the catarrhal state of the membranes of the nostrils and bronchiæ, are altogether different in nature, and are elaborated by the vessels of the skin and of those membranes respectively. There cannot therefore be a transportation of a matter, which should be discharged by the one, back again through the circulating mass, to be excreted by the other. All that the external application of cold can produce, is a diminution of the action of the cutaneous vessels by which a larger proportion of blood must circulate to the internal parts; but how this should be determined upon the membrane of the nose it is not easy to explain. An application of cold to the skin, indeed, is not necessary to produce catarrh, according to an observation stated by Mr. Mudge; who cautions people in health, from trying his “*Inhaler*” with cold water, as breathing through it for a short time will almost infallibly produce a catarrh. In this case, then, the speculations on the suppression of the cutaneous discharge, and on the balance of circulation, are altogether nugatory.

Dr. John Brown, on the other hand, denied that catarrh was the immediate result of the operation of cold, and affirmed that it was rather the consequence of the subsequent application of heat. As in other *sthenic* diseases, the excitability of the body having been accumulated or increased by the application of cold, which is but the absence of the stimulus of heat, when that stimulus is again applied, it produces the inflammatory action, which in one case constitutes *catarrh*, in another pleurisy, and so on. This hypothesis, however, is not, we believe, generally true; as many people must have had experience of the commencement of the symptoms of catarrh, even during the exposure to cold, which excited it. It is not easy, in this, as in many other forms of disease, to give any account of its production that may be completely satisfactory.

The immense number of people, who suffer repeated attacks of catarrh with impunity, is a proof, as Dr. Cullen has observed, that the disease is generally devoid of danger. But this is far from being the case invariably. In any state of constitution,

constitution, if it be neglected, or if cold is repeatedly applied during its course, it may lead to inflammation of the lungs, and all its dangerous consequences. In old people, and those of relaxed and debilitated habits, it thus often goes on to a fatal form of peripneumonia, which has been called *peripneumonia nobis*; in which a rapid effusion takes place into the cells of the lungs, which suddenly depresses the powers of life, and often proves fatal. In those who are predisposed to pulmonary consumption a neglected catarrh frequently lays the first foundation for, or accelerates the approach of the disease; and in others a permanent asthma has been often traced to the same source, or a constant and troublesome dyspnoea. In the old and infirm, it has been occasionally observed to induce hydrothorax, or dropsy of the chest, and sometimes even to bring on a general dropsy. So that, although simple catarrh is a slight complaint, when carefully attended to, great numbers die of its occasional consequences: an observation which strongly points out the necessity of not neglecting it.

In common cases of the disease, when the symptoms are moderate, it is merely necessary to avoid any exposure to cold, to dispense with the use of animal food, and of wine, and fermented liquors, and to drink freely of gruel or some diluting liquor, by which a gentle perspiration may be kept up. Saline diaphoretic medicines may be administered; and to those of weak habits a little thin wine-when may be proper. A few days will generally remove every symptom under this management. When the symptoms are more violent, the disease must be treated as a slight degree of *pneumonia*, or pulmonary inflammation; the antiphlogistic regimen must be more strictly adhered to; and more active remedies employed. The most useful expedient, especially if there is pain in the chest, is the application of blisters to some part of the thorax. For allaying the cough, which is often troublesome, and produces considerable irritation by the mechanical agitation of the body, mucilaginous medicines are useful; they are less disagreeable to the stomach, in general, than oily medicines, or even spermaceti. The stimulant expectorants, such as gum ammoniac, squill, volatile alkali, &c. are frequently employed for the same purpose; but their efficacy is doubtful. If the inflammatory symptoms are considerable, they are probably hurtful. When the inflammatory condition is allayed, opium constitutes the most effectual remedy for the cough; but there is little doubt, that the free use of it, from the early stage of a severe catarrh, has contributed to render it extremely obstinate, and sometimes to extend it to a severe pneumonia. When properly used, opium not only allays the irritation of a frequent cough, but seems to contribute even to render the expectoration more free and easy: by diminishing the sensibility of the parts, it produces a temporary suppression of the expectoration, during which the mucus and exhaling fluid of the lungs accumulate, and are then removed with greater facility.

An expedient has been suggested by Mr. Mudge of Plymouth, which he terms "a radical cure for a catarrhus cough;" namely, the inhalation of the vapour of warm water into the lungs, by means of an instrument, which he calls an "Inhaler." He observes, that when the inhaler is used in the very recent and ordinary state of the cough, viz. the evening of the attack, the patient is sure of being surprised with an immediate cure: so sudden, indeed, that it is more than probable he will cough no more, except once or twice perhaps the succeeding morning, to discharge what is drilled into the branches of the bronchiae, and which, as the thinner parts have during the night evaporated, is easily,

and with a very gentle effort, spit off in a concocted state." p. 129. Mr. Mudge's inhaler is now to be procured in the shops. Where there is a sense of rawness in the trachea, the steam alleviates the uneasiness considerably, and in moist cases relieves the cough; but in some instances it rather aggravates the symptoms and oppresses respiration.

Where the catarrh is violent, the patient must of course avoid every source of irritation which may tend to render the symptoms more inflammatory; such as great heat, exertions of body, stimulating diet, &c.; and the bowels must be kept moderately loose.

The best means of removing the chronic remains of a catarrhal affection is by some exercise of gestation diligently employed, according to Dr. Cullen; and the best means of securing the patient from a recurrence of the disease after a recovery, is by the use of warm clothing, especially by casing the body in flannel, as the susceptibility of the skin to the impression of cold is sometimes very great, particularly where much perspiration has been excited.

CATARRH *chronic*, or *catarrhus senilis*, as it is sometimes denominated, differs so much from simple catarrh in its nature, and requisite mode of treatment, as to render a distinct consideration of it necessary. In old people, of relaxed constitutions, catarrh, after being frequently repeated, becomes at length almost habitual, and is much aggravated by cold seasons, or by occasional exposure. The mucous glands of the bronchiae pour out a large quantity of fluid, and this secretion contributes in every way to increase the debility of the patient: not only by a diminution of the circulating mass, but by clogging up the air cells, and thus preventing a free and regular circulation through the lungs, and a proper change in the blood, and by rendering great exertions necessary, to expel the load of mucus from the lungs, which exhaust his strength. Hence the symptoms of this form of catarrh are, a constant, harassing cough, with a copious expectoration of viscid mucus; great difficulty of breathing; a sense of load, fullness, and constriction in the breast, with much anxiety; a feeble, labouring, and often irregular, pulse; a slightly livid tinge in the lips and cheeks; inability of much exertion; occasional vertigo; and lowness of spirits, with languor, loss of appetite, &c.

The object of medicine in simple catarrh, in young and strong habits, is to avoid, or to allay any tendency to inflammation, to support a diaphoresis, and to obviate particular symptoms as they occur: but in the *chronic* form of the disease, the chief object obviously is to enable the patient to free his lungs from the load of accumulating mucus, to lessen the secretion, and to support his strength. Expectorants, emetics, blisters, gentle sudorifics and stimulants, are the remedies which seem best adapted for these purposes.

Of the expectorant medicines, the active or stimulant ones, such as have been called *incidentia*, must be employed; as gum ammoniac, asafetida, &c. Where the heat of the body is not much increased, the volatile alkali is extremely beneficial, and when combined with squill, or the gummifins just mentioned, it appears to afford the most effectual assistance to the expectoration, and also contributes to support the strength. When the mucus becomes hard and difficult to be moved, the inhalation of the steam of warm water is sometimes of material benefit in softening and loosening it. But the most considerable and immediate relief is frequently obtained from emetics, which not only evacuate the contents of the stomach, but also of the bronchial vessels, and excite a diaphoresis. Blisters too are often productive of relief, especially where there is any particular

pain of the breast: they seem also to promote expectoration. Antimonials are occasionally useful, but chiefly where some degree of feverishness is present.

While these medicines are administered with a view to relieve the lungs, we should endeavour to support the general strength of the patient. A light and nutritious diet should be taken, such as milk; and the chamber of the invalid should be well supplied with a pure air, by which the important function of respiration may be aided. Rest should be also obtained from the exhausting exertions of coughing; with which view a small quantity of opium may be combined with the volatile alkali, or other expectorants, which will counteract the detrimental effects that might ensue from opium given alone.

CATARRH epidemic. See INFLUENZA.

CATARRHAL FEVER signifies that form of catarrh, in which the symptoms of general fever are considerable, and which requires a strict adherence to the antiphlogistic method of treatment. See CATARRH.

CATARRHUS SUFFOCATIVUS, of some of the older authors, is the more active form of the catarrh of old people, or the *peripneumonia notta* which ensues, when this catarrh is aggravated by a fresh application of cold. It was so denominated, because it often terminates speedily by inducing suffocation. See CHRONIC CATARRH.

CATARRHUS vesicæ, a term used by Lieutaud and other writers to designate a disease, which consists in a copious discharge of mucus from the bladder along with the urine. Other authors, especially the nosologists, have applied various other denominations to the same complaint. Sauvages, by a sort of solecism, has described it under the terms of *pyuria mucosa*, and P. *viscida*. (Nosol. Method. class. ix. ord. iii. genus 28.) Linnæus denominates it *glus*, and defines it simply, "Urinæ viscosæ micuratio." (Class. ix. ord. iv.) Dr. Cullen considers it under the genus *dysuria*, species 6. D. *mucosa*. And Hoffman has detailed a case at length, under the title of "Rarus vesicæ morbus," in his *Consil.* (Respon. Med. Cent. II. cas. 93.) By some it has been termed cystirrhœa.

The patient is troubled with a frequent desire of making water, which passes with some difficulty, and in a small stream. He feels a painful sensation of resistance about the neck of the bladder, which extends, together with a sense of great heat, along the urethra. The urine has a whitish milky appearance when emitted, and frequently contains many floating filaments; and after standing some time, a thick, viscid mucus, not unlike the white of eggs, is deposited in the vessel.

A discharge of mucus from the bladder is frequently a consequence of the existence of a calculus in that organ, and is generally enumerated among the symptoms of that complaint. And other discharges, as of purulent matter, or sanies, occasionally occur from the same cause, or from ulcerations and injuries of the substance of the bladder. These disorders can only be removed by curing the original disease, of which they are merely symptoms. But there are several cases on record: and other examples must have occurred to the observation of every experienced practitioner, in which such discharges with the urine appeared to arise from some particular condition of the internal surface of the bladder, which, without any extraordinary or morbid irritation, poured out the unusual secretion. Such cases have continued for some time; and, either by the aid of medicine, or the efforts of the constitution, have at length terminated in perfect health. The remedies recommended for the relief of this discharge, have been chiefly such as are obviously carried in part to the bladder, and probably excite some stimulus

there; such are the various balsams, especially balsamum copaibæ; the oil of turpentine, &c. Linnæus affirms that he has seen the disease cured by a copious use of onions in diet. On the same principle the cathartics might perhaps be usefully administered. Hoffmann recommends two medicines, which he thinks he has found beneficial; these are a compound of essence of cascariila with essence of amber; and amber prepared in the form of a dry powder with deliquesced kali, or oil of tartar per deliquium. Alkaline medicines, as in other irritations of the bladder, have been found to give relief; and the ura uris has also been recommended. It must be added, however, that, in some cases, a variety of medicines has been successively tried with little benefit; and, after they were altogether relinquished, a spontaneous cure has ensued. Hoffmann suggests the propriety of avoiding great corporeal agitations, particularly on horseback, and of dispenting with the use of strong liquors.

CATARZENA, in *Ancient Geography*, a country of Asia, in Greater Armenia, placed by Ptolemy in the vicinity of the Moschic mountains.

CATASARCA, from *κατα*, under, and *σαρξ*, flesh, in the *Greek Church*, denotes the undermoist altar-cloth, or that next the altar; which see.

Over the catasarca is the antimensa; which see.

CATASCOPIUM, from *κατασκοπειν*, I explore, in *Antiquity*, an exploratory vessel, answering in some measure to a brigantine among us. See BRIGANTINE.

We find *catascopium* used in this sense by Cicero, ad Attic. lib. v. ep. 11.

CATASCOPUS, in *Antiquity*, denotes a spy; which see.

In *Ecclesiastical Writers*, catascopus is said sometimes to denote an archdeacon.

CATATA, from *κατασκευα*, I place, in *Antiquity*, a wooden scaffold, wherein slaves were placed for sale naked, that those disposed to purchase might see every limb and part. The word was also used for an elevation, on which persons were executed; and for an engine of torture, otherwise called equuleus.

The catata does not appear to have been the same with the equuleus, but rather a kind of frame or scaffold, on which the equuleus was mounted, to render the executions more public and visible. Prudentius calls the *cratis*, or grid-iron, on which some of the martyrs were broiled, "igneæ catata."

CATASTASIS, in *Poetry*, the third part of the ancient drama; being that wherein the intrigue or action, set on foot in the epitasis, is supported, carried on, and heightened, till it be ripe for the unraveling in the catastrophe. The word comes from *καταστασις*, constitution; this being, as it were, the mean, tenor, state, or constitution of the piece.

CATASTROMATA, from *κατασκευα*, I cover, in *Ancient Military Writers*, a sort of scaffolds or floorings in ships of war, wherein the soldiers were posted for their defence in fight. The *catastromata* appear to have been chiefly erected over the head and stern of the vessel, it being in these parts that the soldiers were most commonly posted.

CATASTROPHE, from *καταστροφη*, I subvert, in *Poetry*, the change or revolution of a dramatic poem: or the turn which unravels the intrigue, and terminates the piece. The catastrophe made the fourth and last part in the ancient drama, or that immediately succeeding the catastasis; or, its seat in modern tragedy is the fifth act. See ACT.

The catastrophe is either simple, or complex; whence also the fable and action are denominated. In the first there is no change in the state of the principal persons, nor any discovery or unraveling; the plot being only a mere passage out

of agitation, to quiet and repose. This catastrophe is rather accommodated to the nature of the epopea, than of tragedy. Indeed, we meet with it in some of the ancients, but it is rejected by the moderns. In the second, the principal person undergoes a change of fortune; sometimes by means of a discovery, and sometimes without. Mr. Dryden thinks a catastrophe resulting from a mere change in the sentiments and resolutions of a person, without any further machinery, may be so managed as to become exceeding beautiful, nay preferable to any other. The qualifications of this change, or *peripetia*, are, that it be probable and necessary: in order to be probable, it is required to be the natural result or effect of the foregoing actions; i. e. it must spring from the subject itself, or take its rise from the incidents; and not to be introduced merely to serve a turn. The discovery in the catastrophe must have the same qualifications as the catastrophe itself, of which it is a principal part: it must be both probable and necessary. To be probable, it must spring out of the subject itself; nor be effected by means of marks or tokens, rings, bracelets, or by a mere recollection, as is frequently done, both by the ancients and moderns. To be necessary, it must never leave the persons it concerns in the same sentiments they had before, but always produce either love or hatred. Sometimes the change consists in the discovery; sometimes it follows at a distance; and sometimes results immediately from it, which last is the most beautiful kind.

Bosfu divides the catastrophe, at least, with regard to the epopea, into the unravelling, or *denouement*, and the *achievement*, or finishing; the last of which he makes the result of the first, and to consist in the hero's passage out of a state of trouble and agitation, to rest and quiet. This period is but a point without extent or duration; in which it differs from the first, which comprehends every thing after the knot, or plot laid. He adds, that there are several unravellings in the piece; because there are several knots, which beget one another: the finishing is the end of the last unravelling.

The ancients were fond of unravellings, which turned upon what is called an "Anagnorisis," or, a discovery of some person to be different from what he was taken to be. When such discoveries are artfully conducted, and produced in critical situations, they are extremely striking; such as that famous one in Sophocles; which makes the whole subject of his *Edipus Tyrannus*, and which is, undoubtedly, the fullest of suspense, agitation, and terror, that ever was exhibited on any stage. Among the moderns, two of the most distinguished Anagnorises are those contained in Voltaire's *Merope*, and Mr. Home's *Douglas*; both of which are great master-pieces of the kind.

Another rule concerning the catastrophe is, that it ought always to be simple; to depend on few events, and to include but few persons. Passion never rises so high when it is divided among many objects, as when it is directed towards one, or a few. And it is still more checked, if the incidents be so complex and intricate, that the understanding is put on the stretch to trace them, when the heart should be wholly delivered up to emotion. Dr. Blair observes, that the catastrophe of the Mourning Bride offends against both the preceding rules. In the last place, the catastrophe ought to be the reign of pure sentiment and passion. In proportion as it approaches, every thing should warm and glow. No long discourses; no cold reasonings; no parade of genius in the midst of those solemn and awful events, that close some of the great revolutions of human fortune. There, if any where, the poet must be simple,

serious, pathetic; and speak no language but that of nature.

It is a dispute among the critics, whether the catastrophe should always fall out happily, and favourably on the side of virtue, or not? i. e. whether virtue is always to be rewarded, and vice punished, in the catastrophe? But the reasons on the negative side seem the strongest. Aristotle prefers a shocking catastrophe to a happy one; because the moving of terror and pity, which is the aim of tragedy, is better effected by the former than the latter. But it is not essential to the catastrophe of a tragedy, that it should terminate unhappily. In the course of the play, there may be sufficient agitation and distress, and many tender emotions raised by the sufferings and dangers of the virtuous, though, in the end, good men are rendered successful. The tragic spirit, therefore, does not want scope upon this system; and, accordingly, the *Athalie* of Racine, and some of Voltaire's finest plays, such as *Alzire*, *Merope*, and the *Orphan of China*, with some few English tragedies likewise, have a fortunate conclusion. But, in general, the spirit of tragedy, especially of English tragedy, leans more to the side of leaving the impression of virtuous sorrow full and strong upon the heart. See *DRAMA* and *TRAGEDY*.

CATATANUS, in *Ancient Geography*, an episcopal see of Asia Minor, in Lycia.

CATATHRÆ INSULÆ, islands belonging to Africa; being the same, according to Ptolemy, with the *Chalontides*.

CATAVANA, CATABANA, or CATAMANA, a place of Asia, marked in the Itinerary of Antonine upon the route from Germanica to Edessa, by Samosata.

CATAWESSY, in *Geography*, a township of America, in the county of Northumberland, and state of Pennsylvania; situated on the S.E. bank of the east branch of Susquehanna river, opposite the mouth of Fishing creek, and about 20 miles N.E. of Sunbury.

CATAX, in *Entomology*, a species of *PHALÆNA*, (*Bombyx*) with ferruginous one-coloured wings, and a white point: found in the European oak.

CATAZETI, in *Ancient Geography*, a people of Asiatic Sarmatia, whose habitation is assigned by Pliny on the other side of the Tansis.

CATBALOGAN, in *Geography*, a town of the island of Samar, one of the Philippines, in the East-Indian ocean.

CATCH, in *Musick*, is a song in parts generally of a facetious kind; in which, by the disposition and arrangement of the words, some latest humour or jest is produced in singing, which, in reading the words, does not appear. We can trace attempts at this species of humour up to the time of Henry VII. and canons much higher. See *CANON*. But among the productions for vocal purposes must not be forgotten canons, rounds, and catches; of which ingenious and exhilarating species of composition, the first collection that was ever printed, appeared during the reign of James I. under the title of "Pammelia Musicks Miscellanies; or mixed varieties of pleasant rounddances and delightful catches of 3, 4, 5, 6, 7, 8, 9, 10 parts in one. None so ordinarie as musical, none so musical as not to all very pleasing and acceptable. Lond. printed by William Barley, for R. B. and H. W. and are to be sold at the Spread Eagle at the north doore of Pauls, 4to, 1609." The names of none of the composers of these epigrammatic and pointed effusions have been preserved; but many of them seem of great antiquity, which is discoverable both by the words and style of composition. Great musical science is manifested in the canons, and the harmony and contrivance of the rest

are excellent. The words, indeed, except those of the canons, which consist of small portions of the Psalms and other parts of Scripture, in Latin (which seems to imply that they were set before the reformation), are, in general, devoid of wit, humour, poetry, and common sense. But our lyric poetry, during the 16th and part of the 17th century, was in a barbarous state, and far inferior to the music of the times. But the composers seemed so little solicitous about the words they had to set, as frequently to prefer the syllables of solifitation "Ut re ni fa lo la; hev down down, derry down;" or merely, fa la, to songs of Spencer and Shakspere.

The second collection of catches, Hilton ventured to publish in 1652, in spite of the Psalm-roaring, and sanatic gloom which then prevailed, under the title of "Catch that Catch can," or a choice collection of catches, rounds, and canons, for three and four voices. They helped to solace the royals in private, during the triumphs of their enemies, and suppression of all public amusements. Though many of these rounds and catches were afterwards reprinted by Playford, and retailed in later collections; the book, which is of a small oblong form, is not only scarce, but valuable; as it contains several canons and ingenious compositions which are not yet common.

The third publication of catches had John Playford for editor, in 1667, under the same title as that of Hilton; "Catch that Catch can," or the musical companion; which was, indeed, but a second edition. However, in a second part to this publication, there appeared dialogues, glees, ayres, and ballads, of two, three, and four voices, wholly different from Hilton's second part, which consists of about 40 hymns and canons.

But we must not terminate this article without an honourable and grateful memorial of the catches, rounds, and glees of Purcell, of which the humour, ingenuity, and melody, were so congenial with the national taste, as to render them almost the sole productions of that facetious kind that were in general use for near fourscore years. And though the countenance and premiums bestowed of late years upon this species of composition, as well as modern refinements in melody and performance, have given birth to many glees of a more elegant, graceful, and exalted kind, than any which Purcell produced; yet he seems hardly ever to have been equalled in the wit, pleasantry, and contrivance of his catches.

Canons, rounds, and catches were never published in score till after the institution of the Catch-Club, in 1762. This society was first suggested by the then earl of Eglington, lord March, the present duke of Queensbury, and ——— Myneel, esq. who soon invited under their banners the lords Sandwich, Orford, Fortescue, &c. &c. This institution has given birth to many excellent glees, in purer harmony and more polished melody than those of former times could boast; but of catches and canons the stock has not been equally augmented. Purcell's catches are still the best models of that species of composition; and except Dr. William Hayes's pleasant canon, "Let's drink and let's sing together," Bird's "Non nobis Domine" is the only canon that has continued in constant favour and circulation, among all our efforts at similar productions.

CATCH-basin, in the *Construction of Canals*, is the same with *Counter-drain*; and sometimes it denotes a sort of levels or feeders for a reservoir.

CATCH-fly, in *Botany*. See *LYCHNIS*.

CATCH-land, in *Agriculture*, is a name given to such common field-land as is not certainly known to which parish it

belongs; and, therefore, the minister who first gets the tithes of it enjoys it for the year.

CATCH-pole, or **CATCH-pole**, (one that catches by the pole,) a term now used, by way of reproach, for a bailiff's follower, or assistant. Anciently, it was a term of credit, applied to those we now call *serjeants of the mace, bailiffs*, or any other that use to arrest men on any action.

CATCH-word, among *Printers*, denotes the last word of a page, which is put also at the top of the succeeding page, in order to shew how the leaves and sheets follow each other, and facilitate the folding and binding.

The French sometimes only put the catch-words at the end of each sheet, or even quire or gathering.

CATCH-work, in *Husbandry*, is a term made use of in the practice of irrigation, to signify the method of turning the cuts and trenches for throwing the water of springs, and small streams over such lands as lie on the sides, slopes, and declivities of bills.

CATCH-work meadow, that sort of meadow which is formed by turning the water of a spring or a streamlet along the slope of a hill or declivity, so as to water the lands between the cut or *main carriage*, and the original water-course, which, in this instance, becomes the main drain. This is sometimes effected in particular cases, simply by making the new-cut level, and stopping it at the end; so that when it is full, the water may run out at the side, and flood the land below it. But, as the water would soon cease to run equally for any great length, and would wash the land out in gutters, it has been found necessary, according to the Agricultural Survey of the county of Wiltshire, to cut small parallel trenches or carriages, at distances of 20 or 30 feet, to catch the water again; and each of these being likewise stopped at its end, lets the water over its side, and distributes it till it is caught by the next, and so on over all the intermediate beds, to the *main drain* at the bottom of the meadow, which receives the water, and carries it on to water another meadow below; or, if it can be so contrived, another part of the same meadow, on a lower level. And in order to draw the water out of these parallel trenches or carriages, and lay the intermediate beds dry, a narrow, deep drain crosses them at right angles, at about every nine or ten poles' length, and leads from the main-carriage at top to the main-drain at the bottom of the meadow. When this meadow is to be watered, the ends of the carriages adjoining the cross-drains are stopped with turf dug on the spot, and the water thrown over as much of the meadow as it will cover well at a time, which the watermen call a *pitch of work*; and when it is necessary to lay this pitch dry, they take out the turfs and let the water into the drains, and proceed to water another pitch.

This sort of watered meadow is seldom expensive. The stream of water being usually small and easily manageable few hatches are requisite; and the land lying on a declivity much less manual labour is necessary to throw the water over it regularly, and especially to get it off again, than in other sorts of watered meadows. The expence of forming such meadow-lands is, in general, from about three to five pounds the acre; while the improvement is frequently from fifteen to forty shillings the acre, and the usual charge for keeping up the works and watering the lands, which is mostly done by the acre, seldom comes so high as five and sixpence. See *IRRIGATION*, and *WATERING f Land*.

CATCHER, **CRAB-CATCHER**, in *Ornithology*, the name by which *Sloane distinguishes alcedo alcyon, var. ♀, Martin-pêcheur de la Loufiane* of Buffon.

CATCHER, SPIDER-CATCHER, *certbia muraria*, is so named by Willughby.

CATCHES, in *Clock Work*, those parts of a clock that hold by hooking, and catching hold.

CATCH-OWL, in *Geography*, one of the Nicobar islands. N. lat. $7^{\circ} 55'$. E. long. $93^{\circ} 58'$.

CATCHWANA, a town of Hindoostan, in the country of Agimere; 36 miles W.N.W. of Agimere.

CATEAU CAMBRESIS, or *Le Cateau*. a town of France, in the department of the North, and chief place of a canton, in the district of Cambrai, belonging, before the revolution, to the archbishop of Cambrai, and exempt from imposts. In 1539, a treaty of peace was made here between Henry II. king of France, and Philip II. king of Spain: 15 miles S.E. of Cambrai. The place contains 4000, and the canton 17,026 inhabitants; the territory comprehends $16\frac{1}{2}$ kilometres, and 16 communes. Near this place the French were defeated, in 1794, by the prince of Coburg, with the loss of 5000 killed.

CATECHESIS, from *καταγω*, *I teach first principles*, in a general sense, denotes an instruction given any person in the first rudiments of an art or science, but more particularly in the principles of the Christian religion.

Those who give such instructions are called CATECHISTS, and those who receive them CATECHUMENS.

CATECHESIS is also used for a book containing the rudiments of the Christian religion, adapted to the use and instruction of novices. See CATECHISM.

The catecheses of St. Cyril, are the principal works of that father.

CATECHETIC, or CATECHETICAL, something that relates to oral instruction in the rudiments of Christianity. In the early ages of the church there were catechetical schools, wherein sacred learning and philosophy were taught. These were public auditories, distinct from the church, but probably adjoining to them. In a novel of the emperor Leo, they are called *καταχωμαια*, and represented as a sort of edifices belonging to the church. St. Ambrose speaks of these auditories as held in the baptistery. Bingham. Orig. Eccl. lib. iii. cap. 10. § 4.

CATECHISM, *Catechismus*, in its primary sense, an instruction or institution in the principles of the Christian religion, delivered *viva voce*, and so as to require frequent repetitions from the disciple or hearer of what had been said. Anciently, the candidates of baptism were only to be instructed in the secrets of their religion by tradition, *viva voce*, without writing; as had also been the usage among the Egyptian priests, and the British and Gaulish druids, who only communicated the mystery of their theology by word of mouth. Shaftesb. Charact. vol. iii. p. 241. not.

CATECHISM is more frequently used in modern times, for an elementary book, wherein the principal articles of religion are summarily delivered in the way of question and answer.

CATECHIST, *Catecheta*, he that catechises, i. e. instructs novices in the principles of religion.

CATECHIST more particularly denotes a person appointed by the church to instruct those intended for baptism, by word of mouth, in the fundamental articles of the Christian faith.

The catechists of churches were ministers usually distinct from the bishops and presbyters, and had their auditories or *catechumena* apart. Their business was to instruct the catechumens, and prepare them for the reception of baptism. But the catechists did not constitute any distinct order of the clergy, but were chosen out of any other order.

CATECHU, in *Botany*. See ARECA.

CATECHU, in *Chemistry* and the *Materia Medica*, or *Terra Japonica*, (improperly so called,) is an extract prepared in several parts of India from a species of *Mimosas*, by decoction of the inner wood, evaporation, and inspissation in the sun. The tree is called in the Bahar province *coira*, and the name given to the extract in the country is *catechu*, *cuteb*, or *cobou*.

Mr. Kerr gives the following account of its preparation. (*Medica Observations*, vol. v.) After the trees are felled, all the exterior white part of the wood is cut off and rejected. The inner wood, which is red, is then cut into chips and boiled with water, till half of it is evaporated. This strong decoction is then poured off, without straining, into a shallow earthen vessel, and evaporated to one third by fuel, after which the thorough drying is completed by the heat of the sun, the soft extract being spread on a mat, and exposed to the air.

There are two varieties of catechu brought to this country, that from Bombay and that from Bengal, each differing but slightly from the other in chemical qualities.

Catechu is of a reddish brown colour, sometimes nearly black, shining in its fracture, and without smell. When taken in the mouth, it gives an astringent and rather bitterish taste, which is succeeded by a peculiar sweetness, which is very permanent, and by no means disagreeable. It dissolves slowly and totally in the mouth, the foreign impurities excepted.

By the analysis of Mr. Davy, (*Phil. Trans.* for 1803,) it appears, that there is very little difference between the two species, and they are both very remarkable for containing a larger portion of tan than any other vegetable matter, the gall nut not excepted.

Catechu is almost totally soluble in hot water. This solution is of a deep reddish brown, and slightly reddens litmus. By adding the solution of siinglafs, or other animal jelly, a very copious precipitate is formed indicating a large quantity of tan; and the solutions of iron strike a deep black, shewing the presence of gallic acid. Besides these two important ingredients, catechu contains a peculiar extract, and also a substance resembling mucilage. The latter is left nearly pure after the action of alcohol, which dissolves all the other ingredients. This mucilage scarcely differs from common gum mucilage, which latter is also procured from another species of *mimosa*. The extractive matter of catechu is soluble in water, but less easily than the tan is, and hence, they may be separated almost with accuracy, by repeatedly pouring cold water on the powdered catechu, and allowing it to remain only a short time in digestion. The tan will be known to be exhausted, when the water, the last added, no longer gives any precipitate with solution of siinglafs, after which the red extract is left nearly pure, most of the mucilage being also dissolved by the water. This residuary extract is but slightly astringent, but considerably sweet.

Mr. Davy found that 200 grains of the Bombay catechu contained about 109 of tan, 68 of extract, and 13 of mucilage, with 10 of earthy residue. The same quantity of the Bengal catechu contained of the above substances, in the same order, 97 grains, 73, 16, and 14.

Catechu is used largely in the East, medicinally, but especially when mixed with the betel-nut, for chewing, a practice almost universal over the Indian continent.

In this country it is employed medicinally in those cases in which a mild unirritating and powerful astringent is required, as in immoderate alvine flux, autumnal diarrhoeas, &c. It is one of the most useful medicines of this kind, and is employed either in watery solution, or tincture.

The

The former is the mildest form, and is prepared almost immediately by pouring hot water on the powdered catechu. With this indication it may be usefully joined with the bitter, tonic, and aromatic bark.

It is also used in the form of troches, mixed with gum-arabic and sugar, to dissolve slowly in the mouth, and in this form it often much assists the clearness of the voice, in persons that have occasion to speak long in public. Catechu is, besides, applied externally as a topical astringent, to ulcers in the mouth, and other parts of the body.

CATECHUMEN, compounded of *κατα* and *αγωμαι*, in *Ecclesiastical History*, a candidate for baptism; or, a person who prepares himself for receiving it. Towards the end of the first century Christians were divided into two orders, distinguished by the names of *believers* and *catechumens*. The latter, as contradistinguished from the former (see *BELIEVERS*), were such as had not yet been dedicated to God and Christ by baptism, and were, therefore, admitted neither to the public prayers, nor to the holy communion, nor to the ecclesiastical assemblies. They were distinguished from the *fideles*, or believers, not only by name, but also by their place in the church: being disposed of with the penitents, in the portico or gallery at the extremity of the church, opposite to the choir. As they were not allowed to assist at the celebration of the eucharist, the deacon dismissed them, after sermon, with this formula, proclaimed three times, "Ite, Catechumeni; missa est." Catechumens formed the lowest order of Christians in the primitive church; and were admitted into this state by the imposition of hands, and the sign of the cross. The children of believing parents, it is said, were admitted as catechumens, as soon as they were capable of instruction, but it is not certain at what age those of heathen parents might be admitted; nor does the time of their continuance in this state seem to have been fixed by any general rules. The methods of instructing the catechumens differed according to their various capacities. Those, in whom the force of natural reason was small, were taught no more than the fundamental principles and truths, which are, as it were, the basis of Christianity. Those, on the contrary, whom their instructors judged capable of comprehending, in some measure, the whole system of divine truth, were furnished with superior degrees of knowledge; and nothing was concealed from them, which could have any tendency to render them firm in their profession, and to assist them in arriving at Christian perfection. The care of instructing such was committed to persons who were distinguished by their gravity and wisdom, and also by their learning and judgment. Hence it was, that the ancient doctors generally divide their flock into two classes; the one, comprehending such as were solidly and thoroughly instructed; the other, those who were acquainted with little more than the first principles of religion; nor do they deny that the methods of instruction applied to these two sorts of persons were extremely different.

There were divers orders or degrees of catechumens in those churches and ages where the term of catechising for two or three years was observed; but ecclesiastical writers are not agreed as to the precise number and appellations of these different orders. Some, however, have reckoned four orders; the first were those that were instructed privately without the church, and who were kept at a distance for some time from the privilege of entering the church, in order to make them more solicitous for obtaining it. Those of the second degree were the "audientes," or "auditores," (see *AUDIENTS*), so called from their being admitted to hear sermons, and the scriptures read in the church; but not allowed to join in the prayers. The third sort is said to have

comprehended the catechumens, denominated "genu-flectentes," because they received imposition of hands kneeling. Those of the fourth order were the "competentes," (see *COMPETENTS*) and "electi," denoting the immediate candidates for baptism, or such as were appointed to be baptized at the next approaching festival; before which, they were strictly examined as to their proficiency in the several stages of catechetical exercises. After examination they were exercised for twenty days, and laid under an obligation of fasting and confession: for some days before baptism they wore a veil; and it was customary to touch their ears, saying "ephrata;" was opened; and also to anoint their eyes with clay; both which ceremonies professed to be imitations of the practice of our Saviour, and intended to shadow out to the catechumens their true condition both before and after their admission into the Christian church.

CATECHUMENUM, a name given to an upper gallery in the ancient churches. The name catechumenum was also given to a sort of school-house near the church, where the catechumens met to receive the instruction of the catechist.

CATEGOREMA, from *καταγορευμα*, *I declare*, is defined a noun substantivæ, so absolute and independent, that it may stand at the head of a class apart.

CATEGOREMA properly denotes the name whereby a category, or class of beings, is represented. See *CATEGORY*.

CATEGORIÆ, in *Literary History*. Aristotle has a book extant under the title of *Κατηγοριαι*, which Curio, Tomlius, Vives, and others, deny to be written by him, and ascribe to Andronicus; but without such foundation, since that work is cited as Aristotle's by Simplicius, Ammonius, and Lucianus.

CATEGORIARES, a minister in the Greek church, whose business is to publish or proclaim the feast days. He had also the care of the lights, and to see the church kept clean.

CATEGORICAL, in a general sense, is applied to those things ranged under a category.

CATEGORICAL, also imports a thing to be **ABSOLUTE**, and not restrained to conditions. In which sense it stands opposed to **HYPOTHETICAL** and **CONDITIONAL**. A categorical answer denotes an express and pertinent answer, made to any question or objection proposed.

CATEGORUMENUM, denotes the **PREDICATE**, or that part of a proposition which is affirmed of the subject. Some mistakenly call this *categorema*.

CATEGORY, in *Logic*, a system, or assemblage, of all the beings contained under any *genus*, or kind; ranged in order. The word category was borrowed by the schools from the *forum*, or courts of justice; for as, in a trial, the plaintiff or prosecutor in accusing the criminal, or prisoner, must charge him expressly, or affirm that he did this or that in positive terms: whence the word category, viz. from *καταγορευμα*, to aver, or declare a charge of accusation: so in the doctrine of categories every higher may be expressly and absolutely predicated, or affirmed, of every lower.

The school philosophers distribute all beings, all the objects of our thoughts or ideas, into certain *genera*, or classes, in order to get a more distinct and precise notion thereof; which classes the Greeks call categories, and the Latins *predicaments*: and which Mr. Harris has styled in the title of his work, *Philosophical ARRANGEMENTS*.

The ancients, after Aristotle, generally make ten categories; under the first all substances are comprised; and all accidents or attributes under the nine last; viz. quantity, quality,

quality, relation, action, passion, time, place, situation, and habit; which are usually expressed, or signified by the following technical distich:

“Arbor, fex, fervos, ardore, refrigerat, uilos,

Kuri, cras, flabo, nec tunaticus ero.”

But as these ten categories of Aristotle, which logicians make such mysteries of, are arbitrary, they are now almost excluded. Accordingly, some philosophers think all nature may be better considered under these seven things, spirit, matter, quantity, substance, figure, motion, and rest: and others make but two categories, substance and attribute, or subject and accident. This arrangement of the ten categories was borrowed from the Pythagorean school, in which the number ten was esteemed the most perfect. It is said to have been first invented by Archytas of Tarentum. From him Plato received it, when he conversed with him in Italy; and from Plato it would of course pass to Aristotle. See on the subject, and in vindication of the categories of Aristotle, Harris's *Philosophical Arrangements*, chap. ii. where this ingenious writer represents the doctrine of categories, predicaments, primary genera, or philosophical arrangements, as a valuable, copious, and sublime theory; a theory which, when well understood, leads, by analogy, from things sensible to things intelligible; from effect to cause; from that which is passive, unintelligent, and subordinate, to that which is active, intelligent and supreme; a theory, which prepares us not only to study every thing else with advantage, but makes us knowing withal in one respect, where particular studies are sure to fail; knowing in the relative value of things, when compared with one another; and modest, of course, in the estimate of our own accomplishments. In another part of his work (ch. xviii.) he observes, that in contemplating these orderly, these comprehensive arrangements, we may see whence the subordinate sciences and arts all arise: history, natural and civil, out of substance; mathematics, out of quantity; optics, out of quality and quantity; medicine, out of the same; astronomy, out of quantity and motion; music and mechanics, out of the same; printing, out of quality and site; ethics, out of relation; chronology, out of when; geography, out of where; electricity, magnetism, and attraction, out of action and passion; and so in other instances.

CATEIA, in *Ancient Writers*, a kind of dart or javelin, in use among the ancient Gauls and Germans, made of heavy matter, and therefore not fitted to fly far, but doing great execution where it did reach, having withal an apparatus by which the person who threw it might draw it back again. It is spoken of by Virgil, *Æn. lib. vii. ver. 741*.

“Teutonico ritu soliti vibrare cætes.”

CATEL, WILLIAM, in *Biography*, a learned counsellor of the parliament of Toulouse and a good magistrate, was born at Toulouse in 1569; and being profoundly versed in literature, he wrote “*A History of the Counts of Toulouse*,” 1623, fol. and “*Memoirs of Languedoc*,” fol. 1653. He was the first who verified history by ancient charters and other documents. He was a judicious writer, and rejected false or exaggerated facts. Catel died in 1621. *Nouv. Dict. Hist.*

CATELA, in *Ancient Geography*, a place of Syria, on the route from Constantinople to Antioch, six miles from Laodicea, according to the Itinerary of Antonine.

CATELÉ-VEGON, in *Botany*, Rheed. Mal. See ARISTOLOCHIA *indica*.

CATELLA. Among the Romans this was a small chain which was put round the neck, and was a sort of military present.

CATEMA, in *Geography*, a town of Arabia; 120 miles S.E. of El Catif.

CATENA, in a general sense, a CHAIN.

CATENA, in *Anatomy*, a muscle, otherwise called TIBIALIS *anticus*.

CATENA *patrum*, in *Ecclesiastical Writers*, denotes a sort of commentary on scripture, composed of separate passages or interpretations of the fathers, reduced to the order of chapters and verses of the book. The first who used catena in this sense was Thomas de Aquinas. The reason of the appellation seems to be this: that a chain consists of several links connected together, so do these commentaries consist of a number of different passages, or the sentences and expositions of different writers, tacked together so as to form one work. *Fabr. Bibl. Græc. tom. vii. lib. v. cap. 17*.

CATENARIA, in the *Higher Geometry*, a mechanical curve line, which a chain, or rope, forms itself into, by its own weight, when hung freely, between two points of suspension, whether those points be horizontal or not. It is otherwise called the *Elastic curve*.

The nature of this curve was investigated by Galileo, who supposed it to be the same with the parabola; but though Jungius detected this mistake, its true nature was not discovered till the year 1691, when M. J. Bernouilli published it as a problem in the *Acta Eruditorum*. Dr. D. Gregory, in 1697, published a method of investigating the properties before discovered by Bernouilli and Leibnitz; (*Phil. Trans. ab. vol. i. p. 39, &c.*) when he undertakes to shew, that an inverted catenaria is the best figure for an arch. Bernouilli Opera, vol. i. p. 48, &c. and vol. iii. p. 491, &c. Cotes's *Harm. Mens.* p. 168. To conceive the general nature or character of this curve, suppose a line heavy and flexible (See *Plate Geom. III. fig. 49*), the two extremities of which, F and D, are firmly fixed in those points; by its weight it is bent into a certain curve FAD, which is called the *catenaria*.

Let BD and *bd* be parallel to the horizon, AB, its axis, perpendicular to the horizon and to BD, and D δ parallel to AB; and the points B, *b* infinitely near to each other. From the laws of mechanics, any three powers in equilibrio, are to one another as the lines parallel to the lines of their direction (or inclined in any given angle), and terminated by their mutual concourses: hence, if D*d* express the absolute gravity of the particle D*d* (as it will, if we allow the chain to be every way uniform), then D δ will express that part of the gravity, that acts perpendicularly upon D*d*; and by the means of which, this particle endeavours to reduce itself into a vertical position; and as it proceeds from the ponderous line DA, it is, *ceteris paribus*, proportional to the line AD, which is the cause of it. Farther, the lineola *d δ* will express the force which acts against that concavity of the particle D*d*, by which it endeavours to restore itself into a position perpendicular to the horizon, and hinders it from doing so. This force is constant, being no other than the resistance of the point A; and may therefore be expressed by any given right line *a*. Supposing the curve FAD, therefore, as before, whose vertex (the lowest point of the *catena*) is A, axis AB, ordinate BD; fluxion or the axis D δ =B*b*; fluxion of the ordinate *d δ* ; the relation of these two fluxions is thus expressed, viz. D δ :*d δ* : DA curve = *a*; which is the fundamental property of the curve, and may be thus expressed (putting $\Delta B = x$, and $BD = y$, and $AD = z$)

$$\dot{x} : \dot{y} :: z : a, \text{ or } a \dot{x} = \dot{y} z \text{ i. e. } \dot{y} = \frac{a \dot{x}}{z}.$$

From this fundamental equation, we may easily deduce by proper analogy, or similar combinations of the terms, this other property; $\dot{x} : \sqrt{x^2 + y^2}$ or $\dot{z} :: z : \sqrt{a^2 + z^2}$, or $z \dot{z} =$

$x \dot{x} = \dot{x} \sqrt{a+x^2}$, or $\dot{x} = \frac{z \dot{z}}{\sqrt{a+z^2}}$; and the fluents of these give $x = \sqrt{a+z^2}$. But, at the vertex of the curve, where $x = a$, and $z = 0$, this becomes $0 = \sqrt{a^2+0} = a$; and, therefore, by correction, the true equation of the fluents is $x = \sqrt{a^2+z^2} - a$, or $a+x = \sqrt{a^2+z^2}$; and hence also $z = \sqrt{(a+x)^2 - a^2} = \sqrt{2ax+x^2}$, and $a = \frac{z^2-x^2}{2x}$.

Any of these expressions will give the equation of the curve in terms of the arc and its absciss; in which it appears, that $a+x$ represent the hypothenuse of a right-angled triangle, whose two legs are a and z . So that if in BA and HA, parallel to BD, and representing the direction in which the tension at A acts, produced, there be taken AD = a, and AE = the curve z or AD; then will the hypothenuse DE be = $a+x$ or DB. And hence, any two of these three, a , x , z , being given, the third is given also.

Again, from the first simple property, viz. $\dot{x} : \dot{y} :: z : a$, or $a \dot{x} = z \dot{y}$; by substituting the value of z above found, it becomes $a \dot{x} = \dot{y} \sqrt{2ax+x^2}$, or $\dot{y} = \frac{a \dot{x}}{\sqrt{2ax+x^2}}$, and the fluent of this equation is $y = 2a \times \text{hyp. log. of } \sqrt{x+\sqrt{2a+x^2}}$. But, at the vertex of the curve, where $x=0$, and $y=0$, this becomes $0 = 2a \times \text{hyp. log. of } \sqrt{0}$; therefore the correct equation of the fluents is $y = 2a \times$

$\text{hyp. log. of } \frac{\sqrt{x+\sqrt{2a+x^2}}+a}{\sqrt{2a}}$; an equation to the curve also, in terms of x and y , but not in simple algebraic terms. This last equation, however, may be brought to much simpler terms in different ways; as, first, by squaring the logarithmic quantity, and dividing its coefficient by 2; then $y = a \times \text{hyp. log. of } \frac{a+x+\sqrt{2ax+x^2}}{a} = a \times \text{hyp. log. of } \frac{a+x+z}{a}$; and secondly, by multiplying both numerator

and denominator by $\sqrt{2a+x^2} - \sqrt{x}$, then squaring the product, and dividing the co-efficient by 2, which gives $y = a \times \text{hyp. log. of } \frac{z+x}{z^2-x^2} = a \times \text{hyp. log. of } \frac{z+x}{z^2-x^2} = z \times \text{hyp. log. of } \frac{z+x}{a-x}$.

CATENATION, in *Medicine and Physiology*, from *catena*, a chain, a term, employed by Dr. Darwin, and adopted by some other modern writers, to express the connection or association of certain actions of animal bodies. "All animal motions which have occurred at the same time, or in immediate succession, become so connected, that when one of them is reproduced, the other has a tendency to accompany or succeed it." *Zoonomia*, f.c. iv. 7. This law of the animal economy, which Dr. Darwin has illustrated, is one of important consideration, not only with the physiologist, but with the practical physician. All the mechanical arts of man consist in the acquisition of these catenations, by which the motions of many of his muscles become gradually linked together in trains, tribes, or circles of motion. However difficult the first attempt at these combinations may be, the force of the catenations is pointed out by this circumstance, that when they have been once formed by frequent repetitions, we can exert our attention strongly on other objects,

and the concatenated circle of motions will nevertheless proceed in due order; as whilst we are thinking on any subject, we use a variety of muscles in walking along the street, or directing a horse on which we ride. This may be most satisfactorily exemplified in the art of playing on a musical instrument; "and when we recollect," says the author of *Zoonomia*, "the variety of mechanic arts which are performed by associated trains of muscular actions catenated with the effects they produce, as in knitting, netting, weaving; and the greater variety of associated trains of ideas caused or catenated by volitions or sensations, as in our hourly modes of reasoning, or imagining, or recollecting, we shall gain some idea of the innumerable catenated trains and circles of action, which form the tenor of our lives, and which began will only cease entirely with them." Sect. xvii. 2. In beginning to learn music, we first voluntarily apply ourselves to the characters of the music book, and endeavour by many repetitions to catenate them with the proportions of sound of which they are symbols. The ideas excited by the musical characters are slowly connected with the keys of the harpsichord, and much effort is necessary to produce every note with the proper finger, and in its due place and time; till at length a train of voluntary exertions becomes catenated with certain irritations. As the various notes by frequent repetitions become connected in the order in which they are produced, not only the musical symbols of crotchets and quavers, but the auditory notes and tones, at the same time, become to many useless or synchronous links in this circle of catenated actions. At length the motions of the fingers become catenated with the musical characters, and these no sooner strike the eye, than the finger presses down the key, without any voluntary attention between them; the activity of the hand being connected with the irritation of the figure of the musical symbol on the eye. But not only is this facility acquired, we can even play with great exactness an accustomed tune, and think, and converse at the same time on other subjects. To the same tendency to catenation of motions, the odd habits and singularities of individuals are to be attributed.

In diseases the catenation of motions is frequently conspicuous, and contributes to prolong their continuance. Thus in typhus fever, even if it commences with violence, the affusion of cold water on the body of the patient, or the exhibition of a strong emetic, will often completely interrupt the progress of the disease, if resorted to within the first three days; but if the febrile action, however slight, be allowed to continue longer, they become so strongly catenated, that no expedient is sufficient to disliver the associated trains.

By some extension of the meaning of the term, many other animal actions are said to be *catenated* with our daily habits of life, or with certain portions of time, or degrees of exhaustion, &c. Thus, if the pain of hunger be not relieved by taking food at the usual time, it is liable to cease till the next period of time, or other habits recur. "Our times even of respiration are not only governed by the stimulus of the blood in the lungs, or our desire of fresh air, but also by our attention to the hourly objects before us." Hence, when a person is earnestly contemplating an idea of grief, he forgets to breathe, till the sensation in his lungs becomes very urgent; and then a sigh succeeds for the purpose of more forcibly pushing forwards the blood, which is accumulated in the lungs."

Upon the same principle our periods of sleeping and waking, of evacuating the bowels, &c. are much regulated; and hence the propriety of Mr. Locke's recommendation for obviating colicwinds. The periods of female menstruation are catenated with longer but more regular times. In diseases the

CATERPILLAR.

the hectic and quotidian fever obey the intervals of solar or lunar periods; the tertian is connected with a solar interval of 48 hours; the quartan with one of 72. Similar periods are observed in gout, in asthma, in hemicrania, in hæmorrhoids often, and in returns of arterial hæmorrhages; and often in Innacy, whence its name has been derived. See Darwin *Zoonom.* vol. i. sect. xxxvi.

CATENENSES, in *Ancient Geography*, a people of Asia, in Pamphylia, who, according to Strabo, inhabited the territory of Selga.

CATERER. See **PURVEYOR**.

CATERG, the name of the public carriers in the Grand Seigneur's dominions, who give earnest to the merchants, and others, as a security that they will carry their goods, or not get out with them.

CATERPILLAR, in *Botany*. See **SCORPIURUS**.

CATERPILLAR, in *Entomology*, more properly **LARVA**, the worm-like state in which all the lepidopterous, and most other insects appear on quitting the egg. See **LARVA**, article **ENTOMOLOGY**.

CATERPILLAR, in *Gardening*, a well-known highly destructive insect, that frequently does great injury to various sorts of trees of the fruit and other kinds, by stripping them of their foliage, and preventing the setting of the fruits.

There are several kinds; but those that are most destructive to vegetables and fruits in the garden or field are the yellowish-green, the black, and the dark rough-skinned leathery sorts. The first is generated from the *ova* of the white butterfly, deposited upon the leaves and other parts of the plants. Those of the second sort mostly shew themselves in March, when the weather is dry, upon trees of the pear, apple, and other kinds, sometimes contained in large webs; they deposit their *ova* on the leaves, and in the crevices of the bark of the trees, from which new insects are generated during the summer months. Mr. Hit supposes some of them to remain in these situations during the winter; having found them in nail-holes and under pieces of old bark in February. The last sort is generated in the middle of the inclosed leaves of different sorts of plants; such as those of the cabbage, brocoli, and other similar kinds. These produce much mischief by eating through the stems and other parts of the plants. Darwin observes that there are two breeds of these insects in the year, the *larvæ* of the first devouring the spring leaves, and those of the second the summer shoots. Various methods have been attempted for destroying the different sorts of caterpillars, both such as are destructive to esculent plants, and to trees of the fruit kinds. With respect to the first, much advantage may be gained by a careful attention in picking them off from the leaves or other parts of the plants on their first appearance. The beds or other places where the vegetables grow should also be carefully examined early in the mornings, in order to destroy them before they retire into the holes and crevices that conceal them during the day-time; and as they are in general the most prevalent when the weather is dry, it seems not improbable that considerable benefit may be obtained by watering the plant frequently, both with common water, and with such liquids as contain ammonia or volatile alkali, either from the effects of such waterings on the caterpillars themselves, or from their promoting the growth of the plants in so vigorous and rapid a manner as to render them incapable of being devoured by them.

Mr. Forsyth advises that during the winter and spring months, every *chrysalis* that can be discovered, either under the copings of walls, on gates or palings, and about the eaves, doors, and windows of houses, should be completely removed and destroyed. Where caterpillars abound, all the

leaves that are affected should be removed with care, and swept up in order to be destroyed by fire, or formed into a compost with other substances.

The ten-threaded caterpillar is eagerly sought after by birds, and is capable of being easily destroyed; but when neglected, the *ova* are deposited in great abundance in the latter part of summer, as about July, on the under sides of the leaves in rows, with little white specks, and quickly hatched on account of the heat of the season, the young caterpillars coming forth in swarms to destroy the autumnal leaves. At this season they may be picked off the infected leaves, and their generation be by that means prevented.

Bushes or plants that are much affected with caterpillars one year, are extremely liable to be attacked with them afterwards.

In the second case, or with fruit-trees, "the best method of preventing them from being infested is, according to Mr. Forsyth, to scrape the stems with a piece of bone or wood, made in the form of a knife, taking care not to bruise the bark; and afterwards to wash the tree and wall with an equal quantity of soap-suds and urine mixed, and as soon as the leaves are off the trees in autumn, they should be raked and swept up; then carried to the melon-ground, and mixed up with other leaves and dung for hot-beds;" by this means a great number of eggs of insects that are deposited on the under sides of the leaves may be got rid of. Afterwards all the stems of the trees, and all the ends of the buds, should be washed, taking care not to hurt the buds; in doing this, it is observed, that what falls will destroy the slugs that take shelter on the officers of the walls and in the borders, before they are dug for planting lettuces, endive, &c. This washing should be repeated about the beginning of February, which will destroy any eggs of different insects that may still remain about the trees. A painter's brush may be used for laying the mixture on the trees, and a soft broom or brush made of the ends of garden matting for washing the wall. The matting seems preferable, as, being soft and flexible, it will enter the holes and crevices. And the mixture that falls on the borders and offsets of the walls, in this second washing, will destroy those slugs and insects that made their appearance early. The stems and branches of the trees may be washed two or three times, or oftener, in the spring, before the buds begin to swell; but the branches must not be rubbed after the trees come into flower; they may, however, be sprinkled over with the mixture from a watering pot with a rose just before the buds begin to open, but by no means after they are open; as it would, by its glutinous nature, render the bloom liable to be scorched by the sun. These washings, &c. are recommended for all trees, standards as well as those on walls; particularly apple, cherry, and plum-trees. Where any caterpillars remain, they may be discovered by the curling of the leaves; for every curled leaf has one or more caterpillar, or other insect in it; such leaves should therefore be carefully pulled off, and the insects crushed, as when neglected they frequently devour every leaf, leaving the tree quite naked, and of course destroy the fruit for that season at least.

In order to remove the gregarious sorts of caterpillars, which are inclosed in great numbers in nets or bags resembling strong cobwebs, and fixed to the branches of trees or shrubs, the nets should be carefully picked off, and the insects crushed, by which vast numbers of them may be destroyed. After the trees have been thus cleared, they should be washed as above, to destroy those stragglers that may still remain on them. But after the trees come into flower, instead of washing them with urine and soap-suds, they should

be well watered with clear lime-water, and cleaned with tobacco-water.

It is remarked by Mr. Forfyth, that as there are several sorts of moths, that in the caterpillar state are very hurtful to plums and other fruit-trees, it would be a great advantage to destroy them on their first appearance. In clearing trees from insects of other kinds, caterpillars should also be carefully looked for and picked off. They will be found to shelter themselves at the ends of the shoots in the flowers, and at the bottoms of the footstalks of the flowers. It is added, that there are two or three sorts that infest fruit-trees, two of a brown and one of a green colour.

The success of this method of clearing and washing has been very evident in the practice of Mr. Forfyth, in different sorts of apple-trees, they recovering themselves afterwards in a rapid manner.

It has long been a common opinion that cold and severe frosts have considerable effects in destroying caterpillars as well as the *larvæ* and *ova* of different insects: but the experiments of Reaumur and Bonnet seem to shew that this is not the case, as on the former subjecting a parcel of young caterpillars to a degree of cold lowered to fifteen degrees below zero on his thermometer, according to Dr. Anderson, they suffered no injury; and the latter found the same thing to be the case with the common cabbage caterpillar, and also the chrysalis of the common butterfly. It seems therefore not improbable but that cold frosty winters produce the good effects that are generally said to be found from them, in destroying these animals, by preventing them from obtaining food in that proportion which is necessary for their existence. The circumstance of long frosts being the most effectual is also favourable to the same supposition."

With respect to the gooseberry caterpillar, a method that has been recommended as successful by Dr. Anderson, is "to notice the bushes with care in passing through the garden, towards the beginning of June, and whenever the appearance of a leaf stripped by the caterpillar is perceived, instantly to examine the place with a view to eradicate the disease. It will always be perceived that the first appearance of this malady is towards the bottom of the bush. If one leaf be eaten up, you may be assured the caterpillar has been there; and if search be made with care it will infallibly be found. This is a gregarious reptile, and while they are young they herd very close together; so that at this early period, the whole nest will frequently be found upon one leaf, and by picking off that leaf the whole destroyed at once. As they advance in size they grow more hardy, and separate more, and therefore spread upon a number of leaves at once; but before they have attained the size of half an inch in length; they are generally found in large clutters, and may be easily destroyed. Their progress is always from the bottom upwards; and this will generally be found upon those leaves, on the same branch, that are immediately above those that have been already eaten and abandoned, leaving only the hard ribs of the leaf standing. They always fix on the under side of the leaf, and begin to gnaw off its edges. If they have but newly fixed on the leaf, no indication of them will be perceived there when viewed from above, but if the leaf bit be seen wanting, on one side of a leaf, it may be concluded they are there. These leaves and all others suspected should be pulled off, by pinching away the footstalk, with the thumb gently, so as not to shake them off; though they adhere to it so firmly when thus small, as not to be easily disengaged from it. If there be several leaves in one tuft, they may

be all taken off at once; or if the malady appears upon a young shoot of this year (which is very often the case), the easiest and shortest way is to take away the whole branch entirely.

All the leaves, thus picked off, should be either carried away in a basket, or laid in a heap upon the ground at some distance from the bush, and crushed by the foot before they are left, for it is an active reptile, and if left in life, may regain the tree afterwards. If this operation be performed with due attention, at a sufficiently early period, few will escape: nor is it a tedious process; for the most part twenty or thirty large bushes may be thus cleared by one person in the space of an hour, not one of which would perhaps have been left with a single leaf upon it, had no pains been bestowed upon them. But it is not right, says he, to trust to once searching only, for in spite of ever so much attention, it will often happen that a whole loaded leaf will escape unnoticed; and more frequently a few stragglers will pass unobserved. It is right, therefore, to look at the bushes afterwards, to see if any more leaves are bitten, and to pick them off after the same manner. This becomes the more necessary, because the eggs do not all hatch at one time, so that a whole brood may be hatched after your first search, which would of course totally escape were it no farther attended to. The task is easy if taken in time, and many thousands may be thus destroyed in the space of an hour; but if they be once suffered to disperse, and have fixed themselves about the middle of the bushes, among the small leaves that spring out of the old wood, the task then becomes much more difficult. It is advised that those who wish to try the efficacy of this mode of proceeding should never depend upon the efforts of others to ascertain whether it is effectual or not. They may order servants to practise it; but if they wish never to be deceived, let them make choice of one, two, or more bushes, to be picked by themselves only, and they will thus, with little trouble, satisfy themselves whether it be practicable or not, and can check their servants if they attempt to impose on them."

In the third volume of an useful periodical work, the Farmer's Magazine, some observations are offered on the destruction of this and the cabbage caterpillar. The writer says, he has "tried the effect of tobacco juice, and of quick-lime, both to bushes and cabbages, to destroy these insects, but without accomplishing the end in view; he took every different method that solicitude could suggest or sedulous attention could execute; and that smoking with brimstone has been lately recommended. This method he has also attempted, but with no success. He applied quick-lime in two ways, first by wetting the infested bush or cabbage with a watering pan, and then scattered on it powdered quick-lime; and secondly by putting quick-lime into a watering pan, with which the infested bush or plant was sprinkled; but also with little effect. It is further stated that tobacco is noxious to all the insect tribe. Gardeners scatter the *smoke* of it upon their hot beds and on their flower-beds, when their delicate plants become in danger of being destroyed by minute vermin, which completely answers the purpose. A pinch of snuff put on the back of a frog or toad, occasions to these reptiles violent convulsions and death. One might therefore, he says, expect that the application of tobacco, or snuff, to bushes swarming with caterpillars, would be attended with a powerful effect. But having applied it to his bushes in both ways, in which he tried the quick-lime, he found it unavailing; for caterpillars, though easily crushed to death, are otherwise wonderfully tenacious of life. Failing in these modes of application of those remedies, he

wished to see what power they had to destroy caterpillars, when applied to them in the closest possible manner. With this view he put a small quantity of tobacco snuff into one plate, and some quick lime into the other. Into these he put a number of caterpillars; but they having crawled off without being hurt, he mixed these articles with water. Out of this solution the insects also crawled, seemingly unharmed; he then prevented them from getting out of the liquor, and they expired. This was satisfactory evidence to him that caterpillars cannot be destroyed by any ordinary application of tobacco or quick-lime to a bush on which they swarm. Afterwards he tried how far the smoke of brimstone is baneful to these insects, by the following experiment. He put a dozen of them on a plate, over this he inverted a bowl which had in it some burning brimstone. This did not kill the caterpillars, which made him have recourse to a more effectual method of confining the vapour. He placed a few of these insects in a small bottle, into which, having thrust a bit of paper with inflamed sulphur, he stopped the aperture of the bottle with a cork. The effect of the vapour then became too powerful for any animal life to resist, and the insects died. This experiment, however, convinced him that the smoke of brimstone cannot be effectually applied for exterminating caterpillars on bushes. Despairing of success from any mode of general destruction of these vermin, he set servants and others to work to pick them off as above, or rather to crush them on the bushes. This effectual method at first glance may, he says, appear an insurmountable labour; but let it be tried, and it will be found by no means so tedious or laborious as at first suspected. Indeed it is a matter of absolute necessity, and as such is practised by some gardeners, who know well, that if a swarm of caterpillars, on any one bush, are not quickly destroyed, they will go over and ruin every bush and berry in the garden. Not only will black currant bushes, which they are not so fond of, become a prey to their voracity, but he has had experience of the same vermin adjoining to peach trees, and other fruit trees. Nor is there any tree, though even distant, that they will not rob of its leaves, rather than want food for their voracious appetites. Neither is this all, for if these vermin are left to plunder and to live, they infallibly secure an abundant posterity to destroy all the small fruit of the ensuing and succeeding summers." The only effectual means are, he thinks, by picking them off as directed above, the labour of which may, it is supposed, be somewhat abridged by shaking well the infested bush, and crushing with the foot those caterpillars that fall to the ground. The writer is informed that the Messrs. Culleys, those active and enterprising farmers, on the same principle, make the caterpillars be hand-picked from their extensive crops of turnips. And it is remarked that cabbages and greens may in general be preserved from caterpillars by plucking off the large undermost leaves (which may be given to cows) in the month of August, or when the common white butterfly begins to appear in numbers. These butterflies lay their eggs, which produce the cabbage caterpillar, on the under side of the largest leaves of the cabbage and kale plants. There is also said to be another remedy, which he cannot answer for. The learned professor of natural history in the university of Edinburgh has assured him, that sowing beans among cabbages will greatly prevent the breeding of these worms. It is said the butterfly has an antipathy to the flavour of beans. And he adds that "the moths (*phalene grossulariata* of Linnæus) from which the gooseberry and currant caterpillars (which are the same) are bred, are small, having yellow bodies, with many black spots, and their wings white, with yellow streaks spotted with black. They

appear in the month of July, in the evenings, and ought to be carefully killed by all attentive gardeners. They seldom fly far from the bushes on which they deposit their eggs. They live about twenty days, during which (for many of the moth tribe have not even mouths) they eat little or none. The eggs, which are yellow, are glued below the clefts, and under the longer arms near the bottom, and sometimes on the leaves of the bushes that are proper for serving the young progeny for food. One moth produces upwards of one hundred and fifty eggs: the young worms generally appear, he thinks, in spring, but they are frequently hatched in autumn. He has observed the young in great numbers devouring the leaves of the gooseberry bush as early as the 15th of August, that is about three weeks after the eggs are laid. They sometimes eat up the embryo of the new leaves and flowers of the bush in October, which renders any hope of fruit for the ensuing year abortive. Neither the frost or snow of winter destroys them. He has taken particular notice of some of these remaining on a currant bush, without being affected with cold or hunger, from November till March. During winter, and the early parts of spring, they lurk in clusters below the cleft, and then is the time they ought to be crushed. At all times, till they are ready to go into the intermediate, or nymph state, previous to their being changed into moths, they have, though ordinarily voracious, a vast power of living without food. If put into a box, even in summer, they will not seem the worse for being kept without meat."

Another writer in the same work has found great advantage from the use of *sulphur vivum* in destroying these caterpillars, after other methods had failed. "It was used," says he, "in the following manner: the bush was first lightly sprinkled with water, so as to moisten the upper part of the leaves, and immediately after dusted with the sulphur, which was put into a tin box, with the lid perforated like a pepper holder. The moistening of the leaves made the sulphur adhere to them; and the weather continuing dry, it remained upon them. The consequence was, that by next morning not a single caterpillar could be seen upon any of the bushes that had been so treated, unless in crevices, or upon some of the grains that it had not reached. Hitherto, he says, the sulphur does not appear to have been at all hurtful to the foliage, as the bushes, to which it was applied, are in the same state of forwardness, and look equally well as others that were not infested with the vermin. To ensure success, it seems essential, he says, that the sulphur should be used in dry weather, as, if rain fall immediately after the application, it will be washed off and its effect lessened."

It is ingeniously suggested by Mr. Forsyth, that by a better and more intimate acquaintance with the habits and economy of these animals, we might, probably, be enabled to discover more certain methods of destroying them.

CATERPILLAR-*cateris*, in *Entomology*; see ICHNEUMON.

CATERVA, in *Ancient Military Writers*, a term used in speaking of the Gaulish or Celtiberian armies, denoting a body of 6000 armed men.

The word *caterva*, or *catervarius*, is also frequently used by ancient writers to denote a party or corps of soldiers in disorder or disarray: by which it stands distinguished from *cohort* or *turma*, which were in good order.

CATESBÆA, in *B.tany* (a name formed by Gronovius, in honour of Mark Cateby, author of the Natural History of Carolina). Linn. Gen. 136. Willd. 113. Schreb. 106. Juss. p. 199. Vent. vol. ii. 571. Class and order, *tetrandria monogynia*. Nat. ord. *Luride*, Linn. *Rubiaceæ*, Juss. Vent.

Gen. Ch. *Cal.* perianth superior, very small, four-toothed, acute, permanent. *Cor.* monopetalous, funnel-shaped; tube long, straight, gradually enlarging upwards; border semi-quadrifid, broad, erect, flat. *Stam.* filaments four, within the neck of the tube; anthers oblong, erect, rather longer than the corolla. *Pist.* germ inferior, roundish; style filiform, the length of the corolla; stigma simple. *Peric.* berry oval, crowned, one-celled (two-celled, Vahl). *Seeds* many, angular.

Ell. Ch. *Cor.* monopetalous, funnel-shaped, very long, superior; filaments within the throat of the corolla. *Berry* many-seeded, two-celled, Willd.

Sp. 1. *C. spinosa*, Linn. Sp. Pl. Lam. Illust. Pl. lxxvii. fig. 1. Curtis, Bot. Mag. Pl. 131. (*C. longiflora*, Swartz. Prod. 30. Frutex spinosus, &c. Catef. by carol. tab. 100.) "Tube of the corolla very long; berries oval." A shrub. *Stem*, twelve or fourteen feet high, about four inches thick; bark smooth, of a greenish russet colour; wood tough and hard. *Leaves* small, resembling those of box, growing in clusters, with intervals of about an inch; each cluster accompanied by two sharp plant thorns. *Flowers* five or six inches long, yellowish, pendant, solitary in the axils of the upper leaves. *Fruit* the size of a pullet's egg; with a smooth yellow skin, and a pulp like that of a ripe apple, which has a grateful tartness and a pleasant smell. Found by Catefey, near Nassau Town, in Providence, one of the Bahama islands, who brought seeds to England. 2. *C. parviflora*, Willd. Mart. Swartz. Prod. 30. Vahl. symb. ii. p. 31. Ecol. i. p. 12. Lam. Illust. Pl. lxxvii. fig. 2. bad. (*Rhamnus foliis buxici*, &c. Sloane, Jam. 2. tab. 207, fig. 1.) "Tube of the corolla four-cornered, abbreviated; berries roundish." A native of Jamaica. Obs. Swartz, though at first he received this species as a *Catefeya*, has since made it a distinct genus, which he calls *Scolofanthus*, with the following character: *Cal.* very small, four-cleft; *Cor.* tubular, border curved, four toothed. *Stam.* four. *Pist.* germ superior; style bifid. *Peric.* drupe white, one-seeded. A branched, thorny shrub. *Leaves* opposite, nearly sessile, roundish. *Flowers*, some solitary; at the extremity of the young spines, abortive; others in the axils of the leaves fertile. Bosc. in Nonv. Dicht. art. Scolofanthe.

Propagation and culture. The first species has been propagated in England both by seeds and cuttings. The seeds succeed best when they are brought over in the entire fruit preserved in sand. They should be sown in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tanner's bark. The plants will appear in about six weeks if the seeds were good, and the pots have been occasionally, but sparingly watered. It will then generally be proper to turn over the tan to the bottom; and if the heat be not sufficient, to increase it by adding a little fresh tan. When the pots are plunged again into the tan-bed, they should be supplied with fresh water every day according to the warmth of the season, and frequently refreshed with water in small quantities: if the weather prove cold, the glasses should be covered with mats every evening. In the autumn the pots should be removed into the stove, and plunged into the tan-bed: during the winter the plants should be watered with great caution; and in the spring should be carefully taken up and planted in separate pots, which should be plunged into a fresh hot-bed of tanner's bark. In summer they should have a good deal of air; but in autumn must be removed into the stove, where they should afterwards constantly remain, and be treated like other tender exotic plants.

The cuttings should be planted during the months of June

and July, in small pots filled with light earth, plunged into a moderate hot-bed of bark, and closely covered with small bell-glasses. In two or three months they will put out roots, when they should be transplanted into separate pots, and treated as the seedling plants. Miller.

CATESBY, MARK, in *Biography*, an eminent English naturalist, was born about the latter end of 1679, or the beginning of 1681. An early propensity to the study of nature first led him to London, which he emphatically styles "the centre of science;" and afterwards impelled him to search further scenes of information on this favourite subject in distant parts of the globe. Having some relations in Virginia, he visited that country in 1712, where he remained seven years, industriously employing himself in collecting the various productions of the country, and occasionally transmitting seeds and specimens of plants to his correspondents in England, and particularly to Dr. William Sherard. On his return to England in 1719, he was encouraged by the assistance of several of the nobility, of Sir Hans Sloane, Dr. Sherard, and other naturalists, to return to America, with the professed design of describing, delineating, and painting the more curious objects of nature. He arrived in Carolina, which was selected as the place of his residence, in 1722; and having first examined the lower parts of the country, on occasional excursions from Charlestown, he afterwards sojourned, for some time, among the Indians in the mountainous regions at and about Fort Moore; and he also extended his researches through Georgia and Florida. Having spent nearly three years on the continent, he visited the Bahama islands; and residing in the Isle of Providence, he prosecuted his plan, and made various collections of fishes and submarine productions. After his return to England in 1726, being well received by his patrons, he acquired the art of etching; and, retiring to Hoxton, he devoted his time to the completion of his great work, which he published in numbers, of 20 plants each. The figures were etched by himself, from his own paintings; and the coloured copies were done under his own inspection. Although his attention was principally restricted to plants, yet most of his plates exhibit some subject of the animal kingdom. The first number appeared towards the close of the year 1730; and the first volume, consisting of 100 plates, was finished in 1732; the second in 1743; and the appendix, of 20 plates, in 1746. Of each number, a regular account, written by Dr. Cromwell Mortimer, secretary of the Royal Society, was laid before the society as it appeared, and printed in the Philosophical Transactions. The whole work is entitled, "The Natural History of Carolina, Florida, and the Bahama Islands, &c.;" and is comprised in two volumes, imperial folio. It contains descriptions of many curious and important articles of food, medicine, domestic economy, and ornamental culture; and has been allowed to be the most splendid work of its kind that had then been published in England, or even on the continent; that of Mad. Merian excepted. The principal defect of the work is the want of a separate delineation of all the parts of the flower, the necessity and importance of which, however, the state of botanical science at the time did not suggest. This work has been republished in 1754 and in 1771; and, to the last edition, a Linnæan index has been annexed. Soon after his second return from America, Mr. Catefey was elected a fellow of the Royal Society, and lived in social and friendly intercourse with many of the most respectable members of that body; being "greatly esteemed for his modesty, ingenuity, and upright behaviour." He was the author of a paper, printed in the 44th volume of the Philosophical Transactions, "On

Birds of Passage;" in which he proves the reality of their emigrating in search of proper food, from a variety of observations which he had an opportunity of making during his voyages across the Atlantic. He died in London in 1749, at the age of 70, leaving a widow and two children. His name has been perpetuated by Dr. Gronovius, in the plant called "Cathæba." Pulteney's Hist. and Biog. Sketches of the Progress of Botany in England, vol. ii. ch. 44.

CATFALL, in *Ship-Rigging*, denotes the rope that forms the tackle for heaving up the anchor from the water's edge to the bow. It reeves through the sheaves at the outer end of the cat-head, (which see,) and through the sheaves of the cat-block alternately.

CATFINTHVOE, in *Geography*, a bay on the north-east coast of the island of Shetland; 10 miles N. of Lerwick.

CATHA, in *Botany*, Fork. Arab. See **CELASTRUS edulis**, and **paniflorus**.

CATHÆI, in *Ancient Geography*, a people of India, mentioned by Arrian, who says, that they selected the most handsome man among them for their king; that they were valiant, and surpassed their neighbours with regard to their experience in the military art; and that their females had the custom of burning themselves after the death of their husbands. Strabo adds, that they determined, within two months after the birth of a child, whether his form was so perfect as to render him worthy of being preserved; otherwise they destroyed him. They are also said to have tinged their beards with various colours by way of ornament; and their marriages were the result of mutual choice on the part of the contracting parties. See **CATHAIA**.

CATHENA, a town of India, mentioned by Steph. Byz.

CATHÆRETICS, in *Surgery*, καθήρετικα, from καθίρειν, to remove; corollive remedies which destroy and eat off superfluous flesh, by chemically decomposing its natural texture. Cathæretics have been otherwise denominated *scarabæagous medicines*, q. d. *fly-eaters*; such as red precipitate of mercury, burnt alum, verdigris, preparations of vitrol, &c. &c. which differ only in degree from *caustics*, or *escharotic* applications, these latter being much more violent and destructive in their operation. Dr. Cullen observes that, as the operation of the different medicines of this class is not always the same, nor their different operations well explained, the propriety of the general term may be doubtful.

CATHAIA, or **CATHÆA**, in *Geography*, a country in the north-eastern part of Asia, about the precise situation of which authors are not agreed. Some have supposed that it was the country of the Sophites, and that it was called by Curtius Sophites; and they place it between the rivers Hydaspes and Acesines, where lay the extensive and rich country of Porus, containing about 300 cities. Others say that it lay beyond the Acesines and Hydrates, on the borders of the territory of Porus, a cousin of the Porus who was captured by Alexander. Arrian says, that Sangala, which probably lay between Lahore and Moultan, was a city of great strength and importance in the country of the Cathæi. Diodorus Siculus calls the same people "Catheri," or "Katheri," and they may very easily be recognized under the name of "Cathy," in Thevenot; that is, the "Kuttry" tribe, or "Rajpoots." Thevenot, speaking of the people of Moultan, says, "there is a tribe of Gentiles (i. e. Gentoos, or Hindoos,) here, called Cathy, or Rajpoots; and this is properly their country, from whence they spread all over the Indies. Diodorus Siculus marks them by the custom of their women burning themselves alive, on the

funeral piles of their husbands. From Arrian we learn that the Cathæi were confederated with the Malli and Oxycdrææ, that is, the people of Moultan and Outeh, and which lay to the S.W. of the place where Alexander might be supposed to cross the Hydrates (or Rauvee) in his way into India. Sangala, therefore, lies to the S.W. of Lahore; and as to its distance, Alexander reached it the third day after crossing the Hydrates, and for these three marches it will be sufficient to allow 48 road miles or 36 geographical miles in horizontal distance. Although no idea is given in Arrian, Diodorus, or Quintus Curtius, of the distance between Sangala and the Hyphasis; yet we may collect from Arrian's manner of speaking, that they were not near each other. Diodorus places the kingdom of Sophites and of Phugeus between the Cathæi and the Hyphasis; and hence we may infer that there was a considerable space between them. See **SANGALA**. In the name of this country the learned Bryant (Anal. Mythol. vol. iii. p. 553.) perceives traces of the Cuthite migration. One of the most considerable colonies, (he says) which went from Babylonia, was that of the Judi, or Sindi; who had been further distinguished by the name of the Eastern Ethiopians. They settled between the Indus and Ganges; and one of their principal regions was Cuthaia, rendered Cathaia by the Grecians. They traded in linen and other commodities, and carried on an extensive commerce with the provinces to the south. A large body of them passed inland towards the north, under the name of Saccæ, or Sacæians; who ranged very high and got possession of Sogdiana, and the regions upon the Jaxartes. From thence they extended themselves eastward quite to the ocean. They were (says Bryant) of the Cuthic race, and represented as great archers; and their country was called Sacæia and Cuthia. The chief city was Sacæistan. These people got possession of the upper part of China, which they denominated Cathaia; and this learned writer suggests, that Japan was in some degree peopled by them.

CATHARA, a town of Asia, in Melopotamia, situated near the Tigris, according to Ptolemy.

CATHARCLUDORUM REGIO, a country placed by Pliny in the mountains which lie to the west of the Indians.

CATHARI, in *Ecclesiastical Writers*, ancient Christians, who made profession of greater purity in discipline and sanctity of life than others. The appellation cathari was chiefly given to the sect of **NOVATIANS**. In after-times, however, the name was also applied to several other sects, who pretended to extraordinary purity, and particularly to a fanatical sect, who came from Greece into Italy, and were first discovered in the Milanese about the middle of the 11th century. They were called in France, and other countries, **ALBIGENSES**, **BONSHOMMES**, **PATERINI**, and **PUBLICANS**. See also **PAULICANS** and **PURITANS**.

These Cathari held many tenets of the Manichean heretics, blended with other opinions, common to them and the Vaudois, against the doctrines, and hierarchy, and superstitious practices of the church of Rome. The Cathari, however, were entirely free from the Manichean errors, and would not have consented to a public confession of the Roman Catholic doctrines, as the true Christian faith, even to save their own lives. But the Cathari thought it lawful to dissemble in these points, and had secret or inward doctrines. It appears that on their examination before the inquisitorial commissioners at Toulouse, they scrupled to swear to their belief of opinions which they falsely professed; yet, at the end of a written declaration of their faith, they inserted words which in reality amounted to an oath. But though they adopted many inconsistencies and absurdities

among their articles of belief, the severe inquisition which they underwent could not discover a single evidence of any criminal act, punishable by the lay courts, that could be alleged against them. However, in 1179, the council of Lateran issued a canon, for excommunicating all the Cathari in the southern parts of France, as audacious heretics, who openly propagated their notions, and likewise all who afforded them protection or harbour in their houses or lands, or carried on traffic with them; declaring, that any persons who should die in that sin should have no benefit from any indulgence granted to them, nor from any oblation made for them, nor be allowed Christian burial. After all, it is certain that many, who held none of the errors of the Cathari, but only joined them in opposing the flagrant corruptions of the church of Rome, were, in the following century, confounded with them, and involved in the massacre, which, under the orders of Simon de Montfort, the general of the popes, deluged all the south of France with innocent blood. See the articles above cited, and particularly ALBIGENSES.

CATHARI, or CATHERI, in *Ancient Geography*, a people of India. See CATHAI.

CATHARINE of France, in *Biography*, the youngest child of Charles VI. and Isabella of Bavaria, was born in 1401, and in 1420, by the conditions of the treaty of Troyes, married to Henry V. king of England, then declared successor to the crown of France. In consequence of this marriage she became mother to Henry VI. crowned in his cradle king of both countries. After the death of Henry V. Catharine formed a connection with sir Owen Tudor, a gentleman of Wales, of small fortune, but descended from the ancient princes of the country. By a clandestine marriage with him, she had two sons, the eldest of whom, Edward earl of Richmond, was father of Henry VII. king of England, the first of the line of Tudors. Catharine died in 1438, and was buried at Westminster. Hume's Hist. vol. iii. Moreri.

CATHARINE of Arragon, the fourth daughter of Ferdinand and Isabella, king and queen of Castile and Arragon, was born in 1433, and married in 1501, in pursuance of a design that had been projected and negotiated for 7 years, to Arthur, prince of Wales, son of Henry VII. At this time the prince was nearly 16 years of age, and the infant 18. In a few months after this marriage, the young prince sickened and died, much regretted by the nation. Henry, desirous of continuing his alliance with Spain, and also unwilling to restore Catharine's dowry, which was 200,000 ducats, obliged his second son Henry, whom he created prince of Wales, to be contracted to the infant. The prince, who was then a youth of 12 years of age, resisted this injunction to the utmost of his power; but the king was invincible, and the espousals were at length, by means of the pope's dispensation, contracted between the parties. Immediately after the accession of Henry VIII. to the crown, in 1509, the king began to deliberate on his former engagements. The previous marriage of Catharine with his brother, and the inequality of their years, were the chief objections urged against his espousing her; but, on the other hand, the advantages of her known virtue, modesty, and sweetness of disposition were insisted on; the affection which she bore to the king; the large dowry to which she was entitled as princess of Wales; the interest of cementing a close alliance with Spain; the necessity of finding some confederate to counterbalance the power of France; and the expediency of fulfilling the engagements of the late king, were considerations which determined the council, though contrary to the opinion of the primate, to give Henry their advice for celebrating the marriage. Notwithstanding the submissive deference paid to

papal authority before the reformation, the prejudices of the people were in general averse to a conjugal union between such near relations, as Henry and his brother's widow; and the late king, though he had betrothed his son, at the age of 12 years, gave evident proofs of his intention to avail himself of a proper opportunity of annulling the contract. He ordered the young prince, as soon as he came of age, to enter a protestation against the marriage; and on his death-bed, he charged him, as his last injunction, not to furnish an alliance so unusual, and exposed to such insuperable objections. In the year 1527 several circumstances occurred which combined to excite scruples in the king's mind concerning the lawfulness of his marriage. The dates of Calixte had opposed the emperor Charles's espousals with Mary, Henry's daughter, and, among other objections, had insisted on the illegitimate birth of the young prince's. And when the negotiations were afterwards opened with France, and mention was made of betrothing her to Francis, or the duke of Orleans, the bishop of Tarba, the French ambassador, revived the same objections. These events naturally raised some doubts in Henry's mind, and they concurred, with other causes, which tended much to increase his remorse, and to render his conscience more scrupulous. The queen was six years older than the king; and the decay of her beauty, together with particular infirmities and debilities, had contributed, notwithstanding her blameless character and deportment, to render her person unacceptable to him. Though she had borne him several children, they all died in early infancy, except one daughter, Mary, afterwards queen of England; and he was the more struck with this misfortune, because the curse of being childless is the very threatening, contained in the Mosaic law, against him who espoused his brother's widow. The succession too of the crown was a consideration that occurred to every one, whenever the lawfulness of Henry's marriage was called in question; and it was apprehended, that if doubts of Mary's legitimacy concurred with the weakness of her sex, the king of Scots, the next heir, would advance his pretensions, and might throw the kingdom into confusion. Besides, Anne Boleyn had lately appeared at court, as maid of honour to the queen, and had acquired an entire ascendancy over his affections. The king was thus impelled, both by his private passions, and by motives of public interest, to seek the dissolution of his unpropitious, and, as it was esteemed, unlawful marriage with Catharine. The archbishop of Canterbury was consulted, and he was required to advise with his brethren. All the prelates of England, except Fisher, bishop of Rochester, unanimously declared, under their hands and seals, that they deemed the king's marriage unlawful. Wolsey also fortified the king's scruples; partly with a view of promoting a total breach with the emperor, Catharine's nephew; partly desirous of connecting the king more closely with Francis, by marrying him with the duchess of Alençon, sister to that monarch; and perhaps too somewhat disgusted with the queen herself, who had reproved him for certain freedoms, unbecoming his character and station. Accordingly Henry determined to apply to the pope, Clement VII. for a divorce. He founded his application, not on any general doubts concerning the papal power to permit marriage in the nearer degrees of consanguinity, but on particular grounds of nullity in the bull, which Julius had granted for this particular marriage. It had been said in the preamble, that the bull had been granted upon Henry's solicitation; though, it was known, that at that time he was under 12 years of age. It was also affirmed, as another motive for the bull, that the marriage was requisite in order to preserve peace between the two crowns; though it is certain, that no ground or appearance of quarrel then subsisted between them.

These false premises in Julius's bull seemed to afford Clement a sufficient reason or pretence for annulling it, and granting Henry a dispensation for a second marriage. Clement, though at first disposed to favour Henry's application, and though he actually concerted measures for its successful issue, was overawed and embarrassed in his proceedings by the interference of the emperor, Charles V., Catharine's nephew; and the negotiation was protracted to such a length as to tire Henry's patience, and to induce him to adopt other measures for accelerating the accomplishment of his wishes. The pope, important by the English ministers, put into their hands a commission to Wolsey, as legate, in conjunction with the archbishop of Canterbury, or any other English prelate, to examine the validity of the king's marriage, and of Julius's dispensation. He also granted them a provisional dispensation for the king's marriage with any other person; and promised to issue a decretal bull, annulling the marriage with Catharine; but he enjoined secrecy, and conjured them not to publish these papers, or to make any farther use of them, till his affairs with regard to the emperor were in such a train as to secure his liberty and independence. After considerable hesitation and delay, the legates, Campeggio and Wolsey, to whom the pope had granted a new commission for the trial of the king's marriage, opened their court in London, May 31st, 1527, and cited the king and queen to appear before it. They both presented themselves, and the king answered to his name, when called; but the queen, instead of answering to her's, rose from her seat, and throwing herself at the king's feet, made a very pathetic harangue, which her virtue, her dignity, and her misfortunes rendered the more affecting. She concluded with declaring, that she would not submit her cause to be tried by a court, whose dependence on her enemies was too visible, even to allow her any hopes of obtaining from them an equitable or impartial decision. She then rose, and making the king a low reverence, she departed from the court, and never would again appear in it.

After her departure, the king did her the justice to acknowledge, that she had ever been a dutiful and affectionate wife, and that the whole tenor of her behaviour had been conformable to the strictest rules of probity and honour. He only insisted on his own scruples with regard to the lawfulness of their marriage; and he explained the origin, the progress, and the foundation of those doubts, by which he had been so long and so violently agitated. He acquitted cardinal Wolsey from having any concern in encouraging his scruples; and he craved a sentence of the court agreeable to the justice of his cause. The legates, after citing the queen anew, declared her *contumacious*, notwithstanding her appeal to Rome, and then proceeded to the examination of the cause. After the prolonged investigation of various particulars, Campeggio, very much to the surprize of the king, who every day expected a sentence in his favour, suddenly, without any warning, and upon very frivolous pretences, prorogued the court to a future day; and the evocation of the cause to Rome terminated all the hopes of success which the king had so long and so anxiously cherished. Thus disappointed, the king's mind was agitated by a variety of contrary motives; but at length an expedient was proposed, which, as it promised a solution of all difficulties, was embraced by him with the greatest joy and satisfaction. Dr. Cramer suggested, that the readiest way, either to quiet Henry's conscience, or extort the pope's consent, would be to consult all the universities of Europe with regard to this controverted point; if they agreed to approve of the king's marriage with Catharine, his remorse would naturally cease; if they condemned it, the pope would find it difficult to resist

the solicitations of so great a monarch, seconded by the opinion of all the learned men in Christendom. The king was delighted with the proposal, and swore, with more alacrity than delicacy, that Cramer had got the right way by the ear; and having previously consulted this learned divine, engaged him to write in defence of the divorce; and immediately employed his agents to collect the judgments of all the universities in Europe. Several of these, without hesitation, as well as without interest or reward, gave verdict in the king's favour. Those of Oxford and Cambridge made some difficulty; because, being alarmed by the profress of Lutheranism, and dreading a defection from the holy see, they scrupled to sanction measures, which in their consequences might prove fatal to the ancient religion. Their opinion, however, conformable to that of the other universities of Europe, was at last obtained; and the king, in order to give additional weight to all these authorities, engaged his nobility to write a letter to the pope, recommending his cause to the holy father, and threatening him with the most dangerous consequences in case of a denial of justice. The convocations too, both of Canterbury and York, pronounced the king's marriage invalid, irregular, and contrary to the law of God, with which no human power had authority to dispense. But Clement, still subject to the influence of the emperor, continued to summon the king to appear, either by himself or proxy, before his tribunal at Rome; and the king, apprized that no fair trial could be expected there, refused to submit to such a condition, and would not admit of any citation, which he regarded as a high insult, and a violation of his royal prerogative. In the progress of this business, the queen's appeal was received at Rome. The king was cited to appear; and several consistories were held to examine the validity of their marriage. The king retained his purpose of not sending any proxy to plead his cause before this court, and alleged, that the prerogatives of his crown must be sacrificed, if he allowed appeals from his own kingdom. For the purpose of adding greater security to his intended defection from Rome, he procured an interview with Francis at Boulogne and Calais, and renewed his alliance with that monarch; and it is said, that he even persuaded Francis to follow his example, in withdrawing his obedience from the bishop of Rome, and administering ecclesiastical affairs without having further recourse to that see. Fully determined in his own mind to hazard all consequences, he privately celebrated his marriage with Anne Boleyn, Nov. 14th, 1532; and in April of the following year he publicly owned it; and in order to remove all doubts with regard to its lawfulness, he prepared measures for declaring, by a formal sentence, the invalidity of his marriage with Catharine. Catharine, however, did not quit the kingdom; but fixed her abode for some time at Amptill, near Dunstable in Bedfordshire, where, after several preliminary steps, Cramer pronounced a sentence which annulled the king's marriage with her as unlawful and invalid. By a subsequent sentence he ratified the marriage with Anne Boleyn, who was soon after publicly crowned queen, with all the pomp and dignity suited to that ceremony. Catharine still continued obstinate in maintaining the validity of her marriage; and she would admit no person to her presence who did not approach her with the customary formalities. Although Henry employed menaces against such of her servants as complied with her commands in this particular, he was never able to make her relinquish her title and pretensions. As far as the pope was concerned in this business it terminated in the king's final breach with Rome; and in a parliament assembled in 1534, the marriage of the king with Catharine was declared unlawful, void, and of no effect; the primate's sentence, annulling it, was ratified; and

the marriage with queen Anne was established and confirmed. Catharine had removed from Donstable to Kimblyton castle in the county of Huntingdon, where she was seized with a lingering illness, which at last brought her to her grave. She died on the 6th of January 1536, in the 5th year of her age. A little before she expired, she wrote a very tender letter to the king, in which she addressed him as "her most dear lord, king, and husband," and inculcated upon him counsels of moral and religious prudence; concluding with these words; "I make this vow, that many eyes desire you above all things." The king is said to have shed tears on occasion of receiving this last tender proof of Catharine's affection. In her retreat she is said to have composed some devotional treatises. *Hume's Hist.* vol. iii. and iv.

CATHARINE DE MEDICIS, queen of France, was the only daughter of Lorez de Melun, duke of Urbino, and of Magdalen de la Tour. She was born at Florence in 1519, and by the influence of her uncle, pope Clement VII., was married in 1534 to Henry, duke of Orleans, son of Francis I. She contributed, in a high degree, by her personal and mental accomplishments, to adorn the splendid court of her father-in-law, and by her compliance and dissimulation contrived to ingratiate herself with persons of opposite characters and interests. At the death of Francis I., her husband succeeded to the crown under the title of Henry II., and she became queen. Although she had been barren for the first ten years after her marriage, she had afterwards ten children; three of her sons being successively kings of France, and one daughter queen of Navarre. During Henry's life, she devoted herself to the education of her children; and in this employment she gained that ascendancy over them, which enabled her for a long time to maintain supreme authority. Upon the death of her husband, in 1549, her son, Francis II., succeeded to the throne, at the age of 16 years; and during his reign, though she was obliged to concur in some degree with the violent and persecuting measures of the family of the Guises, they were not agreeable to her inclinations, and she manifested her desire of more moderate proceedings, by raising to the post of chancellor, the virtuous Michael de l'Hopital. In 1560, Henry II. was succeeded by his brother, Charles IX., in his eleventh year. Catharine still maintained her authority, and, in order to counteract the power of the Guises, inclined to the party of the king of Navarre and the associated princes. Upon the death of the duke of Guise in 1562, the two contending parties, that had occasioned a civil war, were reconciled; and Catharine, possessed of full powers, began to display in their full extent her dissimbling politics. Whilst she courted the catholics, she laid plots for the total destruction of the Hugonots, the consequence of which was the renewal of civil war; and she pursued such a course of dissimulation and treachery, in her attempts to destroy that party which could not be subdued by force of arms, and received such assistance from her execrable son, whom she had initiated in every art of disguise, as to prepare the way for that massacre on St. BARTHOLOMEW'S day, 1571, which has doomed to infamy the name of Catharine de Medicis, one of its chief contrivers. Instead of this composing the troubles of France, every thing remained in a tumultuous state during the remainder of this reign, which was terminated by the death of Charles in 1574. Upon this event Catharine was declared regent, till the return of her next son, Henry III., from Poland, of which kingdom he had been elected the sovereign. In this high official character, she exerted herself with wisdom and vigour, in preventing those disturbances which the collision of existing parties had a tendency to produce, and thus delivered the kingdom to her son

in a condition, which, with prudence and virtue, on his part might have ensured a prosperous reign. But he had derived his principles from her instruction, and his conduct was formed on her example of infincerity and dissimulation. Her own character was such, that it warranted no confidence in any measures of which she had the direction. The party of the Guises revived; the league was formed; war was renewed with the protestants; and during the prevalence of public disorders, aggravated by Henry's attachment to his minions on the one hand, and the popularity of the Guises on the other, Catharine lost her authority, and she lived only to lament the misgovernment of her son, as the result of the insidious policy, which he had laboured to inculcate. Soon after the assassination of the duke of Guise, from the guilt and reproach of which she endeavoured to exculpate herself with strong execrations, Catharine, having incurred the detestation of all parties, died in January 1589, in her 70th year. Under a suspicion of having been concerned in the duke's murder, notwithstanding all her protestations, the Parisians threatened to throw her body, if it was brought into their city for interment, into the river or common sewer. On her death-bed she is said to have given excellent advice to her son; though little conformable to her former precepts and example.

"Catharine de Medicis," as one of her biographers closes his brief account of her, "is said to have been possessed, in a degree superior to any woman of her time, of all the arts of insinuation and allurements, of all the graces of her sex, and the splendid qualities of her situation; she was affable, courteous, magnificent, and a liberal encourager of learning and the polite arts. She was likewise endowed with extraordinary courage and presence of mind, strong judgment, and great fertility in expedients. But she had the common fault of her country, of aiming at excessive refinement of policy; and by alternately caroling and siding with every party, she in the end lost the confidence of all. With respect to her moral qualities, there is nothing diabolical in the human character with which she has not been charged by her enemies; and even her friends are obliged to make large concessions on this head. Scarcely preserving the decorum of her sex, she was loose and voluptuous in her own conduct, and was continually attended by a train of beauties, whose complaisant charms she employed in debauching those minds which she could not gain by the common allurements of interest. Nearly indifferent to modes of religion, she was much addicted to superstitious and of the darkest kind; and believed in and employed the delusive practices of magic and judicial astrology. The depth of her dissimulation, and bloody strain of her perfidious policy, have sufficiently been shewn in the sketch of her actions; and many instances might be brought of the savage pleasure or indifference with which she viewed the cruelties she had dictated. Perhaps the heaviest charge against her is the detestable principles in which she brought up her children, whom she early inured to blood and perfidy, while she weakened their minds by debauchery, that she might the longer maintain her power over them. Accordingly, except Francis, who can scarcely be said to have displayed any character, her other sons, Charles, Henry, and the duke of Alençon, were compounds of every thing abominable and despicable. To conclude, the historian Davila, who was peculiarly attached to her service, and favoured by her, terminates a copious eulogy on her personal and mental qualifications, with confessing that she was totally void of faith, and more indifferent to the shedding of human blood than became a woman." *Moreri. Nouv. Dict. Hist. Mod. Un. Hist.* vol. xx. p. 373, &c. vol. xxi. p. 1. 40. *Gen. Biog.*

CATHARINE I. empress of Russia, was of obscure origin, being a natural daughter of a country girl at Ringen, a small village upon the lake of Virtcherve, near Dorpat, in Livonia, and where she was born, according to her own account, on the 5th of April, 1683, but according to other more probable statements, in the year 1683. Count Rosen, a lieutenant-colonel in the Swedish service, and proprietor of the village of Ringen, supported, according to the custom of the country, both the mother and child; and for this reason was supposed to be her father. At the age of three years she lost her mother; and, Rosen dying about the same time, she was left in a condition to describe, that she was received by the clerk of the parish into his house. Soon afterwards Gmelk, a Lutheran minister of Marienburgh, took her under his protection and employed her in attending his children. In 1701, she married a dragoon of the Swedish garrison of Marienburgh, who, as some say, lived with her eight days after their marriage; but others have asserted, that on the morning of the nuptials her husband was sent with a detachment for Riga. So that the marriage was never consummated. At the time, however, when Marienburgh surrendered to the Russians, the dragoon was absent, and Catharine saw him no more. On the capture of this place general Bauer saw her among the prisoners, and being smitten with her beauty, took her to his house, where she superintended his domestic affairs, and was supposed to be his mistress. In a little while she passed into the family of prince Mentchikof, who was no less her admirer than the general, and she lived with him till the year 1704; when she became the mistress of Peter the Great, and gained such an interest in his affections, by her unremitting attention, by the gentleness of her disposition, and by the liveliness of her temper, that the emperor, who was thus foothed in his occasional intervals of gloom, suspicion, and even madness, privately married her in 1710 or 1711. From this time she became his constant companion in his journeys into foreign countries, and in all his military expeditions. In 1711, she attended him in his campaign against the Turks; and the peace of Pruth, which rescued the Russian army from certain destruction, has been ascribed to her powerful interposition. The occasion was this: when the emperor had led his troops into a very dangerous situation, he formed the desperate resolution of cutting his way through the Turkish army in the night; and retiring to his tent in an agony of despair, he gave positive orders that no one should be admitted, under pain of death. In this important juncture, the principal officers, and the vice-chancellor Shafirof, assembled in the presence of Catharine, and drew up certain preliminaries for the purpose of obtaining a truce from the grand vizir. Plenipotentiaries were immediately dispatched, without the knowledge of Peter, to the vizir, and a peace was obtained on more reasonable conditions than could have been expected. With these conditions Catharine, notwithstanding the orders issued by Peter, entered his tent, and obtained his signature. By this conduct she gained great popularity, and the emperor himself specifies her behaviour at Pruth, as one of the reasons which induced him to crown her publicly at Moscow with his own hand. In 1712, her marriage, which had taken place secretly in the preceding year at Lawerof in Poland, was publicly solemnized at Petersburgh. Catharine maintained her influence undiminished until a short time before the death of Peter, when an event occurred, which might have occasioned a total rupture, if death had not intervened. The emperor, probably not unapprized of some of her amours, suspected that she had an illicit connection with Mons, her first chamberlain. Having concerted measures for making a discovery, he surprised

Catharine in an arbour of the garden with her favourite; while his sister, madame Balke, who was first lady of the bed-chamber, was in company with a page, upon the watch without the arbour. Peter struck Catharine with a cane, and then retired without uttering a single word. Soon after Mons and his sister were taken into custody. The former was examined, on a charge of bribery, in the presence of major-general Uchakof, and being threatened with the torture, he confessed the corruption had to his charge, and was beheaded. His sister received five floggings of the knout, and was banished into Siberia; two of her sisters, who were chamberlains, were also degraded, and four as common soldiers among the Russian troops, in Persia. On the day subsequent to the execution of the sentence, Peter conveyed Catharine in a coach to a carriage under the grill work, to which was nailed the head of Mons; and the emperor, without changing colour at this dreadful object, exclaimed, "What a pity it is, that there is so much corruption among courtiers!" This event happened in the year 1724, when she had been publicly crowned at Moscow, and had received the imperial insignia from the czar's own hands. As it was soon followed by his death, and as Catharine recalled madame Balke, she was suspected of shortening the days of her husband by poison. But, notwithstanding the critical situation of Catharine at the time of his decease, and her subsequent elevation, this charge is destitute of proof; for the nature of the disorder with which Peter had been long afflicted, and the peculiar symptoms of his last illness, sufficiently account for his death, without recurring to poison. As it had been decreed in 1722, that the reigning sovereign should have the power of appointing his successor, Peter ought to have made provision accordingly; but his last illness, and the circumstances of excruciating torture attending it, prevented the performance of this necessary duty. Amidst the cabals which succeeded his death, Catharine, by means of her friends, claimed the throne in right of her coronation and inauguration at Moscow; and these recent acts on the part of Peter were interpreted by them as a sufficient proof of his intentions. The art of Catharine, and the activity of Mentchikof, ultimately prevailed against the party, which supported the claims of Peter Alexowitz, the czar's grandson; and, notwithstanding her mean and base origin, she was established on the throne of the czars of Russia, to the prejudice of its lineal heirs. The empress, who had neither inclination nor abilities to direct the helm of government, placed implicit confidence in Mentchikof, the original author of her good fortune, and the sole instrument of her elevation to the throne; and the reign of Catharine was, in fact, the reign of this confidential favourite. To her humanity and compassion, which were distinguishing features in her character, may be imputed the recall of many exiles from Siberia, as well as the demolition of the wheels and gibbets on which the bodies of criminals had been exposed during the severe reign of her husband. She generally pursued in the course of her short administration the plans of Peter for the improvement of his dominions; and in 1725 completed the institution of an order of knighthood for the reward of those who had signalized themselves in the service of their country. See ALEXANDER NEVSKOI. Her life, during her short reign, was very irregular; averse from business, she would frequently pass whole nights in the open air, and indulged to excess in the use of Toabay-wine and strong liquors. These irregularities, joined to a cancer and a dropsy, hastened her end; and she died on the 17th of May, 1727, a little more than two years after her accession to the throne, and in the 39th year of her age. The personal attractions and mental abilities of this empress have been much ex-

aggerated by her panegyrics. In her person she was under the middle size, and in her youth delicate and well-formed, but as she advanced in years inclined to corpulency. She had a fair complexion, dark eyes, and light hair, which she was accustomed to dye black. She could neither read nor write. She is said, however, to have maintained the pomp of majesty united with an air of ease and grandeur; and Peter himself frequently expressed his admiration at the propriety with which she occupied her high station, without forgetting that she was not born to that dignity. Her estimable qualities, after all the abatements of panegyric, were generally acknowledged. She was humane in an exemplary degree, good-humoured and obliging in her temper and manners, and duly mindful of the good offices which had been performed for her in her low condition. She availed herself of her ascendancy over Peter, in softening the asperity of his passions and restraining their violence; inasmuch that a word from her, in behalf of a wretch, who was about to be sacrificed to his anger, would instantly disarm him; and if he determined to indulge his resentment, he would give orders for the execution when she was absent, for fear she should plead for the victim. Upon the whole she merited the honourable title, bestowed upon her by the celebrated Munk, of "the Mediatrix between the monarch and his subjects." *Coxe's Travels in Russia*, vol. ii. ch. 11.

CATHARINE II. empress of Russia, originally denominated Sophia Augusta Fredereca, was the daughter of Christian Augustus, prince of Anhalt-Zerbit-Dornburg, and of the princess of Holstein, a woman eminent for talents and beauty. She was born at Stettin in Prussian Pomerania, May 2, 1729, educated by her mother, and in early life distinguished by her good humour, intelligence, and spirit. During the first 15 years of her life, she lived alternately in Stettin and in Dornburg, or Zerbit, occasionally accompanying her mother in several little journeys, which much contributed to the forming of her mind and manners; and at this period, she devoted her time to reading, reflection, learning, and employment. About the beginning of the year 1744, she visited Berlin, and continued her journey to Russia. Her access to the court of Petersburg was rendered easy by the marriage which had been projected between the empress Elizabeth, and her mother's brother, the prince of Holstein-Lutin, but which the premature death of the latter had prevented; and her mother, fully apprized of the tender remembrance preserved by Elizabeth for her brother, resolved to avail herself of it for securing a throne to her daughter. Accordingly, Elizabeth received the young princess with a partial regard; and determined to accomplish a matrimonial union between her nephew, the grand-duke, afterwards Peter III. and Sophia; who, though instructed, under the tuition of her mother, in the Lutheran doctrines, embraced the religion of the Greek church, and on this occasion changed her name to that of Catharine Alexievna. As soon as the choice of Elizabeth had been announced to the council and to the foreign ministers, the day was fixed for the nuptials, and preparations were arranged for its celebration in a manner worthy of the heir of the throne of Russia. A circumstance, however, occurred, which retarded this wished-for event. The grand-duke was seized with the small pox, which, being of a very malignant nature, endangered his life; and so much deformed the comeliness of his face, as to render it for a time distorted, and almost hideous. This metamorphosis produced a horror in the mind of the young princess at the first interview, which, however, she had sufficient art to disguise, and which proved no impediment in the way of their speedy union. The empress contemplated this alliance with pleasure; the princess of Zerbit was pas-

sionately desirous to see it concluded; and the suggestions of ambition acting more powerfully on the heart of Catharine than the will of her mother, and that of the empress, did not allow her a moment's hesitation. In 1745 the nuptials were accordingly solemnized; but, notwithstanding the attachment which was so manifest between the grand-duke and the princess from the first moment of their meeting, their love was fated to be of no long duration; nevertheless, they lived for some time with an apparently good understanding, which Catharine supported as long as she conceived it to be necessary. Their dispositions and their accomplishments, however, were very different: whilst Peter blushed at the superiority of his wife, she often blushed at seeing him so little worthy of her; and, incapable of making each other happy, their mutual dislike was soon visible to those who frequented the court; it every day increased, and became more and more apparent. Whilst the enemies of Peter contrived to excite prejudices against him in the mind of the empress, and he was led by various artifices on their part, and by the jealousy manifested by Elizabeth, to retire from court, and to indulge himself in the vices of drinking and gaming, Catharine was busily employed in gaining partisans from the most powerful persons of the court. Her violent disposition to pleasure was controuled by views of ambition; and if she did not succeed so far as to captivate the friendship of the empress, she at least extorted her esteem. The princess of Zerbit, at the same time, abused the confidence reposed in her by the empress; and taking advantage of the influence she had acquired, she mixed in the intrigues of the courtiers, made herself the dispenser of imperial favours, and pryed into the secrets of the most important concerns. Her arrogance disgusted the favourites, and her curiosity was vexatious to the ministers. At length they united together to rouse the jealousy of the empress, and by degrees induced her not only to withdraw her misplaced confidence, but to issue orders that the princess should quit the empire. Catharine herself regretted her mother's departure; but the hope of the throne which had fortified her against other misfortunes, supported her under this; and love soon became a source of consolations, which lightened those which pride administered. In the number of those who formed the parties of the grand duke, Soltikof, the prince's chamberlain, was particularly distinguished by his taste for the arts, as well as by the graces of his person; and vanity, perhaps, more than love, led him to conceive the nefarious design of captivating the heart of Catharine. His continued attentions at length produced effect; he became master of the affections of the grand duchess; and the passion which was at first feigned on his part, grew up into a real attachment; their mutual partiality, avowed to each other, became too unguarded to be concealed from the courtiers, who envied the preference that was conceded their pride. They therefore determined to communicate to the empress their suspicious of an amour between the chamberlain and the grand duchess. Elizabeth, though of an amorous disposition herself, declared, in the first bursts of her indignation, that Soltikof should pay for his temerity by an exile into Siberia; the chamberlain contrived to avoid the danger that menaced him by complaining to the grand duke of the calumnies that had been so audaciously spread; and by requesting that, in order to furnish no farther pretence to the jealousy of his enemies, and to calm the mind of the empress, he might obtain permission to retire to Moscow. The credulous prince, thus deluded, ordered him to remain in his station; and in an audience with the empress, vindicated the innocence of Soltikof, with so much vehemence and by such a variety of arguments, that Elizabeth herself was inclined to ascribe to envy the inju-

rious reports that had been circulated against him. Catharine alſo pleaded his caufe, and that of her own honour, with fo much eloquence, that her victory over the emperfs was more complete than that of the grand duke. The intercourse between Soltikof and the grand-duchefs was renewed and continued; and Catharine acquired boldnefs from her ſuccels, and from the example of Elizabeth, whoſe manners were becoming daily more and more corrupt, and who, engaging from day to day in ſome new follies, ſeemed to afford ſome excuſe for her paſſion. In 1754, when Soltikof thought himſelf perfectly ſecure, the grand chancellor Beſtuchef contrived his ruin, and prevailed with the emperfs to appoint him miniſter plenipotentiary from the court of Ruſſia to Hamburg, where he was to reſide. He alſo counteracted the influence which the grand duchefs was induced to employ for his recall: and her ambition impoſed ſilence on love. For ſome time they contended with each other; but in 1755 the young count Stanilaus Poniatowſky ſupplanted Soltikof in the attachment of Catharine, and in the following year they declared to one another their mutual affection, and conſulted on the means of indulging their inclinations without reſtraint. The emperfs Elizabeth was ſoon informed of this new intrigue of her adoptive niece, and ſhe ordered Poniatowſky to quit Ruſſia without delay. The chancellor Beſtuchef, in the mean while, was gradually ſtrengthening his party with that of the grand duchefs; and in 1756 he engaged count De Bruhl, prime miniſter of the king of Poland, to procure the nomination of Poniatowſky as miniſter plenipotentiary of the republic and king of Poland to the emperfs Elizabeth. This meaſure having ſucceeded, the plenipotentiary arrived, and Catharine made fo little ſecret of the intimacy ſubſiſting between them, that public report was very loud to his prejudice. The grand duke was the only man at court who knew nothing of what was paſſing. His time was wholly occupied in attending the ufeleſs manœuvres and painful exerciſes of his ſoldiers, and when theſe were finiſhed, in indulging the exceſſes of the table, and boaſting, in the delirium of intemperance, that he would one day be conqueror of the north, and the rival of the Perſian hero. At length, however, the jealousy of Peter was alarmed; and no time was loſt in ſolliering the furniſhes of the husband into proofs of the infidelity of the wife, in her love for the Polander, and the criminal correſpondence they mutually entertained. The prince was overwhelmed with grief and conſternation; forbade the grand duchefs to be ſeen with Poniatowſky; and haſtening to the emperfs, beſought her to avenge the affront he had received; informing her, at the ſame time, that the grand chancellor had not only favoured the miſconduct of the grand duchefs, but had repeatedly betrayed the confidence of his imperial aunt. Elizabeth, moved at the ſorrows of her nephew, and incenſed at the treachery of Beſtuchef, gave orders to arreſt him; and in the ſequel he was deprived of his place, tried, pronounced guilty of high treaſon, and ſentenced to death, which ſentence was afterwards commuted for baniſhment to an eſtate 120 verſts beyond Moſcow. Catharine, apprehending every thing from the reſentment of her husband, and forſaken by her courtiers, was reduced to a very diſtreſſed and almoſt hopeleſs ſituation. In the year 1761, the health of Elizabeth began viſibly to decline, and the neceſſity of repoſe, added to her natural indolence, made her more negligent than ever of the affairs of government. Woronzof was grand chancellor, and on him depended the conduct of the public buſinefs; and the emperfs, hardly able to purſue her customary diſſipations, amuſed herſelf with the idle tales that were brought her of the amorous revels of her nephew Peter with one of the daughters of Woronzof. Catharine renewed her efforts for

a reconciliation with the emperfs; but ſhe would liſten to no accommodation, except on the moſt mortifying conditions. It was afterwards propoſed to her by a meſſage from Elizabeth, to confeſs her guilt, and to ſubmit to the clemency of her husband and the emperfs. From this moment Catharine ſummoned up all her pride. She purpoſely avoided appearing at court, kept cloſe to her apartments, and aſked leave of the emperfs to retire into Germany; a permiſſion which ſhe knew would not be granted; becauſe, well apprized of the extreme fondneſs of Elizabeth for the young Paul Petrovitch, ſhe had no reaſon to apprehend that the princefs would conſent to the departure of the mother of a child, who would thereby be expoſed to the hazard of being hereafter declared illegitimate. The ſtratagem ſucceeded, and an accommodation ſoon enſued. At the very moment when ſhe was thought on the brink of irremediable diſgrace, to the great aſtoniſhment of the court, ſhe made her appearance at the theatre, by the ſide of the emperfs, who carefully drew upon her the notice of the ſpectators by the particularity of her attentions. The ambition of Catharine was roused by Elizabeth's approaching diſſolution, and ſhe felt the neceſſity of conciliating the popular favour by an exterior of piety, which, by thoſe who beſt knew her, was ſuppoſed not to proceed from her heart. However, ſhe was punctual in frequenting the churches at the ſtated times of public devotion; but more particularly at the prayers that were now daily put up for imploing the re-eſtabliſhment of the health of the emperfs. She employed herſelf alſo for ſeveral days in framing the form of the proclamation acknowledging the emperor, as well as that of the oath to be taken by the troops. At length, on Chriſtmas day, 1761, the emperfs Elizabeth expired; and Peter III. aſcended the throne. In the beginning of his reign his conduct was not only blameleſs, but laudable; he appeared to be ſuddenly transformed into a different being; as grand duke, he had been inconfiſtent, impetuous, and wild; but as Peter III. he appeared equitable, patient, and enlightened. He was kind to all who had been attached to the late emperfs; he continued in their poſts all the great officers of ſtate; and he pardoned all his enemies. The grand duchefs received from him the moſt flattering ſalutations and marks of the greateſt confidence. He ſeemed to forget the wrongs he had ſuſtained in the elegancies of her mind, and the force of her genius. He paſſed a great part of the day in her apartments, diſcourſed with her in a free and friendly manner, and conſulted her on all affairs of delicacy and importance. The courtiers were ſurprized, and congratulated Catharine on her happy lot. Catharine was almoſt the only perſon who was not deceived. She ſaw that her husband was not capable of governing by himſelf, and ſhe was too well acquainted with his character to miſtake that for benevolence, which was only weakneſs. The firſt meaſures of his government were popular and auſpicious. Unſteady and capricious in his temper, his private and public conduct was verſatile and fluctuating, and indicated that levity of diſpoſition which was the predominant feature in his character. His enthuaſtic attachment to the king of Prussia gave offence to his ſubjects, led him to ſlight all the foreign miniſters, excepting the Prussian envoy and Mr. Keith, the British ambaffador, and occasioned alterations in his plan of conduct and government, which created a great number of enemies, and evinced, that if he had ſometimes good intentions, he was deficient in judgment, and eſpecially in that energy of character ſo neceſſary for the ruler of a nation. Together with the wiſeſt plans, he often adopted ſuch as were ufeleſs, and others that were even dangerous. The deſire of making improvements induced him imprudently to hazard premature reſormations. By converting the vault poſſeſſions of the

church into domains of the crown, and assigning to the clergy yearly salaries, and by other measures of an ecclesiastical nature, he irritated a numerous class of men, whose influence was very extensive. His enemies found a report from one end of the empire to the other, that he had only feigned to embrace the Greek communion in order to qualify himself for sitting the throne; but that he was still a Lutheran at heart, of which he was every day giving fresh proofs, by shewing a profound contempt for the rites, the ceremonies, and the religion of the Russians. It was industriously propagated, that he never spoke but with disdain of the Russian empire, and never mentioned the Germans but with respect. All these reports, circulated with artifice, soon alienated from the prince those hearts which the first measures of his reign had attached to him. To the army, also, he gave great offence, by manifesting a decided preference of the German soldiers to the Russian troops, and by a variety of other measures, which were subjects of general murmur. Besides, he displeased all parties by his declared intent on taking by force of arms the duchy of Schleswick, on which the kings of Denmark had seized to the prejudice of the dukes of Holstein. Many of his measures were adopted in direct opposition to the counsel of the king of Prussia, who was well acquainted with the character of Peter and that of Catharine, and who had long foreseen that event which afterwards happened. Moreover, Peter sensibly resumed his vicious habits; frequently passing the whole day in drinking and smoking amidst a company of base courtiers, most of whom were eagerly seeking his ruin, and perfidiously applauding his fantastical humours and his most dangerous innovations.

His behaviour to the empress was no less inconsistent than other parts of his conduct. While he was paying homage to the superiority of her mind, he would allow to escape from him some intimations of the indignation which had taken possession of his breast on account of the wrongs he had suffered. In the most sacred and pompous ceremonies of the Russian church, such, e.g. as the benediction of the waters (see CONSECRATION), he caused her to appear adorned with all the marks of imperial dignity, while he contented himself with following her train in the rank of a simple colonel, as if he intended to shew to his people, that she was born to reign, and that it was his province to obey. At court he would often leave her to execute the whole of the representation; while he, dressed in the uniform of his regiment, respectfully came and presented to her his officers, whom he called his comrades. But this apparent honour conferred on the empress was of no long duration. As soon as he thought himself well settled on the throne, he no longer concealed his indifference, and he sometimes manifested it in the most humiliating manner. At the time of the celebration of the peace with the king of Prussia, Peter, who, during the exhibition of the fire-works, was seated by the side of Catharine, on seeing the countess Woronzoff, his mistress, pass by, called to her, and made her sit down by his side; upon which Catharine immediately retired, without any endeavour to detain her being vouchsafed on the part of her husband. Other instances of mortification occurred, which Catharine felt to such a degree, that her tears interested the spectators, whilst the harshness of Peter excited their indignation. It was by such treatment, however, that the hopes of the empress revived. She opposed to his flights and rudeness great circumspection and singular arts of address; and thus gained the hearts, which the emperor was losing. Instructed from her infancy in the arts of dissimulation, she affected, in the sight of the multitude, sentiments very foreign to her mind. The pupils of the philosophers assumed the air of a bigot; she sedulously repaired every day to the churches of Petersburg, praying with all the semblance of a sincere and fervent

devotion, punctual in the most superstitious practices of the Greek religion, accosting the poor with benignity, and treating the peopls with reverence; who did not fail afterwards to proclaim her praise from house to house. In the apartments of the palace the mode of life pursued by this married pair was not very different from that of their public conduct. While Peter III. was shut up with the countess Woronzoff, Mr. Keith, some Prussian officers, and others of his favourite; while he was so far from losing of his rank as to live familiarly with buffoons, and to make them at times sit at table with him; the empress kept her court with a mixture of dignity and affability which charmed all who approached her; and she particularly directed her attention to those persons, who, by their reputation, courage, or intrigues, might serve her cause. By such arts of imprudence as we have now recited, the czar disappointed not only the greater number of the Russians, but almost all the agents from foreign courts. Having concluded a treaty with the king of Prussia, Peter III. caused the peace to be celebrated with the greatest magnificence; and in the midst of these festivities, he manifested a particular attention to the countess Woronzoff, who was always making a increase of ascendancy over him, and who found means to induce the czar, by flattery at one time, by seducing at another, and sometimes by a degree of daring ostentation which led her even to boast him, to renew the promise he had made, while she was only grand duke, that he would marry her, and place her in the room of Catharine on the throne of Russia. Proud of this hope, she had the imprudence to boast of it; and this imprudence brought on her ruin. Peter III. no less insincere than the countess, did not disguise his intention to repudiate Catharine; and to declare the illegitimacy of her son, Paul Petrovitch. He determined, however, to cover this act of despotism with an appearance of justice; fondly imagining, that when he published to the world the proofs of the infidelities of Catharine, his conduct would gain the approbation of all his subjects and the rest of Europe. Hopeless of an heir, on account of a certain imbecility that was ascribed to him, though he lived openly with the countess Woronzoff, held frequent assignations with a handsome stage-dancer of Petersburg, and had various adventures of gallantry; he conceived a singular project for supplying the place of Paul Petrovitch. He determined to adopt prince Ivan, who had been dethroned by Elizabeth, to declare him his successor, and to unite him in marriage with the young princess of Holstein-Beck, who was then at St. Petersburg, and whom he cherished as his daughter. But such were the indifferences of the czar, that they revived from day to day the hopes of Catharine; and the designs he had formed against her, some part of which was well known, emboldened her to run all hazards in order to prevent them. Dismissed to Peterhof, and lodged in one of the apartments of the palace that was most retired, she passed her days in meditating the project for precipitating her husband from the throne, and her evenings in the company of a peculiar intimate, whom she had made the most intrepid of the conspirators. Gregory Orloff, for that was his name, possessed neither the advantages of birth nor those of education; but he had received from nature what are often found more useful, courage and beauty. He had a post in the artillery, while his two brothers were only common soldiers in the regiments of guards; he had also been selected by court Peter Scherzafoff, grand-master of the artillery, as aide-de-camp; and for his misdeeds he had one of the most illustrious and the handsomest women of the court, the princess Korakin, who preferred him to his general. The general, however, having surprised them together, threatened to exert his intercess for procuring the banishment of Orloff to Siberia. The story of this adventure reached the retreat

in which Catharine was compelled to do penance; and her curiosity to see him being excited, was gratified by the condescension of Catharine Ivanovna, the most ingenious of confidants, and the least scrupulous of duennas. After repeated interviews, the empress unveiled to Orlof, of whose boldness and discretion she had previously assured herself, the ambitious designs which she had been projecting. Orlof conspired with her wishes; entered into a conspiracy with her, and engaged his brothers, together with several officers, by whose instrumentality he gained to his party some companies of guards; but without imparting to them his real design. Catharine was only grand-duchess when her connection with Orlof commenced; and her correspondence with him, as well as with other officers, was carried on with no less art than success. Some of the courtiers also participated her favours; but not having sufficient confidence in their talents, she merely made them her friends, without disclosing to them her secret. Lieutenant-general Vilebois was one of those whom she particularly distinguished. When she was seated on the throne, she attached to her interest the remainder of those conspirators, at the head of whom Beluchof and the Schuvalofs had successively appeared, and of which the lieutenant Karail Razumofsky, the prince Volkonsky, nephew of the exiled Beluchof, and major-general of the guards, and count Panin, were the most powerful supporters. She had also been able to form another conspiracy, contrived by the young princefs Daskhof, who, at the early age of 15 years, was singularly active and impetuous. All the accomplices of these several factions acted without the knowledge of each other; and Catharine, who directed and animated them all, seemed to have no share in the plot. Princefs Daskhof had in her train an adventurous Piedmontese, named Odart, whom penury and the hopes of making his fortune had brought to St. Petersburg; and by her interest with the empress, she obtained for him the title of private secretary; in consequence of which appointment, Odart became one of her confidants in her ambitious designs. The princefs Daskhof and Odart contrived to engage Razumofsky, count Panin, prince Volkonsky, and the archbishop of Novgorod in their party. Glebof, whom the czar had raised from the lowest forms of chicane to the important place of procureur-general to the senate, joined this band of conspirators. The aim of all those who severally conspired against Peter III. was to dethrone him; but they had different sentiments with regard to the proper mode of accomplishing their purpose. Panin, Razumofsky, and Orlof thought it best to begin by seizing his person at Peterhof, the imperial palace, situate on the shore of the Cronstadt gulf, at the conclusion of one of those orgies which could not fail to take place on his coming thither to celebrate the anniversary of St. Peter and St. Paul. One of the conspirators, lieutenant Pafick, the most ferocious of his countrymen, fitted on assassinating him with a poignard in the midst of his court, and actually lay in wait for this purpose; but he was disappointed in his design. The conspirators, who differed as to the means of dethroning the czar, were still less agreed on the manner of supplanting his place. Catharine aspired to the sole possession of the supreme authority, and this pretension was supported by the princefs Daskhof and Orlof. Panin, on the other hand, proposed, that she should govern only in the name of regent; and that the title of emperor should devolve on the young grand-duke Paul Petrovitch. And in this opinion the hetman Razumofsky concurred. Those who wanted to confer the supreme power on Catharine, vied with each other in their endeavours to induce count Panin to alter his mind; and if their efforts had not been aided by the court's passion for

the princefs Daskhof, they would have proved altogether ineffectual. The conspirators being agreed, proceeded to devise means for the execution of their plan. Whilst the friends of Catharine received constant information of the movements of the czar, he was ignorant of all their proceedings. Expecting, in indolent security, the festivities of Peterhof, to which we have already adverted, his majesty was gone to pass some days at his country palace of Oranienbaum, whither he was accompanied by some of the handsomest women of the court, and where he had purposed to cause the empress to be arrested. In the mean while some persons, who had perceived that a plot against the czar was in agitation, advertised him of it; but he disregarded the information, and could not be prevailed on to seize the traitors. However, when the conspirators were about to accomplish their design on the arrival of the czar at Peterhof, their plot was discovered, and Pafick was arrested; so that it became necessary to hasten its execution; the time of action was the silence of the night, without allowing the czar an opportunity for forming an inclination to prevent it, nor the troops and the people time to arm for his detestation. Catharine, under a pretence of leaving the apartments of the palace free for the festival that was to be celebrated, and in reality with the view of facilitating her own escape, was lodged in a remote summer-house, called Monplaisir, situate at the extremity of the garden, on the shore of the gulf of Finland. Here she had a small boat, which might occasionally be of service in the secret visits of her favourites, and for facilitating her own escape into Sweden, if the conspiracy should be discovered. At the hour of two in the morning, when the empress was in a profound sleep, she was suddenly roused by a soldier, unknown to her, who delivered a note from princefs Daskhof, and accompanied it with a declaration; "Your majesty has not a moment to lose; get ready to follow me;" upon which he immediately disappeared. Catharine, astonished and terrified, called Ivanovna; and having disguised themselves by their dress, so that they could not be known by the sentinels about the palace, they hastened to a carriage that was waiting for them at the garden-gate. As soon as the empress had seated herself in it, Alexey Orlof, one of the conspirators, took the reins, and set off at full speed. An accident happened to the horses, which retarded their flight, and threw them into confusion. Their danger was imminent; and they resolved to make the best of their way on foot; but they had not proceeded far, before they met with a light country cart, which conveyed them with speed and safety to Peterburgh. Catharine, worn out with fatigue and anxiety, but sufficiently self-possessed to assume a sedate and tranquil air, arrived in the city at 7 in the morning, on the 6th of July, N. S. 1762. She was received by a small band of soldiers with clamorous shouts of joy; and though their number was small, they swore to die in her defence. Their example was soon followed by other soldiers, who, with one consent, declared her sovereign. The oath of the troops was received on a crucifix, fetched from the altar by the chaplain of the regiment of Ilimailof; and the Simeonofsky and the Preobajinsky guards joined those of Ilimailof. In the interval of two hours the empress saw herself surrounded by 2000 warriors, and a great part of the inhabitants of Peterburgh, who mechanically followed the motions of the soldiers, and were eager to applaud them. The hetman Razumofsky advised her to repair to the church of Kazan, whither she was attended with a vast concourse of spectators, who mingled their acclamations with the shouts of the soldiers, and where the archbishop of Novgorod, accompanied by a great number of priests, set the imperial crown on her head, and proclaimed

proclaimed her with a loud voice from the top of the Ruffias, by the name of Catharine the Second, as I declared, at the same time the young grand-duke, Paul Petrovitch, her first-cousin, A Te Deum was then chanted, accompanied with the flourish of brass, and the rattle of the musketry. The empress then repaired to the palace that had been occupied by Elizabeth; and for several hours crowds of people flocked thither, who fell on their knees before her, and took the oath of allegiance. Before the end of the day, Catharine had already received 80,000 men of foot troops; the city was in a formidable state of defence; strict order every where prevailed; and not one drop of blood was shed. What the empress remained in the palace, she sent for her son Paul Petrovitch, and held him in the balcony of the palace to the view of the people, whose acclamations were redoubled at the sight of the child, thinking that in him they beheld the new czar. The principal nobles, who had taken no share in the conspiracy, as soon as they heard of it in the morning repaired to the palace, and united their homage and oaths of fidelity to those which the empress had just been rendering to Catharine. A manifesto was distributed through the city, and a notification was delivered to the foreign minister of the day when they were to be admitted to present their compliments of congratulation on the event that had taken place. The troops, incessantly supplied with beer and brandy, expressed their satisfaction by reiterated vociferations of *hurrah!* and by tossing up their hats and caps; but one regiment of cavalry, of which Peter III. had been colonel while he was grand-duke, and which he had incorporated with the guards on his accession to the throne, took no participation in this tumultuous joy. The officers having refused obedience to Catharine, were put under arrest, and replaced by the officers of other regiments. Fearless of this regiment, the ruling party began to march the troops from the city, to proceed against the czar. Peter III. had yet no suspicion of the important event that had occurred. Such and so unaccountable was his security, that he set out, after having received some intimations of the conspiracy, from Oranienbaum in a calash, with his mistress, his favourites, and the women of his court, for Peterhof, to be present at the grand festivities already mentioned. In the way, Gudovitch, the general aide-de-camp, met one of the chamberlains of the empress, by whom he was informed of his escape, and of the perplexity that had, in consequence of it, filled the whole palace of Peterhof; and upon his communicating the intelligence to Peter, he turned pale, and appeared much agitated. On his arrival at Peterhof, his agitation and confusion increased, when he found that the empress had actually left the palace; he was afraid to ask any questions, and his attendants could not summon resolution to give him any information. At length he received the certain and unacceptable tidings of the revolution that had been accomplished; and the chancellor Woronzoff offered his services to hasten to Peterburg, engaging to bring the empress back. The chancellor, on entering the palace, found Catharine surrounded by a multitude of people in the act of doing homage; and forgetting his duty, he took the oath with the rest. He was permitted, however, at his earnest request, to return to his house, under the guard of some truly officers; and thus secured himself from the vindictive spirit of the partisans of Catharine, and from the suspicions of the czar. After the departure of the chancellor, Peter became a prey to the most distressing anxieties, and he every instant received some fresh intelligence of the progress of the revolution. He was inactive and irresolute with regard to the measures that were proper to be pursued at this interesting crisis. Although his Holiness

guards were firmly attached to him, and the veteran marshal Munich offered to risk every thing for his service, he remained hesitating and undetermined: and after a fruitless attempt to gain possession of the fortrefs of Cronstadt, and adopting some other measures, equally unavailing, for conciliating the empress, he found it not only expedient, but absolutely necessary, to submit unconditionally to her will. The empress deputed count Pain to announce to him her purpose; and he was compelled to sign a most humiliating act of abdication, in which he declared his conviction of his inability to govern the empire, either as a sovereign, or in any other capacity, and his sense of the distress in which his continuance at the head of affairs would inevitably involve it. While the signature to this fatal act was obtained, count Pain left him; and Peter seemed to enjoy a greater composure of mind. In the evening, however, an officer with a strong escort came and conveyed him prisoner to Ropcha, a small imperial palace, at the distance of about 20 versts from Peterhof.

Thus was effected in one day and without shedding a single drop of blood, a revolution of immense importance. The unfortunate emperor enjoyed the power of which he made no political use, no longer than six months. Upon his removal from Peterhof, he was blind to the fate that awaited him. He sent a message to Catharine, requesting that he might retain in his service the negro, who had been attached to him, and who amused him with his singularitys, together with a dog, of which he was fond, his violin, a bible, and a few romances; assuring her, that, disgusted at the wickedness of mankind, he would henceforward devote himself to a philosophical life. Not one of these requests was granted. After he had been at Ropcha six days without the knowledge of any persons besides the chiefs of the conspirators, and the soldiers by whom he was guarded, Alexis Orloff, accompanied by Teploff, came to him with the news of his speedy deliverance, and asked permission to dine with him. While the officer amused the czar with some trifling discourse, his chief filled the wine-glasses, which are usually brought in the northern countries before dinner, and poured a poisonous mixture into that which he intended for the prince. The czar, without distrust, swallowed the potion; on which he was seized with the most excruciating pains; and on his being offered a second glass, on pretence of its giving him relief, he refused it with reproaches on him that offered it. Being pressed to take another glass, when he called for milk, a French valet-de-chambre, who was greatly attached to him, ran in; and throwing himself into his arms, he said, in a faint tone of voice, "It was not enough then to prevent me from reigning in Sweden, and to deprive me of the crown of Russia! I must also be put to death." The valet-de-chambre interceded in his behalf; but the two miscreants forced him out of the room, and continued their ill treatment of him. In the midst of the tumult, the younger of the princes Baratsinsky, who commanded the guard, entered; Orloff, who, in a struggle, had thrown down the emperor, was pressing upon his breast with both his knees, and firmly gripping his throat with his hand. In this situation the two other assassins threw a napkin with a running knot round his neck, and put an end to his life by suffocation, July 17th, just one week after the revolution. These particulars are confirmed by the account of one who was in the confidence of prince Potemkin; who is earnestly said to have been present on the occasion. It was, however, announced to the nation, that Peter died of an hemorrhoidal cancer. When Catharine received the news of Peter's death, she appeared at court, whether she was going, with a train of officers; and afterwards

afterwards shut herself up with Orlov, Païin, Razumofsky, Glebov, and some other confidential persons, to deliberate whether the senate and people should be immediately acquainted with the death of the emperor, or whether it might not be more advisable to wait for that purpose till the ensuing day: the latter alternative was adopted. When the news of this event was communicated to the public at large, the empress rose from her seat with her eyes suffused with tears; she dismissed the courtiers and foreign ministers, shut herself up in her apartment, and for several days exhibited tokens of real and profound grief. The body of the unfortunate czar was brought to Peterburg, and exposed for three days in the church of the monastery of St. Alexander Nefsky, and buried before the rails of the altar. The Holstein soldiers were, on the day following that of the interment, embarked for their own country; prince George, whom Peter III. had constituted duke of Courland, was obliged to renounce that title; but he was compensated by the empress with the administration of Holstein, where he settled, and ever after served Catharine with fidelity and zeal. The chancellor Bessuchef, the most inveterate enemy of Peter, was recalled from exile, and restored to his rank of field-marshal, and to his place in the council, with an annual pension of 20,000 rubles. Several other exiles and prisoners were on this occasion set free; but neither Ivan nor any of his family. Biren, who had been recalled by Peter, was reinstated by Catharine in his dukedom of Courland, where he favoured, to the utmost of his power, the views which the empress had already formed on Poland. Catharine, with a magnanimity which did her honour, wisely manifested no resentment against the few who had preferred their attachment to Peter, and received to favour marshal Munich, who readily transferred his fidelity from the dead to the living. She even pardoned her rival, countess Woronzof, and allowed her to retain the fruits of her lover's munificence.

Although none of the sovereigns of Europe were ignorant of the steps by which Catharine had mounted the throne, they made no hesitation in acknowledging her title. Whilst she was endeavouring to secure peace with the kings of Europe, she neglected no measure that was likely to preserve it within her own empire. In the month of September she took a journey to Moscow, for the purpose of celebrating her coronation in that ancient capital of the empire. Her numerous cavalcade made a pompous entrance into the city; but she was received in a manner that shewed she was far from possessing the hearts of all her subjects. As soon as she was crowned in the presence of the soldiery and the people of the court, she hastened her departure, though she indolently concealed her chagrin, and re-took the road to Peterburg. The presents and promotions which were made on occasion of the coronation, fell mostly to the share of her adherents in the late revolution. The revolts and conspiracies that diquitted the commencement of her reign were suppressed without much difficulty; and the only severities that were exercised on the occasion were a few banishments to Siberia. To foreign courts Catharine displayed all the greatness of her character; and at home, combining policy with firmness, she found means to soothe the most dangerous of the priests, and to put a stop to the cabals of the monks. She recalled to court princefs Dashkoff, whom she had ordered to Moscow; and she sent away the Piedmontese Odart, who had incurred the hatred of the whole court. The health of the young grand duke was established; and the flattering expectations that were justly raised by the good conduct of that prince drew off the public attention from the unfortunate Ivan; and the Russians accou-

modated themselves to a yoke, which they had in vain attempted to shake off. Ambition, however, did not extinguish in the breast of Catharine the love of pleasure. By the latter she gained the increasing attachment of her courtiers; nevertheless, she could surrender pleasure when the more arduous concerns of government demanded her attention. She assisted at all the deliberations of the council, read the dispatches from her ambassadors, either dictated or minuted with her own hand the answers that were sent to them, and afterwards attended to all the particulars of their execution. Jealous, says one of her biographers, of solid renown, she set before her the example of those illustrious monarchs who effaced their weaknesses by the grandeur of their exploits; and, with the infirmities of men, merited and obtained the grateful acknowledgments of all succeeding times, as the friends and benefactors of the human race. She followed the maxims which she frequently quoted: "We should be constant in our plans. It is better to do amiss than to alter our purpose. None but fools are irreflexive."

Catharine ratified the peace, which her husband had negotiated, with Prussia, and also with Denmark. As soon as she was securely established on the throne, she meditated a variety of enterprises and plans of improvement, which would serve to divert the attention of her subjects from the measures by which the late revolution had been effected, and which, in the result, would redound to her own glory and the benefit of her country. She applied with unremitting assiduity and care to the administration of her large estates, the advancement of commerce, the augmentation of the marine, and especially to the means of recovering the finances, without being reduced to the necessity of observing a parsimonious economy. After engaging in business with her ministers, she would frequently converse, in private, with Bessuchef and Munich. With one she studied politics and the resources of the several courts of Europe, and the other communicated to her the plan he had been meditating, during his exile in Siberia, for driving the Turks from Constantinople; a plan, the object of which was singularly gratifying to the aspiring mind of Catharine, and which, about 30 years after, seemed to have been on the point of being effected. In many of her manifestoes and ukases, she adopted a style that admirably expressed a regard to justice and to the true interest of her subjects. When she banished to Siberia for life an officer of the government-chancery of Novgorod, on account of his having taken money for administering the oath of allegiance, she at the same time issued a severe decree against bribery and extortion. By an ukase, dated Moscow, Oct. 13, 1762, she confirmed the abolition of the secret-inquisition-chancery; rightly judging that she could obtain the love and attachment of the people by better means than by the encouragement of spies and informers; and, therefore, she was no sooner seated on the throne, but she put a complete end to the political inquisition. At the abolition of this inquisition, the objects of which were at first the capital crimes of high treason, attempts against religion, and treason against the state, but which afterwards extended its jurisdiction, Catharine settled the practice to be pursued in future, in the ordinary tribunal, under charges of state crimes, and so plainly and distinctly determined the particular cases of delinquency against the person of the sovereign, and against the welfare of the state, that there remained no room for malicious and sinister interpretations. The crimes denominated religious were entirely suppressed. Catharine farther ordained that the truth should be investigated entirely without torture; and, with Frederic of Prussia,

Prussia, the lifewife, exhibited, in this respect, a model for the rest of Europe. Her criminal laws breathe throughout a mild and gentle spirit; and though the law too, like Elizabeth, made a vow to punish no one with death, yet, during her long reign, a sentence of death was extremely rare. Catherine, in order to invite foreigners to settle in her country, drafted, by a number of the most eminent and welcome foreigners in the Russian empire; and soon after her accession several foreigners came to settle in it. In order to hold out farther inducements to them, she marked out the districts that were most wanted, and peopled, by particular notices, which were for a while land, a widow's land, &c. and what all that is based upon rivers, and what the Siberians might still. Besides, she encouraged persons to come, on a little for several purposes in the Russian empire, in whatever town they would, such as merchants, artificers, and the like persons. In order to increase the population, or more properly to eradicate a physical and moral cause of depopulation, the empress had the foundation of the foundling and lunatic hospital at Moscow, and afterwards of another at St. Petersburg. She also founded the medicinal college of the empire in the latter city. In the year 1765, when Catharine was alarmed with various plots against her person and throne, she was busied in all the most effectual and useful measures of government with as much calmness and alacrity as if her reign was to be everlasting. She founded colleges and hospitals in every part of her empire. She encouraged commerce and industry; and ordered new ships of war to be put upon the stocks. The beneficial consequence of the spirit she manifested, and of the regulations she adopted, have been since manifest in a variety of instances. Courland, on the Baltic, with its havens, was subjected by her to the Russian sceptre; and on the opposite side of Europe the Euxine lavas her extensive conquests; Otechakow, the Cherfon, the Crim, and the Cuban, bear witness to the force of her arms. The falls of her flag, of commerce and of war are spread even in the Mediterranean. On the Greek islands the Russian banners are displayed. Her troops opened a road into Egypt, and there, in 1772, fought in support of Ali Bey, against the Turks. The free inhabitants of the extreme north-eastern point of Asia, the Tchuktshes, were at length obliged to submit; and a channel of no great width (the straits of Behring) there only divides the empire from America. A multitude of Russian islands in the northern part of the Southern ocean, the Kurils, and several additional acquisitions, connect it with other islands, and even with the continent of the fourth quarter of the world; and even upon that the Russians have got a firm footing. The increase of navigation by these acquisitions, and the very lucrative commerce of the furs here procured, the costly skins of the sea otter, and other animals, is of the utmost consequence. The differences that arise with China in 1778, were at length compromised; and if no cavans go from Moscow to Peking, yet the merchants of these two great empires prosecute their trade together, and perhaps better, in the frontier towns of Kiachta and Maimintshin. Orenburg, in Asiatic Russia, is excellently situated for commercial intercourse with the East Indies; the caravans require only three months for the whole journey; accordingly, at the half-way thither, at Ba'ka, a town in Bactriana, or Khorasan, Russian and East-Indian caravans already meet together. From this detail we perceive, in part, the benefits resulting to Russia from the commercial spirit of the empress, and from the commercial regulations she established. Towards the end of the year 1763, Catharine gave a proper

form to the supreme college of the empire, the Privy Council senate, which had been instituted by Peter I. She divided it into six departments, of which the four former should have their seat in St. Petersburg, and the two latter in Moscow. With a view to the introduction and diffusion of science and literature among her subjects, she established several useful institutions; she corresponded with princes and emperors in various parts of Europe, and encouraged their freedom to visit her own country; and she awarded herself in name, as well as in reality, a power which they communicated to their respective courts of the empress.

Peter III. when the throne of Poland had become vacant by the death of Augustus III. in the October of the preceding year, Catherine disposed of her political talents and address, in the selection of her most favourite count Brankowicz to the crown. At this time she made a tour through Lithuania, Lwow, and Cracow; but, during her absence, on the 25th of August, 1762, she was proclaimed empress. But when Elizabeth was proclaimed on the throne, the infant, together with her mother, Anne, his mother, and his whole family, was confined in the towers of Schlußburg; from the place he was transported, together with his family, to the fortress of Riga; from Riga they were conveyed to Dinamunda, and afterwards to Oranienburg, a town built by Mentchikof, in the old province of Voronech. There he was separated from his family, and being arrested at Smolensk, in his way to Germany, under the conduct of a monk who released him from prison, he was for some time confined in a monastery in the Valtai, near the road that leads from St. Petersburg to Moscow; and, in 1756, by order of the empress Elizabeth, who wished to see him, he was remanded to Schlußburg, where he had been placed immediately on his dethronement. Here he was closely confined, that he never was allowed access to the open air, or to the light of day; a lamp was kept constantly burning in his cell; and, as no clock was to be seen or heard, he knew no difference between night and day. His interior guards, a captain and a lieutenant, were shut up in the same cell, but were not permitted to hold any intercourse with him. It is no wonder, therefore, if his ignorance should have increased on this eye. Elizabeth herself had caused him once to be brought in a covered cart to Petersburg, and there saw and conversed with him. Peter III. was, when he proposed to restore her to the throne, visited in incognito. Catharine too, soon after the commencement of her reign, had a conversation with him, in order, as it is said, in her marriage of the 28th of August, 1762, to form a judgment of his understanding and talents; in both which respects she found him extremely deficient. At the period to which we now refer, he was arrived at the age of 24 years; and, whatever might have been his incapacity, he was a fit instrument for exciting dangerous commotions; and from the depth of his dungeon, he afforded hopes to those who held the present usurpation in abhorrence. Accordingly, whilst the regiment of Smolensk was in garrison, in the town of Schlußburg, a sub-lieutenant, of the family of Murovitch, formed the bold plan of setting him at liberty, and raising him to the empire. But the two officers, who slept with him in his cell, had a discretionary order signed by the empress, enjoining them to put the unhappy prince to death, whenever any infurrection should be made

made in his favour, provided that it could not otherwise be quelled. Mirowitch, having gained the concurrence of a few associates, pointed a piece of artillery at the door of the dungeon, where the prince was confined, and prepared to batter the place; but at that instant the door opened, and he entered, un molested with his whole suite. In the meanwhile the officers who guarded Ivan, after previous consultation, determined to assassinate the unfortunate captive, who, though naked, defended himself for a considerable time. Although his hand had been pierced through, and his body was covered with wounds, he seized the sword from one of the monks, and broke it; but while he was struggling to get the piece out of his hand, the other stabbed him from behind, and threw him down. He who had his sword broken, now plunged his bayonet into his body, and several times repeating his blow, the unhappy prince expired: they then opened the door, and presented to Mirowitch the bleeding body of the murdered prince, and also the order by which they were authorized to put him to death, if any attempt should be made to convey him away. Mirowitch, struck with horror, started back some paces; and after expressing his grief for the event that had occurred, surrendered himself to the governor, who confined him and his accomplices. Mirowitch was afterwards condemned to death, and publicly executed in pursuance of his sentence. The inferior actors, on this occasion, being about 58 in number, did not suffer death, but were subjected to other punishments, perhaps not less severe. The officers, who assassinated the prince, were amply rewarded for their fidelity, in consideration of their good intentions with respect to the tranquillity of the state. Some have asserted that Mirowitch had been secretly instigated to this attempt for the rescue of the prince by the court, and thus to justify the execution of the orders that had been previously given to the guard; but the punishment of Mirowitch, and the confession which he is said to have made, that the scheme was wholly his own contrivance, seem to acquit the empress of this horrid crime. On the other hand, it has been alleged that his behaviour during his trial, and the composure with which he walked to the scaffold, on which his sentence was to be executed, manifested a kind of assurance, that he should obtain a pardon, which, report says, had been actually promised. But if he entertained this hope, he was cruelly deceived; the time of his execution was accelerated, and the unhappy wretch, if he had before been the instrument, was now the victim of a barbarous policy. Those who considered him in the former point of view were astonished that the empress should suffer him to be put to death. But how could he have screened him from punishment without manifestly drawing upon herself the charge of having prompted his crime? And if she were really concerned in it, can it be thought that she would hesitate a moment in getting rid of a witness who would have exposed her to everlasting vexation? Soon after this shocking event, Catharine, whose throne was now established, returned to Petersburg from her journey through the conquered provinces; and, on her entry into the city, she was surrounded by an immense concourse of people, who endeavoured to find out by her countenance what was passing in her heart; but always mistress of herself, the face of that princess was ever covered with smiles. Her step was as firm, and her front as serene as those of persons who feel no inward reproaches usually are. The beneficial effects of the empress's regulations and establishments, for the internal administration of government, were every day becoming more apparent in all parts of Russia: she exerted herself to the utmost in giving new spirit to the commerce of her coun-

try, in augmenting her navy, and above all, in softening the manners of the people, who were not yet far advanced in civilization; but the progress of her institutions was at first slow, and it was much retarded by want of zeal on the part of the great personages of the empire, and by the spirit of division that continued to reign in Petersburg. What most afflicted the empress was the misunderstanding that prevailed between her favourite Orlov, and her chief minister Panin. In order to silence murmurs of a political nature, and to divert the disaffected, she displayed her taste for splendour and magnificence, by a species of entertainment called a "craoufal," consisting of tilts and tournaments, sumptuous entertainments, repeated with considerable variations for several days, and vying in pomp and pageantry with any of the feasts of ancient chivalry. But Catharine knew also to employ more worthy means for establishing her authority. She stilled herself in making reforms, and in the establishment of useful institutions. She corrected the tribunals, founded schools, built hospitals, and planted colonies. She endeavoured to infuse into her people a love for the laws, and to soften their manners by instruction. Jealous of a power that knew no bounds, greedy of every species of glory, she was determined to be at once both conqueror and legislatrix. Amidst conspiracies formed for overturning her throne, occupied with preparations for war, which seemed sufficient to arrest her whole attention, and yet finding time for attachments of gallantry, she was unmindful of nothing that could attract the reverence of mankind, and captivate their admiration. The perplexed and uncertain jurisprudence of Russia engaged her particular attention; and she resolved to apply a remedy to the various disorders that occurred in this department of the state. Although the success of her patriotic attempt has not yet been complete, yet, in consequence of it, the laws of the Russian empire have been much simplified, and the administration of justice is become much milder and more impartial. Having formed the senate and the colleges into separate departments, and having augmented the emoluments of the judges, in order to deprive them of all pretext or excuse for either negligence or prevarication; she set herself to work on a new code of laws. With this view she summoned deputies to Moscow from all parts of her vast empire, that she might obtain their ideas on the laws that were fittest for their peculiar exigencies; and she herself repaired to that ancient capital. When they were assembled, she wished to leave them in possession of uncontrolled liberty, and therefore, though she attended in the hall where they met, and could see and hear all that passed, she herself was not perceived. The instructions, which she had previously composed, with the assistance of Mathonius and Rozetky, and which had been chiefly taken from the writings of Montesquieu and some others of the French philosophers, were translated into the Russian language from the original French, and the business of the assembly was begun by the perusal of them. The original copy, almost entirely in the hand-writing of Catharine, has since been deposited, enclosed in a magnificent case of silver gilt, in an apartment of the Imperial Academy of Sciences at St. Petersburg. Copies of these instructions were afterwards dispatched to the sovereigns, whose approbation Catharine most coveted. They complimented her on her laborious enterprise, and made no hesitation in pronouncing that it would be an eternal monument to her glory. It unquestionably re-ounds much to the praise of the empress, that these instructions are founded on the principles of an enlightened humanity; and that, though autocratrix, and possessing unlimited power, she recognizes no legitimate authority but that which is founded on justice; and that every particular in her

laws has a tendency to enervate despotism, and to render a just authority respectable. Her purpose was to form a solid, and not an arbitrary legislation. Her whole plan was directed to prevent all those who governed under her from exercising a capricious and cruel authority, by subjecting them to inviolable laws, which no authority should be able to infringe. The empress, proceeding in other respects on the same enlarged and enlightened plan, continued to cultivate and encourage the arts and sciences; to make her empire an asylum to the learned and ingenious; and to reform the manners and instruct the minds of the people, through the extent of its most distant provinces. The transit of Venus, which happened in 1769, afforded an opportunity of exhibiting as well the munificence of Catharine as the attention she paid to astronomy. It may seem surprising, however, that while Catharine was striving to build her fame upon a solid basis, she made it a matter of much importance to obtain from all the powers of Europe the title of imperial majesty, which some of them had refused her. About the middle of the year 1767, the empress conceived the useful project of sending several learned men to travel into the interior of her immense territories, for the purpose of determining the geographical position of the principal places, of marking their temperature, and of examining into the nature of their soil, their productions, their wealth, as well as the manners and characters of the several people by whom they are inhabited. The selection of the learned travellers destined for this expedition, the helps that were granted them, and the excellent instructions that were given them, will be a lasting honour to the Academy of Sciences, by which they were appointed. About this time, viz. in 1768, the court of Catharine became the asylum of the sciences, to which she invited learned men from every part of Europe. She encouraged artists and scholars of all denominations; she granted new privileges to the Academy of Sciences, and exhorted the members to add the names of several celebrated foreigners to those which already conferred a lustre on their society. Nor was she less attentive to the Academy of Arts, by increasing the number of its pupils, and adding such regulations as tended more than ever to the attainment of the end for which it was endowed. See ACADEMY. For the further encouragement of the fine arts in her dominions, the empress assigned an annual sum of 5000 rubles for the translation of foreign works into the Russian language. The improvement of the state of physic was another important object of her concern; and in order to give the highest possible sanction to the salutary practice of inoculating for the small pox, she herself submitted to the operation under the care of an English practitioner, and she persuaded the grand duke to follow her example. In 1768, Dr. T. Dinwiddie, of Hertford, was invited to Russia for the purpose of introducing inoculation; upon the recovery of the grand duke, Catharine rewarded his services by creating him a baron of the Russian empire, and appointing him counsellor of state and physician to her imperial majesty, with a pension of 500*l.* a year, to be paid him in England; besides 10,000*l.* sterling, which he immediately received; and she also presented him with a miniature picture of herself, and another of the grand duke as a memorial of his services. Her majesty likewise expressed her approbation of the conduct of his son, by conferring on him the same title, and ordering him to be presented with a superb gold snuff-box, richly set with diamonds. On December the 3d, 1768, a thanksgiving service was performed in the chapel of the palace on account of her majesty's recovery and that of the grand duke from the small-pox: and the senate decreed, that this event should be solemnised by an anniversary festival, which has been regularly observed ever since.

With regard to her foreign relations, whilst she was giving law to Poland, amending Austria, conciliating the friendship of Prussia, and treating with England, she was also tampering with the other courts of Europe, and labouring efficaciously towards very soon making herself dreaded by them.

Her schemes of foreign aggrandisement, which compose so great a part of her history, commenced with her violent and arbitrary interference in the affairs of Poland, which in 1768 caused the Ottoman Porte to declare war against her; but he was very unequal to the contest, which in its progress brought on a series of disasters to the Turks. They lost several battles on the Pruth, Dniester, and Danube, with the towns of Bender and Ackerman, the capital of Bessarabia. The news of these signal successes augmented the pride and strengthened the security of Catharine. The disaffected, who surrounded her throne, dared no longer to conspire against a princess, who was triumphing at such a distance over her most formidable enemies. The provinces of Wallachia, Moldavia, and Bessarabia, submitting to the Russian arms, sent deputies to Petersburg to do homage to the empress; who received them with magnificence, and loaded them with benefits. Whilst the Turks were thus harassed by land, and the fleets of the empress were triumphing on the Euxine, she resolved to attack them even in the isles of Greece. With this view, in September 1769, two squadrons of Russian men of war sailed from Archangel and Revel, which were soon followed by others from the Baltic, and steered their hitherto unattempted course for the Mediterranean. The fleet now consisting of 20 sail of the line, 6 frigates, several transports, a number of bomb-ketches, galleys, and vessels with troops for land-service, left the Baltic, crossed the North sea, passed the straits of Gibraltar; and after having been dispersed by a tempest, collected again, and displayed in the Archipelago its victorious flag. This fleet was commanded by admiral Spiridof, but that admiral himself was under the orders of Alexey Orlov, whose share in the Russian revolution had advanced him all at once from the low condition of a simple soldier to the rank of general, and whose audacity served him instead of experience and talents. This naval expedition of Russia forms a remarkable æra in the history of marine tactics. Before the arrival of this fleet, some secret agents had been disposing the Greeks to rise up in arms. They were led to expect the Russians as their deliverers; and at the instant when their squadron had gained the height of Cape Matapan (formerly the promontory of Tenaros), the whole Archipelago thought itself free. The Mainots, descendants of the ancient Lacedæmonians, were the first that took up arms; their example was soon followed by their neighbours; and the Turks were massacred in several of the islands. But the latter cruelly revenged themselves for the insurrection of the Greeks. Some thousands of these miserable people were exterminated by the fabric of the Janizaries.

The squadron of Spiridof was soon joined by that of Elphinston, a native of England, vice-admiral in the Russian service, and far more capable of commanding than the officer under whose orders he served. To this double squadron was opposed that of the captain pacha Hassan, furnished Gazi, or the victorious, by the sultan on account of the courage he displayed in the engagement with Spiridof. This Turkish admiral first forced the Russians to retire from Lemnos; but the two fleets afterwards met in the channel that separates the isle of Scio from Natolia; and a very furious engagement ensued. The Turks, though possessing a superior navy, were compelled to shelter themselves in the narrow bay of Tschesmé, near Lemnos, where some of them ran aground, and the others were so pressed for room, that it

was impossible for them to act. The Russians, perceiving their disadvantageous situation, sent among them some fire-ships, under the conduct of the admirals Elphinston and Greig, and commanded by lieutenant Dugdale, all British officers, and destroyed their whole fleet. After the total destruction of the Turkish squadron, the Russians anchored at Paros; whence they might easily command all the Grecian seas, and where not a single vessel was suffered to appear without lowering its top-sails. This great success, however, was not improved as might have been expected by Alexis Orlov, the empress's hero and supreme commander in the Mediterranean; for though a new squadron was fitted out to reinforce that which was already in the Archipelago, the Dardanelles, which were the keys of Constantinople, remained secure; for, as the winter season came on, the Russians were obliged to quit their station in these seas, and the trade through the straits was of course again opened. Crim Tartary, however, was entirely conquered by the Russians, whose fleets rode triumphant on the Black Sea; and the grand vizir was attacked in his camp, and routed with great slaughter. A terrible plague at Moscow, and other domestic disasters, counterbalanced in the estimate of true policy these foreign advantages. In 1772, the most iniquitous measure, the division of a large part of Poland between the three bordering powers, Russia, Prussia, and Austria, which had been long projected, and for which preparations were made by the advances of their several armies into the country, avowedly took place in the face of Europe, which was shamefully passive to go great a violation of all public faith and equity. While Catharine was acquiring by negotiations a part of the provinces of Poland, her armies continued to ravage the frontiers of Turkey; and the war was not terminated till the year 1774, when the grand vizir, being invested on all sides by the Russian armies, was reduced to the necessity of signing a peace; of which the principal conditions were, the independence of the Crimea, the free navigation of the Russians on the Euxine and through the Dardanelles, with the stipulation that they should never have more than one armed vessel in the seas of Constantinople, and a cession to them of that tract of land that lies on the Euxine between the Bog and the Danube. Russia, retaining Azof, Toganrok, Kertsels, and Kinburn, restored the rest of her conquests. Russia also obtained a large sum of money to defray the expences of the war, and the title of "pedishah," or empress, was no longer refused to the Russian monarch. Nothing could exceed the joy and felicity which prevailed at Petersburg upon the confirmation of this happy peace. The empress ordered eight days to be devoted to public feasts and rejoicing; liberal rewards to be distributed as usual; the prison doors to be opened for the release of all, who were not charged with high treason; and the return of all exiles from Siberia, who had been banished since the year 1746. But, notwithstanding the external prosperity of the Russian empire, many circumstances combined to produce internal distress. The finances of the country were in a disordered state; succours from England were procured by granting immense advantages to its commerce; the pestilence had made dreadful ravages at Moscow and in the adjacent countries, and had extended its fatal influence to the army and navy; the provinces of Kazan, Astrachan, and Orenburg, were a prey to revolt, which menaced even Moscow; and a remarkable emigration was changing countries that were flourishing with commerce into waste and deserted tracts. All these circumstances rendered an accommodation with the Turks peculiarly acceptable. But besides these grievances which must induce the empress to rejoice in the establishment of peace, an open rebellion, and its attendant,

a civil war, distressed the Russian empire. This calamity originated in Asia, and extended to Moscow; the author of it was Pugatshof, a Cossack, born at Simoveisk, a village on the borders of the Don. He had served as a common soldier in the army in 1756; he made the campaign of 1769 against the Turks, and fought under general Panin at the siege of Bender; and on the surrender of that town he applied for his dismissal, which was refused; upon which he fled to Poland and obtained concealment and an asylum among some hermits of the Greek confession. These hermits, perceiving or feigning some resemblance to Peter III., encouraged him to assume his name and character. The imposture was carried on for some time in Little Russia, and a number of followers attached themselves to this deceiver, who had combined professions of sanctity and self-denial with his delusion. Among the inhabitants of the banks of the Yaik, since called Ural, he formed a strong party of Cossacks, whom he engaged to accompany him into the mountains of Caucasus, with the assurance that they would there find powerful succours. Being arrested for inciting the people to sedition and committed to prison, he was frequently visited by the popes, who furnished him with money, and thus enabled him to corrupt his guards, and to make his escape. Having by various arts of imposture collected a formidable party, he publicly declared that he was the emperor Peter III., delivered by a miracle from the hands of his assassins. This revolt was a favourable diversion to the Turks, and in 1773 wrought powerfully in their behalf. Pugatshof, besides assuming the name and character of Peter III., had sufficient discernment to perceive, that it would much favour his design to blend religious pretences or prejudices with the political motives that might operate towards bringing on a revolution. Other circumstances concurred to countenance his imposture, and to increase the number of his adherents. The rebellion instigated by this impostor obtained a general spread; and at length Catharine was much alarmed, and seriously set about checking its progress. She published manifestos and ukases, and Pugatshof did the same, affixing to those he issued the name of Peter III. By one of these he enfranchised all the boors; and he caused rubies to be struck with his effigy, and this inscription; "Peter III. emperor, and autocrat of all the Russias;" and on the reverse, "Redivivus et ultor." This revolt, the particulars of which we cannot detail at length, after causing great devastations, and the loss of many lives, was finally terminated by the capture of Pugatshof at the close of the year 1774, and his subsequent decapitation. It has been justly alleged, as a proof of the mildness of Catharine's administration, that this atrocious rebel was executed without torture. Five of his principal accomplices were likewise beheaded; three others were hanged; and 18 more underwent the knout, and were banished to Siberia. Catharine, during the tumultuous state of the empire, employed herself in promoting its internal welfare; by encouraging the sciences and the arts of peace; and soon after the punishment of Pugatshof, she had a fresh opportunity of displaying her clemency, by granting a pardon to men, who were justly deserving of capital punishment: they were the treasurers of the empire, who had embezzled the public money. She had overcome what was naturally irascible and violent in her temper, and had learnt patience and lenity from the lessons of philosophy. Notwithstanding the heavy burdens incurred by her foreign and domestic wars, she took off most of the taxes that were laid for their support; and, as if the strength and riches of government in her country increased with its expence, she also abolished a number of the ancient taxes, which were considered either as discouraging to agri-

culture, or oppressive to particular provinces or orders of the people. She also lent large sums of money, free of interest, and for a specified term of years, to those provinces which were ruined by the late rebellion. She likewise established a number of other regulations, that tended to the security, advantage, and happiness of her subjects; abolishing pernicious distinctions, destroying numerous monopolies, restraining the cruelty of punishment, removing oppressive or impolitic restrictions or prohibitions, and restoring mankind to a more equitable degree of equality, in the different ranks which they occupy in society. Imprisoned debtors were, under certain circumstances, released from confinement; and all the heirs of the debtors to the crown were discharged from their bonds and obligations. The insurgents every where returned to their duty; nor were the victims to justice numerous. As a general famine prevailed in the desolated countries, government was at great expence and trouble in supplying them with corn and meal from the magazines at Moscow and other places; and various methods were devised for preventing the progress of famine. The comprehensive mind of the empress, which had been occupied in the extension and establishment of its external force, in laying the foundations of a philosophical system of legislation, in the improvement of education, in the diffusion of illumination and taste, and in the reformation of numberless abuses, directed its views to the important object of forming a constitution for Russia. See PETERSBURG and RUSSIA.

In the year 1775, when peace was established abroad, and every thing was quiet at home, Catharine employed herself in cultivating the arts of peace, in the improvement of the country, and in opening the minds of her subjects; and in the prosecution of these objects she found Potemkin so useful, that he soon acquired an ascendancy that was almost absolute. To him all persons looked as the dispenser of all bounty, and the source of all honours. Every day he acquired some new dignity or some accession of revenue; he attained the most important post in the Russian empire; and he possessed an authority scarcely compatible with that of a superior. Catharine was not unapprised of his ambition and love of power; and, therefore, she wished to retain Gregory Orlov, her former favourite, though he requested permission to retire from the court, as a check on the petulance and audacity of his rival. After having long opposed Panin to Orlov, she now thought of opposing Orlov to Potemkin.

The independence of Crim Tartary soon produced an open rupture between the Turkish and Russian parties; and in 1778 it produced a declaration of war. From the measures that were pursued it sufficiently appeared, that the ambition of the empress would not be satisfied till she had gained entire possession of that peninsula. Her intrigues in the neighbouring courts of Denmark and Sweden tended to render these powers little more than dependencies on her crown; however in 1780 her influence over them was employed in establishing the famous "armed NEUTRALITY," the purpose of which was to protect the commercial rights of neutral states, then continually violated by the belligerent powers, and particularly by England, which availed itself of its superiority at sea, in preventing France and Spain from receiving naval stores from the Baltic. In this year Catharine had an interview at Mohilow with the emperor of Germany, Joseph II., and they travelled together in familiar intercourse into Russia; the prince of Prussia (afterwards Frederic William II.) also visited her court; and it was customary for the neighbouring princes to make visits of policy or curiosity to Peterburg, where they were always treated with

a magnificence not paralleled in any other part of Europe. In 1782, Catharine, with a view of affording an asylum to the prescribed order of Jesuits, and probably imagining that all the Jesuits of Europe and America would bring into White Russia their treasures and their industry, erected a Roman-catholic archbishopric at Mohilow, for the spiritual government of her subjects of that persuasion, and also gave him a Jesuit coadjutor. But whatever might be her expectations, the spoils of Paraguay never found their way to Mohilow. This establishment, however, evinced a mind, like that of the king of Prussia, superior to religious prejudices; and, considered merely with a view to the exercise of religion, it was laudable. This year was marked by an event which indicated Catharine's respect for the memory of Peter the Great, whom she affected to imitate: it was the erection at Peterburg of his famous equestrian statue, which was executed by Stephen Falconet of Paris. This artist conceived the design of having for the pedestal of his statue a huge and rugged rock, in order to indicate to posterity, whence the heroic legislator had set out and what obstacles he surmounted. This rock, the height of which from the horizontal line was 21 feet by 42 in length, and 34 in breadth, was conveyed, with great labour, from a bay on the gulf of Finland to Peterburg, through the distance of 11 veils, or about 41,250 English feet. On the side next the senate it has this Latin inscription, which is in a style of sublime and proud simplicity: "Petro primo, Catharina secunda;" "Catharine the second to Peter the first."

In the following year, 1783, Catharine augmented the splendour of her court, by instituting the new order of St. Włodimir, or Vladimir. This year gratified the ambition of Catharine with regard to the Crimea. Having acquired, without a war, the sovereignty of the Crimea, of the ile of Taman, and a great part of the Kuban, she called the former of these countries Taurida, and the other Caucasus. Thus Catharine gained a point of much importance towards the main object of her own ambition, as well as that of her prime minister Potemkin, i. e. the destruction of the Turkish empire in Europe; in the view of which she had named the grand-duke's second son Constantine, and had put him into the hands of Greek nurses, that he might be thoroughly acquainted with the language of his future subjects. Instructed by Potemkin, the empress formed a design, in 1787, of being splendidly crowned in her new dominions: "queen of Taurida;" but the expence being objected to by some of her courtiers, she contented herself with making a grand progress through them. At her new city of Cherson, she had a second interview with the emperor Joseph. She then traversed the Crimea, and returned to Moscow, having left traces in her progress of her munificence and condescension. This ostentatious tour was probably one cause of the new rupture with the Turkish court, which imprisoned the Russian minister in the Seven Towers, and commenced the war. In this bloody contest the emperor of Germany engaged as ally to Russia, and the king of Sweden as ally to the Porte. The latter prevented the empress from sending a fleet into the Mediterranean; and even endangered Peterburg itself by a sudden incursion into Finland. The danger, however, was averted by the empress's own vigorous exertions, by the desertion of some of Gustavus's troops, who would not fight against the Russians, and by an attack of Sweden, on the part of the prince of Denmark, who proceeded as far as Gottenburgh. The Turkish army, though superior to that of the emperor, could not resist the efforts of the Russian generals. Potemkin at the head of a numerous army, and a large train of artillery, laid siege to Otchakof, and it was at length taken by storm, with the loss of 25,000 Turks

CATHARINE.

and 12,000 Russians. Catharine regarded the capture of this strong town an event of such importance, that she liberally rewarded Potemkin, and conferred honorary distinctions on prince Repnin and general Suvarof, and the other commanders concerned in reducing it. During the progress of this war, the Turks lost many important places, and their naval force on the Euxine was almost annihilated. In the conflicts between the Russian and Swedish fleets in the Baltic, the former were generally victorious; but they terminated in 1790 in a separate peace. The war with the Turks was prolonged; the strong fortresses of Ismail was stormed by Suvarof and taken with the loss of 15,000 Russians; and the armies of Catharine obtained, though with the expence of many lives, several very decisive victories. The empress, however, perceived that even her conquests were ruinous, and that peace was desirable; but she had too much pride to sue for it, and therefore she chose to continue fighting. At length she determined to close the war, and engaged count Bernstorff, the Danish minister, to negotiate the preliminaries of peace with the cabinets of Berlin, of London, and of the Hague. By his mediation, an accommodation was settled between these three powers and Russia; and they agreed to propose to the Ottoman Porte the terms offered by the empress, declaring, that if the Turks would not accept of these conditions, they would abandon their cause, and leave them to prosecute the war alone against Russia. A congress was assembled at Shistova; and the negotiators having removed to Galatch, the preliminaries of peace were signed, on the 9th of January 1792, by prince Repnin and the grand vizir. The definitive treaty, concluded at Yassy, soon after followed. In the war, thus happily terminated, it has been calculated, that Austria lost 130,000 soldiers, and expended 300 millions of florins. Russia lost 200,000 men, 5 ships of the line, 7 frigates, and 80 smaller vessels, and expended 200 millions of rubles. The Turks lost 330,000 men, 6 ships of the line, 4 frigates, with several other vessels, and expended 250 millions of piastres. Sweden had expended 70 millions of rix-dollars, and lost 12 ships of the line, 3 frigates, and 40 smaller vessels of war. After signing the treaty, Bezborodko declared, that the empress gave up her claim to the 12 millions of piastres which the Porte had stipulated to pay her as an indemnity for the expences of the war; and the Ottoman plenipotentiaries jolly testified their admiration of an act of generosity so truly imperial. By this treaty of peace, the Dniester was declared to be for the future the limit of the two empires. The English prime-minister manifested a strong desire to compel Russia to restore Otchakof to the Turks, but not being supported by the nation, this point was conceded, and Russia retained that important place and its territory. Before the conclusion of this treaty, Catharine lost her prime-minister, prince Potemkin, who died the 15th of October 1791, at the age of 52, in the vicinity of Yassy, and was buried at Cherson. In consequence of this loss, the empress employed herself with singular assiduity in the administration of the empire; devoting to public business 15 hours together, and dividing among her ministers the direction of the affairs which had belonged to Potemkin. When the revolution in France began to agitate the crowned heads of Europe, the empress, and the king of Sweden, seem to have been the first who formed a resolution of opposing it by force of arms. But when Catharine perceived that the hazard and difficulty of this enterprise were encountered by the nearer powers of Prussia and Austria, she directed her attention to Poland, and exerted herself in checking and subduing the new spirit of liberty which was rising in that country. For this purpose she marched an

army thither, overcame all resistance, annulled the new constitution, and finally broke the spirit of the Poles by the dreadful massacre made on the inhabitants of the suburbs of Warsaw under the obdurate Suvarof. A new division of the country between the three former pillagers ensued, which at length totally blotted out Poland from the map of Europe. See POLAND.

Catharine, having conquered, either by her arms or by her intrigues, almost one half of Poland, the Crimea, the Kuban, and a part of the frontiers of Turkey, had no occasion for recurring to armaments and battles in order to usurp another rich and well-peopled country. Her intrigues were sufficient to gain possession of Courland and Semigallia. Whilst she was thus extending her territories, she was not remiss in manifesting her abhorrence of the new principles propagated in France, by ostentatious attention to the forms of religion, and by a cordial reception of noble emigrants from that country, and by sending a Squadron of men of war to co-operate with the British fleet. Inured to conquests, she turned her arms against Persia; and under pretence of defending Loif-Ali-khan, an offspring of the race of the Sophis, she wanted to be revenged on Aga-Mahmed, and to gain possession of the provinces which border on the Caspian. With this view, her general Zubof, at the head of a numerous army, penetrated into the province of Daghestan, and, after a short siege, made himself master of Derbent. Her success in this quarter inspired her with the hopes of obtaining a greater triumph. Having concluded a treaty with Great Britain and Austria, called the triple alliance, and signed in February 1795, she thus secured the assistance of these two powers against Turkey, and flattered herself with the full accomplishment of her darling project, which was that of driving the Ottomans out of Europe, and of reigning in Constantinople. In this case the immense empire of Catharine would have had for its frontiers the Thracian Bosphorus to the south, the gulf of Bothnia to the north, the Vistula to the west, and the sea of Japan to the east. But death disappointed her hopes, and put a stop to that career of her ambition which nothing else could restrain. In the course of her life, she had seldom experienced any illness, which was probably owing to her even and cheerful temper. On the morning of the 6th of November 1796, she was in good spirits, and having taken her coffee as usual, she retired to her closet; but not returning so soon as her attendants expected, they began to be alarmed; and on entering the outer room where she was, they found her stretched on the parquet, with her feet against the door, and speechless. Her majesty's chief physician, Dr. Rogerson, being sent for, he pronounced her attack to be a fit of apoplexy; and having ordered her to be twice bled, she obtained temporary relief; but she was unable to utter a single word, and at 10 o'clock in the evening of the following day she expired. She was succeeded by the grand duke, her son, who was immediately proclaimed emperor, by the name of Paul I. Her remains were deposited in the tomb of the unfortunate Peter III. in the church of the monastery of St. Alexander Nefsky. On the coffin of that prince the emperor caused to be placed the imperial crown, which was fetched from Moscow for this purpose; the coffin was then laid in slate by the side of that of the empress, with a true-love knot reaching from one to the other, on which was inscribed in Rufus characters: "Divided in life—United in death." Alexis Orlov and prince Baratinsky, the two assassins of Peter III. were ordered to stand, one on each side of his coffin, as chief mourners. The former betrayed no signs of emotion; but the latter seemed to be overwhelmed with grief, and could scarcely be preserved from falling into

CATHARINE.

a swoon. When this act of punishment was concluded, Orlof received permission to travel, and Baratouky was ordered never more to appear at court.

Catharine II. had been handsome in her youth; and at the age of 70 years she preserved some remains of beauty, connected with a peculiar gracefulness and majesty. Her stature was of the middle size, somewhat corpulent, but well proportioned; and as she carried her head very high and raised her neck, she appeared very tall; she had an open front, an aquiline nose, an agreeable mouth, and her chin, though long, was not misshapen. Her hair was auburn, her eye-brows black (brown, says Rulliere), and rather thick; and her blue eyes (animated hazle eyes, says Rulliere, discovering shades of blue), indicated a gentleness which was often affected, but more frequently a mixture of pride. Haughtiness, says Rulliere, was the true character of her physiognomy. The grace and kindness, which were likewise visible in it, seemed, to the penetrating observer, only the effect of an extreme desire of pleasing; and these seducing expressions manifested too perceptibly even the design of seducing. A painter, desirous of expressing this character by an allegory, proposed to represent her under the figure of a charming nymph, who, with one hand extended, presents wreaths of flowers, and in the other, which she holds behind her, conceals a lighted torch. The empress was usually dressed in the Russian manner. She wore a green gown (green being the favourite colour with the Russians), somewhat short, forming in front a kind of vest, and with close sleeves reaching to the wrist. Her hair, slightly powdered, flowed upon her shoulders, topped with a small cap covered with diamonds. In the latter years of her life she used much rouge; for she was still desirous of preventing the impressions of time from being visible in her countenance; and she always practised the strictest temperance, making a light breakfast and a moderate dinner, and never eating any supper. In her private life, the good humour and confidence with which she inspired all about her, seemed to keep her in perpetual youth, playfulness, and gaiety. Her engaging conversation and familiar manners placed all those who had constant access to her, or assisted at her toilette, perfectly at their ease; but the moment when she had put on her gloves to make her appearance in the neighbouring apartments, she assumed a sedate demeanour, and a very different countenance. From being an agreeable and facetious woman, she appeared all at once the reserved and majestic empress. A person, who then saw her, would spontaneously pronounce, "This is indeed the Scamias of the north." Her mode of saluting was dignified and graceful; by a slight inclination of the body, not without grace, but with a smile at command, that came and vanished with the bow.

As to the character of Catharine, it may be sufficiently estimated by the history of her actions. Her reign, for herself and her court, had been brilliant and happy; but the last years of it were particularly disastrous for the people and the empire. She governed too much by her favourites; and these, with their dependents and subordinate officers, became petty despots. The two most celebrated of these favourites were count Gregory Orlof and prince Potemkin; the former was a coarse vulgar man, of surprising muscular strength and brutal manners; the other shone with some splendour, and his memory still enjoys in Russia that sort of fame which is attached to conquells and military exploits. Let the reader judge from the following statements, what honours and emoluments these favourites and others of a similar description possessed, and how they must have abused the confidence of the empress, and pillaged the country in order to acquire

them. The dignities and titles conferred by Catharine on prince Potemkin may be seen in the annexed summary; "Knight of the principal orders of Prussia, of Sweden, of Poland, and of all the orders of Russia; field marshal, commander in chief of all the Russian armies; chief general of the cavalry; high admiral of the fleets of the Black Sea, of the sea of Azof, and of the Caspian; senator, and president of the college of war; governor-general of Ekaterinof and of Tagorid; adjutant-general, and actual chamberlain of the empress; inspector general of the armies; colonel of the Preobragensky guards; chef-du-corps of the horse-guards; colonel of the regiment of cuirassiers of that name, of the dragoons of Peterburg, and the grenadiers of Ekaterinof; chief of all the workshops of arms and founderies of cannon; grand hetman of the Cossacks," &c. &c. &c.

The subjoined statement exhibits the sums of money which the favourites of Catharine received from her during her reign, or rather which they wrested in various ways from the poor peasantry, her subjects:

	Roubles.
The five brothers <i>Orlof</i> received in lauds, palaces, jewels, plate, and money	17,000,000
<i>Efessenky</i> , two months in favour	300,000
<i>Vassilievskoi</i> , 22 months in favour	1,110,000
Prince <i>Potemkin</i> , a fortune estimated at	50,000,000
<i>Zavodoffky</i> , 18 months a favourite	1,380,000
<i>Zaritzky</i> , one year	1,420,000
<i>Korzakof</i> , 16 months	920,000
<i>Lanski</i> , about four years	3,200,000
<i>Yermolof</i> , 16 months	550,000
<i>Momonof</i> , 26 months	880,000
<i>Plato Zoubof</i> , in place at the death of the empress	2,700,000
<i>Valerian Zoubof</i> , his brother	800,000
Farther, an annual sum of 250,000 rubles for the expenses of the favourite, which for a term of 34 years makes	8,500,000
Sum total	88,820,000
To each estate were attached thousands of boors and their families. It is generally computed that of these were given:	
To the family of <i>Orlof</i>	45,000
To <i>Vassilievskoi</i>	7,000
To <i>Zavodoffky</i>	9,800
To <i>Korzakof</i>	4,000
To <i>Yermolof</i>	3,000
Total of boors	68,800

This statement does not include those given to *Potemkin*, to *Lanski*, nor to *Zoubof*, three favourites best beloved by Catharine, and to whom, of course, she gave the most.

During this reign, almost all the people in office and authority were fortunate adventurers. If we except the Soltikoffs, we shall find at this period no family of distinction in favour.

With respect to the government of Catharine, it was as mild and moderate, within the immediate circle of her influence, as it was arbitrary and terrible at a distance. Whoever, directly or indirectly, enjoyed the protection of the favourite, exercised, wherever he was situated, the most undisguised tyranny. He insulted his superiors, trampled on his inferiors, and violated justice, order, and the "ukases," with impunity. The empress having usurped a throne, which she was desirous of retaining, was under the necessity of treating her accomplices with kindness. Being a foreigner in the empire over which she reigned, she endeavoured

to identify herself with the natives by adopting and even flattering its tastes and its prejudices. She often knew how to reward, but never could resolve to punish, and it was solely by suffering her power to be abused, that she succeeded in preserving it.

The spirit of toleration that animated the whole of Catharine's administration exhibits a very remarkable and almost singular phenomenon in a despotic government. Notwithstanding all opposition, the empress adhered to the resolution she had formed at the commencement of her reign; and, from that moment to the day of her death, not one instance occurred, of a human being suffering, in any respect whatever, on account of his religious opinions. Towards heretics she always evinced great lenity of disposition. "Poor wretches," she once said, smiling, "since we know that they are to suffer so much and so long in the world to come, it is but reasonable that we should endeavour, by all means, to make their situation here as comfortable to them as we can." Not only the conquered provinces were protected in the free exercise of their religion, but Lutherans, Calvinists, Moravian brethren, Papists, Mahometans, Heathens, and people of all countries and persuasions, might aspire to any post under government, and hold any civil or military employment or dignity, if they were but worthy, or deemed worthy of it. The intolerant of more polished nations might go to the provinces of Lithuania, Livonia, Finland, and Russia, to take lessons of moderation and Christian forbearance. But at Petersburg the general and peculiar feature in the public character is toleration; and this virtue has there acquired so general and extensive a sway that it is not easy to find a spot of earth upon the globe, where, in this respect, a man may more quietly pass his days than at St. Petersburg.

The empress, not satisfied (as we have already observed) with having appointed a catholic archbishop, and established a seminary of Jesuits at Mohilow, and with having supported toleration in the Crimea, gave to her people almost every year some solemn instance of the protection she granted to the liberty of worship. On the day of the benediction of the waters, her confessor, by her orders, invited to his house the ecclesiastics of all communions, and gave them a grand entertainment, which Catharine called "the dinner of toleration." It has been calculated, that the offices of religion are performed in Petersburg in 14 different languages.

Catharine had two passions which never left her but with her last breath; the love of the other sex, which degenerated into licentiousness; and the love of glory, which sunk into vanity. By the former of these passions she was never so far governed as to become a Messalina; but she often disgraced both her rank and sex, and continued to be by habit what she had been from constitution. By the second, she was led to undertake many laudable projects, which were seldom completed: and to engage in unjust wars, from which she derived that kind of fame which is the usual result of success.

The generosity of Catharine, the splendour of her reign, the magnificence of her court, her institutions, her monuments, and her wars, were precisely to Russia what the age of Louis XIV. was to Europe; but considered individually, Catharine was greater than that prince. The French formed the glory of Louis; Catharine formed that of the Russians. She had not, like him, the advantage of reigning over a polished people; nor was she surrounded from infancy by great and accomplished characters. She had some subtle ambassadors, not unskilled in the diplomatic art, and some fortunate generals; but Romanzoff, Panin, and Potemkin excepted, she could not boast a single man of genius; for the wit, cunning, and dexterity of some of her ministers, the fetu-

rious valour of Suvarof, the ductile capacity of a Repnin, the favour of a Zakhof, the readiness of a Besborodko, and the assiduity of a Nicholas Soltikof, scarcely deserve to be admitted as excellencies. It was not that Russia did not produce men of merit; but Catharine feared such men, and they kept at a distance from her. We may conclude, therefore, that all her measures were her own, and particularly all the good she did. It should be recollected that in her private character, notwithstanding all the misfortunes and abuses that cast a shade over her brilliant reign, she appeared to be thoroughly humane and generous, as all who approached her experienced: all who were admitted to her intimacy were delighted with the good humoured follies of her wit: all who lived with her were happy. Her manners were gay and licentious, but she still preserved an exterior decorum, and even her favourites always treated her with respect. Her love never excited disgust, nor her familiarity contempt. She might be deceived, won, seduced; but she would never suffer herself to be governed. Her active and regular life, her moderation, firmness, fortitude, and even her temperance, are moral qualities which it would be highly unjust to ascribe to hypocrisy. How great might she not have been, if her heart had been as well governed as her mind! She reigned over the Russians less despotic than over herself; she was never hurried away by anger; never a prey to dejection, and never indulged in transports of immoderate joy. Caprice, ill-humour, and petulance, as they formed no part of her character, were never perceived in her conduct. "I will not decide," says the writer who has thus sketched the outlines of her character, "whether she was truly great, but she was certainly beloved." Her crimes, it is said, were the crimes of her station, not of her heart: the terrible butcheries of Ismail and of Praga appeared, to her court, to be humanity itself. If she had known misfortune she might probably have possessed the purest virtues; but she was spoiled by the unvaried prosperity of her arms. Vanity, that fatal rock to women, was so to Catharine; and her reign will ever bear the distinguishing characteristic of her sex. But, in whatever light she is considered, she will ever be placed in the first rank among those who by their genius, their talents, and especially, by their success, have attracted the admiration of mankind. Her sex, giving a bolder relief to the great qualities displayed by her on the throne, will place her above all comparison in history; and we must recur to the fabulous ages of an Isis and a Semiramis, to find a woman who has executed, or rather undertaken such daring projects. Whilst none surpassed her in noble and useful institutions, in the patronage of science and of the arts, and in the promotion of the arts by which a nation is civilized and exalted; and whilst by the travels of Palas, Græchin, and other philosophers and naturalists, she obtained an extensive acquaintance with the various parts and productions of her vast empire; she seems to have been too much seduced by splendid novelties, and by her assiduity and zeal in the purchase of expensive rarities throughout Europe, she merely sacrificed to her vanity, and sunk the wife and beneficent sovereign into the collector of toys and trinkets. Misled by an extravagant confidence in her own abilities, and jealous of every kind of fame, she was desirous of acquiring the reputation of an author, and of thus sharing in the honour which Frederic of Prussia had obtained by his writings. She accordingly wrote her celebrated "Instructions for a Code of Laws;" several moral tales and allegories, for the education of her grand-children; and a number of dramatic pieces and proverbs, which were acted and admired at the Hermitage. Her grand and futile undertaking of collect-

ing a number of words from 300 different languages, and forming them into a dictionary, was never executed. Of all her writings, her letters to Voltaire are certainly the best. They are more interesting than those of the old philosophical courtier himself, who repeats in his letters the same ideas and compliments in a hundred different forms, and excites her continually to drive the Turks out of Europe, instead of advising her to render her own subjects free and happy. Catharine was neither fond of poetry nor of music; and she often confessed it. She could not even endure the noise of the orchestra between the acts of a play, and therefore commonly silenced it. At her Tauridian palace she constantly dined with the two pictures of the sacking of Otechakof and Ismail before her eyes, in which Cazauova has represented, with hideous accuracy, the blood flowing in streams, the limbs torn from the bodies, and still palpitating, the demoniac fury of the slaughterers, and the convulsive agonies of the slaughtered. It was upon these scenes of horror that her attention and imagination were fixed, while Galparini and Mandini were displaying their vocal powers, or Sarti was conducting a concert in her presence.

Previous to the death of Catharine the monuments of her reign resembled already so many wrecks and dilapidations: colleges, colonies, education, establishments, manufactories, hospitals, canals, towns, fortresses, every thing had been begun, and every thing given up before it was finished. As soon as a project entered her head, all preceding ones gave place, and her thoughts were fixed on that alone, till some new idea was started and drew off her attention. She abandoned her code, to drive the Turks out of Europe. After the glorious peace of Kainardgi, she seemed for a time to attend to the interior administration of her affairs; but the whole was presently forgotten, that she might be queen of Tauris. Her next project was the re-establishment of the throne of Constantine; to which succeeded that of humbling and punishing the king of Sweden. Afterwards the invasion of Poland became her ruling passion; and then a second Pugathief might have arrived at the gates of Petersburg without forcing her to relinquish her hold. She died, again meditating the destruction of Sweden, the ruin of Prussia, and mortified at the successes of France and republicanism. This was she incessantly led away by some new passion still stronger in its influence than the preceding, so as to neglect her government, both in its whole and in its parts. This mania of Catharine, of planning every thing and completing nothing, drew from Joseph II. a very shrewd and satirical remark. During his travels in Taurida, he was invited by the empress to place the second stone of the town of Ekatarinoflaf, of which she had herself, with great parade, laid the first. On his return, he said, "I have finished in a single day a very important business with the empress of Russia; she has laid the first stone of a city, and I have laid the last."

We shall close this sketch of the character of Catharine with observing, that with all her various and contradictory qualities, she seems to have obtained the love as well as the reverence of her subjects in general; who forgot her private crimes and the evils of her bloody wars, in her greatness and apparent regard to the public good. Coxe's Travels, vol. i. and ii. Tooke's Life of Catharine II. in 3 vols. Rulhiere, Hist. on Anecdotes sur la Revolution de Russie, &c. Paris, 1797. Segur, Vie de Catharine II. Imperatrice de Russie, &c. 2 vols. 8vo. Paris, of which an enlarged translation in English was printed in three vols. 8vo. 1798. Secret Memoirs of the Court of Petersburg, &c. translated from the French.

CATHARINE of Sienna, St. was born in the city, whence

her name was derived, in 1347; and having vowed virginity at eight years of age, assumed the Dominican habit. Pretending to extraordinary revelations, and distinguished by her piety and charity, she obtained considerable influence; so that she succeeded in effecting a reconciliation between the Florentines and pope Gregory XI., by whom they had been excommunicated, and in persuading this pontiff to restore the papal seat to Rome, after it had subsisted 70 years at Avignon. During the schism that afterwards took place, Catharine adhered to Urban VI. She died in 1380, and in 1461, was canonized by pope Pius II. Of her works there are extant a volume of "Italian Letters," written to popes, princes, cardinals, &c. first printed at Venice in 1506, and translated into French in 1644; "Six Treatises on the Providence of God;" "A Discourse on the Annunciation of the Blessed Virgin," and a treatise entitled "The Divine Doctrine delivered by the Eternal Father speaking to the Spirit;" with some other devotional pieces. Du Pin. Eccl. Hist. vol. v. p. 73. See *Fraternity of St. CATHARINE.*

CATHARINE of Bologna, St. a nun of the order of St. Clare, was born at Bologna in 1413, and became, in consequence of her reputation for sanctity, superior of the monastery of the order to which she belonged, in her native city, and which was completed before her death, in 1463. Besides other writings in Latin and Italian, her own "Revelations" were left, sealed, to her confessor. She was canonized by Clement VII. Du Pin. Eccl. Hist. vol. v. p. 84.

CATHARINE, *Fraternity of St., at Sienna*, a sort of religious society instituted in that city, in honour of St. Catharine, a saint famous for her revelations, and for her marriage with Jesus Christ, whose wedding-ring is still preserved as a valuable relic. This fraternity yearly endows a certain number of destitute virgins, and has the privilege of redeeming annually two criminals condemned for murder, and the same number of debtors, by paying their debts.

CATHARINE, *Knights of St., of Mount Sinai*, an ancient military order, erected for the assistance and protection of pilgrims going to pay their devotions to the body of St. Catharine, a virgin of Alexandria, distinguished for her learning, and said to have suffered martyrdom under Maximin.

The body of the martyr having been discovered on mount Sinai, caused a great concourse of pilgrims; and travelling being very dangerous, by reason of the Arabs, an order of knighthood was erected in 1063, on the model of that of the Holy Sepulchre, and under the patronage of St. Catharine: the knights of which obliged themselves by oath to guard the body of the saint, keep the roads secure, observe the rule of St. Basil, and obey their grand master. Their habit was white, and on it were represented the instruments of martyrdom whereby the saint had suffered; viz. a half wheel armed with spikes, and traversed with a sword stained with blood.

CATHARINE, *order of St., in Modern History*, belongs to ladies of the first quality in the Russian court. It was instituted in 1714, by Catharine wife of Peter the Great, in memory of his signal escape from the Turks in 1711, or as others say, by Peter, in honour of his wife Catharine, on account of the assistance which she gave him in the camp on the Pruth.

The ensign of this order is a medal of gold, enriched with diamonds, having on one side the image of St. Catharine, and on the other a cross pattée, enameled. This is worn pendant to a broad white ribbon resting on the right shoulder, and brought under the left arm. On the left breast

breast of the upper vestment is an embroidered star with a cross in the centre, and this motto round it; *Pour l'amour de la fidelité envers la Patrie*; which was intended to commemorate the display of those virtues in the behaviour of Catharine on the banks of the Pruth. This order is bestowed only on ladies; it is extremely honourable; and worn only by a few of the first distinction, among whom are several of eminent rank in Germany. In 1790 their number was 25.

CATHARINE, St. Island of, in Geography, an island in the captainship or province of St. Vincent, on the coast of Brazil, extending from $27^{\circ} 19' 10''$, to $27^{\circ} 49' S.$ latitude, and in $W.$ longitude $47^{\circ} 37'$. Its breadth from $E.$ to $W.$ is not more than two leagues in the narrowest part. It is separated from the continent only by a channel of 200 toises in width. On the point at the mouth of this strait is built the city of "Nossa Senhora del Desferro," the capital of this commandery, where the governor resides. It contains, at most, 3000 inhabitants, and about 400 houses; and its appearance is very pleasing. According to Frezier's account, this island served, in 1712, as an asylum for a number of vagabonds, who escaped thither from different parts of Brazil, and who were but nominally subject to Portugal, as they acknowledged no lawful authority. The country is so fertile that they were able to subsist without any supplies from the neighbouring colonies; and as they were destitute of money, they could neither offer a temptation to the avarice of the governor-general of Brazil, nor inspire him with the hope of subduing them. The vessels which touched there gave them nothing in exchange for provisions but clothes and shirts, of which they were almost destitute. It was not till about the year 1740, that the court of Lisbon established a regular government in this island, and the adjacent parts on the continent. The government extends from north to south 60 leagues, from the river St. Francisco to Rio-grande. Its population amounts to 20,000, and is visibly increasing. Its present state is very different from that in which Frezier and lord Anson found it; as it has been considerably increased by the introduction of a great number of families, at the expence of the Portuguese government, during the years 1752, 1753, and 1754. This increase of population gave a new face to the establishment; and as these new colonists were diligent, laborious, and skilled in agriculture, the progress of the population must have been augmented, in proportion to these qualities of the inhabitants, and the great fertility of the soil, which produces, almost spontaneously, all sorts of fruits, vegetables, and grain. Its air is wholesome, and the inhabitants are healthy. Sassafras, guaiacum, oranges, lemons, citrons, cotton, and other trees, grow here in great perfection; and the potatoes of St. Catharine's are esteemed the best in the world. The island is covered with trees, that are always green; but so intermixed with briars and thorns, that the forests are impassable, without cutting away with the hatchet; and these are said to be infested with serpents whose bite is mortal. The houses, both on the island and continent, are all on the edge of the sea; and the woods which surround them yield a most delightful fragrance, from the number of orange-trees, and other aromatic plants and shrubs, with which they abound. Notwithstanding these advantages, the country is very poor, and wholly destitute of manufactures; inasmuch that the peasants are almost naked, or covered with rags. Their soil would be very suitable for the cultivation of sugar; but not being rich enough to purchase slaves, it is said that they cannot employ it for that purpose. The whale-fishery is very productive; but the crown has conferred an exclusive right to it on

a company at Lisbon. This company has, upon the coast, three considerable establishments, where they take about 400 whales every year, the produce of which, both in oil and spermaceti, is sent to Lisbon by way of Rio-Janeiro. The approach of ships to this island is very easy; as at 18 leagues in the offing there are 66 fathoms of water, over a bottom of soft mud, gradually shoaling till within four cables' length of the shore, where there are still four fathoms of water. The ordinary channel is between the island of Alvaredo and the north point of St. Catharine; but there is another between the islands of Gal and Alvaredo, which, however, has not yet been sufficiently explored. The best anchorage is half a league from Fortes island, in 6 fathoms, and oozy bottom; the citadel bearing $S. 3^{\circ} W.$, the fort on the larger point $S. 6^{\circ} E.$ There are several watering places both on the island and the continent; and that creek may be chosen where the wind renders the landing most easy. The navigation of boats is very difficult in this harbour, which is two leagues wide as far as the bight where the town stands; and there is a violent surf always breaking on the lee-shore. The tides are very irregular; and the flood comes in between the two channels lying north and south. Up to this bight it rises but three feet. In this harbour provisions of every kind may be easily and cheaply procured, as they are very plentiful. A large ox costs eight piasres, a hog of 150 lb. weight costs four, and turkeys are sold for a piasre the pair. Fish may be obtained in abundance by merely throwing the net. Oranges are sold at the rate of 500 for less than half a piasre, and vegetables of every kind are reasonable. The inhabitants are very hospitable, and their manners are gentle and obliging; but they are very superstitious, and jealous of their wives, who never appear in public. The government is in this island, as it is in all the Portuguese colonies, purely military. It has three forts, which form nearly an equilateral triangle, the base of which is to the northward, and the vertex towards the south. That to the east stands on the N.E. point of St. Catharine, about $\frac{1}{2}$ of a league from the Perrouget island: that to the west, which is the most considerable, is on an islet near the continent of America, and the third is upon the largest of the two islands called "Les Ratones." The road, which is open only to the N.E. winds, is sheltered to the east by the island of St. Catharine, and on the west by the continent; on the south by the land both of the island and the continent, which approach so near, that they leave between them only a strait of less than 300 toises wide. Its entrance cannot by any means be shut against ships of war of any rate or construction. It is so extensive that although the forts are mounted with guns of a great calibre, ships may anchor there very commodiously and securely, out of the reach of these guns. The principal fort, which is in fact only a large enclosed battery, is situated on a little island, of moderate elevation above the level of the sea, at about 300 toises from the terra firma, and opposite a rideau much higher than itself, is incapable of making a regular defence; yet this fort is the post of honour, where the general officer, who commands the whole settlement, would fix his quarters in case of an attack; but in time of peace he resides at "Nossa Senhora del Desferro," a town that is absolutely open, and only defended by a small battery, *à barbette*, on the island of St. Catharine, and on the easternmost point of the little strait above-mentioned, behind which the town is built. The garrison of the principal fort was, in 1785, composed of 50 men, badly clothed and ill paid, under the command of a captain. Perouet's Voyage, vol. i. and ii.

CATHARINENBURGH, or ECHATERINENBURG,
N
a province

a province of Asiatic Russia, formerly included in the government of Tobolsk, and since constituting one of the two provinces of the government of Perm. This is also the name of one of the seven districts of the province, seated on the river Iset, not far from its origin. Near Catharinensburgh are gold mines; the ore is very martial, commonly of a cubic form in a quartz matrix; and the gold is extracted by washing. The annual produce of pure gold never exceeded 200 pounds, and was commonly much less; in 1772 it was only 100 pounds. The gold is obtained at the rate of 40 guineas per pound; when coined, it produces 68l. 5s. so that the profit is not very considerable. At Catharinensburgh the crown has established a mint for coining the copper, produced from the imperial and private founderies, into that species of money which is current throughout Russia, and is transported by water to Moscow, Petersburg, and other parts. The value of copper money, annually coined, is 400,000l. The crown receives a pood of this metal upon an average at 1l. 2s. 6d. and issues it, when struck, at 3l. 4s.; so that government gains upon the copper coinage 257,625l. The town is seated upon the river Iset, which runs through it, and is regularly built in the German manner. It was begun by Peter I. in 1723, and finished in 1726 by his consort the czarina Catharine, from whom it derived its name. This town may be reckoned the centre of all the Siberian mine-works belonging to the crown; and on this account it is the residence of the director of the Siberian mines, who issues out his instructions to the sub-directors, and passes their accounts.

CATHARINENSLAF, CATHARINOSLAV, or ECATERINENSLAF, a government of Russia, which contains the greatest part of that territory which was wrested by the late empress Catharine II. from the Turks, and comprises New Russia, the former government of Azof, and Crim Tartary. It is divided into two provinces, viz. Catharinenslaf, including New Russia and Azof, and comprehending 14 districts, and Taurida or Crim Tartary. It is also the name of one of the districts of the province, seated on the Dnieper.

CATHARINENSLAF, CATHARINOSLAV, or the "glory of Catharine," the capital of the province built by the late empress, and seated near the spot where the small river Kiltzin falls into the Samara. It is colonized by many Greeks and Armenians from Crim Tartary, and by others who served in the preceding war against the Turks; 78 miles N.E. of Cherfon. N. lat. 47° 23' E. long. 35° 15'.

CATHARMA, from καθαρμα, *I expiate*, in *Antiquity*, some miserable or flagitious wretch, sacrificed to the gods, as an expiation for the plague, or other calamity. Such was the prophet Jonas, cast into the sea; and such, as some have supposed, does St. Paul wish himself to be. See **ACCURSED**.

CATHARMA, καθαρμα, from καθαρμα, *to purge*, in *Medicine*, imports the excrements purged from any part of the body; as the stomach, intestines, or bladder.

CATHARMOS, in *Medicine*, of the same derivation, implies purgation by medicines, or the cure of a disorder by superstitious ceremonies or sacrifices. The cure of the king's evil, by the royal touch, if such a thing had been effected, might be said to be performed by a *catharmos*.

CATHARPINS, in the *Rigging of a Ship*. See **CATHARPINGS**.

CATHARTIC EXTRACT. See **EXTRACTUM catharticum**.

CATHARTIC salt, sal catharticum amicum, a denomination given to what we improperly call Epsum salt.

CATHARTIC medicines, are those substances which quicken and increase the evacuation from the intestines by stool.

Medicines of this class have been employed by physicians

since the first dawn of physic; and have been administered with various views and intentions, according to the prevalent theories of the time, or the favourite doctrines of individuals. Those who were tainted with the tenets of judicial astrology, preferred purgatives at certain times and seasons; conceiving that they would prove more beneficial or hurtful, according to the junction or opposition of the planets, or the age of the moon. Those again, who were partial to the doctrines of the humoral pathology, employed cathartics with the intention of expelling peccant matter which had been separated from the mass of fluids by an appropriate fermentation. The same pathologists taught that different cathartics possessed distinct powers, and moved different fluids by a specific action. Hence they have denominated some of these substances *cholagogues*, others *phlegmagogues*, *hydragogues*, and *melanagogues*, as they were supposed to expel more particularly bile, phlegm, water, &c.; and they have displayed much apparent sagacity, in selecting the cathartic adapted to the expulsion of the fluid prevalent at the time. But these doctrines are now exploded, and the specific operation is not confirmed by subsequent experience.

Modern physicians have two objects in view in the administration of cathartic medicines; the one is to empty the bowels simply, or to bring off their contents, which are out of the course of the circulation, and therefore, already, in a manner, extraneous to the body; the other is to excite an increased secretion of fluids into the cavity of the intestines, or, in other words, to induce purging. The medicines thus employed have generally been assorted into two classes; those which produce the former effect, being denominated *laxatives*, and those conducing to the latter, *purgative*.

The operation of a purgative medicine on the intestinal canal may be considered as three-fold. In the first place, it stimulates the muscular fibres of the intestines, quickens their action, and therefore augments the natural peristaltic motion of the bowels, by which means their present contents are more quickly propelled and discharged. Secondly, it stimulates the exhalent vessels, which terminate in the inner coat of the intestines, and excites them to pour out a more copious discharge of fluids; and also the mouths of the excretory ducts of the mucous glands, by which the natural mucus of the intestines is much increased; and hence the evacuations by stool are not only quicker, but the fecal matter is thinner and more abundant. And, thirdly, the stools are rendered still more copious, by an additional portion of the fluids furnished by the neighbouring viscera, the liver, pancreas, &c. to which the stimulus of a purgative, especially of the more active ones, extends. These effects are probably communicated to the whole range of the intestinal canal, from the upper orifice of the stomach to the lower extremity of the rectum, or anus.

From this view of the immediate effects of cathartic medicines upon the intestines, their utility in some diseases, and their injurious tendency in others, as well as the necessity of varying their degree of activity under different circumstances, will be readily understood.

If we consider the great length of the alimentary canal, and the number of vessels and mucous follicles, as well as the larger ducts from the liver and pancreas, which open upon its inner surface, it will be obvious that purgatives, even of a moderate stimulating power, by opening at once all these outlets, may occasion a great general evacuation and diminution of the fluids of the body. Hence, in acute inflammatory diseases, where over-distention of the vessels is to be avoided, and the preternatural increase of the active powers of the system is to be restrained, the evacuation of the intestines by purging is (next to blood-letting) the most powerful expedient,

dient, and generally makes an important part of what is called the cooling or antiphlogistic plan of treatment. When purgatives are given with this intention, however, the principle must be pursued with some limitation, and those of the most acrid and drastic nature must be avoided; because the diminution of general stimulus produced by the depletion of the vessels, and the expulsion of the feces, would be counterbalanced by the extraordinary irritation of an acrid purge.

Another circumstance apparently results from the evacuation by purging, which renders it of considerable importance in particular diseases; namely, a change in the distribution of the blood to the different parts of the system. It seems to follow, of necessity, that if an evacuation be made from one set of vessels, the afflux of fluids to these will be increased in order to supply it, and, consequently, the afflux to other parts of the system will be diminished. Upon this principle, Dr. Cullen explains the utility of purgatives in disorders of the head, which arise from over-fullness or over-activity of the vessels of the brain; such as apoplexy, and other comatose affections, mania, phrensy, head-ach, &c. The afflux of fluids in the vessels of the abdomen, which supply the intestines, being increased by purging, the afflux will be proportionally diminished in the vessels which carry blood to the head, and both the quantity and impetus of the blood in the head will thus be lessened. (Cullen, *Mater. Med.* vol. ii.)

In the same way he partly explains the good effects of cathartics in the small pox, and other cutaneous diseases, from the balance of the distribution of the fluids between the internal parts and the external surface. But it is probable that they are more useful by removing the local irritation of the feces, and occasioning a considerable depletion, and a consequent diminution of fever in the system at large. For in diseases of the skin, unconnected with fever, their good effects are very inconsiderable.

Whenever the contents of the intestines are morbidly retained, whether in consequence of a slowness of the peristaltic motion, from a torpor of the moving fibres; or from a laxity of the intestines, which permits the feces to accumulate; or from a deficiency of bile; or from habitual neglect of regular evacuation; (see CONSTIPATION,) the use of cathartics of one kind or the other is indicated, in order to prevent the accession of more serious complaints, which will ultimately result from the costiveness. The nature of the cause, or the concomitant circumstances will point out the particular sort of medicine, which may be most appropriately employed. If the costiveness, for instance, be accompanied with a flaccid habit, or with symptoms of nervous mobility, or much flatulence, and irregular distention of the bowels, some of the warmer aromatic laxatives should be administered. If the secretion of bile appear to be deficient, mercurial and aloetic medicines, the latter of which tend to supply the deficiency, and the former to restore the bilious secretion, should be preferred.

In those cases, however, in which the morbid retention of feces is not habitual, but accidental, and accompanied with some more acute symptom;—as with violent pain, constituting the colic;—with pain, tenesmus, and slimy or bloody stools, as in dysentery;—or with pain and acute fever, as in inflammation of the bowels;—cathartics, though absolutely necessary, must be varied in their nature and mode of administration, after a cautious view of the circumstances. In colic, for example, they will be of little advantage in many cases, and more especially in the colic produced by lead, until the painful spasmodic contraction of the bowels has been relaxed by the previous use of opiates. In dysentery, they must be combined or alternated with opiates, otherwise the irritation

which they occasion, in that tender state of the intestines, will counterbalance the effects of the evacuation, and keep up the symptoms of the disease. And in enteritis, or inflammation of the coats of the alimentary canal, the same irritation will tend to increase the inflammatory condition, and the consequent constriction, and therefore impede, rather than expedite, the evacuation of the fecal matter, if they be employed before blood-letting and other remedies have reduced the inflammatory state. See COLIC, DYSENTERY, &c.

In a work lately published by an excellent practical physician, Dr. James Hamilton of Edinburgh, a degree of importance is assigned to cathartic medicines, in the treatment of several diseases, which they have not hitherto been considered as entitled to. Independently of the generally admitted opinion, that a loaded and constipated state of the intestinal canal is a common cause of general bad health, he maintains that this state usually accompanies and aggravates the other symptoms of fever; and that it is also the immediate cause, or a leading and permanent symptom, of certain disorders peculiar to children and young people; these are chorea, or St. Vitus's dance; *marasmus chlorosis*, or green sickness; *Hæmatemesis*, or vomiting of blood; and even in *Hysteria*, and some chronic nervous diseases. In these diseases he never uses medicines in a purging dose; his intention being simply to expel the present contents of the intestines, and not to increase the secretion of the fluids into them. He considers glysters as inefficient expedients for moving and conveying off, through the whole extent of the intestines, the feculent matter, rendered offensive and irritating, especially in fevers, by constipation, and by the changed nature of the secreted fluids, which seems to take place in the febrile state. In Typhus fever, he says, "it is now some years since I have left off almost entirely the practice of ordering emetics and glysters. I trust to a purgative, to ensure a regular alvine evacuation: for this purpose, however, a daily purgative is not always required. Thus I think I conduct the treatment of typhus fever to a favourable issue, with more certainty, and with the greater ease and comfort of the patient." We have had an opportunity, in a few instances, of verifying in a very satisfactory manner this important practice.

Chorea, or St. Vitus's dance, has been almost invariably treated with tonic medicines, especially with bark and metallic preparations, and with various stimulants and antispasmodics. It is unnecessary to say with how little effect in general. In every instance Dr. Hamilton has found that a large quantity of black and offensive feculent matter was collected in the bowels, and his plan of cure has consisted in a regular exhibition of laxatives, until the stools (which in all the diseases before mentioned should be regularly examined by the practitioner) assumed their natural appearance. With this intention the practitioner must persevere firmly in his measures, especially in the confirmed state of chorea; for if he relaxes he will be unsuccessful. By this treatment, which consisted in giving three grains of calomel, with six, eight, or ten, of jalap, daily, "Chorea is speedily cured, generally in ten days or a fortnight."

By means of the same, or similar medicines, exhibited in the same way, he has speedily succeeded in removing the symptoms of chlorosis, and hæmatemesis, and of some other hypochondriacal and nervous complaints; and he attributes the relief, which patients under these disorders derive from drinking mineral waters, to their purgative qualities, rather than to any other property which they may in a slight degree possess. (See Observations on the Utility and Administration of Purgative Medicines.)

When morbid or extraneous bodies are introduced into or generated

generated in the intestines, as in the case of worms, &c. cathartics are obviously indicated. But it should be observed, that the indiscriminate use of active purgatives in these cases, especially in young and delicate children, is often productive of more harm to the constitution, than the worms which they are intended to expel. They should be administered sparingly, and at some intervals; sufficient time being interposed for the operation of medicines, which may be deleterious to the animal, and of those, which, by purgating the intestines, may prevent that morbid production of mucus, which is probably a nidus favourable to their generation.

Cathartics, either in a laxative or purgative degree, are useful in several other complaints, partly by exciting the intestines to evacuation, and partly in consequence of the extension of their stimulus to the neighbouring viscera of the abdomen: as in jaundice, indigestion, suppression of the menses, &c.

Another important operation of cathartic medicines remains to be noticed; namely, the stimulus they exert on the absorbent vessels, by which these vessels are excited to an unusual action, and thus to take up fluids which are morbidly effused. The fact is undoubted, whatever may be the principles on which it is explained. Dr. Cullen observes, on this subject, that, "as in every cavity of the body there is an exhalation and inhalation, or absorption, constantly going on, it is presumed that there is some balance constantly preserved between the secretory and absorbent powers; so that if the former are increased, the latter will be also; and, therefore, that when the secretions are, upon occasion, much increased, the action of the absorbents may be particularly excited. This explains why purging often excites the action of the absorbents, to take up more copiously the fluids that were otherwise stagnant in the adipose membrane, or other cavities of the body, and thereby often proves a cure of dropsy." (Mater. Med. vol. ii. p. 502.) This explanation is perhaps, little more than an explicit statement of the fact. It is certain, however, that *ascites*, or dropsy of the abdomen, has been often affected by means of acrid, drastic purgatives, such as gamboge, scammony, &c. when diuretic remedies have failed. But it is obvious that these remedies can only be administered to those, who retain considerable strength of constitution, debilitated neither by inveterate intemperance, old age, nor a long disease.

Cathartic medicines may be introduced into the alimentary canal either by the mouth, or by the inferior aperture in the form of clyster. The preceding observations apply to the former mode of administering them. The latter must be adopted in those cases, in which the stomach is unable to retain, or would be injured by irritating medicines; as in *gastritis*, or inflammation of the stomach, and in febrile complaints attended with extreme debility, especially in the latter stages: since by this mode the contents of the lower parts of the intestines are simply evacuated, without any stimulus to the secreting vessels, and with little or no irritation of the system at large. See *CLYSTER*.

In delicate and irritable constitutions the ill effects of an active purgative may be considerably diminished, without impairing its evacuating power, by combining a portion of opium with it. The nausea and griping, which are excited by some species of cathartics, may be alleviated by the addition of some aromatic medicine; or by the minute division of the substance by means of trituration with some other; as of jalap with crystals of tartar, &c.; or by giving it in divided doses at short intervals. This last mode is

generally to be preferred with regard to very drastic cathartics; by which means the full effect is ensured, and any febrile or dangerous degree of irritation is avoided.

CATHAY, in *Geography*, an ancient name of China; which see.

CATHEDRA, in a general sense, a chair.

The word is more particularly used for a professor's chair, and a preacher's pulpit.

CATHEDRA is also used for the bishop's see, or throne, in a church.

CATHEDRA, *ex*, a phrase used in speaking of the solemn dictates or decisions of prelates, chiefly the popes, delivered in their pontifical capacity.

The advocates for the papacy maintain, that the pope is infallible, *ex cathedra*, a term of modern theology entirely unknown to the ancients. Even those who used it do not agree in the explication of it.

CATHEDRAL, a church wherein is a bishop's see, or seat. See *CHURCH* and *BISHOP*.

The word comes from the Greek *καθῆδρα*, *chair*, of *καθίζω*, *to sit*.

The denomination cathedral seems to have taken its rise from the manner of sitting in the ancient churches, or assemblies of primitive Christians; in these the council, i. e. the elders and priests, was called *presbyterium*; at their head was the bishop, who held the place of chairman, *cathedraticus*, or *cathedraticus*; and the presbyters, who sat on either side, were also called by the ancient fathers *assessores episcoporum*. The episcopal authority did not reside in the bishop alone, but in all the presbyters, of whom the bishop was president.

A cathedral, therefore, originally, was different from what it is now; the Christians, till the time of Constantine, having no liberty to build any temple; by their churches, they only meant their assemblies; and by cathedrals, nothing more than consistory:—whence appears the vanity of some authors, especially the Spaniards, who pretend their cathedrals to have been built in the times of the apostles.

CATHEDRAL Service. At the beginning of the reformation, the whole English choral service, including the preces, prayers, and responses, was set to musical notes, and first published in 1550, by John Marbeck, organist of Windsor. The premature reforming zeal of this musician, nearly made a martyr of him, in the time of Henry VIII. He had, indeed, the honour of being condemned to the stake, with three other persons, who were burnt for heresy, but was pardoned by the intercession of Sir Humphrey Folster.

His notation of the English cathedral service was published under the following title:

The Booke of Common-Prayer, noted.

1550.

Imprinted by Richard Grafton, Printer to the Kinges Majestie, *cum privilegio ad imprimendum solum*.

As this book is become very scarce, we shall present the reader with a considerable extract from it.

"In this booke is conteyned fo muche of the order of common-prayer, as is to be song in churches: wherein are used only these iiiii sortes of notes.

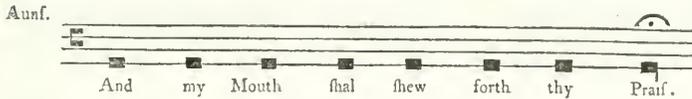

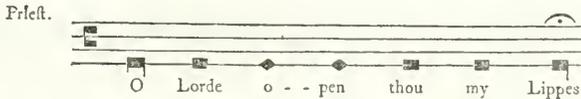

CATHEDRAL SERVICE.

The first note is a firene * note, and is a breve. The second is a square note, and is a femy-breve. The iii, a prycke note, that prycke is half as muche as the note that goeth before it. The iiii is a clofe, and is only used at the end of a verfe." and is a mynymme, and where there is a prycke by the square

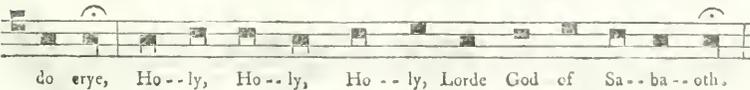

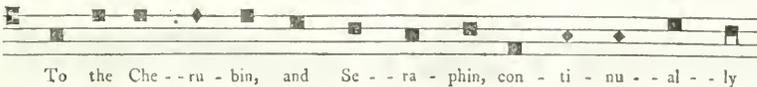

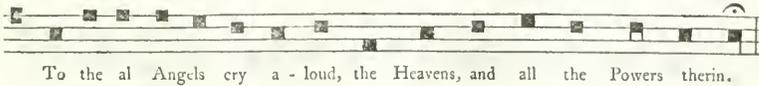

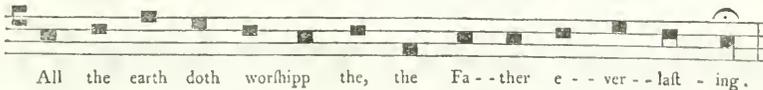

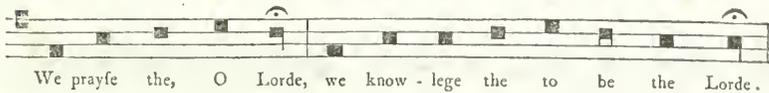

* Strained, or stretched out: perhaps from its being the longest note used in chanting. Junius makes firene and frairn synonymous.

MATTINS.

The Quere with the Priest.

Te Deum Laudamus.

CATHEDRAL SERVICE.

CATHEDRAL SERVICE.

After the Second Lesson one of these that follow.

BENEDICTUS DOMINUS.

Bleſ - ſed be the Lorde God of If - - ra - - el

The ſame Chant repeated to the end.

for he hath Viſit - - ed and Redeem - ed his People, &c.

Bleſ - ſed be the Lorde God of If - - ra - - el for he hath

Vi - ſi - ted and Re - de - med his People, &c. to the end.

In this manner the whole Morning and Evening Service, as it is now Chanted, is ſet; except the Litany. At the end is the name of JOHN MERBECKE.

At this time, the *plain-fong* of the Romiſh church in the chants of the principal hymns and reſponſes, remained nearly the ſame, as may be ſeen in comparing the *Te Deum laudamus*, and other parts of the cathedral ſervice, in this publication, with the miſſals, graduals, and antiphonaria of thoſe times. The chant to the *Te Deum*, as publiſhed by Meibomius, (*Antiquæ Muſ. Auc̄t. Sept. Amſt. 1652. Vide præf. Lectori benevolo*.) from a copy nearly as ancient as the hymn itſelf, and another example of the ſame *Canto Fermo*, given by Glareanus, (*Dodecad. p. 110.*) in 1547, correſpond exactly with that which was retained by Marbeck, at the time of the reformation: as the mode, the dominant, and mediũs, are all the ſame; nor is the leaſt deviation diſcoverable, except where the different number of ſyllables in the tranſlation required it, and which affect the melody no more, than thoſe ſlight changes which happen in the manner or uſe of any two choirs in ſinging the ſame chants, or even in adjusting different ſtanſas of any ſong to the ſame tune.

Marbeck was admitted, in 1549, to the degree of bachelor in muſic, at Oxford, according to Anthony Wood, (*Faſti Oxon.*) who erroneouſly calls him James Marbeck: he is honourably mentioned by Bale, becauſe he had been perfeſted by the Catholics, and his name is omitted by Pitts, for the ſame reaſon.

It ſeems as if we may ſafely conclude, that the chief part of ſuch portions of Scripture, or hymns of the church, as have been ſet by Engliſh muſicians to Latin words, were produced before the reformation, or, at leaſt, in queen Mary's time; that is, before the year 1558, when queen Elizabeth aſcended the throne, by which time a ſchool of counterpoint was formed in this country, that was equal, at leaſt, to that of any other part of Europe. A reaſon, however, may be aſſigned for the choral muſic of every

Chriſtian country approaching perfeſtion by nearly equal ſtrides.

Before the reformation, as there was but one religion, there was but one kind of muſic in Europe, which was plain chant, and the diſcant built upon that foundation; and as this muſic was likewiſe only applied to one language, the Latin, it accounts for the compoſitions of Italy, France, Spain, Germany, Flanders, and England, keeping pace with each other, in ſtyle and excellence. All the arts ſeem to have been the companions, if not the produce, of ſucceſſful commerce; and they will, in general, be found to have purſued the ſame courſe, which an admirable modern hiſtorian has ſo well delineated: (*Hiſt. of Charles V. vol. i. ſect. 1.*) that is, like commerce, they will be found, upon inquiry, to have appeared firſt in Italy; then in the Hanſeatic towns; next in the Netherlands; and by tranſplantation, during the 16th century, when commerce became general, to have grown, flouriſhed, matured, and diffuſed their influence, in every part of Europe.

If this were a place to illuſtrate ſuch an idea, it would be eaſy to ſhew, that eccleſiaſtical muſic, in the middle ages, was alſo derived from the papal chapel, and court of Rome; that counterpoint was firſt cultivated for their uſe; that it travelled thence to the Hanſeatic towns, and the Netherlands, where the ſilence, which flowed from ſucceſſful commerce, afforded encouragement and leiſure for its cultivation; till about the middle of the 16th century, when, by the general intercourſe which traffic and the new art of printing introduced, all the improvements in harmony, which had been made in Italy and the Low Countries, were communicated to every other part of Europe; which not only ſtimulated the natives to adopt and imitate them, but to improve and render them more perfeſt, by their own inventions and refinements.

CATHEDRATIC *doctōr, doctōr cathedraicus*, denotes a doctōr possessed of a chair or fellowship in some of the universities of Spain.

They say a *cathedratic doctōr* of Salamanca, of Alcalá, &c.

CATHEDRATICUM, in *Ecclesiastical Writers*, denotes a sum of money, amounting to two shillings, anciently paid annually by the inferior clergy to their bishop, or as often as he visited his diocese, *ob honorem cathedrae*, i. e. as an argument of their subjection, and for the honour of the bishop's see or cathedra. This was otherwise denominated *synodaticum*, and by modern writers *PROCURATION*.

CATHEDRATICUM also denotes a sum which bishops newly ordained gave partly to bishops or patriarchs, by whom they were consecrated, and partly to the clerks and notaries who officiated on the occasion.

This was also called *επισκοπιον*, as being given on account of the throne, or chair, they had now obtained, and *synodaticum*, or *SYNOVALS*.

Bishops consecrated by patriarchs or metropolitans, provided their church was not worth less than thirty pounds of gold, were to pay a hundred solidi by way of cathedral-tiaticum.

CATHEM, in *Geography*, a town of Arabia, 80 miles S. of Bassora, and 170 N. of El Catif. N. lat. 29°. E. long. 47° 14'.

CATHERON. See **CATTENOM**.

CATHERETIC. See **CATHARETIC**.

CATHERINA, SANTA, in *Geography*, a small Grecian island, which seems to have been detached from the south point of the isle of Rhodes. It is a remnant of the land which joined it to another country, in like manner insulated, and which bears the name of the island of Scarpanto.

CATHERINE, in *Biography*. See **CATHARINE**.

CATHERINE, ST. in *Geography*, a pleasant island in the harbour of Sunbury, and itate of Georgia, in North America.—Also, a small productive island on the south coast of St. Domingo, 20 leagues E. of the town of St. Domingo.

CATHERINE'S Town, a town of America, in the state of New York, and county of Ontario, situate 3 miles S. of the S. extremity of Seneca lake.

CATHERINE Bay lies at the E. end of the island of Jersey, fourthward of the point so called, and affords a good road in westerly winds.

CATHERINE, St. Cape, lies on the W. coast of Africa, in S. lat. 2° 9', and E. long. 10° 38'.

CATHERINE'S Foreland lies in the straits of Maghellan, near the east end. N. lat. 52° 48'. W. long. 67° 50'.

CATHERINE'S Island, an island of N. America, on the coast of Florida. N. lat. 31° 36'. W. long. 81° 41'.—Also, an island off the coast of Honduras. See **PROVIDENCE island**.

CATHERINE Sound lies, with a small island of the same name, on the coast of Georgia, in N. America, in 31° 10' N. lat.

CATHERINE'S St. Tower, a sea-mark on the summit of St. Catherine's hill down, on the back of the Isle of Wight, about 750 feet higher than high-water mark. N. lat. 50° 34'. W. long. 1° 19'.

CATHERLOUGH. See **CARLOW**.

CATHERTER, in *Surgery*, a curved tube employed for drawing off the urine, or injecting fluids into the bladder. The term *καθετήρ* is derived from *καθίςμι, demitto, to thrust into*; and although it signifies a hollow instrument, or siphon, for the above purpose, in the writings of Celsus, Galen, and Paulus Æginetæ, this word has a very different meaning in

the works of Hippocrates, who uses it to denote a piece of twisted cotton or lint introduced into ulcers. Vide *Defin. Medic. Gorrhæi*.

It appears from lib. vii. cap. 26. of *Corn. Celsus's* surgical work, that catheters were formed at first of polished copper or brass, though the Arabians made them of silver, lead, tin, or leather; and there can be no doubt that they were used by the ancients, not only for drawing off the urine, but for the purpose of removing obstructions in the urethra, as we now employ *boagies*: this is further evident from a passage in Galen, *De Locis Affectis*, lib. i. where he treats of *carmcles* in the urinary passage. See likewise Galeni *De Meth. Med. lib. v. cap. v.*

It is also perfectly certain (notwithstanding the late claims of Mr. Jesse Foot, in his tract upon the "Vesicæ Lotura,") that the older surgeons were accustomed, on various occasions, to inject the bladder through a catheter or cannula, precisely in the manner we administer an *enema*. Vide Pauli Æginetæ, lib. vi. cap. 59. "De Catheterismo & Clystere Vesicæ;" likewise, Albucaasis, lib. ii. sect. 50. "De Modo Vesicæ Liqueore Syringa infundendi, & de Forma Instrumentorum ad hoc idoneorum." Gorrhæus describes the operation of using the catheter as follows: "Καθετήρῃς ἐστὶν ἀδμινηστῆρις χιρουργικῆς ratio qua injicimus per Catheterem in vesicam id quod ad ejus curacionem convenit; vel eximimus id quod impedit ne urina reddatur, five contentus intus sanguis sit, five aliud quippiam, recto siphone immisso, quem Græci καθετήρα vocant." For a particular account of the ancient modes of injecting the urinary bladder, we refer the inquisitive reader more especially to the 59th section of Albucaasis, already quoted, and to Avicenna, lib. iii. Fen. 19. Tract. 2. cap. 9. This practice was continued by several surgeons of the middle age, but soon afterwards appears to have been generally neglected, until it was revived by Le Dran.

Although the original as well as the present use of the catheter null necessarily have required it to be made of a tubular form, it is strange that this instrument has been described by many respectable French surgeons as a solid instrument! Thus, for example, M. Sue (in his *Dict. de Chir.*) expressly says, "Mal-à-propos confond-on le cathéter avec la sonde: Le cathéter n'a point de cavité intérieure, mais seulement une cannelure qui regne tout le long de sa partie convexe, au lieu que le sonde est creuse intérieurement. Le premier instrument sert à connoître les pierres qui sont dans la vessie, & à faire l'opération de la taille. Le second sert à évacuer l'urine contenue dans la vessie. Il est vraie que, dans plusieurs cas, celui-ci peut supplier à l'autre, mais non pas le premier au second." Again he tells us, "Le cathéterisme n'est autre chose que l'introduction du cathéter dans la vessie, p ur s'assurer de l'existence d'une pierre, ou faire l'opération de la taille & non pas pour évacuer l'urine; ce qui peut se faire qu'avec la sonde."

In the old French Encyclopédie, M. Louis says, that "some authors are accustomed to give the name of catheter "more particularly to a grooved sound which serves to conduct the lithotome in the operation of cutting for the "stone;" whereas, by all English surgeons, this instrument is called a *staff*. (See Article **LITHOTOMY**.) The *sound* is a solid steel instrument, without any groove: the *staff* is made of the same form and materials as the *sound*, but is grooved on its convex side; and the *catheter* is hollow throughout its whole extent, whatever materials it be made of. The *sound* and the *staff* are always curved to the shape of the urethra, and are inflexible; but the catheter may be made either of a rigid or a yielding substance; and in the

former case it may also be curved like the sound. The flexible catheters are now generally made of wove silk cylinders, covered with a coat of elastic gum; the bell has been fabricated hitherto by M. Bernard of Paris, but they are at present well manufactured by Mr. Walsh of London. Their size and form vary, according to the sex or age of the patient. Bernstein, in his dictionary of surgery, gives the following account of this instrument, as it is fabricated in Germany.—“One of the most useful inventions which have been made with respect to these instruments, is to construct them of elastic gum, and the merit of this invention is to be ascribed, without doubt, to Mr. Theden. (*Neue Bemerkungen u. Erfahrungen, &c.* Th. ii. Berlin, 1782. pag. 133.) They were afterwards improved by a silver-smith at Paris, of the name of Bernard, who directed not to apply the dissolved elastic gum to a wire-cylinder, as Mr. Theden had done, but to one made of smutted silk; and these catheters certainly deserve to be recommended in preference to all others. But with respect to their price, the elastic catheters that are prepared by prof. Pichel, (Richter's Chirurg. Bibliothek. B. vi. p. 512.) of Wirzburg, deserve particular recommendation. These consist of silk cylinders plaited or worked upon a probe, and afterwards covered with the following varnish. Three parts of white lead, minium, or sugar of lead with boiled linseed oil, which is the common varnish used by cabinet makers, mixed with one part of melted amber, and the same quantity of oil of turpentine. With this varnish he spreads the silk cylinders, and repeats this three times as soon as the former coating has dried in the open air; after which he puts the catheters into a baker's oven 24 hours, when bread has been baked in it the last time, and when it retains the temperature of 60°—70° Reaum. Here he lets them remain 10 or 12 hours. When he has taken the catheter out of the oven, he rubs the inequalities off a little with pumice stone, sews up the end, cuts into it the oblong lateral aperture, and then spreads it 12 or 15 times more with the varnish formerly mentioned. Every time, however, the catheter must be well dried in the open air before the varnish is spread upon it again, and after every third coating which it has received, it must be put again into the bake oven, so that in all it must have received from 15 to 18 coatings with varnish, and have been laid five or six times in the oven. The end is smoothed off with oil. Each of these catheters costs a dollar.”

The flexible catheters possess great advantages over those made of metal. For, in the first place, they can be introduced much more easily than the metal ones, even by an unpractised hand. 2. They may be suffered to remain in the urethra and bladder as long as is necessary, without occasioning much inconvenience. 3. There is no danger of injuring the tender surface of the urethra with them, or of pieces breaking off and remaining behind. 4. They may be used equally conveniently both for children and adults.

Another very important use may be made of elastic catheters in all cases in which the introduction of nourishment by the mouth is impeded or obstructed, as in wounds of the pharynx, in tetanus, hydrophobia, &c. In such cases an elastic catheter is introduced through the nose into the œsophagus, where it may be suffered to remain without occasioning any material inconvenience to the patient; and nourishment and drink may thus be introduced through it into the patient's stomach. In applying the instrument, it easily happens that the end of the tube gets into the larynx instead of the pharynx. This error is generally discovered merely by the circumstance that the flame of a candle, when held before the external aperture of the tube, is thrown into violent motion.—Dr. Hales describes a catheter of a new

structure, contrived for the more advantageous injection of lithontriptics into the bladder. Its cavity is divided lengthways by a thin partition into two separate channels, which end in two diverging branches. By one of these branches the menstruum is to be injected into the bladder, in the common, or rather in the hydrostatic way, while it returns mixed with urine by the other. Hales, *Hæmorrhæ. p. 112.*

There is likewise a description in the Philosophical Transactions, vol. xliii. p. 400, of an ingenious catheter invented by M. Le Cat, at Rouen; and other surgeons have recommended an instrument made of silver-wire, flattened, and turned spirally, so as to be hollow and flexible. These contrivances are certainly very specious, but they are too complex to be useful in ordinary practice.

Concerning the introduction of the catheter into the urinary bladder, see the following article.

CATHETERISM, is the act of passing a catheter into the urinary bladder, with a view to draw off the urine, or to facilitate the introduction of fluids into the bladder by means of a syringe.

The introduction of a flexible catheter, of elastic gum, such as is in common use among surgeons, can scarcely give any trouble; unless there be a considerable obstruction in the urethra, which may prove the occasion of insuperable difficulties. The observations which follow are intended chiefly to apply to the silver male catheter, which is generally used in cases requiring an evacuation of urine, or the injection of some fluid into the bladder. This little operation, simple as it may appear to an inexperienced bystander, is, in fact, sometimes one of the most perplexing to men of real ability, and therefore deserves the young surgeon's particular attention.

“I do not know,” says Mr. John Bell, in his Principles, of Surgery, vol. ii. p. 209, “that even the operation of lithotomy itself is more difficult than that of introducing the catheter; more important it cannot be, than an operation which gives relief in accidents and difficulties so extremely common and so very afflicting.” The first cause of embarrassment in performing this operation arises often from the incumbent position of the patient, which renders it necessary (at least surgeons have generally thought it necessary) to pass the catheter with its concave part towards the abdomen. This position, however, except in male subjects requiring lithotomy, is seldom the most eligible; as we have found a standing posture by far the most convenient for the operator's accommodation, provided the patient is not exceedingly fat and corpulent.

Suppose the surgeon sits on a low chair, or kneels on his right knee, while the patient stands before him, leaning against something immovable. The operator then holds the penis with the middle finger of his left hand, and the glans with the fore finger and thumb of the same hand; chiefly in order to expose the orifice of the urethra. The handle of the catheter, previously oiled, he holds with his fore finger, thumb, and middle finger of the other hand, and directs it in such a manner that its straight posterior part is placed near the belly of the patient, and parallel with the axis of his body; and he thus introduces its point into the orifice of the urethra. The surgeon then draws the penis gently towards him and extends it, pushing the catheter forwards at the same time with the utmost caution, till its point has arrived at the bend of the os pubis; and in order now to introduce the catheter completely into the curvature of the urethra, the operator must suddenly depress the hand, with which he holds the upper part of the catheter, towards the thighs, and thus raise up the point of the instrument; so that it passes behind the pubis, into the bladder itself.

In the other method, the operator gives the catheter such a direction, with the hand next to the patient's thighs, as to turn the elevated convex part of the instrument upwards, and to place the straight part under the belly before the thighs; the point of the catheter is then cautiously introduced into the orifice of the urethra and the bladder, whilst the penis is somewhat extended with the other hand. When the point of the catheter has arrived at the place where the urethra passes under the os pubis, the operator must turn both the catheter and the penis, so as to make both describe a femicircle: this he does by turning them towards the groin at the opposite side; and from hence towards the belly; in which motion the point of the catheter must represent the centre, as it were, round which the other parts revolve. At last the hand with which the catheter is directed, must be lowered a little, and the rest of the operation completed in the same manner as before. These two methods of introducing the catheter, differ only in this, that in the first the introduction is performed at once; but in the second (which is conceitedly termed "*sonder par le tour du maitre*") it is done by two different manœuvres, and consequently the operation is unnecessarily lengthened.

CATHETOLIPES, in *Natural History*, the name of a genus of fossils of the class of the *selenites*, but differing from the common kinds in the disposition of the constituent plates.

The word is derived from *καθητες*, perpendicular, and *πλαταις*, a scale or plate, and expresses a set of these bodies whose plates are ranged perpendicularly. All the known *selenites*, except those of this genus, are composed of a number of parallel plates, or thin flakes, ranged evenly horizontally on one another.

CATHETO-PLATEUS, in *Ichthyology*, a term with its opposite, which is *plagioplateus*, very much used by Artedi, in his description of fishes, but not adopted by Linnæus, or more recent ichthyologists; they may be explained in English by the two familiar words, compressed and depressed. The heads of fishes are the parts principally characterized by these terms.

CATHETUS, in *Architecture*, is a perpendicular line, supposed to pass through the middle of a cylindrical body, as a column.

Cathetus is sometimes applied to a line in the Ionic capital, passing perpendicularly through the eye or centre of the volute. This is otherwise called the axis of the *volute*, which see.

CATHETUS, in *Botany*, Lourciro; Flor. Cochinch. Clafs and order, *diacia monandria*.

Gen. Ch. Male. Cal. Leaves six, almost round, concave; three outer ones smaller. Cor. none. *N.S.* six two-lobed glands. Stam. Filament one, short; anthers three, oval. Female. Calyx six-cleft; segments roundish, concave. Cor. none. Pist. germ superior; style thick; stigma trifid. Peric. capsule compressed, roundish, six-lobed, three-celled. Seeds angular, two in each cell.

A shrub. Leaves fascicled, small, oval, entire, flat, smooth. Flowers axillary, solitary, very small. A native of Cochinchina.

CATHETUS, in *Geometry*, a perpendicular, or a line, or radius, falling perpendicularly on another line, or surface.

Thus, the *catheti* of a right-angled triangle, are the two sides that include the right angle.

CATHETUS of incidence, in *Catoptrics*, is a right line drawn from a radiant point, perpendicular to the reflecting line, or the plane of the speculum, or mirror.

CATHETUS of reflexion, or of the eye, a right line drawn

from the eye, or from any point of a reflected ray, perpendicular to the plane of reflexion, or of the speculum. See REFLEXION.

CATHMANDU, or **CATMANDU**, in *Geography*, the capital of an independent kingdom in the kingdom of Nepal or Nepaul, in Hindoostan, situate to the northward of the plain of Nepal, 105 geographical miles N. of Malilly, that is, in N. lat. 28° 6'. This city contains about 18,000 houses; and the kingdom extends, from south to north, to the distance of 12 or 13 days' journey, as far as the borders of Tibet, and it is almost as extensive from east to west. The king of Cathmandu has always about 50,000 soldiers in his service. To the eastward of Cathmandu, at the distance of two or three miles, is a place called "Tolu," by which flows a small river, the water of which is esteemed holy, according to the superstitious ideas of the inhabitants; and thither they carry persons of high rank, when they are thought to be at the point of death. At this place is a temple, which is not inferior to the best and richest in any of the capital cities. They have also a tradition, that at Tolu, as well as two or three other places in Nepal, valuable treasures are concealed under ground; but no one is permitted to make use of them, except the king, and that only in cases of necessity. These treasures, it is said, have been thus accumulated: when any temple had become very rich from the offerings of the people, it was destroyed, and deep vaults dug under ground, one above another, in which the gold, silver, gilt copper, jewels, and every thing of value were deposited. At Cathmandu, on one side of the royal garden, there is a large fountain, in which is one of their idols, called "Narayan." This idol is of blue stone, crowned, and sleeping on a mattress of the same kind of stone; and both the idol and the mattress appear, as if they floated upon the water. This stone machine is very large, about 18 or 20 feet long, and proportionably broad, but well wrought and in good repair.

In a wall of the royal palace, there is a stone of a single piece, about 15 feet long, and four or five feet thick, on the top of which are four square holes at equal distances from each other. On the inside of the wall they pour water into the holes, and on the court-side, each hole having a closed canal, every person may draw water to drink. At the foot of the stone is a large ladder, by which people ascend to drink; but the curiosity of the stone consists in its being quite covered with characters of different languages cut upon it. Some lines contain the characters of the language of the country; others, the characters of Tibet; others, Persian; others, Greek; besides several others of different nations: and in the middle there is a line of Roman characters; but none of the inhabitants know how they came there, nor do they know whether or not any European had ever been in Nepal before the missionaries, who arrived there in the beginning of the last century. They are manifestly two French names of seasons, with an English word between them. To the northward of the city of Cathmandu is a hill called "Simbi," upon which are some tombs of the Lamas of Tibet, and other people of high rank of the same nation. The monuments are constructed in various forms; two or three of them are pyramidal, very high and well ornamented. Round them are remarkable stones covered with characters, which probably are the inscriptions of some of the inhabitants of Tibet, whose bones were interred there. The natives of Nepal regard the hill as sacred; and conceive that it is protected by their idols; and, therefore, they never station troops there for its defence, although it is a post of great importance, and only at a short mile's distance from the city. Adjoining to the tomb they

have found, in digging, considerable pieces of gold, with a quantity of which metal the corpses of the grandees of Tibet are always interred. Asiatic Researches, vol. ii. p. 307, &c. See NEPAL.

CATHOLIC, from *καθολος*, and *εδος*, *ubohol*, denotes a thing that is universal, or general. Some have said, that Theodosius the Great first introduced the term catholic into the church; appointing by an edict, that the title should be applied, by way of pre-eminence, to those churches which adhered to the council of Nice, in exclusion of the Arians, &c.—Catholicism, however, soon changed hands; for under the emperor Constantius, Arianism became so predominant, that the Arians were called the catholics. But the term was used much more anciently, as by Polycarp and Ignatius. "Ubi fuerit Jesus Christus, (says the latter) ibi est ecclesia catholica." The Romish church now assumes the distinguishing appellation of the catholic church. See CHURCH.

The term *catholic*, or *Roman catholic*, is now sanctioned by law (see the title to the act of 31 Geo. III., c. 32.) as well as by common usage, to denote the religion formerly called *Papery*, and the professors of it usually denominated *Papists*. See PAPISTS and POPERY.

CATHOLIC Epistles, in *Biblical History*, a denomination given to seven epistles of the New Testament, signifying universal or general, because they are not written to the believers of some one city, or country, or to particular persons, as St. Paul's epistles are, but to Christians in general, or to Christians of several countries. This is the case of five, or the greater part of them, with which the two others are joined. When the first epistle of Peter, and the first of St. John, were called catholic by the most early Christian writers, the two smaller of St. John were unknown, or not generally received. The antiquity of this denomination is easily ascertained. They were so called in the time of Eusebius (H. E. l. ii. c. 23. l. vi. c. 14), and, probably, before. Of this fact we have good proof. For St. John's first epistle is several times called a catholic epistle by Origen in his remaining Greek works, as well as in others. It is likewise so called several times by Dionysius, bishop of Alexandria. Athanasius, Epiphanius, and later Greek writers received seven epistles, which they called catholic. They are so called likewise by Jerom. The epistles bearing this appellation are, one of James, two of Peter, three of John, and one of Jude; but they are recited in a different order by ancient authors. Of these epistles two only, viz the first of St. Peter, and the first of St. John, were universally received in the time of Eusebius; though the rest were then well known. All the seven were received by Athanasius, Epiphanius, Jerom, Augustine, and many other writers. However, the Syrian churches received only three of these epistles; nor does it appear, that more were received by Chrylостom or Theodoret. These epistles were also called canonical by Cassiodorus, about the middle of the sixth century, and by the writers of the prologue to these epistles, ascribed (erroneously) to Jerom. The propriety of this latter appellation is not satisfactorily ascertained. Du Pin says, that some Latins have called these epistles canonical, either confounding the name with catholic, or also to denote, that they also are a part of the canon of the books of the New Testament. See EPISTLE.

CATHOLIC furnace, is a little furnace, so contrived, as to be fit for all kinds of operations, which do not require an intense fire.

CATHOLIC king, is a title which has long been hereditary to the king of Spain. Mariana pretends, that Reccarede first received this title after he had destroyed Arianism in his kingdom, and that it is found in the council of Toledo for

the year 589. Vafed ascribes the origin of it to Alphonfus in 738. Some allege that it has been used only since the time of Ferdinand and Isabella. Colomiere says it was given them on occasion of the expulsion of the Moors. The Bolandists pretend, it had been borne by their predecessors, the Visigoth kings of Spain; and that Alexander VI. only renewed it to Ferdinand and Isabella. Others say, that Philip de Valois first bore the title; which was given him after his death, by the ecclesiastics, on account of his favouring their interests.

In some epistles of the ancient popes, the title catholic is given to the kings of France, and of Jerusalem, as well as to several patriarchs and primates.

CATHOLICA, in *Geography*, a town of Italy, in the province of Romagna. It derived its name from being the place whither the orthodox bishops retired in the year 359, after being outvoted by the Arian party, in the council of Rimini; 9 miles S. S. E. of Rimini.

CATHOLICA, La, a town of Sicily, in the Val di Mazara, situate in a spacious plain open to the sea, and shut up on the north side by a broken theatre of mountains. It is the chief town of the district. It was founded in 1612 out of several small hamlets by Francis Isar, lord of the soil, but is now possessed by the family of Bonanni, who take the title of princes of La Catholica. The number of its inhabitants exceeds 7000. The prince of La Catholica derives from Siculiana an annual income of 14,000 crowns.

CATHOLICIANI, in *Middle Age Writers*, the officials or ministers of the catholici, or receivers of the taxes of a diocese, sometimes also denominated **CÆSARIANS**.

CATHOLICON, in *Pharmacy*, a kind of soft purgative electary; so called, as being supposed universal; or a purger of all humours.

Different authors give different recipes for it: that called *Catholicon Nicolai* was long in use; it consists of sixteen ingredients, the chief whereof are: turpids, cassia, fena, and rhubarb. It was called the double catholicon, when there was a double portion of fena and rhubarb.

The *CATHOLICON for dysuria*, only differs from this, in that it had no rhubarb, and that honey was used in it instead of sugar.

CATHOLICUS, the title of a dignitary, or magistrate, under the Roman emperors, who had part of the administration, and particularly the care and receipt of the revenues and taxes in Roman dioceses.

The catholici was the name with what was denominated by the *Latinus procurator*, and *rationalis Cæsaris*. Such was the catholici of the diocese of Africa, mentioned by Eusebius, and other ancient writers.

CATHOLICUS, among *Ecclesiastical Writers*, an appellation given to the primates or metropolitan prelates of several churches in Asia, subject to the see of Antioch; but whose jurisdiction and dioceses are of such extent that they have assumed the title of *catholici*, q. d. *universal bishops*. See PRIMATE.

CATHON, in *Ancient Geography*, an island of Greece, S. of the Peloponnesus, in the gulf of Laacedæmon.

CATICARDAMNA, a town of India, on this side of the Ganges, according to Ptolemy.

CATIEH, in *Geography, a town of Egypt, near the coast of the Mediterranean, 70 miles N. E. of Suez, and 130 miles N. E. of Cairo. N. lat. 30° 54'. E. long. 33° 30'.*

CATIF, or **KATIF**, EL, a town of Arabia, in the province of Lachfa, seated on the coast of the Persian gulf, at the distance of about 5 German miles from the isle of Bahrein. The inhabitants earn their subsistence by the pearl-fishery. When any are too poor to fish at their own risk

risk and expence, they hire their labour to stranger-adventurers, who resort hither in the hotter months of the year, which are the season for fishing. The air of this country, however, is believed to be very salutary in summer. The ruins of an old Portuguese fortress are still to be seen near this place. It is 142 miles S. of Bassora, and 420 S. of Ispahan. N. lat. 26° 20'. E. long. 48° 4'. Niebuhr's Travels, vol. ii.

CATIFONS, in *Ancient Geography*, a fountain from which proceeded the stream called "Aqua Petronia," which was a river of Italy that discharged itself into the Tiber.

CATILINE, **LUCIUS SERGIUS**, in *Biography*, was descended from the illustrious patrician family of Sergii at Rome, but rendered infamous by a series of debaucheries, incests, murders, and the most atrocious crimes. He began his licentious career at an early age, by debauching a female of distinction, and afterwards marrying the daughter he had by her. He was also accused of holding a criminal intercourse with a vestal, the sister of Terentia, Cicero's wife, and of murdering his own brother, whose name he prevailed upon Sylla to insert in the list of proscribed persons for the purpose of justifying his crime. During the sanguinary administration of Sylla, he was the chief instrument of his cruelties, and headed a band of assassins, who dragged out of the houses and temples persons, whose names were included in the list of proscription, and cruelly murdered them in the presence of his employer. He was also active in searching out and assassinating many knights and senators, before they knew they were proscribed. As a recompence of these savage services, and in consideration of his birth and brutal courage, he was advanced, by the favour of the dictator, to the principal dignities of the state. Accordingly, he had been quaestor, legate in Macedonia under C. Curio, and pretor in Africa; but in all these employments, he had disgraced himself by his debaucheries and enormous oppressions. As he had dissipated his patrimony, and was overladen with debts notwithstanding his uncontrolled exactions, he had no prospect of retrieving his affairs but by the subversion of the state; and he, therefore, seized all opportunities that occurred for exciting and promoting civil confusion. Upon his return from Africa, B.C. 67, he formed a conspiracy with other discontented and turbulent persons for murdering the consuls, Aurelius Cotta and Manlius Torquatus, together with the greater part of the senators, and violently seizing the government. This plot, though the execution of it was twice repeated, proved unsuccessful, in consequence of a mistake in the signal on the part of Catiline; and he was therefore under a necessity of deferring the accomplishment of his purpose to a future period. Having strengthened his party by the accession of a great number of senators and knights, of debauched young persons in the city, and of old soldiers and officers of Sylla's army, who had reduced themselves to indigence by the profuse expence of all the gains of their oppressions, he concerted a more extensive plan for the total subversion of the commonwealth. With a view to the more easy and certain execution of it, he offered himself a candidate for the consulship, and had Cicero for his competitor. In the mean while, the conspiracy of Catiline had been discovered to Cicero by Fulvia, a woman of distinction, who had dishonoured her family by a criminal correspondence with Quintus Curtius, one of the party concerned; and this discovery, though not fully authenticated, had excited suspicions against Catiline, which defeated his election, and favoured that of Cicero, his avowed adversary. A.U.C. 691, B.C. 63. Catiline, enraged by the success of his rival, determined to offer himself a second time for the consulate, and prepared for an open rebellion, in case of his failure.

With this view he borrowed large sums of money, and engaged Manlius, one of Sylla's old officers, who then resided at Fesulæ, to make levies of soldiers throughout Etruria. Manlius, however, whom Pompey had succeeded in the East, being informed of these hostile preparations, made a report of them to the senate, and assisted the consul with all his interest in the prosecution of the traitor. Cicero also kept up a correspondence with Fulvia, and had even gained over some of the conspirators, who, pursuant to his directions, pretended to be the most ardent promoters of the plot. By means of this information, he discovered the designs of Catiline, the various sentiments of his accomplices, their number and quality, and the general, as well as the private, views of each of the conspirators. By them he was informed, that on a day appointed the conspirators were to set fire to several parts of the city; and that, during the confusion and uproar, which so general a conflagration would occasion, some were to murder the chief men of the senate in their houses, others to assemble the mutinous populace, seize the Capitol, and fortify themselves there, till Manlius should arrive from Etruria with his veterans. Two Roman knights were appointed to murder Cicero in his own house; but the consul, previously informed of every thing that had passed in their assembly, summoned the senate, and boldly apprized the conscript fathers, in Catiline's presence, of the danger to which they were all exposed. The senate, having been made acquainted with the whole plot, issued a public decree, according to an ancient form, which had been observed in times of national danger, "that the consuls should take care that the republic suffered no detriment." Cicero, thus invested with ample power, adopted every necessary measure for keeping in awe the principal cities in Italy, and for guarding Rome, the capital; and the senate, by his advice, promised not only a pardon, but ample rewards, to any of the conspirators, who should make farther discoveries of this detestable attempt. Although the consul might, on his own knowledge, have condemned Catiline and his accomplices to death without appeal, this would have been a perilous measure; and he thought it more advisable to induce Catiline to leave Rome, and take refuge in Manlius's camp near Fesulæ. With this view he assembled the senate, and pronounced, in the presence of Catiline, that most severe and spirited invective, still extant under the title of the first oration against Catiline, in which he lays open all his murderous designs, assures him that they are fully known and guarded against, and exhorts him to leave that city which can no longer endure his presence. Catiline, retaining full possession of himself, with an air of great plausibility intreated the senate not to credit the accusations of a declared enemy, who had not in Rome so much as a house of his own, and who was attempting to raise his own character by the defeat of a conspiracy forged by himself, and thus to acquire the title of defender of his country. When he proceeded to invectives against the consul, he was interrupted by the clamours of the whole assembly, and the senate-house echoed with the names of incendiary, parricide, and enemy to his country. Stung with these reproaches, and foaming with rage, Catiline exclaimed, "Since you have provoked me to the utmost, I will not perish alone, but will enjoy the satisfaction of involving those who have sworn my ruin in the same destruction with myself." Having thus spoken, he left the senate-house, and accompanied by about 300 friends, hastened to the camp of Manlius in the vicinity of Fesulæ. Here he assumed the command of the troops, together with all the ensigns of a supreme magistrate, being preceded by lictors, carrying their axes and fasces. The senate, as soon as information was received of this act of open rebellion, declared Catiline and Manlius enemies of their country;

country; and gave orders, that Antonius, the advocate of Cato, in the consulship, should take the field with a proconsular army, and that Cicero should continue in Rome to watch the motions of the conspirators. Some of the party, who still remained in the city, made an attempt to attach to their cause the ambassadors of the Allobroges, who were then at Rome, and thus to obtain assistance from Transalpine Gaul; but these ambassadors, by the intervention of Sanga, the protector of their nation, communicated the whole affair to Cicero; and he instructed them to proceed in the negotiation, and to obtain the draft of a written treaty, subscribed with the names of the conspirators. Cicero, being informed by the ambassadors when they were to leave Rome, sent privately two prætors, with a sufficient number of troops, to seize them, together with the conspirators, and bring them all to Rome. The prætors faithfully executed their commission; and the ambassadors, together with Vultureius, who had undertaken to conduct them to Catiline, in order to obtain his ratification of the treaty, were stopped in the way, and brought back to Rome, with all the papers which either the Allobroges or Vultureius had in their custody. Cicero, having thus got into his possession undeniable proofs of the conspiracy, dispatched proper officers to arrest Lentulus, Cælius, Cethegus, and Statilius, and to commit them to safe custody. He then assembled the senate, in the temple of Concord, laid before the assembly the proofs of the plot, and having obtained a decree for the execution of the criminals at a subsequent meeting, ordered them to be capitally punished.

During these transactions at Rome, Catiline resolved to lead his army into Transalpine Gaul, where he expected very general support; but he was prevented from accomplishing his purpose by Q. Metellus Cælar, who, leaving Picenum, which he had guarded the last year, posted himself with three legions at the foot of the Alps, while Antonius followed Catiline in the rear, who, kenneled in by two bodies of troops, made a retrograde march, and falling in with the proconsul near Pistoria, now Pistoia in Tuscany, offered him battle. Antonius, who had formerly been of Catiline's faction, appeared unwilling to engage; but his troops, insisting on being led to action, he pretended indisposition, and devolved the command on his lieutenant Petreius, a veteran of tried and distinguished valour. The engagement was severe and obstinate; but at length, when Manlius and another commanding officer were killed, it terminated, after a long and dubious contest, in favour of Petreius, who was left master of the field. Catiline, having lost Manlius and his associates, during the engagement, found himself unable to rally the fugitives; and, therefore, determining not to survive the ruin of his party, threw himself into the midst of the victorious enemy, where he was found among the dead bodies of those whom he had slain, still breathing, and retaining in his countenance the traces of that ferocious valour which distinguished his character. Thus the Catiline conspiracy, which was detected by Cicero in October, was terminated in December. B. C. 63. The character of Catiline has been sufficiently delineated in the orations of Cicero; and his portrait is thus drawn by the strong pencil of Sallust: "His powers of mind and body were extraordinary, but his disposition bad and depraved. From his youth he took delight in civil contests, murders, rapines, and intestine wars, and injured himself to the practice of them. His constitution was, beyond credibility, patient of hunger, cold, and watchfulness. In temper he was daring, deceitful, capable of every kind of flattery and dissimulation, greedy of the property of others, lavish of his own, ardent in his desires, plausible,

rather than deep, in discourse. His boundless soul always aimed at things immoderate, excessive, and out of probability." In other times he appears to have served as an example of desperate and savage treason; and Virgil has irrevocably fixed his doom, in making him the figure by whose punishment the regions of Tartarus are discriminated on the field of Æneas.

" ——— et te, Catilina, minaci

Pendentem scopulo, Pœnarumque ora tremementum."

Æn. viii. 668.

" There Catiline, o'er-hung a mountain's brow,
And fludd'ring view'd the Furies glare below."

CATINA, in *Ancient Geography*, a town of Peloponnesus, in Arcadia. Pliny.

CATINGA, in *Botany*, Jussieu, p. 321. Aublet Gnia. tab. 203, fig. 1 and 2. Trees, the fructification of which is imperfectly known. Nat. Ord. *Myrti*. Calyx four-lobed. Cor. unknown. Stam. filaments numerous. Pyl. unknown. Peric. drupe as large as an orange or citron, crowned with the very small calyx, fibrous within, rind thick, covered with vesicles, which contain an aromatic essential oil; nut brittle, kernel reddish, veined. Leaves most commonly opposite, oval, oblong, entire, besprinkled with transparent points. Fruit axillary. These trees grow on the banks of rivers in Guiana. There are two species; one of which bears a round, the other an elongated fruit.

CATKIN, the English name of a species of inflorescence, called by Linnaeus *amentum*, and improperly considered by him as a species of calyx. It consists of numerous chaffy scales, containing either the stamens or pistils separately, or very rarely both together, and ranged along a slender stalk, which is the common receptacle. By the older botanists it was styled *julus*, *nucamentum*, and *catinus*. The latter term, corresponding with the English *catkin* and the French *chaton*, is derived from its fancied resemblance to a cat's tail. The amentaceous plants constitute the sixteenth natural order of Linnæus in his *Philosophia Botanica*, and the fiftieth in his posthumous lectures published by Giseke. In the latter work the order consists of the following genera; *salix*, *populus*, *platanus*, *sloanea*? *fagus*, *juglans*, *quercus*, *corylus*, *carpinus*, *betula*, *myrica*, *piletacia*, *cydonium*. Jussieu and Ventenat have also a natural order of the same name which is thus divided by Jussieu: 1. With hermaphrodite flowers; *fothergilla*, *ulmus*, *ceitis*. 2. With dioecious flowers; *salix*, *populus*, *myrica*. 3. With monoecious flowers; *betula*, *carpinus*, *fagus*, *quercus*, *corylus*, *liquidambar*, *platanus*. The three species of the first division have not their flowers in true catkins; and Ventenat observes that, although they have some affinity with the amentaceæ, they may more properly be placed in a distinct order. Tournesfort, Boerhaave, and Royen, have also a class or order distinguished by its amentaceous flowers; a character which the former extends to the conifers of Jussieu; but the latter, according to Ventenat, although in many respects allied to the true amentaceæ, have several peculiar important characters which necessarily keep them distinct. Besides their difference in habit, the conifers have a cylindrical embryo, surrounded by a fleshy perisperm;

perm; whereas the true amentaceæ have a flat embryo without a perisperm.

CATLENBURG, in *Geography*, a town and bailiwick of Germany, in the circle of Lower Saxony, and principality of Grubenhagen; 16 miles S.S.E. of Einbeck.

CATLIN, among *Surgeons*, is a dissection knife, for cutting off any corrupted part of a body. See *Surgical Plates on Amputation*.

CATO, MARCUS PORCIUS, distinguished by the appellation of "the Censor," in *Biography*, was born at Tusculum in the year of Rome, 519, B. C. 235; and was brought up at a small farm near the country of the Sabines, possessed by his father, which he cultivated with his own hands. At the age of 17 years, he made his first campaign under Fabius Maximus, when Hannibal was ravaging Italy; and five years afterwards he accompanied the same general in his expedition against Tarentum. At the commencement of his military career, he attracted notice by his singular sobriety, valour, attention to discipline, and all the virtues of the ancient Roman soldiery. On his return from the army, he joined his domestics in the culture of his small estate, devoting himself at his leisure hours to the study of eloquence at home and to the practice of it in the adjacent cities, where he pleaded on behalf of those who applied to him. His talents and virtues engaged the notice of Valerius Flaccus, who had lands contiguous to the small farm of Cato; and who belonged to one of the most noble, affluent, and powerful families of Rome. With the advice and under the promised patronage of this rich neighbour, he determined to try his fortune at Rome, where the successful eloquence of his pleadings and the interest of his friend laid the foundation of his future preferment. In his 30th year he served as military tribune in Sicily; and he was afterwards quaestor under Scipio in the African war; but disgusted with the splendid liberality and popular manners of this great man, he came to Rome and joined with Fabius in accusing Scipio before the senate. But though Scipio was honourably acquitted and continued in his command, Cato gained estimation with the public for his rigid economy. Besides, his masculine strain of rhetoric, which occasioned his being denominated the Roman Demolisher, gave him great influence in the assemblies of the people. Having passed through the office of edile, he was appointed praetor in the province of Sardinia; and in this station he displayed, in a very eminent degree, his temperance, integrity, and rigid justice. His predecessors in this office had ruined the country, by extortions for supplying the means of profusion; whereas Cato distinguished himself by the simplicity of his habit, table, and equipage, and never touched a single farthing of the public money. At this time Sardinia abounded with usurers, who, under a pretence of assisting private persons with the loan of sums of money for particular occasions, utterly ruined them; but Cato expelled from the island all persons of this description. In the year of Rome 558, B. C. 106, he was elected consul, in connection with his friend Valerius Flaccus, and the Hither Spain was assigned to him as his province. But before his departure he vigorously opposed the repeal of the Appian law, which restrained the propensity of the female sex to indulge in show and ornament; but Valerius the tribune, having carried this point against him, which he defended with his single voice, he proceeded to his province, where he undertook the discipline of his troops consisting of new levies, and set them an example of encountering every kind of hardship. His habit was always plain; his provisions were the same with those of the common soldiers; and he took part with them in the

labour of forming the entrenchments of his camp. Having thus prepared his troops for contending with the natives, who, in their previous wars with the Romans and Carthaginians, had learned the military art, and who were naturally brave and courageous, he dismissed his fleet, that his soldiers might solely confide in their own valour. In this war he gained several victories, and by demolishing the fortifications of the towns which he captured, he completely subjected the province to the Roman dominion. To each of the soldiers, besides the spoils, he gave a pound of silver out of the rich booty which he acquired; and when some of the officers expressed their surprize at his liberality, he told them, "It is better that many of the Romans should return home with silver, than a few only with gold." However, he appropriated to his own use no part of the booty; but continued to live in as frugal a manner as the meanest soldier. At the close of the campaign, he sailed back to Rome with his troops, and next year was honoured with a triumph. Notwithstanding this merited dignity, he still continued freely to serve his country in the forum and the field; and when the public service did not call for his active concurrence, he enjoyed the pleasures of retirement, and devoted his hours of leisure to study. In the campaign of M. Acilius Glabrio against Antiochus the Great in Greece, Cato served as a military tribune; and by his advice and assistance enabled the consul to force the Syrian's strong entrenchments in the pass of Thermopylae, as the Persians had formerly done, and to oblige him to abandon Greece, and retire to Ephesus. About ten years after his consulate, viz. in the year of Rome 569, B. C. 185, he offered himself as a candidate for the office of Censor; but the known severity of his character alarmed the nobles, and they set up seven competitors against him; however, the people persisted in the choice of Cato, and they nominated as his associate his consular colleague, Valerius Flaccus. Many of the senators, who had been guilty of scandalous enormities, were rejected; others were degraded on more frivolous grounds; and Cato seems to have indulged a personal pique against the Cornelian family, by taking from Scipio Asiaticus the horse which the public kept for him as a knight. The rigid censor executed his office with great severity; he laid a heavy tax on rich furniture, jewels, and all superfluities; and by such popular acts, he made himself acceptable to the people, that they erected a statue to him in the Temple of Health. After the expiration of his censorship, he merely attended his duty as a private senator, and his advice was received with deference and respect. The necessity of destroying Carthage was a point which he always strenuously inculcated; and in his estimation this necessity seems to have been justified by the single circumstance, that Carthage was the inveterate foe and rival of Rome. Cato, considering the original rude character of the Romans as the standard of perfection, strenuously opposed every kind of innovation, and for a long time resisted the introduction of Grecian letters and philosophy into Rome. To this purpose he exerted himself in halting the dismission of Carneades the academic, and Diogenes the stoic, who had been sent on a public embassy from Athens. He seems, however, in his old age, to have changed his opinion; as he became a convert to the cause of learning, and assiduously studied the Greek language. He became a writer himself, and composed a variety of works, of which the principal was a History of the Roman affairs, and of the origin of all the cities of Italy, from that circumstance entitled "Origines." A few fragments of the seven books which he lived to finish, are still extant. He also published a large number of his orations, letters, a treatise on the military art, and another on rural

aTars: the letter of which still remains, and is usually printed with the *Scriptores de Re Rustica.*"

Cato married for his first wife a woman of family, who was profuse in her expenses and perverse in her temper, and who therefore afforded sufficient exercise to his philosophy. By her he had a son, whose education he himself conducted, but he would not allow him to be taught the learning of the Greeks, alleging, that the only study of a Roman ought to be, how to conquer, and how to govern conquered nations. In his advanced years he was a widower, and not choosing to marry again, he took a young female slave to his bed, at which his son being displeas'd, he married the daughter of Salomon, who had been his secretary; and by her he had a son named Salomon, who was the grandfather of Cato of Utica. The censor lived to an advanced age, and died in his 86th year, as some say, and according to others in his 91st, in the year of Rome 605, B. C. 149, at the commencement of the third Punic war, which his advice very much contributed to promote.

Cato was a great soldier, an eloquent orator, a learned historian, and well skilled in rural affairs; but these accomplishments were counterbalanced by great defects, and very unamiable qualities. As a master, he was stern and unfeeling; so that he considered his slaves as a sort of labouring animals, whom he wished to get rid of when exhauled by age and servitude. His economy degenerated into avarice; and though he was incorrupt in the management of public money, he descended to very mean and unwarrantable practices to amass a private fortune. For money lent he took exorbitant profits; and received even from his own male slaves a certain pecuniary consideration for the liberty of frequenting the females. He used to say to his son, that no man deserved any esteem till he had doubled his fortune. In public he was ever extolling continence; but he indulged his pastimes in private with a beautiful female slave; and it is also said that he was equally faulty in the excessive use of wine.

"Narratur et prisca Catonis,
Sape mero caluisse virtus."

HOR.

His public censures of private men seem sometimes to have originated from envy and personal pique; and thus we may account for his having been 44 times impeached, which probably would not have been the case if he had not provoked private resentment by the unjustifiable severity of his temper. However, on all these occasions he was acquitted by the people, in whose estimation his virtues preponderated his defects and vices; so that whilst he lived he was held in extraordinary veneration, and his name has descended with honour to succeeding generations. Cicero exhibits him in an amiable point of view, by making him the principal speaker in his beautiful dialogue on old age, which some have considered as a kind of fancy portrait, founded, however, on the real traits of the man, though softened and embellished. Plutarch has made him the subject of one of his lives, and Cornelius Nepos, at the request of Atticus, wrote a particular account of him, of which a brief sketch only is extant. Plutarch, t. ii. Cicero. Livy. Corn. Nep. Anc. Un. Hist. vol. xi. Rollin's Rom. Hist. vol. iv. and v.

CATO, MARCUS PORCIUS, CATO *Minor* of Plutarch, surnamed of *Utica*, from the place of his death, was great grandson to Cato the Censor, the subject of the preceding article, and born about 94 years B. C. As he lost his parents at a very early age, he was brought up in the house of Drusus, his maternal uncle, and a man of high rank and character. Whilst he was a child, he manifested that steadiness of temper and solidity of understanding, which were

the distinguishing features of his character; and though his apprehension was slow, his memory was tenacious. His passions, though seldom displayed by outward signs, were durable in their influence; and his inflexibility approached even to stubbornness. However, when his reason was convinced, he readily complied; and this was found by the instructors of his youth to be the only method for securing his obedience. Of his firm and unyielding temper, when he was an infant, Plutarch mentions a singular instance. The Italian allies of Rome having demanded admission to the right of citizenship, Pompeius Silo, one of their deputies for urging this claim, was a guest at the house of Drusus, and in a jocose manner asked young Cato to recommend his suit to his uncle. The child was silent; but expressed by his looks and an air of dislike in his countenance, that he would not comply with the wishes of Pompeius. Pompeius renewed his solicitations, but was unable to prevail. At length he took up the infant Cato in his arms, and carrying him to the window, threatened to let him fall out of it if he persisted in his refusal. But fear was equally unavailing with intreaty. Pompeius, on letting him down in the room, exclaimed, "What an happiness it is for Italy, that thou art but a child! For if thou wert at age, we should not have a single vote." At the age of 14, Cato was introduced by his tutor, Sarpedon, to the house of Sylla, the dictator, which, on account of the proscriptions and cruelties of this tyrant, was a scene of torture and of blood. When the youth observed the heads of several noble victims that had been murdered carried out, and the bye-standers secretly fighting on account of the horrid spectacle, he asked his tutor, why nobody killed such a tyrant. "It is," replied he, "because he is still more feared than hated." Cato exclaimed, "Give me a sword, that I may kill him, and deliver my country from slavery." He uttered these words with a tone of voice and an aspect that made his tutor tremble; and from this time he was very watchful of his pupil, lest he should attempt some rash and daring action.

Notwithstanding the firmness and intrepidity of Cato's temper, he was not insusceptible of tender emotions, nor destitute of kind affections. His love to his brother Cæpio was manifested on a variety of occasions, whilst he lived; and when he died, grief seemed to triumph over all his philosophy. He shed many tears whilst he embraced the dead body; for some time he indulged dejection and melancholy, and expended great sums in his funeral, and in erecting a monument of costly marble in the forum of Enus, a town of Thrace, where he died, nor did he quit his abode till he brought them into Italy. But though he was led by fraternal affection to incur this expence, and though in his mature years he received a considerable sum of money from his share of the paternal estate, the habits of his life were simple and frugal, and he cultivated the manners of a philosopher rather than those of a young patrician. The course of his studies was adapted to his peculiar temper; and the principles of the Stoic philosophy, which he assiduously cultivated, under Antipater of Tyre, habitually influenced his judgment, disposition, and conduct. With a view of being better qualified for defending the cause and claims of justice, and enforcing wise and salutary counsels, he studied eloquence; but his eloquence was altogether destitute of artificial ornaments; it was simple and grave, and occasionally intermixed with dry humour and sarcasm. Cato not only cultivated his mind; but he inured himself to bodily exercise, and to every kind of fatigue and hardship, in order to acquire that corporeal strength and that firm tone of nerves which were suited to his mental disposition, and which would qualify him for the various active services to which he devoted

voted his life. He was also distinguished by his self-denial and temperance; and he avoided every kind of luxury in dress and in diet, which began very much to prevail among his countrymen. He has been charged, however, with occasional excess in the use of wine; and his advocates have found it difficult altogether to exonerate him from the charge of drunkenness. The charge was strongly urged by Cæsar, who may be considered as an enemy; but as he was regarded by all Rome as a model of private as well as public virtue, and peculiarly distinguished for his temperance, we may infer that his conduct in this respect must have been maliciously exaggerated. Cicero, in his defence of him against Memmius, who accused him of passing whole nights in drinking, could only allege, that he could not reproach him with passing whole days at dice; and Seneca, his extravagant panegyrist, very absurdly says, "that it is more easy to make drunkenness a virtue than Cato vicious." In his dress he also affected singularity, and seemed to glory in counteracting the taste and fashion of the age in which he lived. We may also add, that he blended with that greatness of soul and constancy, which have been justly admired, a degree of haughtiness and contempt for others, attributable perhaps to the principles of his philosophy, which in a degree degraded his general character and rendered it less amiable. After all the allowances which truth and candour are constrained to admit in forming a general estimate of his character, Cato has been justly considered as one of the most virtuous Pagans that ever lived. Cato acquired from inheritance an ample fortune; which he employed very differently from his ancestor, the Censor, in loans and gifts among his friends, without recurring to usury for its increase. Disappointed in his first views of a matrimonial nature, by the prior claims of Metellus Scipio, he formed a connection of this kind with Attilia, the daughter of Soranus, whom he repudiated for her infidelity, after having had two children by her. The first military service of Cato was in the "Punic war," under the consul Gellius, against Spartacus; on which occasion his conduct was so much approved by his general, that he offered him some military rewards, which he declined, alleging, that he had done nothing that deserved such honours. Soon after he obtained a tribune's commission, with which he was sent to the army in Macedonia under Rubrius. This general gave him the command of a legion, which became, in consequence of his sedulous attention to the morals as well as the discipline of his men, the most orderly as well as the most martial in the service. It was at this time that his brother Cæpio died. When the term of his tribunitian service expired, he made the tour of Asia, without burdening the allies of Rome, which was too frequently done by the journeys of Romans of distinction. At Ephesus he was introduced to Pompey, who received him with very distinguished tokens of respect; but though he paid him particular attention whilst he was present, he does not seem to have regretted his departure, as he did not wish to have his conduct inspected by so rigid an observer. After having visited the whole of Asia and Syria, Cato returned to Rome, accompanied by the celebrated Stoic philosopher, Athenodorus, who resided in his house. Having acquired those maxims of wisdom and habits of virtue which qualified him for the service of his country, he now wished to employ them for the benefit of the public. His philosophy, so far from aiming at that imaginary perfection, which consists in abstraction from all the common duties of life, was such as the poet Lucretius represents;—

"—— patriæque impendere vitam,
Nec sibi, sed toti genitum se credere mundo."

Phars. ii. 332.

"To hold his being at his country's call,
And deem his life was lent a common good for all."

Accordingly he first aspired to the office of quaestor, having previously studied with diligence the rights and duties of this office. Having succeeded in obtaining it, he began with reforming a variety of abuses, which had been introduced by his predecessors; and, heedless of private enmities, he brought all defaulters to account with the public, and established such checks and orders that might effectually serve to prevent future fraud and peculation. One of the boldest and most popular acts which he performed was that of calling to strict account the infamous assassins employed by Sylla and extravagantly recompensed out of the funds of the treasury for the apprehension and murder of proscribed persons. These men he caused to refund their ill-acquired gains, reproaching them at the same time for their crimes, and indicting them for their atrocious murders before the criminal judges. Such were the integrity and assiduity, with which he discharged all the duties of his office, and such was the high estimation in which his conduct was held, that his name became in a manner proverbial for uprightness. To this purpose we may adduce the compliment paid to him by a popular orator, who, once objecting to the decision of a cause by the testimony of a single witness, said, "One man's evidence is insufficient, were it even Cato's." His fidelity in performing the duty of a senator was no less exemplary than the discharge of his functions as quaestor. He was the first in the senate, and the last that left it; and as he frequently passed a considerable interval of time, before the house was assembled, he brought a book, and read till it began to deliberate; nor did he ever quit the city during the session of the senate. Although he attached himself at this time to none of those who led the prevalent parties in the state, but rather opposed and suspected all, he inclined to that of the aristocracy, from an opinion that the existence of the republic was chiefly endangered by men of great popular influence. No man was ever less governed by that ambition, which actuated the leaders of all parties, than Cato. Nevertheless, he thought it his duty to step forward, whenever he apprehended that his country needed his services. With these views he altered his purpose of retiring from the public scene, when Metellus Nepos, whom he knew to be a man of dangerous character, was offering himself for the office of tribune; and became a candidate, as his competitor. They were both chosen; and Cato, as tribune elect, served his country very essentially at the time of the conspiracy of Catiline. Concurring with Cicero in his measures for the safety of the state, he supported them by his influence, honoured him with the appellation of "Father of his country," and by his eloquence counteracted the speech of Cæsar, who wished to shew lenity to the conspirators, and procured their capital condemnation. He afterwards opposed a motion of Metellus for recalling Pompey from Asia, that he might have the command against Catiline; but his opposition was followed by a tumult, excited by Metellus and aided by Cæsar, which very much endangered his life. After Pompey's return to Rome Cato exerted himself in defeating his unconstitutional projects; and when the first triumvirate was formed, he alone perceived the danger that might result from such an union of power. When Cæsar proposed his agrarian law, Cato raised an outcry against it, alleging that it was not proper to disturb the public tranquillity, and that he did not so much apprehend the division of the lands, as the wages that would be required of the people by those who sought to invigilate them by this present. Cæsar, who was then consul, was so much

provoked by the invincible opposition of Cato that he committed him to prison; but he was soon after released. Cicero used many arguments to mollify the inflexibility of Cato's temper; and fearing that banishment might be the consequence of his continued opposition, addressed him with these words, "If Cato has no need of Rome, Rome has need of Cato." At length Cato yielded; the agrarian law was passed; and the triumvirs became irresistible. Their principal agent was Clodius; and as Cato resisted his measures, he determined to remove him from Rome. With this view, he expressed confidence in his integrity, and having obtained a decree for depriving Ptolemy, the king of Cyprus, of his dominions, on the ground of personal animosity and revenge, he assigned to Cato this odious employment, and obtained a law, investing him with the authority of praetor, for the execution of his iniquitous purpose. Whilst Canidius, a friend of Cato, was sent to acquaint Ptolemy with the determination of the Roman people, and to propose to him terms of surrender, he waited at Rhodes to learn the result of the negotiation. In the mean while Ptolemy, fully apprised that resistance would be vain, preferred death by poison to acquiescence in this arbitrary decree. As soon as Cato heard of the event, he sent Brutus, his nephew, to secure the royal treasures; and having re-establihed the exiles of Byzantium, which was another object of his commission, he repaired to Cyprus, where he disposed of all the treasures he found amounting to near 7000 talents or about 1,850,000 pounds sterling; reserving to himself only a statue of Zeno, the founder of the Stoic sect. This wealth was safely transported to Rome, and lodged in the treasury; and it seems to have been a just retaliation on the inquiry of the measure by which it was procured on the part of the Roman people, that it was soon after seized by Cæsar and employed in the destruction of their liberty. After Cato's return to Rome a contest took place between Cicero and Cato, respecting the legitimacy of the tribuneship of Clodius, and the consequent validity of every thing that had been done by Cato in the island of Cyprus; but the interruption of friendship and coolness that were thus occasioned between these two distinguished persons soon terminated.

We have already mentioned Cato's first marriage of Atilia and his subsequent divorce. When this event took place, he married Marcia, the daughter of his friend Philippus, and by whom he seems to have lived in conjugal harmony and by whom he had several children. However, at the time when she was actually pregnant, he resigned her to Hortensius at her request, and having obtained her father's consent, gave her away in marriage to his friend. This transaction, though altogether inconsistent with modern ideas and manners, was conducted with gravity and decorum, and seems to have occasioned no scandal. After the death of Hortensius, who bequeathed his large fortune to his widow, Cato took her again. In this case, as a new marriage ceremony was performed on both occasions, it cannot be justly said that Cato lost his wife. Moreover, he only availed himself of the unlimited right of divorce allowed by the Roman law, in first surrendering his wife to Hortensius and then marrying her again as his widow. It has been said, however, that notwithstanding the established usage among the Romans, a person of Cato's dignity and character should not have sanctioned it by his example.

Cato, who still persisted in his opposition to the triumvirs, took an active part in the debates of Domitius his sister's husband, for the consulship against Pompey and Crassus; but whilst they were soliciting votes in the Campus Martius, they fell into an ambuscade prepared by the

rivals of Domitius, and Cato was wounded by the assassins. This intrepid Roman, who was not to be deterred by any violence from serving what he apprehended to be the cause of liberty, exposed himself to new danger by his strenuous opposition to the Trebonian law, which proposed to assign to the consuls the government of Syria and of Spain for five years, with as many troops as they should judge proper, and with the power of making war and peace according to their own pleasure. After all the efforts of a constancy equally obstinate and fruitless, Cato was seized by the sergeants of Trebonius and conveyed to prison; but the tribune fearing the consequence of this unpopular measure, caused him soon to be released. The next, and the highest civil dignity, to which he was advanced, was that of praetor, and in the execution of this office he engaged the senate to issue a decree against bribery; but Rome was reduced to such a state of corruption, that the decree offended both the candidates for offices who purchased votes, and the people who sold them.

After the death of Crassus, the agents of Cæsar were industrious in their exertions on his behalf; and Cato, perceiving that the power of Pompey might serve to counteract their efforts, diverted his ambitious friends from the plan they were pursuing of making him dictator, and proposed the less obnoxious measure of creating him sole consul. Pompey was not insensible of his obligations; and Cato, who professed to have served him with a view to the interest of the public, took the liberty of giving him free advice, and of checking him when he thought his conduct was improper. In the following year Cato became a candidate for the consulship, but not condescending to make a popular canvass, he was rejected. The disappointment, though much regretted by Cicero, was slightly felt by Cato himself; and from this time he resolved never more to aspire to this dignity. On this occasion he observed, that an honest man, and good citizen, should not decline the administration of public affairs, when he was thought fit to be employed; but that he ought not to be immoderately anxious and ardent in seeking it. In the year 59, B. C. the predictions of Cato were fulfilled by the commencement of the civil war. On the division of the provinces by the senate, he was appointed as praetor to the government of Sicily, and in the discharge of his office he acted with his usual vigilance and diligence in fitting out ships and raising forces; but when Curio arrived there with three of Cæsar's legions, he abandoned the island and removed to Pompey's camp at Dyrrachium, where he was left to guard the treasure and military stores, when Pompey had set out in pursuit of Cæsar; and thus he was preserved from being present at the battle of Pharsalia. During their previous intercourse, it was his advice to procrustinate the war, and thus to leave room for a negotiation; for so patriotic were his feelings, that he indulged no satisfaction from anticipating the continuance of the contest, whatever might be the side to which victory inclined; and after the victory at Dyrrachium he could not participate the joy and triumph manifested by others on the occasion. From the commencement of this contest, apprehending the loss of many brave citizens which it must unavoidably occasion, he neither shaved his beard, nor cut his hair, nor wore any other garb besides that which testified the anguish of his mind. His humanity was very signally displayed in prevailing upon Pompey and the council of war to pass an order, that no city subject to Rome should be sacked, nor any Roman put to death, except in the field of battle. After the disastrous battle of Pharsalia, Cato sailed with his troops to Coreyra, where he offered the command to Cicero, as superior officer; but Cicero, conscious

scious of his unfitness for the arduous and important undertaking, declined accepting it; upon which Cæsius, the son of Pompey, was so provoked, that he drew his sword and would instantly have killed Cicero, if his hand had not been staid by Cato, who conveyed the orator from the camp privately by night. From Coreyra, Cato proceeded to Africa, in order to join Pompey; but immediately on his arrival he received the news of his assassination. Adhering still to the cause of liberty, which he conceived any hope remaining, he proceeded with his troops to Cyrene; whence he pursued his march across the deserts, encountering many toils and dangers, with a view of joining Scipio, the father-in-law of Pompey, who had landed before him in Africa, and taken refuge with Juba, king of Mauritania. In this fatiguing and hazardous march, he exhibited every quality that was adapted to inspire his soldiers with esteem and attachment, leading them for seven days on foot, and subjecting himself to hardships equal to those to which the meanest of them were exposed. At length a junction of the whole force was effected at Utica; and when a contest arose concerning the supreme command, Cato, in opposition to the wishes of the whole army, yielded to the pro-consular dignity and auspicious name of Scipio, and persuaded all to acquiesce in his superiority. But he had afterwards reason to repent of his self-denial. As the inhabitants of Utica were justly suspected of entertaining a secret inclination for Cæsar's party, Juba, whose temper was violent and cruel, wished to destroy the city and exterminate its inhabitants, many of whom were Romans. Cato humanely interposed, and, though Scipio concurred with Juba in opinion, he inveighed with so much vehemence and indignation against so unparalleled an act of cruelty, that he put a stop to the execution of this barbarous project. At the desire of Scipio, and in compliance with the request of the inhabitants, Cato undertook to defend the city; and with this view he formed ample magazines of corn, repaired its walls, erected turrets, and prepared a fort of camp without, enclosed with a ditch and palisade, in which, after having taken away their arms, he lodged all the youth of Utica. As for the rest of the inhabitants, he kept them within the walls, strictly watching their motions, but at the same time protecting them from the insults of his soldiers. From this place, thus stored and guarded, he furnished Scipio with arms, money, and provisions; and thus rendered it the grand magazine for the supply of the army. Whilst Cato was thus employed, Scipio and Labienus were opposed to Cæsar in the field. It was the decided opinion of Cato, that the war should be protracted; and to this purpose he repeatedly counselled Scipio not to engage in a general action with a commander of Cæsar's abilities; but Scipio rejected his advice with disdain; and the consequence of disregarding it was that almost the whole republican army was destroyed at Thapsus. This fatal battle was fought at the distance of about three days' journey from Utica; and this garrisoned city was the only place in Africa that had not submitted to the conqueror. Cato, having quelled the tumult of its inhabitants, and dispelled their alarms, assembled the council of 300, which he had formed into a kind of senate, and exhorted them to unite, with their persons, property, and counsel, against the common enemy. With a firmness and prudence for which he was eminently distinguished in the moment of impending danger, he exerted his utmost efforts in calming their apprehensions, composing their differences, and animating their constancy. But his endeavours produced only a temporary effect, and served only to delay the threatened evil. Upon the arrival of Scipio's cavalry, which had retreated from the field of

battle towards Utica, his hopes revived; but when he received from them a message, expressing their attachment to him, and their distrust of the Uticans, he was again alarmed: more especially when they stipulated their assistance in the defence of the city, on the savage condition of previously killing or expelling the suspected inhabitants. Cato thought this proposal no less unreasonable than cruel, and declined accepting it. Cæsar was now approaching, and the senators resolved to send deputies to him for the purpose of imploring his clemency; avowing at the same time that the first and principal object of their solicitations should be Cato, for whom if they failed in obtaining protection, they would not accept any pardon for themselves, but would fight in his defence to the last moment of their lives. Cato acknowledged himself obliged to them for their kind intentions, approved of their design of submitting to Cæsar, and advised them to lose no time. But he forbade them to make any mention of him in their solicitations. "It is for the vanquished," said he, "to have recourse to supplications, and for those who have done injustice to sue for pardon. As for me, I have been invincible during the whole course of my life, and even now am as victorious as I wish to be, and triumph over Cæsar by the superiority of justice and equity. It is he that is conquered; it is he that is overpowered; being this day attacked and convicted by undeniable evidence (notwithstanding he has always denied it), of plotting against his country." The cavalry, who had impatiently waited the result of Cato's deliberation, were now leaving the city, and before they departed enriching themselves with plunder, which Cato made every possible effort to restrain; and as most of the senators preferred escaping by sea to putting themselves under the protection of Juba, Cato, perceiving that their danger was increased by the departure of the cavalry and the approach of Cæsar, took the last measures for hastening and securing their retreat. His own resolution was fixed; and that was neither to ask his life of Cæsar, whom he regarded as an usurper, nor to dishonour himself by flight, and thus protract a fruitless contest. Having determined to put an end to his own existence, he prepared for the last scene by acts of kindness to his friends, and grave discourses with philosophers. In the last evening of his life, he first bathed and then supped in the midst of a large assembly of his friends, and the magistrates of the city, whom he had invited to this last interview. They sat late at table, and the conversation was lively, gay, and instructive, turning on certain points of moral philosophy. Supper being ended and the company dismissed, he walked for some time, according to his usual practice, and then retired to his chamber, where he read Plato's dialogue, entitled "Phædo," on the immortality of the soul. Having made a considerable progress in it, he looked for his sword, and found that it was withdrawn; his son having taken it away, while they were at supper. Upon this he called his slave to question him concerning his sword; but receiving no answer he resumed his reading. He again asked for his sword; but perceiving, when he had done reading, that it was not brought, he called all his slaves one after another, and raising his voice, insisted on their bringing it. "What," said he, with a great degree of indignation, "do my son and family conspire to deliver me to my enemy, unarmed and defenceless?" His son then appeared, accompanied by other friends, who besought him with tears, and in the most suppliant manner, to alter his purpose. Cato's indignation was more roused, and he vehemently remonstrated against their conduct. "Brave and generous son," said he, "why do you not put your father in chains? why do you not tie my hands behind me, till Cæsar come, and find me incapable

of defence? Had I a mind to destroy myself, I could equally effect it without a sword; since by holding my breath for some moments, or only once dashing my head against the wall, I could dispatch myself, were I so disposed." Afterwards recovering his calmness, he vindicated to the two philopoiets, Demetrius and Apollonides, who attended him, the reasonableness of his purpose, and the folly of attempting to deprive a man, already determined, of the means of death. A young slave at length brought him his sword, which he drew and examined with attention; and finding it sharp and fit for execution, he said, "Now I am my own master." He then laid it down, took up his book, and read it from the beginning to the end. Plutarch assures us, that he afterwards slept, and so soundly, that those who waited without, and listened at the door, heard him snore. Some, however, have questioned this fact, and ascribed to him an affectation of tranquillity, by which he hoped to augment the false glory which he expected to derive from a voluntary death. However this be, about midnight he dispatched one of his freedmen to the sea-side, in order to bring him information whether or not his friends had set sail; and being told that the wind was very high and the sea rough, he expressed great concern. He sent again to the port to know, if any remained, and if they wanted any assistance, and during the absence of the messenger, renewed his sleep. Being at length assured that all was quiet in the port, he desired to be left alone, and then stabbed himself with his sword. The noise occasioned by his fall summoned his son and his friends into the chamber, where they found him still alive, but weltering in his blood, and part of his bowels hanging from the aperture in his body. Attempts were made, during a fainting fit, to preserve his life by replacing his bowels and sewing up his wound; but as soon as he came to himself, he violently tore it open again, and instantly expired. This event happened in the year B. C. 46, when Cato had attained the age of 45 years. As soon as the news of his death was spread through the city, the Uticans loudly lamented it, and caused the air to resound again with encomiums on his character, as their benefactor and their saviour. Notwithstanding Cæsar's approach, they solemnized his obsequies with great pomp, and erected a monument to him near the sea-shore, where, in Plutarch's days, was a statue of Cato, holding a sword in his hand. When Cæsar received information of his death, he is said to have exclaimed, "O Cato! I envy thee the glory of thy death; for thou hast envied me that of saving thy life."

It would lead us into a wide field of discussion to state the arguments that have been used by some to extenuate and even to justify, and by others to criminate and condemn this last act of Cato. In judging concerning his conduct, we should advert to the principles of his philosophy. Professing to believe with the sect whose tenets he embraced, that it might or might not, in particular circumstances, be expedient for a man to preserve or lay down his life, it remained with him to determine whether his own situation was such as to warrant the voluntary termination of his existence. But it has been alleged, in reference to this latter view of his case, that he acted inconsistently with that virtue, on which he chiefly valued himself during the whole course of his life; and this was an invincible constancy, superior to all events. The situation of his country, though discouraging, was not absolutely desperate. The remains of Pompey's party began to revive in Spain, and became afterwards very formidable. Cato, therefore, it is said, in conformity to his character, ought yet to have tried that resource, or waited for some unforeseen and unexpected change favourable to his views; and consequently by the act of suicide, while any

hopes yet subsisted, or whilst there remained a possibility of some favourable revolution, he was deviating from his own principles, and abandoning too soon the cause of liberty. Some, indeed, have ascribed his death to that pride and insubility of temper, which the Stoical philosophy was adapted to produce and cherish. Accordingly it has been said, that he doted on such an humiliation as that would have been of owing his life to Cæsar, and that he might not be obliged to his enemy for it, he preferred depriving himself of it by an act of despair. If we appreciate his conduct by the principles of an enlightened theism, and more especially by those which we derive from our holy religion, we cannot hesitate in condemning it. See *SUICIDE*.

It was, however, for many ages, and has been by some in modern times, extolled as an act of heroism; and it gained among his countrymen general admiration. Horace, though writing under Augustus, places the "noble death" of Cato (Catonis nobile lethum, *Carm. lib. 1. od. 12*) among the greatest and most honourable events of the Roman history. Plutarch's Cato Minor *apud oper. t. 1. p. 759*, &c. Sallust. *Rollin's Rom. Hist. vol. vii. viii. and ix.*

CATO, VALERIUS, a Latin poet and grammarian, was a native of Gallia Narbonensis, and driven by a civil war which occurred in his country in the time of Sylla to Rome, where he opened a school of grammar and polite literature, that was frequented by persons of the first rank. His friend, Marcus Furius Bibaculus, gives his eulogium in these two lines:

"Cato grammaticus, Latina siren,
Qui solus legit, et facit poetas."

From the competence acquired by his professional labours, he fell into poverty, which he bore with great unanimity, and died at a very advanced age, B. C. 20. He was the author of several grammatical works, and some poems, one of which (if it be his) entitled "Dinæ" expressive of his sorrow at quitting his native country and his Lydia, has reached our times. It was printed separately by Christopher Arnold at Leyden, in 1652. 12mo. and is contained in Mattaire's *Corpus Poetarum*. Gen. Biog.

CATO'S *Distichs*, in *Literary History*, a well-known metrical system of ethics, which has been erroneously ascribed by some to Cato the censor, and by others to Cato of Utica; although it is perfectly in the character of the former, and Aulus Gellius (*lib. xi. cap. 2*) has cited with commendation M. Cato's "Carmen de Moribus," which is altogether different from this. It is entitled "Disticha de Moribus ad Filium," which are distributed into four books, under the name of Dionysius Cato. This work has been absurdly attributed by some writers to Seneca, and by others to Aulonius. It is, however, more ancient than the time of the emperor Valentinian III., who died in 455. On the other hand, it was written after the appearance of Lucan's *Pharsalia*, as the author, at the beginning of the second book, commends Virgil, Macer, Ovid, and Lucan. The name of Cato probably became prefixed to these distichs, in a lower age, by the officious ignorance of transcribers, and from the acquiescence of readers equally ignorant, as Marcus Cato had written a set of moral distichs. Whoever was the author, this metrical system of ethics had attained the highest degree of estimation in the barbarous ages. John of Salisbury, in his "Polycraticon," mentions it as the favourite and established manual in the education of boys. It is also much applauded by Isidore, the old etymologist, Alcuin and Abelard; and it must be owned, that the writer, exclusive of the utility of his precepts, possesses the merit of a nervous

nervous and elegant brevity. It is perpetually quoted by Chaucer, who calls the writer Caton or Cathon; and Caxton observes, that it is "the beste boke for to be taught to yonge children in scole." But he supposes the author to be Marcus Cato, whom he duly celebrates with the two Scipios, and other noble Romans. It was translated into Greek at Constantinople by Maximus Planudes; and at the relloration of learning in Europe, illustrated with a commentary by Erasmus, which is much extolled by Luther. There are also two or three French translations. Fabr. Bb. Lat. t. ii. p. 213. Wharton's Hist. of English Poetry, vol. ii. p. 168.

CATO, in *Geography*, a military township of New-York state in America, 12 miles S.E. of lake Ontario, and about 20 S. of Oswego fort.

CATOCHE, or CATOCHUS, in *Medicine*, from $\kappa\alpha\tau\acute{\alpha}\chi\eta\varsigma$, *I occupy*, or *d.tain*, are terms nearly synonymous with CATALEPSIS. Galen observes that the ancient physicians denominated the disease Catochus, which the later authors have named catoche and catalepis. The latter term was first used by Aesclepiades. The ancients, however, it is obvious, did not distinguish the different forms of soporose diseases, with that accuracy with which they are now discriminated, and hence there is considerable difficulty in ascertaining the precise meaning of their terms. It appears that the word catochus was applied by different writers, not only to catalepsy, but to *Coma* and to *Tetanus*, and perhaps to other diseases, in which the voluntary power of muscular motion was diminished, or destroyed. Among modern nosologists, Dr. Cullen considers the catochus of Galen, as a variety of tetanus; and Sauvages refers it to the same class; observing, however, that it differs from the tetanus; 1. in being a slow or chronic disease; and, 2. because it is not attended with vehement agitation of the breast and difficulty of breathing. It is equally difficult and unimportant now to affix a precise signification to a word, which was never accurately appropriated by those who originally used it.

CATOCHEITES, in *Natural History*, the name of a fossil mentioned among the ancients, as having great virtues in medicine, and in the cure of wounds. It is said to have been found in Corsica; and Pliny records this remarkable property of it, that if the hand were held upon it for some time it would stick to it in the manner of glue. Hence it appears to have been a bitumen.

CATODON, in the Artedian system of *Ichthyology*, the name given to a genus of cetaceous animals, the characters of which are these: the teeth are placed only in the lower jaw; there is no fin upon the back, and the siltulous aperture is placed either in the head or the snout.—This genus is not admitted by Linnæus; his genus PHYSETER comprehends those cetaceous animals which have teeth in the lower jaw, and none in the upper; and the species P. catodon is one of the two species of that genus, which has no dorsal fin.

CATOLUCA, in *Ancient Geography*, see CATUACA.

CATOMUM, or CATOMUS, from $\kappa\alpha\tau\acute{\alpha}$ and $\mu\acute{\alpha}\sigma\iota\varsigma$, *shoulder*, in *Middle Age Writers*, denotes that part of the body below the neck, and between the shoulders.

CATONBELLA, in *Geography*, a large river in Africa, in the kingdom of Benguela, which runs into the river, called by the Portuguese Rio de las Vacas, or Cow's river. It is composed of three large streams united, and of a salish nature: along the banks the natives dig large channels to receive its briny liquor, which is afterwards condensed into a good salt.

CATONIA, in *Botany*, Juss. p. 441. Brown Jam. Class and order, *tetrandria monogynia*, Nat. ord. undetermined. Gen. Ch. Cal. superior four-cleft. Cor. none. Stam. four.

Pist. Germ inferior, globular; style one; stigma one. *Peris.* Berry, succulent, crowned, four-seeded; one or two of the seeds often abortive. A shrub. *Leaves* opposite. A native of Jamaica.

CATOPSPIS, in *Surgery*, a disorder of the sight; more usually called NYOPIA.

CATOPTRICS, derived from $\kappa\alpha\tau\acute{\alpha}\nu\tau\epsilon\rho\iota\varsigma$, *speculum*; of $\kappa\alpha\tau\acute{\alpha}$, and $\sigma\tau\alpha\sigma\iota\alpha$, *video*, *I see*, the science of reflex vision; or that branch of optics, which illustrates the laws and properties of light, reflected from mirrors or specula.

The principles and laws of catoptries, as a distinct branch of optics, will be found under the articles, REFLECTION and MIRROR. See also LIGHT and VISION.

The principal authors who have treated of catoptries, among the ancients, are Euclid, Alliazan, and Vitellio. Euclid's treatise is the first that is extant on this subject; it was published in Latin in 1604, by John Pena, and is included in Herigon's course of mathematics, and in Gregory's edition of the works of Euclid. Some, however, have suspected that this piece was not written by that great geometer; and though it is ascribed to him by Proclus (lib. ii.) and by Marinus in his preface to Euclid's Data. See EUCLID. Ahazen was an Arabian author, and composed a large volume of optics about the year 1100, in which he treats pretty fully of catoptries. See ALHAZEN. Vitellio was a Polish writer, and composed another treatise on this subject about the year 1270. Among the moderns, many authors have either directly or indirectly treated of this subject. Taquet has demonstrated very much at length the properties of plane mirrors in the first book of his Catoptries, printed in the collection of his works in folio. Fabri has also written on this subject in his book, entitled "Synopsis Optica." James Gregory in his "Optica Promota," and particularly Dr. Isaac Barrow in his "Optical Lectures," have also directed their attention to the principles and laws of catoptries. Dr. Barrow, in the last mentioned work, has laid down and demonstrated the principles of this branch of optical science with peculiar accuracy and clearness; and deduced from them the properties of spherical mirrors, both concave and convex. We have also David Gregory's "Elements of Catoptries;" Wolhus's "Elements of Catoptries;" Dr. Smith's elaborate work on optics, in which he has amply discussed the laws of catoptries; and many others of less note or of later date; either printed separately or comprehended in those courses of mathematics and philosophy, both theoretical and experimental, to which we have occasion to refer in various parts of the dictionary.

CATOPTRIC Dial, a dial which exhibits objects by reflected rays. See DIAL.

CATOPTRIC Telescope, a telescope that exhibits objects by reflection. See Reflecting TELESCOPE.

CATOPTRIC Cistula, a machine or apparatus, whereby little bodies are represented extremely large; and near one, extremely wide, and diffused through a vast space; with other agreeable phenomena: by means of mirrors, disposed by the laws of catoptries, in the concavity of a kind of chest.

Of these there are various kinds, accommodated to the various intentions of the artificer: some multiply the objects: some deform; some magnify, &c.—The structure of one or two of them will suffice to shew how many more may be made.

To make a catoptric cistula to represent several different scenes of objects, when viewed at different holes.

Provide a polygonous cistula, chest, or box, of the figure of the multilateral prism, ABCDEF (*Plate IV. Optics, fig. 1.*) and divide its cavity by diagonal planes EB, FC,

DA, intersecting each other in the centre, into as many triangular locuses, or cells, as the chest has sides. Line these diagonal planes with plane mirrors: in the lateral planes make round holes, through which the eye may peen within the cells of the box. The holes are to be covered with plain glasses, ground within-side, but not polished, to prevent the object, in the cells, from appearing too distinctly. In each cell are to be placed the different objects, whose images are to be exhibited; then covering up the top of the box with a thin transparent membrane, or parchment, to admit the light; the machine is complete.

For, from the laws of reflection, it follows, that the images of objects, placed within the angles of mirrors, are multiplied, and appear some more remote than others; whence the object, in one cell will appear to take up more room than is contained in the whole box. By looking, therefore, through one hole only, the objects in one cell will be seen, but those multiplied, and diffused through a space much larger than the whole box; thus every new hole will afford a new scene: according to the different angles the mirrors make with each other, the representations will be different: if they be at an angle greater than a right one, the images will be monstrous, &c.

The parchment that covers the machine, may be made pellucid, by washing it several times in a very clear ley, then in fair water, and bracing it tight, and exposing it to the air to dry. If it be desired to throw any colour on the objects, it may be done by colouring the parchment. Zahuus recommends verdigrise ground in vinegar, for green; decoction of Brazil wood, for red, &c. He adds, that it ought to be varnished, to make it more pellucid.

To make a catoptric cystula to represent the objects within it prodigiously multiplied, and diffused through a vast space.

Make a polygonous cystula, or chest, as before, but without dividing the inner cavity into any apartments, or cells; (*Plate IV. Optics, fig. 2.*) line the lateral planes CBHI, BHLA, ALMF, &c. with plane mirrors, and at the foramina, or apertures, pare off the tin and quicksilver, that the eye may see through: place any objects in the bottom MI, v. g. a bird in a cage, &c.

Here the eye looking through the aperture *hi*, will see each object placed at bottom, vastly multiplied, and the images removed at equal distances from one another. Hence, were a large multangular room, in a prince's palace, lined with large mirrors, over which were plain pellucid glasses to admit the light; it is evident the effects would be very surprising and magnificent. For other modes of applying and combining mirrors, see MIRROR.

CATOPRITES, in *Natural History*, a name given by some writers to a stone of the marble kind, which, when polished, was capable of serving as a speculum, either flat, and only used to represent the images of things; or concave, and used as our reflecting burning-glasses. The hard black marbles were most frequently used for this purpose; but sometimes the reddish ones, and sometimes one or other of the jaspers. All these were indiscriminately called by the name *catoprite*; when put to this use.

CATOPROMANCY, formed from *κατοπτρον*, *speculum*, and *μαντις*, *divinatio*, a kind of divination among the ancients: so called, because it consisted in the application of a MIRROR.

Pausanias says, it was in use among the Achaians; where those who were sick, and in danger of death, let down a mirror, or looking-glass, fastened by a thread, into a fountain, before the temple of Ceres; then, looking in the glass, if they saw a ghastly disfigured face, they took it as a sure

sign of death; on the contrary, if the face appeared fresh and healthy, it was a token of recovery. Sometimes glasses were used without water, and the images of things future, they, way, were represented in them.

CATO-SILVIUS, P. TIV. in *Zoology*. See LEMUR VOLANS.

CATRA, or CATIFA, in *Ancient Geography*, a town of the island of Crete. Steph. Byz.

CATRALEUCOS, a town of Spain, placed by Ptolemy in Lusitania.

CATRENSIS, an episcopal see of Africa, in Mauritania Cesariensis.

CATROPITÆ. See AGONISTICI.

CATROU, FRANCIS, in *Biography*, a learned and ingenious writer, was born at Paris in 1653, entered among the Jesuits in 1677, and took his vows at the college of Bourges in 1694. He officiated as a preacher for 7 years, and then abandoning that office, on account of the difficulty of committing his sermons to memory, he devoted himself to literature, and was employed from 1701 for 12 years in writing for the "Journal de Travaux." In 1702, he published "A general History of the Mogul Empire," from the Portuguese memoirs of Manouchi, a Venetian; to the third edition of which, in 1715, is annexed the reign of Aurangzebe. His "History of the Fanaticism of the Protestant Religion," containing only that of the Anabaptists, appeared in 1706; and in 1733 he added, in two volumes, that of Davidism and of the Quakers. His "Translation of Virgil in Prose, with historical and critical notes," began to be published in 1708, and was completed in 6 vols. 12mo. in 1716. With many defects and faults, this work displays both ingenuity and industry. The most elaborate performance of Catrou is his "Roman History, from the foundation of Rome," which employed the greatest part of his literary life, and in which he was assisted by his brother Jesuit, Julian Rouillé. This appeared in 1737, with the notes, dissertations, medals, &c. in 20 volumes 4to. and, without these appendages, in 20 volumes 12mo. The history was brought down by Rouillé, after the death of Catrou, in one volume 4to., to the end of Domitian's reign. The work displays great labour and research, and contains an ample and well-connected collection of facts; though the style is affected, and not characteristic of a solid and dignified historian. It has been translated into Italian and English. Catrou died in 1737, in the 78th year of his age, and retained to a very advanced period the force and vivacity of his imagination. *Nov. Dict. Hist. Gen. Biog.*

CATRY, in *Geography*, a particular sect of Hindoos, mentioned by Thevenot, who places them in the vicinity of Moultan, and who says that they spread from hence over all the Indies. He explains this tribe to mean "Rajpoots," or warriors; that is, the Kutry tribe, properly. These Catries, according to Rennell, were the Catheri of Diodorus Siculus, and the Cathi of Arrian; with whom Alexander contended on the borders of the Malli. See CATHEIA.

CATSAL, a town of Chinese Tartary; 28 miles W. of Concha.

CATABANIA, in *Ancient Geography*, a country of Arabia Felix, according to Steph. Byz.; called by Strabo *Catalania*.

CATFACK, or CUTFACK, in *Geography*, a city of Hindoostan, and capital of a district of the same name, in the province of Orissa. It is seated on the river Mahanuddy, and is an important post, as it lies in the only road between Bengal and the northern circars; and the possession of this city and its dependencies gives the Berar rajah more consequence in the eyes of the Bengal government, than even his

extensive domain and central position in Hindoostan. It is distant 785 miles from Agra, 452 from Benares, 1034 from Bombay, 251 from Calcutta, 902 from Delhi, 651 from Hydrabad, 641 from Lucknow, 779 from Madras, 482 from Nagpore, 822 from Ougain, and 968 from Poonah. N. lat. 26° 32'. E. long. 86° 1' 30".

CATTAHUNK, one of the Elizabeth isles, in the state of Massachusetts.

CATTALIO, a town of Italy, in the Paduan territory; 5 miles S. of Padua.

CATTARO, or CATARO, a town of Dalmatia, capital of the territory of the same name, surrounded with thick walls, and defended by a castle; the see of a bishop, suffragan of Bari. It is subject to the state of Venice, and seated on a gulf of the same name. N. lat. 42° 25'. E. long. 19° 19'.

CATTECORONDE, in the language of the Ceylonese, prickly cinnamon. This is a bark very much resembling cinnamon, but produced by a tree which differs very much in the shape of the leaves, and is full of sharp thorns, which the true cinnamon tree is not. The bark has nothing either of the taste or smell of cinnamon, though so like it externally. The natives use the root, leaves, and bark of this tree externally, to soften tumours. *Phil. Trans.* N° 409. See *CASSIA* and *CINNAMON*.

CATTEGAT, or SCAGGERAC, in *Geography*, a large gulf of the North Sea, between North Jutland to the west, Norway to the east, and the islands of Zealand and Funen to the south; about 120 miles from north to south, and from 60 to 70 from east to west. This gulf is sprinkled with an astonishing number of rocks and islands. See *BELTS*.

CATTENOM, a town of France, in the department of the Moselle, and chief place of a canton in the district of Thionville. The place contains 1067, and the canton 14,876 inhabitants; the territory comprehends 297½ kilometres and 47 communes.

CATTERTHUN, a remarkable Caledonian post, situated a few miles N. of the town of Brechin, in the county of Angus, in Scotland. Mr. Pennant represents it as a very strong post, and particularly describes its structure and dimensions. Near it is another similar fortification of inferior strength, called "Brown Catterthun," from the colour of the ramparts, which are composed only of earth; the other consisting of stones. The former is of an oval form; but that of the latter is circular. Catterthun denotes "Camp-town;" and Mr. Pennant is of opinion, that these might be posts occupied by the Caledonians before their engagement at the foot of the Grampian mountains with the Roman general Agricola.

CATTI, in *Ancient Geography*, a people of Germany, who lived in the vicinity of the Cherusci. They were a warlike people, and their infantry was reckoned the best in Germany. The most remarkable places of their country were Castellum Cattorum and Mentium. Under the lower empire they were divided into two bands or classes; one of which joined the Cherusci, and the other established itself in a district of the country of the Batavi.

CATTIER, ISAAC, in *Biography*, born at Paris in the early part of the 17th century, received his education at Montpellier, where he took his degree of doctor of medicine, in 1657. Returning to Paris, he was made physician in ordinary to the king, and ranked among the most eminent physicians of his time. He was author of several learned works. "On the Waters of Bourbon;" "On the Powder of Sympathy," which he did not admit to be possessed of the qualities attributed to it; "De Rheumatismo, ejus Na-

tura, et Curatione," Paris, 1653; 12mo.; "Observationes Medicæ rariores," published the same year. They were afterwards joined with the observations of Peter Borelli. Among them is one of a malefactor who was executed at Paris, in whom the viscera of the thorax and abdomen were found to be transposed; those belonging to the right side being placed on the left, and vice versa. He has also observations on varieties observed in the lacteals, and in the thoracic duct, and on some monstrosous births. *Haller. Bib. Anat. et Chirurg.*

CATTIGARA, in *Ancient Geography*, a considerable port of India, the position of which corresponds, as M. d'Anville endeavours to prove, with that of Mergui, on the west coast of the kingdom of Siam.

CATTING *the Anchor*, is the operation of hauling the stock of the anchor up to the cat-head.

CATTIVELLAUNI, in *Ancient Geography*, the inhabitants of that part of Britain which lay north of the territory of the Trinobantes, and east of that of the Dobuni, in the country which now comprehends Hertfordshire, Buckinghamshire, and Bedfordshire. These ancient British people are sometimes called by Greek and Roman authors Catti, Cassi, Cattiocliani, Cattidudani, Cattiocudani, Catiucyulani, &c. It cannot be doubted that they were of Belgic origin, and it is not improbable, that they derived their name of Catti from the Belgic word Katten, which signifies illustrious or noble, and that the addition of Vellauni, which denotes on the banks of rivers, might be given them after their arrival in Britain, as descriptive of the situation of their country. (*Baxt. Gloss. Brit.*) However this may be, the Cattivellauni formed one of the most brave and warlike of the ancient British nations, when Cæsar invaded Britain, and long after. Cassibelanus, their prince, was made commander in chief of the confederated Britons, not only on account of his own personal qualities, but also because he was at the head of one of their bravest and most powerful tribes. In the interval between the departure of Cæsar and the next invasion under Claudius, the Cattivellauni had reduced several of the neighbouring states under their obedience; and they again took the lead in the opposition to the Romans, at their second invasion, under their brave but unfortunate prince Caractacus. The country of these people was much frequented and improved by the Romans, after it came under subjection to them. It made a part of the Roman province called Britannia Prima. Its capital was Verulamium. *Cæs. Bell. Gall. l. v. c. 9. Dio. l. lx. Tacit. Annal. l. xii. c. 33. Henry's Hist. vol. i.*

CATTIVO, *Ital. bad: in Music*, it is chiefly used in speaking of accentuation, as *tempo buono*, an accented part of a bar; *tempo cattivo*, an unaccented part. Of the former, in common time of 4 crotchets in a bar, the 1st and 3d are accented, and the 2d and 4th unaccented.

CATTLE, in *Rural Economy*, a name commonly applied to a certain kind of quadrupeds or beasts of pasture, as those of the *bos*, or cow and ox tribe; which are animals of vast importance in the practice of husbandry.

As marking the division of domestic animals, or what is usually termed live stock, they are often denominated *meat*, or the *larger-horned* cattle, and in some districts *black cattle*, though this last appellation is more frequently employed to signify a particular breed or variety of this sort of animals. See *BLACK CATTLE*. It seems not improbable but that all these sorts of animals were originally in a wild or untamed state, and that in proportion as the art of cultivation increased, such as were the most proper and best suited to this purpose and that of domestication, were gradually selected and made subservient to the power of man. This is more prob-

Some being still found in a state of nature in different parts.

The characteristic distinctions of the genus or kind, according to the very intelligent naturalist, Mr. Pennant, are that they are "cloven footed, with or without horns, the horns bending out laterally; eight cutting teeth in the lower jaw, and nine in the upper; the skin along the lower side of the neck pendulous; rounded horns with a large space between their bases."

This species constitutes the principal particular sorts, being formed from the original and most remarkable divisions or distinctions; and the varieties are produced by the inter-copulation of these, which, from their being accidental, as well as from the great diversity of soil, food, and climate, must obviously assume a vast diversity in respect to shape and form. Some of these varieties, whether original or acquired, have, however, been preserved in a permanent state by the efforts and attention of the careful breeder. But notwithstanding the variations produced in neat cattle by the influence of climate, or the agency of other causes, the principal specific distinction which has been made in their kind by the naturalist is that of the *urus*, or common bull of temperate climates in its native wild state, and the *bison* or bull of the more hot regions, having a bunch between his shoulders, which in some of the largest is said to be of considerable weight and exquisite flavour, and to form the characteristic distinction of the animal: while the elevated crest, and in some cases the lion's mane, form nearly a characteristic mark of the common bull, the former of which being individually preserved to the ultimate stages of domestication, as is occasionally seen in the Devonshire, Alderney, and other kinds or breeds.

Before we come to consider the various breeds and varieties of domesticated cattle in our own country, it may be of advantage to take notice of some particulars respecting those in others, that are the most remarkable.

In regard to the *urus*, or native wild bull, it has in general a curled shaggy coat, especially on the forehead: the hair constantly long on the fore quarters, neck, and forehead, and depending from the chin; the neck elevated, thick and short, with the tail long, the eyes red and fiery; the horns thick and short. It grows to a large size, the female being larger than our largest bull, and is of a black colour.

The *bison* has the same hairy appearance in his fore part only; his long shaggy mane forms a sort of beard under his chin, but he differs from the former in having a lump or bunch between his shoulders, and the tail and legs are short, the eyes fierce, the forehead large, and the horns extremely wide.

The former of these sorts of animals are dispersed over the more temperate and cold climates, and especially throughout America, probably imported from Europe; while the latter have spread over most of the more southern parts of the world, but with considerable diversity in respect to their size and form:—Those met with in the island of Madagascar, in Malabar, as well as other parts of India, in Persia, the Ukraine, Calmuck Tartary, the Upper Ethiopia, and in Abyssinia, being of the proper *bison* or large kind; while those of Africa, the higher southern latitudes of India, and some parts of Arabia, are of the small dwarf or *ætes* kind; in which the hair is more fine, glossy, soft, and beautiful, than that of the common cow:—The largest animals of the different sorts being constantly met with in those temperate situations or districts, where the supplies of water and herbage are the most regular and abundant.

In some of the former of the above countries the animals rise to a very large size, sometimes being wholly without horns, but in other cases with extremely large branching or

pendulous ones, having a very great substance or thickness at the bases. They are in much estimation, especially the oxen, when of a fine white colour, for the purpose of quick draught in carriages. And in some of the more barren and less fruitful parts of the latter countries the sort is found extremely useful in carrying loads, though often not more than three feet in height.

The Indian cattle have been occasionally brought from their native situations, and blended with the breeds of this country.

The *musk bull*, which is found in the interior parts of North America, between Churchill and Seal rivers, may perhaps be considered as a variety of the above sort produced by inter-copulation with the wild European kind, as the wild bull of this part of the globe emits a musky scent. It is described as somewhat lower, but more bulky than the deer; the legs short, a small hump or bunch on the shoulder; the hair of a dusky red colour, very fine, and so long as to reach the ground; beneath which the body is covered with an ash-coloured wool of exquisite fineness, capable of forming stockings finer than silk. The tail not more than three inches in length, being covered with long hairs, which the Esquimaux Indians convert into caps. The horns are close and large at the base, bending downwards, and turning out at the tips, being two feet in length or more.

The *farne*, or grunting ox of Tartary and Thibet, where it is brought into a domestic state, from having the hump between the shoulders, and being capable of generating with the bison, may obviously be concluded to belong to that kind. The chief circumstance in which it differs, is that, instead of lowing, as in the ox kind, it has the peculiarity of grunting like the hog, but it varies in other particulars. It has the whole body covered with a very long hair, which hangs down below the knees, mostly of a black colour, except on the ridge of the back and the mane, which is white. The horns are short, upright, sharp, and slender at the extremities. The tail in the form of that of the horse, but white and bushy. It butts or strikes with its head like the goat, and in its wild state is extremely unruly. The tail is held in high elevation for various purposes of ornament.

How far any of these foreign breeds or varieties of cattle are capable of being introduced with advantage into this country, remains to be further proved by the test of actual experiment, in respect to the qualities or properties of bardingness, quickness of fattening, fineness of flavour in the meat, and many other points, as has been ingeniously suggested by Dr. Anderson.

In regard to the cattle of our own country, as they are not less numerous in their varieties than those of the foreign kinds, and of much more importance to the farmer in a variety of different points of view, but particularly in that of profit; the greatest care and attention should obviously be bestowed on the breeding, rearing, and providing such sorts as are the best suited to the particular nature of the farm, or land on which they are to be supported. And as no one particular breed is suitable for every situation or kind of farm, much circumspection should be employed in adapting them to the peculiar nature of the climate, situation, and soil.

The circumstances that are to be more particularly regarded, in respect to the breeds themselves, in so far as they interest the farmer, have been already explained, in considering the methods of breeding this sort of live stock. See BREEDING.

It is not well ascertained what were the primitive or original sorts of cattle in this island, but it seems probable from those breeds which have, from particular circumstances, remained

remained without being much debased by the admixture of other sorts, such as the Highland, the Welsh, and the North Devon, as well as perhaps the Lancashire long-horns, that, in the more hilly regions and the low valleys, they consisted of the long and middle-horned varieties, perhaps without any of the short-horned sort, which have, probably, been since introduced from the opposite continent. Some, however, think, with much probability, that the long-horned sort was originally brought into this country from Ireland, from the native flock of that island consisting wholly of that breed, and from no other country possessing cattle, which have a similarity of form and size of horn.

Poland is likewise supposed to have supplied the breed, which, from their having no horns, is termed the *pollled*, though it is probable from the want of horns being a part of the generic character, that a mixture of this sort of cattle may have originally existed in the country, notwithstanding they are now so blended and intermixed with others as not to leave a possibility of discovering the original.

It is probable that the primitive or original sorts of cattle have not deviated much from their standard forms, except in what has proceeded from an increase of size, bulk, and substance, in consequence of being better supported from the improved state of husbandry, and their being blended and moulded into different varieties by crossing, and other means made use of by the breeder.

The numerous breeds and varieties of cattle which are to be found in different districts of this kingdom have been principally designated either from the appearance which they immediately present to the farmer, or the places in which they are found to prevail in a state of the greatest perfection; though no very correct enumeration of them has hitherto been given, only a few of the more valuable and useful sorts having been fully described.

These are the *long-horned* or Lancashire breed; the *middle-horned* breed; the *short-horned* breed; the *Wiltshire* breed, the *pollled* or Galloway breed; the *Scotch* breed; the *Alderney* or *French* breed; and the *wild* breed.

It has been observed by Mr. Cuiley, in his "Treatise on Live Stock," that the *long-horned* or Lancashire breed of cattle are distinguished from others by the length of their horns, the thickness and firm texture of their hides, the length and closeness of their hair, the large size of their hoofs, and coarse, leathery, thick necks; that they are likewise deeper made in their fore quarters, and lighter in their hind-quarters, than the other breeds in general. And Mr. Donaldson says that in size they are superior to the Suffolk duns, but inferior to the short and middle-horned breeds. Mr. Cuiley thinks also further that they are narrower in their shape, less in point of weight than the short-horns, though better weighers in proportion to their size; and that the cows give considerably less milk, though it is said to afford more cream in proportion to the quantity.

These cattle are more varied in colour than any of the other breeds; but whatever the colour be, they have generally a white streak along their back, which the breeders term *finched*, and mostly a white spot on the inside of the hough. And in the bending of the horns there is an equal variety in this sort of cattle.

It is likewise remarked by the same author, that many people contend that they are the native or original breed of this island. It is not easy, he says, to ascertain this matter; but if he may venture a conjecture, he thinks it is probable these have been the inhabitants of the open plain country; whilst the wild breed, or perhaps the Welsh and Scotch, possessed the woody, wild, and mountainous parts of the island.—"However," says he, "Lancashire at present, and for a

long time past, has as much right to be called the mother country for long-horned cattle, as Lincolnshire has for the large long-woulded sheep; for though all or most of the cheese-dairies in Cheshire, Gloucestershire, &c. and indeed the greatest part of the midland counties employ a kind of long-horned cows, yet they are only a shabby mixed breed, much inferior in size and figure to the Lancashire breed, from whence it is very probable they all originated." The author of "The present State of Husbandry in Great Britain," however, thinks it probable that the long-horned breed originated in importations of cattle from the neighbouring country of Ireland; and that bulls and cows brought from that island, having been coupled with the ancient breed of the district, produced the sort of cattle known by the name of the Lancashire or long-horned, and which now occupy a large portion of the pasture lands of this kingdom. It is added, that besides Lancashire, the long-horned cattle are also very general in the counties of Warwick, Leicestershire, Gloucester, Cheshire, and several others of the midland counties; and what is surprising, and shows great attention in the one instance, and equal neglect in the other, this sort of cattle is said to be found in greater perfection in the county of Leicestershire than in the district whence they take their name. This has arisen, according to the observations of the author of the Treatise on Live Stock, from the graziers of these counties buying their best bulls and heifers for many years past, before the people of Lancashire were well aware of it. "The former paid more attention to that kind which were of a true mould or form, and quicker feeders: while the latter contented themselves with the old-fashioned, large, big-boned kind, which are not only slower feeders, but when fed, are not such good beef. In short, the little farmers in Lancashire, tempted by the high prices given them for their best stock, had lost their valuable breed before they were sensible of it." It is evident that the original breed of this sort of cattle spread themselves from the great breeding districts of the northern parts of Lancashire, Westmoreland and Cumberland, into the extensive grazing and dairying districts of the midland counties, where they are at present met with in the most improved state.

It is asserted that this breed is understood by graziers to be in general rather slow feeders, except that particular kind selected and recommended by the late Mr. Bakewell, which are said to eat less food than the others, to become remarkably fat in a short space of time, and to lay their fat upon the most valuable parts, but have little tallow in them when killed; and, when used in the dairy, give very little milk. This variety also differs from the rest of the long-horned cattle, in having very fine, clean, small bones in their legs, and thin hides. They are stated to be "a middle-sized, clean, small-boned, round-cased, kindly-looking cattle."

It is supposed by Mr. Cuiley that the Irish cattle are a mixed breed between the long horns and the Welsh or Scotch, but more inclined to the long horns, though of less weight than those in this part of the kingdom.

It was from the midland long-horned breed of meat cattle that the late Mr. Bakewell selected the stock for his great improvements in these animals. Much attention had indeed been previously paid to the procuring and introducing of the best cow flock of this sort into this district by others, and it was by selecting from these that Mr. Webber constituted the noted Canley flock. And from cows of this celebrated sort with Westmoreland bulls the very intelligent breeder just mentioned commenced his plan, which, after breeding repeatedly from the best of the same kind, constantly choosing individuals with the roundest forms and smallest bones, he produced that variety, which has since acquired so high a character

a character for their fattening property. It is, of course, obvious that this variety which has been denominated the *Dishley* or *new Leicester*, is principally calculated for the purposes of the grazier, while the original long-horns have preserved their superiority for the pail. The size of this improved sort is considerable, and its utility sufficiently shewn by the high prices that are frequently given for them.

There is a sort of mixed kind which are termed half long-horns, that are an useful sort of stock, and which will be noticed below.

The *middle-borne* or *middle-corn* according to the author of the Treatise on Live Stock, most frequently met with in the fourth and fourth west parts of the county, as Suffex, Dorsetshire, Hampshire, Devonshire, &c. and have also reached so far north as Herefordshire, in which district, perhaps the best breed of this sort of cattle are now to be found. The cattle of this breed that are met with in Devonshire are said by Mr. Culley to be found in the greatest purity, and of the best kind, in the vicinity of Barnstaple; these are of a high red colour; if they have any white spots they reckon the breed impure, particularly if those spots run into one another; with a light dusky ring round the eye, and the muzzli of the same colour; fine in the bone, clean in the neck, horns of a medium length bent upwards, thin-faced and fine in the chops, wide in the hips, a tolerable barrel but rather flat on the sides, tail small and set on very high; they are thin-skinned, and silky in handling, feed at an early age, or arrive at maturity sooner than most other breeds; they are well fitted for draught, both as to hardiness and quick movement, and their shoulder-points are beautifully fitted for the collar.

But according to Lord Somerville, who has given a full account of them in the "Annals of Agriculture," and who must be allowed to be no mean judge of this breed of cattle; they are, when described, "not as they might be in imaginary individuals, but as they really are found, in general, speaking of this as of all other breeds, that conclusions must not be drawn from the shape and size of the bulls, but from the general quality of their stock. Certain it is (he says) that individually handsome bulls are often to be found in other breeds; and it is as certain, that this race, of which the whole produce is brought to view, stands the confessed favourite, or among the very first at Smithfield, where prejudice cannot find the way. And in forming an estimate of merit or demerit, the annual produce is to be the object attended to; this in oxen, which for superiority of grain, activity in labour beyond all competition, and what in horses is termed blood, will be found a right criterion to judge of the bulls which got them."

And that "beginning with the shape of the bull, in any very handsome individual, the horn is (he says) found neither drooping too low, nor rising too high, nor with points inverted, called here *flag-headed*; tapering at the points, and not too thick, or *goary* at the root; the colour yellow, or waxy. The eye clear, bright, and prominent; looking well behind and shewing much of the white;—a dead-eyed ox not often a good prover, or fine in skin;—an occasional variation of colour round it. Forehead flat, indented, and small:—this found almost universally in this breed, and is a point that shews much blood. Cheek small and muzzle fine:—if the forehead is fine the muzzle is too. The nose of a clear yellow, if possible like the horn, or mottled:—a black nose always to be avoided; for although occasionally a black-nosed ox may bear work, and do well, yet it is a point often demonstrative of a bad constitution, of such as turn scourers, or *skinters* provincially, and particularly when the salt of the coat is of too pale a colour. The nostril high

and open. In respect of throat, the bulls of this breed are sometimes reproached with being *throaty*, or with the skin too profuse and pendulous. The hair curled, giving an apparent coarseness to the head not to be found in the New Leicester bulls, when carefully trimmed with scissars. The neck perhaps thick and *goary* in the estimation of strangers, with which property the oxen of this breed are not to be reproached, or they would not labour as they do.

"Generally speaking (he thinks) the bulls are relatively to oxen not of a large size; and it should be observed respecting size in general, that nature operating in food and climate is imperious, and will produce oxen proportioned to those two circumstances in due course of time, whatever may have been originally the size of the bulls and cows.

"Here end (he says) the points wherein there is any essential difference between the bull and the ox; the variation in size is small and unessential: a remark which is, however, subject to limitation; for individual instances will occur, which if too much attended to, would seem to establish a different rule.

"The neatness of form, and energy and vigour in labour, greatly, if not wholly, in this breed arose (he supposes) from breeding by heifers and year-old and two years' old bulls. Although an old ewe may produce a finer lamb than a younger one, yet the quality of vigour is unnecessary and extraneous (he says) to the sheep. This, (continues he) is a prejudice deeply rooted in the minds of all practical men, although much, in the estimation of some, may be given to climate.

"Compared with the horse, the shoulder is (he conceives) low. It should correspond with the general thickness of the animal; on no account projecting. If a bull *ck* is *in-kneed*, or bending towards each other, the point of the toe must be out; the point of his shoulder must be the same; and he must be hollow behind the withers, (an incorrigible point in an ox for feeding) and he must be, of necessity, a slow worker.

"The bosom is not sharp with a loose, pendulous dewlap; but wide in form, and mellow in handling. In buying an ox great notice should be taken of the breadth of the bosom, and between the fore-legs, standing quite wide, the legs like straight pillars supporting a great burden. Much in buying is lost or gained by attention to this point: it is not for symmetry only, but implies strength and speed; a proportionate breadth of breast giving wind: and here we find (he says) the application to a working ox.

"The legs are straight; and the more blood an ox shews, the smaller will they be. The circumstance of this breed shewing more blood than any other in the kingdom, has (he observes) been remarked by many persons ignorant of cattle, but deeply skilled in horses. The leg neither too long, nor too short: an undue length is to be avoided.

"Very much of a bullock's proof is admitted, (he adds) on all hands to depend on the size of the rib, roundness of the barrel, and mellowness of the skin. There are the first points to handle in a lean and in a fat ox. The two hind ribs should be bold, prominent, and widely independent of each other. The skin rising easily from the ribs, mellow, and elastic, affording room to lay fat on below it. A man buying a lean ox would do well to handle him on both sides: it often happens, that the frame or barrel is not equally round on both; one being evidently to the eye and hand flatter than the other.

"The hips, or pins, lie so high as to be on a level with the back, either in a fat or lean state; by no means dropping. The older the animal, the lower the upper flank drops, and consequently, the higher the hips appear. In this point of

the upper flank, a skilful judge will (he thinks) discover much of the inward properties of a fat bullock. The hind quarters from the pin to the catch, or point of the rump, should be long and well filled up: handling the centre of this space is a leading feature, in the estimation of choice judges, and ascertains more of the substantial quality of the flesh and fat of a beast than the prominence of fat so much admired by bad judges on the catch of the rump.

"The fetting on of the tail is on a level with the back, something elevated, nothing depressed: five long, small, taper, and with a round bunch of hair at the bottom; the tail, as in a horse, denoting much of high blood.

"The galkins are not too much cut away, nor, as in the Holderness breed, heavy and loaded: bearing always in mind, that these oxen are not bred for inactivity, but for wind, vigour, and strength: for although a breadth in the bosom, inasmuch as it is essential to wind, in a working animal, is beneficial; yet a load of flesh on this hind part tends nothing to activity; and being of second-rate quality, is not desirable for profit.

"In point of skin they are among the thinner classes, rather than the thicker. It is very rarely that an ox is found with a hard or very skin. Much depends on colour: the shades most admired are the mahogany; and the more glossy filkins, if smooth, the better. Those with curled hair are deemed excellent provers, and a very glossy mahogany skin, paler or lighter, with curls like ripples of wind on a smooth mill-pond, is also in the highest estimation. It is hard to say which of these is the best; all turning out such numbers of good fat oxen. The paler shades, if the eye is clear and good, will bear hard work, and prove as well as any. This rule only is absolute, that a pale skin, hard under hand, with a dark and dead eye, too often denote a *skinker* in hard work, and rarely under any indulgence, a good prover.

"Respecting the lower flank and the cod, they do not deserve that attention which many persons pay them, who consider these points of prime importance.

"The graziers like this breed (he says) best at five years old. The worked-out fleeces of the vale sell for more, at five years, than at six: but six is the proper age. At eight, nine, and ten, they are going back in all their points; and in their value after seven. No ox should be kept after seven, or, at most, after eight.

"They (the red cattle) are (he says) yoked at two or three years old, and lightly worked; labour increased at four; from that period till six full worked. Worked oxen attain a larger size than unworked; finish their growth generally at six years old; but the larger size grow the longest."

From the actual experience of the noble writer, "the pole and yoke form the true lever of an ox, and he can draw a greater weight in yoke, than in collar and harness, particularly in a deep country. The bullocks never come home in the middle of the day; a bundle of hay is carried into the field; all the calves of this breed are reared."

These oxen are "not (he says) parted with by the tillage-farmers until the barley-sowing is over, and, in many cases, the turnip-ground once sowed; yet they are grazed fat, in six or eight months, to the average weight of forty-five score: these, kept on, after Christmas, fattened on hay alone, which, in the grazing districts of the west, is held equally nutritious with any other sort of corn; oil-cake feeding not practised: these hay-fed oxen stand the drilt to London without wattle. Instances of marsh-feeding heifers bought in April or May, quite poor, fit for the butcher by the middle of July; in August uncommonly fine beef."

"The station of this breed begins (his lordship observes) at Barnstaple, and is traced, by pursuing the line of the river Taw, as high as Chumleigh, then to Tiverton on the Ex, Wellington, and nearly to Taunton. Then turning north straight to the sea, over the eastern boundary of the Quantock hills, to Stoke Courcy; from which place, on the eastern extremity, to the mouth of the Barnstaple river on the western, includes the whole, to the length of forty-five miles, and to the breadth across, from Tiverton to Minehead, of twenty-two. To the east of this range, the breed gets into a mixture of Gloucester, Welsh, Upper Somerset, &c. being a varied dairy fample; and more to the west, a Devon, verging on the principle of the Cornish flock. To the south, the variety of the fourth hams is found; coarse, with a good deal of white and brown, with black and white mixtures, of uncertain properties. Exmoor is the highest point of the district thus defined, the country sloping from it in every direction, the source of all the rivers, and the head-quarters of all the cattle. At Bampton and Wyvelshoeb, they are found in great perfection."

It is observed by Mr. Lawrence, in his "Treatise on Cattle," that "the red cattle of North Devon and Somerset are, without doubt, one of the original breeds, and one of those which has preserved most of its primitive form: the excellence of this for labour is best proved by the fact, that the fashionable substitution of horses has made no progress in the district of these cattle; by their high repute as feeders, and for the superior excellence of their beef, which has been acknowledged for ages."

It was remarked by Mr. Bakewell, that the Devonshire could not be improved by any cross with other breeds.

This breed has been supposed by some to run too great length of leg, crooked behind, or *sickle-hamned*, and to be of insufficient general substance, as well as to be more apt to be *in-kneed*, that is, crooked in the fore legs.

It is suggested, by the writer just mentioned, that "by a proper selection from their own flock, they might be bred somewhat more square and substantial, without at all detracting from their delicacy, shew of blood, or speed. Their labouring powers might be thus increased, and their quantity of beef, without either debasing its fine qualities, or rendering necessary a larger portion of keep. These cattle have generally, for a century past, it is added, commanded the best price at Smithfield; but of late years the buyers there have shrewdly remarked, that although blood and fine form are very pleasing to the eye of the gentleman breeder, yet substance and weight are, and ever must be, the grand objects at market."

It is stated that "the Devonshire variety of this breed is the quickest working oxen in this country, and will trot well in harness; in point of strength, they stand in the fourth or fifth class. They have a greater resemblance to deer than any other breed of neat cattle. They are rather wide in the horns, in part inclining. Some, however, have regular middle horns, that is, neither short nor long, turned upwards and backwards at the points. As milkers, they are so far inferior to both the long and short-horns in quantity and quality of milk, that they are certainly no objects for the regular dairy. They have, however, been formerly used with success at Epping in Essex, in one or two instances; as a balance to which they are universally rejected by the dairies of their own and the neighbouring counties."

It has been stated by Mr. Young, "that the *natt* or *pollie* Devonshire breed, in the neighbourhood of Barnstaple, is coloured, middle-sized, thick-set, and apt to make fat, but

power to the cultivation of the heaviest clays, and to draught over the deepest roads; in temper somewhat quick, like the Devons. These different varieties of the middle-horned breed of cattle are said, for their particular excellencies, to deserve the utmost care from breeders, and to be one of the first objects of national interest, to spread them through the country as beasts of labour.

He supposes that the *Kentish Homelands*, which are raised from dairy heifers, are of a mixed breed, the Suffex generally forming the base, crossed with Welch long-horns, Alderney, &c. A variety is, he says, thus raised of excellent butter-cows of a small size; and he suggests it to the breeders of that district whether it may not be worth while to establish and render the breed permanent.

A good specimen of a bull of this sort raised from Suffex bulls, introduced into that county about forty years ago, was remarkable for shortness of the leg, length of carcass, and vast substance; the bone somewhat coarse, and crooked in the hams. It is observed by the same writer that, of the white cattle of Surrey, mentioned by old authors, he knows nothing, nor does he believe Surrey was ever a breeding county. The notion may have arisen, he thinks, from some temporary introduction of Alderney, or other flock of light colour. "In fact, says he, it is said, that some gentleman, about fifty years since, brought up from Lincolnshire, into Surrey, a lot of white cows, very large milkers, and that the same kind were at that time kept in Suffolk; they were probably, he thinks, of Dutch extraction."

The author of the "Present State of Husbandry in Great Britain" remarks, that when all the properties which should attach to a useful breed of cattle are considered, the middle-horned may be said, as a general variety, to come nearer to perfection than any other in England. They are of a large size, well formed, and in disposition to fatten, they are probably, he thinks, much on a par with the short-horned, and generally superior to the Suffolk. As dairy-cattle, they are also as valuable as any that fall under the description of quick feeders; for although they give a less quantity of milk than the Suffolk or the long-horned, it is said to be of a richer quality.

The *short-horned breed* of cattle, according to Mr. Culley, differs from the other breeds in the shortness of their horns, in being wider and thicker in their form or mould, consequently feeding to the most weight, in affording by much the greatest quantity of tallow when fattened, in having very thin hides, and much less hair upon them than any other breed, except the Alderney; but that the most essential difference, he thinks, consists in the quantity of milk they give beyond any other breed; there being instances of cows of this breed giving 36 quarts of milk per day, and of 48 firkins of butter being made from a dairy of 12 cows; but the more general quantity is 3 firkins per cow in a season, and 24 quarts of milk per day. The great quantity of milk, thinness of their hides, and little hair, are, he says, probably the reasons why they are tenderer than all the other kinds, except the Alderney. It is said of this kind, and he supposes very justly, that they eat more food than any of the other breeds; nor can we, says he, wonder at this, when we consider that they excel in these three valuable particulars, viz. in affording the greatest quantity of beef, tallow, and milk. Their colours are much varied; but the generality of them are red and white mixed, or what the breeders call *speckled*, and, when properly mixed, a very pleasing and agreeable colour. They are chiefly to be found in Lincolnshire, and the eastern parts of the counties of York, Durham, Northumberland, and Berwick. And this breed, in consequence of its having been originally imported from Holland, is, he adds, frequently called the Dutch, and sometimes the Holderness breed, from a place of

that name in Yorkshire, where it would seem it was first established in this kingdom. Destitute of the exertion and agility of the middle-horned sort, says Mr. Donaldson, they are not so well adapted for the cart or the plough. And considering their size, and the quantity of food they devour, it is probable, he thinks, that they are inferior to any of the above-mentioned; and, when compared with the Suffolk duns, greatly so. Much attention, he observes, was formerly bestowed by the graziers in the midland districts on the improvement of the long-horned breed of cattle; and probably a greater number of eminent breeders have lately embarked in the laudable undertaking of improving the short-horned breed; and from their knowledge, assiduity, and exertions, much may be expected. Mr. Charles Cellings at Ketnes, near Darlington, in Yorkshire, is supposed at present in possession of the best breed of short-horned cattle in England.

There are many reasons, says the author of the "Treatise on Live Stock," for thinking this breed has been imported from the continent. First, because they are still in many places called the Dutch breed. Secondly, because we find very few of these cattle any where in this island, except along the eastern coast, facing those parts of the continent where the same kind of cattle is still bred, and reaching to the southern extremity of Lincolnshire to the borders of Scotland. The long horns and these have met upon the mountains which separate Yorkshire from Lancashire, &c. and by crossing have produced a mixed breed, called half-long-horns; a very heavy, strong, and not unuseful kind of cattle; but we do not find that the one kind has spread further west, nor the other further east. This breed, says he, like most others, is better and worse in different districts; not so much from the good or bad qualities of the land, as from a want of attention in the breeder."

It has been observed, that the northern short-horned species is the largest breed in the island, the Herefords being the next. They are an original breed, but whether those of the northern counties are so or not, cannot at present be ascertained; "that is to say, whether they are aboriginal, or were imported in very early times, as we know they have continually been during several centuries."

Contrary to the long-horns, this sort has great depth of carcass; but with ample substance, large bone, thin hide, and gives much milk, which is not distinguished for its richness. They are not of first-rate character as labouring cattle, as has been seen, which, nevertheless, the Holderness variety, Mr. Lawrence says, seems to promise by their form. "We look, continues he, to the coarse, square, Dutch beefy breed, as the basis of this species. In many parts of the north, they remain, he adds, still coarse, and by no means equally disposed to large milking. The common Lincolnshire cattle are coarse in head and horn, large boned, high upon the leg, and, to borrow a jockey phrase, *ragged hipped*. Equally coarse internally, but producing flesh in great quantity. The Lincoln neat cattle, in fact, plainly, he thinks, demand a Bakewellian improvement, such as their sheep have received. The most accurately marked and distinguishable permanent varieties of the northern short-horns appear to him to be the Holderness and Lincolnshire. Culley, says he, tells us, that amongst the old flock there were some with black flesh, which would grow, but never fatten, provincially called *hyery*; these were to be known by the roundness of their shape, approaching, in many respects, that of an ill-formed cart-horse. And the extreme coarseness and size of the northern short horns led, he thinks, to the introduction of Norman or Alderney bulls at some period of the 18th century, with the precise date of which we are unacquainted." And he supposes "that there never was a more fortunate cross,

C A T T L E.

as in no other country exists so excellent a breed of cattle, including all the useful properties. In one, perhaps the most important, respect, great milking, they are (say he) superior, and even without rivals. Their beef is finer than that of the old short-horned breed, and they fatten much earlier and quicker, ear-yrng fill a vast depth of natural flesh, and tallowing within in the first degree. They have both speed and strength enough (he supposes) for labour, and their shoulders are well formed and well poised for draught. Being beautifully variegated in colour, spotted, striped, sometimes fleeced red and white, or black, or brown and white, they make a fine park flock. From their superior quantity of milk, they rival, in his opinion, the best long-horns in the cheele and butter dairies, and for suckling are unrivalled. It may be presumed (he says) they are at least equal to the Herefords in the stall, at all points: and there seems but one respect in which they are, in any considerable degree, inferior to any breed which can be named, which is fineness of flesh; in that particular, it is obvious, they can never equal certain other breeds without the entire overthrow of their Dutch basis by a repetition of the Norman or some other cross, which would go to destroy the present superior breed. An occasional mixture, however, of Norman blood may, he says, keep the Holdernes stock sufficiently fine, and prevent its degeneration on the other side; or a selection might be made of very elegantly shaped and fine-boned Holdernes cows, with the view of improvement. These are well known as the stock generally kept by the London cow-keepers. They have small short horns, in the shape of a half-ring, rather a long plain head, fine skin, the legs seldom too long, the carcass large but compact, good back and loin, the general figure square. They are not the species of stock for short keep, however small their size; indeed they are said to be great consumers." But "this high character of the Holdernes cattle (he desires) should be received with considerable reserve. It relates to the cows chiefly, and to a selection of the oxen; to what they ought, and might be, rather than what they generally are." They are too often, he thinks, "the worst shaped cattle in the island, and perhaps the least profitable. Long, gaunt, deep carcasses, without adequate substance, placed upon high stilts of the coarsest timber; slow feeders, never fat, and the flesh excessively coarse. The feeding such ill-shaped stock must (he farther observes) be immensely disadvantageous, and is particularly disgraceful in districts which produce the best models." The first object, in respect to their improvement, is (he supposes) to shorten the legs; "which might be effected (he thinks) by a conjunction of the best Teefwater and Holdernes bulls, with selected short-legged cows. It is a striking fact, obviously (he supposes) indicative of a rapidly increasing population, that, notwithstanding unprecedented prices, encouragement, and improvements, store cattle are at this instant so scarce, that many graziers must come short of their needful quantity."

The following statement has been given, by the author of the "Treatise on Live Stock," as the weight of a five years old beast of the Teefwater sort killed in 1759, allowing 14lb. to the stone.

	Stone lb.	£.	s.	d.
Two fore-quarters	74 8½	14	18	5
— hind ditto	75 10	15	18	7
<hr/>				
Weight of carcass	150 4½	30	17	0
— tallow	16 0	5	4	0
— hide	10 11	2	11	0
<hr/>				
Total	177 1½	Value	£ 30	4 0

It is added, by Mr. Lawrence, that the best and quickest

feeders of this breed are not remarkable for milking, and that the *Teefwater* short-horns are a valuable variety of the Teefwater sort.

It is believed, by the same writer, that the northern *holf long-horns* are the immediate produce of a conjunction of the long and short-horns, which must, of necessity, frequently happen upon, and in the vicinity of those mountains which separate the native districts of the two kinds. The horns of this variety, he thinks, generally run out pretty straight and even, unlike those which are called middle or wide-horns. They are a large and long breed of cattle, partaking equally, as may be supposed, of the qualities of each species, and therefore ought to be good dairy cattle, as uniting quality and quantity of milk, and size; in fact, he has been assured, by an intelligent Essex dairy-man, that they have the best title to such character, and many years since, when cow-flock was at a low rate, he preferred going to the price of 16 or 17 guineas a piece, for this description. They are not, he thinks, so permanently established and generally known as their originals.

And "the northern or *Yorkshire polled* cattle have (according to him) the same qualities as the short-horned, carrying vast substance, and some he has seen lately are of great size, although in that particular they are most conveniently various. In his opinion they are a most excellent breed, and well merit improvement, with the view of labour, by a selection of the finest bred and most active individuals. From the shape of these polled cattle, they hold a strict affinity in all respects with the short-horned, amongst which they are found; and it seems that various breeds of horned cattle are attended with hornless, but perfectly congenial varieties."

The *Berwickshire* cattle have probably, he says, a relation to this breed, having been improved by Teefwater bulls from Northumberland. They rise, at three years old, to sixty, or perhaps nearly eighty stones, of fourteen pounds, and at five or six from the last to one hundred and twenty. The best cows affording so high as six gallons of milk in the day. The ox is deserved as having a "long face, open countenance, clean and small, turned up, curving, and spreading horns, straight shanks, straight and round along the back, full and deep in the ribs, short legs, thighs turned out, open boned." This breed in the improved sort is highly valuable.

The *Wells* breed of cattle, especially such as are found in Cardiganhire, are, the author of modern agriculture says, mostly black, with thick horns turned upwards; of a small size, clean boned, of a good shape, especially where the native breed has not been injured by injudicious crossing with others from England. They are hardy and active; and in great request in the southern counties of England, on account of their being quick feeders. The quantity of milk which the cows of this breed afford is trifling; but they are, upon the whole, a breed well adapted to that country, although still capable of very great improvement; which might be effected with more certainty, and to a greater extent, he thinks, by selecting the best individuals of the native breed, than by bringing others possessing probably very different qualities from England. But the author of a late treatise on cattle supposes that there may have been originally two distinct breeds, in this district of the kingdom, as the mountain kind having large wide horns, thick hides, and much bone in proportion to their size; the cows affording but little milk; and the low land or southern sort, which are of a larger size and finer form, having middle horns, being in some instances good milkers, those of some parts, as Glamorganhire, being in high estimation for the purpose of draught on the lighter sorts of hilly lands. In general, he thinks, the cattle of this district are, however,

accp

deep and flat in form, "some of them cloddy and of great substance also."

Those of the above part, *Pembroke* and *Montgomeryshire*, are considered as the most valuable sorts of the cattle of this part of the kingdom.

It is supposed that the principal defects in these cattle are, at present, the want of substance, and great length of leg; the remedy of which is supposed to be a *Herefordshire* cross in the view of beef or labour. Their appearances in the different counties of this breeding district, are stated by a late writer somewhat as below.

"The original *Carmarthenshire* sort, Mr. Lawrence says, is "black, coarse, ill formed, short and thick, having wide horns of great substance at the base. The cattle, in course, small in the mountain districts, and of large size in the vales, in good keep." "They improve there," he adds, "have tried various crosses. Hereford, Shropshire, Leicester, *Pembroke*, *Glamorgan*, but they say without the desired success. The produce of a *Pembroke* heifer and *Hereford* bull, is, he says, the favourite stock in this county, where, in truth, the prior object ought to be an improvement of keep."

The *Glamorganshire* cattle are, according to the same writer, "in the cows rather small, of light bone, in colour black or brown, handsome, and few much blood. They milk well, and feed quick, and are used as beasts of labour: they need no improvement from alien crosses (he thinks); but there are inferior varieties of them, from being mixed with the stock of the borders. This breed (he supposes) prevails in *Monmouthshire*, and is to be found at the fairs and markets of *Pontypool*."

But the *Pembrokeshire* cattle are, he says, "coal black, sometimes dark brown, finched, or white towards the tail; some have white faces. They were originally finer than at present, probably the same race as the *Glamorgans*, which some of the *Pembroke* cows resemble at this time: but the breed has been crossed with the *old Leicester*, with the view of obtaining milk, in which the improvers did not succeed so well; as in rendering their stock coarse, bony, and unfit for labour. If butter was the object, they had better, he thinks, probably, have retained the imported long horns unmixed. This cross accounts (he supposes) for the *Pembrokes* being finched, and having long and round carcasses. They generally labour on the roads, yoked with horses, and their journeys are performed with a speed unknown elsewhere. But the *Pembroke* ox is too leggy, but he becomes early ripe, and will make fat at four years old. He attains the weight of 80 to 130, or 140 stone London weight, and is said to stand his dirt or journey better than any from *Wales*, whence he finds a preference particularly in the counties adjoining the metropolis. Two year old *Pembroke* bulls are bought up at the fairs, at considerable prices, by the improvers of the neighbouring counties."

The native *Brecknockshire* sort are, he thinks, "much the same as those of *Carmarthen* and *Pembroke*; but being crossed with *Hereford*, and some with *Devonshire* bulls, labour seems to be the object, and with such crosses, and attention to good keep, a very excellent breed may (he believes) be raised."

And the *Cardiganshire* breed are "smaller variety of the *Pembroke* and *Carmarthen* sorts; according to the same writer, being hardy, and less milky than most breeds.

The *Racenorshire* sorts are, Mr. Lawrence observes, "dark red, and brindled in consequence (he supposes) of the original black flock being crossed with the bulls of *Hereford* and *Shropshire*, which are adjoining counties. Although these crosses produced flock too large for the hills, they make excellent cattle, in good keep, and of considerable size, namely,

from 100 to 120 stone London weight. But it is said that the produce of the *Hereford* cross has not the characteristic bald face."

The *Montgomeryshire* sort are in the favourite colour blood red, with a thick face. The oxen from this county produce good prices.

The *Merionethshire* sort are, according to Mr. Lawrence, a small and ill shaped breed, said to be the worst in *Wales*; but in Mr. Corbet's improvements, in crossing with good *English* stock, much advantage has, he says, been obtained.

The *Carnarvonshire* is a hardy native sort, which has been formerly crossed and improved by *English* bulls and cows, some of the *New Leicester* and *Warwickshire* kinds. The improvement succeeded, and with a small additional expence in rearing, the stock has been found sufficiently hardy, whether on the mountains or plains; and the improved cattle at two or three years old, are, in the opinion of the above writer, worth more by two or three pounds than the original breeds.

The *Denbighshire* and *Flintshire* sorts have, he says, been much crossed and mixed with those of *England*. There are some good milk cows in these sorts, which give six or seven gallons per day, three or four months after calving.

The *Anglesey* sort is, he observes, "a small black breed, with wide and thick horns, being prevalent there, and in far greater purity than in most other parts of *Wales*. This hardy race is preferred on account of the constant winter exposure, and defect of winter provision, and also because they are approved by the purchasers. An *English* cross has been attempted without success, which was a necessary result, unless the keep were at the same time improved. The breeders decline keeping any cattle beyond the age of three years, not finding themselves reimbursed the charge of another year. The weight, when fat, at three or four years old, from 60 to 120 stone, the fore quarters being the heaviest. No cross could (Mr. Lawrence supposes) possibly improve these islands, unless bulls could be found of superior form, and equally hardy; such are, perhaps (he says) to be sought for in the *Ile of Sky*."

The same writer thinks, that, in the quality of the *Welsh* cattle, generally, there is no appearance of improvement of late years, notwithstanding the encouragement held out by prices, of which no former age can furnish a precedent. Indubitably the want of winter keep, and a good winter system, is, he thinks, the chief cause of this defect.

According to the above writer, the *Shropshire wide-horns*, which are large, square, deep, and bony, with thick hides, in colour brindled red and brown, the horns branching, points turned upward and backward, are used for labour, and said to be better milkers than their neighbours of *Herefordshire*, with which they are doubtless, he says, often blended. Of the origin of this variety no accounts, he observes, are extant, or how long; they have been a permanent or established breed. It has, probably, he supposes, originated in a mixture of the old long horns, the *Welsh*, and the red breed of the western districts.

According to Mr. Culley, the *pollled* or *Galloway* breed of cattle are a very valuable breed, and seem to be, in weight and size, as much less than the long-horns, as these are than the short-horns; they generally weigh from 40 to 60 stone. Some particular ones reach 70 and upwards; but their most essential difference from every other breed of cattle is, their having no horns at all: some few indeed, in every other respect polls, have two little knobs or unmeaning horns, from two to four inches long, hanging down loose from the same parts that other cattle's horns grow, and are joined to the head by a little loose skin and flesh. In most other respects,

except

except in that of wanting horns, these cattle resemble the long horns, both in colour and shape, only they are shorter in their form, which probably makes them weigh less. Their hides seem to be in a medium between the two last-mentioned breeds, not so thick as the long horns, nor so thin as the short horns; but like the best feeding kind of long horns, they lay their fat upon the most valuable parts, and their beef is well marbled, or mixed with fat.

We find, he says, a few of this breed straggling through different parts of England; an English reeve, he remembers the earl of Darlington having had a very handsome variety of them, finely globed with red and white. But we must, he says, look for the original of these in Galloway, a large district in the south-west of Scotland, where they are mostly bred upon the moors or hilly country, and grazed upon the lands nearer the sea, not til rising four or five years old, when the graziers and drovers take them up in great numbers to the fairs in Norfolk and Suffolk, previous to the turnip-feeding season, from whence the greater part are again removed in the winter and spring, when fat, to supply the amazing consumption of the capital, where they are readily sold at high prices; few or no cattle selling so high in Smithfield market, from their being such nice cutters up, owing to their laying the fat upon the most valuable parts; a great excellence in all feeding cattle. It is no uncommon thing, in this refined market, says he, to see one of these little bullocks outsell a coarse Lincolnshire ox, though the latter be heavier by several stones. And he has been informed, from good authority, that the polled cows are very good milkers, in proportion to their size, and the milk of a rich quality, yielding much more butter from a given quantity of milk than the short-horns; and also that the oxen and spayed heifers answer well for the draught; which certainly adds to the value of this excellent breed. But though the generality of the cattle of the above district are polled, yet they have several with horns, which, they say, are a ballard or mongrel breed, by crossing with long-horned bulls from Westmoreland and Cumberland. They prefer the polled ones, and of these the black or dark brindled ones, to any other; and all allow them to be the original breed of the country. The breeders in Galloway complain of their old breed being lost, or at least much worn out; probably by want of proper attention in the breeder.

Mr. Lawrence supposes that the moors of *Monigaff* and *Glenloue* are the only places where this sort of cattle at present exist in their original purity, and that they are generally thinner in the hind quarters than those which have been crossed with other breeds. They are likewise prevalent in Dumfriesshire, especially on the Nithsdale side.

There are frequently among the common Galloway cattle some that are white faced and pied, with small grizzly horns, which is supposed to be from a mixture of Dutch or English short-horned bulls, and to "detract 20 per cent. from the worth of the beast."

In respect to form, according to the above writer, this sort of cattle are broad and square in the shoulders, long and round bodied, but deep, straight and broad on the back, with a thick shaggy coat, the legs of a middling length, with large feet. It is added, that the *pelvis*, or hinder part beneath the tail, and between the two bones, is frequently too narrow in the cows of this sort, from which they want assistance, and occasionally fail in bringing forth their calves.

The oxen of this sort, as well as the spayed heifers, make middle sized beef, which is of an excellent quality. It is supposed that all the calves of this sort are reared in their native district, and more of the females spayed than of any

other breed, the operation being performed on the yearlings in the month of May. This sort of cattle are usually sold at about two years and a half old, the graziers in England being supposed to take off 30,000 head annually.

It is probable that this useful sort of neat cattle might be much improved in their native district, by having better accommodation and protection during the severity of the winter season, and a more abundant supply of different sorts of food.

The *Suffolk dun* breed is so called from its being the prevailing kind of neat cattle in the county of Suffolk, and which some may think a distinct sort, but which Mr. Culley is inclined to believe no more than a variety of the Galloway breed; which might easily, he says, take place from the great connection that has long subsisted between the Scotch Galloway drovers of cattle and the Suffolk and Norfolk feeders or graziers of them. Both kinds are in general polled; and though the Suffolks are almost all light duns, while the others are of various colours, yet this might at first proceed from a partiality to that colour. But from whatever place or cause this variety took its rise, they are, he says, at present a very useful kind of little cattle, particularly for the dairy; and great numbers of them are employed in that line, in some parts of Suffolk, where, perhaps, the best butter and the worst cheese in the kingdom are made. The cows give great quantities of milk. Mr. Young asserts that they give in common 24 quarts a day, which is nearly equal to the best short-horned cows. We find the cows of this kind, like all other deep-milkers, very lean, very plain in their forms, and very big-bellied. The weight of this breed of cattle is about 50 stone on an average.

These are said to have a lighter colour, and to be smaller and finer in the bone than the Galloway sort; and to be long, with a large carcass, clean throat, the neck tapering to the head, the tail thin, and the legs rather short. They are excellent for the purposes of milking, whether for the dairy, or private use; though the milk is probably less rich than that of either the Alderney or long-horned sorts. It has been suggested that this breed is incapable of being rendered more valuable by the art of crossing.

The *Scotch* breed of cattle are, according to Mr. Culley, still less in proportion to the polled cattle than they are to the long-horns; this breed are also covered with a long close coat of hair, like the polls and long-horns; and, like these, their beef is fine grained, well flavoured, and mixed or marbled, but not so handsome on the outside of the beef when killed, being not of so bright a colour, and often spotted with black, even upon the best parts, except when made very fat. When grazed, they feed very readily, their weight in general being from 20 to 25 stone. The most prevalent colour is black, some are brindled or dun; but the breeders here, like those in Galloway, prefer the black ones. These hardy animals are in possession of all that extensive and mountainous country called the Highlands of Scotland, together with the western shires, bounded on 21 sides by the sea and the Grampian hills; the latter of which begin on the north side of the Firth of Clyde, and run callward into the sea near Aberdeen. This sort of cattle are frequently termed *Lithers* in these parts of the country, probably from a district in Ayrshire, called Kyle, where they prevail much. But all the lowlands of Scotland, except Galloway, have a mixed breed of cattle; towards Cumberland they are half long-horns, half polls; on the borders of Northumberland they are mixed with short-horns until you reach Tivendale, where they become altogether a coarse kind of short-horned, or what the Yorkshire jobbers call rants, except a few pretty good short-horned cattle, bred in that pleasant and fine country,

country, the Tweed side. This same kind of ruintifh coarse breed continues all the way to the firth of Forth. Crossing this narrow sea into Fifeshire, you would at first imagine the Fife cattle a distinct breed, from their upright white horns, being exceedingly light lyered, and thin thighed; but he is pretty clear it is only from their being more nearly allied to the Kyles, or Scotch breed, and consequently having less of the coarse kind of short-horns in them. The cattle all along this coast continue to change more and more, growing still less, until upon the edges of the mountains they become quite of the Kyle kind; but still much inferior to that pure, unmixed, valuable breed of Kyles which we meet with on the more northern and western Highlands, and all the isles; but particularly in the Isle of Skye, and that tract of country called Kintail. It is in these two districts that you meet with the native breed of Kyles: a hardy, industrious, and excellent breed of cattle, calculated in every respect to thrive in a cold, exposed, mountainous country, and better adapted to the cold regions where they are bred than any other kind we are acquainted with. These cattle are driven to the southwards in great numbers every autumn; many into the western districts of Yorkshire; but the greatest part are sent into Norfolk, Suffolk, Essex, and other parts in the south of England, where they are fattened, and either slaughtered at their home-markets or sent to Smithfield.

The great demand for this breed in the southern parts of the island has rendered its improvement more attended to than formerly, and attempts have been made by different spirited breeders by crossing the Isle of Skye cows with bulls of the long-horned kind.

Though it is allowed that the beef of the Kyle sort is superior to that of others, it is believed by some that there is a deficiency in respect to quantity on the acre, so that it is the best it is not the least expensive.

The Highland cattle sometimes, however, rise to a considerable weight, especially when crossed with the larger breeds.

The bulls of the Isle of Skye sort are held in high estimation by the breeders and improvers of this kind of cattle, the principal distinguishing marks of which are fine eyes and horns, with a thick pile, and not thick-skinned. They excel in the quality of the milk, but with regard to the quantity, should be crossed with the Norman or some other breed that is known to afford a large quantity of milk. This property is likewise said to be increased by crossing with the Fife sort. The Highland cattle are hardy, and very little subject to diseases of any sort.

The *Orkney islands* are said to contain a small breed that are good milkers, and which afford beef of a good quality; but they are a badly formed sort.

The Fifehire sort are of considerable size, being of a black colour, lively and uphorned. They feed with expedition, and are fitted for labour, being held in high estimation by the graziers in the southern parts of the kingdom. As milkers, they are valuable for the quality of milk and steadiness of continuing it, rather than the quantity. It is probable that they might be improved in this last respect by crossing with those smaller breeds that produce it in larger quantities.

The *Renfrew, Ayrshire*, or what are termed the *Dunlop* sort, are considered, in relation to their size, the most valuable for the purpose of milking in the island, excelling equally in the quantity and quality. Mr. Lawrence says they produce "from $3\frac{1}{2}$ to 7 gallons per day," and that they "have the character of being the best possible poor man's cows," from their ability to shift on very scanty keep. In appearance they are, he says, small and ill-looking, with the shape and pile of Highlanders, yet bearing more resemblance to the Dutch

than to any native Scotch breed. Their horns, he adds, "are short and small, standing remarkably irregular and awkward; the colour generally pied, or of a sandy red. They appear unthrifty and thin like the Alderney, even in the best pasture, and the few which are bred up to oxen make but a poor figure in grazing, scarcely reaching the common weight of Kyles." He "apprehends this milky race to be the result of crossing the cows of the country with Alderney bulls; the cows, perhaps, having previously a portion of Dutch blood."

The *Alderney or French* breed of cattle is mostly to be met with, according to the authors of the "Treatise on Live Stock," about the seats of our nobility at Grafton, on account of their giving exceedingly rich milk. He imagines this breed to be too delicate and tender ever to be much attended to by British farmers, because they are not able to bear the cold of the island, particularly the northernmost parts of it. They are very fine-boned in general, light red or yellow in colour, and their beef generally yellow or very high-coloured, though very fine in the grain, and well-flavoured. They make themselves very fat; and none of them are in the least subject to lycer, or have black flesh. He has seen some very useful cattle bred from a cross between an Alderney cow and a short-horned bull. See **ALDERNEY CATTLE**.

The *Wilt* breed of cattle, from their being untameable, can, in the opinion of Mr. Caley, only be kept within walls or good fences; consequently very few of them are at present to be met with, except in the parks of gentlemen, who keep them for ornament, and as a curiosity: those at Chillingham-Castle in Northumberland, a seat belonging to the earl of Tankerville, are, he says, invariably of a creamy white colour, with black muzzles; the whole of the inside of the ear, and about one third of the outside from the tips downward, red; horns white, with black tips, very fine, and bent upwards: some of the bulls have a thin upright mane, about an inch and a half or two inches long. The weight of the oxen of this breed is from 35 to 45 stone, and the cows from 25 to 35 stone, the four quarters, 14lb. to the stone.—The beef is finely marbled, and of excellent flavour. From the nature of their pasture, and the frequent agitation they are put to by the curiosity of strangers, it is scarcely to be expected that they should get very fat: yet the six-years old oxen yield generally very good beef, from whence it may be fairly supposed, he thinks, that in proper situations they would feed well. When the cows calve, they hide their calves for a week or ten days in some sequestered situation, and go and suckle them two or three times a day. If any person come near the calves, they clap their heads close to the ground, and lie like a hare in form to hide themselves: this is a proof of their native wildness. The dams will not allow any person to touch their calves, without attacking them with an impetuous and savage ferocity.

It would seem clear from the above general descriptions of the different breeds of cattle, that all the sorts taken notice of are not equally profitable to the breeder, the rearer, the dairyman, the grazier, the butcher, or the consumer. Some have greater disposition to fatten than others. Some, being cleaner boned and better formed, have less offal. Some give a greater quantity of milk than others. In a word, some of the particular properties for which cattle are estimable are more discernible in one breed than in another. Whether, says Mr. Donaldson, these can be all united in the same animal, or whether a breed of cattle, possessing all the requisite qualifications, would be equally suitable to all situations, are questions not easy to be determined. In regard to the first, says he, it seems universally agreed, that

there are two properties for which cattle are esteemed valuable, that cannot be united; that is a disposition to fatten, and a tendency to yield a large quantity of milk. The former of the animal most remarkable for the first is very different from that of the other; in place of being fat, the hide is thin and big in the belly, as all great milkers are, it is thin-skinned and light-bellied: in a word, its body is bare formed, while that of the other is more fitted to embrace a large collar with the wide side downwards. It is not probable, therefore, that the properties of two breeds of cattle so opposite in form and general appearance, can ever be united in the same animal. If a large quantity of milk, whatever be its quality, is the object, the dairyman must content himself with such plain ill-looking animals as have been described above. And as the milk of all cows is well known not to be of the same quality, it appears, he says, highly probable that in proportion as the cows of the milking tribe exceed those that are more disposed to fatten in quantity, it nearly the same proportion will their milk be inferior in quality. If this should prove to be the case, the superiority of the quick feeders, one would suppose, says he, to be completely established; as while cattle of this description are confessedly better for the purposes of the graziers, the butchers and the consumers, they would, if this point were determined in their favour, be also more valuable for the dairy. No person will think of asserting, that a gallon or two of whey or of butter-milk extra (for the quotation, he thinks, comes to that) is a sufficient reason for preferring a breed of plain-looking, ill-formed cattle, to one that, except in this particular, is more valuable in every respect. In a word, no person who pretends to a knowledge of the different breeds of cattle, will think of supporting an opinion so erroneous, as, that cattle which are disposed to fatten quickly, and at an early age, that, from the superior excellence of their form, have a small proportion of wool, or what the breeders call non-essentials, and that although they yield not a large quantity of milk, yet make up that deficiency in the richness of its quality, are no more valuable than those which have nothing to recommend them, but the single property of being great milkers.

It has been remarked by the author of the "Treatise on Live Stock," in comparing the breeds of long and short-horned cattle, that the long-horns excel in the thickness and firm texture of the hide, in the length and closeness of the hair, in their beef being finer grained and more mixed and marbled than that of the short-horns, in weighing more in proportion to their size, and in giving richer milk; but they are inferior to the short-horns in giving a less quantity of milk, in weighing less upon the whole, in affording less tallow when killed, in being generally slower feeders, and in being coarser made and more leathery or bullish in the under side of the neck. In few words, says he, the long-horns excel in the hide, hair, and quality of the beef; the short-horns in the quantity of beef, tallow, and milk.—Each breed have long had, and probably may have, their particular advantages in different situations. Why not, the thick, firm hides, and long loose-set hair of the one kind, be a protection and security against those impetuous winds and heavy rains to which the west coast of this island is so subject; while the more regular seasons and mild climate upon the east coast are more suitable to the constitutions of the short-horns?—When he says the long-horns exceed the short-horns in the quality of the beef, he means that preference is only due to the particular variety of long-horns, selected, improved, and recommended by that attentive breeder Mr. Bakewell; for, as to the long-horned breed, in common, he is inclined to think their beef rather in-

ferior;—superior, to that of the generality of short-horns; and there is little doubt, he thinks, but a breed of short-horned cattle might be selected equal, if not superior, to even that very kindless short horn of Mr. Bakewell, provided any true feeder, or half-true feeder, would pay as much attention to these as he and his neighbours have done to the long-horns. But it has hitherto been the misfortune of the short-horned breeders to pursue the largest and big-bellied ones for the best, without considering that those are the best that pay the most money for a given quantity of food. However, the ideas of our short-horned breeders being now more enlarged, and their minds more open to conviction, we may hope in a few years to see great improvements made in that breed of cattle. Such rapid improvement has indeed lately taken place in the breeding of short-horned cattle, that he has reason to think they must soon surpass their rivals the long-horns. But he adds that, notwithstanding these two breeds have hitherto been in possession of the best part of the island, he is inclined to think that the Galloway cattle, and even the Scotch or Kyles, might be bred with advantage in many situations, so as to be more profitable than either the short-horns or the long-horns: he has a very high opinion of both these breeds of cattle, as true quick feeders, and being kindly-fleshed, or excellent eating beef; which character they have established in the first market in the island.

He is likewise of opinion that the Scotch or Kyles are better adapted to cold, exposed, heathy, mountainous situations, than any other breed we have; and that particular breeds are probably best adapted to particular situations; on which grounds he recommends to breeders of cattle to find out which breed is the most profitable and best suited to their situations, and to endeavour to improve that breed to the utmost, rather than try to unite the particular qualities of two or more distinct breeds by crossing, which is a precarious practice; for, says he, we generally find the produce inherit the coarseness of both breeds, and rarely attain the good properties which the pure distinct breeds individually possess.

It must be plain from what has been already advanced, that, in order to have good cattle of any breed, particular regard must be paid in selecting those that are the most complete and perfect in their form, shape, and other qualities, and to breed from them. See BREEDING, BULL, and COW.

The author of the Rural Economy of Yorkshire has well remarked, that the horn is a good criterion for distinguishing the different species, if the term be applicable, of cattle. It is a permanent specific character. The colour, though not altogether accidental, is changeable; and neither the form nor the flesh is permanently characteristic of any particular species. Good form and good flesh may be found in every species; though they are by no means equally prevalent, nor equally excellent in all; but a horn six inches long was never yet produced by the Craven long-horn breed; nor one a yard long by the Holderness breed. And the middle-horned breed of Herefordshire, Suffolk, and other parts of the island, appears to be as distinct a species as either of the former. He is not, however, a bigot to horns of any shape or length: as he would as soon judge of a man's heart by the length of his fingers, as of the value of a bullock by the length of his horns. If his flesh be good, and well laid on, and his ossal be proportionally small; if he thrive well, fatten kindly at an early age, or work to a late one if required; he would much rather have him entirely without horns, than with any which enthusiasm can point out. But the horn, as a permanent specific character of cattle, may, in varieties,

varieties, have its use as a criterion. Thus, says he, supposing a male and female of superior form and flesh, and with horns resembling each other as nearly as those of males and females of the same variety naturally do, no matter whether short or long, sharp or clubbed, rising or falling; and supposing a variety to be established from this parentage, it is highly probable that the horns of the parents would continue for a while to be characteristic of the true breed, and might by inferior judges be depended upon, in some degree, as a criterion. But still, says he, it is indisputable that horns remain the same while the flesh and fattening quality change; but every man of superior judgment will depend more upon the form and handle of the carcass, than upon the length and turn of the horn. For it is a notorious fact, that the individuals of a given variety may have exactly the same horns, without having exactly either the same fashion or the same flesh. If, however, there be any criterion or point of a beast which may be universally depended upon as a guide to the grazer, it is, he thinks, the eye, not the horn. The eye is a mirror in which the health and habit of the animal, at least, may be seen with a degree of certainty.

In respect to the rearing of cattle, different methods are pursued in different districts; but it is obvious that the better they are fed, at an early period, the better stock they will, in general, make. The rearing of cattle is become, in the opinion of Mr. Marshall, as stated in the Rural Economy of Norfolk, a subject of the first importance to this country; as an universal and growing scarcity of neat stock is experienced, more or less, throughout the kingdom. He has, therefore, paid more than common attention to the rearing of calves, (the first and most difficult part of the business) in this district; not only as being a primary object in the East-Norfolk system, but because the practice there is, in many respects, peculiar to the country. The number, he says, varies with the quantity of meadow or other natural grass-land belonging to a given farm; and sometimes, but not always, with the time at which the cows happen to come in. Some farmers "bring up" all the year round; rearing every calf they have dropt. Others rear in winter, only fattening their summer calves for the ped-markets; or, at a distance from them, for the butcher. Norfolk farmers, in general, begin early in winter to rear their calves: some so early as Michaelmas; in general, if their cows come in before Christmas: not only as being fully aware of the advantage of rearing early, but in order that they may rear as many of their own calves as possible; drove calves being always hazardous and sometimes scarce. No distinction is made as to sex: males and females are equally objects of rearing, and are both, occasionally, subjected to castration; it being a prevailing custom to spay all heifers intended to be fattened at three years old; but such as are intended to be finished at two years old are, he believes, pretty generally left "open," as are, of course, such as are intended for the dairy. There are two reasons, he observes, for this practice: they are prevented from taking the bull too early, and thereby frustrating the main intention; and by this precaution they lie more quietly; and are kept from roving at the time of fattening. This may be one reason why spayed heifers are thought to fat more kindly at three years old, and to be better fleshed than open heifers. The method of treatment depends, in some measure, on the time of rearing. The raising of the young animals in winter requires more milk than the later ones.

The particular practices that are followed in different places, in respect to the treatment of calves in rearing them,

have been described more fully under the head to which they belong. See CALVES, Rearing of.

In the management of young cattle, it is remarked by Mr. Donaldson, that the method of managing them during the first winter is pretty generally the same in every part of the island. They are almost always housed; sometimes bound up to the stall; but more frequently allowed to remain at freedom. The way of feeding them in England is chiefly with hay, or hay and straw mixed; and in Scotland, sometimes hay, but more frequently straw and turnips. They are mostly turned out on some of the inferior pastures on the farm the following summer, and maintained the second winter on straw in the straw-yard, or in houses or sheds erected for the purpose. Some farmers in the more northern parts of the kingdom, from being situated at a distance from any market at which they can dispose of stall-fed beef, very frequently give a considerable part of their turnip-crop to their young cattle. This is, he thinks, an excellent practice; and one that ought to be followed even by those who, from being better situated in regard to markets, can adopt other methods of using turnips to advantage. The benefit of green winter food for live stock is so great, that there is, probably, he says, no way in which turnips can be used, by which the farm or the farmer would reap greater benefit, than by giving the young cattle a daily allowance during the first two or three winters. There is but very little variation in the management of young cattle from this during the time they remain in the breeder's possession, which must be longer or shorter, according to the peculiar circumstances of the case and the nature of the farm. In some districts, he further observes, it is the usual practice to allow the young heifers to take the bull at two years old; in which case, those which are not necessary for keeping up the stock are disposed of the following spring, before they drop their calves. And where the practice of ploughing with oxen is continued, or has been a second time introduced, young oxen are broken into work in the course of the second summer; this, however, is by no means common, as, he says, probably nine-tenths of the cattle reared in Great Britain remain in the breeder's possession till the spring of the third year. The young cows are then disposed of to the dairy-farmers, who often do not breed a sufficient number to supply themselves; or to the cottagers, who have the means of keeping a cow in summer, but not in winter. And the young oxen are sold, either for the purpose of supplying the ox teams, where there are still kept; or to the graziers, who sometimes fatten them for the butcher in the course of the grass-season, but more frequently content themselves with only putting them in condition to be stall-fed during the following winter. The premature age at which such cattle are not employed in the operations of husbandry are now fattened, is, he thinks, a positive evidence of the scarcity of that species of live stock. Exclusive of the cattle used in the plough or the cart, which are permitted to live a year or two longer, the oxen in this country are, in general, killed before they are four years old;—an age at which, it is well known, an ox does not fatten to the greatest advantage. And Mr. Marshall says, that in Norfolk, when the latemath and stubbies are finished, the yearlings, provincially "buds," are put to turnips; either as followers to the bullock, or have some fresh turnips thrown to them: in either case, they sleep in the par-yard, and generally have a separate par allotted them; though sometimes they are paired with the two year-olds. In the yard, the best of the "flower" is allowed them, and, perhaps, a little ordinary hay; it being

a maxim, pretty generally adopted among good farmers, to keep their young flock as well as they can the first winter. In spring and summer they follow the bullocks, and run in the meadows; or, if there be wanting, are sometimes sent out to summer graze in the marshes, or grazing-grounds. The two-year-olds run in the stubbles, and broken grafs till Christmas, or until turnips can be spared them; when they generally follow the bullocks. In winter they are always "paired" at night; sometimes with the cows; sometimes with the buds; sometimes alone. Good farmers generally keep them separate; if paired with the buds, they rob them; if with the cows, they are liable to be "horned," and are never at all; except while the cows are eating up the bell of the fodder. Some farmers, when turnips run short, "put out" their two-year-olds in winter; and others, when they are plentiful, "graze;" that is, fat their two-year-olds. In general, however, they are "kept over-years," on meadows or lays, or are sent to the marshes or grazing-grounds, as situations and circumstances point out; and, at Michaelmas, are put to couples as fattening cattle. The agument price for two-year-olds, from May-day to Michaelmas, varies with the keep.

On the management of young stock it is also observed, in the Rural Economy of Yorkshire, that they are invariably housed the first winter; generally loote, and mostly indulged with the best hay the farm will afford. Their summer pasture is such as conveniently will allow them; frequent y of a secondary nature. In the open-field state, the common was generally their summer pasture. The second winter cat-draw is the common fodder of young cattle; generally tied by the neck in hovels, or under sleds. Their summer pasture, commons, woody wastes, rough grounds, or whatever best suits their owner's convenience. At two years old the fleers, provincially "flots," are generally broke-in to the yoke; but are not, by good husbandmen, worked much at that age. At two years also the heifers, provincially "whies," are generally put to the bull. This, however, is not an invulnerable practice. In the state of commonage they were frequently kept from the bull until they were three years old; now, in the state of inclosure and improvement, and at the present high rents, they are frequently suffered to take the bull when yearlings, bringing calves at two years old. This, says he, is an interesting subject in the management of cattle. Farmers in every district differ in their opinions respecting it. The arguments for bringing heifers in at two years old are, that they come sooner to profit; and that farmers cannot afford, at the former rate of rent, to let them run, unprofitably, until they be three years old. On the other hand, the argument in favour of bringing them in at three years old is, that, not being flatted in their growth, they make larger, finer cows than those which are suffered to bear calves at a more early age. But we have not yet met with any man who even attempts to prove which of the two is, upon the whole, the more profitable practice. The gardener, he remarks, seems to be well aware that, suffering a tree to bear fruit too early, checks its growth; and there may be some analogy, in this respect, between vegetables and animals. But even admitting this, if the cow receive no injury, as to thriving, calving, milking, nor any other than that of being checked, in point of size, the objection appears to fail. If, however, early production check not only the cow but her progeny likewise, an objection, no doubt, will lie against it. He has long been of opinion that it is, in general, the farmer's interest to let his heifers take the bull whenever nature prompts them. There is, undoubtedly, some present profit arising from their coming in at an early

age; and whether a middle-sized cow may not afterwards afford as much neat profit as one of larger flature, is certainly an undetermined point. Much, however, depends upon keep. A traveling heifer will not take the bull at a year old. Nor ought any yearling heifer, which has taken the bull, ever afterwards to be flatted in keep. If she be ill kept, while with calf, there will be danger at, or after the time of her calving. If afterwards pinched, there will be danger of her not taking the bull next year. Hence, he thinks, we may infer, with a degree of safety, that the propriety or impropriety of bringing heifers into milk at two years old depends principally upon soil and situation. On a good soil, and in a genial climate, in which heifers do not experience a check from the time they are dropped, they ought, he is clearly of opinion, to be permitted to take the bull whenever nature prompts them. But in less genial situations, where lean ill-herbage lands are to be pastured with young cattle, it appears to him equally evident, that heifers ought not, in strictness of management, to be suffered to come into milk before they be three years old.

Neat cattle are capable of living a considerable length of time, as fifteen or twenty years; but they are unfit for many purposes of the farmer after they become aged, and especially that of being employed as grazing flock; hence they are usually disposed of before they have attained their ninth year. For the purpose of breeding, they may, however, be kept much longer. With respect to the males, or bulls, where the chief object of the farmer is having good cattle flock, great attention should be paid to them, both in the rearing and their management afterwards, as well as to the form and kind. They should likewise be kept separate in a paddock inclosed for the purpose, and be constantly fed in the best manner, and not be employed till they are three years old, when the cows should be separately admitted to them. Some farmers are, however, of opinion, that a little work does not in the least injure them, while it has the tendency of rendering them more tame and gentle.

But in other cases, as merely for the purpose of the dairy, where rearing the produce is not practised, less attention is necessary with regard to these animals, it being of little consequence to the farmer, provided the cows be duly served. In these cases the bulls are for the most part kept along with the cows, in sufficient proportion to the number of cows that may be kept. Under these circumstances they are seldom kept in any better manner than the cows; but it is probable that much loss may often be experienced by the dairy-farmer on this account, as it would seem proper that they should constantly be much better fed. In these instances they are often employed while very young, being frequently castrated, or what is termed *segged*, in the third year of their age. The use of such young bulls is not, however, in general to be recommended. See BULL.

In respect to the management of the cows, it must of course vary in some measure according to circumstances, and the particular objects of the farmer. Such as are in calf should constantly have a sufficient supply of good food both during the summer and winter seasons, and in the latter should be well protected from the severity of the weather by proper houses, sleds, or fold-yards. With the straw some other sorts of food should be combined, such as hay, turnips, cabbages, &c. as the first is insufficient for keeping them in proper condition, and they will repay the increased expence of such keep, by their superior appearance, by the greater quantity and better quality of the milk, and by the better size and form of the young flock. Under the contrary

erary circumstances they readily dwindle, and become less valuable.

With regard to the season of putting cows to the bull, it is different, according to the views of the farmer; where his principal object is the milk, it is a matter of little consequence at what time they take the bull; but where the calves are to be reared, it is a point of material importance to have them dropped when the season begins to be warm, and there is a spring of young grass, as at that season they can be reared with the least trouble and expence, and in the most perfect manner. In the winter time this sort of business is attended with great expence, and the animals are often injured by the severity of the weather.

There is another point that ought likewise to be regarded in this sort of stock, which is, that the cows should not be too greatly exhausted by milking them too long, or too near the period of their calving; but when they have good rich keep, they may be milked to a much later period without injury, than under the contrary circumstances. It is usual to let them become dry six weeks or two months before the period of their calving; but, with good keep, a month may be sufficient.

It is a bad practice to have bullocks in the same place with cows, as much injury may be done both to themselves and the cows, by their riding upon them. Some farmers think it a point of importance to prevent cows to the bull with full udders.

It is of great utility in the management of cow stock, that exact accounts be kept of the periods at which they receive the males, as well as of the times at which the young are brought forth. In large concerns, a sort of *stock book* should be kept for the purpose of entering various memoranda of this nature, as by such means accidents and uncertainty may be in a great measure prevented. As the time of calving approaches, more strict attention should be bestowed upon the cows, in order that, at the period of it, every necessary assistance may be afforded, and the welfare of the animals insured. It, however, rarely happens that any extraordinary aid is required where they are left wholly to themselves.

It is the practice of some farmers to lessen the quantity of food for a little time before the cows calve, from the idea that they do not succeed so well when they are in too high condition; but this is most probably a supposition which is not by any means well founded, as cows that are kept in good order are, in general, the least liable to accidents in these cases. It is of much consequence that, at these times, the cows be provided with due shelter, especially during the inclement parts of the year; as much injury is frequently done by letting them calve in exposed situations without any protection from the inclemency of the weather. See *Cow*.

Such young cattle stock as is intended for labour, should be gradually accustomed to be handled from their infancy, and by that means be rendered perfectly tame and gentle, which will be of vast advantage afterwards when they are brought into labour. See *Oxen* and *Team*.

With regard to the management of cattle, there cannot be any doubt but that a large stock in feeding demands considerable and constant attendance, and that of steady and capable hands: as, unless a proper regard be paid in these respects, much confusion must occur, especially when fed in the fold-yard. Next to proper food, says the author of the "Farmer's Calendar," the two great points in feeding animals to profit are, regularity, and a particular care of the weaker individuals. On this last account there ought ever to be plenty of trough or rack-room, that too many may not feed together, in which very common case the weaker are not only trampled down by the stronger,

but they are worried, and become cowed and spiritless, than which there cannot be a more unfavourable state for thrift; besides, these are ever compelled to shift with the worst part of the meat. This domineering spirit is so remarkably prevalent amongst horned cattle, that he has a hundred times observed the master beasts running from crib to crib, and absolutely neglecting their own provender for the sake of driving the inferior ones from theirs. This is much oftener than suspected, the chief reason of that difference is visible in a lot of beasts, after a winter's keep. It is likewise, he says, a very common and very shameful sight in a dairy of cows, to see several of them gored and wounded in a dozen places, merely from the inattention of the owner, and the neglect of tipping the horns of those that butt. The weaker animals should be drawn and fed apart; and in crib-feeding in the yard it is a good method to tie up the master-beasts at their meals. Where a sufficient number of cattle are not bred upon the farm, they are generally bought in at the neighbouring fairs to fat at spring, and about Michaelmas. Those bought in at spring will be fat in July, August, or September, according as they are forward, and there is keeping for them; and those which are bought in at August, September, or October, must be either for sale in winter or in spring, and must be forward in flesh to be improved the beginning of winter, and kept up in flesh during the winter with burnt hay, turnips, carrots, or other kinds of food, to be fit for a good market whenever it offers; or they must be young lean cattle, that may, by their growth, pay for their wintering, and be fit to fat the next summer. Some, upon ordinary land, buy in young Welsh heifers, which, if they prove with calf, they fall in spring, with a calf by their side for the dairy; and those that are not with calf they fatten; all which ways frequently turn to good account: but as most commonly all meat, either at Christmas, or in the spring, is one third part dearer than in summer; as all have not the convenience either of hay, turnips, &c. to fatten cattle with in winter; it is best to have them ready for the markets about these times.

The farmer who intends to graze cattle to the most advantage, should be particularly attentive to these three things: first, to raise a good quantity of artificial grass for hay and aftermath. Secondly, to turn a good quantity of ground into rich pasture, by feeding it, dunging it, and laying on it other manure, to make it fit for raising the bullock or heifer in the spring, when they come first from hay to grass, and to receive them with a vigorous aftermath, when other grasses, as clovers and other grass aftermath, go off. Thirdly, to have hovels or other buildings inclosed with close walls, to shelter the cattle in the winter from winds and rain. By adopting these methods in fattening cattle, the grazier, from having plenty of hay, will be enabled to purchase barren beasts before the spring grass comes, when it is most likely they will be cheap, and may be bought to the best advantage, allowing for the value of the hay they may eat in consideration with the purchase: and if, by winter-haying some meadow-ground after it has been kept high in heart by feeding, &c. he can, early in the spring, by April, or sooner, have a bite to take off such grazing-beasts from hay to grass, it will be very advantageous before clovers can be ready, which, in many places, are seldom so till a week or a fortnight in May; and, by keeping such meadows for an aftermath, which, towards the end of summer, are in very good heart, he may support his bullocks, and carry them on when the strength of other grass fails. All fattening cattle, whether barren cows or oxen, require a proportional progression from coarser to better food, as they grow more and more into good flesh; otherwise, when half

half fat, they will frequently go back, and the grazier will not, with ut great difficulty, be able to raise them again; which must be a great loss. See *GRAZING*.

In regard to the system pursued with oxen, they are in most places, where they are worked, turned off to fattening at two seasons of the year, which, in several respects, are very convenient. The first is about May-day, when the labour is pretty well over for the spring season; the spring corn being then generally all sown. The second is the beginning of winter, as, from the first of October to the middle of November, when the wheat and winter vetches are mostly put into the ground.

In regard to the various kinds of food with which cattle are generally fattened, it may be reduced under the following heads; grass, turnips, grains, wash from the distilleries, oil-cakes, corn, cut chaff, and a few other kinds.

The fattening cattle, according to Mr. Donaldson, are usually put to grass in May or June, according to the season and situation in regard to climate. The period necessary for fitting an ox for the butcher depends on several circumstances; as the condition he was in when put to grass, the nature of the pasture, and many others: but in ordinary cases, an ox will be completely fattened in three months. There is, he says, one method of fattening, connected with the grazing system, that the farmers in England are enabled, from the superior excellence of the climate, to adopt with success, which can never, he thinks, be attempted with propriety in Scotland. It is very common, at the close of the grass season, when the fattening stock happens not to be fully in condition for the butchers, to render them so, by giving them hay two or three times a-day in the field, or in hovels erected for the purpose, into which they have access at pleasure.

When turnips are employed for the purpose of fattening this sort of stock, especially if they are put up to the stalls in proper condition, which, considering the season of the year (November), must, with ordinary attention, always be the case, from 12 to 13 weeks is fully sufficient to render them fit for market.

It is observed, that the fattening of cattle with grains may, in some respects, be considered as a branch of the distillery business; but yet there are some instances wherein those who cultivate farms practise it with a double view of obtaining a profit on the sale of the cattle, and the acquisition of a valuable treasure of useful manure. Mr. Adam, the rector of the farm of mount Nod, near Streatham, in the county of Surry, has erected a very complete building, for the purpose chiefly of fattening cattle on grains. In this building, says he, may sometimes be seen several hundred head of cattle.

And the method of fattening cattle with oil-cake, corn, cut chaff, &c. is practised in many of the English counties, with a degree of success sufficient to warrant farmers in other parts of the island to follow the same practice. The cattle are commonly put up to fatten at the end of the grass season. The usual allowance of oil-cake, after it is broken in a large mortar, or, in the fruit districts, in a cyder-mill, is about half a peck per day, which is given, one half in the morning, and the other in the evening; to which is added hay, and in some cases ground corn, that is, oats and barley of inferior quality, and cut straw, provincially "chaff." As bullocks fattened in this manner, get regularly five, sometimes six, meals a-day, it is sufficiently evident that, although it may be upon the whole an expensive mode of fattening, yet it must be both expeditious and effectual. But the subject of fattening cattle in the stall will be fully considered in another place. See *STALL FEEDING*.

Mr. Marshall, in speaking of a Cotswold grazier, observes, that his fattening cattle are all tied up, some in single, some in double stalls. His reason for this practice is not altogether that of saving room; he is clearly of opinion that they do better, fat faster, than bullocks which are kept in loose stalls. His reasoning is, he thinks, fair. Besides the indisputable advantage of their not being liable, in this case, to foul their meat and water; he holds out another which is not so obvious, but may nevertheless, perhaps, be equally true: cattle, which are tied up, are more cañish (tamer, less wild) than those which are kept in loose stalls. A loose bullock (so we loose bullocks at least), when a stranger enters the shed or any disturbance happens in it, will rise and fly into the yard for refuge; while a bullock which knows that he has not the power of flight will lie still and chew his cud. In the yards, loose bullocks are equally liable to disturbance; and quietness is no doubt essential to quick fattening. Each bullock has two troughs, a small one for corn, a large one for hay, with a water trough, which runs the whole length of the shed, and is covered by a board: each bullock having a hole (large enough to admit the nose) to drink at. The water trough (a hollow tree) forms, as it were, a top rail to the partition wall of the gangway. The others are beneath it, nearly level with the bed of the stall. The corn is ground, and given to them, mixed among cut hay, two or three times a day, beginning with half a peck, and increasing to about a peck a-day. The method of feeding with hay, which, in this instance, is practised, does, he says, the practitioner infinite credit. He feeds his bullocks with hay as cart-horses are usually fed with corn; giving it to them by handfuls at once; never more at a time than the two hands can grasp; continuing to feed them in this manner until they lie down, or till they refuse to eat. Thus they never have any hay to blow upon (the great objection against tying up bullocks); even at night, they have not a mouthful left before them. The leading principle of this practice is, that fattening cattle should never be cloyed with food; but should always eat with an appetite. In the morning they are fed with the worst of hay (if any difference); for, being then hungry, they eat it with an appetite. Thus the hay is eaten up clean, and the bullocks are preserved in a thriving habit; while the extraordinary expence, where a number of cattle are fatted at once, is inconsiderable. In this case it is proper to appropriate a man's time to their attendance; and he might as well be employed in feeding them by handfuls, he thinks, until they lie down, as in cloying them with armfuls, and idling the rest of his time away.

According to the author of the Agricultural Report of Lincolnshire, about Hauckthorn the larger farmers buy in beads in autumn, put them to eedhill, and then feed with cake; and sell from Christmas to May-day; this is done for the sake of the dung, and it is thought if that is cleared that it answers well. Mr. Thorpe at Kinton, he says, fattens many beads every winter on cake; his landlord, Mr. Harrison, having built him for that purpose very convenient stalls, in a double range, with a gangway between their heads. They are in the Hereford style; the beads may be loose or tied; a pump supplies water by troughs to cisterns; the whole well executed. He has sold beads from these to 38l. a head, and fats 45 in a season. The same farmer has, on his farm at Owerby, another bullock-house, in the same form nearly; here he fats all on oil-cake; but the dearth of it induced him to substitute lint-feed, boiled and mixed with barley meal; two quarters of barley, four bushels of lint-feed; and mixed, to give cold, in the form of a rich jelly: this quantity will go as far as half a ton of cakes, colting less, when barley is not extravagantly high, that is, 24s. a quarter:—

half a peck of lint-feed is hoiled in four gallons of water. He inquired of Mr. Thorpe particularly if he had reasons adequate to the expense for not tying beasts in their stalls, instead of giving them so much room separately; and he is clear they fatten much better: this necessity, however, he says, is not ascertained; for the question can hardly be considered as answered in any case where a farmer builds and a landlord pays. Mr. Thorpe buys his beasts at Lincoln: he thinks the Holderness too big for his purpose; but there is a very good cross of long and short-horns about Spillby, which fatten kindly, and which he likes to buy. He is of opinion, from very considerable experience, and speaking of grazing in general, both summer and winter, that middling sized beasts will pay better than large ones, for instance two of 50 stone will answer better than one of 100; they do not take so much food to bring them to their weight; and will do on worse pasture.

It is added, that at Knaith, in the same county, where the pasture is not of the first quality, Mr. Dalton has fattened Teeswater beasts to 130 stone, at seven years old, and gave only half a ton of cake to each. He prefers this breed to any other he has tried. His beasts of 80 stone will be fat at five years from grass, without any cake; and his regular return is seven a year, at four years old. The cows are good milkers in their own country, but here are not equal to Lincolns. He is of opinion, in relation to the size of fattening animals, that an ox of 80 or 85 stone will not eat more than one of 50, and his bailiff thinks he will not eat so much. At Bankside, Mr. Webster feeds his cows, and his team horses, with steamed turnips and cut chaff, with great success. Mr. Ellison, at Sudbrook, buys in about 30 bullocks annually; from April to Midsummer; which are put to grass till a fortnight after old Michaelmas; then he places part in stalls, and part remains in grass till near Christmas.— In the stalls, he feeds with cake and hay; they eat about 2½ casks a day, at 7lb. each, and about half a ton of hay each beak; and are up about 10 weeks, some 12. They were bought in at 15l. each (1788); and sold at about 26l. In general, he reckons them to pay 13l. each, which answers well. He prefers the short-horned breed, and has tried long-horned Cravens, but they did not answer at all. His bailiff chooses the finest boned ones he can get, clean heads and muzzles, wide in the hips, out in the ribs, and deep in the fore quarter. The greatest fault in the Lincoln short-horns is, he thinks, being thin in the backs and chimes; it is not universal, but very common; but upon the whole they fatten kindly. He observes, that the oil-cake dung is uncommonly rich, so as by mixing to make the straw dung excellent. Mr. Mody, of Risholm, fattens many beasts upon oil-cake, even as far as buying 100 tons of cake in a year. He keeps them loose in a straw yard, and finds them to do well without any hay, giving straw only in addition; and has sold beasts thus fed at 40 guineas. The duke of Ancaster fattens many beasts; he buys in from Candelmas to Midsummer generally Scotch and Welsh bullocks of from 34 to 50 stone, 10 inches larger; sells fat from Midsummer to December. He gives on an average, for the two last springs, 8l. 8s. or 9l. each, and sells at 13l. to 17l. They are kept through the winter in the park, and go off at Midsummer, twelve months after. They have no fodder, except in a blaid. North Wales, Pembroke, and Highland Scots, are found very little different in advantage; the Welsh grow rather more, and come to greater weight. The Fifes grow more than any, when they happen to be bought, but they require food-ning.

It is observed by the author of the Rural Economy of Norfolk, that the practice of fattening bullocks on turnips is now beginning to obtain in every part of the kingdom; but it may be said to be still in a late of infancy every where

except in Norfolk; therefore an accurate account of the practice of this parent country cannot fail of being useful to every other turnip-land district. Impressed with this idea, he spared no pains, nor let slip any opportunity of making himself acquainted with the subject. The only species of cattle fatted in East Norfolk, he says, may be said to be the home-breeds and Scots. Some Irish beasts have at different times, but not regularly, been brought into the country, and have generally done very well. In West Norfolk, great numbers of Lincolnshire and Yorkshire oxen were formerly, and some few, he believes, are now fattened; but in this district they have always been considered as much inferior to the Scotch and home-bred flock. Home breeds consist of steers, spayed heifers, open heifers, barren cows, and running calves. The last is a species of fattening cattle peculiar, perhaps, to this country. They are calves which are suffered to run with their dams until they be a twelvemonth or more old; the cow being all the while at head-keep, of which the calf partakes, as well as of the milk of its dam; while herself, in the mean time, generally gets fat enough to be sent to Smithfield with her calf (perhaps as heavy as herself) by her side. The Scotch cattle fatted in Norfolk consist of Galloway Scots, other Lowland Scots, Highlanders, and those of the Isle of Skye. The Galloway Scot is large, thick, short-legged, molly hornless, and of a black or brindled colour; the flesh well grained, and the form altogether beautiful, chine full, back broad and level, quarter long and full at the nache, round barrel, deep girt, and the bone, head, and clasp, in general, fine. This, he apprehends, is the genuine original Galloway Scot, and a principal part of the bullocks brought into Norfolk under that name is of this description; but the droves are generally adulterated with a mongrel sort, the produce of a cross with the long-horned breed. This species of adultery, he remarks, is said to be committed and encouraged by the nobility and landed gentlemen of the counties they are bred in; but the fact appears to be, that they have already one of the finest breeds of cattle in the world upon their estates; and it behoves them to hand it down to posterity as pure at least as they received it. In this age of improvement it might be laudable, he says, to endeavour to improve it to the utmost; not, however, by foreign admixtures, but by giving the most beautiful females to the most beautiful males of their own breed. They appear to him to have much to lose, but nothing to gain, from crossing, not even with the present long-horned breed of the inland counties. This species of Scotch cattle appears, he says, to be originally of the county of Galloway, which forms the southern extremity of Scotland; but they are now, it is said, propagated in other parts of the Lowlands, especially in the rich land counties of Lothian, in the neighbourhood of Edinburgh. He has known them fattened to 80 stone, and has been informed, from authority which he has no reason to doubt, that they have even reached near 100 stone, of 12 pounds each.

Lowland Scots are the ordinary breed of black cattle in the Lowland counties, size below the Galloways, and appear to be a mixture between these and the Highland Scots. Sixty stone is a good weight for a Lowland Scot. In form and inclination to fat they partake of the Galloway breed; the former, however, is seldom so near perfection as that of the true Galloway Scot. Lowland Scots are some of them horned, some of them polled; their colour black, or brindled, or dun.

The Highland Scots seem to be a distinct breed. The size is beneath that of the Lowland Scots; 40 to 50 stone is the ordinary weight of a Highland Scot. In form, flesh, and fattening quality the Highlanders resemble much the Galloway Scots, except that their backs in general are

curlier,

coarfer, their bone proportionably larger, and in that they have in general, but not always, horns of the middle size, and mostly bent upward, like those of the Welsh cattle, but finer. In general appearance there is a strong resemblance (their horns apart) between the Highland Scots and the black cattle of North Wales; but with respect to flesh and fattening quality, the main objects, the comparison is greatly in favour of the Scotch breed, which the gentlemen of North Wales are said to fetch annually out of Scotland, or to buy them up at the English fairs to be fattened for their own tables.

Those of the Isle of Skye appear to be only a variety of the Highland breed, contracted by soil or climate, or both. They are, in point of size, the lowest in the gradation; but with regard to flesh and fattening, and growth while fattening, they may be said to stand foremost. He has known an Isle of Skye Scot bought at 2½ years old, for less than 40s., reach, in about 20 months, to 45 stone. At that age, says he, their growth in England is astonishing; owing, perhaps, not more to their nature than to a change of climate and a change of food. Much, however, depends upon their age. If they be intended for immediate fattening, the age of four years is the most proper. An Isle of Skye or a Highland Scot at two or three years will grow, but he will not fatten; at five or six he will fatten, but he will not grow, while fattening, equal to a four-year-old bullock. At this age the weight of Isle of Skye Scots, when fat, varies from 25 to 45 stone.

There are four species or varieties of cattle which are brought by the Scotch drovers to the Norfolk fairs and which are bought up and fattened by the Norfolk farmers under the foregoing names. A comparative statement of the proceeds, expence, and profit attending the dressing of three different kinds of Scotch cattle grazed in Norfolk, is given by Mr. Burton in the Appendix to the Agricultural Report of that county. The first is a bullock bought at St. Faith's for about 6l. turned of four years old, in such condition as is fit to be put immediately to turnips. This bullock is supposed to be brought to him from 50 to 52 stone. He is put to turnips for about 24 weeks, the average expence of which, including turnips, carriage, and attendance, and in case of bad weather, when a little hay is usually given, besides the straw, cannot be reckoned less than 4s. per week; this brings him to 11l. 18s.; and such a bullock generally will fetch about 5s. 7d. per stone of 14lb. which amounts to 14l. 16s. The second bullock is bought quite lean, about the same time as the former, for about 6l. and is a year younger than the former. He is first put into stubble or ordinary grass till the straw-yard is over, and then he is put to straw at night, and eat the usual turnips after the better beasts in the day-time; he keeps in this way 24 weeks, till May-day, may be let at 1s. 6d. per week; he is sold then be put to marsh, or into good pasture, till a fortnight after Michaelmas, which lay 26 weeks, at 2s. 3d. per week, is 3l. 3s.; he then goes to cornish, like the former bullock, for 8 weeks, at 3s. which is 1l. 4s.; his aggregate charge is then 12l. 3s. His weight may be expected to be 44 stone, and value 32s. 2s. The third is supposed to be purchased at Hareleton, in December, a lean beast of the same age as in the first case, at 7l. which goes immediately to straw and usual turnips for about 8 weeks, at 1s. 7d. which is 12s.; then goes to full keeping at turnips by day, and lies in the straw-yard at night, for about 10 weeks, at 2s. 6d. which is 11. 5s. It is then put to the second year's lay, or good pasture, till harvest, for about 26 weeks, at 2s. per week, which brings it to 11l. 18s.; it will then have attained in general about 46 stone, at 7s. 7d. which will amount to 12l. 13s.

On this it is remarked, that the first deduction to be drawn is that the first pays 10 per cent. interest upon the capital laid out, as well as a fair price for every thing that it con-

sumes. That the second returns no interest for the original cost, but pays a fair price for what it consumes. That the third pays 15 per cent. for the original sum laid out, besides paying as the others for what is consumed. It is obvious that in this system the principal advantage is in the large supply of dung that is raised.

The author of Modern Agriculture has well observed, that, considering the early period at which the cattle of this country are generally slaughtered, it is not now of so much importance to lay down rules when by to ascertain their age with precision, yet in many cases it must prove useful. The age of cattle, like that of horses, is discernible by their teeth. They lose the first fore-teeth at the age of 10 or 11 months; these are replaced by others of a larger size, and when about a year and a half old, the teeth next to those in the middle drop out. These are also replaced by others; and at the age of three years the others are renewed in like manner. They then appear white, even, and regular, and pretty long, becoming gradually black, unequal, and short, as the animal advances in age. Another mark by which to determine the age of cattle, is the appearance of the horn. Cattle shed their horns at the end of three years; and towards the root of the second set of horns there is a kind of ring or joint, formed every year that the animal lives afterwards; so that, reckoning three years for the top or plain part of the horn, and one for every interval between the rings or joints, the most ignorant person may, with considerable certainty, ascertain the age of any ox or cow that has horns. See AGE of *Anim. Cattle*.

The diseases of cattle make the subject of that art, called by the ancients *vulvo medicina*, and *vetularia*; and by us *farriung*.

The ancient riches consisted wholly in the number of cattle; whence it is supposed to be, that the Romans called money by a name formed from that of cattle; *pecunia* from *pecus*.

By the 6th article of the Union, no Scots cattle brought into England shall be liable to any other duties besides those to which cattle of England are liable. 5 Ann. c. 8. By 5 Geo. III. c. 12. made perpetual by 17 Geo. III. c. 8. all sorts of cattle may be imported from Ireland duty free. By 5 Geo. III. c. 43. Balthias may be freely imported from the Isle of Man.

Factors, and those who sell cattle for others, are prohibited to buy any ox, steer, runt, cow, heifer, or calf, and to sell the same again alive in the same market or fair; on pain of forfeiting double value, half to the king, and half to him who shall sue. Stat. 3 and 4 Edw. VI. c. 19. 3 Ch. I. c. 4. See DROVERS.

Stealing of cattle, or killing them with an intent to steal any part of the carcasses, or assisting in such offences, are now made felony without benefit of clergy. See 14 Geo. II. c. 6. and 15 Geo. II. c. 34.

By cattle, in this act is to be understood any bull, cow, ox, steer, bullock, heifer, calf, sheep, and lamb, and no other cattle whatever. Stat. 13 and 16 Geo. II. c. 54. And every person who shall apprehend and prosecute to conviction any offender, shall have 10l. reward. See also BUCKERS.

CATTLE FARM, in Agriculture, is that sort of farm in which the principal object of the occupier is the profit of live stock in some way or other. And from the different modes in which advantage is derived from this kind of stock, it is obvious that they must be of several different kinds, as breeding farms, where the chief object is that of raising young animals of the several kinds for the purposes of sale, dairy farms, in which the main object is that of either milk, butter, or cheese, or the two latter; the first sort being sometimes called cow-farms; grazing farms, when the chief point

point is the fattening of different sorts of animals for the butcher; and suckling farms, as where the principal point of attention is the fattening of calves for the market. See FARM.

CATTLE-SHED, in *Rural Economy*, is that sort of erection which is made use of for the purpose of containing cattle while feeding or otherwise. Houses of this kind are most readily and cheaply constructed when placed against other buildings or offices, and are of very different forms according to circumstances and situations.

This sort of buildings may be used as cow-houses or feeding-houses, being built to answer either one purpose or the other, and they are either single or double: in the latter way a great many cattle may be accommodated at a very small expence.

The principal requisites in these buildings are, according to Mr. Beaton, the following: "1st. That they be capable of being well aired. 2. That they are to be constructed as to require the least possible labour in feeding the cattle and clearing away the dung. 3. That the stalls be so formed as to keep the cattle as dry and clean as possible, with sufficient drains to carry away, and reservoirs to collect the urine and dung. He observes, with regard to the first requisite, that a free ventilation is as necessary in these buildings as in stables. How often do we see, says he, on entering a house where there are a good many cattle or cows, most of them, perhaps, in the highest state of perspiration, and smoking as if they had been at the hardest labour? at the same time the whole timbers of the roof are completely wet by the condensed fumes arising from the heat and breath of the cattle. This can only happen in close buildings, which must undoubtedly be extremely unwholesome; and, he supposes, must prevent the cattle thriving so well as they might otherwise do. To a feeder of cattle, says he, who looks eagerly forward to the profits he is to reap, and who estimates every additional pound of weight that a bullock ought to take on each day, it would be well worth his attention to consider, whether any bullock, in a perspiring state, can fatten so well as when kept in a proper degree of temperature. He thinks it stands to reason he cannot. When such buildings are in the form of sheds, they are not so liable to this want of ventilation; but wherever the timbers above appear wet by the heat and perspiration of the cattle, it is an evident proof there should be some additional air-holes, which, in his humble opinion, ought principally to be in the roof, as recommended for stables. If there are gable ends, they should, he thinks, have a window in each, as high up as possible, with moveable boards, as in granary windows, which may, by means of a cord or small rod, be easily opened or shut at pleasure. The advantages of this free and wholesome ventilation to the cattle must be very evident, and also to the preservation of the timbers of the building; for where the timbers are often wet in this manner, they cannot be of long duration, consequently the expence of repairing or renewing them would be greatly increased.

With respect to the second qualification, there are many different constructions of these buildings, but chiefly in the interior parts. "In many (he observes) the cattle are fastened to stakes ranged along the wall at the distance of about three feet from each other, with a space of 18 or 20 inches between the wall and the stakes to lay their food in. This is a very general construction in many parts of the country; but it is somewhat remarkable (he says) in this as well as in many other things, that the plan most generally followed is the very worst that could have been thought of: according to this construction, except sometimes, when the cattle are fed from without, the feeder is obliged to go in among them to give

them their food, which occasions a great waste of time as well as being attended with many other inconveniences. No construction can, he supposes, be more commodious than when a sufficient space is left before the cattle, for the feeder to go with a large wheelbarrow to distribute their food. This may (he thinks) be obtained, either in single sheds, or in double ones, by making the cattle face each other, and leaving a free space of about four feet to admit a wheelbarrow," in the foddering of them.

He adds that the single ones may be formed as in *Plate IV. fig. 3. Agriculture*, in which A is the passage before the cattle, B the rack for their hay or straw. C a place for laying fodder or litter in occasionally. Or it may be constructed as in *fig. 4.* D the passage, E a perpendicular rack behind which an thin deals all along in the position F, for laying the hay upon; and under F is a square hole C, opposite each stall, through which the cattle are fed from the passage D. This is a very good construction for this sort of shed, and is taken from the new offices of Mr. Bilton's, of Kilsal in Shropshire, where economy in labour and convenience have been much attended to.

Double sheds may be constructed as in *fig. 5*, in which A is the passage; B, B are the stakes to which the cattle are bound; C, C are posts or pillars to support the roof. It might, he thinks, be an improvement here to adopt Mr. Bilton's plan, and make similar racks, with holes below, as is shewn in *fig. 4.* Another way of constructing these double sheds is shewn in *fig. 6*, by which a very convenient loft may be obtained in the roof. A is the passage between the cattle, and B the loft above, which, if close boarded, may serve many useful purposes. These double sheds are, Mr. Beaton supposes, perhaps the best construction for feeding-houses, being not only the most commodious, but requiring less building for the same number of cattle than by having them all to face one way.

It is justly remarked, by the same writer, that where cattle are fed from the outside through holes left for that purpose, many inconveniences may arise, either in wet weather or in a severe frost, or by a heavy fall of snow. When they are fed within, no sort of weather can occasion any interruption, especially if there is a proper place adjoining, to keep the provender in security and under cover. In single sheds, it would be convenient to have a place above the cattle, as at B, *fig. 6.* for holding occasionally some hay or straw. This place might be boarded, and made to open from without by covers suspended on hinges, which, when opened, will afford an easy access for putting in the fodder from a cart. It would there lie ready for the feeder to throw into the racks when required. The roof is in this case to be supported by posts or pillars about three or four feet high, on the top of the wall, and placed about eight or ten feet distant from each other, as at A, A, A, &c. *fig. 1.* in *Plate V.* B, B, B, &c. are the hinges of the covers, and C, C, C, &c. the rings to raise them up. D is one of the covers open, which may be held up in various ways, as by a catch, F, *fig. 2.* moveable on a small iron pin, the heaviest end, E, being within the fixed boards, and F without to catch in a hole in the cover, when opened.

In the third place, great attention is, he says, necessary to keep cattle clean and dry. The common method of taking away the dung in wheelbarrows is attended with a good deal of labour, and where there are many cattle or cows will require perhaps several men's attendance. If this labour can, therefore, be abridged, and one or two men's work saved by a proper construction of building, it will be a great advantage. This should be considered in the original design before the building is begun, and must be determined in a great

measure by the form and situation of the ground. If a proper receptacle can easily be had immediately behind the cattle, for throwing in the dung at once with a shovel, without wheeling it, this would be the easiest way, and will not only save trouble and expence, but if properly contrived, the dung will be the better for it. By the common method, the dung is, he says, in general scattered about, and exposed to the weather, that a great part of its virtues is exhaled and lost; a matter of great importance to the farmer; for it is not merely the quantity, but the quality also of dung that is to be considered.

To preserve dung under cover would be attended with an expence in the construction of a proper place, that perhaps few would chuse to go to; at the same time, there is no object of more consequence to the farmer than preserving the quality of his manure.

It is added that the facility of keeping cattle clean and dry, depends very much on the construction and paving of the stalls, of which there are various kinds. In many places, however, there is no such thing known as a stall for cows or oxen, they being bound to stakes, without any division whatever betwixt them. In some parts again, particularly in Cheshire and Lancashire, he observes cows are bound in pairs, at least there is but a very small division betwixt them, as will be seen by *fig. 3.* in *Plate V.* in which is a plan of these stalls; A.A.A. &c. being the stakes to which the cows are bound. In other parts they are not bound at all, but every cow or ox has a separate stall divided from the rest by rails of wood, that they cannot get out, and so narrow that they cannot even turn about. At *fig. 4.* is a plan of these stalls; S,S,S. &c. are the stalls. P is the passage betwixt them; T,T. &c. are the troughs out of which the cattle feed; At *fig. 5.* is an elevation of the rear of these stalls. RR is a rail that lifts out at the end of each stall. Sometimes there is a little door that opens, as at G. *Fig. 6.* is a section of these stalls, in which it will be observed there is a short rail or brace at A, to prevent the cattle touching each other with their horns. Some people are of opinion, that cattle feed much better and quicker in stalls of this kind than when they are bound.

It is supposed that double stalls may be made without the short division, as already mentioned. The division between them, however, ought to be sufficiently boarded at the top, to prevent the cattle seeing their neighbours in the next stall. At each stake should be a trough for holding meat, and between these two troughs, another common to both cattle, for holding water, with which it may be supplied by a pipe communicating with a cistern or reservoir without.

These three troughs may be of stone, as in *fig. 7.* and all of one piece, if thought proper. A perpendicular rack for holding hay or straw may be placed over them, as represented in *fig. 8.* which is a section or view of one of the stalls, and *fig. 1.* is a plan. Perhaps it would be an improvement to divide them by a rail in the middle, as at AB, *fig. 7.* which would prevent the cattle turning too much about, and spreading their dung over the whole stall, for the more they are made to dung in the same place, the easier it will be to keep them clean. But although the double stalls here recommended are a good deal used for milch cows in different parts of England, yet they have in general only one trough for each cow, without any for water; nor indeed has he seen any with this conveniency, except at Burleigh, in Rutlandshire, a seat of the earl of Winchelsea, where offices and farm-houses are on an excellent construction, being planned chiefly by himself.

In paving stalls for cattle, the same author remarks, "that there is generally too great a declivity made, which will

cause them always to stand uneasy and uncomfortable; for, when feeding, there cannot be too much attention paid to their ease and comfort, as well as to their food. If they are constantly wet and dirty, or in pain by standing in an unnatural position, it is impossible they can thrive so well as otherwise they might. Yet (says he) how little attention is there in general paid to this. One would almost be led to suppose it is the opinion of many, that if they stuff their cattle quite full of food, whatever may be its quality, it is all that is necessary. Sometimes they are chained so close to a stake that they can hardly move, nay, it is a practice in some places to fasten their heads between two stakes, by which they can neither lie down in comfort nor can they have it in their power to destroy or dislodge those teasing tormenting vermin which frequently prey upon them. Besides this, they are often suffered to be befouled on the back, and either smothering with heat for want of ventilation, or shivering with cold. No animal can thrive well under such mismanagement, let his food be ever so plentiful, or of ever so good a quality; for, as an ingenious author says; to keep cattle clean and well littered, is to them half food. Cows are more easily kept clean than oxen, for they do not wet their stalls so much; but even oxen, when confined to stand nearly in the same place, cannot wet their stall above half way up, if properly constructed, and that generally about the middle. It is therefore clear, that if the moisture is immediately conducted away, and prevented from spreading, the ox will be easily kept dry. The best way to do this is, (he thinks) in the manner described for paving the stalls of stables." See *TABLE.*

The stalls of oxen or other cattle should, he says, "be paved in the same manner; but as their dung is of a more liquid nature than that of horses, it would be proper to have some commodious method to carry it off. Perhaps in some situations, where there is a proper declivity, this might be done by having an iron grating behind each ox or cow, immediately over the stall drain, and as nearly as can be judged to the place where the dung will drop, which by continuing the drain, or a wooden spout, to a pit or reservoir without, and giving it a sufficient slope, will, with the assistance of the other moisture, run and empty itself therein. If it should require the aid of a rake or hoe fitted to the drain, that may be easily applied, especially if those drains are made open and covered with a strong plank to take up when necessary. The moist dung being thus carried away, the remainder will be easily removed.—Something of this principle, suited properly to the situation of the place, would, (he thinks) save a great deal of labour, and very much facilitate the keeping of the cattle clean, and also be the means of saving a great deal of litter when scarce or dear. The advantage of proper drains to carry off the moisture from within the offices, and reservoirs for collecting it in, are therefore very obvious, as without such drains it cannot be expected that the offices or the cattle within them can be kept sufficiently dry."

But though these forms and modes of constructing cattle-sheds and feeding-houses are, probably, the most frequently met with in different parts of the kingdom, they are often built on other places and in other forms, such as the circular and long square; the first of which, though rather more expensive in the construction, is probably the most economical in respect to labour, and the most convenient in the distribution of the food, especially where a great number of cattle are to be kept. In this case, the animals, contrary to the usual method, stand all round having their tails to the out wall, by which much convenience is afforded in throwing out the dung through crevices left for the purpose

in the wall into covered pits made on the outside in order to receive it. The area or space within is converted to the use of feeding and attendance. There should be a room above in order to store up different sorts of food that may be wanted for the animals, to render the plan complete. The passage or gangway next the wall is left sufficiently large to permit the cattle to pass to and from their stalls; and the openings in the wall for the discharge of the dung should be contrived as to be capable of being shut up when the weather is severe.

The long square likewise admits of much room and convenience, and is a form in which many houses of this description have lately been erected. For this sort of shed the length of fifty or sixty feet affords room for a great number of cattle; the roof being made shelving, having the height of fourteen feet in the highest part and six or seven in the low; the large place destined for the reception of the cattle being separated from that where the dung is to be deposited by a wall or some other convenient division. For the former the space of eighteen or twenty feet on the inside is sufficient to afford good room, the stalls being made each about twelve feet long, having the width of four feet, or four feet and a half; the gangways at the heads and behind the cattle being made three feet, or three feet and a half in breadth, doors being fixed to each, one for the admission of the animals, and the other for that of the persons who attend them. And when the buildings are of great length, it may be convenient to have doors at each end. There should likewise be troughs in each stall for the reception of water, which, where it can be made to run through them, is of great advantage; and boxes or mangers for particular sorts of food, as well as racks for hay, are also necessary to render them complete. The bottoms of the stalls may be formed of strong planking laid so as to have a very slight descent, and be perforated with holes for the ready passage of the urine into the reservoir for it. There should be openings made in the wall behind the cattle, for the purpose of discharging the dung, between every two stalls of about two feet square, with proper shutters fitted to them; and also a wooden window of about the same size to each stall, to admit light and free ventilation, being placed as high as the house or shed will admit. The reservoir for the dung and urine should extend the whole length of the shed or building.

A shed on this plan has been found useful in practice by a person who has bestowed much attention on the convenience of this sort of farm building. See *Cow-House*.

CATTU-GASTURI, in *Botany*, Rheed. Mal. See *HIBISCUS abelmoschus*.

CATTUPHUS, or COSSOPHUS, in *Ichthyology*, a name given by Aristotle and other Greek writers to a species of Labrus of a bluish black colour; the *MERULA*, and *TURDUS nigricans* of some Latin authors. It is rather uncertain which of the Linnæan species is intended by those writers.

CATTUS, or CATUS, *catouffe*, was in ancient history a sort of covered sled, sometimes fixed on wheels for the purpose of moving it, in some respects similar to the *vinca* and *pluteus*.

CATTU-SCHIRAGAM, in *Botany*, Rheed. Mal. See *CONYZA antihelmintica*.

CATTUSE, in *Geography*, a town of America, in the state of Georgia; 12 miles W. of Tugelo.

CATTU-TIRPALI, in *Botany*, Rheed. Mal. See *PIPER longum*.

CATUDÆI, in *Ancient Geography*, a name given by Strabo to those who dug their habitations under ground; such were the Troglodytes.

CATUIACA, erroneously written *catolua*, *carluce*, a

place of Gallia Narbonnensis, between Alaunium and Apta Julia, according to the Itinerary of Antonine.

CATULENSIS, an episcopal see of Africa, in Mauritania Cæsariensis.

CATULLI-POLA, in *Botany*, Rheed. Mal. See *PANCRATIUM zeylanicum*.

CATULLUS, CAIUS VALERIUS, in *Biography*, an eminent Latin poet, was descended from reputable parentage, and born at or near Verona, about the year of Rome 668, B. C. 86. At Rome, where he settled at an early age, he formed an intimate acquaintance with some of the principal persons in that city, as Cicero, Cinnus, and Plancus, to whom he recommended himself by his wit and gaiety, and by the beauty of his poetical compositions, the obscurity and lasciviousness of which seemed to have been no great hindrance to his reception among the ancient Romans. In some of his poems he attacked the private character of Cæsar with severity; but a slight apology effected a reconciliation; and Catullus was again admitted to his table. Although he accompanied the prætor Memmius to Bithynia, Rome seems to have been the place of his staid residence; where he lived under the character of a wit and a man of pleasure. He possessed, however, a small villa at Tibur, whither he occasionally retired for relaxation, and he also speaks with an amiable enthusiasm of his paternal seat on the peninsula of Scrinio, delightfully seated on the lake Benacus. He was much attached to a mistress, whom he has rendered immortal by the name of Lesbia, though her real name was Clodia. That the unrestrained libertinism of Catullus had not extinguished in his breast the amiable feelings of fraternal love and friendship, we have sufficient evidence in the tender lines which he addressed to a friend on the death of a brother. The Eusebian chronicle has placed the death of Catullus in the year of Rome 696, B. C. 58; but as he alludes in a poem (*Carm. iii.*) to the consulate of Vatinius, in 707, he must have survived that period. In Blair's tables his death is placed in the year of Rome 714, B. C. 40. Joseph Scaliger extends his life to 71 years, and consequently refers his death to the year of Rome 739, B. C. 15; but Mr. Bayle has examined his arguments for this date and refuted them.

The rank of one of the principal Latin poets is assigned to Catullus by Ovid, who places him on a parallel with Virgil:

“ Mantua Virgilio gaudet, Verona Catullo.”

Amor. l. iii. el. 15.
Martial also acquiesces in the same opinion; (*lib. xiv. Ep. 195.*), and modern critics reckon him one of the most valuable examples of the golden age of pure Latinity. “ He is the earliest remaining writer who gives specimens of a great variety of measure; and his subjects and styles of writing are almost equally various. His peculiar excellence is thought to consist in the sweet and tender, combined with a sort of playful simplicity, and no pieces have been more frequently repeated than some of his short tributes of affection to Lesbia. They have, indeed, by their endearing diminutives, served as a model to a whole class of imitators. In other compositions Catullus aims at a higher flight, and exhibits much strength of imagination and expression, not without some of the harshness of a mode of verification not yet arrived at its due polish and correctness. His epigrammatic pieces are of various characters; but such are the licentiousness of idea and freedom of language in most of them, that nothing can be more offensive to moral purity.” His amorous poems are likewise often in the extreme of warmth.” Of his works we have extant, his “*Liber Epigrammatum variorumque Potamuni*,” dedicated to Cornelius Nepos. His poems are divided into three books, one of lyrics, another

of elegies, and a third of epigrams, which division appears in the edition of Venice, 1467, fol. The most approved editions of Catullus are those of Vossius, Lond. 1684, 4to. with a commentary, and Utr. 1691; of Vulpius, Patav. 1710, 4to. with annotations and an index; of Corradini, Ven. 1778; the "Variorum," by Grævius, with the poems of Tibullus and Propertius, Utr. 1680; and Mattair's, in 1715, 12mo., and in the Corpus Poetarum, with Tibullus and Propertius, Lond. 1713, fol. A correct edition was printed a few years ago by an alderman of London; but not sold; and in 1705 was published an English translation, entitled "The Poems of Caius Valerius Catullus, in English verse, with the Latin text revised, and classical notes;" prefixed to which are engravings of Catullus and his friend Cornelius Nepos, 2 vols. Fabr. Bib. Lat. T. 1. c. 5. p. 60. &c. Nouv. Diét. Hist. Gen. Diét. Gen. Biog.

CATULUS, in *Ichthyology*, a name by which old authors have described the spotted dog-fish, *SCQUALUS CATULUS* of Linnæus, which see.

CATURIGES, in *Ancient Geography*, a Celtic people, who inhabited the mountains of Gallia Lyonnensis, or the Cottian Alps; placed by Ptolemy between Ebrodunum and Vapincum. The country which they occupied was called in Latin "Cottii regnum;" and in Celtic "Cou-rich;" or "Catt-rich."

CATURIGES, or CATURIGÆ, a town of Gallia Lyonnensis, and the capital of the Caturiges, between Ebrodunum and Vapincum, according to the Itinerary of Antonine and the table of Peutinger, who names it "Caturigomagus;" its modern name is thought to be Chorges.

CATURIGIS, a place of Gaul in Belgica Prima, N.W. of Namur, on the route to Durocororum.

CATURACTONIUM, a town of the Brigantes in Britain, which was unquestionably the present Cattarick near Richmond, in Yorkshire. In the time of the Romans it appears to have been a great city; and seems to have derived its name from a fort of catarract in its vicinity. Here one of the Roman highways crossed the river Swale. On its banks are the foundations of large walls, and a mount cast up to a great height. Many Roman coins and urns have been dug up here. The city was finally destroyed by the Danes.

CATURUS, in *Botany*, Linn. Mant. Class and order, *Æscia triandria*. Nat. Ord. *Tricocceæ*, Linn. *Euphorbia*, Jusl.

Gen. Ch. Male. *Cal.* tubular, three-cleft to the middle, or three-leaved, permanent; segments egg-shaped, acute, concave. *Cor.* none. *Stam.* filaments three, capillary, longer than the calyx; anthers roundish. Female. *Cal.* from one to three-leaved; leaves egg-shaped, flat, permanent. *Cor.* none. *Pist.* germ villous; styles three, long, multifid, pinnated, coloured, stigmas acute. *Peric.* capsule roundish, trilocular, three-celled. *Seeds* solitary, round.

Sp. 1. *C. spiciflorus*, Linn. Mant. Mart. Lam. Illust. Pl. 805. (*Acalypha hispida*, Burm. Flor. Ind. 303. tab. 61. fig. 1. Watta-Tali, Rheed. Mal. 5. p. 63. tab. 32. Cauda felis agrestis alba, Rumph. Amb. 4. p. 84. tab. 37. fig. 1.) "Spikes axillary, solitary, pendulous." A shrub. *Stem* from 15 to 20 feet high; wood white and close; bark thick, dusky, unctuous, inodorous; pith yellow. *Bran.* herb diffuse. *Leaves* alternate, petioled, nearly heart-shaped, acute, bright green above; midrib pale, hairy, with a few lateral nerves. *Flowers* in axillary, solitary, hispid, pendulous spikes; but, according to Burman, the spikes in most of the plants brought from the island of Java are not pendulous. *Fruit* round, yellowish-green, insipid. A native of

the East Indies, where a conserve of the flowers is used in diarrhœa, and all disorders arising from a laxity of the vessels. From a comparison of Rumphius's figures in tab. 36 and 37. with those of Rheede and Burman, La Marck inspects that several species are confounded together. 2. *C. scandens*, Mart. Lour. Coch. 612. "Spikes axillary, upright; leaves oblong, somewhat serrated; stem climbing." An unarmed shrub. *Stem* long, branched, climbing, but without tendrils. *Leaves* alternate, acuminate, veined, smooth. *Flowers* very small, white, in close short spikes, with awl-shaped bractes; calyx of the male flower three-leaved. A native of the woods of Cochinchina.

CATURUS ramiflorus, Linn. Lam. See *BOEMERIA ramiflora*.

CATUS, in *Geography*, a town of France, in the department of the Lot, and chief place of a canton in the district of Cahors; 2½ leagues N.N.W. of Cahors. The place contains 1344, and the canton 9907 inhabitants; the territory includes 200 kilometres and 10 communes.

CATUS pardus, in *Zoology*. See *FELIS pardalis*.

CATUS zibibicus, a name given by some old writers to the civet, *VIVERRA civetta* of modern naturalists; called also by Gesner and others *felis zibibi*. The English name is civet, this being the animal which produces the perfume of that name: it is oftentimes, though improperly, called the *civet-cat*.

CATUSIACUM, in *Ancient Geography*, *Chaours*, a place of Gaul, in Belgica secunda, at some distance N. of Durocororum.

CATU-TSIERN NAREGAM, in *Botany*, Rheed. Mal. See *LIMONIA acidiffina*.

CATWYCK, in *Geography*, a village of Holland, on the borders of the sea, near which the Rhine loses itself in the sand. The Romans built a castle near this spot, and the ruins may be sometimes seen, when the sea retires more than usual; 2 leagues N.W. from Leyden.

CATY, CATI, or CATTI, an East India weight, used especially in China. It is equivalent to one pound five ounces and two drams English.

The caty is divided into sixteen taels, and the pic into an hundred caties.

The caty is also used in Japan, Batavia, and other parts of the Indies, where it weighs more or less, according as it contains a greater or less number of taels; the caty of Java is equivalent to twenty taels; that of Cambaya to twenty-seven; the caty of Siam is double that of China, and amounts to about 150 French pounds.

The Chinese also give the denomination caty to the Siamese *seban*.

CATY is also a small weight whereby the lapidaries of the East weigh their emeralds, equivalent to three grains.

CATY is also a money of account, used in Java, and some of the neighbouring islands, amounting to about nineteen florins Dutch money.

In the island of Sumatra, caty is said to denote a piece of money valued at six shillings and eight pence sterling.

CATZ, JAMES, in *Biography*, an eminent Dutch statesman and poet, was born at Brouwers-haven in Zealand, in 1577; and became so much attached to literature, that he resigned very elevated posts under the civil government for the sake of study and repose. He was prevailed upon, however, by the States to undertake the arduous office of ambassador to England in the critical and tumultuous time of Cromwell. On his return he retired to one of his estates at Sorgvliet, where he died in 1660. His poems in Dutch, almost all of which are on moral topics, have been held in

high estimation by his countrymen, and have passed through several editions. The latest edition was that of 1726, in 2 vols. fol. Nouv. Dict. Hist.

CATZENELNBOGEN, or **KATZENELNBOGEN**, County of, in *Geography*, a county of Germany, in the circle of the Upper Rhine, which devolved to the landgrave of Hesse in 1479, after the decease of Philip, the last count. It is composed of many districts, which, if they were united, would form a county 20 leagues long, and 10 broad; but the city of Mentz, with its territories, insulated in this country, makes an interruption of 10 leagues. The Mayn passes through it, and divides it into Upper and Lower; the Upper belongs to the prince of Hesse-Darmstadt, and is called Darmstadt from the capital. The Lower county fell to the landgrave of Hesse-Rhinels in 1648, except the town of Catzenelbogen, Brubach, and the castle of Marburg, which belong to Darmstadt.

CATZENELNBOGEN, a town and castle of Germany, in the circle of the Upper Rhine, seated on a mountain which gives name to a county belonging to the prince of Hesse-Darmstadt; in its vicinity are mines of iron; 28 miles N.N.W. of Mentz, and 2 E.S.E. of Coblenz.

CAVA, in *Anatomy*, is a name applied to some large veins.

The superior or descending vena cava is the vessel which returns the blood from the head, upper extremities, and chest, to the right auricle of the heart.

The inferior or ascending cava receives the blood from the lower extremities, abdomen, and pelvis, and pours it into the right auricle.

The vena cava hepatica are the returning veins of the liver, which join the inferior cava. For a description of these vessels, see **VEINS** and **LIVER**.

CAVA, in *Ancient Geography*, a large village of Asia, mentioned by Xenophon; and supposed to be in Bithynia.

CAVA, in *Geography*, one of the smaller Orkney islands, about a league S. from Pomona.

CAVA, LA, a town of Naples, in the province of Principato Citra, the see of a bishop, immediately subject to the pope. Since a new road has united the Sorrentine promontory with the Apennines, which passes by Cava, it has brought to this city a concourse of travellers and merchants. It has also been encouraged to traffic by many valuable privileges; a cloth manufactory has enlivened it, and increased its population; and it carries on a great trade in silk and linens. It is distant 2½ miles N.W. from Salerno. N. lat. 40° 26'. E. long. 14° 55'.

CAVADO, a river of Portugal, which runs into the sea near Efpofenda.

CAVEDIUM, in *Architecture*. This term, derived from the words *cava adium*, signifies a vacant space within the body of a house; it has therefore the same meaning with our word court. Vitruvius has a chapter upon *cavediums* (lib. 6. cap. 3.) which he divides into five kinds, called, from their various forms, Tuscan, Corinthian, Tetrastyle, Displuviated, and Telfudinated. The Tuscan *cavedium* was a square court, with a roof projecting from the sides to shelter the walls, and convey the rain water towards the middle. The Corinthian *cavedium* was similar to the last, except that the roof, projecting further, was supported by columns underneath. The Tetrastyle was so called, from having four columns supporting the angles of the roof. The Displuviated was entirely open, having no roof projecting from the sides, and was therefore lighter and more agreeable for the windows of winter apartments to look into. The fifth kind was covered over, being telfudinated or vaulted;

this manner was used when the span was not very great; and the space above was used for chambers or other apartments.

CAVAGIRO, in *Ichthyology*, a small fish found in the Mediterranean, which Ray describes as being something of the eel shape; but thinner and flatter. The same writer also calls it *Tænia rubra*, and Freggia. This is the *CEPOLA TENIA* of recent authors, which see.

CAVAGLIA, in *Geography*, a town of Italy in the lordship of Vercelli; 16 miles W. of Vercelli.

CAVAILLON, a town of France, in the department of Vaucluse, and chief place of a canton in the district of Avignon, and abounding with remains of Roman magnificence; 4 leagues S.E. of Avignon. The place contains 5192, and the canton 6875 inhabitants; the territory includes 115 kilometres and 6 communes. N. lat. 43° 54'. E. long. 4° 17'.

CAVAILLON, a town on the south side of the south peninsula of the island of St. Domingo in the West Indies, about three leagues N.E. of Les Cayes, and five W. by S. of St. Louis.

CAVALA, LA, a town of European Turkey, in the province of Romania; 30 miles E. of Emboli.

CAVALCADE, a pompous procession of an assemblage of people on horseback, with their equipages, &c. by way of parade in order to grace a triumph, a public entry, or the like.

CAVALCADOUR, or **CAVALCADEUR**, anciently denoted a riding-master; but at present is disused in that sense, and only employed to denote a sort of equerries, or officers who have the direction of princes' stables. The French say, *euyer cavalcadour* of the king, the duke of Orleans, &c. Menage writes it *cavalcadour*, and derives it from the Spanisht *cavalcador*, a horseman.

CAVALCANTI, **BARTHOLOMEW**, in *Biography*, a learned Italian, the descendant of a noble family, was born at Florence in 1503; and having been led by the disturbances of his country to assume the profession of arms, he displayed his eloquence and his valour in an oration on liberty, which he pronounced in 1530; armed with a corselet. Taking part against the house of Medici, he was under a necessity of withdrawing from his country after the assassination of Duke Alexander and the election of Cosmo. He then settled at Rome, where he was employed by Pope Paul III. and his grandson Ottavio Farnese, in many important negotiations. He also faithfully served Henry II. king of France in the cause of the Siennese, as long as they were able to defend their liberties. After the termination of the war between France and Spain, he resided at Padua, where he devoted himself altogether to literature, and where he died in 1592. His "Rhetoric," first printed in 1559, and several times reprinted, has been reckoned among the best works of the kind in that age, when it was the common fault to regard Aristotle as infallible. His "Treatises on the best Forms of Republics ancient and modern," printed in 1555, are also valued. He also wrote an Italian commentary on the first books of Aristotle's Poetics, and translated into Italian the "Caltrametation of Polybius." Moreri. Gen. Biog.

CAVALCANTI, GUIDO, one of the very early Italian scholars, was born of a family of rank at Florence, in the 13th century; and became the disciple of Brunetto Latini, and an intimate friend of Dante. His father, having been a free speculator in philosophy, was placed by Dante in his Inferno, among the condemned Epicureans in the lower regions;

gions; and Boecacio intimates, that the son was addicted to similar opinions. Guido was fond of a retired and contemplative life, and attained among his countrymen a high character both as a philosopher and a poet. In his pilgrimage to St. James of Compostella, he formed an amorous attachment to a lady at Toulouse; but having taken part in the contentions of his country against Corso Donati, a principal person of Florence, was in danger of assassination in his pilgrimage. In the year 1300 he was banished to Serezano; but on account of the unhealthiness of the place, where he fell sick, he was allowed to return to Florence, and died there in that or the following year. His poems, for which he is chiefly distinguished, are, allowing for the times, elegant and correct. They consist of sonnets and canzones, and were printed at Florence in 1527, in a collection of ancient Italian poets. Gen. Dict.

CAVALE, LA, in *Geography*, a small town on the northern point of the island of Taffo, in the Archipelago, west of the bight formed by Cape Asperosa: the town projects into the sea, and has some resemblance of a horse, whence its name. This town, which was formerly called BUCEPHALA, was for a long time in possession of the Genoese and Venetians; of late years it has become a very active point of the Levant trade; its harbour, though not very safe, is frequented by ships which load there with corn, tobacco, and other commodities.

CAVALER MAGGIORE, a town of Italy, in the principality of Piedmont; 3 miles north of Savigliano, and 19 south of Turin.

CAVALERI, a small island in European Turkey, in the Archipelago between the south-west end of the island of Negropont, and the continent of Greece. N. lat. 38° 7'. E. long. 24° 17'.

CAVALERIE, LA, a town of France in the department of the Aveyron, and chief place of a canton in the district of Milhau, two leagues S.E. of Milhau.

CAVALET, in the *Glass Art*, a small iron ring which surrounds the lumella, or hole in the center of the floor, in the tower of the LEER, used for annealing glass vessels.

CAVALIA, a town of Africa, on the Ivory coast.

CAVALIER, in *Military Language*, a trooper, a man of warfare or soldier, that serves and fights on horseback. The appellation of *maitre* or *maller*, has sometimes been given to him. Thus they say, *cette compagnie est de trente ou quarante maitres*, non compris les officiers, this company consists of thirty or forty maiters, exclusively of the officers. This name is very old. And they inherit it from the men of arms, the first corps of cavalry that was raised under Charles VII. of France. These men at arms, who were gentlemen, carried each of them into the field with him three archers, one cutler, and one page or valet. The numbers of each were distinguished by so many maiters, so many archers, so many cutlers, and so many pages. When these last were sent on detachments, by themselves, some of the *gens d'armes* commanded them. And the officers did not march but with the *gens d'armes* alone. This term was formerly confined or restrained to a knight or miles, and had the same import or meaning as that which the French at present annex to the word *chevalier*. The word now denotes any soldier that serves and combats on horseback: and he is reckoned a good cavalier who takes particular care of his horse and his equipage.

CAVALIER *bas*, the same in a military sense as *Bachelier*, which title was formerly given to a young cavalier, who had commenced his military career, served his first campaign, and received the military cinchure.

CAVALIER, a term in *Fortification*, made use of to denote

a work raised generally within the body of the place from ten to twelve or more feet higher than the rest of the works. Its most common situation is within the bastion, and nearly of the same form. It is sometimes placed in the gorge of a bastion, and sometimes on the middle of a curtain, in which case it is usually made somewhat in the form of a horse-shoe, but a little flatter, or not quite so much rounded, or circular.

The principal use of cavaliers is, to command all the adjacent works, and the country around them. They are seldom or ever made but when there is a hill or rising ground, which overlooks some of the works.

Sometimes the earth of the rampart fills up the whole bastion, which is then called a full bastion: and sometimes the rampart follows the *moffer-line*, or first draught, running parallel to the parapet of the bastion, which is then called an empty or hollow bastion. The empty spaces in hollow bastions are convenient for magazines of provision and ammunition, and for various other purposes. But when the bastions of a fortified place are full, and there are any eminences or rising grounds near it, that command any parts of the works or outworks, terraces or mounds of earth, called cavaliers, more or less raised as there is occasion, are made in them, which are sometimes walked round, and always have, like other works, a parapet for covering the cannon placed in them for removing such exterior commands, or for defending the faces of the opposite bastions, as well as the bastions themselves, in which they are raised, should the enemy make lodgments in them. Such a cavalier is called *cavalier de bastion*; and, when made nearly of the same figure with one, forms a sort of double bastion, which is often attended with great advantages. To construct such a cavalier in a bastion, draw two right lines parallel to the faces of the bastion, about twenty yards within, and distant from the face; and form, at this distance, an interior bastion, with flanks either straight, or with orillons, similar to those of the outer bastion, or the bastion itself, and you will get the magistral line of the cavalier.

Cavaliers are often made on the middle of the curtains, and near the parapet, in order to command a view of the field from the place, to discover the enemy in his works, and to double the fire which defends such parts of the town as may be attacked. At other times when any parts of the place or works are liable to be *enfiladed*, cavaliers are raised to cover them against an *enfilade*.

A work of this nature is sometimes erected in the ditch of a fenny place, for the purpose of covering a gate, or lodging a guard in it against surprisals. It is then called a *horse-shoe*, and when very irregular, *paté*.

Ever since the invention of modern fortification, cavaliers have been in estimation and use in many fortified towns, as appears from Palma-Nova, Orbi-Novo, the citadel of Turin, and various other places. They are raised considerably higher than any other parts of the works; and as they have different uses, or answer different purposes, they are also of different figures, being sometimes rectangular, sometimes round, sometimes oval, sometimes of the bastion form, &c.; for which, see *Fortification*, Pl. 1. fig. 2.

The principal advantages of cavaliers are these, that they molest a besieging enemy as long as he is in the field, expose him to the view of the beleagued in his works and approaches, annoy him in his batteries, and oblige him to open his trenches at a greater distance from the place than he otherwise would. They subject him to this inconvenience, that, to be under cover from them he must perform more labour and make greater excavations to raise his trenches and other works a good deal higher than he need do, were it not for them, which, when there is but a small depth of soil and rock

under

under it, is attended with much difficulty. At the same time he cannot, but with extreme difficulty, raise works in the field sufficiently high to command them. They serve also for covering those parts of the works or place, that are exposed to an enfilade, and, when conveniently situated, almost double the fire of the faces of the bastions. They likewise answer for firing into the retrenchments from the moment the enemy makes a lodgment in the bastion.

Some engineers disapprove of them, alleging, that they are of no great use or service, and do not contribute much towards the defence of a place, because, being retired from the out-works, they cannot keep the enemy at a distance. Then they observe, that the height of these works is attended with much inconvenience in different respects. First, in the raising of them, as it is difficult to heap up earth upon earth in this manner, and afterwards place a parapet at top of all; secondly, that they are butts for the enemy to fire at; thirdly, that, besides this, in time of need, and, when the enemy is near, they serve in no stead for the purposes of defence, because the men in them cannot point their cannon on objects near and below them, without either exposing themselves, or greatly diminishing the thickness of the parapet; and, lastly, that they hinder the making of retrenchments in the bastions, and that when the enemy once gets possession of them, he can turn them to a good account, and make use of them to great advantage.

In answer to these objections, it may be very justly observed, that several engineers of reputation have made use of them with great advantage, conscious that, when added to good fortifications, they assuredly render it much stronger.

Thus, although they are retired within the body of the place, their height remedies that defect, enabling them to see and command whatever is in front of them. That the difficulty of making them is not so great as has been supposed, as they are actually to be found in many places, and that it ought not to be objected to them, as they afford advantages much more than sufficient to counterbalance it. And that as to their being butts for the enemy's cannon to destroy and batter down, it ought to be considered that, for this purpose, he must face his batteries, and raise them very high, during which operations he is liable to be greatly annoyed and interrupted by the fire of the cavaliers, and to perform a great deal of labour before he can put his own in a condition to do them any essential damage. And after he has made them, they are subject to be more suddenly battered down by the cavaliers, than the cavaliers are by them, as the one is composed of earth well settled and rammed, and the others of earth, loose, and suddenly thrown up.

When there is but little soil on the outside of a fortified place, the besieged may derive great advantages from such works, as they can raise them before-hand at their leisure to what height they choose, and may diminish the means and power of the besiegers to injure them, by bringing the earth from the outside for that purpose, which will compel the enemy to bring earth and materials from a distance to raise his batteries and approaches sufficiently high to counteract the effects, and cover him from the command and fire of the cavaliers; an operation that must be always attended with much loss of time, as well as great labour and fatigue.

Such works cannot fail to be useful by being high, since when placed near the extremities of the curtains, they afford a defence to the opposite bastions; and not only commanding but firing to a distance, they can greatly injure and annoy the enemy after he gets into the ditch, and compel him, when he is going to make the traverse, to raise it very high, in order to put himself under cover. When they are thus placed, they do not interfere with the making of retrench-

ments in the bastions, but furnish a very good defence for them. To say that the enemy will be able to make use of them, after he once gets possession of them, as so many citadels against the town, city, or fortified place, is no argument at all against the construction and use of them. For on the same ground, it might be alleged, that we never ought to make bastions. When it is considered, that after the besiegers shall have taken all the bastions, and all the retrenchments within them, which they must do before they can become masters of the cavaliers so situated, the place will hardly be able to defend itself, whether there be cavaliers or not; and when there are such works there will still remain this defence after the great injury the enemy must have sustained by them before he was able to force all these other works.

It may not be improper to observe, that it would not, however, be advisable to introduce cavaliers as a principal component part of the works of the body of a place, or to retrace them like bastions, and employ them as such. For when the bastions of a fortification are at too great distances one from another to furnish a good mutual defence, or when the curtains are excessively long, it is better to place ravelins before them than to introduce cavaliers into the middles of them.

The height of cavaliers above the level of the rampart, must depend on convenience and the purposes for which they are raised or erected. It ought to be from 10 to 15 feet or more. The length of one should be at the least 14 fathoms, in order to receive conveniently 4 or 6 pieces of cannon, and its breadth 6 fathoms, for them to have room to recoil in, and to be served commodiously. The said height in such works is exclusive of that of the parapet, which should look outwards, or towards the field, like that of the rampart, and ought to be 4 feet 4 inches high, and from 15 to 20 feet thick. On the part looking towards the town a very thin parapet is all that is necessary, and the slope or ascent there, for carrying the guns up should be from 10 to 12 feet broad.

When there are hills or eminences near the works, cavaliers are sometimes made sufficiently large to hold 10 or 12 guns each and are raised much higher.

Different forms of cavaliers are respectively best adapted to different purposes, and much depends in this respect on the judgment and knowledge of the engineer who constructs them. The round or circular form, however, is exceedingly good. Of all figures under the same periphery it contains the greatest area. The fire from it is equally distributed in every direction, which is not the case with that from the rectangle, square, &c. A cavalier of this form is less exposed and less liable to be ruined or battered down in any particular place than one in the form of a rectangular figure. The same advantages are in a great measure attributable to one of an oval form, as it differs but little from the circular. The exterior slope of the parapet ought always to be considerable, particularly if it be made of loose or bad earth; and so ought also that of the cavalier itself to be, wherever it is not faced with masonry.

Some are for placing them in the entrance or gorge of the bastion, between the two flanks. This position enables them to see and to defend the faces of the opposite bastions. But it interferes with the retrenchments in these works, and is too much retired from their salient angles for commanding effectually the parts without the body of the place. Those in the citadel of Turin are thus situated, but it is in order to command the town.

Cavaliers placed near the extremities of the curtains neither hinder the erection nor occupy the places of other defences, but rather increasing them have a great command of the traverse, which the besiegers make for approaching the bastion.

bation. The fortifications, therefore, seem to be very proper for placing them in.

The capital of a cavalier placed at the middle of a curtain, should be at right angles to the same. Its salient angle should be nearly a right one, which will enable the faces containing it to furnish a pretty great and good defence to those faces of the two bastions that are opposite to them. The middle of the curtain is a bad position for a cavalier, when it is otherwise constructed. No cavalier, indeed, placed on the middle of a curtain ought to be raised high above the rampart; for if it be, its fire along the faces of the adjoining bastions will be too plunging to produce much effect. And, on the other hand, if it be kept low, it cannot command the field much better than the curtain itself. For these reasons the middle of the curtain does not appear to be an eligible or advantageous situation for a cavalier.

That a plunging shot is not near so destructive and annoying as a horizontal one, or one nearly so, is a truth so obvious, that it hardly stands in need of demonstration. For a shot fired horizontally or from a very small elevation grazes and bound along, and may hurt or injure situ objects in its progress, but its force is entirely spent; whereas one fired from a considerable height at an object at a moderate distance, or from a small height at one very near, never rises if it can bury itself. But let $A K$, fig. 1, represent the line of the horizon, $A B$ the altitude of any place, work, or height above the same, and let $A D$, $A F$, $A M$, $A K$, be different distances on the horizontal line, from the foot, A , thereof. Now if $E G$ be the height of an object, at which a gun is to fire from B , $G O$ be drawn parallel to $A K$, and from the points L , N , O , where $G O$ intersects $B D$, $B M$, $B K$, right lines $l H$, $N L$, $O a$ be drawn parallel to $A B$, the relative degrees of the extent of offence in firing from B at an object of the height, $E G$, placed at the points E , H , L , a will be as $E D$, $H F$, $L M$, and $a K$ respectively, or as the tangents of the angles $A B D$, $A B F$, $A B M$, $A B K$, to the radius $E G$.

The chances then of hitting an object of a given height from B , at different distances from A , will, *ceteris paribus*, be as the tangents of the angles, which lines drawn from B along the top of the object at these distances to meet $A K$, form with $A B$, to the height of the object as radius. But if it be considered that a shot fired from B meeting the surface of the earth at D or F will bury itself if the ground admit of it; whereas, meeting the surface at M or K it may have a first, second, and even third graze, in each of which it may hit and injure almost a number of objects, it will be found, that the chance of doing mischief is greatly beyond the foregoing ratio in favour of the shot that is fired horizontally. Heights create dead parts for some distance in front of them, which is the cause why troops in ascending them are generally exposed to but little danger from fire-arms and fusils as little loss.

In maritime places cavaliers are placed either in the bastions or on the curtains, according as their situations are best calculated for enabling them to command a view of the sea, and to fire on shipping at a distance.

Wherever a cavalier is placed within the body of the place, there should be a passage of 6 or 8 feet between the parapet and it, for the convenience of the soldiers, and to prevent its ruins when it is battered, from falling into the ditch.

Some are for placing cavaliers without the body of the place, beyond the places of arms. But this seems to be a bad plan, as they must in such situations be raised very high, be revetted, and after all can furnish no flanking defences to other work.

CAVALIER *de tranchée*. Trench-cavalier, is a work raised by the besiegers, of earth, and such other materials as they can meet conveniently procure, as gabions, &c. sometimes half way between the termination of the glacis and the covert way; sometimes only a third part of the breadth of the glacis distant from the covert-way; and sometimes close on the very crest or highest part of the glacis. It is difficult to establish a work. It cannot, indeed, well be done without batteries *a ricochet* to enfilade completely the covert-way. But when the cavaliers *de tranchée* are once well established, they prevent frequent sallies, and soon compel the besieged to retire well to the body of the place. For it is then easy to push on direct trenches or approaches to the salient angles of the covert-way, and to make at these angles small lodgments in the forms of circular arcs, by means of which the besieged may be driven entirely out of the places of arms, and from which the besiegers can extend their lodgments to the right and to the left, in directions parallel to the branches of the covert-way, or inside of the glacis, and about three toises distant from the same; which thickness of earth will serve as a parapet to their lodgments, and shelter them from the fire of the cannon of the place.

In order to oblige the besieged to abandon their cavaliers, or at least to diminish the briskness of their fire, it is necessary to keep almost constantly throwing large shells into them. These damage them materially, dismount the guns on the batteries in them, break the carriages, and prevent the besieged from re-placing, or re-establishing them, without great loss, if they persist in working on the cavaliers.

If the cavaliers of the besieged be revetted and in the bastions it is also necessary to batter them with heavy cannon, in order to fill up with the rubbish and ruins that part of the rampart, which is at the foot of each, as not to leave sufficient space for them to retrench themselves to oppose the assault or attack of the bastions.

When the miners once get so far as to penetrate into the earth of the rampart, and into that of a cavalier, they should make use of mines to throw as much as they can of the earth of both into the ditch, to assist in filling it up. After that, they should continue working on the breach, to render it practicable and of easy access, after which the besieged having no retracements, either in the bastion or in the cavalier, will naturally surrender, to avoid having the place stormed or carried by assault.

Should the besiegers, however, be driven to the necessity of storming the bastion, they will as soon as they reach the top of the rampart make small lodgments at the foot of the cavalier, on each side of the breach to support that of the top of the breach in the cavalier.

CAVALIERS *a cheval*. This is an appellation given by the Italians to the large square towers, which they make over the gates of cities for the purpose of placing cannon on them.

The ancients raised cavaliers or terraces of wood and earth against the walls of towns they were besieging, in order to throw fire, darts, &c. into them.

CAVALIERI, EMILIO DEL, a Roman gentleman, who first set the dialogue, of an oratorio, or sacred drama, to narrative music, or recitative. This oratorio was entitled; *Del Anima e del Corpo*, and was performed at Rome in 1600, the same year that Rinnuccini's *Orfeo*, the first opera, was set by Jacopo Peri at Florence, and performed to similar music: so that the Italians themselves are unable to determine who was the inventor of the musical declamation called recitative, which has been cultivated and continued in the musical dramas of Italy, sacred and secular, ever since; and which

which, though attempted in other dialects elsewhere, seems to suit no language but that of the country where it had its birth. See *RECITATIVE, OPERA, and ORATORIO.*

CAVALIERS, or CAVALERS, in English History, the appellation given by one of the parties in the distracted time of Charles I. called the *ROUND-HEADS*, on account of the short cropped hair which they wore, to another party composed of reduced officers, and young gentlemen of the Inns of court, who offered their service to the king. Under these party names the different factions rendezvoused, and signalized their mutual hatred. See *TORIES.*

CAVALLERI, or CAVALLERIUS, BONAVENTURA, in Biography, an eminent Italian mathematician, was born at Milan in 1508, and entered at an early age into the order of Jesuits or Hieronymites. In the course of his studies he manifested such talents, that his superiors, after he had taken orders, thought proper to send him to Pisa in order to enjoy the advantages of the university established in that city. Cavalleri at first regretted this change of situation; however, it was to this circumstance that he owed the celebrity which he afterwards acquired. Here, with the advice of Benedict Castelli, the disciple and friend of Galileo, he applied to the study of geometry, in order to relieve the pains of the gout to which he was subject; and in this science he made such progress, and acquired such an accurate acquaintance with the ancient geometers, that Castelli and Galileo concurred in predicting the eminence at which he afterwards arrived. Soon after this period he invented his method of indivisibles. In 1629 he communicated to some ingenious persons and to the magistratus of Bologna, his treatise of indivisibles and another on the conic sections; and thus he obtained the honour of succeeding Maginus as professor in the university, in the year 1629. See *INDIVISIBLES.* Besides his celebrated work on indivisibles, entitled, "Geometria Indivisibilium continuum nova quâdam Ratione promotâ," and published at Bologna in 1635, 4to. and again in 1653; he also published a treatise of conic sections, under the title of "La Specchio Utorio ovvero Trattato delle Settoni Coniche," or "De Speculo Utorio, &c." Bologna, 4to. 1632; a system of trigonometry under the title of "Directorium generale Uranometricum," 4to. 1632, including an account of logarithms, together with tables of the logarithms of common numbers and trigonometrical tables of natural sines, and logarithmic sines, tangents, fluents, and versed sines; of which a new and enlarged edition was published at Bologna in 1643, 4to. entitled, "Trigonometria Plana ac Spherica, Linearis ac Logarithmica, &c.;" a "Compendium Regularum de Triangulis;" and a "Centuria Problematum Astronomicorum." He was also the author of a treatise of astrology, entitled "Rota Planetaria;" and published under the appellation of Sylvius Philomantius; and this publication was the more surprising, as he was an enemy of judicial astrology. The last of his works was entitled "Exercitationes Geometricæ sex," 4to. Bonon. 1647, and contains exercises on the method of indivisibles; answers to the objections of Guldinus; the use of indivisibles in Cossic powers, or Algebra, and in considerations about gravity; with a miscellaneous collection of problems. Towards the close of this year, 1647, he died a martyr to the gout, which had deprived him of the use of his fingers. Montucla, Hist. des Math. vol. ii. p. 57, &c.

CAVALLERIA, among the Ancient Spaniards, a kind of tax, or imposition on the inhabitants of great towns and cities, for the support of horsemen.

CAVALLEROS, in Geography, a town of North America, on the north-west part of the bay of Panama; 75 miles S.W. of Panama.

CAVALLES, a cluster of small islands in the Southern Pacific ocean, near the coast of New Zealand; 3 leagues N.W. from Point Pocock.

CAVALLI, FRANCESCO, a Venetian dramatic composer, who furnished the theatres of Venice, during the year 1639 and 1666, with 35 operas. Of his genius, science, and fertility, we are now unable to judge, except by *Erismona*, one of his operas that has been preserved in England, and which having examined, we find the music as good as that of any of the time and kind. And indeed, the number of his operas is a strong eulogy upon his genius, in a city where the musical drama was more cultivated in the 17th century, than in any other part of Italy.

CAVALLI Marini, in Natural History. These are described by old writers as being little dried animals about the length of a man's thumb, found on the sea-coast near Puzzuoli. The head, they observe, resembles that of a horse, and the body terminates in a tail like that of a shrimp. Women, it is said, use them to increase their milk; and apply them as an anodyne for the breast. Bruised with vinegar and honey they are applied as a plaster to the part bitten by a mad dog. This species of fish is also found on the other side of Italy, along the coast of the Adriatic; but not in such abundance. The marine animal, so curiously described, is no doubt the small species of Syngnathus, or pipefish, known among modern naturalists by the name of *Hippocampus.* See *SYNGNATHUS HIPPOCAMPUS.*

CAVALLINI, PIETRO, in Biography, a historical painter of the thirteenth century, was born at Rome in 1279, and became the disciple of Giotto. The number of his paintings is said to have amounted to 1300, and his piety was no less extraordinary than his assiduity as an artist, in consequence of which he has been esteemed as a saint. His principal works are at Rome, where he assisted Giotto in the celebrated picture in Mosaic, which is over the grand entrance into the church of St. Peter; but his performance in fresco was in the church of Ara Cœli at Rome; in which he represented the Virgin and child above, surrounded with glory, and below was the figure of Octavian, and also that of the sibil, directing the eye and the attention of the emperor to the figures in the air. It has been suggested by Mr. Vertue (see *Anecdotes of Painting*, vol. i. p. 17) that the shrine of Edward the Confessor, and the crosses erected to the memory of queen Eleanor, were constructed from the designs of Cavallini by Abbot Ware; and he supposes Cavallini to be the inventor of Mosaic, alleging that Giotto was 20 years younger than the other. But this appears, by the testimony of Vasari, and of other writers, to be an anachronism; as Giotto was three years older than Cavallini, and was, in reality, his instructor in the art of Mosaic. Besides, the abbot Ware died in 1283, when Cavallini was only four years old, and eight years before the death of queen Eleanor, who died in 1291. Pilkington.

CAVALLO, in Geography, a sea-port town of America in the province of Venezuela, on Terra Firma, or isthmus of Darien, 21 miles N.E. of St. Jago de Leon. It is well fortified, and in a former war was unsuccessfully attacked by Commodore Knowles, S. lat. 10° 17'. W. long. 68° 12'.

CAVALLOS d' Fern, two small islands in the Atlantic near the coast of Portugal, about half a league S.S.W. of Epoufenda. N. lat. 41° 20'. W. long. 8° 6'.

CAVALQUET. This is the name given to a particular sound of the trumpet, which the cavalry make use of on approaching towns or passing through them.

CAVALRY, in French cavalerie, or cavallerie, in Military Language, a body or bodies of troops, who serve and fight on horse-back. Of these there are different descrip-

tions in almost every country. In this, independent of the yeomanry and volunteer cavalry, we have two regiments of life-guards, one of horse-guards, seven of dragoon-guards, five of dragons, and nineteen of light-dragoons.

The two regiments of life-guards, in consequence of the reduction of the horse-grenadier guards, are kept for the purpose of guarding the metropolis and of securing his majesty. They are generally called the first and second life-guards. Each of them consists of six troops and a kettle drum.

The royal regiment of Horse-guards, which is commonly called the Oxford-blues, from having been originally raised by the earl of Oxford, consists of nine troops. The quartermaster of this corps holds his appointment under the sign manual, and is, in this respect, an exception to the general regulations, that affect the quartermasters of all our other regiments of cavalry, who hold theirs only by warrants.

The order of precedence among our cavalry is the following. First, the life-guards; secondly, the horse-guards; thirdly, the dragoon-guards; fourthly, the dragons; and lastly, the light-dragoons.

Horse is also a general term, as well as cavalry, for mounted soldiers. In Ireland there are four regiments of horse-guards. The first troop of horse in our service was raised in 1660.

The dragons, though regiments of horse or cavalry, differ from the rest in this circumstance, that they are liable to be dismounted, and are obliged, when necessary, to fight on foot as well as on horse-back. The first regiment of dragons was raised in 1681.

Light-horse is an appellation given by us to all cavalry in general, that is composed of small and lightly accoutred men mounted on light and swift horses. Ours were first raised in 1757.

Hungarian cavalry, now commonly called *Hussars*, wear a short waistcoat, with a pair of breeches and stockings in one, with short light boots, generally red or yellow, and a doublet, that has five rows of buttons, which hangs loosely on the left shoulder. The men wear large fur-caps adorned with cock's feathers. But the officers have eagles' or herons' feathers in theirs. They are armed with long crooked sabres, light carbines, and pistols. Before they begin an attack they lay themselves so flat on the necks of their horses, that it is almost impossible to discover their force or number. But when they come within pistol-shot distance of their enemies, they raise themselves up with astonishing quickness, and charge with such vivacity and alertness, that it is extremely difficult for those they attack, to preserve their order. Being dextrous horsemen, when they find it necessary to retreat, they move with so much celerity, in consequence of their horses being so capable of enduring fatigue, and their equipage being so light, that no other cavalry can pretend to follow or keep up with them, as they leap over ditches and swim across rivers with surprising ease and facility. Most of the German powers have cavalry under the name of Hussars, as well as France, into which they were first introduced by Louis XIII., and were called Hungarian cavalry: which circumstance shews that this appellation was prior to that of *Hussars*.

Cuirassiers is a term made use of to denote a sort of heavy cavalry armed with cuirasses, as most of the German horse are. The several German powers, particularly the emperor and the king of Prussia, have regiments of cuirassiers. And the late king of France had one. But there have been no cavalry of this description in England, since the time of the revolution. The Austrian cuirassiers are reckoned the emperor's best troops.

Of the French cavalry.

Before the year 1638 the regiments of French cavalry consisted of two, three, or four squadrons: each squadron consisted of three companies, and each company of a captain, a lieutenant, a marshal des Logis (quarter master) and fifty maitres (troopers).

During the war of 1688 their ancient regiments were divided into squadrons, and every squadron consisted of four companies. A company consisted of 40 maitres, and had four officers, as formerly. The new regiments consisted each of four squadrons, of which each had three companies. And each company was composed of 50 maitres and four officers.

During the war of 1701 the squadrons consisted each of four companies; and each company had 35 maitres and four officers.

Before the breaking out of the war of 1741 each regiment of their cavalry consisted of four squadrons; each squadron of four companies, and each company of 25 maitres. During the war the companies were increased each to 35 men. The regiment de Royal Allemands, and that de Roien, consisted each of six squadrons, and each squadron of three companies of 50 men each. The regiment of Fitz-james had four squadrons, and each squadron three companies of 46 men each. That of Nassau had the same number of squadrons and companies, but each company had 50 men.

The ordinance of the 15th of March 1749 reduced the cavalry to 129 squadrons, consisting each of four companies, and each company of 30 men.

The ordinance of the 25th of March 1776 made each regiment consist of four squadrons of cavalry, and one of light horse, of one company each. By the 11th article of that ordinance there was attached to each regiment of cavalry a squadron under the title of an auxiliary squadron, for the purpose of replacing, in time of war, the men, that might be deficient or wanting in the squadrons of cavalry or light-horse.

The ordinance of the 8th of August, 1784, made some alterations in this arrangement, and made each regiment of cavalry consist of four squadrons, and each squadron of one company. By it both a peace and a war establishment was prescribed. But in both the one and the other the number of officers and non-commissioned officers of all ranks, was to be the same.

By it also the six regiments of light-horse were reunited to the cavalry, and every regulation for them was prescribed. And they were to retain the rank they then held among themselves, and with regard to the other regiments of cavalry.

The offensive arms of the cavalry are, the pistol, the carbine, the blunderbuss, the fusée and bayonet, the sword and the sabre.

The defensive arms of the cavalry are the calotte or leather cap, the casque, and the demi-cuirasse, or half cuirass.

As the Franks, before they conquered Gaul, had but very little cavalry, it is probable they employed in their armies by degrees the Gaulic cavalry, which possessed much reputation, and for a long time had formed the most numerous part of the Roman cavalry. Clovis, at the battle of Tolbiac, fought at the head of his cavalry, and in 537 Theodebert carried some with him on his expedition into Italy. At the battle of Tours, in 732, we are told, that the French army consisted of 60,000 foot, and 12,000 horse, which last-mentioned body had neither boots nor defensive armour, and had no other offensive weapon than the lance or javelin.

Under Pepin, in 768, the number of their cavalry was augmented.

augmented. Under Charlemagne its number almost equalled that of their infantry. This probably was owing to the vast extent of his empire and the insurrections, that were constantly taking place in it, which required prompt and expeditious movements from one place to another. In his time the horsemen or cavaliers were armed with swords, and coats of mail made of small rings, inter-wrought or connected like links together.

Towards the end of the second race of French monarchs, and the beginning of the third, their armies were almost entirely composed of cavalry; a circumstance which arose out of the nature of their situation. Not willing to confide the defence of their country to the body of the people, who were then serfs or slaves, it was left in a great measure solely to the noblesse, who would not serve but on horseback. They, accordingly, formed a corps of cavalry or horse, to which the name of *gendarmerie* was given. The gendarmes were armed with cuirasses, brasslets, cuisses, greaves, gauntlets, helmets, with the lance, the sword, and the hatchet. Their horses were covered with plates of iron, or with thongs of leather. The infantry were employed in going after forage, raising up the wounded gendarmes, and in performing similar services.

The cavalry, that got the name of *light*, was composed of the vassals whom the seigniors or noblesse carried along with them. They had not all the arms of the gendarmes, and did not fight in the same line with them. They were furnished with very little defensive armour; they carried the hatchet, the club, and sword, and served nearly as hussars do.

Louis le Gros, having established communities, formed from that militia, in 1105, some light horse. But there was no regular formation or establishment of cavalry in France before the time of Charles VII., who made one under the name or appellation of *compagnies d'ordonnance*, and one of infantry, at the same time under that of *Francs-archers*. Then the cavalry assumed a more regular form, and fought in squadrons; whereas, before that time they had not been accustomed to fight but in a single rank, because no one of the nobles that composed it chose to stand behind another.

The gendarmerie is the first corps of French cavalry next to that of the *Maison du Roi*, and has always been remarkably distinguished for its valour and intrepidity. Charles V. having applied to Francis I. in 1552, to lend him a sum of money, and that illustrious corps, to assist him in repulsing the Turks, by whom he was at that time hard pressed, received for answer from the French monarch to the first of his demands, "that he was not a banker;" and to the second, "that his gendarmerie never fought but with their king at their head."

In 1445, Charles VII. observing the difficulties he experienced in assembling the noblesse, who then composed the French cavalry, the continual wars they were engaged in having exhausted their means of supporting the expence, and wishing, for various good reasons, to have a corps of cavalry that should be constantly engaged in his service, and which he could dispose of at all times, and on all occasions, as he might think proper, created or formed fifteen companies, to whom he gave the name of *hommes d'armes d'ordonnance du Roi*. These companies were composed of the bravest and most experienced men in military service then in the kingdom. Each of these companies consisted of 100 lancers, or *hommes d'armes*, and each *homme d'armes* had five followers or aids, viz. three archers, one cutler, and one page or valet. Each company then contained 600 men, all mounted on horseback; and the fifteen companies formed together a body of 9000 cavalry. This was the commencement of a

standing army in Europe. That sagacious king set the example to other monarchs, and pointed out to them the most effectual method of not only counterbalancing, but also of lowering, by degrees, the exorbitant power of their nobles.

The officers of these companies were all seigniors of the first distinction. The *hommes d'armes*, or *maîtres*, themselves were gentlemen, and their followers were obliged to wear the livery of the captain of the company to which they belonged. For this purpose they ornamented their coats with the colours that composed it.

This uniformity of dress in each company was established that they might be known in action, and when they were guilty of any irregularities; whence proceeded that uniformity in clothing that has been since established among troops in every nation. These companies afterwards diminished, in regard to the number of men in each, but always retained their reputation for valour. This diminution was occasioned by the establishment of a considerable body of light horse or cavalry, in which several of the gendarmes accepted of employment; so that under the reign of Henry IV. the armour cap-a-pie having been abolished, the gendarmes ceased to be distinguished from the other cavalry but by their name and prerogatives. At last under the reign of Louis XIV. at the time of the peace of the Pyrenees, all these ancient companies were reduced to the four first, of which the king chose to be captain, and to some others that belonged to the princes of the blood. These last were suppressed as the princes died. The same king afterwards, however, augmented that corps to the number of sixteen companies, at which establishment it was continued.

The Scotch company of gendarmes du Roi was the only one that remained of the fifteen which Charles VII. established in 1445. It had the appellation of *cent lances*, or the hundred lances, and was unquestionably the oldest troop in the kingdom. It possessed some privileges superior to those of the Scotch body guards, though these held the first rank, and was always held in such high estimation, that, so long as it was composed of Scotchmen, it was commanded by Scotch noblemen of the first qualification, and even by several of the blood-royal. The sons even of the kings chose to bear the title of captain of that company, which, of right, belonged to them, as appears from several treaties, and the example of the duke of York, afterwards king of England, under the title of James II.; who was captain of it in 1667. And it was not till after he resigned the command of it, that it was commanded by a French seigneur.

Under Henry IV. there were carabins, who did not form a separate corps, but were put by fifties into the companies of light horse, and had no other captains or cornets, than the captains and cornets of these companies. These carabins, under Louis XIII., formed regiments, and were disposed of in separate corps, in the same manner as the carabineers, who were distributed among the regiments of light cavalry, were, in the reign of Louis XIV., formed into regiments of carabineers. Since his time the French cavalry has consisted of different bodies. Some were in companies, others in corps or regiments. The body guards of the king, the gendarmes, the light horse, the mousquetaers, have been on the footing of companies, and have not formed regiments. The rest of their cavalry have been distributed in regiments commanded by colonels, and gone under the general name of light cavalry, which, however, is distinct from the *compagnies des chevaux légers d'ordonnance*.

The Spanish cavalry is naturally good. And were it properly disciplined and taught to make the best use of its

force, there are hardly any troops that could stand its shock.

The Turks, the Tartars, the Arabs, and even the Moors themselves, or the people of the kingdoms of Fez and Morocco, have excellent horses for cavalry as well as the Spaniards. But their horses, though of a good temper, are not so useful or so well calculated for doing execution, as the Spanish sword, or even the swords of the Germans. Besides the advantage of good and fleet horses, they sit so short on the stirrup, that they can stand up quite straight at a full gallop, and, supporting themselves with their stirrups, can make a better stroke than those who use long ones, and at a greater distance.

The Turkish cavalry owes its origin to the Scythians, a race of people, that were always fond of making war on horseback, and transmitted that passion to the Turks.

The Sultans so tyrannized over their new subjects, after conquering them, as even to deprive them of their lands, and appropriate them to the maintenance and support, not only of the *Serratusly* infantry, and the marine, but also to that of the cavalry. At the same time they left the conquered countries divided into and distinguished by the names of kingdoms, provinces, great and small departments; and issued for each of these districts precise and distinct orders, touching the prompt raising of the militia and the support of the cavalry.

Their cavalry is not all on the same footing in regard to pay. It is divided into the cavalry *capiculy*, the cavalry *topachly*, the cavalry *ferratusly*, and the cavalry *de tribut*.

The cavalry *capiculy* or *spahis*, possess no lands, but are paid by the grand sultan, and serve as a guard to his person. Their number amounts to about 15,000, one half of whom are called *sibataris*, and are distinguished by a yellow standard or cornet, and the other half are called *spahis glanis*, or *spahaoglari*, who are distinguished by a red cornet or standard. Originally these last served the first. But having in an engagement given astonishing proofs of valour to the shame and disgrace of those, whose servants they had been, they were formed into a separate and distinct corps. Their offensive armour consists chiefly of the sabre and the lance, which they call *mizrack*. They frequently also carry bows and arrows, and sometimes pistols and carbines. And they make use of the long dart or javelin, called *gerit*, which they handle with much address and dexterity, catching it up from the ground, when their horses are even at full speed, if they miss their aim in throwing it at the enemy. When the grand seignior takes the field in person, it is customary to make a present of 5000 aspres to each spahi to enable him to purchase bows and arrows.

When the spahis are on a march, they follow their standard without observing any certain order, advancing in a confused manner in small bodies, sometimes in the van of their own corps, and sometimes in the rear.

Besides these two bodies of spahis, there are four others, who are not called on to serve but when the urgent necessities of the state render their services absolutely necessary. The first of these are called *sag-uleggi*, and carry a standard red and white; the second *sol-uleggi*, and carry a standard white and yellow; the third *sag-gurebia*, with a green standard, and the fourth *sol-gurebia*, with a white one. All these spahis receive a daily pay, from 12 to 20 aspres, and are liable to perform every kind of service.

There are likewise spahis called *timariots*, who are obliged to serve at their own expense as soon as the *beys*, *berbers* or governors of provinces command them, in consequence of the lands they possess, the revenues of which are appropri-

ated to this service. Of these there are two kinds, the one called *tenkereliers* and the others *tenkeretis*.

The *Tuzkererbirs* receive the grants of their *timars* from the court of the grand seignior. But the greatest revenue of one of them must not exceed 1099 aspres.

The *Tenkeretis* take their letters patent from the *beglerbey*; and the revenue of one of their *timars* is commonly from 3000 to 6000 aspres.

The *Chiaus* also form a branch of the cavalry *capiculy*. They are people of the court as well as of war, carrying, like aides-de-camp or adjutants, the orders of the sultan, the vizier, or other general, to the officers of the army, whether these be verbal or in writing. They escort the couriers dispatched on affairs of importance, and serve themselves when it is necessary. They are always within reach of the vizier, and assist to pass for inferior *agas*. Their chief, called *Chiaus-bassey*, is immediately about the vizier.

The cavalry *topachly* or *topachlyis*, properly speaking, that which the officers of the countries subject to the Ottoman empire support out of the revenues of the lands called *Maly-mukata*. These officers not only pay this cavalry, but also furnish them with provisions under the name of *usciur*, which exactly signifies titles.

The cavalry *ferratusly* is a militia destined to guard the frontiers. They are obliged to remain on the confines of the Ottoman empire, both to prevent incursions by the enemy and to act as escorts when wanted.

The horsemen of this corps, on the frontiers of Hungary between the Imperialists and the Turks, were the choicest and very brave men. They are commanded by one or more officers called *alaybey*, who arrive at these commands by their valour and experience in war. They are, for the most part, natives of the environs of the frontiers, that, from their knowledge of them, they may be the more expert in guarding them against inroads or incursions. Besides the Turkish they speak the Hungarian and Slavonian languages.

The cavalry *de tribut*, or tribute cavalry, is so called from its being furnished by provinces, where the people are not only tributary to, but even slaves of the empire, as they can have no particular prince to govern them, but those only who are entirely subject, in all respects, to the will of the *porte*. The government can change them, depose them, and nominate them at pleasure. These princes are moreover obliged to acknowledge the sultan as their absolute sovereign, and to do homage to him as his vassals. Bessarabia, Moldavia, and Walachia, are of this number.

Of the advantage, use, and application of cavalry.

In open, plain, extensive, and level countries, or in those that are intersected with deserts, there always have been, and ever must be, a considerable proportion of cavalry employed on all enterprizes, and on operations, both of offence and defence, on account of their singular utility and the necessity of making use of them. They are singularly useful in protecting the wings and centre of an army; for engaging in an open plain; for furnishing detachments; for escorts; for forming blockades; for intercepting supplies intended for places besieged; for foraging; for scouring a country; for procuring intelligence; for the speedy conveyance of dispatches; for harassing and fatiguing an enemy's army; for covering a retreat; &c. &c. Cavalry, indeed, is so peculiarly useful and necessary for a great variety of operations, in countries where it can act successfully, and to advantage, that it has in all ages been held by the greatest generals in high estimation. The very successful services, which troops of this description have performed, the vast number of de-

cific advantages, that have been obtained by means of them, in the most important battles, of which history, ancient and modern, furnishes the details, the unanimous testimony in their favour of authors regarded as judges of military affairs, and masters in the art of war, prove beyond the possibility of contradiction, that cavalry is not only useful, but absolutely necessary in armies. The great Turenne used to say, that it was with good cavalry that one could go moleft and harafs an enemy's army, as to ruin it by degrees. It is, however, often attended with inconveniences to have a great number of cavalry, as you cannot take the field with a numerous body of them till there is grass or green forage for the horses. The Turks, whose military force consists greatly in cavalry, on this very account, open their campaigns later than other people, and retire from the field sooner. Besides a very great number of cavalry occasions such a prodigious consumption of forage as sometimes to compel a general to quit an advantageous camp or position contrary to his inclination, or sooner than he wishes, from other considerations.

It ought also to be remembered that open and level countries only are favourable for the operations of cavalry. And they cannot be maintained but at a great expence. Accordingly in mountainous countries, and states that were but small and at the same time not very fertile, rich, or wealthy, there have generally been but few cavalry. The military force of Switzerland has for the most part consisted chiefly of infantry. In the states of Greece, if we except Theffaly, a great part of which was level, rich, and fertile, their cavalry formed but an inconsiderable proportion of their forces.

The Theffalians were dextrous horsemen, and carried the discipline and arms both offensive and defensive of their cavalry to great perfection. The other parts of Greece imitated them. And from the Greeks the Romans borrowed the arms and armour for their cavalry, who, as Polybius expressly informs us in his sixth book, were in his time armed exactly as those of the Greeks. His words on this subject are the following.

“The manner in which these troops (the Roman cavalry), are armed, is at this time the same as that of the Greeks. But anciently it was very different. For, first, they wore no armour upon their bodies; but were covered in the time of action with only an under garment. In this method they were able indeed to defend their horses, or leap up again upon them with greater quickness and facility. But as they were almost naked, they were too much exposed to danger in all close engagements. The spears also, that were in use among them in former times, were in a double respect very unfit for service. First, as they were of a slender make and always trembled in the hand, it not only was extremely difficult to direct them with exactness towards the destined mark, but very frequently even before their points had reached the enemy, the greatest part of them were shaken into pieces by the bare motion of the horses. Add to this, that these spears not being armed with iron at the lower end, were formed to strike only with the point, and when they were broken by this stroke were afterwards incapable of any farther use. Their buckler was made of the hide of an ox, and in form was not unlike to those globular dishes that are used in sacrifices. But this was also of too infirm a texture for defence. And as it was at first not very capable of service, it afterwards became wholly useless when the substance of it had been softened and relaxed by rain. The Romans therefore having observed these defects, soon changed their weapons for the armour of the Greeks. For the Grecian spear which is firm and stable, not only serves to make the first push or stroke with the point in just direction and with sure effect, but with the help of the iron at the opposite end,

may, when turned, be employed against the enemy with equal steadiness and force. In the same manner also the Grecian shields, being strong in texture and capable of being held in a fixed position, are alike serviceable both for attack and for defence. These advantages were soon perceived and the arms adopted by the cavalry. For the Romans above all other people are excellent in admitting foreign customs that are preferable to their own.” It was by using both ends of such a spear that Philipomen killed Machanidas the tyrant of Sparta at the battle of Mantinea.

The same judicious historian in his remarks on the battle of Cannæ, in which the Romans left 70,000 men on the field, observes that the Carthaginians on that occasion, as well as in the other battles they fought under Hannibal with the Romans, were chiefly indebted for the victory to the numbers of their cavalry; and that hence succeeding ages would be able clearly to perceive, that in time of war it is far more advantageous to have a great superiority of cavalry, with no more than half the infantry, than an army that is in all its parts equal to that of the enemy. In that action the Romans had eighty thousand Foot and somewhat more than six thousand Horse; and the Carthaginians had somewhat more than forty thousand infantry, including the Gauls and Spaniards, and about ten thousand cavalry.

At the battle of Trebia, Hannibal had upwards of ten thousand cavalry, the Gauls included, whereas Tiberius had only about four thousand. On the other hand Hannibal had only about 20,000 infantry, whereas Tiberius had 36,000.

In the action near the Ticinus between the Roman and Carthaginian cavalry and light infantry, Hannibal had a superior number of horse. There is a circumstance, however, that ought not to be lost sight of, namely, that Polybius, in making these observations, supposes the armies to be acting in an open country or in one favourable for the operations of cavalry. For he expressly tells us, that Publius, after his defeat near the Ticinus as the country round him was all flat and open, and the Carthaginians superior in their cavalry, marched in haste through the plains, repassed the Po, and then went and encamped near Placentia, a colony of the Romans. He also informs us, that at the battle of Trebia, the ground that lay between the Roman and Carthaginian camps, was a smooth and naked plain; but that the banks of the river were considerably high and covered with close shrubs and bushes, which suggested to Hannibal the idea of an ambushade. We likewise learn from him, that the country where the battle of Cannæ was fought, was all plain and open, and that on this very account, and the superiority of the Carthaginians in cavalry, the consul Æmilius thought it would be prudent to decline a general engagement till he could draw the enemy to some other ground where the infantry might bear the chief part in the action. For the same reason, the prudent and sagacious Fabius kept along the sides of the hills, observing the motions of the enemy, without descending into the open plains. The battle of Zama, too, was fought in an open and level country. And Scipio Africanus was chiefly indebted for the victory he there gained over Hannibal, which terminated the oblongate and long contested struggle between Rome and Carthage, for the sovereignty of the world, to his superiority in cavalry. It must therefore certainly be allowed, that a superior number of good cavalry is of prodigious moment in a country or in situations where it can act to advantage. But on the other hand it must also be allowed, that in a woody, mountainous, broken, abrupt, and uneven country, where it cannot act to advantage, it is very little useful, and least of all in an enclosed country like Great Britain, which in this respect is widely different

from the continent of Europe or indeed any other country. Any person acquainted with military manœuvres, or accustomed to reflect on them attentively, must be sensible that cavalry cannot be employed to advantage in either attacking or defending this country, and that therefore for the purposes of national defence, a very small proportion of them indeed is necessary. He must also be equally sensible, that neither the Prussian nor German tactics can be of any utility, or even be made use of in carrying on military operations in this country; and that therefore in defending it, that very constitutional, and at the same time very considerable part of our force, called the volunteers, as well as the militia, if properly employed and disposed of in the moment of invasion, should it ever arrive, will be equal, if not superior to our regular forces, particularly in their own countries. The same reasoning will extend to our numerous horse-artillery, which in most situations could, in case of invasion, be of little or no use in defending this very and singularly enclosed country, in which no operation, or even series of operations of an invading enemy can prove decisive, if we only adopt a proper mode of defence.

It was anciently the custom of the Romans to choose their cavalry as well as their infantry, and to add two hundred horsemen to every four thousand foot. But in the time of Polybius, the citizens from whom the cavalry was taken or selected were first enrolled, having been before appointed by the censors according to the rate of their revenue. And three hundred of them were assigned to every legion, which then consisted of 4200 foot. The number of the Roman cavalry then in his time bore but a small proportion to that of their infantry, being to it in the ratio of only 3 to 42 or 1 to 14, whilst the cavalry of the allies was to their infantry in the ratio of 1 to 7.

Scipio Africanus, after taking New Carthage in Spain by storm, paid great attention to his cavalry before he took the field with them, and even introduced among them a new system of evolutions, discipline, and exercise, which is described by Polybius in his tenth book, and is well deserving of the most serious attention of cavalry-officers even at this day.

The order of battle now generally adopted and practised in Europe, is to place the cavalry on the wings, and the infantry in the centre, each to be sustained or supported by itself alone, instead of arranging them in such a manner as to make them furnish mutual support and assistance to each other. The placing of the cavalry in a line with the infantry on its flanks certainly retards the motions of the whole, as no part of the line can advance unless the whole does.

Marshal Saxe in his order of battle therefore places small bodies of cavalry, not only behind his infantry in the centre of his first and second lines, but also in the reserve, at the distance of about thirty paces; and half way between his two lines of cavalry, on the wings, battalions armed with pikes and formed into squares with large intervals between them, for the free movements of the horse and for the facility of their rallying under cover of and behind these battalions in square, if broken or repulsed. He also places transversely between his two lines of infantry and nearly in the directions of right lines joining their extremities, battalions drawn up in the usual depth to flank those in square, and to cover the flanks of his infantry.

General Lloyd being decidedly of opinion, that cavalry should never appear till the moment it is brought into action, places none of it in the wings, but the whole of it in two lines behind the infantry. This last he forms in such a manner as to leave an interval of 150 yards between every two battalions. His first line of cavalry is placed in separate squadrons at a proper distance behind his infantry, and opposite to the intervals between the battalions. And his second

line of cavalry is, in like manner, placed in separate squadrons at a proper distance from and opposite to the intervals between those of the first. His flanks he covers with battalions in the rectangular form, armed with pikes, and at right angles to his line of infantry. In front of his army he has two lines of square redoubts with one angle of each towards the enemy; and in front of each of his battalions he has an epaulement, leaving however sufficient intervals for the whole to manœuvre on.

CAVAN, in *Geography*, an inland county of the province of Ulster, Ireland, situated midway between the Atlantic ocean, and the Irish sea, the extremities of the county being but 14 miles distant from either of these waters. It is bounded on the north by the county of Fermanagh; on the north-east and east by Monaghan, on the south by Meath, Westmeath, and Longford, and on the west by Leitrim. Its greatest length from east to west is 40 Irish miles (51 English); and its greatest breadth from north to south 22 miles (28 English). Its area is 470 square miles (755 English) or 321,000 acres (483,573 acres, English measure) of which about 28,000 may be ranked as mountain, bog, or water. The number of houses in 1791 was 18,133, from which we may estimate the population at about 90,000, which is 5 to a house, and much less in proportion to the number of acres than that of some other northern counties. The number of parishes, according to Dr. Beaufort, is 30, of which 26 with 24 churches are in the diocese of Kilmore, 3 in the diocese of Ardagh, and one in that of Meath. It sends only the two county members to the house of commons, the boroughs of Cavan and Belturbet having lost the privilege of being represented in consequence of the union. The face of the county is very irregular, being entirely hill and dale without any extent of level; in some places it is rocky, but excepting the mountains and water very little under actual waste. To the north and west the prospect is bleak, dreary, and much exposed, but in the other parts, especially on the banks of the Erne, it is not well sheltered and woody, but the scenery is highly picturesque and engaging. Numerous lakes of great extent and beauty adorn the interior, and, generally speaking, the features of the country are strikingly disposed for ornamental improvements. The barriers of the county on the north and west are highly marked by Sliebh-Ruffell, and the mountains of Ballynageeragh; and Bruce Hill is a striking feature in the southern extremity. The climate is cold, chilly and boisterous, but not unwholesome, and the inhabitants, inured to it, are a hardy race, remarkable for good health and longevity. The soil is not fertile, though considerably engaged in tillage; it is chiefly a stiff brown clay, over heavy yellow argillaceous substrata, and produces naturally a coarse rushy pasture. Wheat is very little cultivated, but there is great abundance of oats. The mountainous parts contain several minerals; in Quil mountain is a rich iron mine, and there are also found lead ore, manganese, coal, fullers' earth, pipe-clay, and other substances which may hereafter be turned to a good account. There are also some mineral waters, especially the sulphureous one at Swanling bar. See SWANLING-BAR.

The principal river is the Erne which crosses the county from south to north, and receives some small streams in its way to the celebrated lough of the same name in the county of Fermanagh. The lakes are numerous; some of them very extensive sheets of water, which cover several hundred acres. Many of them are dry in summer, and others considerably less than in winter. So that by proper management much land might be reclaimed, and the falls are such that a considerable supply of water might be conveyed to a canal that

that would connect Coote-hill and Cavan with Lough Erne. Such a canal, besides the conveyance of manufactures, would facilitate the carriage of lime-stone, which is much wanted for manure. The linen manufacture is carried on in this county, and the average sale of linen manufactured in it is valued at about 100,000*l.* The principal bleach-grounds are in the neighbourhood of Coote hill, and Kilskeandra. The average value of land is about 15*s.* the acre. This county was formerly called *East Meath*, and also *O'Reilly's county*, from the Irish family which possessed it. It was forfeited at the beginning of the reign of James I.; when it was divided amongst English and Scotch undertakers, servants, and natives. Some changes were made by Oliver Cromwell, but many of the allotments are at present possessed by the descendants of James's settlers. The assizes are held, and other public business transacted at the town of Cavan. Coote's Stat. Acc. of Cavan, Beaufort's Memoir, Transactions of Dublin Society, &c.

CAVAN, the assize town of the preceding county, is a poll and market town, but has no manufacture, nor is it in any way of importance. There is an endowed school with an income of eight hundred a year in lands, set in the same manner as bishops' lands, secured to it at the time of settling the county, and the presentation to which is with government. Until the act of union Cavan returned two members to parliament. Distance N.W. from Dublin 54 Irish miles. N. lat. 54°. W. long. 7° 16'.

CAVAN, a place in the county of Donegal, Ireland, near Lifford, where Mr. Mason erected a temporary observatory by appointment of the Royal Society in 1769 for the purpose of observing the transit of Venus. From a number of observations made during a residence of near eight months, he determined the longitude of this place to be 7° 23' W.; and the latitude to be 54° 51' 41" N.; and thus afforded an important datum for the construction of future maps of the county, of which Dr. Beaufort has availed himself.

CAVANA, or **CABANA**, in *Ancient Geography*, a town of Arabia Felix, according to Ptolemy.

CAVARES, or **CAVARI**, in *Ancient Geography*, a people of Gallia Narbonensis, who inhabited the bank of the Rhodanus opposite to that occupied by the Volceæ. Ptolemy assigns them the colonies of Arausio and Cabello, and some others. Strabo represents them as a very powerful people, who held in subjection several others. They possessed the districts of the towns of Orange, Avignon, Cavaillon, and Carpentras.

CAVATINA, *Ital.* cut off. This term in *Musick*, which in times of *Da Capo*, when almost every opera song had a second strain in a different key from the first, implied a short Air without a second part, is now seldom used as a section of an air, but as an entire air of short duration.

CAVATUM Sal. in the *Materia Medica*, a term used by some of the old Roman writers, as a name for the finest sort of *sil GEMMÆ*.

CAVAZATES, in *Geography*, a town of the island of Cuba; 120 miles E. of Havana.

CAVAZION, or **CAVASION**, called also **CAVING**, in *Architecture*, the underdigging, or hollowing of the earth, for the foundation of a building. Palladio lays, it ought to be the sixth part of the height of the whole building. See **FOUNDATION**.

CAUB, in *Geography*, a town of Germany, in the palatinate of the Rhine; seated on the Rhine; 20 miles S. of Coblentz, and 28 W. of Mentz.

CAUCA, a river in the illiusus of Darien, which has its source in common with La Magdalena, in the lake Papos,

near the 3th degree of S. latitude, and which falls into this last river.

CAUCA, in *Ancient Geography*, *Coca*, a town of Hither Spain, S.W. of Raoda. Appian speaking of the treatment which this place received from Lucullus, against the faith of treaties, calls the glory which the Romans derived from it "hateful glory." The emperor Theodorus was a native of this city. The Itineraries place it on the route of Segovia. According to Appian, it seems to have been situated between the Tagus and Darius. The position of the modern *Coca* is that which has been above assigned to it.

CAUCADÆ, a people of Asiatic Sarmatia, placed by Pliny near the river Lagous.

CAUCALIS, in *Botany*, (*κωνιαρι*; Theoph.) *Tourn.* Class 7. 6. gen. 2. Linn. gen. 331. Schreb. 464. Willd. 528. Juss. p. 224. Vent. vol. iii. p. 31. Gart. 94. Class and order, *pentandria monogynia*. Nat. ord. *Umbellata*, Linn. *Umbellifera*, Juss. Vent.

Gen. Ch. *Cal.* Umb-*l* universal, unequal, with very few rays; umbel partial with more rays, the exterior ones larger. Involucere universal; leaflets generally the number of the rays, undivided, lanceolate, membranous at the edge, egg-shaped, short; sometimes none. *Inv.* partial, with similar leaflets, longer than the rays, often five. *Perianth* proper, five-toothed, protruded. *Cor.* universal irregular, radiate; floriets of the disc generally abortive. *Cor. proper of the disc* male, small; petals five, inflexed-cordate, equal: of the rays, hermaphrodite; petals five, inflexed-cordate; unequal, outer one the largest, bifid. *Stam.* Filaments five, capillary; anthers small. *Pist.* Germ oblong, scabrous, inferior; styles two, awl-shaped; stigmas two, spreading, obtuse. *Peric.* Fruit ovate-oblong, longitudinally striated, hispid with rigid bristles. *Seeds* two, oblong, convex on one side, flat on the other.

Ess. Ch. Leaflets of the involucre undivided. *Corolla* radiate; flowers of the disc male. *Fruit* somewhat egg-shaped, striated, armed with rigid bristles.

Sp. 1. *C. grandiflora*, Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Gart. tab. 20. fig. 5. Lam. Illus. Pl. 192. fig. 1. Jacq. Austr. tab. 54. (C. umbellis planis; Hal. helv. 742. *C. arvensis* echinata magno flore; Bauh. pin. 152. *Tourn.* 323. *Muric. hist.* tab. 14. fig. 3. *Echinophora* flore magno; Riv. pent. 25. *E. pyenocapus*; Column. Epirh. 1. p. 91. tab. 94.) "Each involucre five-leaved; one leaf double the size of the rest." Linn. "Umbels flat; exterior petals very large; involucre of about five leaves." Lam. *Root* annual. *Stem* a foot high, channelled, branched. *Leaves* twice or thrice winged, finely cut, pale green, slightly villous. *Umbels* more than two inches in diameter, consisting of from five to eight rays. *Flowers* white; inner ones with very small petals; outer ones with a bifid petal four or five lines long; so as to make the general umbel, but not the partial ones, appear completely radiate. *Leaves of the involucre* membranous, and whitish at their edges. *Lam.* *Seeds* somewhat compressed, having four thick dotted ribs, each of which is armed with rigid, ascending, pungent spines placed somewhat alternately or in pairs; and between these three elevated furrows, furnished with small, short, bristle-shaped prickles, divaricated and incurved upwards. *Gart.* A native of corn-fields in the south of Europe, flowering in July and August. 2. *C. daucoidea*, Linn. Mant. p. 351. Syll. nat. 2. Smith Engl. Bot. 197. Jac. Flor. tab. 157. Gart. tab. 20. (*C. leptophylla*; Hudf. *Flur.* Aug. 11 Ed. but not of Linnæus. *C. parviflora*; Lam. Cnium Royeni; Linn. Sp. Pl. 550. *Echinophora*

tertia leptophyllon purpurea, tab. 97. fig. 2. Five-leaved bur-parley) (small bur-parley. "General umbels trifid, without an involucre; partial ones with about three fertile flowers, and a three-leaved involucre. *Leaves* thrice compound." *Root* annual, ip-n-le-shaped, small. *Stem* branched, zigzag, divaricated leafy, angular, a little rough at the angles. *Leaves* alternate, triply winged; leaflets pinnatifid, smooth, prickly underneath, on the nerves. *Umbels* lateral and terminal; peduncles longer than the leaves, divaricated, furrowed; general ones, of scarcely more than three rays; but sometimes with one or two more, which are smaller and barren; partial ones of about five, almost sessile flowers, of which three only perfect their seeds; petals sometimes quite white, but generally reddish, nearly equal. *Dr. Smith. Seeds* oblong, nearly semi-cylindrical, having four thick dorsal ribs which are armed with rather remote, rigid, spreading, prickles; the intervals between them slightly grooved, and sometimes beset with minute spines or hairs. *Grert.* A native of England and other parts of Europe, chiefly on a calcareous soil, flowering in June. 3. *C. latifolia*, Linn. Syst. Nat. 7. Mart. 3. Lam. 6. Willd. 3. Eng. Bot. tab. 168. Jacq. Hort. tab. 128. Grert. tab. 20. fig. 5. (Tordylium latifolium; Linn. Sp. Pl. Huds. Flor. Ang. 4th Ed.) Great bur-parley. "General umbel trifid, involucred; partial ones with five fertile flowers; leaves pinnate, serrated." *Root* annual. *Stem* three feet high, erect, branched, angular, rough with extended or ascending bristles. *Leaves* alternate, unequally pinnate; pinnae lanceolate, decurrent, opposite, acutely serrated, rather glaucous, scabrous. *Peduncles* opposite to the leaves or terminal, very long, scabrous; general rays rarely four, *Root*, angular, rough; leaves of the involucre three or four, egg-shaped, short, membranous at the edge; partial umbels of several nearly sessile flowers, flowers red, a little radiate; leaves of the partial involucre similar to those of the general one, sometimes auricled at the keel. *Fruit* egg-shaped, mucicated with purple scabrous bristles. *Dr. Smith. Seeds* two, rather large, egg-shaped, gibbous on one side, and mucicated with seven ribs; three broader and thicker, generally armed with a double series of rigid, pungent spines; the other four furnished with only a single series of spines; flattish on the other side, and marked in the middle with an elevated line, which is channelled near the base. *Grert.* A rather rare native of England, found in Hampshire, Cambridgeshire, Bedfordshire, and Derbyshire, flowering in July. 4. *C. mauritanica*, Linn. Sp. Pl. 3. Mart. 4. Lam. 9. Willd. 4. Mehr. E.N.C. 1742, vol. vi. p. 401. Walth. Hort. 127. "General involucre one-leaved; partial one three-leaved." A native of the coast of Barbary. 5. *C. maritima*, Lam. 5. Poiret itin. 2. p. 16. 2. Cav. ic. 2. tab. 101. (C. pumila; Willd. 5. Vahl. Symb. 2. p. 47. Gouan. Fl. monsp. 285. Bauh. pin. 152. Tourn. 323. *C. involucre* universal-diphyllo; Ger. Prov. 237. tab. 10. Morif. tab. 14. fig. 7. Lappula canaria; Bauh. hist. 3. p. 1. Daucus mucicatus 2. Linn. Mant. 552.) "Stem low, pubescent; segments of the leaves rather obtuse; umbels involucred; fruit egg-shaped, thick, beset with unequal yellowish prickles." Lam. It varies in the number of the leaves of the general involucre, which has occasioned a difference in authors with respect to this character. *Root* annual, simple, long, white, with few fibres. *Stems* from three to five inches long, a little cylindrical, pubescent, and almost soft to the touch. *Leaves* petiolated, villous, yellowish green, rather thick, twice winged, with small, somewhat obtuse segments. *Peduncles* long, pubescent. *Umbels* biind in the plants, described by Gouan, Gerard, and Morifon; multibind, i. e. from three to five, or even seven-leaved, in those

of Vahl, Bauhin and Tournefort. *Flowers* reddish. A native of the sea coast in the north of Europe and in Barbary. 6. *C. orientalis*, Linn. Sp. Pl. 5. Mart. 5. Lam. 10. Willd. C. Pallas It. 3. p. 522. Bellon. It. tab. 200. *C. orientalis* altissima. folio ferax; Tour. Cor. 23. "Umbels spreading, partial leaflets thrice compound, lucinated; lall divisions linear." Linn. Obs. Martyn, La Marck, and Willdenow, have all quoted this specific character without a comment; but the terms *partial leaflets* is solely obscure, if not inaccurate, referring, not as may be thought at first sight, to the leaflets of the involucre, but to the proper leaves of the plant. *Root* biennial. *Stem* two or three feet high, cylindrical, a little branched. *Leaves* twice winged, finely cut. *Umbels* terminal, loose, very large; consisting of from twelve to fifteen rays, two or three inches long; partial umbels very small, of nine or ten short rays. *General and partial involucre* very short, many leaved. *Seeds* rough with bristles terminated by a small viscid gland. A native of the East. 7. *C. capensis*, Lam. 12. (*C. africana*, Willd. 7. Thunb. prod. 49?) "Stem very low, rough; general and partial involucre generally five-leaved; fruit globular, mucicate." Lam. "Umbel trifid; partial umbels five; leaves twice pinnatifid, hairy." Thunb. *Stem* two inches high, slender, angular, zig-zag, with one or two branches. *Leaves* small, twice winged; segments linear, acute. *Umbels* terminal, of four or five rays, very rough. *Flowers* white, a little radiate. *Fruit* small, globular, beset with short points. La Marck, from a dried specimen communicated by Sonnerat. A native of the Cape of Good Hope. 8. *C. leptophylla*, Lam. 6. Willd. 8. Ger. Prov. 236. Hoff. germ. 93. (Echinophora tertia leptophyllon purpurea; Col. 1. p. 96, tab. 97.) "Leaves thrice winged, very slender; umbels generally trifid, without an involucre; little umbels three-leaved, three-seeded." Lam. "General involucre almost always none; umbels bifid; partial involucre five-leaved." Willd. *Root* annual. *Stem* from eight inches to a foot high, branched, slightly angular, a little villous on its upper part. *Leaves* more finely cut than in any other species of the genus, triangular, thrice winged; segments short and fine. *Umbels* three, sometimes four and even five-rayed. *Seeds* large, rough with long points. La Marck, from a living plant. A native of the South of France. *Dr. Smith* observes (Eng. Bot. 197) that it is not certain what plant Linnaeus originally intended by his leptophylla. 9. *C. platycarpus*, Lam. 7. Willd. 9. Gouan fl. monf. 285. Roth. Beyst. 1. p. 122. (*C. monspeliaca echinatus*, magno fructu. Bauh. pin. 153. Tourn. 323. Morif. hist. 3. tab. 14. fig. 2. Echinopora alata asperior platycarpus, Col. Eeprh. 1. tab. 64.) "Umbel trifid; general and partial umbels three-leaved." *Root* annual. *Stem* a foot and half high, a little branched, angular, beset with a few scattered hairs. *Leaves* large, green, twice winged. *Peduncles* very long. *Umbel* very short, rarely of four rays; one of the leaves of the involucre sometimes gashed; partial umbels with from seven to ten flowers, of which seldom more than two are fertile. *Fruit* large, oval, slightly compressed; rough, with long, unequal, purpleish points. Lam. A native of Italy and the south of France. According to La Marck Linnaeus confounded this plant with Daucus mucicatus. 10. *C. infesta*, Curtis Flor. Lond. fasc. 6. tab. 23. Smith Flor. Brit. 4. Eng. Bot. pl. 1314. Relh. Flor. Cant. 108. (*C. arvensis*, Willd. 10. Hudson. Withering, Holl. Sibthorp, Abbott, Lightfoot. C. helvetica, Jacq. hort. Viad. vol. iii. tab. 16. *C. fegetum* minor, Anthriscus hispido similis, Rai. Syn. 220. *Scandix* infesta, Linn. Svf. nat. ed. 12. Herb. Linn.) spreading hedge-parley. "Umbels of many close rays. General involucre almost always

none. Leaflets pinnatifid. Branches spreading." Smith. Root annual, tapering, white. Stem about a foot and a half high, erect, leafy, round, furrowed, rough, divided into numerous alternate, divaricating branches; terminal leaflet elongated. Leaves alternate, rough, pinnate, deeply cut, and sometimes almost bipinnate. Umbels terminal, erect; general umbel sometimes of one leaf; partial ones of several sharp rough leaves. Flowers somewhat radiate, white, or cream-coloured, rarely flesh-coloured; anthers yellow, sometimes purplish. Fruit rather large, ovate, rough, green or reddish, but not tipped with purple. A native of fields and way-sides in England, Germany, Switzerland and France; flowering in July. Nearly allied to the next species. 11. *C. anthrificus*, Mart. 8. Willd. 11. Curt. Lond. Fasc. 6. tab. 22. Fl. Dan. tab. 919. (*C. aspera*, Lam. 2. *Tordylium anthrificus*, Linn. Sp. Pl. Jacq. Aust. tab. 261.) Upright hedge-parsley. "Umbels of many close rays. Involucres of many leaves. Leaflets pinnatifid. Branches rather erect." Smith. Root annual, tapering, yellowish. Stem almost three feet high, erect, leafy, furrowed, rough, with closely deflexed hair; branches alternate. Leaves alternate, scabrous; terminal leaflet elongated; common petiole dilated, channelled. Umbels terminal, erect; involucre of many awl-shaped, scabrous leaflets, much flatter than the ray; partial umbels clustered, flat; partial involucre about the length of the pedicels. Flowers white or reddish, small, but little radiate; anthers violet-coloured; styles divaricate, reflexed. Fruit egg-shaped, larger than that of the preceding species, armed with incurved bristles, violet at the tip. A native of England, and other parts of Europe, in hedges and waste places; flowering in July. 12. *C. japonica*, Willd. 12. "Involucres many-leaved: seeds egg-shaped; leaves twice compound; leaflets wedge-shaped, pinnatifid; stem hairy." A native of Japan. 13. *C. hispanica*, Lam. 11. Hebr. Inard. & Vaill. MSS. "Umbels compound, sessile, lateral; leaves thrice-winged, finely divided, whorled at the flower bearing knots." Stem scarcely a foot high. Leaves petioled, three together in a whorl, occupying the place of the general involucre. Umbels generally of five rays, two of which are so short that the partial umbels appear sessile; partial involucre two or three, generally simple, but sometimes resembling the leaves of the plant. 14. *C. nodiflora*, Mart. 9. Willd. 13. Rai. Syn. 220. Hudf. Fl. Ang. 114. Eng. Bot. tab. 199. (*C. nodiflora*, Lam. 3. *Tordylium nodiflorum*; Linn. Sp. Pl. Jacq. Aust. app. tab. 24.) Knotted stone or bastard parsley. "Umbels lateral, simple, nearly sessile; stems prostrate." Root annual, small. Stems branched, leafy, striated, roughish with reflexed hairs. Leaves somewhat glaucous, twice-winged; pinnules pinnatifid and gathered. Umbels opposite the leaves, solitary. Flowers white, or reddish, small, clustered, on short peduncles, surrounded by the linear hairy leaflets of the involucre. Seeds small; outer ones mucicated with longish, straight, rough, rigid hairs; inner ones rough with warty points. Whether the latter are abortive has not yet been determined. Dr. Smith. A native of England and the south of Europe on the borders of corn fields, and on banks; flowering from May to August.

CAUCALIS carota, Roth. See *DAUCUS Carota*.

CAUCALIS major dawcoides tingitana, Morif. Ray. See *DAUCUS muricatus*.

CAUCALIS funicula, Crantz. Roth. See *SANICULA*.

CAUCALIS scandix, Scop. - Scandicina, Withering Flor. Dan. See *SCANDIX anthrificus*.

CAUCALIS pergrina, Bauh. pin. See *TORDYLIUM pergrinum*.

CAUCALIS maxima, Bauh. pin. See *TORDYLIUM maximum*.

CAUCANA, in *Ancient Geography*, a port of Sicily, mentioned by Ptolemy, and placed 200 *stadia* from Syracuse.

CAUCANTHUS, in *Botany*, Lam. Encyc. Bosc. Nouv. Dict. Forstak. Clafs and order, *decandria trigynia*.

Gen. Ch. Cal. one-leaved, bell-shaped, five-cleft. Cor. Petals five, six times larger than the calyx, ciliated and curled on one side. Stam. Filaments ten. Pist. Germ superior, oval, villous; stigmas truncated.

There is only one known species. A shrub. Leaves clustered at the top of the branches, opposite, orbicular, entire. Flowers white, in terminal corymbs. A native of Arabia on the mountains.

CAUCASUS, in *Ancient Geography*, the name of the highest and most extensive range of mountains in the northern part of Asia; and which the ancients erroneously considered as a continuation of mount Taurus. See *Taurus*. According to Strabo (tom. ii. p. 766) this mountain extended from the Euxine to the Caspian sea, including, as within a wall, the isthmus that separated these seas. It divided Albania and Iberia towards the south from the level country of the Sarmatæ on the north; and abounded with various kinds of trees, some of which were used in the construction of ships. According to Herodotus (lib. I. and III.) it commenced above the territory of Colchis, and bounded the northern part of the Caspian sea. Procopius says, that the eastern limit of this mountain had two defiles, one of which was called the "Caspian way," and the other the "Caucasian way." These defiles served as a passage to the Huns when they invaded the territories of the Persians and Romans. Pliny says, that Seleucus Nicator had formed a project of joining the Euxine and Caspian seas by a wall; and it is also said that Antiochus Soter or Antiochus Theus executed Nicator's project. This wall sunk into ruin after the fall of the Selucidæ. Herodotus mentions the two passages in this mountain; and he says that the Scythians and Cimmerians made use of them in their incursions into Upper and Minor Asia. They are also mentioned by Pliny, Tacitus, and Lucan. The ancient mythologists report that Prometheus was bound on this mountain for having stolen fire from heaven, and that Hercules came hither to release him; and it is reported by some historians, among whom is Strabo, that the rivers of this mountain brought down gold sand, which was collected in sheep-skins. The inhabitants of this mountainous region were very numerous, and formed, as some say, 70, and according to others 300, different nations, who spoke various languages, and subsisted upon the flesh of wild beasts, fruit, and milk, having, on account of their uncultivated and savage manners, no intercourse with one another. The appellation of Caucasus is supposed to have been transmitted to the Greeks by their intercourse with the Persians, in whose language *cau* or *cob* signifies a mountain; whence, it is said, was formed *Cob-cau*, or the mountain of the Chafas, an ancient and formidable tribe, who inhabited this immense range from the eastern limits of India, to the confines of Persia, and probably as far as the Euxine and Mediterranean seas. Captain Wilford informs us (*Asiatic Researches*, vol. vi. p. 455) that the Chafas are often mentioned in the sacred books of the Hindoos. Their descendants still inhabit the same regions, and are called to this day by the same name. They belonged to the class of warriors, but they are now considered as the lowest of the four classes; having been thus degraded, according to the institutes of Menu, by their omission of the holy rites, and by seeing no Brahmins. Isidorus (Orig. l. 14. c. 28.) says, that Caucasus, in the eastern languages, signifies *white*; and that a mountain close to it is called *Casus* by the Scythians, in which language it signifies snow and whiteness.

The Caucasus mountains have been well delineated by Russian travellers, and represent them as forming a range from the mouth of the river Kuban to the north-west to the outlet of the river Kur, into the Caspian sea, to the south-east. A chain probably extends from Caucasus south-west to the vicinity of the bay of Scanderoun. This ridge seems to have been the Attitatus of antiquity, various parts of which have been known by different names. At the other extremity of the Caucasus other chains branch out into Persia, which they pervade from north-west to south-east; but terminating in the deserts of the south-eastern part of Persia, or at least, formingly connected with the mountains of Hindoo-Kush, that it would be difficult to trace any continued chain. Much less can they be regarded as an extension of Mount Taurus, which terminates at the Tophrates and deserts of Algeria. The Caucasian mountains, as far as they have yet been explored on the Russian side, are an alpine range, extending between the Euxine and the Caspian, from west to east, in length about 750 English miles, and towards the north and south in a level country all around. As they approach both the seas, they very much decline. The whole range has a tract of about 5 miles in breadth, at the greatest elevation of the chain, which is covered with perpetual ice. Its breadth on the northern declivity extends at most to 50 miles, and runs along the prodigious northern plain, which, taken in the quadrature, measures one thousand English miles; being bounded on the east by the Sinenan, and on the west by the Vakhshan mountains. The Marshal Von Biberstein, who remained in these regions a considerable time, and took pains in investigating them, states the extent of the Caucasus, in length, from its western extremity at Gh. Kae to Taghuz, 65 German miles, and in breadth, on the side adjoining the Caspian sea, 55; in the middle, where the river Perak to the north and Arakel to the south form a division between the eastern and western halves; and in the western part, along the Porta Cumana, a contracted narrow pass, 150 miles. The icy ridges of the Caucasus, as well as the others, at their highest points, consist usually of granite; the sides being towards the next mountains, of all kinds of slate, and the outward sides of lime-stones, &c. The alpine chain, formed by the highest side, covered with snow or ice, and exhibiting, in some open fissures bald rock without earth, plants, or trees, seemed to Goldsmith not more than from 5 to 7 versts in breadth. The two sides which compose the main mountain, measured from south to north, or right across, on an average, 70 versts; and the north side is visibly 10 per or higher than the southern, as it declines in a far narrower or smaller breadth, or rather only sinks down towards one part. The lime-stone mountain runs in a flat clayey field of 20 miles in breadth, gradually declining, till it ends in a promontory to miles broad, which consists almost wholly of sand-stone; and this again runs out afresh in a level plain about 8 miles broad, in which numerous sand-stones are scattered. In this plain common salt and natron abound; and in the promontory are iron-stone, sulphur-pyrite, volcanic pyrotrons, and warm sulphurous springs: some purifications are also found here, chiefly in bit. Specimens of lead and copper rarely occur in the promontory, but frequently in the higher mountains. The slate contains alum. As to what regards the quality of the superior regions of the Caucasian ridges, it is remarked that the river Hippas in Iberia bears gold; that the mountains in that region are very rich in minerals; and that the gold mines at Cumana were wrought by the Romans; that the mountains on the Kura, and especially in the district of Azerbaidjan, likewise contain very rich ores; that in the plains of that river are found flint-marble, coal, and warm springs;

that in the mountains by the Terek, as far as the village Stepheantz-mis, there is lead, silver, and iron ore; in the Georgian province Som-heta, rich silver and iron ore, marble, and jasper; in the circle of Qoucho, copper-ore; in the principality of Toubiut, rich lead, silver, and gold mines; in the principality of Lori, considerable copper-mines, and gold-mines; in the principality of Utaour, rich copper-mines; in the parts about Asdax, gold, silver, and copper; and in the province of Albanie, marble and alabaster, iron, warm baths, pyrotrons, and quick-silver. From this detail it appears, that the Caucasian chain of mountains is, in its highest point, covered with ice-mounts; that it has its highest, high, middle, and low mountains or promontories, the ridges nearest to the level of the plain; that its sides are very rich in minerals; and, probably, in those parts which are now added to the Russian empire, contain a treasure of the precious metals. Its eminence, on the whole, is considerably and many of the rocky parts very steep and prominent. In many of its extremely fertile valleys, it is furnished with valuable woods, consisting of excellent forest trees of various kinds. On the Russian side of these mountains the rivers Terek, Kuban, Kouma, and a number of smaller streams take their rise. We may therefore conclude, says Guldenstadt, that mining might be begun and carried on in the northern Caucasus to great advantage, especially for Russia; provided that care be first taken to establish strong and well-garrisoned posts for the protection of the miners against the ravages of the uncivilized tribes that inhabit the mountains, till they have attained to a greater degree of civilization, and till they themselves manifest an inclination for mining.

The mountainous regions have been, from time immemorial, and still are, the habitation of bold and valiant warriors, who have with determined resolution repelled the reiterated attacks of the Mongols, Arabs, Persians, Tartars, and Russians, and maintained, in a considerable degree, their freedom and independence. On the ridge of Caucasus, and in the elevated and almost inaccessible valleys, there is found a most singular mixture of small people of various denominations, whose origin and different languages it is extremely difficult to explore. Their distinct and appropriate languages are very numerous, and branch out into an incredible diversity of dialects; some of which deviate so entirely from the known languages of Asia and Europe, that they admit of no comparison with them; others again are known languages without any foreign admixture; and others are a mixture of several known ancient languages, to which class belong the old Georgian, Mongolian, Persian, Arabic, and Tartarian languages.

The various tribes of mount Caucasus consist of a motley mixture of the original inhabitants with colonies of their conquerors, the Mongols and Tartars, particularly the latter; and on account of the difficulty of reducing them to their primitive stocks, they are usually all comprised, the Georgians excepted, under the denomination of "Mountain-Tartars." Several of these tribes are properly Russian subjects; others are vassals; and others again are protected by Persia and the Porte, or have hitherto maintained their independence. Among the inhabitants of the northern half of Caucasus, we find, besides the Nogasans and Truchmenians, who are genuine Tartars, three particularly numerous and nearly related tribes, composing the ground plot of most of the Caucasian nations; viz. the "Tcherkessians" (see CIRCASSIANS), "Auchasians" (see AUCHASSIS), and "Zichians" or "Tichkians, called by the Russians Yasi, and principally inhabiting the site of Tamen, which see. Under the former appellation of Tcherkessians are often comprised not only the other two items just mentioned, but even several

petty tribes of Caucasus, as the Tschetschengians, the Kiffenzians, &c. The people properly bearing this name inhabit that part of Caucasus which is called the Great and the Little Kabardia, the islands of the lower Kuban or Cuban, and the northern bank of that river. They denominate themselves Adige, i. e. islanders; by the Russians they are called Tscherkessii, and by the rest of Europe Circassians. The other two tribes are, properly speaking, only one collateral branch of the former, and have belonged to the Russian empire, as inhabitants of the Cuban or Caucasus, since the year 1783. The following tribes are as yet only vassals to Russia; viz. the "Kumyks," who inhabit the plain bordering on the rivers Sunsha and Terk, and in whose territory are the famous hot-baths of Kitzlar. See КОМЕР.—The "Tschetschengians" or Mikschengians, who live in the eastern part of the Great Kabardia, and in time of war can raise 5000 horsemen.—The "Killenzians," who inhabit the Little Kabardia and whose force is nearly equal to that of the preceding people.—The "Osetinzians" or Olfes, probably sprung from the ancient Uzes or Polovtzes, and found in the middle part of the Caucasian mountains. They consist of several small stems, who are either governed by myrzas, or live under one common prince, who is a vassal of the Russian empire. The other Caucasian tribes have little or no connection with Russia; and the most remarkable are the "Lefghians," who inhabit the province of Lefghistan in the eastern Caucasus, between Kakhetty and Daghestan. They are divided into 27 stems, and are totally independent.—The "Taulintzians," who occupy the summits of the mountains, consist of several petty tribes, and acknowledge the protection of Persia.—The "Amberlinians" dwell in the vallies formed by the mountains of Ghilan, and often change their patron-sovereign, but are at present under the Persian monarch.—The "Georgians" or Grusinians are the most numerous and powerful body of the mountaineers of Caucasus. See GEORGIA. Tooke's View of the Russian Empire, vol. i.

CAUCASUS, in *Ancient Geography*, a sea-port of the island of Chios, mentioned by Herodotus, lib. v. c. 3.

CAUCASUS, *province*, in *Geography*, one of the governments of Russia, in the southern region, which comprises the Cuban, and all that district to the east and south now in the possession of Russia, between the rivers Don and Cuban, and between the Caspian and Euxine, extending as far as the confines of Georgia, and continually augmenting by the reduction and submission of the wandering hordes of mount Caucasus. By the treaty concluded between Catharine II. of Russia and the Ottoman Porte, June 21, 1783, authenticated by the seal of government, Jan. 6th, 1784, the provinces of the Crimea and the Cuban, to which the emperors gave the ancient names of Taurida and Caucasus, were annexed to the Russian dominions.

CAUCHABENE, in *Ancient Geography*, a people of Arabia Deserta, according to Ptolemy.

CAUCHUMILLI, in *Geography*, a small island belonging to the Turks, in the Mediterranean; 20 miles S.W. of Stanchio. N. lat. 36° 30'. E. long. 26° 24'.

CAUCHI, in *Ancient Geography*. See CHAUCHI. An ancient people of Ireland under this denomination, according to Ptolemy, are supposed by Camden to have inhabited the present county of Wicklow; and they are said by Mr. Ledwich to have come, with the Menapii, direct from Germany to Ireland.

CAUCHI Nummi, a base sort of coin, current under the lower empire; thus called because concave, like a little cup, from the barbarous Latin, *caucus*, a cup. Haloander and Meursius are mistaken in saying this coin was so called from

having the figure of a cup on it. Du-Cange. The cauci are the same with what are popularly called among the Italians, *medaglie di S. Elena*, sometimes superstitiously worn by the women.

CAUCOLIBERUM, in *Ancient Geography*, a name given about the 7th century to a town of Gaul, now Collioure.

CAUCON, in *Botany*, a name used by Pliny, and some other authors, for the *cyphium*, or horse-tail.

CAUCON, in *Ancient Geography*, a river of Greece in the Peloponnesus, which passed by Dyma, and discharged itself into the Teutheas, according to Strabo.—Also, a maritime place of Sicily, 200 stadia from Syracuse; called Caucana by Ptolemy.

CAUCONES, an ancient people of Paphlagonia, who inhabited the coast of the Euxine Sea from the Mariandynians to the river Parthenius, according to Strabo; but in other times this space was comprised in Bithynia. Some authors pretend that they were driven from Arcadia together with the Pelagi, and that they had been wanderers like them. Others say, that they were Scythians; and others say, that they were Macedonians. One part of this nation settled in Greece near Dyma, in the district of Lepusium and the Lower Elide. Another part occupied the territory of the Lepreates and Cyparissians, and the town of Macitia in Triphylia. Herodotus speaks of these last; (lib. i. c. 147.) and gives them the name of Pylans to distinguish them from those of the Lower Elide near Dyma. Homer mentions the Caucones; who were Paphlagonians, and who came to the succour of Troy.

CAUCUS, in *Ichthyology*, a species of carp about eighteen inches in length, that inhabits the fresh waters of Chili. Molina describes it in his natural history of that country, as having thirteen rays in the anal fin; the body tubercle, and slightly tinged with silvery. See CYPRINUS CAUCUS.

CAUDA, in a general sense. See TAIL.

CAUDA is sometimes also used in *Anatomy* to denote the CLITORIS.

CAUDA Lovis, in *Ancient Geography*, a promontory of the island of Cyprus, so called by Ptolemy, and placed by M. d'Anville at Boos Ura to the south west.

CAUDA Capricorni, in *Astronomy*, a fixed star of the fourth magnitude, in the tail of Capricorn, called also by the Arabs, *Dineb Algeld*; marked γ by Bayer.

CAUDA Ceti, a fixed star of the third magnitude; called also by the Arabs, *Dineb Kætos*; marked β by Bayer.

CAUDA Cygni, a fixed star of the second magnitude in the Swan's tail; called by the Arabs, *Dineb Algege*, or *Ed-gigich*, marked α by Bayer.

CAUDA Dolphinæ, a fixed star of the third magnitude in the tail of the Dolphin; marked ϵ by Bayer.

CAUDA Draconis, the Dragon's tail, the name of the moon's southern or descending node.

CAUDA Equina, in *Anatomy*, a name applied to that portion of the medulla spinalis, which is contained in the lumbar vertebra; and the canal of the sacrum. For a description of this, with the rest of the spinal marrow, see BRAIN.

CAUDA Equina also denotes a medicinal herb, whose leaves are reputed to have a strengthening virtue. This, in *Linneus*, is called the *horse-tail*. The official kind is more particularly called by botanists *equisetum majus*, in English, the great marsh-horse-tail.

CAUDA Leonis, in *Astronomy*, a fixed star of the first magnitude in the Lion's tail; called also by the Arabs, *Dineb El-ceed*, and marked δ by Bayer. It is called also *Lucida Coma*.

CAUDA Urse Majoris, a fixed star of the third magnitude,

in the extreme part of the tail of the Great Bear; called also by the Arabs, *Alaliob* and *Benenath*, and marked α by Bayer.

CAUDA *Urse Minoris*, a fixed star of the third magnitude, in the extreme part of the tail of the Lesser Bear; called also the polar star, and by the Arabs, *Ahrubabah*, marked α by Bayer.

CAUDAMATRIS, in *Geography*, a town of the island of Ceylon; 64 miles N.W. of Candy.

CAUDAR, a river of Spain, which runs into the Xucar a little above Cuenca.

CAUDATUM, in *Conchology*, a species of *Buccinum* with an ovate shell furnished with roundish ribs; the beaks a little prominent. Knorr, &c.

This shell is fuscous, umbilicated, with a large aperture, the lip of which is plaited and toothed within; spire with six short inflated whorls. The length is three fourths of an inch; very thin, of a straw colour, brownish in the ribs, with five horizontal lines in the whorls of the spire.

CAUDATUS, *Lat.* in *Music*, a musical note with a tail to it; as a minim to distinguish it from a semibreve, which is round. In the early period of counterpoint, a tail added to a note made it of double its natural length; as a tail to a breve made it a long \square \square . See the ancient time table.

CAUDEBEC, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton in the district of Yvetot; seated on the Seine, surrounded with walls flanked with towers; a town, though not large, populous and commercial; 5 leagues W. of Rouen, and 8 E. of Havre. The place contains 2800 and the canton 13,624 inhabitants; the territory comprehends 210 kilometres and 18 communes. N. lat. $49^{\circ} 33'$. E. long. $0^{\circ} 37'$.

CAUDEBEC, in *Manufactures and Commerce*, a sort of hats, thus called from the town of Caudabee above mentioned, where they manufacture a great number of them. They are made of lamb's wool, of the hair or down of ostriches, or of camel's hair.

CAUDEC, in *Ornithology*, the name given by Buffon in his natural history of birds to the Gmelinian *muscipa audax*, and yellow crowned fly-catcher of Latham. Buffon in another work, Pl. enl., calls it gobmouche tachete de Cayenne.

CAUDECOSTE, in *Geography*, a town of France, in the department of the Lot and Garonne, and district of Agen; $2\frac{1}{2}$ leagues S.E. of Agen.

CAUELLENSESIS, in *Antient Geography*, a people of Gallia Narbonensis, S. of the Vaugientes. They were the ancient inhabitants of Caduet, where has been found an inscription that adorned the front of a small temple or sacellum, built near the place and dedicated to the goddesses Dexiva. Many medals of silver, and other curiosities, have been dug up at the same place.

CAUDEX, in *Botany*, is considered by Linnæus as one part of the root of plants, of which the radicle is the other. It is divided by him into the caudex descendens, and the caudex ascendens. The caudex descendens is the stock or main body of the root, gradually sinking downwards into the ground, and producing the radicles which extract the nourishment from the earth, and are the only essential part of the root; for annual plants have most frequently no descending caudex. The caudex ascendens is a continuation of the same stock gradually rising above the ground, and producing the proper herb of the plant, or the branches and leaves with their various appendages. There are many

plants, both annual and biennial, in which it is not found. In trees it is usually titled the trunk; in shrubs the canis or stem; and as it has never been admitted into the popular idea of a root, it is nearly fallen into disuse. Indeed it was never much employed by Linnæus himself in his practical works.

CAUDEX, in *Gardening*, a term, which, by some early writers on vegetation, signifies the stem or trunk of a tree; but according to the later ones the stock or body of the root, part of which ascends and part descends. It has been observed by Dr Darwin on the authority of Linnæus, that the part which joins together the plumula, or leaf, and the radicle, or root-fibres, is called the caudex, when applied to entire plants; and may, therefore, be termed *caudex gemme*, when applied to buds. In herbaceous plants, the caudex is generally a broad, flat, circular plate, from which the leaf-stem ascends into the air, and the radicles or root-fibres descend into the earth. Thus the caudex of a plant of wheat lies between the stem and the radicles, at the basis of the lowermost leaf, and occasionally produces new stems and new radicles from its sides. Thus the caudex of the tulip lies beneath the principal bulb, and generates new smaller bulbs in the bosom of each bulb-leaf, besides one principal or central bulb; the caudex of orchis, and of some ranunculuses lies above their bulbous roots; whereas the caudexes of the buds of trees constitute the longitudinal filaments of the bark, reaching from the plumula or apex of the bud on the branch to the base of it, or its root-fibres beneath the soil. Nor, continues he, is this elongation of the caudexes of the buds of trees unanalogous to what happens to some herbaceous plants; as in wheat, where the grain is buried two or three inches beneath the soil, an elongation of the caudex occurs almost up to the surface, where another set of fibrous roots is protruded, and the upright stem commences. The same happens to tulip-roots when planted too deep in the earth, as he has witnessed, and, as he supposes, to those of many other vegetables.

He is also of opinion, that the caudex of the buds of trees not only descends, as above described, but also ascends from each bud to that above it; as on the long shoots of vines, willows, and briers, in this respect resembling the wires of strawberries and other creeping plants. Thus the caudex of perennial herbaceous plants consists of a broad plate, buried beneath the soil to protect it from the frost; while the caudex of buds of trees consists of a long vascular cord, extending from the bud on the branch to the radicle beneath the earth, and endures the winter frosts without injury. The long caudexes of the individual buds of trees, which constitute their bark, are, he says, well seen in the cloth made from the mulberry bark brought from Otahite. On inspecting this cloth the long fibres are seen in some places to adhere, where it is probable they occasionally insensate, like some of the vessels in animal bodies; because, when some buds are cut off, the neighbouring ones flourish with greater vigour, being supplied with more of the nutritious juices. This informs us, he says, why the upper bark of a tree grows downwards with so much greater expedition than the under one grows upwards to meet it: as the descending caudexes of the individual buds are supplied directly with nutriment from the vegetable arteries, after the oxygenation of the blood (sap) in their leaves; whereas the under lip of the wound is nourished only by the lateral or insensating vessels; which, he thinks, supplies us with an argument against the individuality of trees, and in favour of that of buds. See BUD.

CAUDI-CAPONES, in *Ancient Geography*, a place of Italy, mentioned by Horace.

CAUDIES, in *Geography*, a town of France, in the department of the East Pyrenes, and district of Perpignan; 9 leagues W. N. W. of Perpignan.

CAUDIMANE, in *Zoology*. Some French naturalists discriminate by this name those animals which have the tail flexible, muscular, and prehensile, such as the Sapajou tribe of monkeys, &c.

CAUDINÆ *saucæ*, or *surcule*, in *Ancient Geography*, a defile by which the Romans, after a defeat, were obliged to pass from Campania into Samnium, in 432, and where they preserved their lives under the humiliating condition of passing under the jugum or yoke.

CAUDISONA *Vipera*, in *Zoology*, a name by which authors call the RATTLE-SNAKE.

CAUDIVERBERA *Peruviana*, the name given by Laurenti to the Gmelinian LACERTA *caudiverbera*, which feeds.

CAUDIVERBERA *Egyptiaca*, Laur. is variety β of the same species.

CAUDIUM, in *Ancient Geography*, a small town of Italy, in Samnium, belonging to the Hirpini, on the route from Capua to Benevento.

CAUDO, an island of the Mediterranean, in the neighbourhood of that of Crete. *Suidas*.

CAUDROT, in *Geography*, a town of France, in the department of the Gironde, and district of La Reole, seated on the Garonne; 5 miles W. of La Reole.

CAVE, a subterraneous hollow place of a certain extent. Some authors distinguish between a *cave* and a *cavern*, making the first the effect of art, and the latter of nature. Caves were doubtless the primitive habitations; before men brought themselves to erect edifices above ground, they took shelter under it. The primitive manner of BURIAL, was also to repose bodies in *caves*, which appears to have been the origin of the catacombs. *Phil. Transf. N^o 244. p. 344.*

Badmington cave, in Wiltshire, consists of a series or row of uniform holes, wherein pieces of armour are said to have been found, whence they are by many supposed to have been tombs of ancient warriors.

Caves long continued the proper habitations of shepherds. Among the Romans, *caves, antra*, used to be consecrated to the nymphs, who were worshipped in caves, as other gods in the temples.

The Persians also worshipped their god Mithras in a natural cave, consecrated for the purpose by Zoroaster.

Kircher, after Cassarellus, enumerates divers species of caves, divine, human, brutal, natural, and artificial.

Of natural caves, some are possessed of a medicinal virtue, as the *Grotto de Serpente*; others are poisonous or medicinal; and others are replete with metalline exhalations, and others with waters.

Divers oracular caves occur among the ancients, the fumes of which intoxicated the head, and produced a sort of furor or madness, which was interpreted inspiration, prophecy, and divination. Such were the sacred caverns at Delphi, which inspired the Pythia. Such also was the Sybil's cave at Cumæ in Campania, still shewn near the lake Avernus: though Borrichius takes this to be of modern date, and not the true *Antrum Sibyllæ*, so finely described by Virgil. Homer likewise gives a description of *Αἰγῶν Νυφῶν*, the *Cave of the Nymphs*, on which Porphyry has a treatise still extant, containing many of the secrets of the heathen theology, both natural and symbolical. *Virg. Æn. lib. vi. Hom. Odyss. lib. xiii.*

The cave of the nymph Egeria, where Numa held nightly conversations with that deity, is still shewn at Rome.

The cave of Triphonius, originally the mansion of that celebrated Bœotian, became afterwards famous for the ora-

cles which Apollo delivered in it. Pausanias, who visited it, gives a large description of the ceremonies observed by those who entered the cave to consult that god. *Vide Potter Arch. lib. ii. cap. 10. p. 299, &c.*

CAVE, in *Agriculture*, is a term provincially employed to signify the raking off any coarse material, such as the short straws and ears of grain, from the corn in chaff on the barn-floor during the time of threshing, &c.

CAVE, CARVE, or COLT, is a term used for earth that slips down from the banks of canals, &c.

CAVE, *dead, live*, in *Mining*. *See LIVE cave.*

CAVE-Hill, in *Geography*, one of the hills in the county of Antrim, Ireland, near the town of Belfast. It is found to be 1197 feet high.

CAVEA, the place in the ancient theatres where the spectators were seated. The *cavea*, called by the Greeks *κωδον*, stands contradistinguished from the *scenæ frons*, which was the place for the actors. The *cavea* was divided by partitions into three equal parts, rising one over another: *ima cavea*, appointed for the people of quality, and magistrates; the middlemost, *media cavea*, for the commonalty; and the uppermost, *summa cavea*, for the women.

As the theatres were open at top, porticos were erected behind the *cavea*, where the audience might retire for shelter in case of rain.

CAVEA also denoted the middle part in amphitheatres, otherwise called ARENA.

CAVEA was also used for the cage or den of a wild beast, kept for the amphitheatrical shows. *See CAGE.*

CAVEAR, CAVIAR, or KAVIAR, a kind of food or pickle, in great use, and repute throughout Russia: and also introduced upon the English table.

It is formed from the Italian *caviare*, or barbarous Greek *καβίρα*, which signifies the same.

The *cavear* or *caviar*, called by the Russians *ikra*, is an article of great importance in its reference to the industry and commerce, as well as to the palates of the Russians, who derive great advantages from it, not merely as an article of trade, but also of diet, particularly during the three lentils which they observe with great strictness. It is prepared in the parts about the Volga, the Ural, and the Caspian, of the roes of sturgeons, sterlets, fevrugas, and sitras. The lump of roe is the first thing taken out after cutting up the fish. A large beluga will yield above 5 pood of roe; but this, on account of the quantity of viscous matter that is mixed with it, is not much esteemed. From a sturgeon never more than 30 pounds has been taken, and from the fevruga only 10 or 12. As of the beluga roe five eggs weigh a grain, for a large beluga has 6 or 7 millions of eggs. The different treatment of the roe determines the different quality of the *cavear*. The worst sort is the common "pressed *cavear*," "paysunia *ikra*." In the preparation of this the roes are cleaned from the coarsest strings and fibres, then salted with about two pounds of salt to the pood, and spread out upon mats in the sun to dry, which in fair weather requires about six hours, and in cloudy weather, at most, a day. It is afterwards trodden with the feet, the person who treads it having leathern stockings. It is then put into tubs. To make this sort for sale, it is common to take the spoiled roes of dead fish thrown upon the shore, or such as are too greasy for other sorts, and even the fragments and offals that would not pass through the sieve of the finer kind, salt it in boxes, and then tread it down in tight tubs. Such *cavear* costs in Astrakhan half a ruble per pood. A better sort is that called the "grained or seasoned *cavear*," "Sernulua *ikra*," but this is too salt to suit every palate. When the roe is cleaned from the coarser particles, it is shaken into long troughs, salted with 8 or 10 pounds to the pood;

preparation, by stewing it over and over, well mixed. It is now brought to the sieve or stratched network, through which it is strained, and is order completely to separate the remaining solid part; then, like the former, it is pressed in the press, and comes out between one and two rubles; and this is the usual food of the common people during the winter, and is common to the religion of the country; but it is not fit for every one's taste. The clearest and best is that the "falk-cavar," which, to appearance, consists entirely of the eggs of the roes, and does not easily become fetid; it is distinguished from its preparation "mefchik-mafikra." After being cleaned, it is dipped in strong brine, till the grains are quite fit. It is then hung upon long narrow pointed bags of strong linen, resembling jelly bags, which are half filled, about half a pound in each, with fresh roes, and filled to the top by pouring in the brine. When the brine has stood through, the bags, hanging on tow-ropes poles, are powerfully wrung with the hands, one after another, till the moisture is wholly discharged; and after the roes have been left to dry for 10 or 12 hours in the sun, they are put into small casks or tubs, and trodden down by a labourer in leather stockings. This sort requires the roes to be quite fresh, and is the dearest, costing two rubles per pood, and upwards. In winter the roes are fresh, and deemed a great dainty. In general, the brine used for cavar is, the less salt the better; but of course it will keep the less time. In winter large quantities of dried cavar are sent from the Volga to all parts. The method here used is salting the roes by putting them, after being well cleaned and washed, into casks with a number of holes in the bottom; through which they are fit to draw by weights laid at top, or are wrung in linen bags, then pressed in casks, with fish-fat poured over the surface, in order to keep it as much as possible from corruption. The cavar is prepared in like manner, in the other parts of the empire, where they have fish proper for the purpose. Among these are reckoned the white salmon and the pike, from the roes of which a reddish kind of cavar, "kuznitskita," is prepared. The best cavar, as well as the best strogilas, is obtained from the river Ural, where the Cossacks have the best method of preparing them. Formerly the trade in cavar was a monopoly of the crown; and in the time of Peter I. the contract brought him 80,000 rubles; and in the middle of the 18th century 100,000. At present it is free. In 1764 the quantity exported amounted to 48,000 rubles; and in 1768 to 41,000. In later years the quantity exported has been more various than that of strogilas. In 1783 it amounted to 10,700 pood; in 1786, to 22,600 pood; and in 1788, to 17,44 pood. Cavar is exported mostly to Italy (pressed of course, because of the voyage), where it is eaten by the rich in fall time. In Germany, also, with the increase of luxury, it is much more in request than it was about 40 years ago, when a physician in a publication called it a delicacy almost unknown. The English also, partly for their own use, but principally for exportation to Italy, &c. import considerable quantities of cavar. To be good, it should be of a reddish brown colour, and very dry. It is eaten with oil and lemon; sometimes with vinegar; some eat it alone with bread; and others only as a sauce or pickle, like anchovies. A kind of cavar is made from the spawn of a sort of mullet on the coast of the Mediterranean, which is called *Batar*, which see.

CAVEAT, in *Law*, a bill entered in the ecclesiastical court for the proceeding of one who would prove a will, or obtain letters of administration, to the prejudice of another. *See PROBATE.*

It is also used to stop the institution of a clerk to a benefice. An institution, after a caveat entered, is void by the

ecclesiastical law; but this the temporal courts may not regard to, and look upon a caveat as a mere nullity. *Blackst. Com. v. l. c. p. 217.*

CAVATING, in *Fencing*, the art or art of disengaging, or shifting the sword from one side of the adversary's sword to the other.

Cavating is a matter whereby a man brings in an instant his sword, which was presented, on any side of his adversary's, generally, through his hit, to the opposite side; either from within, or without, or *en garde*; or from having its point high, to be low, or the reverse; and either on the same side it is presented in, or the opposite side.

Cavating is so necessary a motion in fencing, that without it there could be scarcely any offensive part, or parry. It is well to easily performed again, if the ordinary tierce and quarte guards, that it gives a constant opportunity to make a number of quick subtle feints, age oil tierces, which by reason of the smallness made by the weapons on these guards, make the parry very easy, and the parade of defence very difficult.

The consideration of this put Sir William Hope on the search of a new method of guard, which, by reason of its greater cuts on the adversary's sword, renders the cavating and making tierces more slow, and consequently the parade more easy.

CAVEDO, in *Commerce*, a long measure used in Portugal, equal to 27 English inches.

CAVELDONE, *Jacomo*, in *Biography*, an historical painter, was born at Sallucio near Modena, in 1780, and educated in the Academy of the Caracci, where he learned design; attending also frequently the schools of Bassi and Pallorotto, to study after the naked. In order to acquire a proper knowledge of colouring, he visited Venice, and attentively examined the pictures of Titian; so that upon his return to his own country, his performance were much admired; and adjudged to possess an agreeable mixture of the style of the Caracci with the taste of Titian. For some time at Bologna, the works of Caveldone were esteemed equal to the pictures of Annibal. His best manner was strong and manly, and the tints of his colouring were natural and beautiful. But at three different periods of his life, this painter is said to have had three different manners; his first excellent, his second indifferent, and his last feeble and very bad; which degradation has been ascribed to the effect of poverty, sickness, and bodily injury, and also of domestic affliction. In the church of St. Salvator, at Bologna, there are several very capital performances of Caveldone; but one of his best performances is in the church of the Mendicants at Bologna, in which he represents Petronius and another saint on their knees, in the lower part of the picture, and the Virgin and child in the clouds attended by angels. This master died in 1760, aged 50. *Pinckton.*

CAVELIN, or rather **KAVELING**; thus they call at Amsterdam, what we and the French style a lot of merchandise.

CAVENDISH, or **CANDISH**, *Thomas*, in *Biography*, an eminent lawyer and naval adventurer in the reign of queen Elizabeth, was the son of William Cavendish, esq. of Trimby St. Martin, in Suffolk, where he was born, and whose estate he inherited. But having consumed his property by early extravagance in his attendance on the court, he determined to retrieve his affairs by a predatory voyage against the settlements of the Spaniards. The fleet which he fitted out for this purpose consisted only of three vessels of 100, 60, and 40 tons, manned with 123 persons of various qualities. Having equipped this small squadron for a voyage of two years,

He took the command, and sailed from Plymouth July 27, 1596. After touching at Sierra Leona in Africa, he stretched over to the coast of South America, and ran along it as far as the mouth of the Straits of Magellan. Here he found, at a place named by him Port Famine, the wretched remains of a Spanish colony which had two years before been dispatched in order to form a settlement in that inhospitable clime. Having reached the South sea, he directed his course northwards, and notwithstanding various encounters with the Spaniards, which gave him an opportunity of displaying with his small number of men very distinguished valour, he succeeded in burning Paita, Acapulco, and some other settlements, in taking and destroying several ships, and ravaging the coasts of Chili, Peru, and New Spain. At length, being off California in November 1597, he performed the extraordinary exploit of capturing, with a force much reduced, the Spanish admiral's ship of 700 tons, well manned and richly laden. Resolved on coming home with his booty, he crossed the South Sea with one of his two small vessels, the other being destroyed, to the Ladrones in 45 days. Thence proceeding through the Indian Archipelago, he passed the Straits of Java, and having touched at the cape of Good Hope, arrived at Plymouth, after having circumnavigated the globe in 2 years, 1 month, and 10 days, the shortest period in which it had then been effected. In 1591, he planned another expedition, and set sail August 27th with three tall ships, and two barks, suitably equipped. This adventure was attended with various disasters, which disconcerted and defeated his projects; so that his principal success was the capture of the town of Santos in Brazil. With part of his squadron, he entered the Straits of Magellan in April, 1592; and being forced by the inclemency of the season into a small bay, his men endured many hardships from the severity of the cold, and want of provisions. Having lost many of his crew, he relinquished his purpose of traversing the South Sea, and proposed to proceed to China by the Cape of Good Hope; but first returning to the coast of Brazil, he suffered many losses by some rash attempts to pillage towns which were prepared to resist him; and deserted by several of his men, and controlled in his schemes by the mutiny of others, he was prevented from accomplishing his purpose of returning to the Strait of Magellan, and sailing to the South Sea. Sickness and chagrin at length terminated his life, probably whilst he was at sea in his way to England. "From the relations we have of this navigator, he seems to have possessed great perseverance, with a true enterprising spirit, but not sufficiently under the control of prudence." Biog. Brit.

CAVENDISH, WILLIAM, duke of Newcastle, a distinguished leader of the king's party in the civil wars of Charles I. was the son of Sir Charles Cavendish, younger brother of the first earl of Devonshire. He was born in 1592, and educated by his father, who directed his attention to that polite and solid literature, which in that age was thought a proper accompaniment to high birth and rank. James I. made him, when very young, a knight of the bath, and when the death of his father devolved upon him a large estate, he was raised in 1600 to the peerage, by the title of baron Ogle, and viscount Mansfield. By Charles I., who honoured him with his favour, he was advanced to the higher title of earl of Newcastle-upon-Tyne. His attendance at court inspired him in expectations beyond his income; but he received some recompence by the honourable trust, committed to him in 1638, of the tutelage of the prince of Wales, afterward Charles II. Some court disgust induced him to resign this honour in 1640. His attachment to the royal

cause, however, was unabated; and on the approach of open hostilities between the crown and parliament, he offered his services for securing the important post and town of Hull, which were then thought premature. In 1642 he took upon himself, in consequence of the king's order, the care of the town of Newcastle and the four adjacent counties; and was soon after invested with a commission, constituting him general of all his majesty's forces raised north of Trent, with very ample powers. With great exertions and expense supplied by his private fortune, he levied a considerable army, with which, for some time, he maintained the superiority of the king's cause in the north. In military matters he chiefly depended upon the professional skill of lieutenant-general King, a Scots officer of merit; whilst he himself indulged in the courtly pleasures and literary society to which he was attached. In following commissions he was charged with a blameable profusion; and his appointment of Sir W. Davenant, the poet, to the post of lieutenant-general of the ordinance, redounded more to his honour as a patron of literature than as a soldier. One of his most splendid actions was a complete victory obtained over Ferdinando lord Fairfax on Adderton-heath near Bradford, which, however, he is said not to have improved to the best advantage. On the advance of the Scots army into England, and its junction with those of Fairfax and Manchester, the marquis of Newcastle, for that was the rank to which he had been promoted, threw himself into York, which was soon invested by the three armies. After a siege of three months, he was relieved by prince Rupert; but this prince resolving upon engaging the enemy, and passing the king's positive orders for that purpose, the marquis opposed his intention; and the fatal battle of Marstonmoor, fought July 2d, 1644, began without his being previously apprized of it. Nevertheless he took part in it with his usual valour, and his infantry was almost totally destroyed. Mortified by this defeat, and despairing of the royal cause, he took shipping at Scarborough, and immediately left the kingdom, to which he did not return till the restoration. Antwerp was the place of his residence, where he suffered with equanimity and resolution much pecuniary distress; though he was treated with great respect by the governing powers of the country and occasionally visited by the exiled king. After an absence of 18 years, he returned with his royal master, who, in 1664, conferred upon him the dignity of a dukedom. From this time he lived for the most part in retirement, prosecuting his inventive studies and endeavouring to repair his shattered fortunes. He died December the 27th, 1676, in his 84th year, and was buried together with his duchess, in Westminster Abbey, where a very sumptuous monument is erected to their memories. He left one son, in whom the title of Newcastle, in the Cavendish family, became extinct. His daughters formed connections by marriage with some of the principal families of the kingdom. The duke of Newcastle ranks among the noble authors of this country. His great work is a book of horsemanship, first published in French at Antwerp in 1678, and afterwards in a few new but different form, in English, Lond. 1697, 4to. This last has been reprinted, and it has been much commended by the judges of that art, and has been rendered particularly valuable by the fine figures of Diepenbeck. The duke also wrote some comedies, applauded at the time of their first exhibition, but since sunk into oblivion. Biog. Brit.

CAVENDISH, MARGARET, countess of Newcastle, wife of the preceding, was the daughter of Sir Charles Lucas of Essex, and in her time much celebrated for her studies. Distinguishing herself under the name of her names by her attachment to study, and visiting Oxford, where the court re-
 ended

sided, in 1643, she was appointed one of the maids of honour to queen Henrietta Maria. She accompanied her majesty to France, and at Paris first saw the marquis of Newcastle, then a widower, who married her in 1645. With him she lived in retirement during his exile; endearing herself to him by the charms of her conversation and the productions of her pen. Upon his reinstatement in his fortunes and honours, she principally devoted herself to the composition of plays, poems, letters, philosophical discourses, orations, &c. in which she became a very voluminous writer; her works at length amounting to 13 folios, 10 of which are in print. She was more distinguished by her disposition to commit to paper any thoughts that occurred to her, however crude or trivial, than by her taste and judgment. So important in her own estimation were these thoughts, that she kept within call a number of young ladies, who rose at any hour in the night when she summoned them, in order to pen down her meditations, lest she should forget them before morning. She seldom bestowed the trouble of revising on her works, "left," as she said, "it should disturb her following conceptions." From the mercenary pedants of the age this folly obtained the most extravagant applause; and both at Oxford and Cambridge the poetry and philosophy of the duchess of Newcastle were applauded with boundless adulation. Her writings have long since been consigned to oblivion, and scarcely a fragment of them is sought after by the English scholar, except a few lines descriptive of melancholy, quoted in the *Connoisseur*, N^o 69, and praised beyond their desert. The duchess had derived much greater honour from her strict attention to domestic duties than from her writings. She died in January, 1673-4. Biog. Brit.

CAVENDISH, WILLIAM, first duke of Devonshire, eminent for his patriotism, was the eldest son of William, third earl of Devonshire. He was born in 1640, educated with great care in classical literature, and brought into public life as knight of the shire for the county of Derby as soon as he was of age. On various occasions, public and private, he distinguished himself by his spirit and personal valour; and in 1677 commenced that steady opposition to the arbitrary measures of the ministers of Charles II., which caused him to be regarded as one of the most determined friends to the liberties of his country. Intimately connected with the patriotic lord Russell, he joined him in all constitutional proceedings for the security of free government and the protestant religion; but as soon as he found a tendency in some of the opposition party to the adoption of illegal and dangerous measures, he withdrew from their meetings. Nevertheless he remained attached to lord Russell with an unabated friendship; on his trial he appeared as a witness in his favour; and he even made the generous proposal of promoting his escape when under sentence of death, by changing clothes with him in prison; which lord Russell declined accepting. After the execution of that nobleman, lord Cavendish testified respect for his memory by marrying his eldest son to the daughter of his friend. In 1684, he succeeded to his father's title; and being regarded as one of the most formidable opponents of king James's arbitrary designs, attempts were made to intimidate him, but they were ineffectual. Having rashly struck a gentleman who had offended him within the verge of the court, he was fined in the exorbitant sum of 30,000*l.*, and being obliged to give a bond for the payment of it, this was held as a pledge against him. He then retired into the country, and employed himself in improving his magnificent house at Chatsworth, where he displayed his taste in architecture and decoration. In this retirement, however, he was not inattentive to public events; and when he observed evident indications of a fet-

tered design for subverting the religion and liberty of his country, he held conferences at Whittington, a village in his neighbourhood, with lords Danby and Delamere, and others, for the purpose of effecting the revolution. On the landing of the prince of Orange, the earl of Devonshire was one of the first who declared for him. He secured the town of Derby, and at Nottingham received the princess (afterwards queen) Anne, whom he conducted to her consort at Oxford. He strenuously supported all the measures which led to the transferring of the crown to king William and queen Mary, and officiated as lord-high-steward at their coronation. In consequence of his zealous attachment to the royal pair, honours and dignities of various kinds were conferred upon him; and, in 1694, he was advanced to the titles of marquis of Hartington and duke of Devonshire. Uncorrupted by these distinctions, he maintained a parliamentary conduct, that was free and independent; and whilst he firmly supported the throne, he occasionally rebuked projects which he thought to be unjust. Under queen Anne he retained all his posts; and was appointed one of the commissioners for treating on the union with Scotland. He died in August, 1707, in the 67th year of his age; and the following inscription was, by his own direction, placed upon his monument:

WILHELMUS DUX DEVON. BONORUM PRINCIPUM
FIDELIS SUBDITUS, INIMICUS ET INVISUS TYRANNIS.

*William duke of Devonshire, a faithful subject to good
princes, hating and hated by tyrants.*

In love and fighting the duke of Devonshire had a strong tincture of the gallantry of the age. His manner was dignified; his spirit bold and free. He was well accomplished in polite arts and studies; and occasionally amused himself in poetical composition, of which two pieces were published; "An ode on the death of queen Mary," and "An allusion to the bishop of Cambria's supplement to Homer." Biog. Brit. Gen. Biog.

CAVERIPATAM, in *Geography*, a town of Hindoostan, in the country of Mysore; 90 miles E. of Seringapatam, and 130 W.S.W. of Madras.

CAVERN. Caverns are, in a great measure, peculiar to mountains; and are seldom or never found in plains. They frequently occur in the Archipelago, and other islands; because islands generally consist of the summits of mountains. Like precipices, they are formed by the sinking or mouldering of rocks, or like abysses, by the action of fire. Caverns may be produced by the same causes which occasion gulfs, apertures, or sinkings of the earth; and these causes are explosions of volcanoes, the action of subterraneous vapours, and earthquakes, which create such commotions in the earth, as must necessarily produce caverns, fissures, and hollows of every kind. The cavern of St. Patrick in Ireland is not to be considered as it is famous; and the same observation will apply to the grotto del Cave in Italy, and to that of mount Beni-guazeval, in the kingdom of Fez, which throws out fire. In the county of Derby in England there is a very large cavern, which is much more capacious than the celebrated one of Bourran, near the Black Forell of Brunswick. The entrance to this cavern, called the "Devil's hole," is larger than the door of any church; a small river runs through it; and after advancing in it some way, the vault of the cavern sinks so low that in order to proceed farther, it is necessary to lie flat in a boat, and to be pushed through the narrow passage by people employed for the purpose; and after getting through this avenue, the roof, or arch, of the cavern rises to a great height; and

after walking a considerable way on the side of the river, the arch sinks again so low, as to touch the surface of the water. Here the cavern terminates. The river, which seems to have its source in this part of the cavern, swells occasionally, and transports heaps of sand, which, by accumulation, form a kind of blind alley, the direction of which is different from that of the principal cavern. See **PEAR, CASTLETON, and BUXTON.** Other remarkable caverns are found in the northern ridge of English mountains. In the vale of Kingdale, on the western extremity of Yorkshire, is **Yordas cave**, which presents a subterranean cascade; this cave is about 50 yards in length. But the most noted is **Wethercoat cave**, not far from Ingleton. It is surrounded with trees and shrubs, in form resembling a lozenge, divided by an arch of limestone; in passing under which, you behold a large cascade, falling from a height of more than 20 yards; the length of this cave is about 60 yards, and the breadth 30. Among other curiosities of a similar kind, we may mention **Hurtle-pot**, in Yorkshire, which is a round deep cavity, near 40 yards in diameter, almost surrounded with rocks about 30 feet perpendicular above its black waters, while the overhanging trees increase the horrors of the scene. The river Ribbles near its origin sinks into a deep cavern; and silently pervades the mountains for about three miles. In **Carniola**, near **Potpechio**, there is a large cavern, in which is a considerable lake. Near **Adelberg** we meet with a cavern, in which a person may travel two German miles, and which contains several deep and tremendous precipices. The **Mendip Hills** in **Somersetshire** present extensive caverns, and very fine grottoes, near which are found veins of lead, and sometimes large oak trees, buried 15 fathoms deep. **Wookey-hole** in these hills, near **Wells**, is a stalactitic cavern of about 600 feet in length, divided by low passages into various apartments; one of which, called the hall, somewhat resembles a Gothic chapel, and is said to be 80 feet high; while the farthest, denominated the parlour, is of moderate height, but extensive diameter. On the north-west side of the **Mendip hills** is a more remarkable curiosity, which is a considerable cavern, at the bottom of a deep ravine, near the little village of **Berrington** or **Burrington**. Here are found human bones gradually incorporating with the limestone rock; a constant dripping from the roof and sides depositing a stalactitic sediment on the bones. Several nodules contain perfect human skulls. At the further end, where the height is about 15 feet, there is a large conic stalactite, which nearly meets a pillar rising from the floor. This cave was very lately discovered; and as the matter increases so rapidly, it is conjectured that it would soon have been closed up. Hence it is probable that these bones are of no remote antiquity, and may, perhaps, be the remains of some wretches who had taken shelter here from the cruelty of **Jeremies**, after the insurrection of **Monmouth**. In the county of **Gloucester**, about five miles north of **Bristol**, there is a large cavern called "**Pen-park-hole**," supposed to have been an ancient mine, at the bottom of which are thirty-two fathoms of water. **M. Buffon** observes, that the **Devil's hole**, and other caverns, from which large springs or bronks issue, have been gradually formed by the operation of the water, and that their origin cannot be ascribed to earthquakes or volcanoes. One of the largest and most singular caverns with which we are acquainted is that of **Antiparos**, defended by **Mr. Tournefort**. See **ANTIPAROS**. The large cave in a mountain of **Livadia**, formerly famous for the oracles of **Trophiou**, is situated between the lakes of **Livadia** and the sea, from which, at the nearest part, it is distant about 4 miles; and it has no less than 40 subterraneous passages, through which the waters run under the mountains.

See **CAVE and GROTTO**. In all countries, which are subject to earthquakes or volcanoes, caverns are frequent. The structure of most of the islands of the **Archipelago** is exceedingly cavernous. The islands in the **Indian ocean**, and particularly the **Moluccas**, appear to be chiefly supported upon vaults. The land of the **Azores**, and the **Canaries** of the **Cape de Verd** islands, and, in general, of almost all small islands, is, in many places, hollow and full of caverns; because these islands, as we have already remarked, are the tops of mountains which have suffered great convulsions either from volcanoes, or by the action of the waters, of the frosts, and of other injuries of the weather. In the **Cordehers**, where volcanoes and earthquakes are frequent, there are many caverns, precipices, and abysses. The famous labyrinth in the island of **Crete** is not the work of nature alone. **M. Tournefort** assures us, that in many parts it exhibits traces of the operation of men; and it is probable that this is not the only cavern which has been enlarged by art. Mines and quarries are constantly dug, and after these have been long deserted, it is not easy to determine whether such excavations have been the effects of nature or of art. Some quarries are very extensive. That of **MacBricht**, for instance, is sufficient to shelter 50,000 men, and is supported by more than 1000 pillars, 20 feet high; and the earth and rock above are 25 fathoms thick. The salt-mines of **Poland** exhibit excavations still more extensive. See **SALT**.

CAVERNOSA corpora clitoridis, in *Anatomy*, two small bodies, resembling in structure, on a small scale, the cavernosa corpora of the male penis. See **GENERATION, Organs of**.

CAVERNOSA corpora penis, two strong ligamentous tubes, filled with cellular substance, and forming the chief bulk of the male penis. See **GENERATION, organs of**.

CAVERNOSUM corpus urethrae, or more properly *corpus spongiosum urethrae*, a peculiar vascular substance surrounding the greater part of the urethra in the male subject. See **GENERATION, Organs of**.

CAVERS, in the *Language of Miners*, are any poor people that go about the mines in **Derbyshire**, to beg or steal ore from the miners. They are punishable in the bergmote or miners court.

CAVERY, or CAUVERY, in *Geography*, a river of **Hindustan**, which rises in the **Bednore** country, passes by **Seringapatam**, **Trichinopoly**, &c. and discharges itself by three branches into the bay of **Bengal**.

CAVESAS, in *Geography, a cluster of small islands in the **Spanish main**, a little to the east of **Cape St. Blas**. N. lat. $9^{\circ} 20'$ to $9^{\circ} 40'$. W. long. $78^{\circ} 25'$ to $78^{\circ} 40'$.*

CAVEON, CAVEON, or CAVEON, in *Horsemanship*, is an instrument of iron or other matter which is applied to the nose of a horse in order to tame him, by pressing hard on his nostrils and squeezing them.

The word is derived from the Spanish *Caveca*, or *Cavega*, head.

The cavefons for breaking young horses are usually of iron, made femicircularly, of two or three pieces turning on joints; others are twisted, others are flat, others hollow in the middle, and indented like saws, called *mordants*: which last are now banished the academics. The rope and leathera cavefons serve for passing the horse between two pillars.

An iron cavefons spares a young horse's mouth in the breaking, since by means hereof he is accustomed to obey the hand, and bend the neck and shoulders, without injuring his mouth. All iron cavefons are muffled with a head-stall and a throat-band, and two straps or reins, with three rings; through the middle ring, one rein is pulled to make a horse work round a pillar, and through the two side rings the other two reins are passed, which the rider holds in his hand,

hand, or fastens to his saddle to keep the horse's head in subjection.

This kind of instrument has been employed and considered from the earliest days of modern horsemanship, even to the present time, as the most effectual, and almost the only means of breaking and reducing a horse to suppleness and obedience. Cavions are variously constructed; but they differ from each other in no essential point, except in being of different degrees of mildness or severity; and, indeed, it is astonishing to what an excess of cruelty they were carried in order to answer the latter purpose. Being tied over the nose, made of iron, and armed with sharp teeth, they harrowed and tore the poor animal in a shocking manner. Nevertheless, it was a sort of proverbial boast among the old horsemen, that a "bloody nose" made a "good mouth;" their chief intention being to restrain and bend the horse by the cavion, and to save the mouth at the expence of the nose: at the same time encumbering the horse with both, without considering that while they thought of saving the mouth, by not making it acquainted with the bit, it could never, till it had been properly worked and formed, be true and faithful to the hand; and that in order to be made, it must first be prepared and seasoned; and although a raw and ignorant mouth may be spoiled by a rough and injudicious hand, yet there is no natural mouth, however good, that does not require to be moulded, and wrought upon by the bit, before it can be brought to such a temper and feeling as to act in a close and delicate correspondence with the hand which is to govern it. Upon this principle and mode of reasoning, it must follow, that if a horse is to be worked only by means of the cavion, and the bit is to be inactive, or slightly employed, let him be ever so well dressed to the cavion, yet, when he comes to be rode with the bit alone, as he ought sometimes to be, his mouth, for want of practice, will be awkward and unformed, though years may have been spent to make him otherwise complete. The cavion, therefore, considered in the most important view of it, and allowing it the most extensive merit, should never be used but as preparatory to the bit, and as an engine to bend and supple the horse. In this latter office, it certainly can boast a power much superior to that of the bit, and such as must entitle it to the greatest applause, if it were not attended by one humbling circumstance, that, while it bends, it pulls down the head, and puts the horse upon his shoulders. Notwithstanding this inconvenience, it is certain, that if the services of the snaffle were not known, the cavion would deserve much praise; and as it is very efficacious in bending and suppling the horse, it may at least dispute precedence with the bit; but the snaffle combines both these advantages. *Bergier's Hist. and Art of Horsemanship*, vol. ii. ch. 11. See BIT and SNAFFLE.

CAVETTO, in *Architecture*, a hollow member or moulding containing a quadrant of a circle. It is frequently used in cornices, see *Plate XXI. Architecture*. The word is Italian, and is no more than a diminutive of *cavus*, hollow.

CAUHQ-ROY, in *Natural History*, a name given by the natives of the East Indies to a sort of fossil which they calcine, and afterwards give in large doses in the leucorrhoea and many other complaints. It is also used in dyeing. The Indians boil it in water, and dye or stain their cloths with it, to make them appear different from others: it is a kind of ochre, or clayey iron ore, and is found in great abundance in the hills, and iron is sometimes extracted from it.

CAVIA, in *Zoology*, a genus of quadrupeds that appears to form an intermediate link between the murine, and rabbit tribes. The animals of the cavia genus have generally a slow and sometimes leaping pace, and are observed to never

comb. They live like the rest of the glires on vegetable substances, and in their natural state inhabit excavations in old trees, or burrows which they dig in the earth. The fore teeth of the cavia, which are two in number, are cuneated; the grinders eight; toes on the fore feet, from three to five; on the posterior feet, from four to five; tail either very short, or none; clavicles, or collar bones, none.

Erxleben, Buffon, Gmelin, and other authors, describe the following species of the cavia genus: C. *Paca*, Acutchy, Aguti, Iperonia, Americana, Aperca, Cobaya, Patanchinca, or Magellanica, and Capybara.

CAVIA *Paca*, the spotted cavy, is tailed; the feet five-toed; and the sides lined with yellowish. *Erxleben—Mus Paca*, Linn.—*Cuniculus Paca*, Brill.—*Paca*, Maregrave.—*Laubtia*, Bancroft.

This species is near two feet in length: the form thick and clumsy, and bearing some resemblance to that of a pig, for which reason it has been sometimes called the hog rabbit. The name *paca* is of Brazilian origin, being pronounced *Pag* by the natives of that part of South America: the French settlers in Surinam call it *levre aquatique*, or the water hare. The head is round; the muzzle short and black; the upper jaw longer than the lower; and the lip divided like that of the hare: the nostrils are large; the whiskers long; the eyes large and prominent, and of a brown colour; the ears short, moderately large, round, and naked; the neck thick; the body very plump, larger behind than before, and covered with coarse, short, thinly scattered hair, of a dull brown colour, deeper on the back; the throat, breast, insides of the limbs and belly, dingy white; and on each side of the body are five longitudinal series of roundish, or slightly angular spots, situated contiguous to each other. The legs are short, and the feet have five toes, four of which are armed with strong and sharp claws; that on the fifth toe being very small. The tail consists merely of a small conic projection not more than half an inch in length.

The spotted cavy inhabits Guiana, Brazil, Paraguay, and other parts of South America, and appears to be common throughout those countries, with the exception of Paraguay, where, according to M. D'Azara, this animal is very rare. It lives principally in burrows which it forms in the banks of rivers, residing in its hole during almost the whole day, and venturing out in quest of food in the night. The flesh of the *paca* is of a good flavour, and is held in esteem in South America as an article of food, but is very fat. It is easily domesticated, and in this state readily feeds on almost every kind of vegetables. The female is said to produce but one young at a birth. A variety of the *paca* entirely white has been found near the river St. Francis.

CAVIA *Autchy*, olive cavy. Tailed, with olive-coloured body. *Erxleben and Schreber—Acouchy*, Buffon.—*Olive Cavy*, Pennant.

This species, which is about half the size of a full grown rabbit, inhabits the woods of Guiana. By some writers the *acouchy* is considered as a variety of the *aguti*, from which it differs in being somewhat smaller, rather thinner, and entirely of an olive colour, paler, or more inclining to whitish beneath: the tail also is rather longer than in the *aguti*. Both animals are natives of the same parts of South America, and their manners are similar, except that, according to M. de Borde, it does not attempt the water like the *aguti*. M. de Bourde observes that the *acouchy* produces but one young at a birth. Its voice resembles that of *Cavia cobaya*, or guinea-pig. This kind is easily tamed, and the flesh is eatable. See AKOUSHY.

CAVIA *Aguti*, long-nosed cavy. Tailed: body tawny brown; belly yellowish; *Erxleben and Schreber—Mus Aguti*,

Aguti, Linn.—*Cuniculus aguti*, Briff.—*Agouti*, Buffon.—*Long-nosed Cavy*, Pennant.

The agouti is an inhabitant of South America, and the West Indies. It is the size of a rabbit; the body plump, and thicker behind than before; the head rather small and somewhat compressed laterally; snout long and rather sharp; nose divided at the tip, and the upper jaw longer than the lower; ears short, broad, naked, and rounded; neck rather long, but thick; legs thin, almost naked and blackish; the hind legs longer than the anterior ones, and furnished with only three toes; tail extremely short, naked, and sometimes scarcely visible; the whole of the animal covered with hard, strong, and shining hair, in general of a rufous brown colour with blackish freckles; rump orange-coloured.

Buffon observes that the agouti has the hair, grunting, and voracious appetite of the hog; and when fully fatiated hides the remainder of its food, like the fox, in different places. It takes delight in gnawing and spoiling whatever it comes near. When irritated, it bites fiercely; its hair stands erect along the back, and it strikes the ground violently with its hind feet. It does not, he remarks, dig holes like the rabbit, but lives in the hollows of trees. Roots, potatoes, yams, and fruits are its principal food. It uses its fore paws, like the squirrel, in carrying food to its mouth; runs swiftly up hill, or on even ground, but its fore-paws being shorter than its hinder ones, it is in danger of falling upon a declivity. The flesh of the agouti being nearly as good as that of the rabbit, and the skin of such a durable quality, as to form an excellent upper leather for shoes, the hunting of these animals is an object of attention among the Indians and negroes. They commonly go in search of them with dogs, or take them in traps; the natives know also how to allure them by whistling or imitating their cries, and kill as many as they please. When they go among the sugar-canes they are easily taken, for sinking at every leaf in the straw and leaves which cover the ground, a man may easily overtake and kill them with a stick. When in the open country, it runs with great swiftness before the dogs; and having gained his retreat nothing can force him to come out but smoke; for which purpose the hunters burn faggots and straw before the mouth of the hole, but the animal seldom quits the place of his concealment till the last extremity. The young agouti is easily tamed. When in a wild state they generally dwell in the woods, where the female chooses the most obscure parts, and there prepares a bed of leaves and grass for her young. She usually brings forth two or three at a time, and in a day or two afterwards, she carries them in her mouth like a cat, into the hollow of some tree, where she suckles them for a short space of time, for they are soon in a condition to run about and provide for themselves. They multiply as fast as rabbits, producing three, four, and sometimes five young ones, during every season of the year. When in a domestic state they never remove to any great distance, and always return to the house; but constantly retain somewhat of their wild disposition. In general they remain in their holes during the night, unless the moon shines bright, but run about most part of the day. See AGUTI.

CAVIA leporina, β of Gmelin, a supposed variety of the aguti, is described by Erxleben as having a tail, and the body of a rufous colour above, beneath white.—*Mus leporinus, cauda abbreviata, palmis tetradactylis Adonine albo.* Linn. Syst. Nat. 12.—*Cuniculus javensis*, &c. Briffon.—*Java Cavy*, Cateby.—*Javan cavy*, Pennant.

This differs from the aguti chiefly in being of a reddish colour above, with the breast and belly white; the legs are long; the posterior part large, and the tail very short. It

is the size of a hare, and is a native of Surinam and other parts of South America. Dr. Shaw observes that this is altogether an American animal, and notwithstanding its common title of the Java hare, is not found either in that island, or in Sumatra as erroneously supposed by Lome. See AGUTI.

CAVIA Americana, γ of Gmelin.—*Cuniculus Americanus*, Scha.—*Cuniculus*, &c. Briffon. A variety of the aguti very closely allied to the preceding, and perhaps not distinct from it. Marcgrave, and other authors after him, speak of the aguti having six toes on each of the posterior feet instead of three. A variety is also spoken of with a yellowish belly, with four toes on each of the anterior feet, and three on those behind. See AGUTI.

CAVIA Aperea, rock cavy. Tailless; body above tawny ash, coloured beneath, white.—*Cavia Aperea*, Erxleben.—*Cuniculus Brasiliensis, Aperea diuisa*, Marcgrave.—*Rock cavy*, Pennant.

This animal is a native of Brasil. The length is one foot; its circumference, seven inches. The general colour is the same with that of our hares, and its belly is white; its upper lip is divided in the same manner, and it has the same large cutting teeth, and whiskers round the mouth, and on the sides of the eyes, but its ears are rounded like those of the rat, and so short as not to exceed a finger's breadth in height; the fore legs are about three inches in length, and the hind legs a little longer; on the fore feet are four toes covered with a black skin, and armed with small short claws; the hind feet have only three toes, the middle one of which is longest; the head is somewhat longer than that of a hare, and its flesh like that of the rabbit, which animal it resembles in its manners of living. This kind retires into holes and clefts in the rocks, whence its name of rock cavy. A variety of this species is described of a black colour spotted with tawny; other varieties differing only in colour are likewise mentioned by authors.

CAVIA Patagonica. Tail short and naked; nose with tufts of curly hair; body ferruginous-grey above; beneath, and patch on each thigh, white; rump black.—*Cavia Patagonica*, Shaw Zool.—*Cavia Magellanica*, Turri. Gmel. Syst. Patagonian cavy, Penn.—*Hare*, Narborough's Voy. to Magell. p. 33.

Sir John Narborough appears to have been the first discoverer of this species. He calls it a hare, and informs us it inhabits Patagonia, where it is by no means scarce. In size this curious animal exceeds the common hare; Mr. Pennant relates in his Hist. Quad. that it has been known to weigh more than twenty-five pounds. Its colour above resembles that of a hare; the under parts whitish; breast and sides tinged with ferruginous; on each thigh is a large oval white patch, and the rump or region round the tail is black: the ears are long, rather broad, and sharp-pointed. On each side of the nose is a tuft of short soft hair, exclusive of the vibrissæ, or whiskers. The legs are long; the claws long, straight, sharp, and of a black colour; they are four in number on the fore feet, and three on the posterior ones. Tail as in the aguti, a naked stump. The flesh is white and delicate, and is considered as an excellent food. This curious species of cavy is described from a fine specimen in the late Leveque Museum.

CAVIA Cobaya, Guinea cavy. Variegated cavy. Guinea pig. Tailless, variegated with white, rufous, and black, Schreber.—*Mus Porcellus, cauda nulla, palmis tetradactylis, plantis tridactylis*, Linn.—*Cuniculus indicus*, Nieemb. Briff. &c.—*Cavia cobaya*, Marcgr. bras.—*Cochon d'Inde*, Buff.—*Guinea pig*, Edwards.—*Rijstje cavy*, Penn.

Though a native of South America, the Guinea cavy lives and breeds in temperate, and even in cold countries,

provided it be taken care of, and sheltered from the inclemency of the weather. This animal is frequently reared in Europe, and though very prolific, the attention they require is but poorly rewarded by the profits derived from them. The skin is of little or no value, and their flesh, which is indeed eaten by some people, is notwithstanding very indifferently. Buffon conceives this objection might be removed by rearing them in warrens, where they might have air, space to range in, and an agreeable choice of herbs. Those kept in houles have the same kind of bad taste with the house rabbit, while the flesh of those kept in gardens during summer is less disagreeable though still insipid. They willingly feed on a great variety of vegetable substances, and may be successfully reared on parsley, cabbage, and sow-thistles. In winter they may be fed with bread, carrots, and various kinds of grain.

The guinea pig is an animal of very warm disposition, being in heat so early as five or six weeks old; their growth, however, is not completed before the end of eight or nine months. The females go with young three weeks, and they have been known to bring forth at the age of two months. The first litter consists only of four or five, the second of five or six, and afterwards they will sometimes have eleven or twelve. The female does not suckle her young more than twelve days, and when the male returns to her, which he never fails to do three weeks after she has littered, he drives them from her, and if they persist in following he often kills them. Thus these animals bring forth at least every two months, and as their young produce in the same period their multiplication is astonishing. In one year, says Buffon, a thousand might be produced from a single couple, but their consequent increase is checked by various means of destruction. They have no distinct sentiment but that of love, and when disputing for a particular female, they will shew themselves susceptible of anger, fight bitterly, and are sometimes killed in the contest before they will yield. In their quarrels they not only bite, but kick each other like horses with their hind feet. They pass their lives in eating, sleeping, and love: their sleep is short but frequent, they eat every hour, night and day, and indulge in their amours almost as often as they eat. It has been observed that the male and female seldom sleep at the same time; but seem alternately to watch each other, one sleeping while the other is feeding. They subsist on all kinds of herbs, especially parsley, which they prefer to either grain or bread; and they are also fond of apples and other kinds of fruit. Like the rabbit they eat little at a time, but precipitately and very often. They grunt like a pig; make a chirping noise when pleased with their females, and have a sharp loud cry when hurt, or irritated. They are very delicate in their constitution, and so chilly that it is difficult to preserve them through the winter, the place where they are kept during that season must be therefore warm and dry. When they feel cold, they assemble and press close together, and in this situation are sometimes found dead. They are naturally of a mild disposition, and in their manners are remarkably neat: they are frequently observed in the act of smoothing and dressing their fur in the same manner as a cat. This little animal is very easily rendered tame, but is seldom observed to shew any very lively attachment to its benefactors; neither is it distinguished by any remarkable degree of docility.

CAVIA Capybara, river cavy. Tailless; anterior feet three-toed and palmated, Schreber.—*Sus Hydrochaeris*, Linn.—*Hydrochaerus*, Brüll.—*Cavia capybara*, Pallas.—*Cabiai*, Buffon.—*Thick-nosed tapir*, Penn.

The capybara inhabits the eastern parts of South Ame-

rica, but is said to be more common in Brasil than in any other regions. This animal grows to the length of two feet and a half, and weighs sometimes one hundred pounds. It feeds not only on various vegetables, and particularly on sugar canes, but also on fish, in which particular it differs from most animals of the *Glires* tribe. The habits of the capybara are adapted to its mode of life; it frequents fenny woods near large rivers, swimming with the same facility as the otter, and, like that animal, dragging its prey out of the water and eating it on the bank. Its excursions in quest of prey are made principally during the night.

In general, the capybara is considered as an animal of a gentle disposition, and is readily tamed and made familiar. The female produces but one young at a birth. These animals are said to go in pairs, and are naturally shy and timid. Their voice resembles the braying of an ass. The capybara runs but indifferently, on account of the length of the feet, and therefore commonly makes its escape by plunging into the water and swimming to a great distance. Buffon supposes from the number of its teats this to be a prolific animal; but this is contradicted, and it is asserted to produce but one at a birth. The flesh has a rank and fishy taste, which renders it but an indifferent article of food.

The capybara has a large head, and a thick divided nose, with strong and large whiskers on each side; the ears are small and rounded; the eyes large and black; the upper jaw longer than the lower; in each jaw are two very large and strong cutting teeth; and the grinders, which are eight in each jaw, are divided into three flat surfaces on the upper part; the neck is very short; the body short and thick, and covered with coarse brown hair; the legs short; feet long, the forefoot divided into four toes, connected to each other by means of a small web at the base, and tipped with thick claws or rather hoofs at the extremities; the hind feet are formed in a similar manner, but are divided only into three toes. This animal sometimes, while feeding, sits up, in the manner of a squirrel, holding its food between its paws. It is said to commit considerable devastation in gardens during the night time, especially among the esculent vegetables.

CAVIA Hudsonis of Klein, is the quadruped called *HYSTRIX dorsata*, by Gmelin, Schreber, and other late authors.

CAVIA Capensis of the twelfth edition of the Linnean Syst. Nat. and of Pallas, is *HYRAX capensis* of Gmelin, and Schreber.

CAVIANA, in *Geography*, an island of the North Atlantic Ocean, under the equinoctial line, formed by the two mouths of the river Amazons, which surround it. W. long. 50° 30'.

CAVIANO, a town of Naples, in the province of Lavora; 7 miles N. of Naples.

CAVIDOS, or *CABIDOS*, in *Commerce*, a Portuguese long measure, used in the mensuration of cloth, linen, and the like, equivalent to two feet eleven lines, Paris measure.

CAVIL, *cavillatio*, is defined by some a fallacious kind of reason, carrying some resemblance of truth, which a person, knowing its falsehood, advances in dispute for the sake of victory.

The art of framing sophisms or fallacies is called by Boetius, *cavillatoria*.

CAVILLARGUES, in *Geography*, a town of France, in the department of the Gard, and district of Uzès; 8 miles N.E. of Uzès.

CAVIN, in *Military Language*, a hollow place or spot of ground fit for covering a body of troops or favouring the approaches to a place. *Cavins* near a place besieged are of great advantage.

advantage to the besiegers, as by means of them they can open the trenches nearer to it, construct places of arms, and station parties of cavalry for the protection of the workmen under cover from the fire of the place. A commandant or governor of a place, who attends to his duty and understands it properly, will know how to turn evasins to the disadvantage of the enemy, from the moment he perceives that the place he commands is menaced or in danger of being attacked.

CAVING. See CAVAZION.

CAVINGS, in *Agriculture*, a term provincially applied to the rakings or coaric materials, as short straws, ears of grain, &c. collected from the corn in chaff, while thrashing.

CAVING CHAFF, the coarse chaffy straw or other similar material raked off from the grain after the operation of thrashing.

CAVING RAKE, the tool or implement employed in the above operation, and which is a sort of barn flour rake with a short head and teeth of considerable length.

CAVITA, in *Geography*, a port town of the island of Luçon, or Luconia, 3 leagues S. W. from Manilla, the capital of the island. It was formerly a very considerable place; but as the great towns in the Philippine islands, as well as in Europe, exhaust the small ones, there now remain in this place only the commandant of the arsenal, a contador or accountant, two port lieutenants, the commandant of the town, 150 soldiers in garrison, and the officers belonging to that corps. All the other inhabitants are metis (a species of mulattoes, half black, or the immediate offspring of a white man with a black woman), belonging to the arsenals, and form, together with their families, which are generally very numerous, a population of about 4000 inhabitants divided between the town and the suburb of St. Roch. There are two parishes, and three monasteries for men, each occupied by two ecclesiastics, though 30 might easily be accommodated. The Jesuits had formerly a very fine house, of which the trading company, established by the government, has obtained possession. In general, nothing is now seen here but ruins: the ancient edifices of stone are deserted, or occupied by Indians, who never repair them; and Cavita, the second town in the Philippine islands and capital of a province of the same name, is now only a paltry village, uninhabited by Spaniards, except the military officers, and those of the civil administration. In the port belonging to this town, the commander has established an order and discipline which give it great reputation. La Perouse's *Voyage*, vol. i. p. 269, &c.

CAVITY, in *Anatomy*, is a term applied to several hollow spaces, lined by membranes and containing the different viscera of the body. As the extent of these cavities is bounded and defined by the membranes, which line them, and they have no external communication, they are frequently called the circumscribed cavities of the body. These spaces are in every instance completely and accurately filled by the contained viscera; which generally have their surface covered by a reflected portion of the membrane which lines the cavity.

The surface of the viscera is in contact with that of the lining membrane, but is prevented from becoming actually adherent, by the secretion of a fluid from the exhalant arteries, by which the opposed surfaces are constantly preserved in a moist state. Hence it will be seen that the anatomical term cavity, in the sense which we have now mentioned, does not denote any void or empty space, and that it differs in that respect from the common acceptation of the term. The following cavities of this kind are found in the body: Cavity of the Abdomen; Pelvis; Pericardium; Thorax;

and Tunica vaginalis testis; for a particular description of which the reader is referred to those articles.—The various joints of the body present examples of similar cavities; they are lined, and circumscribed by the capsular ligaments.

The word cavity is also frequently employed in osteology; where it is not only applied to larger and more circumscribed spaces, as cavity of the cranium, cavity of the orbit, but also to the comparatively superficial impressions which contribute to the formation of joints, and which are denominated articular cavities of the bones. The same term is applied to the space included in any hollow part of the body: thus we have cavities of the heart, of the arteries and veins, of the stomach, intestines, &c. &c.

CAUK, or CAWK, formed probably of the German *kaalk*, *sparr*, is used by miners in the Peak, to denote a coaric sort of spar; being a vitriolated ponderous earth, or narmor metallicum, generally found near lead mines, which will draw a white line like chalk, or the galactites. Phil. Transf. N^o 110, p. 226. Ibid. N^o 39, p. 770. It is unflexible in acids, and fusible by fire. See EARTH, *ponderous*.

It is properly no other than a sparry matter, rendered very coarse, by being mixed with a large portion of earth. In some places it is found more clear and transparent than in others: it approaches in this state to the nature of crystal, and is called ballad cauk, and bright cauk. Philof. Transf. N^o 407.

There is a singular process mentioned by Dr. Lister, which is that of vitrifying antimony by its means. This is done with great readiness and speed by it, and the glass, thus made, will produce some effect on other metals, which no other glass will, nor indeed any other preparation of antimony. The method of preparing it is this; take a pound of antimony, flux it clear; have in readiness an ounce or two of cauk in a lamp red hot; put it into the crucible to the melted antimony, and continue it in fusion: then cast it into a clean mortar not greased, decanting the clear liquor from the lump of cauk. This process gives more than fifteen ounces of glass of antimony, like polished steel, and bright as the most refined quicksilver. The cauk, in the mean time, is found to be diminished, not increased in its weight, and will never flux with the antimony, though ever so strong fire be given it. This is a very odd mineral, and this learned author supposes it to be allied to those white, milky, and mineral juices which are found in mines. The effect of both is evidently the same; for the milky juice of lead mines vitrifies the whole body of antimony, in the same manner that the cauk does in this experiment. Phil. Transf. N^o 110.

That there is somewhat very peculiar in the cauk is plain from this effect on antimony, which no other thing of this kind is possessed of; for lapis calaminaris, sulphur vivum, galactites, mundicia, alum ore, spar, and many other things, have been tried with antimony in the same manner, but not one of them has this effect.

CAUKING, in *Architecture*, signifies dove-tailing down. See DOVE-TAILING.

CAUKING TIME, in *Falconry*, a hawk's treading time.

CAUKING, or CALKING a *ship*. See CAULKING.

CAUL, in *Anatomy*, is the part generally described under the term OMENTUM. See PERITONEUM.

CAUL, or CAULE, among *Mineralists*, a reddish pink-coloured stone, found in the strata of the tin-mines. See TIN.

CAULCI, in *Ancient Geography*, a people of Germany placed by Strabo towards the ocean.

CAULEDON, from *καυδον*, a *stem*, in *Surgery*, is applied to fractures which happen transversely, wherein the parts of
the

the broken bone flart asunder, so as not to lie directly against each other.

CAULESCENT, in *Botany*, a term applied to such plants as have a stem.

CAULIAC, **GUI DE**, or **GUIDO DE CAULIACO**, in *Biography*, a celebrated master of the art of surgery, was born at a small town in the Gavardon, on the frontiers of the province of Auvergne in the early part of the fourteenth century. He studied medicine at Montpellier under Raimond de Moheres, and made such progress that he was early appointed teacher in surgery in that university. He was thence sent for to Avignon, and made physician to Pope Clement the Sixth. This was in the year 1348, at which time a dreadful pestilence broke out, which visited every part of the then known world, and destroyed, it was thought, nearly a fourth part of its inhabitants. Under this prince, whose confidence he gained by his diligence and skill in the performance of his duty, he acquired considerable wealth; and with this wealth, such reputation for his abilities, that he was retained in his office of chief physician to the emperor Innocent the Sixth, and Urban the Fifth. It was during the pontificate of Urban, in the year 1353, that he composed or completed his "Magnam Chirurgiam," which gained him such reputation that Fallopius does not hesitate to compare him to Hippocrates. Cauliac not only restored the surgery that had been taught by the Greeks and by the Arabians, but, what Carpus did in anatomy, he improved what he found, and added considerably from his own stock. He first, Douglas says, taught that incisions over the eyebrows should be made longitudinally in the direction of the fibres of the muscles. He also described more accurately than had been done before, the lower end of the humerus, and the joint of the elbow. He revived the use of the trepan, and invented several instruments, of which he gave the figures; among them, a pair of forceps, to take up wounded arteries. His work may be considered, Haller says, as an abridgment of all that had been done on the subject of surgery before his time; it also contains the names and the practice of several writers on the art, whose works have perished, and who are not noticed by any other writer. His work, originally written in the Latin language, has been printed many times, and translated into all the modern languages. The first impression of it appeared at Venice, in the year 1497, in folio; an English translation of it was published in 1741, fol. A copy of this edition was in the library of Sir Hans Sloane, now in the British Museum. Laurence Joubert published a translation of it into the French language, with explanatory notes and observations, at Lyons, in the year 1785, 4to. Haller Bib. Chirug. Eloy. Dict. Med.

CAULIAS, an appellation given to the juice drawn from the stalk of the filphium, contradistinguished from that drawn from the root of the same plant, which is called rhizias.

Schroder makes the caulias the same with our assafetida.

CAULICI, in *Ancient Geography*, the name of a nation which inhabited the coast of the Ioman sea. Steph. Byz.

CAULICOLES, **CALICULI**, in *Archibotany*, denotes those eight lesser branches, or stalks, in the Cornithian capital, which spring out from the four greater principal caules, or stalks.

The word comes from the Latin *caulis*, the stalk, or stem of a plant.

The volutes of this order are sustained by four caules, or primary branches of leaves; from which arise these caulicoles or lesser foliages.

Some authors confound the caulicoles with the volutes

themselves; some with the helices in the middle, and some with the principal stalks whence they arise.

CAULITEROUS **HERBS**, are such as have a true caulis, stalk, or trunk, which a great many have not; as the capillaries, &c.

They are sometimes divided into *cauliferous*, and *acaulifera*. The former are either perfectly cauliterous, as cabbage; or imperfectly, as mallow.

CAULI-LOWER, in *Botany*. See **BRASSICA CLERAREE**.

CAULI-LOWER, in *Gardening*, an esculent plant belonging to the genus *Brassica*. It is said to have been first brought to this country from the island of Cyprus. By cultivation, this fine vegetable has lately been much improved in size, as well as in its other properties, and become common at our tables during the greatest part of the summer month, and even in the beginning of the autumn. See **BRASSICA**.

CAULI-TINE, in *Botany*, a term applied to the leaves, &c. of that when they proceed from the stem, in contradistinction to those which proceed from the root or branches.

CAULIFLUA, (in Honour of Filippo Cavolin, a Neapolitan gentleman, author of several works on botany and zoology,) a genus separated from *Najas* by Willdow, and described by him in a dissertation published in the memoirs of the Royal Academy of Berlin, 1784, and republished in the *Annals of Botany*, vol. 2. Class and order, *monoclam menandria*. Nat. Ord. *Junciales*, Linn. *Najas*. J. ff.

Gen. Ch. Mle. Cal. none. Cor. none. Stam. filament none; anther oblong, deflexed at the tip. Female. Cal. none. Cor. none. Pstl. g. m. egg-flapped; style filiform, eductuous; stigma bifid. Peric. capsule oblong, one-seeded. Seed oblong, egg-shaped.

Sp. 1. *C. fragilis*. Willd. Ann. Bot. tab. ii tab. 1. fig. 2. (*Najas* 9. Linn. Sp. Pl. N. Minor. Alton, Persem. 2106. Schuhr. Bot. Haid. 3 tab. 2/6. Fluvialis minor. Michx. gen. tab. 8. fig. 3.) "Leaves ternate or opposite, linear awl-shaped, recurved, prickly-toothed, rigid." *Roots* filiform, quere simple, very long and perpendicular. *Stems* in one to seven inches long, branched from the base, diffusely ascending; branches dichotomous, smooth, compressed. *Leaves* 1/4 inch long or more, acute, proceeding from a roundish membranous sheath; teeth alternate, membranous. *Flowers* axillary; stigmas one, two or three. The whole plant very brittle; so much so that when fresh, the stalk and leaves will break to pieces if touched by the hand. A native of lakes and rivers in Italy, France, and Germany. 2. *C. indica*. Willd. Ann. Bot. tab. 2. "Leaves ternate or opposite, linear, awl-shaped, repand; younger ones bristly-toothed." *Stem* a foot and half or two feet long, swimming, round, filiform, dichotomously branched. *Leaves* spreading, bright. *Flowers* axillary, sessile; germ oblong; style filiform; stigmas two, simple. It differs from the preceding species in being large, flexible, and not in the least brittle; its leaves are not recurved; when young, they have sharp, bristle-shaped teeth, which afterwards drop off, whence the full grown leaves become smooth at the border. A native of Tranquebar. 3. *C. flexilis*. Willd. Ann. Bot. tab. 1. fig. 1. "Leaves in six or seven, toothed at the tip, spreading." *Stem* a foot long, firmest at the dichotomous, branched, filiform, round. *Leaves* which, the long quere entire towards the bottom. *Flowers* axillary, sessile; germ oblong; style filiform; stigmas two, simple. A native of Pennsylvania. The whole plant in all the species is constantly immersed in water.

CAULIS, in *Botany*, $\alpha\upsilon\lambda\omicron\varsigma$, $\sigma\tau$, as defined by Theophrastus, is that part of a plant which rises above the ground in a single stock, and is common to annuals and perennials, though, as the venerable botanist observes, in trees it has a peculiar name, and is called $\sigma\tau\alpha\gamma\epsilon\sigma$, or trunk, in the common English sense of the word. The Latin writers seem to confine the term to the stem of herbaceous plants. According to Linnæus, in his *Philosophia Botanica*, it is a species of trunk in its most extensive signification; denoting, in the language of the great Swedish botanist, the organ which multiplies the plant, or, in plainer language, that part in every plant which rises above the ground, and supports the parts of fructification, either with or without branches and leaves. See **TRUNK**.

The **caulis** or stem, in the Linnæan sense of the word, is the most common kind of trunk, that which supports some of the leaves, as well as the fructification: but Willdenow, in his *Principles of Botany*, confines the term to herbaceous plants, and considers the trunk as peculiar to trees and shrubs.

Stems are distinguished from each other as they are,

1. *Simple*, or proceed in a single unbroken form nearly to the summit of the plant. In this point of view they are either quite entire, i. e. without branches; or nearly so, i. e. furnished with only a comparatively few branches, and those so small as not to destroy the integrity of the stem.
2. *Compound*; so subdivided as nearly to lose the appearance of a stem.
3. *Dichotomous*; always divided into pairs as in viscum album, mistletoe, valeriana locusta, corn salad, &c.
3. *Flexuose*, or bending in a zigzag manner, so as to form a number of alternate curves or very obtuse angles.
4. *Climbing*, (scandens); too weak to support itself, and therefore seeking support from other bodies.
5. *Twining*, (volubilis); ascending in a spiral direction round the stem or branches of another plant, or any kind of foreign prop. In some plants, as in humulus, helixine, lonicera, and tamus, the direction is from left to right, i. e. according to the course of the sun as seen by a spectator in our hemisphere with his face to the south: in others, as convolvulus, phaseolus, &c. from right to left, or opposite to the course of the sun.
6. *Erect*; nearly perpendicular.
7. *Nodding*; with the upper part bent outwards towards the horizon.
8. *Incurved*; with the upper part bent inwards.
9. *Declining*; bent downwards so as to form an arch.
10. *Ascending*; growing first in an horizontal direction, and afterwards curving upwards.
11. *Procumbent*; feeble and resting on the ground.
12. *Decumbent*; upright near the root, but afterwards bent down, so that the greatest part of it is procumbent.
13. *Creeping*, (repens); running along the ground, and here and there throwing out roots.
14. *Sarmentous*; filiform, almost naked; or having leaves in bunches only at joints or knots where it strikes root.
15. *Rooting*, (radicans); throwing out lateral radicles, by which it attaches itself to other plants for sustenance or support; as in cucurta, and hedera helix.
16. *Parasitical*; growing entirely on other plants; as viscum, epidendrum, tillandria.
17. *Articulated*; having joints at certain distances.
18. *Knotty*, (nodosus); swollen at the joints.
19. *Geniculated*; knee-jointed, bending at the joints somewhat in the manner of the human knee.
20. *Round*, (teres); cylindrical, without angles.
21. *Half-round*, (semiteres); round on one side, and flat on the other.
22. *Compressed*; having two opposite flat sides.
23. *Acinapital*; two-edged, compressed with sharp edges.
24. *Angular*; having more than two angles separated by angular or curved hollow spaces.
25. *Triquetrous*, &c. three-sided, &c. having the spines between the angles perfectly flat.
26. *Trigonous*, &c. having the spaces between the angles convex.

Linnæus is by no means clear in his definitions of the last three terms, and is differently understood by different authors. We have

endeavoured to construct ours so as to convey distinct and precise ideas; permitting however, that an attention to the etymology of the words is more likely to confound than to enlighten; but for this we are not answerable.

27. *Winged*, (alatus); with a membranous dilatation on each side.
28. *Furrowed*, (sulcatus); fluted or grooved, marked with deep, broad, longitudinal channels.
29. *Striated* or *streaked*; scored with shallow, slender, longitudinal lines.
30. *Even*, (levis); with a level surface, i. e. not furrowed or striated.
31. *Rugged* or *scabrous*; rough with tubercles, or prominent fluish points.
32. *Muricated*; armed with sharp awl-shaped points.
33. *Smooth*, (glaber); with a polished surface, free from every kind of roughness.
34. *Tomentous*; covered with soft hairs so interwoven as to be scarcely discernible.
34. *Villose*; covered with soft close hairs, forming a fine nap or pile like velvet.
35. *Hispid*; beset with stiff bristles.
36. *Sheathed*, (vaginatus); surrounded with the lower part of the leaves.
37. *Perfoliate*; passing through the leaves, as in bupluram rotundifolium, expressly called in English thorough-wax.

CAULKING, **CAUKING**, or **CAUKING**, in *Ship Building*, the operation of driving a quantity of oakum, or old ropes untwined and drawn asunder, into the seams of the planks, or into the intervals where the planks are joined to each other in the sides or decks of the ship, in order to prevent the entrance of water. After the oakum is driven very hard into these seams, it is covered with hot melted pitch or resin, to keep the water from rotting it. The firm among the ancients, who made use of pitch in caulking, were the inhabitants of Phœnicia, afterwards called Corsica. Wax and resin appear to have been commonly used previous to that period; and the Persians, at this time, use a sort of unctuous clay for the same purpose. Kennet derives the word from the barbarous Latin *caulicatura*, *floeing*.

CAULKING IRONS, are iron chisels for driving the oakum into the seams. Some of these irons are broad, some round, and others grooved.

CAULNE, in *Geography*, a town of France, in the department of the North Coasts, and district of Dinas; $3\frac{1}{2}$ leagues S.W. of Dinas.

CAULON, **CAULONIA**, or **VALLONIA**, in *Ancient Geography*, a small town of Italy, situate on the east coast of Brutium. N. of Locri, and S.W. of the promontory Cocintum. It was founded by a colony of Achæans, and for a time made a part of the territory of the Locrians Epizephyxians. This city was demolished, and its inhabitants transported into Sicily by Dionysius the tyrant about 400 years B. C. Ovid and Virgil mention it; but it did not subsist in the time of Ptolemy.

CAUM, a place of Spain, marked, in the Itinerary of Antonine, between Osea and Merdiculeia.

CAUMANA, one of the branches of the river Indus, near its mouth, according to Arrian.

CAUMONT, in *Geography*, a town of France, in the department of the Calvados, and chief place of a canton, in the district of Bayeux; 4 leagues S.S.W. of Bayeux. The place contains 2151, and the canton 11,836 inhabitants: the territory includes 170 kilometres and 20 communes.

CAUNE, **LA**, a town of France, and principal place of a district in the department of the Tarn; 7 leagues E.N.E. of Castres. The place contains 2438, and the canton 7351 inhabitants: the territory comprehends 285 kilometres and 8 communes.

CAUNES, **LES**, a town of France, in the department of Aude, and district of Carcassonne; 7 leagues W.N.W. of Narbonne, and $3\frac{1}{2}$ N.E. of Carcassonne.

CAUNENUS, in *Ancient Geography*, a see of Asia Minor, in Lycia.

CAUNGA,

CAUNGA, in *Botany*, Rhed. Mal. See *ARDEA Ca-techu*.

CAUNGLASS-POINT, in *Geography*, a cape on the southern coast of Dingle bay, county of Kerry, Ireland. N. lat. 51° 58'. W. long. 10° 8'.

CAUNI, in *Ancient Geography*, a people of Mauritania, according to Ptolemy.

CAUNIA, the inhabitants of CAUNUS.

CAUNRA-HEAD, in *Geography*, a cape of the county of Kerry, Ireland. N. lat. 52° 8' 30". W. long. 10° 16'.

CAUNUS, (Sphinx) in *Entomology*, a variety of the Fabrician SPHINX *Andromacha*, is described by Cramer under this name.

CAUNUS, in *Ancient Geography*, *Monaco*, a mountain of Spain, placed by Livy in Celtiberia.—Allo, a town in the island of Crete. Steph. Byz.—Allo, a town of Æolia.—Allo, a town of Asia Minor, in Ionia.—Allo, a town of Caria, on the northern side of the Doride, called "Rhodiorum" or of the Rhodians. It was situated at the foot of mount Tabeus, W. of the small gulf of Glaucus. The air was proverbially infalubrious in summer and autumn, on account of the extreme heat, and the evil was increased by the abundance of its fruits. Steph. Byz. says, that this city took its name from Caunus, known in fabulous history for his incestuous love of his sister Biblilis; whence the proverb denoting this sort of attachment, viz. ὁ Καυνὸς ἔγας, *Caunus Anor*. This city was the native place of the celebrated painter Protegenes. The citadel, according to Strabo, was above the town, and called "Imbros." It has been conjectured that the ancient Caunus has been occupied by the town now called Kaigenez.

CAUPHIACA, a town of Persia, in the interior of the country, according to Ptolemy.

CAURALE, *Buffon*, and CAURALE *Snipe*, of Latham, in *Ornithology*. See *ARDEA HELIAS* of Pallas and Gmelin.

CAURANANI, in *Ancient Geography*, a people of Arabia Felix, whose name denotes their wealth in cattle, according to Pliny.

CAURASIE, a people of Spain, in Bætica.

C. AUREUM, in *Entomology*, a species of PAPHIO, the wings of which are indented, tailed, fulvous with black spots; posterior pair marked beneath with a golden C. Fabricius. This insect inhabits Asia.

CAURIENSES, in *Ancient Geography*, a people of Spain in Lusitania, according to Pliny, who inhabited the town called by Ptolemy *Caurium*; which M. d'Anville places in the country of the Vettones, N. E. of Norba Cæsarea.

CAURIS, in *Conchology*, a name by which certain authors formerly distinguished shells of the CYPRÆA genus. The word cauris is of Indian origin, being the name by which the small *money-couries* are known among the natives of the West Indian islands. It is from a false pronunciation of the word cauris, that these shells are now called *cowries* or *gowries*. See CYPRÆA.

CAURO, in *Geography*, a town of the island of Corsica, or the department of Golo; 9 miles E. S. E. of Ajazzo.

CAURROY, FRANCIS EUSTACHE DU, in *Biography*, an eminent French musician, was born in 1549; and became master of the chapel to the kings Charles IX. Henry III. and IV., and also canon of the holy chapel in Paris, and prior of St. Anoul. By his contemporaries he was named the prince of musicians; and he was much beloved by cardinal du Perron, who frequently wrote verses for him to set to music, and composed a pompous epitaph for his tomb. He died in 1609, and was buried in the church des Grands Augustins at Paris. Of his works, which never seem to

have been known out of France, there remain a "Mets for the Dead," for four voices, which used to be sung annually in the cathedral of Paris, on the commemoration of the faithful deceased; and a book called "Mélanges de la Musique de Lutharic de Caurroy," Paris, 1710. This last is said to be the origin of most of the Chrittian carols sung in France. The merits of this composer will appear to a modern musical critic to have been much over-rated. Burney's *HIST. of Music*, vol. iii.

CAURSINES, *Caursini*, in *English History*, denote Italian bankers or money-changers, who flocked into England, France, and the Nethelands, about the year 1235, calling themselves the pope's merchants, but, by departing from the proper business of merchants, and becoming agents for the pope in his various transactions, they rendered themselves as odious as the Jews. According to Matthew Paris, a contemporary historian, they sometimes exacted no less than 60 per cent. interest per annum. This, together with their ostentatious display of their riches, drew upon them a very severe prosecution. They were several times banished the kingdom for their extortions, and re-admitted by the interrel and intrigues of the popes. Mat. Paris. *Hist. Ang.* p. 403. Du-Cauge.

They are also called *caorcini*, *coarcini*, *catarcini*, *cawarcini*, and *cofsini*. Some will have the name formed from *Caors*, *Cabors*, a city of France, where they flourished more than ordinarily. Others derive it from the *Corfsini*, a family of wealthy merchants at Florence.

CAUS, in *Ancient Geography*, a village of Peloponnesus, in Arcadia, and in the country of Telephusia. According to Steph. Byz. and Pausanias, Æsculapius was worshipped here under the appellation of "Causian."

CAUSA *Matrimonii præloenti*, in *Law*, a writ that lies when a woman gives land to a man in fee, or for life, to the intent he shall marry her, and he refuses to do it in a reasonable time; and in such case for not performing the condition, the entry of the woman into the lands again has been adjudged lawful. The husband and wife may sue this writ against another, who ought to have married her.

CAUSA *Nobis significas*, a writ directed to the mayor of a town, &c. who being by the king's writ commanded to make seisin of lands to the king's grantee, delays doing it. The writ requires him to shew *cause* of the delay.

CAUSALITY, or CAUSATION, in *Metaphysics*, the power or action of a cause in producing its effect.

It is a dispute among the school-philosophers, whether, and how the causality is distinguished from the cause and effect? Some held it a mode, or modal entity, superadded to the cause, &c. others contend for its being the cause itself, only considered *principiative* and *terminative*, &c. See CAUSE.

CAUSALTY, in *Metalurgy*. See CASUALTY.

In the tin-works the causality is thrown in heaps upon banks, which in six or seven years they work over again, and receive a new supply of metal from it. Phil. Trans. N° 138. p. 952.

CAUSE, CAUSA, that which contributes to the production of an effect; or that by virtue whereof a thing is done, or from which it proceeds.—In which sense, *cause* stands essentially related to effect.

In every part of natural philosophy, it is assumed as a fundamental principle or axiom, that no event or change comes to pass merely of itself, that is, without relation to any thing else; but that every change stands related to, and implies the existence and influence of something else, in consequence of which such change came to pass, and which may be regarded as the principle, beginning, or source of the change

change referred to it. Accordingly, the term *cause* is usually employed to denote the supposed principle of change; and the term *effect* is applied to the change considered in its relation to the principle of change whence it proceeded; for it must be observed, that both these terms, as commonly used, are relative. The axiom or principle, to which we have above referred, is usually thus expressed; "For every effect there must be a cause:"—"Nothing exists, or nothing comes to pass, without a cause:"—"Nihil turpius philosopho quam fieri sine causa quicquam dicere." This principle, which is the foundation of natural philosophy, has been regarded both as a physical and as a metaphysical axiom: physical, as expressing an important general fact with respect to the material world; metaphysical, as expressing a corresponding law of human thought, or something which all men of competent judgment think, and cannot help thinking. This axiom, however, though it must be admitted as unquestionably true, has not precluded a difference of opinion with regard to the meaning of the term *cause*, and the relation conceived to subsist between *cause* and *effect*. Mr. Hume is represented by Dr. Reid, as the first author, who maintained (*ubi infra*), that we have no other notion of a cause, but that it is something prior to the effect which has been found by experience to be constantly followed by the effect; but it will appear in the sequel of this article, that a similar opinion, at least with regard to physical causes and effects, had been maintained long before, as well as after his time. Accordingly, his theory regarded events as simply conjoined, and not connected together by any conceivable process, nor produced the one from the other by any operative principle. As all our reasonings concerning matter of fact seem to be founded on the relation of "cause and effect," it is of importance to investigate, and, if possible, to ascertain this relation. Mr. Hume affirms, as a general proposition, admitting of no exception, that the knowledge of this relation is not, in any instance, attained by reasonings *a priori*; but arises entirely from experience, when we find, that any particular objects are constantly conjoined with each other. Let an object, says this acute writer, be presented to a man of ever so strong natural reason and abilities; if that object be entirely new to him, he will not be able, by the most accurate examination of its sensible qualities, to discover any of its causes or effects; nor, he says, can our reason, unassisted by experience, ever draw any inference concerning real existence and matter of fact. This proposition, he alleges, will readily be admitted with regard to such objects, as we remember to have been once altogether unknown to us; since we must be conscious of the utter inability, which we then lay under of foretelling what would arise from them. Such events as bear little analogy to the common course of nature, are also readily confessed to be known only by experience. The case is the same, when an effect is supposed to depend upon an intricate machinery, or secret structure of parts, for we then do not hesitate in attributing all our knowledge of it to experience. But the same truth may not appear to have the same evidence, with regard to events which have become familiar to us from our first appearance in the world, which bear a close analogy to the whole course of nature, and which are supposed to depend on the simple qualities of objects without any secret structure of parts. Such effects we are apt to imagine that we may be able to discover by the mere operation of our reason, without experience. But, in order to convince us that all the laws of nature, and all the operations of bodies, without exception, are known only by experience, Mr. Hume suggests a variety of reflections. The mind, he says, can never possibly find the effect in the

supposed cause, by the most accurate scrutiny: for the effect is totally different from the cause, and consequently can never be discovered by it. And as the first imagination or invention of a particular effect, in all natural operations, is arbitrary, where we do not consult experience; so must we also esteem the supposed type or connection between the cause and effect, which binds them together, and renders it impossible, that any other effect could result from the operation of that cause. Moreover, after we have experience of the operations of cause and effect, our conclusions from that experience are not founded on reasoning, or any process of the understanding. For the author's illustration of this remark, and the evidence adduced in support of it, we must refer to his own train of arguments *ubi infra*. Experience, says Dr. Brown, can inform us only of the past. But the relation of cause and effect has reference to *future* and *invariable* antecedence and sequence, of which our experience can inform us. We believe it indeed, irresistibly; and the belief is not denied; it is only the attempt to found the belief on reason which this proposition opposes. He who asserts, that *A will always be followed by B*, asserts, *more* than he who asserts, that *A has always been followed by B*; and it is this addition which forms the very essence of the relation of cause and effect. Neither of the propositions includes the other; and, as they have no agreement, *reason*, which is the *sense of agreement*, cannot be applied to them. 'Till it be shewn, that the future is involved in the past, we must allow the truth of Mr. Hume's second proposition, that even after experience, the relation of cause and effect cannot be discovered by *reason*. Mr. Hume advances, in the course of his reasoning on this subject, a third proposition, which is, that the relation of cause and effect is an object of belief alone; and this, it has been said, must be admitted, if the two former propositions be received. This belief, not the result of reason, is derived from our nature, and, in its operation, is as certain and powerful as if it were an inference established by a reasoning process. As soon as we believe the relation of cause and effect, the idea of power arises; which idea consists not in the antecedence of one event to another, which has been uniform in all preceding cases, but in the uniform and invariable antecedence that shall take place in all future cases.

A *cause*, says Dr. Priestley, a late zealous advocate for the doctrine of necessity, cannot be defined to be any thing but "such previous circumstances as are constantly followed by a certain effect;" the constancy of the result making us conclude, that there must be a sufficient reason in the nature of things, why it should be produced in those circumstances.

Another ingenious writer (professor Dugald Stewart) who seems to have adopted Hume's general theory with regard to causation, as it respects physical causes, observes, as a fact pretty generally admitted among philosophers, that there is no instance in which we are able to perceive a necessary connexion between two successive events; or to comprehend in what manner the one proceeds from the other. From experience, indeed, we learn that there are many events, which are constantly conjoined, so that the one invariably follows the other; but it is possible, for any thing we know to the contrary, that this connexion, though a constant one, as far as our observation has reached, may not be a necessary connexion; nay, it is possible, that there may be no necessary connexions among any of the phenomena we see; and if there are any such connexions existing, we may rest assured that we shall never be able to discover them. This author remarks that the word *cause* is used, both by philosophers and the vulgar, in two senses that are widely different. When it is said, that every change in nature indicates the operation of a

cause, the word *cause* expresses something which is supposed to be necessarily connected with the change; and without which it could not have happened. This may be called the *metaphysical* meaning of the word; and such causes may be called *metaphysical* or *efficient* causes. In natural philosophy, however, when we speak of one thing being the cause of another, all that we mean is, that the two are constantly conjoined; so that when we see the one, we may expect the other; these conjunctions we learn from experience alone; and without an acquaintance with them, we could not accommodate our conduct to the established course of nature. The causes, which are the objects of our investigation in natural philosophy, may, for the sake of distinction, be called *physical* causes. This doctrine, says this ingenious writer, concerning the object of natural philosophy, is not altogether agreeable to popular prejudices. It is a curious question, what gives rise to prejudices of this kind? In stating the argument for the existence of the deity, several modern philosophers have been at pains to illustrate that law of our nature, which leads us to refer every change we perceive in the universe to the operation of an efficient cause. This reference is not the result of reasoning, but necessarily accompanies the perception, so as to render it impossible for us to see the change, without feeling a conviction of the operation of some cause by which it was produced; much in the same manner in which we find it to be impossible to conceive a sensation, without being impressed with a belief of the existence of a sentient being. Hence it is, as professor Stewart conceives, that when we see two events constantly conjoined, we are led to associate the idea of causation, or efficiency, with the former, and to refer it to that power or energy by which the change was produced; in consequence of which association, we are led to consider philosophy as the knowledge of efficient causes; and lose sight of the operation of the mind, in producing the phenomena of nature. By an association somewhat similar, we connect our sensations of colour with the primary qualities of bodies. In the same way we associate with inanimate matter the ideas of power, force, energy, and causation; which are all attributes of mind, and can exist in a mind only. Our language also, with respect to cause and effect, is borrowed by analogy from material objects; and hence we transfer to certain events the same language which we apply to connected objects. Thus, we speak of a connection between two events, and of a chain of causes and effects. This language is purely analogical, and our knowledge of physical events is restricted to the laws which regulate this succession; and yet it has misled the greater part of philosophers, and has had a surprising influence on the systems, which they have formed in very different departments of science. The maxim that nothing can act, but where it is and when it is, has been always admitted with respect to metaphysical or efficient causes. Whatever objects, says Mr. Hume, are considered as causes or effects, are contiguous; and nothing can operate in a time or place which is ever so little removed from those of its existence; we may therefore, he adds, consider the relation of contiguity as essential to that of causation. But admitting this maxim in relation to causes which are efficient, and which as such are necessarily connected with the effects, there is surely no good reason, professor Stewart conceives, for extending it to physical causes, of which we know nothing, but that they are the constant forerunners and signs of certain natural events. According to this doctrine, indeed, it may be improper to retain the expressions cause or effect, in natural philosophy; but as long as the present language upon the subject continues in use, the propriety of its application, in any particular instance, does not depend on the contiguity of the two events in place or time, but solely on this question, whether the one event be the

constant and invariable forerunner of the other, so that it may be considered as its infallible sign? Notwithstanding, however, the evidence of this conclusion, philosophers have in general proceeded upon a contrary supposition; and have discovered an unwillingness, even in physics, to call one event the cause of another, if the smallest interval of space or time existed between them. In the case of motion, communicated by impulse, they have no scruple to call the impulse the cause of the motion; but they will not admit that one body can be the cause of motion in another, placed at a distance from it, unless a connexion is carried on between them, by means of some intervening medium.

Mr. Hume's theory on the subject of causation, and the relation between cause and effect, has occasioned alarm, and excited an apprehension that it sapped the foundation of those arguments and processes of reason, by which the existence and superintendance of a Deity are illustrated and established. Hence its truth has been disputed and denied; and without considering that the fallacy of the system does not consist in his premises, but in the conclusion which he draws from them, it has been represented as favourable to infidelity. But it ought to be recollected, that the principle which has been frequently ascribed to Mr. Hume as its author, both by his followers and his opponents, or that of restricting the physical inquirer from tracing necessary connections or ascertaining the efficient causes of phenomena, is of a much earlier date, and has been maintained by many of the most enlightened and the least sceptical of our modern philosophers; nor does its dangerous tendency seem to have been suspected till the publication of Mr. Hume's writings, and the gross misapplication which he made of his premises for invalidating the argument for the existence of the Deity derived from his works. An opinion coinciding remarkably with that advanced and illustrated by Mr. Hume is ascribed to Socrates by Xenophon. The sophists in ancient Greece, like their successors in modern times, appear to have entertained some confused notions about a necessary connexion between cause and effect, implying the existence of an operating principle in the cause; they inquired, says Xenophon, "ΤΙΝΙ ΑΝΑΓΚΑΙΣ ΙΚΑΝΑ ΖΗΤΩΝ ΤΩΝ ΦΥΣΙΚΩΝ." The same excellent writer informs us in what light Socrates regarded these by whom such notions were adopted. "ΑΛΛΑ ΚΑΙ ΤΟΥΤΕ ΦΡΟΝΤΙΖΟΝΤΑΣ ΤΑ ΤΟΙΑΥΤΑ ΜΟΡΠΑΙΝΟΝΤΑΣ ΕΠΙΔΕΙΚΝΥΝΤΕΝ." Afterwards he adds, "Εβραμαζομένη, η μη φασιν αληθιν ιστιν, οτι ταυτα εδυνατον ιστιν εβραμαζομενην."

"If we except," says Dr. Barrow (Mathematical Lectures read at Cambridge), "the mutual causality and dependence of the terms of a mathematical demonstration, I do not think there is any other causality in the nature of things, wherein a necessary consequence can be founded. Logicians do indeed boast of I do not know what kind of demonstrations from external causes, either efficient or final; but without being able to shew one genuine example of any such; nay, I imagine, it is impossible for them to do. For there can be no such connexion of an external efficient cause with its effect," (or at least none such can be understood by us) "through which, strictly speaking, the effect is necessarily supported by the supposition of the efficient cause, or any determinate cause by the supposition of the effect." He adds afterwards, "therefore there can be no argumentation from an efficient cause to the effect, or from an effect to the cause which is lawfully necessary."

"All things," says Dr. Clarke (Works, vol. ii. p. 698. fol. ed.) "that are done in the world, are done either immediately by God himself, or by created intelligent beings; matter being evidently not at all capable of any laws or powers whatsoever, any more than it is capable of intelli-

gence;

gence; excepting only this one negative power, that every part of it will, of itself, always and necessarily continue in that state, whether of rest or motion, wherein it is at present is. So that all those things which we commonly say are the effects of the natural powers of matter and laws of motion, of gravitation, attraction, or the like, are indeed (if we will speak strictly and properly) the effects of God's acting upon matter continually, and every moment, either immediately by himself, or mediately by some created intelligent beings. Consequently there is no such thing as what men commonly call the course of nature, or the powers of nature. The course of nature, truly and properly speaking, is nothing else but the will of God producing certain effects in a continued, regular, constant, and uniform manner."

Dr. Butler also, in his Discourse on the ignorance of Man (Sermons) has remarked, "that it is in general no more than effects that the most knowing are acquainted with; for as to causes they are as entirely in the dark as the most ignorant." "What are the laws," he continues, "by which matter acts on matter, but certain effects, which some, having observed to be frequently repeated, have reduced to general rules?" "The laws of attraction and repulsion," says Dr. Berkeley (Siris, p. 108.) "are to be regarded as laws of motion, and these only as rules or methods observed in the productions of natural effects, the efficient and final causes whereof are not of mechanical consideration. Certainly, if the explaining a phenomenon be to assign its proper efficient and final cause, it should seem the mechanical philosophers never explained any thing; their province being only to discover the laws of nature, that is, the general rules and methods of motion; and to account for particular phenomena, by reducing them under, or shewing their conformity to such general rules:"—With more to the same purpose. Professor Stewart has also cited a very remarkable passage from Mr. Locke (Ess. b. ii. c. 23. § 28, 29), which shews clearly, that this eminent philosopher considered the connection between impulse and motion as a conjunction which we learn from experience only, and not as a consequence deducible from the consideration of impulse, by any reasoning *à priori*. The passage is the more curious, because it is this particular application of Mr. Hume's doctrine, that has been generally supposed to furnish the strongest objection against it. Some of Mr. Hume's reasonings concerning the nature of the connections among physical events coincide perfectly with those of Malebranche on the same subject; though they were employed by this last writer to support a very different conclusion.

The author of the "Procedere, Extent, and Limits of Human Understanding," (said to be Dr. Peter Brown, bishop of Cork), lays it down as the first fundamental unerring rule in physics, that it is not within the compass of human understanding to assign a purely speculative reason for any one phenomenon in nature. By a speculative reason, the writer means, assigning an *efficient cause à priori*, together with the manner of its operation, for any effect whatsoever purely natural. "We find, indeed," he adds, "by observation and experience, that such and such effects are produced; but when we attempt to think of the reason why and the manner how the causes work those effects, then we are at a stand, and all our reasoning is precarious, or at best but probable conjecture."

At a still earlier period, Hobbes expressed himself (see his Tripos), with respect to physical connections, in terms so nearly approaching to Mr. Hume's, that it is difficult to suppose that they did not suggest to him the language which he has employed on that subject. "What we call experience," he remarks, "is nothing else but remembrance of what antec-

edents have been followed by what consequents." "No man," he continues, "can have in his mind a conception of the future; for the future is not yet; but of our conceptions of the past we make a future, or rather call past future, relatively;" &c. &c. Lord Bacon also hath plainly taken for granted the doctrine now under consideration, without formally stating it, in all his reasonings on the method of prosecuting philosophical discoveries; for if we could perceive in any instance the manner in which a cause produces its effect, we should be able to deduce the effect from its cause by reasoning *à priori*; the impossibility of which he every where strongly inculcates. "Homo nature minister et interpret tantum facit et intelligit quantum de nature ordine re veliente observaverit; nec amplius scit aut potest." However, lord Bacon's metaphysical notions on this subject do not seem from other passages in his writings to have been very accurate.

The consistency of Mr. Hume's fundamental principle, independently of his application of it, with the most devout impressions concerning the existence and the power of God, is sufficiently evinced by the testimonies of the excellent writers already cited. If it be alleged, that the passages above quoted are furnished by authors prior to Mr. Hume, and who were not fully aware of the consequences which he was afterwards to deduce from them; the following authorities are collected from philosophers and divines of a later date.

"What we observe by our external senses," says Dr. Price (Review of the principal Questions and Difficulties in Morals), "is properly no more than that one thing follows another, or the constant conjunction of certain events, as of the melting of wax, with placing it in the flame of a candle; and, in general, of such and such alterations in the qualities of bodies, with such and such circumstances of their situation. That one thing is the cause of another, or produces it by its own efficacy and operation, we never see."

"With regard to the phenomena of nature," says Dr. Reid (ubi infra), "the important end of knowing their causes, besides gratifying our curiosity, is, that we may know when to expect them, or how to bring them about. This is often of real importance in life; and this purpose is served by knowing what by the course of nature goes before them, and is connected with them; and this, therefore, we call the cause of such a phenomenon." See the sequel of this article.

"There is no necessary connection," says Dr. Waring, Lucasian professor of mathematics in the university of Cambridge, whose zeal for the peculiar doctrines of Christianity has never been questioned, in his "Essay on the Principles of Human Knowledge," "known to us between cause and effect. Can any person by reasoning, independent of experience, from the cause deduce the effect? No one ever has; and, consequently, to mankind there is no necessary connection known between cause and effect." "Is it probable," continues this author, "that any necessary connection is contained in their own nature?" "Newton's conjectures," says the late professor Robison, in his "Mechanical Philosophy," was owing to the modesty of his procedure. He peremptorily rejected all disposition to speculate beyond the province of human intellect, conscious that all attainable science consisted in carefully ascertaining nature's own laws; and that every attempt to explain an ultimate law of nature, by assigning its cause, is absurd in itself, and against the acknowledged laws of judgment, and will most certainly lead to error. It is by following his example that we can hope for his success." For Dr. Gregory's sentiments on this subject, see the sequel of this article.

The language of Mr. Hume, as professor Stewart observes, has even been adopted by philosophers, and by atheists as well as theists. The latter have represented natural events as parts of a great chain, the highest link of which is supported by the Deity. The former have pretended, that there is no absurdity in supposing the number of links to be infinite. Mr. Hume, the professor adds, had the merit of shewing clearly to philosophers, that our common language, with respect to cause and effect, is merely analogical; and that if there be any links among physical events, they must for ever remain invisible to us. If this part of his system be admitted, and if, at the same time, we admit the authority of that principle of the mind, which leads us to refer every change to an efficient cause; Mr. Hume's doctrine seems to be more favourable to them than even the common notions upon this subject; as it keeps the Deity always in view, not only as the first, but as the constantly operating cause in nature, and as the great connecting principle among all the various phenomena which we observe; this, accordingly, was the conclusion which Malbranche deduced from premises very nearly the same with Mr. Hume's. That a necessary connection has been supposed to exist, among physical events by many philosophers, whom it would be unfair to charge with atheism, is a fact that must be allowed. It was the doctrine of the ancient fatalists, that all things above and below are linked together by an inevitable necessity; but they did not, therefore, deny the existence of God. "Cum fatum (says Seneca) nihil aliud sit quam series implexa causarum, ille est prima omnium causa ex qua cetera pendunt."

"While we condemn, therefore, the *conclusion* of Mr. Hume (so far as it has a tendency to weaken the evidence for the existence of the Deity) as sophistical and false, we are constrained," says professor Stewart, "not by that justice which is due to his philosophical abilities, but by our idleness to the cause for which we profess to combat, not to involve both *conclusion and premises* in the same condemnation."

Having stated Mr. Hume's theory of causation, and presented to the view of the reader some of those arguments and authorities that have been urged by its advocates, in order to vindicate it from those licentious consequences with which it has been charged; we shall now give as concise an account as possible of the sentiments of those who have differed from him with regard to this subject. To the class of such persons we may refer Dr. Reid, whose opinions and reasoning claim peculiar attention, and merit the directed examination. They will probably be no less satisfactory to many of the readers of this article, than to the compiler of it. Every thing that begins to exist, says this excellent writer, must have a cause of its existence, which had power to give it existence; and every thing that undergoes any change, must have some cause of that change. This principle appears very early in the mind of man; and it is so universal and so firmly rooted in human nature, that the most determined scepticism cannot eradicate it. From this principle it follows, that every thing which undergoes any change, must either be the efficient cause of that change in itself, or it must be changed by some other being. In the first case it is said to have *active power*, and to *act* in producing that change. In the second case it is merely *passive*, or is *acted upon*; and the active power is in that being only which produces the change. The name of a *cause*, and of an *agent*, is properly given to that being only, which, by its active power, produces some change in itself, or in some other being. The change, whether it be of thought, of will, or of motion, is the *effect*. Active power, therefore, is a quality in the cause, which enables it to produce the effect; and the exertion of that active power in producing the effect, is called *action, agency, efficiency*. In

order to the production of any effect, there must be in the cause not only power, but the exertion of that power: for power that is not exerted produces no effect. With regard to the opinion of Mr. Hume and his followers, who maintain, that a cause is only something prior to the effect, and constantly conjoined with it, Dr. Reid observes, that every man who understands the language knows, that neither priority, nor constant conjunction, nor both together, imply efficiency. Every man free from prejudice must assent to what Cicero has said: "Itaque non nisi causa intelligi debet, ut quod cuique antecedit, id et causa fit, sed quod cuique efficiens antecedit." In common language we say, the sun rises and sets, and comes to the meridian, the moon changes, the sea ebbs and flows, and the winds blow; and as languages were formed by persons who believed these objects to have life and active power in themselves, it was proper and natural to express their motions and changes by active verbs.

Our knowledge of the real causes of the phenomena of nature is very imperfect; but though our acquaintance with external objects must be grounded upon the information of our senses; yet causation and active power are not objects of sense, nor is that always the cause of a phenomenon which is prior to it, and constantly conjoined with it; otherwise night would be the cause of day, and day the cause of the following night. It is to this day problematical, whether all the phenomena of the material system be produced by the immediate operation of the first cause, according to the laws which his wisdom determined, or whether subordinate causes are employed by him in the operations of nature; and if they be, what their nature, their number, and their different offices are? And whether, in all cases, they act by commission, or, in some, according to their discretion? In consequence of this imperfect knowledge of the real causes of the phenomena of nature, ingenious men who have been desirous of exploring and ascertaining them, have formed numberless conjectures and theories: and unwilling to confess their disappointment in the search of causes, they have vainly conceived every thing they stumbled upon to be a cause; and the proper notion of a cause is thus lost, by giving the name to numberless things which neither are nor can be causes. In a very ancient system, love and strife were made the causes of things; in the Pythagorean and Platonick system, matter, ideas, and an intelligent mind; by Aristotle, matter, form, and privation; Des Cartes thought that matter, and a certain quantity of motion given at first by the Almighty, are sufficient to account for all the phenomena of the natural world. Leibnitz conceived that the universe is made up of monads, active and percipient, which, by their active power received at first, produce all the changes they undergo. In the ordinary concerns of life this confusion of various things under the names of causes is of little moment and influence; although it may be very hurtful to found philosophy. A constant antecedent or concomitant of the phenomenon whose cause is sought, may answer the purpose of the inquirer, as well as if the real cause were known. In compliance with custom, says Dr. Reid, or perhaps to gratify the avidity of knowing the causes of things, we call the laws of nature causes and active powers. Thus we speak of the powers of gravitation, of magnetism, and of electricity. But persons of juster discernment perceive, that the laws of nature are not agents; they are not endowed with active power, and therefore cannot in the proper sense be causes. They are only the rules according to which the unknown cause acts; hence it happens that the word *cause*, and other words bearing relation to it, become so ambiguous as to have, in a manner, lost their proper and original meaning; and

vet we have no other words to exprefs it. Every thing joined with the effect, and prior to it, is called its caufe. An inftrument, an occafion, a reafon, a motive, an end, are called caufes; and the related words, *effect*, *agent*, *power*, are extended in the fame vague manner. Were it not, continues this ingenious writer, that the terms *caufe* and *agent* have loft their proper meaning in the crowd of meanings that have been given them, we fhould immediately perceive a contradiction in the terms *necelfary caufe* and *necelfary agent*. If this necelfity, thus combined with caufe and agent, be attributed even to the Deity, it muft follow, that there neither is, nor can be, a caufe at all; that nothing acts, but every thing is acted upon; nothing moves, but every thing is moved; all is paffion without action; all inftrument without an agent; and that every thing that is, or was, or fhall be, has that necelfary excellance in its feafon, which we commonly confider as the prerogative of the firft caufe. If it be evident, fays Dr. Reid, that what begins to exift muft have an efficient caufe which had power to give or not to give it exiftence; and if it be true that effects well and wifely fitted for the beft purpofes, demonftrate intelligence, wifdom, and goodnefs, in the efficient caufe, as well as power, the proof of a Deity from thefe principles is very eafy and obvious to all men that can reafon. If, on the other hand, our belief, that every thing that begins to exift has a caufe, be got only by experience; and if, as Mr. Hume maintains, the only notion of a caufe be fomething prior to the effect, which experience has fhewn to be continually conjoined with fuch an effect, I fee not how from thefe principles, it is poffible to prove the exiftence of an intelligent caufe of the univerfe. Accordingly, Mr. Hume feems to reafon juftly from his definition of a caufe, when, in the perfon of an Epicurean, he maintains, that with regard to a caufe of the univerfe, we can conclude nothing; becaufe it is a fingular effect. We have no experience that fuch effects are always conjoined with fuch a caufe. Nay, the caufe which we affign to this effect, is a caufe which no man hath feen nor can fee, and therefore experience cannot inform us that it has ever been conjoined with any effect. Mr. Hume, according to Dr. Reid, feems to deduce a juft inference from his definition of a caufe, when he alleges that *any thing* may be the caufe of any thing; fince priority and conftant conjunction are all that can be conceived in the notion of a caufe.

The following confequences are ftated by Dr. Reid, as deducible from Mr. Hume's definition of a caufe. It follows, *firft*, he fays, that night is the caufe of day, and day the caufe of night; for no two things have more conftantly followed each other fince the beginning of the world. It follows alfo, *fecondly*, that, for what we know, any thing may be the caufe of any thing, fince nothing is effential to a caufe but its being conftantly followed by the effect. What is unintelligent may be the caufe of what is intelligent; folly may be the caufe of wifdom, and evil of good: and all reafoning from the nature of the effect to the nature of the caufe, and all reafoning from final caufes, muft be given up as fallacious. A *third* confequence from this definition is, that we have no reafon to conclude, that every event muft have a caufe; for innumerable events happen, when it cannot be fhewn that there were certain previous circumftances that have conftantly been followed by fuch an event. And though it were certain, that every event actually obferved by us had a caufe, it would not follow, that every event muft have a caufe; for it is contrary to the rules of logic to conclude, that becaufe a thing always has been, therefore it muft be; to reafon from what is contingent to what is necelfary. *Fourthly*, it

would follow, that we have no reafon to conclude that there was any caufe of the creation of this world; for there were no previous circumftances that had been conftantly followed by fuch an effect. And, for the fame reafon, it would follow from the definition that whatever was fingular in its nature, or the firft thing of its kind, could have no caufe. Having fhewn what he conceives to be the abfurd and dangerous confequences that follow from Mr. Hume's definition of a caufe, Dr. Reid propofes another not chargeable with fuch confequences. "Why," fays he, "may not an efficient caufe be defined to be a being that had power and will to produce the effect? The production of an effect requires active power, and active power, being a quality, muft be in a being endowed with that power. Power without will produces no effect; but when thefe are conjoined, the effect muft be produced. This, I think, is the proper meaning of the word *caufe*, when it is ufed in metaphyfics; and particularly when we affirm that every thing that begins to exift muft have a caufe; and when, by reafoning, we prove, that there muft be an eternal firft caufe of all things. Was the world produced by previous circumftances which are continually followed by fuch an effect? Or, was it produced by a Being that had power to produce it, and willed its production?"

"In natural philofophy," fays this ingenious writer, "the word *caufe* is often ufed in a very different fenfe. When an event is produced according to a known law of nature, the law of nature is called the caufe of that event. But a law of nature is not the efficient caufe of any event; it is only the rule, according to which the efficient caufe acts. A law is a thing conceived in the mind of a rational being, not a thing that has a real exiftence; and therefore, like a motive, it can neither act nor be acted upon, and confequently cannot be an efficient caufe. If there be no being that acts according to the law, it produces no effect."

It can hardly efcape our obfervation, fays Dr. Gregory, (*ubi infra*), that the notion of a caufe, as explained by Dr. Reid, is very different from that commonly adopted by philofophers, either metaphyficians or physical inquirers;—fo very different, indeed, that the axiom, "Every change or effect muft have a caufe," as underftood by him, will fcarcely be admitted even by physical inquirers; and will not only not be admitted by metaphyficians as a principle univerfally true, but will be regarded by many of them, efpecially by Dr. Prieftley, and all the difciples of Mr. Hume, as univerfally falfe, and even impoffible. Dr. Reid, like many preceding philofophers, had attended too much to one kind of *caufe*, or principle of change, namely, what a man, or any other living being, is to his own voluntary actions, or to thofe changes which he produces direftly in himfelf, and indireftly in other beings, by the occasional exertion of his own power. This kind of *caufe* may be called, for diftinction fake, exclufively an *agent*. That there are fuch agents, and that many events are to be referred to them, as either wholly or partly their caufes or principles of change, is allowed as not only certain, but even feifevident. Nevertheless, Dr. Gregory will not allow, that *all events*, without exception, are to be referred to fome *fuch caufes*, and necelfarily imply the operation of *agents*, and the exertion of *power*; becaufe he neither perceives it as a feifevident necelfary truth, nor has ever met with any evidence of it. To this author it appears, that Dr. Reid, and many philofophers, who have thought and argued nearly as he has done on this fubject, have gone as far wrong on one fide as Mr. Hume, Dr. Prieftley, or M. Leibnitz, or, in general, all affertors of the doctrine of necelfity, have done on the other. Thefe philofophers have attended too much

to another kind of cause, called, by way of distinction, *physical cause*; as, e. g. what impulse is to motion, heat to expansion, fusion, and evaporation, the earth to the fall of a stone towards it, the sun and moon to the tides, &c. That there are such causes, or, in other words, that we conceive some relation to subsist between the various things, and events respectively that have been mentioned, this relation we are accustomed to express by the terms *cause and effect*, as certain as that there are agents for other events. However, it seems evident, that these two relations are somehow different from one another; and that both of them are very different, and easily distinguishable, from various other relations of event. When heat is said to be the cause of the melting of ice, a certain relation is expressed between the heat and that event: but very different from that between a man and any of his voluntary actions; different also from that between motive and action; different even from that between evidence and belief; different from that between the vital principle of a plant or animal, and its growth, its functions, and diseases; different from that between the various occasional or exciting causes, (such as air, water, light, heat, cold, contagion, poison, &c.) and the growth, the functions, and the diseases of plants and animals; different even, in some measure, from that between impulse and motion; and different from that between any body and the fall, or tendency to fall, of another body towards it. All these relations, and such like, are easily distinguishable from one another; and cannot be confounded, by any thinking and discerning person, with the simple relation of priority and succession among things and events; as, e. g. between the morning dawn and the rising of the sun. No man surely ever regarded the dawn as the cause of the rising of the sun, or night as the cause of day. But as the philosophy of Mr. Hume, adopted by other metaphysicians, and even his definitions and explanations of the relation between cause and effect, lead men to confound all these notions, it is expedient to keep in view the simple relation of priority and succession, even in our inquiries concerning causes; that we may then be the better enabled to perceive what more there is in the relation of every kind of cause and effect than merely of the sequence of the one to the other. Whilst philosophers have speculated concerning the nature and influence of causes, they have been prone to overlook some of the kinds of causes that have been mentioned, and to confound others of them; to attend chiefly to *physical causes*; to suppose that for every event, even for the voluntary action of a living person, there *must* be such a cause; to maintain that the relation of motive and action is essentially the same with that between physical cause and effect, and thereby to exclude, not only the necessity, but almost the possibility, of the operation of an *agent*, or cause of that kind which Dr. Reid, in the passages above cited, and which many other philosophers have thought universally necessary for the production of change. Dr. Gregory differs from the systems both of Hume and Reid; from the latter, because he thinks there are many events which we have no reason whatever, either from the primary laws of human thought, or from particular observation, experiment, and induction, to refer to *agents*; and from the other, because there are many events, e. g. the voluntary actions of mankind, which, in his opinion, ought to be referred to *agents* as their proper and chief principles of change. When we refer the voluntary action of a person to the agent as the author of it, that is, as the *cause*, or principle of change, from which it proceeded, we cannot reasonably be charged with the absurdity, that there may be an event or effect without a cause. As little can we be charged

with that absurdity, when we refer the melting of ice, and the boiling of water, to heat; and when we refer the falling of a stone to the ground, and the ebbing and flowing of the sea, to the influence of the earth on the stone, and of the sun and moon on the ocean, according to the principle of general gravitation. We have evidence sufficient, corresponding to the nature of the subject and the extent of our own faculties, to believe, that among things inanimate, and consequently incapable of *power* or *activity*, in the literal and common sense of the terms, there are such relations that they may be mutually causes or principles of change to one another, without any exertion of *power*, or any operation of an agent strictly so called. Such relations, for aught we know, may subsist among bodies remote from one another, as well as among those that are really or apparently in actual contact; and they may vary, both in kind and degree, according to the distances between the bodies. We know these relations, however, merely as matter of fact; but the result, in point of event, in any given case of the application of such causes, will be the same, whether the relation among the bodies be necessary, or contingent and arbitrary; provided only that it be established and constant. Some of the relations of event, particularly that of physical cause and effect, comprehending the circumstance of their constant conjunction, as it has been very properly called, which seems always to be implied in strict physical reasoning, as well as in the common notions, and actual conduct of mankind, are necessary, like those of quantity, which are the objects of mathematical reasoning; the opinion, that there *must* be an exertion, or power, or activity, to produce such events, would be not merely erroneous, but absurd; for, on that supposition, no power or agency would be requisite to produce them, any more than to produce the relations of geometry; and no power in heaven or earth could prevent them from being what they are. If such relations, comprehending the circumstance of constant conjunction, subsist only by the will but arbitrary appointment of the Supreme Being, who might, if he had thought fit, have made them different; still the necessity at least, if not the possibility, of any exertion of power, or of any agency, would be completely excluded; while some other relations of events, that do not comprehend the circumstance of the constant conjunction of the cause with its effect, but, on the contrary, imply their occasional and very frequent separation, as, e. g. the relation of motive and action, not only do not exclude, but absolutely require and imply the operation of an agent, and the exertion of power. The question, it should be remembered, is not whether body can act, either where it is, or where it is not; but simply whether it be consistent with the laws of human thought to believe, that such relations may subsist among bodies, either by necessity, or the nature of things, or by the arbitrary appointment of the Deity, that they shall, in certain circumstances, be mutually causes or principles of change to one another. Whatever may be thought of numberless other events, and of their causes, it must be admitted, says Dr. Gregory, that every voluntary action of a person does proceed from some exertion of *active power*, or some such cause as Dr. Reid supposes to be universally necessary for every change. See on the subject of this article, besides the authors, whose works have already been cited, Hume's Essays, &c. vol. ii. § 4. part i. § 7. part i. Stewart's Elements of the Philosophy of the Human Mind, ch. i. § 2. Notes C and D. A short Statement of some important Facts, relative to the late Election of a Mathematical Professor in the University of Edinburgh, &c. 1805. Brown's Observations on the Nature and Tendency of the Doctrine of

Mr. Hume, concerning the Relation of Cause and Effect, 2d edit. 1806. Reid's Essays on the Active Powers of Man, Ess. iv. Gregory's Philosophical and Literary Essays, vol. i. Introduction. See also LIBERTY, MOTIVE, NECESSITY, and POWER.

CAUSE, *First*, is that which acts of itself, and from its own proper power or virtue.—In this sense, God is the only *First Cause*.

CAUSES, *Second*, are those which derive the power and faculty of acting, from a *first cause*.

CAUSES were distributed by Aristotle into four different kinds; viz. the *efficient*, the *material*, the *final*, and the *formal*. *Efficient* causes are the agents that produce certain effects. *Material* causes are the subjects on which the agent performs his operation, or those contingent natures which lie within the reach of the agent to influence. *Final* causes are the motives or purposes, which move to action, or the end for which any thing is done. See MOTIVE. The doctrine of final causes furnishes an obvious and unanswerable argument in proof of the existence of a Deity, infinitely wise and benevolent. This argument is admirably illustrated by Dr. Paley in his "Natural Theology," or "Evidences of the Existence and Attributes of the Deity, collected from the Appearances of Nature." Svo. 1802. This excellent work deserves unprejudiced and attentive perusal; and thus perused cannot fail to produce conviction in every mind. See GOD and PROVIDENCE. *Formal* causes denote the changes resulting from the operation of the agent; or that which determines a thing to be what it is, and distinguishes it from every thing else. See FORM. Instead of dividing causes into these four kinds, it would be more proper to leave out matter and form, as not being proper causes; and the rest might be distributed into four kinds, viz. *emanative*, *efficient*, *instructive*, and *suasive*; and these include all the various ideas of positive proper causes in the most natural and easy view and order. An *emanative* cause is when the effect flows from it without any action to produce it, supposing only that all obstructions be removed. Thus water flows from a spring, and heat from the fire. An *efficient* cause, which most properly deserves the name of a cause, produces the effect by some sort of active power or natural agency. Of efficient causes there are many subordinate divisions. An *instructive* cause is that which produces effect either by way of manifestation of truth, or direction in practice; and may be called manifestative or directive. A *suasive* cause is, properly speaking, from without, which being apprehended by the mind, excites or inclines a voluntary or free agent to act, and it operates either by intreaty or authority, by commands or counsels, by promises or threats, by rewards or punishments, by fear or hope, or any other motives; all which are called moral agency or influence. The end or design is one of the chief motive causes, and is usually called the final cause; of which the schoolmen have given a variety of divisions. They have also given us several other distinctions and denominations of causes, which it is hardly necessary to enumerate. Accordingly causes are distinguished into *physical*, or *natural*, and *moral*. The former is that which produces a sensible corporal effect. See CAUSE, above. The latter is that which produces a real effect, but in things immaterial; thus repentance is the cause of forgiveness.

Others define a physical cause to be that which produces its effect by a physical virtue or natural influence; and a moral cause, that which determines the physical cause, though not necessarily, to produce the effect, or which works by persuasion: in which sense, it is also called a *dispositive*, *excitative*, and *imputative cause*. Thus, the sun is a physical

cause of light: a stone, that breaks the skull, is a physical cause of death: and thus the advice, intreaty, commands, or menaces, which determine us, though not necessarily, to do, or not to do, any thing, are moral causes. In this sense, a moral cause is only applicable to a free intelligent agent: and 't is this notion of a moral and physical cause that is the most full, clear, and distinct.

CAUSES, again, are considered, either as *universal*, or *particular*; *principal*, or *instrumental*; *total*, or *partial*; *univocal*, *equivocal*, &c. An *universal* cause is that, which, by the extent of its power, may produce all effects. Thus the sun, soil, and air, are universal causes of plants, herbs, and flowers; for by the same sort of influences each of them produces various and different effects. A *particular* cause is that which can only produce a single effect; or a certain kind of effects. Thus the particular seeds are the particular causes of each different herb and flower. To these, common and proper causes are nearly allied. A *principal* cause is that which gives motion to the instrument, or which does not operate beyond its own natural efficacy. An *instrumental* cause is that used by the principal to produce its effect; or which is excited to produce an effect, beyond the measure of its own perfection. A *total* cause is that which produces the whole effect. A *partial* cause is that which occurs with some other in producing the effects. An *equivocal* cause is that which is of a different kind and denomination from its effect: as when a man writes a book, when a root produces a stalk and leaves, or when money buys land. An *univocal* cause is that which is of the same kind and denomination with its effect: as when a lion produces a young lion, or when a fountain sends forth a stream of water, or when money being lent, gains money by interest. See WATTS'S Brief Scheme of Ontology, in his Works, vol. v. ch. 10.

CAUSES, *Occasional*, are only the occasions, not the direct causes of their effects. The Cartesians resolve all physical causes into occasional ones. See OCCASION.

The soul, say those philosophers, is not able to act on the body; nor the body reciprocally on the soul: to keep up an intercourse between them, God, on occasion of a motion of the body, impresses a sensation on the soul; and, on occasion of a sentiment of the soul, impresses a motion on the body: the motions, therefore, of the soul and body, are only occasional causes of what passes in the one or the other. Thus, say they, the stroke, or percussion, is only the occasional cause of the motion produced in the body struck; it is God is the direct efficient cause. And thus the action of objects on our organs is not the efficient cause of our ideas and perceptions, but merely the occasional cause which determines God to act on the mind, according to the laws of the union of soul and body.

CAUSE, in *Medicine*, is usually considered in a sense somewhat complex, and different from the ordinary acceptation of the word. It signifies not merely those agents, which, when applied externally or introduced internally, excite in the body or in some of its organs, a state of disease; but it is also employed to express the previous condition of the body, which renders it liable to disease, as well as that which constitutes the disease itself. Thus physicians have treated of the causes of diseases under the two heads of *remote* and *proximate* causes; the former of which they have again divided into *predisposing* and *exciting*, or *occasional*, causes.

The *predisposing* cause, is that which renders the body liable to be attacked by disease, or to be acted upon by an exciting cause; for the operation of an exciting cause alone is generally not sufficient to produce disease. Thus several persons may be exposed at the same time to the same external agents,

agents, e. g. to cold and moisture: in some these agents will excite disease, on others they will act with impunity. In the former persons some circumstances must have existed, which rendered them liable to receive those morbid impressions; in the latter no such predisposition was present. Again, some of those, whom the exciting causes affected, may suffer one species of disease, and others a different species: thus one individual may be afflicted with rheumatism, another with catarrh, a third with dysentery, and so on; a fact implying the existence of some peculiar condition of the body, or of the organs respectively attacked, which is justly deemed a *predisposing cause* of the particular malady, which may have occurred. In some instances the *predisposition* is obvious and well understood: thus one attack of rheumatism, pleurisy, or any inflammatory disorder, generally renders the body more liable to suffer a second: a peculiar formation of the chest, combined with a fair and delicate skin, with dark eyes, lively spirits, &c. implies a tendency to be affected with pulmonary consumption: and a plethoric habit, large head, short neck, very florid complexion, &c. portend a probable apoplexy. In such circumstances the kinds of exciting causes, which ought to be peculiarly avoided, are manifest; and by a careful attention to this suggestion, the diseases, with which the individuals are menaced, may be altogether warded off.

In some instances this *predisposing* condition of the body, after long continuance, becomes gradually a condition of actual disease, without the concurrence of any external exciting cause; or it becomes, in the language of some writers, itself an *exciting cause* of disease. In this light a general mobility or morbid irritability of the system, excessive plethora, &c. must be considered.

The *exciting or occasional cause* is that agent which produces disease in the body already predisposed to receive it. There are some exciting causes, however, so powerful, as to occasion the most severe maladies, in the most vigorous constitutions, from which every predisposition to disease seems to be absent. Such are the poisons of small pox and syphilis, the extremes of heat and cold; and so forth. And again, an *exciting cause* which may not immediately induce disease, may, if frequently applied, undermine by degrees the strongest habit, and render it liable to various infirmities. Such are luxury, intemperance, exposure to inclemency of weather, &c.

The *proximate cause* is usually defined, that, "quæ præfens morbum facit, sublata tollit, mutata mutat." It is that condition or circumstance, from which the symptoms of a disease immediately originate, and on which they exclusively depend. The proximate cause of the generality of diseases is obscure; and this obscurity has led ingenious men to enter into a variety of speculations altogether futile, and tending rather to mislead than to inform the mind; and in some instances indeed altogether unintelligible.

CAUSES and Effects, in Law. In most cases the law hath respect to the *cause* or beginning of a thing as the principal part, on which all other things are founded: and herein the next, and not the remote cause, is most looked upon, except it be in covinous and criminal things: and therefore that which is not good at first, will not be to afterward; for such as is the cause, such is the effect: e. g. if an infant or feme covert make a will, and publish it, and afterwards die of full age, or sole, this will is of no force, on account of the original *cause* of infancy and coverture, &c. Finch 12. Where the cause ceaseth, the effect or thing will cease. Co. Lit. 13.

CAUSED, CAPE, in Geography, lies on the south coast of the island of St. Domingo; 5 miles S.E. of St. Domingo.

CAUSEWAY, or CAUSEY, a massive construction of stone, flukes, and fascines; or an elevation of fat, vitreous earth, well beaten; serving either as a road, in wet marshy places; or as a mole, to retain the waters of a pond, or prevent a river from overflowing the lower ground.

The word comes from the French *chauffée*, anciently wrote *chauffse*; and that from the Latin *calceata*, or *calceata*; according to Somner, and Suetman, à *calceando*. Bergier rather takes the word to have had its rise à *pedibus calcatis, quibus teruntur*.

CAUSEWAY, colectum, or calcea, more usually denotes a common hard raised way, maintained and repaired with stones and rubbish.

CAUSEWAY, Devil's, a famous work of this kind which ranges through the county of Northumberland, commonly supposed to be Roman, though Mr. Horsley suspects it to be of later times. Horsley, Brit. Rom. lib. v. cap. 2. p. 449.

CAUSEWAY, Giants, is a denomination given to a huge pile of stony columns, in the district of Coleraine, in Ireland. See BASALT and GIANTS' Causeway.

CAUSSADE, in Geography, a town of France, in the department of the Lot, and chief place of a canton, in the district of Montauban; 12 miles N.E. of Montauban. The place contains 4142, and the canton 13,183 inhabitants: the territory includes 225 kilometres and 11 communes.

CAUSSIDICUS. See ADVOCATE.

CAUSSIN, NICHOLAS, in Biography, a learned French Jesuit, was born at Troyes in 1580; and having entered into the society of Jesuits at the age of 23 years, taught rhetoric with great reputation at their college. He afterwards became a popular preacher and writer, and was chosen confessor to Lewis XIII. For this situation he does not seem to have possessed the necessary talents; but more attentive to his duty than to the means of maintaining the good opinion of an all-powerful minister, he opposed cardinal de Richelieu in urging the king to recall the queen-mother, and not only lost his post but was exiled from the court to a town in Brittany. After the cardinal's death he returned to Paris, and died in the house of the society in 1651. Among his various works in French and Latin, the most popular of the former was his "La Cour Sainte" in 5 vols. 8vo., indicating piety rather than judgment, but much read, and translated into several languages. His principal learned work is "De Eloquentia sacra et humana," 1619, 4to., which was several times reprinted. It exhibits numerous examples of different styles in writing. He also published "Electorum Symbolorum et Parabolarum historiarum Syntagmata," 1618, 4to.; "Disputes pour les quatre Livres des Rois, touchant l'Education des Princes," fol.; "Tragedie Sacree," 1620; "Apologie pour les Religieux de la Compagnie de Jesus," 1644, 8vo.; "La Vie neutre des Filles devotes," &c. 1644; "Symbolica Ægyptiorum Sapientia," 1647, 4to., and some other works of devotiveness and controversy. Nouv. Dict. Histor.

CAUSTIA, in Antiquity, a kind of woollen cap used by the Macedonians; which was so strong as sometimes to serve instead of a helmet. Mem. Acad. Inscript. vol. ii. p. 394.

CAUSTIC, COMMON, in Chemistry, a fixed alkali deprived of aerial acid and most of its water. If the lixivium of the soap-boilers be evaporated to dryness in a silver or copper vessel, then fused in a crucible, poured out into a basin, and when solid, cut into small pieces, it forms the common caustic; which must be kept in a bottle to prevent its deliquescing. When a piece of this alkali is applied to the skin, for the space of three quarters of an hour, it corrodes

rodes it; forming without doubt a saponaceous compound with its fat parts. It was much used in making issues, before that practice was laid aside. See *CAUSTIC ALKALI*, and *CAUSTIC*, *infra*.

CAUSTIC, in *Surgery*, from *caus*, to burn, a substance, which, by its activity, will erode and consume the animal texture, wherever it is applied; the burning sensation it produces, and the destructive effects which are occasioned by its application, exactly accord with its name. (See *CATHERETICS* and *ESCHAROTICS*.) In some cases of abscesses and deep-seated inflammation, particularly in chronic affections, the use of caustics is very considerable. The reader will find a few observations on the comparative use of caustics, in our article *ABSCESS*, under the head of "*Various modes of opening abscesses.*" We shall here subjoin some remarks on their composition, and the method of employing them.

Caustics are used either in a solid or fluid form; but those which are fluid, can seldom be applied with all the requisite advantages. The stronger concentrated mineral acids are most frequently chosen by surgeons, when they use fluid caustical applications; as they are less liable to spread than an alkaline fluid, such as the aqua kali puri of the London college, or the common lixivium causticum.

The solution of caustic alkali or potash, has, however, been often used as a solvent of the stone in the urinary bladder, (see *LITHONTRIPTIC*); for which purpose M. Fourcroy recommends applying the remedy by injecting into the bladder a tepid solution of potash or soda, so weak as to be borne in the mouth. Before it is injected, the bladder should be completely evacuated of urine, and washed out with warm water. After the solution has been injected, and retained half an hour or more, it may be voided and allowed to settle in a proper vessel. If, on the application of a little muriatic acid to the fluid, a precipitate be formed, we shall have reason to conclude that the calculus contains uric acid, and that the alkali has acted on it.

The strongest caustic of a solid form, in general use among surgeons, is prepared as follows:—evaporate a solution of pure kali or potash in a clean iron vessel to a state of dryness; after which let the saline matter, in a melted state, be poured on a smooth iron plate, and divided into small pieces before it hardens, which must immediately be placed in a well stoppered vial for use. This caustic is very apt to liquify on exposure to the air; it is therefore usually managed, by the admixture of quick-lime, to render it less liable to deliquescence; but this procedure also weakens the causticity of the remedy, so that it is not so fit for surgical purposes.

Some practitioners will even dilute the caustic still more, before they use it, by the mixture of soft soap, &c. which forms a paste; and they apply this in the following manner: put several folds or layers of common adhesive plaster upon the part, through each of which cut a circular aperture for the reception of the paste. Then fill this hollow with the caustical substance, and let it remain for the space of six, seven, or eight hours, according to the effect desired; when it will be found to have penetrated sufficiently deep. Although this method has been sanctioned by the names of many eminent surgeons, it is very far from being the most eligible; as the pure kali rubbed on the skin about three or four minutes, will produce all the purposes wished for, and cannot extend itself or penetrate farther than is proper. The pain caused by this short process, is not to be compared to that of applying a milder caustic several hours together.

When the caustic has produced its full effect, there will be a portion of dead skin or flesh, called an *eschar*, which, by degrees, will separate and leave an opening. The part

should be poulticed until the eschar is cast off; but should the separation of the dead skin be longer in taking place than the surgeon expects, he may puncture it through with a lancet, to facilitate the discharge of the confined matter.

When a superficial and more circumscribed effect is required, the *lunar caustic* will be found preferable to the pure kali; as it is much less apt to dissolve, and therefore is very easily managed even by an unskilful hand. The lunar caustic consists of a solution of pure silver in nitrous acid, formed into long solid pieces, about the size of a goose-quill; which must be always moistened a little, before we apply them to the skin. A scruple or half a dram of this substance, dissolved in an ounce of water, makes a useful lotion for languid phagedenic sores; or it may be now and then injected into fistulous ulcers, until the surface begins to suppurate freely.

The milder caustic substances, are burnt alum, vitriolated zinc, vitriolated copper, verdigris, &c. but they seldom produce much benefit without repeated application, as they are too weak to act upon a part which is not previously deprived of its cuticle.

Arsenical caustics have likewise been employed by surgeons, especially in cancerous cases; but their superiority to more safe applications is very questionable; and it is certain that bad consequences have sometimes arisen from the use of them, even in the hands of skilful practitioners. See *Home* and *Julliamond's Tracts* on cancers.

CAUSTIC CURVE. See *CURVE*.

CAUSTIC, by reflection. See *CAUSTIC CURVE*.

CAUSTIC, by refraction. See *CAUSTIC CURVE*.

CAUSTIC GLASSES. See *BURNING GLASSES*.

CAUSTIC, Lunar, in *Chemistry*, improperly called "*lapis infernalis*," consists of the crystals of silver obtained by solution in nitrous acid, and afterwards fused in a crucible. It is prepared by dissolving very pure silver to saturation in nitrous acid, and separating the crystals by evaporation and cooling. These are to be fused in an earthen crucible, sufficiently large to admit of the frothing and swelling that happen at the commencement of the fusion. The heat must be gentle, because the crystals are very fusible, and the acid easily decomposed and driven off. It requires, however, to be somewhat raised after the ebullition has ceased. As soon as the matter is in quiet fusion, it is to be poured into a mould, consisting of five or six small cylindrical cavities, by which it acquires the form of small pencils, and may conveniently be held in a case instead of touching it with the fingers. The blackness of lunar caustic seems to arise from part of the acid being driven off, and a portion of the silver received. Its causticity or action on animal substances appears to depend on the strong disposition of the silver to recover its metallic state, and consequently is a true combustion.

CAUSTICITY denotes a quality belonging to several substances, by the acrimony of which the parts of living animals may be corroded or destroyed; accordingly, all substances which have so strong a tendency to combine with the principles of organized bodies as to destroy their texture, are said to be caustic. The chief of these are the concentrated acids, pure alkalies, and the metallic salts. See *CAUSTIC*, *supra*.

CAUSTICUM ANTIMONIALE, the name given in the late London Dispensatory to what was before called *butter of ANTIMONY*.

CAUSUS, in *Medicine*, *καῦσος*, from *καίω*, I burn, a term applied by Hippocrates and other Greek writers, to an acute fever, accompanied by great heat of the skin. It is

the same with the *febris ardens* of the Latins. See *Inflammation* FEVER.

CAUTERISATION, in *Surgery*, is the operation of burning any part of the body artificially by means of a hot iron.

CAUTERY, *καυτήρ*, is a surgical instrument made of iron, gold, or silver, which, after having been made red hot, exerts its cauterising power upon the part to which it is applied; and it must be of various dimensions according to the purposes for which it is to be used. It is also termed the *actual cautery*.

The actual cautery was formerly much employed for stopping hæmorrhages, by touching the wounded arteries with it. When this is used, we must, in order to avoid irritating and burning the neighbouring parts, place an iron tube or cannula upon the orifice of the artery, surrounded with cold wet cloths, through which the red hot iron is to be introduced, and the artery touched for a moment with it. Should it be practicable, we ought previously to stop the hæmorrhage by means of the tourniquet, and dry the wound well. But as the eschar produced by the cautery may easily separate, and the hæmorrhage return, the patient should lie quiet and be constantly watched; and in order to prevent the separation of the eschar, it may be frequently moistened with brandy, and the impetus of the blood towards the part diminished by the application of the tourniquet, or by blood-letting: and also in removing the dressings proper caution ought to be observed with respect to the eschar.

In some cases the actual cautery is the only remedy that can be employed with effect: as when the bleeding vessel is deep situated, or when from any cause no other styptic remedy can be used; for example, in hæmorrhages from under the tongue, from the sockets of the teeth, &c. The actual cautery is therefore a remedy which certainly deserves to be more frequently used than is generally done, especially as the irritation and pain which it occasions are by no means so great as is generally supposed. See HÆMORRHAGE. The actual cautery is moreover used in caries and enlargements of the bones; in caries of the teeth; in excrescences, especially of the gums; and in wounds produced by the bites of mad dogs, or venomous animals. Consult on this subject the dissertation of Mr. Le Cat concerning the use of fire in chirurgical diseases, and that of Mr. Spiritus concerning fire considered as a chirurgical remedy, Götting, 1784.

To this head belongs also the cauterisation with moxa, cotton, gun-powder, burning-glasses, or live coals. The moxa is prepared from the plant termed *Artemisia vulgaris*. It must lie for a very long time, even for whole years, in the shade to dry, after which the leaves and superior extremities are pounded and rubbed between the hands till they form a sort of cotton. For the purpose of perfuming it, the Chinese sometimes mix musk or the ashes of the wood of aloes with the artemisia. When this cotton has been perfumed from all coarſe and foreign substances, it is rolled between the hands till it acquires the form of a cone, pointed at the top and broad at the base, like a pyramid. This pyramid is fastened with saliva to the skin, and set on fire; and when it has quite burnt down, it leaves an eschar upon the skin.

The cylinders of cotton, or Mr. Pouteau's bougies, are prepared in the following manner. Take carded cotton, and form it, without twisting it close together, into cylinders four inches long, and one in diameter. The cylinder is next wrapped round with a piece of fine linen, four inches broad and three long, and the two ends are laid over each other

and sewed together, so as to form a small plug. This is then cut through the middle with a pair of scissors, so as to form two cylinders. The rest of the cotton, which projects either at the top or bottom, is to be cut off with the scissors, close to the edge of the linen. In using these cylinders, the lower extremity is placed upon the skin, moistened a little with saliva, to make it adhere. The upper end is then kindled with a wax taper, and kept burning by means of a fan or bellows, till it has quite burnt down. As soon as the heat penetrates into the skin, the cotton is made to stick till fast to the part by means of the augmented perspiration.

The method proposed by Mr. Pascal is still more convenient. The cotton having first been boiled in a strong solution of nitre, the cylinder after being once lighted, burns till it is quite consumed, so that there is no necessity for fanning or blowing the flame. If we confine the cylinder in a wide tube of strong pasteboard, we may hold it between our fingers whilst it is burning, so as to prevent its falling down or injuring the neighbouring parts.

Of such cylinders we may apply one, two, or more, according to circumstances, and yet the operation of the fire will never penetrate deeper than the skin. When the operation is finished, the burnt part may be covered with ung. resin. flav. or *bañicker* spread upon a pledget. When the heat does not penetrate quite through the skin, and into the cellular substance, we frequently fail of our intent on, on which account we must always see to it, that the cylinder burns down to its very last particle, as the end of the combustion is the most efficacious.

Cauteries have been employed with advantage in various diseases, but they are chiefly useful in arthritic and rheumatic pains, in which cases the pyramids of moxa, and especially the cotton cylinders, are preferable to the actual cautery. But before we proceed to the use of these applications, we ought first to have tried every other proper remedy, and when these produce no benefit, we must employ the cautery. We ought always to place these substances exactly upon the part at which the pain is most violent. When the pain shifts, we must follow it with the cylinder wherever it seats itself. However, this method of cauterising is properly applicable only when the pain has actually seated itself in some particular part; for, as long as it is fugitive, we merely make it shift from its temporary seat to another, without radically removing it. Its most speedy and surprising effect is in the lumbago.

It is further useful also in cases of ulcers, and in lymphatic swellings of the joints. However, it is necessary that particular attention should be paid to the nature of the circumstances in applying it. When, for example, the white swelling is combined with a deep seated and violent pain, when there is cause to believe that the ligaments are attacked by an arthritic, rheumatic, or venereal acrimony, cauterisation might tend to increase the evil; which might be the case in a still greater degree if the bones were enlarged and carious, or whenever the lymphatic tumour is the effect of some violent constitutional disease. It is most useful when the tumour is of a primary nature. But powerful as the effects of these cauterising cylinders are, there are some cases in which it is necessary to employ them repeatedly before the pain yields to their operation.

The method of burning with gun-powder is as follows: when (for example, after a person has been bit by a mad dog) the actual cautery cannot be employed, either on account of the irregular shape of the wound or the fear of the patient, gun-powder is sprinkled into the wound, and set fire to, as often as may be necessary.

The ancient surgeons with justice placed great dependence upon cauteries; only they are in some degree to be reprehended for the abuse they sometimes made of them; as are the moderns also, for their too great neglect of these very efficacious remedies.

Actual cauteries are distinguished, according to their degrees of strength, from *caustics*; which are termed *potential cauteries*. The difference between the actual and the potential cautery consists in the circumstance, that though caustics produce an eschar or crust, they do it in a much slower manner, and not till several hours have elapsed; whilst the actual cautery produces its effects instantaneously. The potential cautery is therefore applicable in none of those cases which require the actual cautery. See the article *CARIES*, *sub finem*.

CAUTGUNGE, in *Geography*, a town of Hindoostan, in the country of Bahar, on the north side of the Ganges, opposite to *Bar*.

CAUTING IRON, among *Farriers*, an iron instrument, wherewith they cauterise and sear the parts of a horse which require burning.

CAUTIO, in the *Civil Law*, denotes an assurance or security given or taken for any thing trusted.

CAUTION, in *Military Language*, is: an explanation given before the word of command, by which the attention of the soldiers is called to the regular and correct execution by all of them at the same time of the movement they are about to be directed to perform.

CAUTIONE admittenda, in *Common Law*, a writ which lies against a bishop who holds an excommunicated person in prison for contempt, notwithstanding he offers sufficient caution or security for obeying the commands of the church for the future. *Reg. Orig.* 66. And if a man be excommunicated, and taken by a writ of "significavit," and after offers caution to the bishop to obey the church, and the bishop refuse it; the party may sue out this writ to the sheriff to go against the bishop and to warn him to take caution, &c. But if he has reason to doubt whether the sheriff will deliver him by that writ, the bishop may purchase another writ, directed to the sheriff, reciting the case, &c. When the bishop hath taken caution, he is to certify the same in the chancery, and thereupon the party shall have a writ unto the sheriff to deliver him. *New. Nat. Brev.* 142.

CAUTIONARY TOWNS, places of strength, which one prince or power puts into the possession of another as a security either for the payment of a debt, or performance of some other matter stipulated between them. Thus, when a profusion of expence was incurred by the elevation of the duke of Buckingham in the reign of James I. which was too great for his moderate revenues, the cautionary towns were delivered up to the Dutch, A.D. 1636. In the preceding reign, queen Elizabeth, when she sent the revolted Hollanders large sums of money, required of them a proper deposit, as security for payment. The Dutch, in compliance with this demand, put her into possession of the three important fortresses of Flushing, Brill, and Ramekins. But James, in his present exigence, agreed to evacuate these fortresses, upon being paid only a third part of the money which was due; this measure occasioned a very general discontent.

CAUTIONRY, or *FIDEJUSSIO*, in *Scotts Law*, denotes the obligation by which one person becomes engaged as security for another, that he shall either pay a sum or perform a deed. A cautioner for a sum of money may be bound, either simply as cautioner for the principal debtor, or conjointly and severally for and with him. The first has, by custom, the "beneficium ordinis;" or of discussion: by which the creditor is obliged to discuss the proper debtor, before he can insist for payment against the cautioner. Where a per-

son is bound as full debtor with and for the principal, or conjointly and severally with him, the two obligants are bound equally in the same obligation, each "in solidum;" and, consequently, the cautioner, though he is but an accessory, may be sued for the whole, without either discussing or even citing the principal debtor. Cautioners for performance of facts by another, or for the faithful discharge of an office (e. g. for factors, tutors, &c.) cannot, by the nature of their engagement, be bound conjointly and severally with the principal obligant, because the fact to which the principal is bound cannot be performed by any other. In such engagements, therefore, the failure must be previously constituted against the proper debtor, before action can be brought against the cautioner for making up the loss of the party suffering. The cautioner, who binds himself at the desire of the principal debtor, has an "actio mandati;" or of relief against him, for recovering the principal and interest paid by himself to the creditor, and for necessary damages; which action lies "de jure;" though the creditor should not assign to him on payment. As relief against the debtor is implied in fiduciary obligations, the cautioner, where such relief is cut off, is no longer bound: hence the defence of prescription frees the cautioner, as well as the principal debtor. Nevertheless, where the cautionry is interposed to an obligation merely natural, the relief is restricted to the sums that have really turned to the debtor's profit. Moreover, a cautioner, who pays without citing the debtor, loses his relief, so far as the debtor had a relevant defence against the debt, in whole or in part. Relief is not competent to the cautioner, till he either pays the debt or is discussed for it, except, i. e. where the debtor is expressly bound to deliver to the cautioner his obligation cancelled, against a day certain, and has failed; or 2dly, where the debtor is "vergens ad inopiam;" in which case, the cautioner may, by proper diligence, secure the debtor's funds for his own relief, even before payment or distress. A right of relief is competent "de jure," to the cautioner, who pays against his co-cautioners, unless where the cautioner appears to have renounced it. In consequence of this implied relief, a creditor, if he shall grant a discharge to any one of the cautioners, must, in demanding the debt from the others, deduct that part as to which he has cut off their relief by that discharge. Where the principal debtor, in a bond in which a cautioner is bound, grants bond of corroboration with a new cautioner, both cautioners, as they intervene for the same debt, and at the desire of the same debtor, have a mutual relief against each other; but where the cautioner in the first bond signs as a principal obligant in the corroboration, the cautioner in the new bond, it would seem, would be entitled to a total relief against the first cautioner. Upon this branch of the doctrine of cautionry the decisions of the court of session are not agreed. Cautionry is also "judicial," as in a suspension. It is sufficient to lose the cautioner, that when he became bound, the suspender had good reason to suspend; e. g. if the charger had at that period no title, or had not then performed his part, though these grounds or suspensions should be afterwards taken off. In all maritime causes, where the parties are frequently foreigners, the defender must give caution "judicio sibi et juncatum solvi;" such cautioner gets free by the death of the defender before sentence; but he continues bound though the cause should be carried from the admiral to the court of session. This sort of caution is only to be exacted in causes strictly maritime.

CAUTO, in *Botany*, a name given by the people of Guinea, to a shrub common in that part of the world; a decoction of which they use as a cure for the running of the reins, or a clap. *Phil. Trans.* N^o 232.

CAUTO, in *Geography*, a river of the island of Cuba, which runs into the sea, 20 miles N.W. of *Bayamo*.

CAUTURIER, in *Anatomy*, a name given by the French writers to a muscle of the leg; called by the old writers, *primus fletentium tibiam*; and by the latter writers, *Copper*, *Albinus*, &c. *Jartorius*; by *Riolan*, *fortorius*.

CAUVERY, in *Geography*. See **CAVERY**.

CAUX, a country of France, in Normandy, so called before the revolution, about 50 leagues in circumference, lying between the Ocean and the Seine, *Vexin*, Normandy, *Picardy*, and the country of *Bray*. The land is fertile in grain, hemp, fruits, &c. The coast abounds with fish, and the forests with game. *Caudebec* is the capital.

CAVY, in *Zoology*. See **CAVIA**.

CAVY, *mus*, of Pennant's quadrupeds, is the *Mus pilorides* of *Pallas*, and other late writers. See *Mus pilorides*.

CAVY, *Cape*, of Pennant, is *Hyrax capensis*; which see.

CAWNPOUR, in *Geography*, a town of Hindoostan, in the *Soubah* of *Oude*; 37 miles S.W. of *Lucknow*, and 98 N. W. of *Allahabad*.

CAWOOD, a town in the well riding of *Yorkshire*, England, seated on the banks of the navigable river *Ouze*, over which there is a ferry from this town into the east riding. Here was formerly a cattle, some ruins of which still remain. This was given by *Athelstan* to the archbishops of *York*, and was the birth-place of *bishop Mountain*, who is buried in the church at this place. The cattle suffered materially in the civil wars. Here are a weekly market on *Wednesdays*, and two fairs yearly. The town contains 247 houses, and 1025 inhabitants, the greater number of whom is employed in agriculture. *Cawood* is situated 10 miles S. of the city of *York*, and 187 N. from *London*.

CAWSTON, a small market town of *Norfolk*, England, is held of the *Duchy of Lancaster* in free socage. It is situated on the river *Bure*, and has a small market on *Wednesdays*, and three annual fairs, one of which is well supplied with sheep. *Cawston* is eleven miles N.W. of *Norwich*, and 112 miles N.E. from *London*. Here are 176 houses and 846 inhabitants.

CAXA, in *Commercie*, a little coin made of lead, mixed with scoria of copper; struck in *China*, but current chiefly at *Bantam*, in the rest of the island of *Java*, and in some of the neighbouring islands.

It is somewhat smaller than the French double, and has a square hole through the middle; by means whereof, several of them are hung on the same string: this string, which they call *fantas*, usually contains two hundred *caxas*, equivalent to nine French deniers, or somewhat less than three farthings sterling. Five *fantas* tied together, i. e. a thousand *caxas*, make a *sipacou*.—Nothing can exceed the brittleness of the *caxa*; a string never falls to the ground without breaking at least ten or twelve pieces. Leaving them at night steeped in salt-water, they cling so firm to one another, that they are not to be separated without breaking one half of them. The Malays call them *cas*; and the *Javeses* *piis*. The *caxas* are of two kinds; *great* and *small*; the *small* are those we have been speaking of; three hundred thousand whereof are equal to fifty-six livres five sols, French money. The *large* are old *caxas*; six thousand whereof are equal to the piece of eight, or four shillings and six pence sterling. There are near y the same with the *caches* of *China*, and the *esuyes* of *Japan*.

CAXA MINES, an appellation distinguishing those mines of gold and silver in the province of *Quito* in *South America*, which are contained and confined, as it were, betwixt two natural walls; in contradistinction to those in which the metals are found dispersed and mingled with casts of different species. In these mines, as in the others, the silver and gold

are intimately united with other bodies; and, therefore, it is necessary to separate the grains from the earth by running conduits of water. After having undergone the operation of the quicksilver, which their quality renders indispensable, the substance is washed in order to separate the remaining filth. After the last operation the amalgama is pure, consisting entirely of quicksilver, and gold or silver, according to the species which has been worked.

CAXAMARCA, in *Geography, a jurisdiction of *South America*, in the country of *Peru*, and diocese of *Truxillo*, lying to the eastward of *Truxillo*, and extending along a vast interval between the two *Cordilleras* of the *Andes*. This jurisdiction is fertile in all kinds of corn, fruit, and esculent vegetables, and also in cattle, sheep, and especially hogs, of which they sell a great number to the farmers in the valleys, who, after fattening them with maize, send them to the markets in the large towns. The farmers of the valley of *Chunca*, and others, in particular, carry on a considerable trade in these creatures at *Lima*, *Truxillo*, and other flourishing places. The *Indians* throughout this jurisdiction weave cotton for slip-fairs, bed-curtains, quilts, and other uses, which are sent into the other provinces. Here are also some silver mines, but of little consequence. The principal town is of the same name, and was formerly a royal city, where the emperor *Atahualpa* was put to death, after having been defeated and imprisoned by *Pizarro*: about 70 miles from the *Pacific Ocean*. S. lat. 8°. W. long. 76° 10'.*

CAXAMARQUILLA, or **COXAMARQUILLA**, called also *Patate*, a jurisdiction of *South America*, in the diocese of *Truxillo*. It lies among the mountains at a small distance S.W. from *Caxamarca*, and from its different situations has a variety of products; but it is particularly remarkable for gold mines. The chief commerce consists in exchanging that metal for current money, especially silver coin, which is the more esteemed here on account of its scarcity.

CAXATAMBO, a jurisdiction of *South America*, in the circuit of *Lima*, commencing 35 leagues N. of *Lima*, and extending about 20 leagues, and partly among the mountains, so that the temperature of the air is vari ous; but the fertility is very fertile in grain. It has also some silver mines, which are wrought; and the *Indians* have manufactures of bays, which constitute part of the trade of this jurisdiction.

CAXCAXTOTOTL of *Ray*, in *Ornithology*. See **STURNUS MEXICANUS**, *Gmel.*

CAXINES, *Cape*, or *Ra Acon-nattar*, in *Geography*, a cape on the north coast of *Africa*, in the *Mediterranean*, forming the west point of the bay of *Algiers*. N. lat. 37° 15'. E. long. 3° 30'.

CAXOUL, in *Metalurgy*, a word used to express a cheat of ores of silver, or any other metal, that has been burnt, ground, and washed, and is ready to be refined.

CAXTON, **WILLIAM**, in *Biography*, deserves to be recorded as the first person, who, according to some writers, introduced the art of printing into *England*, or who, according to others, improved and perfected it by the use of fustic types. He was born about the latter end of king *Henry the IVth's* reign, who died in the year 1412, in the *Weald* of *Kent*; and, after having been well instructed by his mother in reading and writing, he was apprenticed to *Mr. Large*, an eminent mercer in *London*, lord-mayor of the city, in 1439, with whom he resided till his death. In the year of his master's death, 1441, he was sent abroad by the mercers' company, as their agent and factor in the *Low Countries*, where he continued in the management of their concerns for about 23 years. His conduct in this department of public trust had been so satisfactory to his employers, and so highly reputable to himself, that he was joined

in a very honourable commission, granted by king Edward IV. in 1464, for the purpose of continuing and confirming the commercial treaty subsisting between his majesty and Philip duke of Burgundy, or, if necessary, of negotiating and establishing a new treaty. Afterwards he appears to have held some office in the household of lady Margaret of York, the sister of king Edward, who, in 1468, was married to the duke's son, Charles, then duke of Burgundy. By his long residence in these countries, as he was of an inquisitive and studious disposition, he became acquainted with the new invention of printing, which was then practised in Holland and Flanders; and he seems to have been actuated by the laudable ambition not only of acquiring the art, but of introducing it into his own country. At the instigation of the dukes of Burgundy, by whom he was probably employed in some literary department; having attained by his diligent application a competent knowledge of the Latin and French languages, he translated from the French a work, which he entitled "The Recuyell of the Histories of Troye, &c." the first book supposed to have been ever printed in the English tongue. Having laboured for three years in the translation of this work, which he began at Bruges, in 1468, and finished at Cologne, in 1471, he undertook the task of printing it in this city, having, as he himself says, "practised and lerned at my grete charge and dispenche, to ordyne this sayde book in prynte." Its date is 1471. After having published "The Book of Troy," he proceeded in printing others; and, at length, having provided himself with presses, types, and all other printing materials, he came over to England, in 1472; and, in a printing-room at the entrance of Westminster Abbey, whence a printing room is to this day called a "chapel," he produced, in 1474, the first book that was ever printed in this country, which was the translation of a French work, and entitled "The Game and Play of the Chess, &c." For other claims to the introduction and practice of printing in England; see the article PRINTING. The next works, printed by Caxton, in the order of time, were "The History of Jason," supposed, though without a date, to have been printed in 1475; "The Dicts and Sayings of the Philosophers," printed at Westminster in 1477; "The Moral Proverbs of Chrylyne of Pyle," printed in the following year; "The Cordyal," printed in the same year; and after printing began to make its first appearance at Oxford in 1479, three books, entitled the "Image of the World," "Ovid's Metamorphoses," and the "Chronicles," with a "Description of England," all printed in 1480. Such was his indefatigable industry, even in the decline of life, that in the space of 20 years he produced between 50 and 60 specimens of his skill and labour, most of them being translations, by himself, from the French, and judiciously selected with a view to the promotion of a taste for literature, and of good morals. Caxton died in 1491, and was buried in St. Margaret's church, Westminster. Although Caxton had no great pretensions to literature, nor to the reputation of an original writer, and though he does not appear to have made any improvement in the typographical art, he is entitled to respect and gratitude for the share he had in introducing and establishing an invention of the highest importance in his own country, and in facilitating and extending the practice of it. As a printer, and also as a translator, he had undoubtedly great merit; as he contributed in a very considerable degree, not only to the perfection of the art of printing, but to the diffusion of useful knowledge. The specimens of his talents and performances as a poet are found in the rhyming introductions and epilogues, with which he frequently decorates his books, and in a poem of

considerable length, entitled the "Work of Sapience." This comprehends not only an allegorical fiction concerning the two courts of the castle of Sapience, in which there is no imagination, but a system of natural philosophy, grammar, logic, rhetoric, geometry, astronomy, theology, and other topics of the fashionable literature. Although Caxton appears, by the prologue, to be the author, yet Mr. Warton, (Hist. of Poetry, vol. ii. p. 194.) thinks it not improbable, that he might on this occasion employ some professed versifier, at least as an assistant, to prepare a new book of original poetry for his press. The writer's design is to describe the effects of wisdom from the beginning of the world; and the work is a history of knowledge or learning. Biog. Brit.

CAXTON, in *Geography*, a small market town of Cambridgeshire, in England, has no other claim to publicity than from having been the birth-place of that respectable old historian; Matthew Paris, and the supposed birth-place of William Caxton, who introduced the art of printing into England. This ancient printer, we are informed by himself, was a native of Keat. In his "Recuyell of the Histories of Troye," he thus informs us. "In France was I never, and was born and learned myne English in Kente in the Weeld, where English is spoken broad and rude." This town is seated on a Roman road, and at present derives its principal support from being situated on a modern public road. The houses are small and mean, and the inhabitants mostly occupied in husbandry. It has a small market on Tuesdays, and two fairs annually.

CAY, a town of China of the second rank, in the province of Pe-tche-li; 125 miles S.S.W. of Peking. N. lat. 38° 3'. E. long. 115° 20'.

CAY. See CAYS.

CAY, or CAI, in *Zoology*, the Brazilian name of a very small monkey that inhabits South America, the prevailing colour of which is deep or coal black. Ray observes, that it lives only in thick woods, and is usually found sitting on the boughs of some of the trees which bear pods, the fruit of which it feeds upon. The species thus described is called by Buffon *tamarin*, and is the Linnæan *femia midas*. Linn. Mus. Ad. Fr.

CAYA, in *Geography*, a river of Spain, which runs into the Guadiana, near Badajoz.—Also, a river of Spain, in Catalonia, which runs into the Mediterranean, near Tamarit.

CAYAHOGA, or CAYUGA, a river of North America, in the state of Ohio, which discharges itself, by a mouth 83 yards wide, into the lake Erie at the south bank, 40 miles eastward of the mouth of Huron; having an Indian town of the same name on its banks, 30 miles S. of lake Erie. N. lat. 41° 20'. W. long. 81° 20'. It is navigable for boats 60 miles to the portage, which is 7½ miles to the head-waters of the Tuscarawa branch of the Muskingum; and it is also navigable for sloops for fifteen miles without any falls or rapids; but at the mouth there is a bar like that of Grand river. In the vicinity of this river are fine uplands, extensive meadows, oak and mulberry trees fit for ship-building, and walnut, chestnut, and poplar trees adapted to domestic uses. Near the mouth of this river are the celebrated rocks which project over the lake. They are several miles in length, and rise 40 or 50 feet perpendicular out of the water. Some parts of them consist of several strata of different colours, lying in a horizontal direction, and so exactly parallel that they resemble the work of art. The view from the land is grand; but the water presents the most magnificent prospect of this sublime work of nature; it is attended, however, with great danger,

fer, if the least storm arises, the force of the surf is such, that no vessel can cleave being dashed against the rocks. The heathen Indians, when they pass this impending danger, offer a sacrifice of tobacco to the water. Part of the boundary line between the United States of America and the Indians, begun at the mouth of Cayahoga, and runs up along the same to the portage between that and the Tullcarawa branch of the Muskingum.

The Cayuga Indian, consisting of 500 persons, 200 of whom are warriors, 40 being resident in the United States, and the rest in Canada, receive of the state of New York an annuity of 2300 dollars, besides 50 dollars granted to one of their chiefs, as a consideration for lands sold by them to the state, and 500 dollars from the United States, agreeably to the treaty of 1714.

CAYAMBE, a village of South America, in the province of Quito, and jurisdiction of Otavalo, seated in the middle of a spacious plain, about 12 leagues N. of Quito. In this place M. Couplet, one of the French mathematicians deputed to measure the length of an arc of the meridian, died on the 17th of September, 1736, after an illness of two days.

CAYAMBURO, a mountain of South America, in the province of Quito, seated at the extremity of the plain of Cayambe, about 11 leagues N.E. from Quito. It is one of the largest mountains of the Cordilleras in this part of the country, being nearly equal in height to that of Chimborazo, that of the latter above the ocean being 19,595 English feet, and that of the former 19,391 feet. Its altitude is so great that it may be seen from the city of Quito. Its summits are covered with snow and ice: and its vicinity renders the whole plain of Cayambe cold, which is increased by the violence and continuance of the winds. It exhibits no appearance of having ever been a volcano, nor is there any tradition to this purpose. Several rivers issue from it, of which those from the west and north run either into the river of Emeralds or that of Mira, but all fall into the South Sea; while those from the east discharge themselves into the river of the Amazons.

CAYANG, in *Botany*, a leguminous plant, cultivated in the Mogul dominions for food. It is a kind of coarse pulse; of which the Europeans use great quantities on ship-board in the East Indies. It is a species of the *cytiscus*, called by the Indians their *kiffery*. *Poiss. Dict. Com.*

CAYAO, or CALAO, in *Ornithology*, a name by which the Linnæan *buceros bicornis*, or Philippine hornbill, is described in the Transactions of the Royal Society, v. 23, p. 1394.

CAYBOBO, in *Geography*, a town of the island of Ceram, in the East Indian Sea.

CAYBOROUGH, a river of America, being one of those rivers, which fall into the channel of Aricway, or north-west branch of the river Amazons; but, though navigable, it is useless for want of towns and inhabitants to trade.

CAYELAC, a sweet scented wood which grows in Siam; the Siamese and Chineses burn it in their temples. It is one of the commodities exported from Siam for China.

CAYENNE, or French Guiana, in *Geography*, a province of South America, to which, but erroneously, is called the island of Cayenne, which was only an inconsiderable part of it, is bounded N. and E. by the Atl. the Ocean, S. by a line not ascertained; and W. by Dutch (now British) Guiana, or Surinam. It extends from the mouth of a small river called Amanay, W. to another called Aracata, E., though an attempt was lately made to extend the

limits at the expense of the Portuguese, to the estuary of the Marañon; its whole extent not exceeding 350 British miles in length by 240 in breadth. The French formed their first settlement in Guiana about the year 1635; and having abandoned it soon after, they were succeeded by the English; but again took possession of the country about the year 1664, and retained it ever since. The coast is low and marshy, and subject to inundations from the number of rivers, which rush down the mountains with great impetuosity. The soil of this colony is in many parts uncommonly fertile; and the productions are on the whole of an excellent quality, and it is easy to gain a subsistence. The Cayenne pepper is a noted produce of this country, and the inhabitants using it to excess, a considerable quantity is always imported from Peru. The other products of the colony are sugar, cocoa, coffee, and indigo, which, with maize, cassia, and vanilla, form the chief articles of its commerce. The interior parts, though much neglected, and remaining obstructed by thick forests and underwood, feed, nevertheless, a great number of horses, sheep, goats, and cattle, which roam at pleasure; the beef and mutton are reckoned excellent. The climate is much more salubrious than that of any of the Antilles; but as the situation of the town is ill chosen, in a swampy isle, its disadvantages have been largely ascribed to the whole territory. The opinion that has been entertained of the unhealthfulness of this climate partly took its rise from the unfortunate expedition to Kourou, 12 leagues below Cayenne, which between 30 and 40 years ago was undertaken by command of the late duke of Choiseul, then prime minister of France; who sent 10,000 persons, very much unprovided with the most necessary articles, and in the most rainy season of the year, to people the immense deserts of French Guiana. This multitude of new colonists, after encountering in their voyage, and on their arrival, numberless inconveniences and hardships, presently vanished, falling victims, as it was said, to the insalubrious climate. Hence an erroneous opinion prevailed in France, which ruined the colony of Cayenne, by preventing the government from paying the least attention to that country, and discouraging a number of Europeans and inhabitants of the West Indian islands from settling in Guiana. In this colony there are, properly, only two different seasons, the dry and the rainy season. The former generally continues from the beginning of June until the end of September, during which time the heat is commonly very oppressive; the air is almost always serene, and scarcely a few drops of rain descend to purify and cool the atmosphere. The heavy falls of rain begin in the month of October, and are very frequent in December, January, February, and March; at which time they begin gradually to decrease until the dry season sets in. During the rainy season, that is, for seven or eight months, the heat is as moderate as can be expected so near to the equator; ray, the negroes sometimes complain of cold; and, upon the whole, the state of health is as good there as in Europe. However, at the time when stagnant waters are dried up and corrupted by the heat, fevers prevail for about two months, which, though not contagious, prove very destructive. The inhabitants of French Guiana are plentifully supplied with all the requisites of a good table, but they generally prefer fat meat and fish to fresh provisions. Being also much addicted to the use of every kind of food that is highly seasoned, they cultivate several sorts of pepper for culinary purposes, however sharp and pungent they may be. The Crocles prefer the cayenne, which is a large round cake, about three lines thick, made of coarse flour of manioc and slightly baked on a tin plate, to the salt and sweet sorts of bread.

Besides

Besides the other articles of subsistence common to Guiana and other colonies, they have a dilt called "calatoll," which is prepared of the fruit of a plant denominated "Combua," which is in frequent use. At every meal a negro presents to the guest a glass of ratifia, as soon as the first course is removed. This liquor is as transparent at Cayenne as the purest spring-water; it is very wholesome, and acquires a more pleasant flavour the older it grows; especially since the colonists have applied themselves to distil it over newly gathered cinnamon. The dress of the male sex consists in white pantaloons and a linen jacket, and the women spend most of their time in a hammock, a piece of furniture much valued in Guiana, and serving both for ornament and convenience. All hammocks are made of cotton; they are in general from six to seven feet in length, and nearly as broad; they are fastened on both ends by a number of small cotton strings; which join, at each end, a large rope of the same stuff. The whole burden is supported by these ropes, which are fastened to the walls of the room by means of large hooks. The hammocks are commonly suspended in the corners of the room, where they hang, like swings, in the form of a garland. Very fine hammocks are made at Cayenne; but the most beautiful are imported from Peru in Brazil, situated on the right banks of the river Amazon. The latter are made of variegated cotton, after various designs, ornamented with borders, tassels, and fringes, and cost about 50 dollars.

CAYENNE, the capital of the above colony, which is the seat of government, and of the courts of justice and the military. It is seated close to the sea, on the right banks, and near the mouth of a river of the same name, which is there about a league in width. The town is small; the houses are badly constructed of wood; and it is surrounded by a swampy moat, and wretched walls, which form a fort of irregular hexagon. The fort, which commands the town, is constructed of earth, and tolerably strong towards the sea, especially for this reason, that, from the want of depth of water, ships of a middle size only can approach it within gun-shot. The palace of the government, and the ancient mansion of the Jesuits, are the only buildings which deserve particular notice. They form two large façades, fronting the place of parade, which presents a pleasing prospect. It is bordered with two rows of orange trees of the largest size, which exhale an exquisite fragrance, and are crowded with colibris skipping from branch to branch. The population of the town of Cayenne, having of late years increased, and its circuit not admitting of a proportionate enlargement, a new town has been built on the neighbouring savanna, separated from the former merely by a ditch. This new town, which is already more considerable than the ancient city of Cayenne, and is daily increasing, is constructed on a regular plan: the streets are wide, admitting the free access and circulation of air, and contain some elegant houses, the beautiful appearance of which becomes more striking from the obvious marks of poverty and wretchedness exhibited by every thing about them. Cayenne, the metropolis of the whole colony, is also the capital of the island of the same name. Cayenne is celebrated on account of the experiment made by M. Richer, by order of the Academy of Sciences at Paris, in 1672, upon the pendulum; for an account of which, see PENDULUM. N. lat. 4° 56'. W. long. 52° 15'.

CAYENNE, or CAYANO, a small island on the coast of Guiana, formed northwards by the sea, and in other directions by the rivers Ouya, Cayenne, and Orayú. It is disjoined from the continent only by a kind of canal. This island, which is but five or six leagues in length, and three

leagues in breadth, is the more distinguished on account of its elevated and mountainous ground; as almost all the other parts of the coast of Guiana are low, and covered with swamp-pines, a species of large trees, which grow in the sea, and form forests at a considerable distance from the shore. All the productions of the continent of Guiana are also supplied by the island, with this difference only, that the latter is as it were exhausted, and does not indemnify the planter for his trouble and expence; while, on the contrary, more remote lands are fruitful in a very astonishing degree. Nevertheless, the produce of the soil, which is a kind of black sand covering a loamy clay and fit for making bricks, is not obtained without labour and expence; and the culture of it has been neglected. The number of inhabitants amounts, exclusively of the garrison, to about 1000 or 1200 whites, most of whom reside in the town of Cayenne; and consist of the feeble remains of Choiseul's unfortunate expedition to Kourou, of poor emigrants from Canada, and some other persons of the lowest class, who are chained down, as it were, to the globe of the colony, because their means will not allow them to emigrate to other parts. They cultivate merely as much land as is requisite for their subsistence; and as they have in vain solicited the support of government, they are incapable of extending their culture. This small number of whites, dispirited by the total neglect which they experienced, and apprized of the insufficiency of their means for any important enterprise, have not presumed to indulge the favourite idea of planters, that of amassing a fortune, and of passing their latter days in Europe. Being necessitated to procure from Europe wine, flour, clothing, and some other things, they raised exactly as many commodities as amounted to the value of those articles, for which they exchanged their produce. They exported, therefore, little or nothing for the benefit of the parent country; and as the latter was obliged to keep agents in Guiana, it began even to consider this colony, which might have become a source of great opulence, in the light of a burthenome possession. Several of the inhabitants, thinly scattered over vast deserts, and separated by impervious brakes and brambles, and at the same time surrounded by negroes, who threatened to endanger their safety and peace, have relinquished the cultivation of the soil, and confined themselves to the rearing of cattle, which could be kept without care and expence in the immense savannas or natural meadows of the country.

CAYENNE river, which gives name to the island and country, rises in the mountains near the lake of Parima, runs through the territory of the Galibis, a nation of Caribbee Indians, and after a course of 100 leagues, discharges itself into the North Atlantic Ocean by a mouth about a league wide near the town of Cayenne.

CAYENNE bay, a bay on the south-west coast of the island of St. Vincent; two miles north-west of Kingstown bay.

CAYES, *les*, a sea-port town on the south coast of the island of St. Domingo, 13 leagues W. by S. from St. Loms. It is surrounded by a plain, 6 leagues long and $4\frac{1}{2}$ broad; its harbour is very inferior, and the air is unwholesome; but the soil is very fertile. N. lat. 18° 13'. W. long. 73° 45'.

CAYEUX, a town of France in the department of the Somme, and district of Abbeville; $3\frac{1}{2}$ leagues N. of Montdidier.

CAYHOCA, or KEYOCCA, a town of Spanish America, in the province of Tabasco; 30 miles W. of Tabasco.

CAYLAR, LE. See CAILAR.

CAYL-

CAYLLOMA, or **CALLOMA**, a jurisdiction of South America, in the country of Peru, and diocese of Arequipa, at the distance of about 30 leagues east from the city of Arequipa, famous for a mountain of the same name, and the silver mines it contains. The produce of these mines has been very considerable; and in the principal village of the same name there is a governor and officer appointed for receiving the king's fifth, and vending the blacksmith used in separating the metal from the ore. The gold in the greatest part of this district is so intricate, that the inhabitants are obliged to have recourse to the neighbouring provinces for the fruits of the earth. In some parts there are wild asses.

CAYLUS, **ANN-CLAUDE-PHILIP DE TUBIERE, DE GRIMOARD, DE PESTELS, DE LEVY**, count of, in *Biography*, an illustrious amateur of the arts, was descended from one of the most noble families of France, and born at Paris in 1692. Having entered at an early age into the military service, he distinguished himself in Calabria in 1714, and at the siege of Fribourg in 1713. But the peace of Rastatt terminated his military career; and from this time he devoted himself to those antiquarian researches, to which his love of the arts powerfully prompted him. In 1715 he joined the train of the French ambassador to the Porte, and visited the ruins of Ephesus, Colophon, and other places in Asia Minor and Greece. Availing himself by his garb and effort of those measures for his security, which prudence suggested, he viewed scenes that had been rarely contemplated by Europeans, and returned to France, in 1717, with a rich collection of drawings and descriptions. He afterwards visited London and other countries of Europe. Having concluded his foreign rambles and researches, he devoted himself to the incessant study of the elegant arts in all their branches. He was a practitioner in music, drawing, painting, and engraving; and the labours of the pencil and graver were aided by his pen in the illustration of classical antiquities. By his encouragement the public obtained a magnificent work, describing the sculptured gems in the king's cabinet, with the figures by Bourbarodon, and the explanations by Maricette. In 1731, he was admitted a member of the Academy of Painting and Sculpture; and in return for this honour he composed the lives of the principal artists that had belonged to it; and he collected in three works all the new subjects for painting, which had occurred to him in his perusal of the writers of antiquity. He also founded an annual prize for the best drawing or model after nature of a head, expressing some particular passion; and he also, at his own expence, caused to be engraved the beautiful coloured drawings of Pietro Santò Bartoli, made at Rome after ancient paintings. In 1742, he was appointed one of the honorary members of the Academy of Inscriptions and Belles Lettres; and thus distinguished he was led to prosecute diligent inquiries into the Egyptian mode of embalming, the preparation of the papyrus, the transportation of enormous blocks of stone from one extremity of Egypt to the other, and several other curious subjects of ancient art. He also elucidated many difficult passages in the elder Pliny, relative to the arts, and by the assistance of a chemist revived the secret of tinging marble and of ENCAUSTIC painting, which see. His academical dissertations amounted to more than 40 in number; and he instituted a prize for a dissertation, explaining the customs of antiquity from monuments, with a view to the improvement of artists in the knowledge of costume. By his various labours he acquired a reputation which extended throughout Europe, and which induced the principal learned academies to associate him with their members. He was justly deemed the Mæceas

of talents and literature; and by his own economical mode of living, he was enabled to indulge his taste both as a collector and a patron. His moral character was amiable: cheerful, good-natured, polite, strictly just, an enemy to flattery, and indifferent to honour, he was a true practical philosopher. His health was preferred to an advanced period, and he died at Paris, after a short confinement, in 1767, aged 75 years. His principal work is a "Collection of Egyptian, Etruscan, Greek, Roman, and Gaulish Antiquities," 7 vols. 4to. of which the first appeared in 1707, with an elogé of the author by Mr. le Peau. Of his other works are, "The History of the Theban Hercules, taken from various Authors," 8vo. 1758; "A Discourse on Ancient Pictures;" and several romances and fairy tales, the productions of his hours of relaxation. *Nouv. Dict. Hist. Gén. Biog.*

CAYLUX, in *Geography*, a town of France, in the department of the Lot, and chief place of a canton in the district of Montauban; 7 leagues N.E. of Montauban. The place contains 5131, and the canton 10 473, inhabitants; the territory comprehends 135 kilometres and 9 communes.

CAYMAN, in *Zoology*, the common name of the alligator in America. Bontius, in his History of Java, calls it *Crocodylus cayman*. See *LACERTA alligator*.

CAYMANS, in *Geography*, three small islands of the West Indies, in the bay of Honduras. 55 leagues N.N.W. of the island of Jamaica, called Great Cayman, Little Cayman, and Cayman Broek. The former is the most southerly, about 14 mile long, and a mile broad, and inhabited by about 160 persons, descendants of the old Buccaneers. It has no harbour for ships of burden, and only a tolerable anchoring place on the S.W. The climate and soil are very salubrious; and the people, who are vigorous, live to a great age. The produce is more than sufficient for the use of the inhabitants. Their chief employment is that of piloting vessels to the adjacent islands, and fishing for turtle; with which they supply Port Royal and other places in great quantities. It is situated in N. lat. 19° 20' W. long. 81 40'. The other two islands are uninhabited.

CAYMANUM LAPIS, in *Natural History*, the name of a stone found in the beds of rivers in many parts of America, and of a yellowish colour, veined with red and white. The Indians have an idle tradition, that it is originally found in the stomach of a crocodile, which in their language they call *caymens*; and thence authors have named it *lapis caymanum*. The natives of America pretend that it has great virtues in medicine, and particularly that it cures quartans by being applied to the wrist; and, to enhance its value, they pretend to take it from the crocodile.

CAYMITES, in *Geography*, three islands near the coast of St. Domingo, in the West Indies, the largest being about 12 miles in circumference; 36 miles W. from cape Donna Maria.

CAYNE, a river of Wales, which runs into the Severn, 4 miles W. from Newtown in Montgomeryshire.

CAYO, EL, a town of the island of Cuba; 60 miles E. of Spirito Santo.

CAYONNE, a river of the island of St. Christopher, in the West Indies; which falls into the sea from the W.S.W. near Little Bay, half a mile S.E. of Madan's point.

CAYOPOLLIN, of Buffon, and Fernard. Nov. Hist. in *Zoology*, a quadruped of the *didelphis* genus, described by Pennant under the name of the Mexican opossum. Schreber calls it *didelphis cayopolim*, which see.

CAYRES, in *Geography*, a town of France, in the department of the Upper Loire, and chief place of a canton in the

the district of Le Puy; 8 miles S.S.W. of Le Puy. The place contains 678 and the canton 3556 inhabitants; the territory includes 190 kilometres and 6 communes.

CAYS, a general denomination applied in the West Indies to small islands or rocks, or other banks above water. The English seamen improperly give them the name of *Kays*.

CAYSTER, in *Ancient Geography*, now *Minderfcarc*, and called also by the Turks *Coutbouk-mindre*, that is, the Little Meander, or the Black Meander, a river of Asia Minor, which had its two sources N. and S. of the mount Tmolus, and having bathed Lydia, and traversed the plain between the mountains Galleus and Corifus, it discharged itself into the Ægean sea near Ephesus. This river was celebrated by the poets for the swans that frequented its banks, and the lakes formed by it on the plain. To this purpose Virgil says:—

“ Jam varias pelagi volucres, et quæ Afæ circum,
Dulcibus in itagnis rimantur prata Cayltri.”

Georg. l. i.

It is also said to have almost as many windings as the Meander itself. From this resemblance several of our modern travellers have been led to mistake the one for the other.

CAYSTRIUS CAMPUS, or CAYSTRUM, a plain of Asia Minor, in Ionia, between mount Galleus to the north and mount Corifus to the south, on which was seated the city of Ephesus. The Cayster traversed it from the east to the west. Pliny says that this plain was formed by the successive depositions of the river.

CAYSTROPEDIUM, a very populous city of Asia, in Phrygia; where Cyrus remained five days and was joined by Epyaxa, wife of Syennesis, king of Cilicia.

CAYUGA, in *Geography*, a beautiful lake in Onondaga county and state of New York, in America, from 35 to 40 miles long, about 2 miles wide, in some places 3, abounding with salmon, bass, catfish, eels, &c. It lies between Seneca and Oswego lakes, and at the north end empties into Scayace river, which is the south-eastern part of Seneca river, whose waters run to lake Ontario. The reservation lands of the Cayuga Indians lie on both sides of the lake at its northern end.

CAZAL, a town of Arabia, 80 miles N.E. of Medina.

CAZALLA. See CAÇALLA.

CAZALS, a town of France, in the department of the Lot, and chief place of a canton in the district of Cahors; 3 leagues S.W. of Gourdon. The place contains 1046, and the canton 7947 inhabitants; the territory comprehends 142½ kilometres and 7 communes.

CAZARES, a town of Mexico. See ANGELO.

CAZAUBON, a town of France, in the department of the Gers, and chief place of a canton in the district of Condom; 6 leagues W. of Condom. The place contains 2275, and the canton 12,174 inhabitants; the territory includes 287½ kilometres and 18 communes.

CAZ-DAGLI, or CAZ-DANGLI, a district of Asia Minor, lying between Anatolia and Caramania, which the Turks believe to have been the country from which the English first drew their origin, and on this account, it is said, that they never fail to claim kindred with the English wherever they meet, especially if they stand in need of their assistance.

CAZECA, in *Ancient Geography*, a maritime town of the Tauric Chersonesus, between Panticapæa and Theodosia, according to Arrian.

VOL. VII.

CAZEMATE, in *Fortification*. See CASEMATE.

CAZENOVIA, in *Geography*, a new and thriving township of America, in Herkmer county and state of New York, 40 miles westward of Whitestown. By the state census of 1796, 274 of its inhabitants are electors.

CAZERES, a town of France, in the department of the Upper Garonne, and chief place of a canton in the district of Muret; 2 leagues S.W. of Rieux. The place contains 2023, and the canton 10,978 inhabitants; the territory comprehends 222½ kilometres and 20 communes.

CAZERNS, in *Fortification*. See CASERNS.

CAZES, PETER-JAMES, in *Biography*, an eminent French painter, was born at Paris in 1676, and having discovered an early inclination for design, he was placed under the instruction first of Feron, and afterwards of Houasse senior. The manner of Houasse being too mechanical for his taste, he received lessons of Boulogne the elder, and became his best scholar, so that he obtained several academical prizes. In 1703, he became a member of the Royal Academy of painting, and from this time began to distinguish himself. His first performances were fabulous subjects in the gallery of the marquis de Clerambaut; but his reputation was established by a large picture displayed at the church of Notre Dame on every first of May, representing the Woman with an Illus. of Blood. He then opened a school, which was much frequented. Being of mild and polished manners, and of an enlarged understanding, he acquired the friendship of several persons of taste. By the Academy his merit was so much noticed, that he was advanced through the gradations of adjunct, professor, governor, and director, to that of chancellor. His particular walk of painting was that of history; and his compositions are grand and well-studied, marked by elevated conceptions, large and flowing draperies, correct drawing, and a good style of colouring. In his church pictures there is much dignity, and grace in his fabulous subjects; and he equally excelled in great and small works. He is principally deficient in expression, and in some of his later pieces, especially, the coldness of age is perceptible. He lost his faculties some time before his death, which happened in 1754. His works are numerous in Paris, and its vicinity, and they are also found at Abbeville, Amiens, and other places. His easel works are met with in several cabinets. The king of Prussia has two excellent ones, which for their beautiful finish are compared to the works of Corregio. *Argenville. Gen. Biog.*

CAZES de Mondenard, in *Geography*, a town of France, in the department of the Lot and district of Montauban; 3 miles S.E. of Lauzerte.

CAZIC, or CAZIQUE, a general title given by the Spaniards to the petty kings, princes, and chiefs of the several countries of America, excepting those of Peru, who are styled *curacas*. The French call them *caïques*, a denomination which they also give to the chiefs of the Tartarian hords.

The cazics in some places do the office of physicians, and in others of priests, as well as captains. The dignity of cazic among the Chiites, a people of South America, does not descend to children, but must be acquired by valour and merit. One of the prerogatives annexed to it is, that the cazic may have three wives, while the other people are only allowed one. Mexico comprehended a great number of provinces and islands, which were governed by lords called *caziques*, dependent on and tributary to the emperor of Mexico; thirty of these *caziques* or vassals are said to have been so powerful, that they could each of them bring an army of an hundred thousand men into the field.

CAZIMI, among the *Arabian Astronomers*, denotes the disc of the sun. A planet is said to be in *cazimi*, when it is not distant from the center of the sun more than 10', the semidiameter of the sun's disc.

CAZOUS, in *Geography*, a town of France, in the department of the Herault, and district of Beziers; 5 miles N.W. of Beziers.

CAZZOLA, a small island in the Adriatic, near the coast of Dalmatia. N. lat. 45° 8'. E. long. 16° 44'.

CAZZONS, in *Rural Economy*, a term provincially applied to signify the dried dung of cattle, which is employed as fuel. It is a sort of fuel frequently made use of in some parts of Yorkshire, as about Holderness.

CEA, in *Geography*, a town of Portugal, in the province of Beira, 7 leagues S.S.E. of Viseu.

CEADAS, or CÆADAS, in *Ancient Geography*, a name given by Pausanias and Strabo to a place of Peloponnesus, in the vicinity of Sparta, in which was a deep cavern, into which they precipitated those who were condemned to death for very atrocious crimes.

CEANIDES, or CEANTIDES, in *Natural History*, a name given by many of the ancients to the stone more generally known under the name of *enclimones*. It was the same with our sparry incrustations on the walls and roofs of subterranean caverns; and, from the opinion of the times, that these stones brought forth young ones, which was founded on their finding little ones daily produced among them, it became a custom to give this internally to women in labour, as a thing that would, by a sort of sympathy, hasten the time.

CEANMHARRA, in *Geography*, a hill in the Scots island of Tiree, remarkable for numerous caves, to which sea-fowl, eagles, and ravens resort; some of the caves are more than 50 yards deep.

CEANOTHUS, in *Botany*, *κεανωθος*, Gr. a name given by Theophrastus to a prickly plant, supposed by Columna to be *feratula arvensis* of Linnæus, but by Adanson to be a species of *circum.*) Linn. gen. 267. Schreb. 361. Willd. 412. Lam. Ill. 358. Gært. 615. Juss. p. 380. Vent. vol. iii. p. 472. Clafs and order, *pentandria monogynia*. Nat. Ord. *Dunofæ*; Linn. *Rhamn*; Juss. *Rhamnoideæ*; Vent.

Gen. Ch. *Cal.* Perianth one-leaved, top-shaped, permanent, five-cleft; segments acute, nearly closed. *Cor.* Petals five, equal, clawed, awl-shaped, inserted into the calyx between its divisions. *Stam.* Filaments five, awl-shaped, erect, opposite to the petals, the length of the corolla; anthers roundish. *Pist.* Germ superior, trigonous; style cylindrical, semitrifid, the length of the stamens; stigma obtuse. *Peric.* Capsule (dry berry; Linn.) obtuse, three-grained or three-celled. *Seeds* solitary, egg-shaped.

Eff. Ch. *Calyx* five-cleft. *Petals* five, clawed, cowl'd, opposite to the stamens. *Capsules* three-grained, three-celled.

Sp. 1. *C. americanus*, Linn. Sp. 1. Mart. 1. Lam. 1. Willd. 1. Lam. Ill. pl. 129. fig. 1. Gært. tab. 106. fig. 4. (Celastrus; Gron. Virg. 23. Evonymus; Com. Hort. tab. 86. Pluk. alm. tab. 28. fig. 6.) New Jersey tea. "Leaves egg-shaped, acute, serrated, three-nerved at the base; panicles axillary, on long peduncles." A shrub, three or four feet high. *Stems* several, slender; branches cylindrical, smooth, reddish. *Leaves* alternate, deciduous, on short petioles. *Flowers* small, white, very numerous, on short about the size of a pepper-corn. A native of New Jersey, Virginia, Carolina, and other parts of North America. An infusion of the dried leaves is used by the common people instead of tea; particularly in the southern states, where,

from its Indian name, it is commonly called pongpong tea. It flowers from July to October, and from the profusion of its blossoms is a very ornamental shrub. 2. *C. macrocarpus*, Willd. 2. Cav. ic. 3. p. 38. tab. 276. "Leaves cordate-roundish, obtuse, three-nerved; corymbs axillary." *Fruit* nodding, large. Sufficiently distinct from the preceding, both in its indolence, and its leaves. A native of New Spain. 3. *C. microphyllus*, Lam. Illust. 2681. "Leaves oblong-elliptical, distantly toothed, final; panicle terminal, composed of alternate peduncled cymes." *Stems* about nine inches high, slender, much-branched. Found by André Michaux in Florida. 4. *C. asifucus*, Linn. Sp. Pl. 2. Mart. 2. Lam. Enc. 2. Illust. 2682. Pl. 129. fig. 2. Willd. 3. (Rhamnus asiaticus; Poir. in Encyc. Art. Nerprun. Gloffularia; Burm. zeyl. iii. tab. 48. Katapa; Rheed. Mal. 5. tab. 47. Carpodetus ferratus; Schreb. 360. Willd. 410. Mart. Forst. prod. 111. gen. p. 33. tab. 17.) "Leaves egg-shaped, somewhat serrated, three-nerved at the base; peduncles axillary, branched, many-flowered, shorter than the leaves." Lam. A shrub of a moderate size. *Branches* stiff, cylindrical, perfectly smooth. *Leaves* alternate, obscurely nerved, veined, smooth. *Flowers* in axillary racemes; most of them abortive. A native of the East Indies, and the isle of France. 5. *C. redimatus*, Mart. 4. Lam. Ill. 2683. L'Herit. Tert. Ang. p. 6. (Rhamnus ellipticus; Willd. 2; Hort. Kew. R. venosus; Poir. Encyc. 25. R. incrimis; Swartz. prod. 50. Fl. ind. 1. p. 497. R. arboreseus; Brown Jam. 172. tab. 29. fig. 2.) "Leaves egg-shaped, quite entire; branches dependent; cymes axillary, shorter than the leaves." Lam. A shrub. The young branches, petioles, peduncles, and calyxes clothed with light yellowish down. *Leaves* alternate, acute; a little villous underneath when young; smooth and bright green above. *Flowers* in small, axillary corymbs; peduncles branched at the summit into short, thick pedicels, petals shorter than the divisions of the calyx, almost linear. A native of Jamaica and St. Domingo. 6. *C. colabrinus*, Lam. Illust. 2684. (Rhamnus colubrinus; Linn. Sp. Pl. 8. Mart. 16. Poir. 15. Willd. 16. Jacq. Amer. 74. n. 2. Hort. 3. tab. 50. R. arboreus; Brown Jam. 2. p. 176. Arbor bacifera; Com. Hort. 1. p. 175. tab. 90.) "Leaves elliptical, quite entire; petioles, peduncles, and calyxes clothed with a ferruginous down." Lam. A tree, twenty feet high in mountain woods; only seven or eight in coppices on the coast. *Branches* spreading horizontally. *Leaves* alternate, acute, smooth and shining above. *Flowers* greenish, in short axillary racemes. A native of the West Indies, called by the French bois couleuvre, or snake-wood. In Cuba, according to Jacquin, the down is silvery, but in the other islands it is always ferruginous. 7. *C. cubensis*, Lam. Ill. 2685. (Rhamnus cubensis; Linn. Sp. Pl. 10. Mart. 15. Poir. 14. Willd. 15. Jacq. Hort. 3. tab. 49.) "Leaves egg-shaped, obtuse, quite entire, wrinkled, tomentous on both sides; cymes axillary." A small upright tree seven feet high, in habit approaching to viburnum lantana. *Leaves* alternate, petioled. *Petals*, examined under a magnifier, ciliated. A native of Cuba. 8. *C. africanus*, Linn. Sp. Pl. 3. Mart. 3. Lam. Encyc. 3. Illust. 2686. Willd. 4. (Celastrus; Hort. Clif. 73. Alaternus; Pluk. tab. 126. fig. 1. Alaternoides; Comm. præl. 61. tab. 11. Ricinoides; Seb. Thes. 1. p. 35. tab. 22. fig. 6.) "Leaves lanceolate, obtuse, serrated; stipules roundish." Lam. A shrub from six to nine feet high, evergreen. *Branches* smooth, reddish brown. *Leaves* alternate, smooth, shining, dark green above, on very short petioles; stipules embracing the stem. *Flowers* small, in axillary and terminal racemes. *Fruit* about the size of a large

large pea, globular, surrounded on its lower part by the calyx, which, having lost its divisions, resembles a little cup. A native of Africa. 9. *C. circumscissus*, Mart. 5. Græc. tab. 106. fig. 4. (*Rhamnus circumscissus*; Linn. jun. Sup. p. 152. Poir. in Encyc. 10. Willd. 32. *Lycium*; Pluk. Amalth. tab. 426. fig. 3.) "Prickly; leaves nearly opposite, in two rows; prickles solitary, recurved opposite to the leaves." A shrub. Branches simple, opposite, widely spreading, angular, with an even surface. Prickles solitary, opposite, fixed, horizontal, recurved, solid. Leaves petioled, inversely heart-shaped, obscurely toothed; stipules two, very minute, caducous. Flowers small, lateral, in axillary corymbs; pedicels four or five, very short, thick, placed near the summit of the peduncle; calyx campanulate, with five small sharp teeth, which fall off as the fruit advances, and leave the body of the permanent calyx apparently cut round; petals of a beautiful white colour, nearly heart-shaped, ciliated, involving the anthers; filaments a little shorter than the calyx; anthers upright, oblong, style short, permanent; stigma, emarginate. Fruit three-celled; Linn. jun. two-celled, two-seeded in the specimens sent to La Marck by Sounera. A native of the East Indies and Isle de France. We have followed Gærtner and professor Martyn in referring this plant to the present genus, on account of its having a dry fruit opening with pressure by two or three regular valves, although La Marck has left it under *Rhamnus*. 10. *C. coccifularis*, Mart. 6. Lam. Ill. Forst. Flor. Ault. p. 18. n. 212. "Leaves ovate-cordate, acuminate, serrated; capsules three-valved." Forst. A native of Otaheite.

Propagation and Culture. The first species was cultivated in England, by bishop Compton, at the beginning of the last century. It was soon after lost, but, in Mr. Miller's time, was re-imported from America, and is become not uncommon in nurseries. It may be raised either from seeds or by layers of the young branches; but the first method is to be preferred. The seeds should be sown in autumn in small pots, which must be kept during the winter in an old hot-bed, and well sheltered from frost, but occasionally exposed to fresh air in mild weather. In March the pots should be plunged into a moderate hot-bed, and when the plants have gained a little strength, they should be exposed in a sheltered situation till autumn, but must be placed under a hot-bed frame to screen them from the frost of the ensuing winter, with a free allowance of open air in mild weather. In the following spring, they should be transplanted before they begin to shoot, some into separate pots, and others into the nursery bed in a warm situation, where they may remain for a year or two, and then be removed to the places where they are designed to remain. They require a dry soil and a sheltered situation; in stiff cold land they put out late in the spring, and their young shoots are consequently so full of sap in the autumn, that they are commonly hurt by the first frosts, and die nearly down to the ground. When propagated by layers, the young shoots should be laid down in autumn, and the surface of the ground covered with decayed tan taken from an old hot-bed, to secure them from frost, and to prevent the winds from drying the mould too much in the spring. In a light soil they will put out roots in about a year; but as the shoots are tender, they are apt to rot if they be more than very moderately watered.

The fourth species may be propagated either by layers or cuttings, but requires the protection of the bark-rove.

The seeds of the sixth species should be sown on a hot-bed in the spring; and when the plants are fit to remove, they should be placed separately in small pots, filled with light sandy earth, and treated like other tender exotic plants.

The eighth species is best propagated by cuttings, which

should be planted in spring, in pots filled with good kitchen-garden earth, and plunged into a very moderate hot-bed. In about two months, if only moderately watered, they will have taken root, and may be treated like the other species. Miller.

CEAUX, in *Geography*, a town of France, in the department of the Vienne and district of Loudun; 2 leagues E. of Loudun.

CEBA, ANSOLDO, in *Biography*, an Italian poet, and a copious writer both in verse and prose, was born at Genoa in 1565, and died in 1623. In verse he wrote two heroic poems, "L'Elther" and "Il Furio Camillo;" and he laid down the rules of epic poetry in a dialogue on the subject more happily than he exemplified them. His "Elther" contained many fabulous additions to the Scripture history, which caused it to be inserted in the prohibited list. He chiefly excelled as a dramatic poet; and of two his tragedies, the "Genelle Capoane" and the "Alcippo" have been inserted by the marquis Maffei in the *Theatro Italiano*. Ceba also wrote a Roman history in Italian, a collection of academical exercises, orations, &c. Tiraboschi. Gen. Biog.

CEBA, in *Ancient Geography*, a town of Liguria, S.E. of Angula Vagienorum. The cheese made near this city is commended by Pliny.

CEBARADEFENSIS, an episcopal see of Africa, in the Byzacene territory.

CEBARSUSSI, another see in the same territory.

CEBASSAT, in *Geography*, a town of France, in the department of the Puy-de-Dome, and district of Clermont Ferrand; 3 miles N. of Clermont.

CEBATHA, in *Botany*, Forsk. *Ægypt.* p. 171. See *MENISPERNUM edule*.

CEBEL, in *Music*, an ancient English air, found among the compositions of the English masters of the violin who lived in the time of Charles II., in duplicate time of four bars or measures repeated at the will of the composer; the strains being alternately in the grave, and the acute series of notes in the musical scale.

CEBENNA, corruptly GEBENNA, the *Cevennes*, mountains of the Gauls, occupied by the Gabali and Ruteni. The Aveni were situated to the north of these mountains, in relation to the Romans, by which they were fortified as by a wall, "ut muro se munitis existimabant," says Cæsar; however, he penetrated their district.

CEBES, in *Biography*, a philosopher of Thebes, and a disciple of Socrates, is supposed to be the author of a beautiful allegorical piece, entitled "Pinax," or the "Tablet," representing a picture of human life. In its moral spirit and character, this piece is truly Socratic; but contains some sentiments which seem to have been borrowed from the Pythagorean school. Professor Meiners in a "Memoir," published in the 5th volume of the "Transactions of the Royal Society of Göttingen," urges several objections against the authenticity of the table of Cebes; and though they are not new, they are acute and judicious. It favours more, he says, of the Stoical than of the Socratic school. He considers it, indeed, as a noble composition; pure in style, as well as in precept; anterior also to the decline of Grecian eloquence, and infinitely superior to all the other productions that have been falsely attributed to the early writers of the Socratic school; nevertheless, he is induced, by various considerations, to pronounce positively, that it was composed long after the time of Cebes. In the first place, the author of this "Tablet" considers poetry, rhetoric, music, dialectics, and all the branches of mathematical science, as a *jallacious philosophy*, which has no tendency to render mankind wiser and better; an opinion,

which does not seem to be consistent with the tenets of the Socratic school. *Secondly*, he mentions the Peripatetic sect, which arose in Greece long after the time of Cebes; and, *thirdly*, he uses several expressions, which, as Meiners thinks, were not in use among the early Socratic writers. The learned Brucker, in his account of Cebes, (*Hist. Crit. Philof.* t. i. p. 578. ed. 2. 1767.) has made several observations, which, if they do not entirely remove these objections, diminish, at least considerably, their force. Some interpolations have been supposed by the learned to have got into the text, perhaps from marginal notes in the MS.; and the passage from which professor Meiners deduces his first and most important objection, has, with no small appearance of evidence, been considered by Fabricius as corrupt and supposititious. The professor, however, maintains, that this passage is so closely connected with what precedes and what follows, that the suspicion of any addition or interpolation is entirely groundless. Be that as it may, all the learned ancients, with one voice, attribute this philosophical table to Cebes, and, most certainly, both with respect to beauty of composition and excellence of matter, it is worthy of the most flourishing period of Athenian philosophy and literature. The editions of this table in various languages have been innumerable. The first complete edition of it was published from a MS. in the king of France's library by J. Gronovius, in 1678. 8vo. It is now usually printed with the Enchiridion of Eusebius, as a manual for students in the Greek language. Brucker, by Esfeld, vol. i. Fabr. Bib. Græc. t. i. p. 831.

CEBESSUS, in *Ancient Geography*, a town of Asia, in Lycia.

CEBESTUS, a town of Asia Minor, in Lycia, according to Quintus Curtius.

CEBRENA, a town of Asia Minor, in the Troade, and in the country named *Cebrenia*, a level country below, and parallel to, Dardania. It is mentioned by Strabo, Thucydides, Pline, and Scylax.

CEBRINUS, a river of Asia Minor, in Cebrenia, mentioned by Herodian.

CEBRUS, a place of Lower Media, according to the Itinerary of Antonine. It was situated to the north-west, on the right bank of the Danube, below Richiaria, at the mouth of a river of the same name.

CEBU, in *Geography*, an island of the East-Indian Ocean. See ZEBU.

CEBU, **SEBOU**, or **SURO**, a river of Africa, in the empire of Morocco, which runs from mount Atlas, through the provinces of Fez and Algar, and in its course cuts its way through two steep rocks of prodigious height near the mountain of Beni-yazza, and falls into that sea near Mamor, a city destroyed by Almanzor, about 20 miles N. of Salles. The mountaineers convey themselves from one side of this dreadful chasm to the other, by seating themselves in a strong basket, that runs by a pulley along a stout cable, which is fastened at both ends to two beams fixed in the rock, and is drawn by the people on the opposite side; so that if the basket or any of the tackle chance to break, as it has sometimes done, by the weight of the passengers, they fall into the river from a height of above 1500 fathoms. This river is reckoned the largest in Mauritania, and abounds with excellent fish, which has been farmed by the emperor at above 20,000 ducats.

CECCO, **D'ASCOLI**, whose proper name was **FRANCESCO DE GLI STABILI**, in *Biography*, was born at Ascoli, about the year 1257; and acquired eminence, according to the age in which he lived, in poetry, theology, medicine, and mathematics. By his mechanical skill, he proposed to

the people of Ascoli to bring the Adriatic under their wall, through an interval of six leagues. He seems to have had for some time an intimacy with Dante, which was interrupted by his free remarks on the *Commedia* of this author; and it is probable that by the severity of his criticisms and by other parts of his conduct he made himself many enemies at Florence. He was invited to Avignon by pope John XXII. in order to be his first physician; though his medical reputation probably depended chiefly on his professed skill in astrology. In 1322, he was appointed professor of astrology and philosophy at Bologna, and there published his *Commentaries on the Sphere of John de Sacrobolus*. "An accusation against him before the inquisition of Bologna was founded on this work, because he had taught that incantation and other wonderful feats might be effected by means of demons inhabiting the first sphere; and the inquisition passed a sentence enjoining penance, and depriving him of the right of ever again reading lectures on astrology. From Bologna he removed to Florence, and became astrologer and physician to Charles, duke of Calabria, who governed that city. Here again the inquisition took cognizance either of his pretended prophecies or heretical opinions concerning the influence of the stars on the human character and conduct; and the power of his enemies prevailed against him to such a degree, particularly that of Dino del Garbo, a famous physician, who had attacked his commentaries, and who was probably jealous of his influence at court, that he was capitally condemned and brought to the stake at Florence in 1327. Dino himself died a few days after, distressed by the reflection that he had been instrumental in promoting this cruel event. Cecco was vain, fraudulent, and superstitious, and licentious in his practice. Besides the commentaries which occasioned his condemnation, he wrote a poem in *Sette rima*, entitled "L'Acerba," which was a medley of physics, morals, theology, and judicial astrology, without much poetical merit; and yet the temporary reputation of the author caused it to pass through 19 editions: and the last year of its publication was 1546. Tiraboselli. Moreri. Gen. Biog.

CECIL, **WILLIAM**, lord Pembroke, an eminent statesman, was son of sir Richard Cecil, master of the robes to Henry VIII. and was born at Bourne in Lincolnshire in 1520. From St. John's college, Cambridge, where he completed his education, he was removed to Gray's-Inn, for the study of the law. In consequence of a dispute with two Irish priests concerning the power of the pope, which he conducted with credit, he was introduced to the king; who conferred upon him the reversion of the place of "Custos Brevium"; and he was then encouraged to push his fortune at court. His first wife was the sister of sir John Cheke, who recommended him to the favour of the earl of Hertford, afterwards so powerful in the reign of Edward VI. under the title of the duke of Somerset. Soon after the commencement of that reign, having lost his lady, he married the daughter of sir Anthony Cook, director of the king's studies; and thus supported, he rose in 1547 to the post of master of requests, and in 1548, to that of Secretary. Some court intrigue occasioned his loss of this place, and his being committed, with some others of the duke of Somerset's friends, to the Tower; whence, however, he was soon liberated. In 1551, he was reinstated in his office, with an increase of favour, knighted, and sworn a member of the privy council. So wary was his conduct amidst the collision of parties, that he stood secure when his patron, the duke of Somerset, fell; and such was his personal influence with the young king, that the haughty duke of Northumberland treated him with respect. Upon the death of Edward

ward he pursued the same cautious conduct, and thus secured a favourable reception from queen Mary; but refusing to change his religion, he forfeited his office. In 1555, he attended Cardinal Pole and other commissioners to the continent in order to treat of a peace with France. On his return, he was deputed to parliament by the county of Lincoln, and distinguished himself by his opposition to a bill brought in for confiscating the estates of fugitives on account of religion. His prudent counsels were also of singular service to the princess Elizabeth in her critical situation; and they were duly acknowledged on her accession in 1558, when, in the arrangement of her first ministry, he was appointed privy councillor and secretary of state. The settlement of religion was one of the first acts of the new reign, in which Cecil took the lead, and in which he manifested great prudence and moderation; and in the recovery of the coin from its debased state he also successfully engaged. With regard to foreign affairs, it was his great object to guard against the dangers impending from the catholic powers; and with this view he thought it of great importance effectually to guard the reformed religion in Scotland. As he was one of the commissioners who accomplished the convention of Leith and the treaty of Edinburgh, which were eminently advantageous to the English interest, he was advanced, in recompence of this service, to the post of master of the wards in 1561. His system of politics, which was prudential and cautious, corresponded, in a considerable degree, with the inclinations of his mistress; and he thus maintained a regular and permanent influence through the whole of his ministry. For his wisdom and activity in suppressing the northern rebellion, he was raised by Elizabeth to the peerage in 1571, by the title of Baron of Burleigh, and in the following year he was made knight of the garter and lord high treasurer. His steady and zealous opposition to the machinations of the popish party, drew upon him the rancorous hatred of the Jesuits, and emissaries of Spain; and their rancour was further inflamed by the part he took in the unhappy fate of Mary, queen of Scots; whom he is charged with having driven from the throne, and kept as a prisoner in England, and whom he considered as the inveterate foe of Elizabeth, so that he never ceased urging her trial and condemnation. Burleigh shared with other actors in the catastrophe of her execution the seignèd resentment of Elizabeth, and it was with some difficulty that he recovered his former credit. At the time of the threatened Spanish invasion, he drew up the plans of defence, and his eldest son served on board Lord Howard's fleet. Soon after this period he sunk into a state of melancholy, in consequence of the death of his wife, to whom he was affectionately attached, and wished to withdraw from public business. However, he was persuaded to retain his employments, and he was diligent to the last in fulfilling the various duties of his station, so that he was regarded as at the head of Elizabeth's counsellors. One of the last services in which he engaged was an effort to bring about a peace with Spain; but being vehemently opposed in his proposed scheme of pacification by the earl of Essex, he contented himself with pointing out to his lordship in a prayer-book the following words, "Men of blood shall not live out half their days." Having attained an honourable old age, Lord Burleigh died in 1598, after having completed his 77th year. Cecil may be justly reckoned the animating soul of queen Elizabeth's ministry, and to his counsels may be attributed, in a very great degree, the singular prosperity of that period in the history of our country. Possessing no distinguished genius, he had other qualities, such as the knowledge of mankind, the wisdom of experience, invincible resolution and indefatigable application, which qualified him

for encountering the difficulties and performing the services, which the critical circumstances of the times presented. Particular emergencies demanded corresponding measures of policy; and it must be allowed, that they offer an apology for some of those adopted by lord Burleigh, who always approved himself a faithful servant of his royal mistress. In his character as a courtier he combined that degree of probity which conciliated esteem; and he seems to have possessed that learning, piety, and decorum, which in that age usually accompanied elevated stations. His manner of living was splendid and yet economical; and though he raised a considerable fortune, it was by no means greater than the various posts which he occupied might justify. His whole life was that of a busy statesman; and therefore he had not much leisure for literary avocations. However, he is said to have been the author of a few Latin verses, and of moral and historical tracts. Several of his letters on business are still extant. *Diog. Brit.*

CECIL, ROBERT, earl of Salisbury, was the second son of the former, and born about the year 1550. As his constitution was feeble and his form distorted, he received the first rudiments of learning at home, under his learned mother and an excellent tutor, and finished his education at St. John's college, in the university of Cambridge. By his father, however, he was instructed in the arts of an accomplished courtier and statesman. He began his political career as assistant to the earl of Derby, ambassador at the court of France, and in 1596, was appointed by queen Elizabeth second secretary of state with Sir Francis Walsingham; and when that minister died, he became principal secretary, which post he occupied as long as he lived. He acquired also other offices of profit and honour, for which he seems to have manifested a greater degree of avidity than his father. His advancement, indeed, was strenuously opposed by the earl of Essex; and for this reason he was a principal instrument in the disgrace and unfortunate end of that eminent nobleman. By the regular correspondence which he attentively maintained with foreign courts, he was enabled to counteract and defeat many conspiracies against his sovereign and his country. Whilst he contributed to support the declining years of Elizabeth by his vigour and prudence, he was not regardless of the favour of her successor. Accordingly he held a secret correspondence with him, and adopted the necessary measures for his quiet inheritance of the crown at the queen's demise; and for these services he was continued as prime minister at the accession of James; who advanced him to the peerage; creating him baron of Essendon in 1603, viscount Cranbourn in 1604, and earl of Salisbury in 1605. In this last year he was appointed chancellor of the university of Cambridge, and admitted to the order of the garter. His politics were altogether adverse to the Spanish interest, which was powerful at court; he steadily opposed the popish party, and placed himself at the head of the protestant cause, inasmuch that he was reproached with the appellation of puritan. He was indispensably necessary to James; and therefore, though the king did not love him, he was chosen, in 1608, as the fittest person to succeed the lord high treasurer, the earl of Dorset, at his death. The king's profusion rendered his post very delicate and trying; and in order to supply the royal coffers, he is said to have had recourse to various methods that have been deemed arbitrary and oppressive. The good of the nation was, however, the object at which he aimed; and he justly merited the praise of the ablest minister in that reign. By his application to business he injured his health; and as he had a weakly constitution, his life terminated by a decline, in 1612. He died at Marlborough in his return from Bath, and was buried

buried at his magnificent seat at Hatfield in Hertfordshire; which manor he had obtained from the crown, in exchange for his feat of Theobalds near Cheffunt.

Lord Salisbury is characterised as a man of more subtle and acute genius than his father; and he was thus led, as some have said, to pursue a more crooked and treacherous system of policy, so that those who were concerned with him in public affairs could repose no confidence in him. The death of Sir Walter Raleigh is in a great degree charged upon him; and he is also reproached with having adopted arbitrary maxims of government, in order to ingratiate himself with his weak master. He was also selfish and avaricious in making lucrative bargains with the crown, and thus aggrandizing his own fortune. His natural temper was mild, gentle, and courteous; and though in the height of power, he met death with philosophical tranquillity. "Ease and pleasure," said he in his last illness, "quake to hear of death; but my life, full of cares and miseries, desirèth to be dissolved." As a writer, he was the author of a work against the papists, of several letters, dispatches, and parliamentary speeches, and of some notes in Dr. Dec's discourse on the reformation of the calendar. Biog. Brit.

CECIL, in *Geography*, a county of America, in the state of Maryland, situate on the shore of Chesapeake-bay, and containing, by the estimate of the population in 1782, 7749 inhabitants.—Also, a township of Washington county in the state of Pennsylvania.

CECILIA, SAINT, in *Biography*. Musical historians have found it very difficult in the lives and legends of saints, to authenticate the claim which this holy personage has to such divine honours and annual celebrations from the wicked sons of Apollo, the divinity whom she had abandoned.

It was natural to expect to find in the "Legenda Aurea" of Jacobus Januensis, and in Chaucer's account of this saint in his second "Nonneste," that some mention would have been made of her musical powers and promise of protection to the art; but neither in Chaucer, nor in any of the histories or legendary accounts of this saint, which we have been able to consult, does any thing appear that can authorize the religious veneration which the votaries of music have so long paid to her; nor is it easy to discover whence it has arisen. Chaucer's account is almost literally translated from the life of St. Cecilia, in the "Legenda Aurea" of Jacobus Januensis. Bede, in his Ecclesiastical History (lib. v. cap. 2), mentions her church at Rome, as the place where Vilibrod was ordained pope in 606; and in his Martyrology, he tells us, that her intended spouse, Valerian, and his brother Tiburtius, suffered martyrdom in the time of the emperor Alexander Severus. Mabillon (De Liturgia Gallicana, p. 175.) has proved, that the festival of this saint was celebrated in France before the time of Charlemagne, by a Gallician Missal, which he has published, and which must have been in use before the Gregorian chant was received in that country. (Cardinal Bona, "De divina Palmod." says, that the MS. of this mass, which was in possession of the late Christina, queen of Sweden, had belonged to the learned Petavius, and was written in the 9th century, as was discovered by the learned from the square form of the letters, and the capitals.) Fortunatus of Poitiers (lib. vii. cap. 4.), the most ancient author who speaks of her, says, that she died, or rather suffered martyrdom in Sicily. Fortunatus wrote at the end of the 6th century; but even this was at too remote a period from that in which tradition tells us the saint lived, as Alexander Severus reigned from 194 to 211.

There was a great festival at Rome in 1599, during the pontificate of Clement VIII. for the finding the body of St. Cecilia among other relics. Cardinal Baronius, who was

himself a witness of this transaction, has left an ample account of it. (Voyez la Vie de Saints, tom. 31. 3^e edit. fol. p. 369, Par. 1715.)

The earliest notice of her as the titular saint and protectress of music seems to have been in the works of the great painters of the Italian school; some representing her in performing on the harp, and others on the organ. Raphael, in his celebrated portrait of the saint, has placed in her hands a column of organ pipes, or rather the front of a portable instrument called the *Organo*, which in Roman catholic times used to be carried by one person and played by another in processions. But when her birth-day first began to be celebrated by assemblies of musicians, we have been able to discover no instance earlier than the latter end of the 17th century, when there was a rage among the votaries of music for celebrating the birth day of this saint, not only in London, but in all the considerable cities and provincial towns in the kingdom where music was cultivated.

We meet with no such constant annual celebrations of this saint on the 22d of November in other countries. In the *Dramaturgia* of Leo Allatius, indeed, 13 dramas, tragedies, and oratorios are recorded, of which this female saint is the heroine.

The first composition expressly produced for a *music meeting* in England on St. Cecilia's day, was called "a musical entertainment performed November 22d, 1683, on St. Cecilia's day, printed in score by John Playford, with a dedication to the gentlemen of the musical society, and particularly the stewards, written by Henry Purcell, composer of the music."

But whoever wishes to trace the celebration of this pious patroness of music in our country from this period, will find an ample account detailed in the life of Dryden, by the diligent and accurate Mr. Malone, who has not only gone over the same ground as the musical historians, but taken a much wider range in search of materials for the life of this saint, and the honourable titles conferred upon her by the sons of Apollo.

The history of this nominal patroness of music is involved in some obscurity, it not very clearly appearing how she became entitled to this honour. She is supposed to have been born in the reign of the emperor M. Aurelius Antoninus, and to have suffered martyrdom in that of Sptimius Severus, in the beginning of the third century; and, according to the legend, she was a noble Roman lady of distinguished piety, who from her infancy had been bred in the Christian faith; notwithstanding which, she was married by her parents to a young Pagan nobleman, named Valerianus, who, on claiming the rights of a husband, was told by her, that she was visited nightly by an angel, who was enamoured of her, and would destroy him if he presumed to approach her. He replied, that he would desist, if he were permitted to behold his rival, and he should prove an angel; but if he were a mere mortal, as he feared, he would put them both to death; to which Cecilia answered, that he should be indulged in what he desired, provided he became a convert to Christianity. To this requisition Valerianus agreed; and after having been baptized by bishop Urban (afterwards pope Urban I.), repaired to his wife's chamber, where he found her at prayer, with the angel by her side, in the form of a beautiful youth, clothed with celestial brightness. The angel had in his hand two crowns, or wreaths, the one of lilies, the other of roses, which he had brought from Paradise; one of them he presented to Cecilia, and the other to her husband, informing him at the same time, that as a reward for his piety, whatever he asked should be granted him. Valerianus replied, that he had a brother named Tiburtius, whom he wished to be made partaker

taker of the same grace which he had received. The angel having granted his request, told him that they both should be crowned with martyrdom; and then vanished. They accordingly were put to death for their faith; but Cecilia was informed, that she should be spared, if she would offer sacrifice to Jupiter. Not choosing to preserve her life on such conditions, she suffered martyrdom, by being shut up in a dry bath, beneath which a large fire was made for the purpose of slowly consuming her. (According to other accounts, she was thrown into scalding water. Fortunatus of Poitiers, who lived in the sixth century, says, she suffered martyrdom in Sicily.) Finding, however, that the fire had no effect, her tormentors put her to death. Malone's *Life of Dryden*, vol. i. pt. 11. p. 255.

"If (says Mr. Malone, as Dryden and others seem to have thought, she had been the inventress of the organ (*ubi supra*, p. 257) an instrument so happily adapted to religious worship, that circumstance might have entitled her to a place, though not to so extraordinary an elevation, among the improvers of the musical art.

All this adoration of the saint seems "to have arisen from a tradition that she was a skilful musician, and that the angel who visited her was drawn from the mansions of the blessed by the charms of her melody; a circumstance to which Dryden has alluded in the conclusion of his ode."

Mr. Malone has been at the trouble of tracing all the great *Cecilian* festivals held in London, from the year 1683 to about the year 1740. And Mr. M. in his very agreeable book has given a chronological list of all the odes written expressly for the celebration of this saint, specifying by whom they were written, and by whom set to music.

CECILIA, in *Ancient Geography*, a town of Syria, near the Euphrates, according to Ptolemy; probably the same with *Ceciliana*.

CECILIA Gemellina, a town placed by Ptolemy in Lusitania; perhaps the same with *Ceciliana*, or *Castra Ceciliana*.

CECILIANA, a town of Asia in Syria, seated on the western bank of the Euphrates, S.E. of Hierapolis.

CECILIONICUM, a place of Spain, marked in the Itinerary of Antonine, between Capara and Ad Lippos.

CECINA FLUVIUS, a river of Italy in Etruria, which ran from the east to the west and discharged itself in the sea.

CECROPIA, in *Botany*, Linn. gen. 1099. Schreb. 1492. Juss. p. 402. Vent. vol. iii. p. 542. Coulequin, Lam. Bosc. Clafs and order, *diacia diandria*. Nat. Ord. *Scabridae*, Linn. *Urtica*, Juss.

Gen. Ch. *Male*. *Calyx* common. Spathe egg-shaped, burbling, caducous; containing many fasciculated, cylindrical aments, imbricated with numerous flowers. *Cal. proper*. Scales top-shaped, compressed-quadrangular, obtuse, with a double perforation at the tip. *Cor.* none. *Stam.* Filaments two, capillary, very short, from the perforations of the scales; anthers oblong, quadrangular. *Female*. *Cal. common*. Spathe oblong, obtuse with a point, burbling longitudinally, deciduous; containing four cylindrical, imbricated aments. *Cal. proper* funnel-shaped, oblong, erect, bifid at the tip; segments roundish, obtuse, concave, erect, small. *Cor.* none. *Stam.* none; but there are two very small, caducous bodies on the divisions of the calyx, which have the appearance of barren anthers. *Pist.* Germs numerous, imbricated, compressed, quadrangular, obtuse; styles solitary, very short; stigmas somewhat capitate, lacerated. *Peric.* Berry the form of the germ, one-celled, one-seeded. *Seeds* oblong, compressed.

Eff. Ch. Male. Spathe caducous. Ament imbricated with

top-shaped, compressed-quadrangular scales. *Cor.* none. *Female*. Germs imbricated. Style one. Stigma lacerated. Berry one-seeded.

Sp. *C. pellata*, trumpet-tree, or snake-wood; Linn. Sp. Pl. Læfl. ii. 272. Jacq. Obf. 2. tab. 46. fig. 4. Amer. pict. 126. tab. 262. fig. 66. (Ambaba; Marcg. bras. 91. Pif. bras. 147. Yaruma Oviedi; Sloan jam. tab. 88. fig. 3. tab. 89. *Ficus furciformis*; Pluk. alm. tab. 243. fig. 5. *C. illo-tapalus*; Brown jam. n. 1.) A tree, about thirty feet high. *Trunk* a foot in diameter, hollow, stopped from space to space with membranous septa, which form slight annular marks on the surface, branched only at the summit. *Leaves* in clusters at the ends of the branches, large, peltate, green and scabrous above, downy-white underneath, deeply divided into nine or ten oblong lobes, on long petioles. *Berries* in flavour somewhat resembling the common raspberry. The wood when dry easily takes fire by attrition; and is employed by the native Indians for kindling their fires in the woods. The bark is strong and fibrous, and used for cordage. The smaller branches, when cleared of their membranous divisions, are employed for wood instruments. Both trunk and branches yield a great quantity of fixed salt with which the French despumate and granulate their sugars. A native of the West Indies, Guiana, and other parts of South America. It may be propagated by seeds brought from its native country in sand, and requires the same treatment as other tropical plants.

CECROPIA, in *Ancient Geography*, one of the first names given to the citadel of Athens, and also to the whole city. See **ATHENS**.

CECROPIA, a burgh of Greece in Attica, between Mount *Ægaleus* and the village of *Acherne*, according to *Thucydides*. A tribe of the same name belonged to it.

CECROPIUS MONS, a name given by *Seneca* the tragedian to a mountain of Greece, in Attica, in the vicinity of Athens; probably the eminence on which was erected the *Acropolis*, which afterwards bore the name of *Cecropia*.

CECROPS, in *Biography*, the first king of Athens, whose history ascends into the fabulous times, is said to have been an Egyptian by birth, and to have brought a colony from the city of Sais in Egypt, whom he conducted after a tedious voyage to the shores of Attica, and settled on the rock, that became afterwards the site of the city of Athens. The period to which this point is referred is, according to the *Eusebian chronicle*, about 1556 years B.C. On this spot *Cecrops* built a fortress, called *Cecropia*; and having taken possession of a country inhabited by a barbarous people, divided it into districts, introduced laws, agriculture, and the arts, social polity, and religion; and, on this account, deserved to be reckoned the founder of the Athenian state. Such was the beneficial effect of the regulations which he established, that Attica was soon peopled by 20,000 inhabitants, who were divided into four tribes. From respect to his memory, the Athenians assumed the appellation of "*Cecropidae*," which they retained to the time of *Erechtheus*. *Cecrops* died after a reign of 50 years. He had espoused *Agraulis*, the daughter of *Acteus*, one of the principal inhabitants of Attica, by whom he had a son, who died before him, and three daughters to whom the Athenians afterwards decreed divine honour. His tomb was long preserved in the temple of *Minerva*; and his memory was perpetuated in the constellation of *Aquarius*, which was consecrated to him. After *Cecrops*, reigned 17 princes, during an interval of about 565 years, the seventh of whom was called *Cecrops*, and the last *Codrüs*. *Travels of Anacharsis*, vol. i. See **ATTICA**.

CECYPHALEA, in *Ancient Geography*, a promontory of Peloponnesus, near which the Athenians gained a naval combat against the Ceginetæ, according to Diodorus Siculus and Thucydides. This has been supposed to be the ile of Cecyphalus, which Pliny has placed near the Peloponnesian Epidaurus. That part of the sea which bathed the island and promontory of this name was called "Cecyphala in mare."

CEDAR, *Barbadoes bastard*, in *Botany*. See **CEPRELA**.

CEDAR, *barbadoes*. See **BUBROMA GUARANA**.

CEDAR, *Bermudian*. See **JUNIPERUS BERMIUDIANÆ**.

CEDAR, *Carolina*. See **JUNIPERUS**.

CEDAR, *of Lebanon*. See **PINUS CEDRUS**.

CEDAR, *Lycian*. See **JUNIPERUS LYCIA**.

CEDAR, *Phœnician*. See **JUNIPERUS PHœNICIA**.

CEDAR, *red*, or **VIRGINIAN**. See **JUNIPERUS VIRGINIANA**.

CEDAR, *white*. See **CUPRESSUS THYROIDES**.

CEDAR, or **KEDAR**, in *Ancient Geography*, a portion of Arabia, near Judea. The Arabians in this district had black tents. See the Song of Solomon, ch. i. ver. 5.

CEDAR, in *Geography*, an island of America, on the coast of Virginia. N. lat. 37° 37'. W. long. 76° 40'.

CEDAR, a river of Canada which runs into the lake Michigan. N. lat. 47° 30'. W. long. 86° 52'.

CEDAR, a lake of North America, N. lat. 52° 30'. W. long. 100° 5'. The entrance into this lake is through a small channel on the left, formed by an island. Banks of rocks appear at intervals, in the approach to it on either side: the rest of the country is low. This is the case along the south bank of the lake and the islands, while the north is level throughout. This lake runs first west four miles, then as much more W.S.W. across a deep bay on the right, then six miles to the Point de Lievre, and across another bay again on the right: then N.W. 8 miles across a hill deeper bay on the right; and 7 miles parallel with the north coast, N.N.W. through islands, 5 miles more to Fort Bourbon, situated on a small island, dividing this from Mud Lake. The Cedar lake is from 4 to 12 miles wide, exclusive of the bays. Its banks are covered with wood and abound in game, and its waters produce plenty of fish, particularly the sturgeon. The river Saskatchewan will probably, in a course of time, by the deposition of earth and sand, convert the whole of the cedar lake into a forest. Mackenzie's Voyages, Introd. p. 68.

CEDAR lick, a salt spring in the state of Tennessee, America, 19 miles from Nashville, 4 from Big Springs, and 6 from Little Spring.

CEDAR Point, a port of entry in Charles county, Maryland, on the east side of Patowmack river, about 12 miles below Port Tobacco, and 96 S. by W. of Baltimore. Its exports are chiefly tobacco and Indian corn, and in 1794 amounted in value to 18,593 dollars.—Also, a cæpe on the west side of Delaware bay, in St. Mary's County, Maryland.

CEDAR-cups, a sort of wooden ware brought from the West Indies. They are made out of the wood of the bastard cedar, and appear of a very close and firm grain; but they are really so porous, that when any liquor is poured into them, it runs out at the bottom.

CEDEBRATIS, in *Ancient Geography, a town of Asia Minor in Lycia.*

CEDEYRA, in *Geography*, a town of Spain, in the province of Galicia; 5 leagues north of Ferrol.

CEDIAS, in *Ancient Geography*, an episcopal town of Africa.

CEDILLA, in the Spanish and French languages, denotes a sort of small *c*, to the bottom of which is affixed a kind of virgula, as *ç*, to denote that it is to be pronounced like *s*. The cedilla is called by some of our printers a *ceceril*. It is used before the vowels *a*, *o*, and *u*; as in *braçes*, *çbago*, *çommença*, *çeron*, and *çega*, &c. in the Spanish, it is sometimes used at the beginning of a word; as in *çamarra*, *çurzur*, &c.

CEDOGNA, in *Geography*, a town of Naples, in the province of Principato Ultra, the see of a bishop, suliragano of Conza, at the foot of the Apennines, in a decayed state; 12 miles N.W. of Melii.

CEDRÆE, in *Ancient Geography*, a town of Asia Minor, in Caria. Steph. Byz.

CEDREI, **CEDRÆANS**, or **CEDARENIANS**, a people of Arabia Deserta, in the vicinity of the Nabatizæans, mentioned by Pliny. They dwell in tents, and commonly occupied the southern part of Arabia Deserta, north of Arabia Petraea and Arabia Felix.

CEDRELLA, in *Botany*, (formed from Cedrus, and so called from its aromatic resin) Linn. gen. 277. Schreb. 385. Willd. 476. Lam. Ill. 375. Jeff. p. 266. Vent. vol. iii. p. 165. Gart. 592. tab. 95. fig. 2. Clais and order, *pentandria monogynia*. Nat. Ord. *Melizæ*, Juss. *Meliceæ*, Vent.

Gen. Ch. Cal. Perianth one-leaved, campanulate, very small, five-toothed, withering. Cor. pentapetalous, funnel-shaped; tube bellied below; petals linear-oblong, obtuse, erect, adnate to the receptacle about a third of their length. Stam. filaments five, awl-shaped, seated on the receptacle; shorter than the petals, adnate to the receptacle, Lam. short, distinct, Juss. united into a tube, half their length, Vent.; anthers oblong, bent outwards at the tip. Pijl. Receptacle proper, five-cornered; germ globular, (elevated on a yellowish receptacle which rises within the flower, Lam. placed at the top of a stipes which has its filaments inserted into its upper part and the petals into the lower, Juss. supported by the tube formed by the union of the filaments, Vent.) style cylindrical, the length of the filaments; stigma capitate, depressed. Peric. capsule woody, roundish, five-celled, five-valved; valves deciduous. Schreb. Lam. (dehiscent from the tip, fixed at the base, not caducous, Gært.) Seeds numerous, fleshy, imbricated downwards, terminated by a membranous wing. (Compressed; upper ones elliptical; middle ones oblong-ovate; lower ones ovate-lanceolate; all of a ferruginous-cinnamon colour, with a nucleus at the top, and a membranous wing beneath, Gært.) Receptacle central, very large, woody, pentagonal, five-angular.

Eff. Ch. Calyx withering. Corolla five-petalled, funnel-shaped, adnate to the receptacle a third of its length. Capsule woody, five-celled, five-valved. Seeds imbricated downwards, with a membranous wing. Nearly allied to Swietenia.

Sp. C. odorata, Linn. Sp. Pl. Brown. Jam. tab. 10. fig. 1. Lam. Ill. Pl. 137. (Cedrus barbadensis, Pluk. alm. tab. 157. fig. 1. Pruno forte affinis. Sloan Jam. tab. 220. fig. 2. Acajou aplanches, Nicols. St. Dom. p. 155.) "Flowers panicled." A straight tree seventy or eighty feet high. Wood soft, light, reddish, of a pleasant smell; bark smooth and ash-coloured when young, rough as it advances in age; having, when fresh, an unpleasant taste and very offensive smell resembling that of asafetida. Leaves sometimes near three feet long, winged with sixteen or eighteen pairs of leaflets without an odd one, with a smell like that of the bark. Flowers whitish flesh-colour, small, very numerous, in much-branched racemes or panicles: branchlets alternate,

nate, rather remote, each bearing two or three flowers. On account of its agreeable odour, the wood is commonly known in the British West India islands under the name of cedar. It is much used there for canoes and periaguas, some of which have been hollowed out of its trunk not less than forty feet long and six broad; the softness and lightness of its wood render it peculiarly proper for this purpose. It is also cut into shingles for the roofs of houses, which are found very durable; and is a valuable material for chests of drawers and other articles of household furniture, because its odour is offensive to insects. A native of South America and the West Indies. Loureiro has another species which he calls C. Rosmarinus, a native of Cochinchina and the neighbourhood of Macao, but Willdenow is of opinion that it ought rather to be referred to the genus *Tea*. A shrub, about four feet high. *Leaves* linear. *Peduncles* axillary, one-flowered. *Seeds* not winged. It yields a fine essential oil, and a spirit not inferior to that which is drawn from rosemary.

CEDRELA, BROWN, JAM. 1758. See *SWIETENIA mahageni*.

CEDRELA, in *Gardening*, comprehends a plant of the exotic tree kind, viz. the Barbadoes ballard cedar (*C. obtusata*), which, in its native situation, rises with a straight stem to the height of seventy feet or more, but is small in this climate. While young, the bark is smooth, and of an ash colour; but, as it advances in age, becomes rough, and of a darker colour; toward the top it shoots out many side branches, which are garnished with winged leaves, composed of sixteen or eighteen pair of leaflets, sometimes near three feet long, and of a pale colour, emitting a rank odour in the summer season: the fruit is oval, about the size of a partridge's egg, smooth, and of a very dark colour. It is a native of the West Indies.

Method of Culture. This is effected in this plant by sowing the seeds obtained from abroad in the autumn or spring months, in small pots filled with a light earth, plunging them in a hot-bed. When the plants are of sufficient growth they should be removed with care into other small pots separately, and be placed in the bark-bed, having afterwards the management of other woody stove plants.

CEDRENUS, GEORGE, in *Biography*, a Greek monk, who flourished in the latter part of the 11th century, and wrote annals, or an epitome of general history, from the beginning of the world to the reign of Isaac Comnenus, in 1057. This work is compiled, without much judgment and critical skill, from different authors. It was translated into Latin by Xylander, and printed at Basil in 1566; and an edition appeared at Paris in 1647, with the notes of father Goar, and the glossary of Fabrot.

CEDRES, in *Ancient Geography*, a mountain of the isle of Crete, near mount Ida, according to Theophrastus.

CEDRIA, a resinous liquor issuing from the great cedar-tree, or cedar of Lebanon. The word is also written *cedrium*, *cedrosus*, and *cedrinum*, *cedrosus*.

Cedria, when good, yields a strong smell, is transparent, of a thick, fatty consistence, so that in pouring it out, it does not fall too fast or freely, but equally drop by drop. It is possessed of two opposite qualities, viz. to preserve dead bodies, by its drying and consuming superfluous moisture, without damaging the solid parts; and to putrefy the soft and tender parts of living bodies without exciting any pain. The cedria is properly the tear of the cedar. Some call it the gum, others the pitch of the cedar. The same denomination is also given to the *cedreleon*, or oil of the cedar, which differs little from the resin, except that it is of a thinner consistence.

Pliny, speaking of the cedar, says, that the tar of it used

in embalming was forced out of it by fire, and called in Syria *cedrim*. His words are, "Cuius tanta vis est, ut in Ægypto corpora hominum defuncturum co perfusa ferventior." Dioscorides calls it the life of the dead, *νεψη ζων*. See Phil. Triam, vol. liv. p. 12.

CEDRINUM (*Timus*), cedar wine; of which there are several sorts, whose qualities are said to be heating, diuretic, and gently astringent; but the *laurinum*, or bay-tree wine, is remarkably heating.

CEDRIPPO, in *Ancient Geography*, a place of Spain, in Bætica.

CEDRIS a river of Sardinia, which flowed towards the East into the sea.

CEDRON, or KEDRON, a town of Palestine, on the borders of the Philistine, in the way to Azotus. It was rebuilt by Cedebens, according to the book of the Maccabees.

CEDRON, KEDRON, or KIDRON, a brook or torrent of Palestine, in a valley on the east side of Jerusalem, betwixt it and mount Olivet, which discharged itself into the Asphaltite lake. Our blessed Lord passed over this brook into the garden where he was betrayed. (John, xviii. 1.) David also, when he fled from Absalom, crossed this brook, (2 Sam. xv. 27.) See also Jer. xxxi. 40. Jerom calls it a torrent or valley, and Josephus denominates it a deep valley. Into this valley was conveyed the blood poured out at the foot of the altar, which, as the blood made the river look black, derived its name from this circumstance, the word "Kiddar," denoting blackness. Others deduce its name from the cedar-trees planted on each side, whence, say they, it is still named in the plural, as by the LXX, (Jer. xxxi. 40.), *τὴν κέδρων*, from these cedar-trees.

CEDRONELLA, in *Botany*, Comm. Hort. See *DRA-COCYPHALUM canariense*.

CEDROPOLIS, in *Ancient Geography*, a country of Thæce, where, according to Aristotle, they trained hawks for the chase.

CEDROSIA. See *GEDROSIA*.

CEDROTA, in *Botany*, Schreb. 600. Wild. 756. (Aniba. Aubl. 1260. Juss. 4 8. Lam. Encyc. Boic. Nouv. Dict.) Clafs and order, *alandria monogyria*.

Gen. Ch. Cal. perianth one-lobed; deeply divided into six ovate, obtuse, concave segments. Cor. none. Stam. filaments eight, short, inserted into the receptacle; anthers roundish, two-celled. Pisl. germ superior, roundish, furrowed by a gland; style short; stigma obtuse. *Peric.* unknown.

Eff. Ch. Calyx six-cleft; segments concave. Corolla none. Germ furrowed by a gland.

Sp. C. *guianensis*, Mart. Willd. (Aniba guianensis, Aubl. Gni. tab. 126. Lam. Illust. Pl. 293.) A tree, forty feet high, two feet thick. *Wood* yellowish, aromatic, heavy when green, becoming light when dry; bark thick, unequal, wrinkled, full of clefts. *Branches* near the top of the trunk, numerous. *Leaves* about seven inches long, two broad, either opposite, or in whorls of three or more together, oval-acuminate, entire, thin, smooth, on short petioles. *Flowers* small, green, loosely racemed, on a long, weak, axillary peduncle; pedicels slender, generally bearing three fertile flowers. A native of the forests of Guiana. The inhabitants call it cedar-wood, and use it for making their proques. It is said also to be fit for sails.

CEDRUS. See *CEDRELA*, *JUNIPERUS*, *PINUS*, and *SWIETENIA*.

CEDRUS, or CEBRUS, in *Ancient Geography*, a small river of Mylia, according to Dion Cassius.

CEESTER, in *Geography*, a town of Germany, in the duchy of Holstein; 11 miles W. of Pinnenberg.

CEESTER-Mube, a town of Germany, in the duchy of Holstein; 13 miles W. of Pinnenberg.

CEFALENSIS, in *Ancient Geography*, an episcopal see of Africa, in the Proconular province.

CEFALU, in *Geography*, a sea-port town of Sicily, in the valley of Demona, on the north coast of the island, the see of a bishop, suffragan of Messina. The harbour will not contain more than 30 or 40 vessels. The number of inhabitants is about 5000; 14 miles E. of Termini. N. lat. 38° 5'. E. long. 14° 5'.

CEGINUS, in *Astronomy*, a fixed star of the third magnitude, in the left shoulder of Bootes, marked γ by Bayer.

CEGLIA, in *Geography*, a town of Naples, in the province of Bari; 5 miles S.S.E. of Bari.

CEGOLITES, in *Natural History*, a name by which some authors have called the *lapis JUDÆICUS*, or *TALCUM* of the ancients.

CEHOLOTL of Ray, in *Ornithology*, the Mexican pigeon, described by Gmelin under the title of *columba mexicana*, which see.

CEIBA, in *Botany*, Plum. tab. 32. Gart. 377. See *BOMBAX ceiba*.

CEILA, or **KEILAH**, in *Ancient Geography*, a city of Palestine, in the tribe of Judah. Joshua, xv. 44. It was attacked by the Philistines in the time of Saul; but rescued by David. Eusebius places it 17 miles from Eleutheropolis, on the side of Hebron. Sozomen says, that the tomb of the prophet Habakkuk was shewn in this place.

CELANESE GODS. See *BUDUN* and *SAKRADEWENDRA*.

CEILING, in *Architecture*, the upper part or interior covering of any room or apartment.

Ceilings are in general composed of a coating of laths and plaster, or stucco applied on the underside of a vault or timber framing; accordingly they are either flat or coved in various manners; they are also either plain or ornamented. The usual method of ornamenting ceilings is to dispose them into compartments or panels forming various geometrical figures, either let into the ceiling, or being flush with its surface, and surrounded with one or several mouldings. The compartments frequently receive ornaments of various kinds; foliage, figures, or grotesques, and executed in relief with stucco or plaster, or painted in colours, or chiaro oscuro. Thus the ceilings have frequently constituted the greatest ornament of palaces, and other splendid buildings, and have employed the talents of the greatest artists.

In England, the custom of ornamenting ceilings has greatly declined, and indeed is scarcely at all practised in private buildings. The use of an inferior covering to the flooring-timbers of a house is considerable, as it preserves a greater equality of temperature in the apartments, and prevents the transmission of sound from one story to another. These advantages are so well understood in this country, that we see none but the oldest and meanest habitations unprovided with plaster ceilings.

CEILING, in *Sea Language*, denotes the inside planks of a ship.

CEIMELIA, from *κεῖμαι*, to be laid up, in *Antiquity*, denotes choice, or precious pieces of furniture or ornaments, reserved or laid up for extraordinary occasions and uses.

In which sense, sacred garments, vessels, and the like, are reputed of the *ceimelia* of a church. Medals, antique stones, figures, manuscripts, records, &c. are the *ceimelia* of men of letters.

CEIMELIARCHIUM, the repository or place where *ceimelia* are preserved.

CEIMELIOPHYLAX, from *κεῖμενος* and *φυλάξις*, *Ilerp*, the keeper or curator of a collection of *ceimelia*; sometimes also denominated *ceimeliarch*.

The *ceimeliarcha*, or *ceimeliophylax*, was an officer in the ancient churches or monasteries, answering to what was otherwise denominated *chartophylax*, and *custos archivorum*.

CEINTURE MILITAIRE, a military cincture, girdle, belt, or sash. This term, however, has been generally employed to denote a broad leathern belt, which was worn round the waist, and was ornamented with gold and silver plates. The chevaliers put on it even jewels and precious stones, as is manifest from the representations of these chevaliers on ancient tombs and monuments. These ceintures must have fatigued them, and particularly their sides, and it must have required good haunches to support them, when furnished with all their military appendages and trifes; for there were attached to this *ceinture* the two swords for combat, the great *gloade*, or rapier, and the *braquemard*, or strong short cutting sword; as also the shield or buckler when the cavaliers were not in the act or attitude of fighting.

The marshal de Bourgogne, in 1241, left by his will to the church of St. Vincent de Chalons two *ceintures*, one of gold and the other of silver, to be wrought up into sacred vases. These sorts of *ceintures*, which ceased to be in use after armour of hammered or beaten iron made its appearance, constituted part of the cavalier's armament of honour.

The *armement d'honneur*, or armament of honour, consisted of those pieces of a warrior's armour, to the loss of which shame or disgrace was attached. A cavalier who lost through cowardice or misconduct in battle his sword or his buckler, was disgraced or dishonoured. Disgrace was equally attached to his losing his military cincture.

The conqueror in depositing his adversary of his *ceinture* thereby manifested a complete victory over him. It was the mark or token of liberty as long as it was carried by one under arms, to which state of liberty that of servitude or slavery succeeded, on his losing it. He who deposed another of it had power or authority to bind him with it.

Honour was so much attached to the military *ceinture*, that the grand seigniors took much delight in enriching theirs, and among the other ceremonies observed at the degradation of a cavalier, that of depriving him of the cincture was one.

Cinctures were in use before the time of Charlemagne. A young cavalier, on first taking that ornament, received it from the hands of an old one. The ceremony observed on such an occasion was a sort of introduction to the profession of arms. When *ceintures* came to be laid aside, they were succeeded by scarfs, bands, and baudoiers.

CEINTURE, in *Ornithology*, the French name of the yellow lark, *Alauda flava*. *Ceinture de pêtre* ou *alouette de Sibérie*, Buffon. The plumage of this bird is rufous, varied with fuscous grey above; beneath whitish; front, chin, and throat yellow; tail-feathers black, edged with grey; the exterior ones edged with white. Length five inches and three quarters. Inhabits Siberia, and is very rare.

CEINTURE d'argent, in *Ichthyology*, the name given by French authors to the fish called by Linnæus *Trichurus lepturus*, which see.

CEINTURON, a waist-belt generally of leather, which succeeded the *bandrier*, or shoulder belt, and was smaller and lighter than it. The *ceinturon* and *bandrier* have, indeed, at times, replaced each other. The shoulder-belt is most common, and certainly gives the soldier a more military and graceful appearance than the waist belt.

CEIRA,

CEIRA, in *Ancient Geography*, a cavern in the country of the Getæ, in the vicinity of the Danube. Dion Cassius says, that Crassus stopped the avenues of this cavern in order to compel the inhabitants of the country who had taken refuge in it, to surrender.

CEIRA, in *Geography*, a town of Portugal, in the province of Beira; one league S.E. of Coimbra.

CEIRA, a river of Portugal, which runs into the Mondego, about a league S.E. of Coimbra.

CEIXUPIKA, in *Ichthyology*. The fish described by Margrave under this name cannot easily be ascertained from the account left us by that writer. He says it is a native of the American seas, and is esteemed a fine and delicate fish, though of an enormous size. It grows to nine or ten feet long, and to the thickness of a man's body; but is chiefly eaten while young. The body is oblong; and the head flattened. The mouth is small for the size of the fish, and it has no teeth in the jaws, but the whole mouth is thickly set with small tubercles. Its back and fins are black, and the belly of a fine bright white. Its sides are all black except the belly ones, which are white with a rim of black at their edge.

CEIZERIAT, in *Geography*, a town of France, in the department of the Ain, and chief place of a canton in the district of Bourg. The place contains 1106, and the canton 8865 inhabitants: the territory comprehends 140 kilometres, and 14 communes.

CELADON, in *Ancient Geography*, a small river of Peloponnesus, in Arcadia; which had its source in Mount Lycæus, and discharged itself into the Alpheus, according to Pausanias.

CELADONE, a town of Greece, in the Locride.—Also, the name of a small river of Spain, called also Celadus or Celadus.

CELADUSA, one of the names of the small island of *Rhenea*, situated in the vicinity of that of Delos.

CELADUSSÆ, an island of the Adriatic Sea, mentioned by Mela and Pliny.

CELÆNÆ, a large town of Asia, in Phrygia, where Cyrus had a palace and a park filled with wild beards. The river Meander traversed this town, and also the Marfyas. Xerxes retired to Celænæ after his defeat, and built the castle and fortrefs. Xenophon mentions this city. Cyrus the younger sojourned here 30 days, and was joined by Clearchus, when exiled from Lacedæmon.—Also, a place of Greece, on the confines of Attica and Bœotia. Suidas.

CELÆNUS, a mountain of Asia, placed by Ptolemy in Galatia. It was also called *Celænus tumulus*.

CELÆTHI, a people of Greece, in Thesprotia, in the neighbourhood of Thesaly. Steph. Byz.

CELÆTHRA, an ancient town of Greece, in Bœotia, in the vicinity of the town of Arne. Steph. Byz.

CELAMA, a village of Africa, in Mauritania Cæsarientis. It lay in the interior of the country, S.W. of the grand promontory, and S.E. of Artifiga.

CELANDINE, in *Botany*. See *CHELIDONIUM majus*.

CELANDINE, *lesser*. See *RANUNCULUS ficaria*.

CELANDINE tree. See *BOCCONIA*.

CELANO, in *Geography*, a town of Naples, in the province of Abruzzo Ultra, seated near the north shore of a lake of the same name, and the head of the earldom that comprehended at one time the greater part of the country of the Marfi. This was the ancient name of the people that inhabited the environs of the lake, allowed by the Romans to be the most intrepid soldiers of their legions, when in friendship, and the most formidable of their enemies, when at variance. It was a common saying, that Rome

could neither triumph over the Marfi, nor without them. In the 662d year of Rome, B. C. 92, they put themselves at the head of the Social war, one of the most obdurate and dangerous oppositions ever made to the progress of the Roman power, which was terminated by a grant of the privileges for which they contended. Their name fill subsists in that of the diocese, for the prelate is styled bishop of the Marfi. In ancient times, the lake was called Fucinus, and was under the protection of a god of the same appellation, whose temple stood on its banks. According to the testimony of ancient authors, it was subject to extraordinary increase and decrease. The actual circumference is 47 miles. (more than 30 miles, says Sir William Hamilton, ubi infra); the breadth, in the widest part, 10, in the narrowest, 4; its depth, on an average, 12 feet. But these measures have been subject to great variations. Two miles up the plain, behind Avezzano, the fragments of boat., shells, and other marks of its ancient extent, have been casually discovered; and, on the contrary, there are people who remember when it did not flow nearer than within two miles of Avezzano. An immense tract of land is lost at every increase of its level; and if any means could be devised for draining it, or, at least, reducing its size, the value of the ground recovered for cultivation would be more than an equivalent for any expence incurred in the works. Round this lake rises a circle of grand mountains covered with snow, some of which are the highest in Italy, if we except the Alps; the most elevated is the Rocca di Cambio. At the foot of these are many villages, and rich, well-cultivated farms. In summer this country must be a delightful residence, for the environs of the lake are well enclosed, and the sides of the hills covered with fine woods; its waters abound with fish of various kinds, though not of the best quality, and hither, at the stated seasons, repair innumerable flights of wild fowl. In the shallow water on the borders of the lake, Sir W. Hamilton saw thousands of water-snakes, pursuing and preying upon a little fish like our thornbacks, but much better armed, though their defensive weapons seemed to avail them but little against such ravenous foes. The necessaries of life are good, plentiful, and cheap. About 1½ mile from the town is the emissary or opening made by order of Claudius Cæsar for the discharge of the waters into the Liris, now the Garigliano, which runs in a deep valley on the other side of the hills. In a line from it, now choked up, up the slope, are six perpendicular wells, and two oblique grooves to the canal, which was driven through the hill into the opposite valley, and there had a vent at Capistrelli, two miles from the lake. As the swelling of this lake was attended with incredible damage, the Marfi had often petitioned the senate to drain it; Julius Cæsar would have attempted it, if his life had been prolonged. His successor declined the project, till, at length, Claudius, who delighted in expensive, difficult enterprises, undertook it. During the space of eleven years he employed 30,000 men in digging a passage through the mountain, and when every thing was ready for letting off the water, he exhibited a superb naval spectacle on the lake, consisting of an engagement between condemned criminals, who, in separate fleets, attacked the parts of Rhodians and Sicilians, and who destroyed one another for the amusement of the court, and of a multitude of spectators that covered the hills. When the emissary was opened, at the close of this savage diversion, the emperor himself, with difficulty escaped being hurried away and drowned by the sudden rushing of the waters towards this vent. However, through either the ignorance or negligence of the engineers, the work did not answer expectation, and Claudius did not live long

enough to complete it. Sir W. Hamilton went with torches into the emiffary of Claudius as far as he could. It is a covered under-ground canal, three miles long, and great part of it cut through a hard rock; the other parts supported by masonry, with wells sunk to give air and light. In its present state, though filled up with rubbish and earth in many parts, and of course useless, it is a magnificent monument of antiquity. Nero abandoned the scheme projected and partly executed by Claudius, through envy. Adrian is said to have let off the waters of the Fucinus; but none now escape except through hidden channels formed by nature, but liable to frequent obstructions. As three considerable streams run into the lake, the least obstacle to a discharge must raise the level. Swinburne's Travels, vol. iv. p. 374. Phil. Transf. vol. lxxxvi. p. 368.

CELANO, a river of Italy, which runs into the gulf of Tarento, 5 miles from Rossano.

CELANTES, in *Logic*, a denomination given by the Peripatetics to the Galenical syllogism; otherwise called CALENTES.

CELARENT, among *Logicians*, a mode of syllogism, wherein the major and conclusion are universal negative propositions, and the minor an universal affirmative. L. gr.

CE *None whose understanding is limited can be omniscient.*

LA *Every man's understanding is limited.*

RENT *Therefore no man is omniscient.*

CELASTRUS, in *Botany*, (*celastrus*; Theophrast.) Linn. gen. 270. Schreb. 372. Willd. 423. Lam. Illust. 361. Juss. 378. Vent. vol. iii. 465. Gart. 593. (Evolvomoides; Inard. A. G. 1716.) Staff tree. Clais and order, *pentandria monogynia*. Nat. Ord. *Dumoseae*. Linn. *Rhamn.* Juss.

Gen. Ch. *Cal.* very small, one-leaved, flat, semicircular; lobes obtuse. *Cor.* Petals five, egg-shaped, spreading, sessile. *Stam.* Filaments five, awl-shaped, the length of the corolla, alternate with the petals; anthers very small. *Pist.* Germ superior, very small, partly immersed in a broad, flat receptacle; style short; stigma small. *Peric.* Capsule inversely egg-shaped, obtuse, trigonous, three-celled, three-valved; partitions in the middle of the valves. *Seeds* few, egg-shaped, smooth, partly involved in a coloured four-cleft arillus.

Eff. Ch. *Calyx* five-lobed. *Petals* five, spreading. *Germ* immersed in the receptacle. *Capsule* trigonous, three-valved. *Seeds* calyptrated.

Obf. Gærtner asserts that there is no solid generic distinction between this genus and evonymus, a difference in the number of cells and valves being, in his judgment, of no consequence, except to the mere carpologist.

* Without thorns.

† *Leaves* entire.

Sp. 1. *C. lucidus*, Linn. Mant. p. 49. Syst. Nat. 6. Mart. 14. Willd. 1. P. Herit. Sp. nov. Fasc. 3. 49. tab. 25. (*C. concavus*; Lam. Illust. 2925. Caffine concava; Encyc. 5. Pl. 130. fig. 2. Evonymus; Pluk. alm. tab. 280. fig. 4.) A native oval, acute, shining, margined; peduncles axillary." Willd. "Leaves somewhat roundish-egg-shaped, rigid, veined, concave above; capsules reflex, blunt." Lam. A shrub five or six feet high. *Stem* a little twisted, with a blackish bark. *Branche*s: stiff, rather long, generally simple, leafy and green. *Leaves* alternate, numerous, rather small, almost sessile, smooth. *Flowers* small, white, solitary, or three together, on short simple peduncles. A native of the Cape of Good Hope, flowering from April to September. 2. *C. microphyllus*, Linn. Sup. p. 154. Mart. 7. Willd. 2. Thunb. prod. 42. "Leaves egg-shaped, obtuse; panicles terminal."

A shrub, native of the Cape of Good Hope. 3. *C. bulbatus*, Linn. Sp. Pl. 1. Mart. 1. Lam. Encyc. 1. Ill. 2691. Willd. 3. (Evonymoides; Inard Act. 1716. Evonymus; Pluk. alm. 139. tab. 28. fig. 5.) "Leaves egg-shaped, acute; panicle terminal." Willd. "Little racemes terminal." Lam. A shrub, eight or ten feet high. *Stems* generally two or three, branched. *Leaves* near three inches long, and two broad, alternate, petioled. *Flowers* white. *Fruit* scarlet, with numerous small protuberances. *Seeds* hard, covered with a thin red pulp. A native of Virginia and other parts of North America, flowering in July. 4. *C. oleoides*, Lam. Ill. 2696. (Caffine oleoides; Encyc. Calistrus laurinus; Willd. 4. Thunb. prod. 42.) "Leaves ovate-lanceolate, margined; corymbs peduncled, axillary." Lam. "Leaves ovate-oblong, entire; panicles axillary." Thunb. A shrub. Smallest branches angular, smooth, leafy, greyish. *Leaves* alternate, petioled, pointed at both ends, smooth, somewhat coriaceous, an inch and half or two inches long. A native of Africa, communicated to La Marck by Somerat. 5. *C. corniculatus*, Mart. 18. P. Herit. tert. anr. 6. Breyer. ic. tab. 22. fig. 3. (*C. rostratus*; Willd. 5. Thunb. prod. 42? *C. tricuspidatus*; Lam. Illust. 2922? Evonymus, Burm. Afr. tab. 67. fig. 1. quoted both by P. Herit. and La Marck.) "Leaves oval, quite entire, perennal; capsules three horned." P. Herit. "Leaves oblong-oval, unequal, quite entire; corymbs dichotomous, axillary; fruit thorny." Willd. "Leaves oblong-oval, shining, quite entire, reflexed at the edges; capsules tricuspidate." Lam. A native of the Cape of Good Hope. 6. *C. filiformis*, Linn. jun. Supp. Mart. 5. Willd. 8. Thunb. prod. 42. "Leaves lanceolate; branches filiform; peduncles axillary, one-flowered." A native of the Cape of Good Hope.

†† *Leaves* serrated or toothed.

7. *C. scandens*, Linn. Sp. Pl. 2. Mart. 2. Lam. Encyc. 2. Ill. 2692. Willd. 9. Gart. tab. 95. fig. 4. Thunb. Transf. Linn. Soc. vol. ii. p. 332. (*C. punctatus*; Thunb. Jap. 97?) "Leaves oblong, acuminate, serrated; racemes terminal; stem twining." Willd. A shrub, twelve or fourteen feet high or more. *Stems* several, twining about other shrubs, or trees, or one another; they twine so closely about trees as to bury themselves in their bark and substance, and finally to destroy them. *Leaves* alternate, petioled, smooth. *Flowers* small, whitish green. A native of Canada and Japan. Willdenow doubts whether the scandens of Linnæus and the punctatus of Thunberg be the same plant, in opposition to the decision of Thunberg himself. La Marck in his Illustrations keeps them distinct, with the following specific characters. *C. scandens*, "Stem twining; leaves egg-shaped, acuminate, finely serrated." *C. punctatus*, "Branches climbing, dotted; leaves egg-shaped, serrated." 8. *C. paniculatus*, Willd. 12. "Leaves egg-shaped, acuminate, obtuse, serrated; panicle elongated, terminal." *Branche*s brown, spotted, cylindrical. *Leaves* two inches long, one broad, alternate, smooth. *Panicle* three inches long. *Flowers* small. A native of the East Indies, described by Willdenow from a dried specimen. 9. *C. procumbens*, Linn. jun. Supp. 153. Mart. 4. Willd. 11. Thunb. 42. "Stem procumbent; leaves egg-shaped, serrated; flowers axillary, generally solitary." A native of the Cape of Good Hope. 10. *C. acuminatus*, Linn. jun. Supp. 154. Mart. 6. Willd. 12. Thunb. prod. 42. (*C. populifolius*; Lam. Ill. 2698?) "Stem erect, limber; leaves egg-shaped, acuminate, serrated; peduncles axillary, one-flowered." Linn. jun. "Leaves egg-shaped, acuminate, serrated; umbels axillary, nearly sessile, few-flowered." Lam. A native of the Cape of Good Hope. 11. *C. caffioides*, Mart. 19. Lam. Ill. 2697. Willd. 13.

P'Herit. fert. ang. tab. 10. "Leaves egg-shaped, acute, remotely toothed, perennial; flowers axillary." A native of the Canary islands, flowering in August and September, introduced into England by Masson in 1779. 12. *C. striatus*, Mart. 10. Lam. Ill. 2702. Willd. 14. Thunb. jap. 98. "Branchlets erect, striated; leaves egg-shaped, acuminate, ferrated; peduncles scattered, one-flowered." Leaves opposite, smooth, spreading, on short petioles. A native of Japan. 13. *C. cernuus*, Willd. 15. Thunb. prod. 42. "Leaves egg-shaped, obtuse, ferrated; peduncles axillary, one-flowered, nodding." A native of the Cape of Good Hope. 14. *C. undulatus*, Willd. 16. Thunb. prod. 42. "Leaves obovate, somewhat wedge-shaped, wave-toothed; flowers axillary, sessile." A native of the Cape of Good Hope. 15. *C. edulis*, Lam. Illuf. 2704. Willd. 17. Vahl. Symb. 1. p. 21. (*Catha edulis*; Lam. Encyc. Forfk. Ægypt. 63.) "Leaves opposite and alternate, elliptical, ferrated; cymes axillary, dichotomous." A tree. Leaves smooth, shining, on short petioles. Flowers white. A native of Arabia. The natives chew the green leaves, which they esteem a preservative against the plague. 16. *C. crenatus*, Mart. 17. Willd. 18. Forfk. prod. 113. "Leaves egg-shaped, crenulate; cymes axillary." A native of the Marquesa islands in the South Sea. 17. *C. dilatatus*, Mart. 9. Willd. 19. Thunb. Linn. Transf. vol. ii. p. 332. (Evonymoides; Thunb. jap. 354. n. 26.) "Leaves inversely egg-shaped, acuminate, ferrated at the tip; flowers terminal." A native of Japan. 18. *C. myrtifolius*, Linn. Sp. Pl. 3. Mart. 3. Lam. Encyc. 3. Illuf. 2693. Willd. 20. (*Myrtifolia arbor*; Sloan Jam. 2. p. 79. tab. 193. fig. 1.) "Leaves egg-shaped, slightly ferrated; flowers in racemes; stem erect." A tree from eighteen to twenty feet high. Wood white, very hard. Leaves alternate, petioled, rounded at the base, acute at the summit, smooth on both sides. Flowers white, small. A native of Virginia and Jamaica. 19. *C. tetragonus*, Willd. 22. Thunb. prod. 42. "Leaves egg-shaped, ferrated; branches tetragonous." A native of the Cape of Good Hope. 20. *C. articulatus*, Mart. 8. Willd. 23. Thunb. jap. 57. (*C. orbiculatus*; Lam. Ill. 2700.) "Leaves rounded, acuminate, ferrated; peduncles axillary, often trifid, sometimes bifid." A shrub. Branches polygonous, smooth, ferruginous, spotted with white. Leaves an inch and half long, smooth, nerved, spreading; petioles channelled, one third of the length of the leaves. A native of Japan. 21. *C. alatus*, Mart. 11. Lam. 2703. Willd. 24. Thunb. jap. 98. "Leaves opposite, acuminate, slightly ferrated, on short petioles; branches winged." A native of Japan. 22. *C. trigynus*, Lam. Ill. 2699. (Sonneratia; Commerf.) "Leaves oblong-egg-shaped, obtusely ferrated; umbels axillary, loose, peduncled; style scarcely any." A shrub. Flowers very small; stigmas three, or three on very short styles. A native of the Iles of France.

** Thorny.

† Leaves entire.

23. *C. linearis*, Linn. Supp. 153. Mart. 15. Willd. 25. Thunb. prod. 42. "Spines leafy; leaves linear." A native of the Cape of Good Hope. 24. *C. integrifolius*, Linn. Supp. 153. Mart. 16. Willd. 26. Thunb. Prod. 42. "Spines leafy; leaves egg-shaped, obtuse; cymes lateral." A native of the Cape of Good Hope. 25. *C. emarginatus*, Willd. 27. "Spines leafy; leaves inversely egg-shaped, emarginate; umbels peduncled." Branches cylindrical. Spines an inch long, rigid, thick, alternate; the younger ones bearing leaves and flowers. Leaves glaucous, smooth, obtuse, on short petioles. Flowers in umbels, at the axils of the leaves; and the tip of the spines; peduncles capillary,

long when compared with the flowers. A native of the East Indies, described by Willdenow from a dried specimen.

†† Leaves ferrated or toothed.

28. *C. busifolius*, Linn. Sp. Pl. 4. Mart. 12. Lam. Encyc. 4. Illuf. 2705. (Lycium, Pluk. alm. tab. 202. fig. 3.) "Spines leafy; branches angular; leaves inversely egg-shaped, obtuse, somewhat toothed; cymes lateral." A shrub, three or four feet high. Stem much branched. Spines alternate, straight, strong, some naked, often leafy. Leaves dark green. Peduncles axillary, supporting a loose cyme or umbel of about five flowers. β . with many-flowered cymes, Lam. Illuf. (*C. multiflorus*, Lam. Encyc.) A native of Africa. 29. *C. Pyracanthus*, Linn. Sp. Pl. 5. Mart. 13. Lam. Encyc. 7. Illuf. 2706. Willd. 30. Gert. tab. 95. fig. 4. (Lycium, Comm. Hort. tab. 84.) "Spines naked; leaves oblong-egg-shaped; teeth few, very short, rather spiny; cymes dichotomous." A loose, irregular shrub, two or three feet high. Branches somewhat cylindrical, brown or dark green, leafy, most of them without spines. Leaves narrowed towards the base, a little pointed at the tip, sometimes obtuse with a small spiny point. Flowers numerous, expanded; cymes loose, lateral, and terminal; terminal ones a little paniced. Fruit large, about the size of a cherry, egg-shaped with three obtuse angles, pendant. A native of Africa. 30. *C. physicanthus*, Mart. 20. Willd. 28. L'Herit. Sert. ang. 6. (*C. Senegalensis*, Lam. Encyc. 6. Illuf. 2707.) "Spines leafy; branches cylindrical; leaves glaucous, unequally toothed; cymes lateral, few-flowered." A bushy shrub, two or three feet high. Young branches reddish. Spines an inch long or more, alternate, strong, generally leafy. Leaves on short petioles. Flowers very small. A native of Senegal. 31. *C. rotundifolius*, Willd. 31. Thunb. prod. 42. "Leaves petioled, roundish, toothed." A native of the Cape of Good Hope. 32. *C. parviflorus*, Lam. Illuf. 2708. Willd. 32. Vahl. Symb. 1. p. 21. (*Catha spinosa*, Forfk. Arab. 64.) "Spines naked; leaves egg-shaped, fcoloped; peduncles filiform, longer than the leaves." Leaves alternate, smooth. Flowers small, white; peduncles axillary; capsules with two cells. A native of Arabia Felix.

CELASTRUS undulatus, L'Herit. Mart. Willd. See SENACIA undulata.

CELASTRUS odogonus. See SENACIA odogona.

CELASTRUS maytenus, Willd. See SENACIA maytena.

CELASTRUS Burm. Cluf. See CASSINE capensis.

CELASTRUS Hort. Clif. See CEANOETHUS americanus and africanus and EVONYMUS americanus.

CELASTRUS, in Gardening, comprises some plants of the evergreen, and deciduous shrubby kinds, as the fludded or evergreen Virginia staff-tree (*C. bullatus*); the climbing-staff-tree, or ballard euonymus (*C. scandens*); the pyracantha-leaved staff-tree, or Ethiopian box-thorn (*C. pyracanthus*); and the box-leaved staff-tree (*C. busifolius*); of which the first in its native situation rises to the height of eighteen feet, but in this climate few of these shrubs are much more than half that height. It generally puts out two or three stems from the root, which divide upward into several branches being covered with a brown bark: the flowers come out in loose spikes at the end of the branches, and are white: the capsule is of a scarlet colour, set full of small protuberances. It flowers in July, but seldom produces good seed here.

In the second sort several woody stalks are sent out which are inflexible, and twill themselves round trees and shrubs, or round each other to the height of twelve and fourteen feet or more, girding trees so closely as in a few years

years to d. l. o. t. m. The leaves are about three inches long, of a lively green above, but paler on the under side; the flowers, produced in small branches towards the end of the branches, are of an herbaceous colour, and succeeded by roundish three-cornered capsules, which are red when ripe, spreading open and disclosing their seeds in the same manner as the spindle-tree. It flowers in the beginning of June, and ripens seeds in the autumnal season.

The third rises with an irregular stalk three or four feet high, sending out several side branches covered with brown bark; the leaves are about two inches long, and more than half an inch broad, some pointed and others obtuse; they are thick, of a lucid green, coming out irregularly from the branches in loose tufts, many from one point, on long peduncles, and of an herbaceous white colour: the fruit is of a fine red colour, opening into three cells, containing an oblong hard seed. It flowers the greatest part of the summer. The last rises with a slender woody stalk to the height of ten or twelve feet, is full of joints, armed with long spines, upon which grow many small leaves; the branches are slender, armed also with spines at every joint; but the whole plant is so weak as to require support: the leaves come out in clusters without order, are shaped somewhat like those of the box-tree, but longer, and of a looser texture; the flowers are on peduncled cymes from the axils, and the fruit globular. It flowers in May and June, and sometimes a little later.

Method of Culture. The two first sorts are capable of being raised either by seeds or layers, but the latter is the more ready method. And in the first mode, the seeds should be sown upon light fresh earth, either in beds or pots, as soon as they are procured from abroad, keeping them perfectly free from weeds till the plants are of sufficient growth to be planted out in nursery beds, watering them occasionally when the weather is dry. They are mostly fit for this in about two years. But in the latter method, layers from the young shoots should be laid down in the autumn, sitting them at a joint on the under sides. They are mostly sufficiently rooted to be taken off and planted out in the nursery rows by the succeeding autumn. The latter of these sorts succeeds best on rather a moist loamy soil.

In the last two sorts the culture may be in the same methods; but they should be in pots in order to their being placed under the protection of frames or other contrivances, when the weather is severe. After they have had a twelve-months' growth, they may be removed into other pots separately. And cuttings made from the young shoots in all the sorts may likewise be stricken in the early spring months in pots exposed to a hot-bed heat. They may be planted out in the following autumn, either in pots separately, or where they are to remain according to their kinds. But these sorts should not be treated too tenderly, as they are apt to be rendered weak in their branches and less verdant.

The first two sorts are of a hardy nature, being well adapted to the borders and clumps of pleasure-grounds in mixture with other shrubs of the more tall growths. The first should, however, have a warm aspect and rather dry soil. The latter succeeds in wilderness quarters, under the shade of tall trees where it winds itself about them to a great height, producing a fine effect in the autumn by the fine colour of its fruit.

The other two sorts are more tender, requiring to be kept in pots, as has been seen, to have the protection of the green-house in winter, where they afford variety in assemblage with other plants of the more hardy nature.

CELATE, in *Military Antiquity*, from the Latin word *celatus*, signifying concealed. It is of the same import as *hearme*, which is derived from the German, and was used to denote a helm, casque, or helmet for covering not only the head, but also the whole face, having an opening only opposite to the eyes, which were secured by cross bars or lattice-work of iron, forming a sort of visier. It has served for several centuries as an ornament on arms armorial, and is still preferred in heraldry as a distinguishing mark of nobility. It was worn not only by the chevaliers or knights when they went to war, but also at tilts and tournaments. Various appellations have been given to this piece of armour, such as *héllement de tete*, or covering for the head, casque, helmet. Under Francis I. it was distinguished by the name of *armet*. At tournaments it was assigned as the prize to him, who behaved best on the part of all those who presented themselves at the barrier of a tournament, and held it against all those that might enter the lists, as the first piece of defensive armour: in the same manner as the sword was given to him, who distinguished himself most on the side of the assailants, as the first arm of offence. Formerly they used to holla, call, or cry out *au hearme*, as they now do *aux armes*.

CELAVO, in *Geography*, a town of the department of Liamore (island of Corfica) and chief place of a canton in the district of Ajaccio. The canton contains 4060 inhabitants.

CELAURIA, in *Ancient Geography*, a small island of Greece, on the coast of the Peloponnesus. It belonged to the Troezenians, and was situated before the port called "Pogon" by Strabo. In this island was a magnificent temple of Neptune; and the tomb of Demofthenes, who died here, is not one of the least of its ornaments. His memory was long held in great veneration on this island, and in the time of Pausanias, strangers, as well as the inhabitants of the island, rendered distinguished honour to this illustrious defender of the liberty of Greece.

CELBIDGE, in *Geography*, a small town of the County of Kildare, Ireland, pleasantly situated on the river Liffey, where the cotton manufacture has been carried on extensively; and also a manufacture of chip hats, which was for some years much encouraged. It is 10 miles west from Dublin.

CELCENSES, in *Ancient Geography*, a people of Spain, who inhabited the town of Cella, seated on the banks of the Ebrus, according to Pliny.

CELE, in a general sense, denotes any tumour, but more particularly that proceeding from a rupture or hernia.

CELEÆ, in *Ancient Geography*, a town of Sicily, S. of Philus. Here were celebrated in every fourth year the mysteries of Ceres, who had a new priest at every return of the festival, so that the priesthood lasted only four years. In a temple of this city was suspended from the roof a car, which was said to be that of Pelops.

CELEBANDICUM JUGUM, a promontory of Spain, in the Mediterranean sea.

CELEBATE, or **CELIBACY**, the state of a person who lives out of marriage.

Scaliger derives the word from the Greek *κελη*, *bed*, and *κελευω*, *linguo*, *I leave*: others say, it is formed from *celi beatitudo*, *q. d.* the blessedness of heaven.

Among the Spartans, though very weighty reasons might authorize them not to marry, yet in old age they could not expect to be treated with the same respect as the other citizens. As a proof of this Xenophon (Hæc Græc. l. 3. p. 40.) as also Plat. in *Lycurg. T. 1. p. 48.* relates an anecdote of Dercyllidas, who had commanded armies with so much glory. That general came one day into the assembly,

bly, when a young man said to him: "I shall not rise to you, because you will leave no children who may one day rise to me." Those who lived in celibacy were also subject to other humiliations. They were not allowed to be present at the exercises in which the girls engaged half-naked: the magistrates might also, in the middle of winter, command them to strip off their cloaths, and go round the forum, singing sarcastic verses on themselves, in which they acknowledged that their disobedience to the laws merited the chastisement they suffered.

The ancient Romans used all means imaginable to discourage celibacy. Nothing was more usual than for the censors to impose a fine on old bachelors. Dionysius Halicarnassensis mentions an ancient constitution, whereby all persons of full age were obliged to marry. But the first law of that kind of which we have any certainty, is that enacted under Augustus, A. U. 762, called "Lex Julia de maritandis ordinibus." It was afterwards denominated "Papia-Poppæa;" and more usually "Julia-Papia," because of some new function and amendments made to it under the consuls Papius and Poppæus. By this law, divers prerogatives were given to persons who had many children; penalties imposed on those who lived a single life, as that they should be incapable of succeeding to an inheritance, except of their nearest relations, unless they married within 100 days after the death of the testator; and that they should not receive an entire legacy. What they were thus deprived of in certain cases fell as an escheat (caducum) to the exchequer or prince's private purse.

The celibate of the clergy, which is still rigorously kept up among the Romanists, is of a pretty ancient standing. It was first proposed by the council of Nice, but without passing; it was, however, in some measure, admitted by the western councils of Elvira, Arles, Tours, &c. and enjoined by the thirty-third canon of the council of Elvira, held about the year 300, though it does not appear that it was either generally or rigorously observed. In the year 340 it was decreed in the council of Arles, that no man incumbered with a wife, should be admitted into holy orders, unless he promised, with his wife's approbation and consent, to abstain for ever from the conjugal duty. From these citations it appears, that those writers are mistaken who affirm, that celibacy was first imposed upon the clergy by Symon; and that it was not required of the ministers of the gospel by any council, but by the popes, in opposition to all councils and synods. Such among the priests as picked themselves on the faculty of continence, took the hint; inasmuch that, towards the close of the fourth century, there were few but made profession of a voluntary celibate. Symon issued a decree in 385, obliging all priests and deacons to observe celibacy: and it was soon after enjoined by the synods of each particular nation, and observed in most of the western churches. In 441, the council of Orange ordered those to be deposed who did not abstain from their wives; and Leo the Great, in a letter written about the year 442, extended the law of celibacy, which was confined by the decree of this council to deacons, and by the letter of Symon to deacons and presbyters, to sub-deacons likewise: but it was Gregory the Great, in 591, who first brought ecclesiastics to admit the celibate as a law. In the council of Trent, it was proposed to set the clergy at liberty again from the yoke of celibate; and this was even made an article of the Interim of Charles V.; but the pope could not be induced to acquiesce.

In Britain the celibacy of the clergy does not seem to have commenced till the arrival of Austin in the 6th century. About the middle of the tenth century, in the reign of

Edred, who surrendered himself to the guidance of Dunstan, commonly called St. Dunstan, abbot of Glastonbury, a new order of monks, called Benedictines, had sprung up in Italy, and was introduced into this country by Dunstan. These monks made a merit of the most inviolable chastity; and their principles and practices were greedily embraced and promoted by the policy of the court of Rome.

The Roman pontiff, who was every day making great advances towards an absolute sovereignty over the ecclesiastics, perceived, that the celibacy of the clergy alone could break off entirely their connection with the civil power, and depriving them of every other object of condition, engage them to promote, with unceasing industry, the grandeur of their own order. He was sensible, that so long as the monks were indulged in marriage, and were permitted to rear families, they never could be subjected to strict discipline, or reduced to that slavery under their superiors, which was requisite for procuring to the mandates issued from Rome a ready and zealous obedience. Celibacy, therefore, began to be extolled, as the indispensable duty of priests; and the pope undertook to make all the clergy throughout the western world renounce at once the privilege of marriage. The undertaking was difficult, as he had the strongest propensities of human nature to encounter: and it is therefore no wonder that this matter-stroke of policy should have met with violent contradiction, and that the interests of the hierarchy and the inclinations of the priests, being now placed in this singular opposition, should, notwithstanding the continued efforts of Rome, have retarded the execution of that bold scheme during the course of near three centuries. In the year 1107, during the reign of Henry I., a synod was held by the instigation of pope Paschal II, and archbishop Anselm, at Westminster, which enjoined the celibacy of priests; and which enacted, that even laymen should not marry within the seventh degree of affinity. By this contrivance the pope augmented the profits which accrued to him from granting dispensations, as well as those from divorces. Another synod was convened at London in 1129, under the pontificate of Honorius, at which presided William archbishop of Canterbury, with the character of the pope's legate, and where all the bishops of the kingdom were present. This council was assembled chiefly for the purpose of enforcing the observance of the canons issued by other councils concerning the celibacy of the clergy; and such of them as still kept concubines, for so their wives were called, were strictly enjoined to put them away before St. Andrew's day next following. At a previous meeting of this council in 1128 the cardinal de Crema presided as the pope's legate; who after severe penalties were enacted on the marriages of the clergy, in a public harangue, declared it to be an unpardonable enormity, that a priest should dare to consecrate and touch the body of Christ immediately after he had arisen from the side of a frumpet, for that was the decent appellation which he gave to the wives of the clergy. "But it happened," says Mr. Hume (Hist. of Engl. vol. 1. p. 343, 8vo.) "that the very next night, the officers of justice, breaking into a disorderly house, found the cardinal in bed with a courtesan; an incident which threw such ridicule upon him, that he immediately stole out of the kingdom. The synod broke up; and the canons against the marriage of clergymen were worse executed than ever."

CELEBES, called also MACASSER, in *Geography*, an island of the East Indian Ocean, situated under the equator, between Borneo on the west, and the Molucca islands on the east; or between 1° 20' N. lat. and 5° 40' S. lat. and 110° and 124° E. long. The form of this island is very irregular, so that it is not easy to ascertain its dimensions, as to length and breadth,

breadth, in miles; but it has been usually reckoned about 200 miles long, and 350 broad; taking those parts whose dimensions are of the greatest extent. It is divided into a number of small kingdoms and states, most of which however depend on the two great kingdoms of Macassar and Boni. The king of Ternate, also, has extensive possessions, which occupy almost the whole of the northern and eastern part of Celebes. The two most powerful kings, whom the Dutch, by the preponderance of their arms, retained as allies, are the kings of Macassar and Boni. The king of Lillo and Sandraboni are in alliance with the king of Macassar; and that of Soping, Locho, and Tanete, with that of Boni. Some small states, such as Wangjo, Mandhar, &c. are independent. Although the kings of Macassar and Boni are allies of the Dutch, they are always sworn enemies to each other; and the policy of the Dutch has contrived to derive great advantage from the discord of these eastern princes. The kingdom of Macassar, or Goach, lies on the western side of the island, of which it occupies the greater part. The king of Goach, and that of Tello, both bear the title of Macasser, though each has a distinct kingdom; they assume the titles of Goach and Tello from their places of residence.

Celebes is surrounded by a variety of islands, all of which may be denominated the Celebesian isles. See MACASSER, GOACH, TELLO, BONI, SANDRABONI, SOPING, LOCHO, TANETE, MANDHAR, CURJULIA, WADJO, TOMATTEA, TOURADJA, CAJELIE, TUERONGAN, BOUTON, SUMBAWA, MAROS, LABACCAN, GALIESCNG, BONTAIN, BOELE-CONBA, BEKA, SALEYER, BONASATTE, CALALWE, TANAKLEI, &c. &c. According to an ancient tradition, the Macassers, like many other nations, deduce the origin of their princes immediately from the gods. Once, they say, after the death of the first sovereign of the kingdom, a beautiful female descended from heaven, suspended by a golden chain. This celestial beauty, named Toemanoccong, was immediately chosen by the Macassers to be their queen. She afterwards married a king of Bantam, and, after being pregnant three years, she brought forth a wonderful child, capable of speaking and walking as soon as it was born, but very ugly and deformed. This young prince was named Toema-Salingaberiang. When he attained to manhood, he broke the golden chain, which his mother had brought with her from heaven, and the mother and her husband instantly disappeared, and left to their son the kingdom, together with one half of the chain. This chain, which, as it is asserted, was sometimes light and sometimes heavy, and sometimes appeared of a pale colour, was long preserved as a valuable part of the regalia of the crown, until it was lost, with various other rarities, during the warlike commotions which took place in this kingdom about the middle of the last century. This Toema-Salingaberiang is considered as the chief of the family of all the kings of Goach. The Dutch were involved in violent disputes with these sovereigns before they were able to establish themselves in their kingdom. In 1778, Goach, the capital, was taken by storm and destroyed; and, in 1781, the sovereign Punduca Siri, sultan Abdal Hadja, was placed on the throne by the government of Batavia. The king of Goach does not possess unlimited power, but is subject to certain laws, which he is obliged strictly to observe. He can undertake no measure of importance without the consent of his council; nor can he inflict arbitrary punishment on criminals, who must be punished according to the laws. His privy-councillors are called Pomani Calangs; and every village is under the direction of a particular chief or governor, distinguished by the title

of Galarang. The Portuguese visited this island about the beginning of the 16th century, and obtained, from the sovereign then on the throne, (viz. in 1512,) permission to form an establishment. The first efforts of this prince intrusted the weights and measures now in use, fixed the prices of merchandise, manufactured gun powder, and planted the first artillery on the walls of Goach. He also not only allowed the Malays to settle in his states, but erect a Mahometan temple. This religion made such progress in the island, that, about the year 1536, deputies were sent to Mecca to bring from thence a Hadja or priest, to instruct the Malays in the doctrine of Mahometanism, which, in 1605, was established throughout the whole kingdom, under the authority of sultan Allsh Oudeen; and three years afterwards they forced the people of Boni equally to subscribe to the doctrines of the Koran. The power of Macassar was at its height about the middle of the 17th century; when its princes not only ruled over almost the whole of Celebes, but had likewise ordered Loma, Mandelly, Bima, Tambora, Domno, and Sengar, tributary to them, and had conquered Bonton, Bungay, Gani, the Xulla islands, &c. Sumbawa. They, moreover, held the government of Saleyer, which had been given to Macassar by Daab Uilach, king of Ternate; they were in strict alliance with the inhabitants of Bali, and coined the first gold coins, which were probably the gold "Mas," of the value of sixty Dutch thivers. About that time also, the alliance between Goach and Tello was renewed; and these two states were so firmly united together, that it was a common saying that there were "two lords, but one people." By the articles of union it was settled, that all levies and contributions from conquered provinces, &c. should be divided into five parts, two of which were to be given to Goach, and two to Tello; while the fifth should fall to the share of the eldest of the two kings; that the eldest of the kings should always exercise the office of regent or prime minister, to his junior col league; that they should both be equal in dignity; and, lastly, that they should both enjoy the title of "San-baneo," signifying as much as emperor. The empire of Macassar has of late so much declined, under the influence of the powerful arms and artful policy of the Dutch company, that the king of Boni is now much superior to Goach, both in extent of territory and number of subjects; although in war a Macasser is better than three Bungeles, on account of their martial character, and undaunted courage, which, notwithstanding all the adverse events that have befallen them in the course of a century, were never subdued, till the year 1775; when a finishing stroke was given to the independence, and power of resistance, of Goach. A rebellion having been raised by the mother of the king, who governed during his nonage, with a view of emancipating the country from the yoke of the company, her forces were vanquished, the city of Goach taken by assault, its fortifications razed, and the government new modelled, conformably to the views of the conquerors. The kings of Macassar have a new name given them after their death, and their successor must be nominated before their interment. The Dutch East India Company possess the castle of ROTTERDAM (which see), called in the language of the country "Adjong Pandang," together with the surrounding district, in consequence of a treaty which they entered into with the prince of Celebes. But as the boundaries of their possessions were, perhaps, not accurately defined, the company always endeavoured to enlarge, and the Macassers, on the other hand, to confine them. The company possess also a peninsula extending from this place towards the north, and a large flat district, which, on account of its fertility, is

considered as the granary of Celebes, together with several places lying between this plain and the mountains, and likewise a great many villages among the mountains. These places border on each other, and are bounded on the west by the sea, on the north by the kingdoms of Tanette and Maros, on the east by Tamari, and on the south by the kingdom of Macasser.

The road of Macasser is one of the most beautiful in India, and at the same time safe for ships at every season of the year. The islands of "Great Ly Ly," and "Little Ly Ly," with their reefs, defend it from south-west to north; and there is a safe anchorage close under "Great Ly Ly," in the bad monsoon, and when the N.W. winds blow violently. The entrance of the road is between the above-mentioned island of "Ly Ly," and a sunken rock, which lies full a quarter of a league S. from the point of the reef of "Ly Ly."

The environs of Macasser are very pleasant. They consist of an extensive plain, reaching to the foot of a high range of mountains, situated seven or eight Dutch miles to the eastward, and dividing this part of Celebes, that lies to the westward of the bay of Boni, and south of the gulf of Tomini, into two parts. This range is called the mountains of Bontain, because the southern part of it terminates in a district of that name. The plain is covered, as far as the eye can reach, with rice-fields and pasture grounds, which are interspersed, here and there, with small groves of fruit-bearing or shady trees, and watered by drains made out of the larger rivers, which descend from the mountains.

Captain Forrest (in his "Voyage from Calcutta to the Merqui, Archipelago, &c.") informs us, that at a place called Kylo, or Kyela, N. of Macasser, and in the Mandhar division, there is said to be a spacious harbour; and that near the harbour are hills free from wood, and covered with grass, where many sheep are bred; though they are generally scarce, whilst goats are much more plentiful. There are also two or three harbours on the east coast of Celebes, and two on the north coast, Kōandang and Amoran.

The seasons in Celebes are the same as in Java. The S.E. monsoon continues from May till November, and is reckoned favourable; the N.W. monsoon, called the bad one, continues from November till May. During the former the sky is serene, and the weather dry; but continual winds and violent rain prevail during the latter. It is singular, however, that on the east side of the above-mentioned range of Bontain mountains, the contrary takes place: for, when fine weather in the S.E. monsoon prevails on the west side of the mountains, hurricanes and rain are found on the east side: so that the boundaries of summer and winter are only eight Dutch miles distant from each other.

As this island lies under the line, the air is very hot; but the heat is moderated by frequent rains and cooling breezes, so that the climate is not upon the whole insalubrious. It abounds with mountains, but the soil is generally fertile. The chief production of the island is rice, of which it yields more than enough to supply its numerous inhabitants, although it is not so good as the Java rice. Cotton of excellent quality is likewise very much cultivated; and the inhabitants manufacture it for the women's dresses, which are held to be the finest in all India. These garments are called "Cambays;" they are red-checked, mixed with blue, but dull-coloured; they reach from head to foot, and are often sold from 6 to 10 Spanish dollars a-piece. The Bouginese often import cotton from the island "Bali," both raw and spun into yarn. They also manufacture beautiful silk belts, in which they fix their knives; also a kind of paper, from the inner bark of a small tree, in which they wrap their fine cambays; this paper they often dye of various colours, and export much of it to Manilla, and several other places; it

resembles the cloth of Otaheite. They make fire-arms, but cannot make gun-locks; they also cast small brass guns, which they call "rantakka," the larger being about six feet long, and carrying a half-pound ball. They are curious in filigree work, both in gold and silver. Captain Forrest was informed, that they failed in their *PADUAKANS*, or proas, to the northern parts of New Holland, probably Carpentaria bay, to gather sea-swallow (biche de mer), which they sell to the annual Chinese junk, at Macasser; they said also that gold was to be obtained there. In this island cocoa-nut trees, mangoes, bananas, melons, and oranges are cultivated in abundance, together with uby, a root used as food, and batta, a kind of buck wheat, which formerly was the chief food of the Javanese before they were acquainted with the use of rice. Here is also plenty of horses, oxen, buffaloes, deer, wild swine, and birds of all kinds, particularly a variety of beautiful parrots. The Dutch carry lither opium, spirits, lac, coarse and fine cloths, &c. and receive in exchange rice, wax, slaves, and gold. Here, as well as in many parts on the coast of Africa, the unfortunate beings doomed to slavery, are not prisoners taken in war, or criminals, but in general persons who have been kidnapped for the purpose of being sold; and it often happens, that relations do not hesitate, for the sake of gain, to deprive their kindred of liberty. Most of the eastern settlements, Batavia and Java, are furnished with slaves from Celebes. About 100 slaves are annually purchased at Macasser by the Dutch company, for their own service, and conveyed to Batavia; the whole remainder of this iniquitous traffic is in the hands of private individuals, and free inhabitants of the above-mentioned two places.

The island is well peopled: on the coast of Celebes alone there are said to be 56,000 inhabitants, 17,000 of whom are capable of bearing arms. Of the various nations who inhabit Celebes, the Bonians or Bouginese, called in general Baggeses by the English, and the Macassers, are the most known: the latter are the most considerable of those who have been forced by the arms of the Company to enter into alliance with them, and their lands likewise lie near those of the Company, and they are, therefore, better known in history than the more distant kingdoms and nations. See BONI and BOUGINESE. Several of the inhabitants of Celebes find employment in the gold mines of this island; and were it better peopled, and the islanders more industrious, these mines might supply a greater quantity of the precious metal. But the Indians who inhabit those parts of Celebes which produce gold, content themselves, like those of other places, with procuring sufficiency to satisfy their urgent wants in the easiest and speediest manner. Accordingly, they obtain the metal by collecting the small particles which have been carried down by the streams, or by washing the sand which they dig up, rather than by working the mines in a regular manner. The gold mines in this island are found in the kingdom of Lochoe, and in the eastern parts; and it is partly collected for the Dutch East India Company at Gorontalo. The mines commence on the southern side of Bulang, and the northern side of Kottabana, or Mogondo, and proceed thence to Dondo on the south-west, and Tamperana on the north-west side, at the bay of Tomini. Every where between these two districts gold is found in a greater or less quantity. Where the land of Celebes becomes so narrow, and the mountains so low, that a person can with ease pass from one coast to the other, in a few hours, the auriferous mountains end; and on the whole coast on the other side, as far as Macasser, a single gold mine is not to be found. The villages, however, in these gold-yielding mountains are very ill-peopled; and, besides, these treasures are neglected on account of the ignorant super-

dition of the natives; who will never venture to dig in any place for concealed riches, until they have sent thither a diviner, as he is called, to find out whether their labours are likely to be attended with success. This kind of divination, called in the language of the country "Talanga," consists in their discovering, as they pretend, by the voice of a certain bird, the probability of success, and the impediments that may occur to obstruct it. When the bird gives a favourable omen, the diviner proceeds to insure the favour of the protecting spirits of the place, by various kinds of offerings; and then the labourers commence their work, and continue it for as many days or months as the bird has prescribed. The instruments used in these mines are the following; viz. a piece of iron about $1\frac{1}{2}$ foot long and 2 inches thick, pointed and sharp at one end, and at the other furnished with a socket, into which is stuck a wooden pole, about 6 feet in length—also, an iron hook, with a short wooden handle, which is employed for loosening and turning up the earth around stones;—a mattock and small shovels;—dulangs, or small round dishes, about 18 inches in diameter, and somewhat hollow, having a small cavity in the middle, which may be closed with a wooden cover, used for the purpose of receiving the black sand that yields gold, and washing it, by stirring it about till the heavy metal subsides into the above-mentioned cavity;—and a pair of gold scales. In many places it is scarcely necessary to go deeper than 10 or 12 feet, but in others the pits must be dug to the depth of several fathoms, and the sides must be supported by means of boards and beams. It has been remarked, that the rocks on the borders of rivers, and most of the stones which are taken up from pits where the ore is rich, have a blue, and sometimes a yellow, colour, and are so soft that they may be used as paint. Where the gold is less rich, the stones are grey or white, and either of a hard texture, or soft like limestone. By these tokens the produce of gold from any mine may be easily ascertained. The quantity and value of the gold which is found in any mine cannot be exactly estimated. In mines that are newly discovered, labourers may sometimes, in the course of 14 days, find to the value of 200 dollars; whereas in other places the value of 20 dollars is scarcely found in the course of a year. In the widely extended mines of the river Palella, which divides itself into several branches, there are some places where gold is exceedingly abundant; but in such places it is of less value, being scarcely 18 carats fine. The best gold is procured from the mines of Popajatu, Moliapat, Ankahulu, Tolodinki, Lembuno, Souffo, and Tamperana; also from the fourth and fourth-west side of Pogiama, Wongo, Tomollas, Bevool, and Tontoly. The gold of these mines is generally above 20 carats fine. Within the extent of the gold mines of Ankahulu there is a place called Longi, which produces gold that in fineness exceeds even that of Popajatu and Ankahulu. It is, however, difficult of access, and furnishes copper, at first supposed to be gold. This is the only mine on the north and north-west side, where copper is found. Near Bevool, on the fourth and fourth west side, there is another, where good copper is dug up in dust, which is as fine as the finest gold dust. In the mines of Bombula, Batodulang, Ankahulu, and Palella, a great quantity of rock-crystal is found, and likewise a kind of iron ore. In all the mines of Celebes, the gold, when separated from the sand, is of considerable fineness. At Pogiama and Palella alone gold ore is found here and there, mixed among other stones; but it is not rich, and the gold must be extracted by pounding the stone, which is not very hard. *Stavorinus's Voyage*, vol. ii. *Von Wurmb's Description of the Island of Celebes or Macassar*, &c.

CELEP, a river of Africa, in the kingdom of Algiers, supposed to be the ancient Carthæna, which falls into the sea about 3 leagues W. of Algiers, after a short course of 18 or 20 leagues.

CELIGERI, in *Ancient Geography*, a people of Mædia, according to Pliny.

CELÆIA, a town of Norica, mentioned by Pliny and Ptolemy, and appearing, by an ancient inscription of Gaster, to be the modern Celley in Lower Stiria.

CELELATES, an ancient people of Italy in Liguria, who, according to Livy (l. xxxiii. c. 29), submitted to the Romans in the year of Rome 555, under the consulate of C. Cornelius and Q. Minutius.

CELEMANTIA, a town of Germania Magna, placed by Ptolemy in the vicinity of the Danube.

CELENDERIS, a burgh of the Argolide, towards the extremity of the peninsula S.E. of the Argolide, on the Saronic gulf.—Also, a sea-port town of Asia, in Cilicia.—Also, an episcopal town of Asia in Iauria, probably the same with that last mentioned.

CELENDERITIS, a small district of Asia, in Cilicia, deriving its name from Celenderis.

CELENNÆ, an ancient town of Italy in Campania, mentioned by Virgil in his *Æneid*. It was a colony, according to a medal of Vespasian.

CELENTA, in *Geography*, a town of Naples, in the province of Abruzzo Citra; 12 miles E. of Civita Borelio.

CELERES, in *Antiquity*, a Latin word made use of to denote cavalry, so called on account of the quickness of their movements, and the celerity with which their service was performed. They were a sort of light-horse, about 300 in number, formed by Romulus for his body-guard, chosen out of the rest of the cavalry, and approved of by the suffrages of the curiæ of the people, each of which furnished ten. In war they constituted the van-guard in advancing towards the enemy, generally beginning the engagement, and the rear-guard in retreating.

Though the celeres were a body of horse, yet they usually dismounted, and fought on foot; their commander was called *tribune*, or *prefect of the celeres*. They were divided into three troops, of one hundred each, commanded by a captain called *centurio*; their tribune was the second person in the kingdom. See CAVALRY, &c.

Plutarch says, Numa broke the celeres: if this be true, they were soon re-established; for we find them under most of the succeeding kings: witness the great Brutus, who expelled the Tarquins, and who was the tribune of the celeres.

CELERINA, in *Ancient Geography*, an ancient episcopal town, in the proconular Africa.

CELERINUS, in *Zoology*, a name by which some authors have called the pilchard, *clupea pilcardus*; called also *aqua membras*, and *chaies*.

CELERITY, in *Mechanics*, is the velocity of a moving body; or that affection of a body in motion, whereby it is enabled to pass over a certain space, in a certain time. See MOTION and VELOCITY.

CELERY, in *Botany and Gardening*. See ASPHUM.

CELERY, wild, *Aspum antarcticum*, in *Botany*, was found in considerable quantities by Mr. (Sir Jos.) Banks and Dr. Solander on the coast of Terra del Fuego. It is like the garden celery in the colour and disposition of the flowers, but the leaves are of a deeper green. The taste is between that of celery and parsley. It is a very useful ingredient in the soup for seamen, because of its antiscorbatic quality. *Hawke's Voyages*, vol. ii. p. 60, &c.

CELESTI, ANDREA, called *Cavalier CELESTI*, in *Biography*, a painter of history and landscape, was born at Venice in 1637, and acquired the principles of design and colouring from Cavalier Matteo Ponzoni. He was much applauded for a beautiful style of painting, in history as well as landscape; but he principally employed himself in the latter. His beautiful views about Venice, and other cities of Italy, were painted both in a large and small size; and his works are very highly prized, but not easily procured. Two of his historical compositions are preserved in the chapel of Madonna della Pace at Venice; the one is St. Luke painting the portrait of the Virgin; and the other, the Adoration of the Magi, which are reckoned excellent performances. Another of his pictures in the chapel of Spedalletto, representing St. Jerome, with the Virgin and some saints, is well designed, soft, and delicately coloured, but rather too ruddy. This master used a purplish tint, resembling the manner of Rubens; but he sometimes erred in the extreme. Birkington.

CELESTIAL, *Globe*. See **GLOBE**.

CELESTIAL, *Sphere*. See **SPHERE**.

CELESTINE, in *Biography*, the name of several of the popes.

CELESTINE I., a native of Rome and the son of one Priscus, was elected bishop of Rome, upon the demise of Boniface, in 422. Soon after his election an appeal was made to him against Antony, appointed bishop of Fussala in Africa by St. Austin; in consequence of which he concurred in the sentence of the prelates of Numidia, who deprived him of all jurisdiction on account of his scandalous conduct. On occasion of another appeal by Aparius, presbyter of Sicca, against his bishop, who had degraded and excommunicated him for several crimes, of which he had been convicted, and which appeal had been in a state of suspense during the pontificates of his two predecessors, the African bishops confirmed a canon that prohibited appeals beyond sea on any pretext, under penalty of excommunication; and Celestine thought it most expedient to give way for the present to the zeal with which they resisted the supremacy of the Roman see. In the year 428 he remonstrated, in a long letter addressed to the bishops of the provinces of Vienne and Narbonne against several abuses that prevailed in the churches of Gaul; and towards the close of the year 429 he concurred with the Gallican bishops, in sending two missionaries into Britain for the purpose of suppressing the Pelagian heresy. But the principal act of his ecclesiastical administration was the part he took in the condemnation of Nestorius. A violent dispute having commenced in 430, between Nestorius, bishop of Constantinople, and Cyril, bishop of Alexandria, concerning the distinction of two natures in Christ and the refusal of the title of mother of God to the Virgin Mary, an appeal was made by both the disputants to Celestine. The Roman bishop convened a council at Rome; which condemned the opinions of Nestorius, as heretical, degraded him from his episcopal office, and allowed him only ten days for recantation; on the failure of which he was to be deposed and excommunicated; and Cyril was appointed to be the vice-gerent of Celestine in the execution of this sentence. An œcumenical council was afterwards summoned by the emperor Theodosius at Ephesus, in order finally to decide concerning the subject in dispute. To this council Celestine sent legates, and he approved its condemnation of Nestorius; upon which he wrote a pressing letter to the emperor, requesting him to banish the heresiarch Nestorius to some uninhabited place, where he would have no power to spread the infection of his doctrine.

For this instance of zeal on behalf of what was then deemed orthodoxy, Celestine has been ranked among the saints of the Romish church. In 431 the pope addressed the bishops of Gaul in a letter, warmly supporting the doctrine of St. Augustine concerning grace and free will. He also sent Palladius into Ireland, in order to propagate the Christian religion among the rude inhabitants of that island; and as this first mission was not attended with much success, he employed, after the death of Palladius, in the same mission, Succathus, a native of Scotland, whose name he changed into that of Patrick, and who arrived among the Irish in the year 432. The success and fame of this missionary are recorded in the annals of that country; and he has been acknowledged and honoured, under the appellation of "The Apostle of the Irish," as the father of the Hibernian church. Celestine died in 432. Several of his letters relating to the Nestorian controversy are extant; and others on various subjects of discipline have been falsely attributed to him. Bower's *Hist. of the Popes*, vol. i. Mosheim's *E. H.* vol. ii. p. 8.

CELESTINE II. a Tuscan, cardinal of St. Mark, and in 1140 legate of the apostolic see in France, and called before his election to the papal chair Guido de Castello, succeeded Innocent II. in 1143. The chief act of his administration was that of absolving the king of France from the interdict which he had been put under by Innocent. He had been a disciple of Abelard, and was respected for his humanity and other good qualities. He died in 1144, after having been in possession of the see of Rome about half a year. Bower.

CELESTINE III. was elected to succeed Clement II. in 1191, in the 85th year of his age. His name was Hyacinth, and he had been cardinal-deacon for 65 years. After some delay he consented to crown Henry V. emperor of Germany, together with his wife Constantia, the emperor having previously stipulated on oath that he would give up the lands and territories that belonged to St. Peter, and restore Tusculum to the apostolic see. He caused the enemies of William, bishop of Ely, and high chancellor of England, who had been appointed governor of the kingdom by Richard I. on his departure to the holy land, to be excommunicated, and the bishop to be restored to the government from which he had been excluded; and he also excommunicated the duke of Austria for having imprisoned Richard on occasion of his shipwreck in his return from the crusade. As Philip Augustus, king of France, had married Ingelburga, daughter of Canutus IV. king of Denmark, within the forbidden degrees of consanguinity, he divorced her under this pretext soon after the consummation of the marriage; and the divorce was declared lawful by the Gallican bishops. The decree of the bishops assembled in council was confirmed by the pope's legates; but it was afterwards reversed on a discovery of the fallacy of the king's plea, by the pope. Philip, however, disregarding the prohibition of the pope, took another wife, and Celestine gave himself no concern in the matter. Being informed that in Poland and Bohemia most of the clergy were either married or publicly kept concubines, he sent, in 1197, a cardinal legate to reform this abuse; and he succeeded in restoring celibacy in Poland, but the opposition in Bohemia was such as to endanger his life. On the death of the emperor Henry, he granted leave to crown his son Frederic as king of Sicily, on condition of the payment of 1000 marks of silver to himself, and the same sum to the cardinals. As his infirmities increased, he wished to resign the papal chair, but the cardinals would not allow him to retire. At length he died in 1198, after a pontificate of nearly seven years. By a particu-

ticular bull, he absolved those who had been devoted, while children, to particular monasteries, from the obligation of confirming their vows at mature age. Bower.

CELESTINE IV. was elected, after a contest among the cardinals, to succeed Gregory IX. in 1241. His name was Godfrey; he was of the illustrious family of Castiglioni of Milan, and his mother was the sister of Pope Urban III. From his retirement among the Cistercians, he was drawn into public life, and created cardinal by his predecessor. It was his declared wish to establish a lasting peace between the church and empire, but his death, on the 18th day of his pontificate, in a very advanced age, prevented his receiving an answer from the emperor to his pacific proposal. Bower.

CELESTINE V. was, before his advancement to the pontifical dignity in 1294, a poor hermit, called Peter de Morrhone, from the name of a mountain near Magella, about two miles from Sulmona in the Further Abruzzo, who was born at Isernia in 1215, and there lived a retired and austere life. When he was acquainted with his election, which took place at Perugia, he at first declined the pontificate; but by the urgent persuasion of Charles, king of Apulia, and his eldest son, Charles Martel, king of Hungary, enforced by Cardinal Latinius, he was prevailed upon to accept it, and made his entry into Aquila mounted on an ass, one of the kings on each side holding his stirrup. Soon after his consecration at Aquila, he made a promotion of 12 cardinals; and before he left the city he confirmed the constitution of Gregory X. by which the cardinals were directed, on a vacancy, to be shut up in conclave till they should agree in a new election. The place of his residence was Naples, which, by the recommendation of Charles, he preferred to the papal dominions, though the old cardinals wished him to remove thither. Totally unfit by his former habits for the papal office, he was persuaded by cardinal Cajetan at the close of the year of his election to resign it. His resolution to this purpose was, however, strongly opposed by Charles and the people of Naples; and a doubt was suggested, whether or not a pope could abdicate. A constitution having been established, empowering all sovereign pontiffs to resign at their pleasure, Celestine availed himself of it; and after reading his act of renunciation, divested himself of the pontifical ornaments, resumed his monk's habit, and sat down at their feet. Cajetan, who succeeded him under the title of Boniface VIII., fearing his future interference, resisted his earnest request of returning to his solitude, and carried him to Rome. He contrived, however, to make his escape, and concealed himself for some time with other hermits, in a wood in Apulia, till he found an opportunity of embarking in a small vessel for Dalmatia; but being driven back by contrary winds, he was arrested by the governor of Capitanata. From thence he was conveyed by order of Boniface to Anagni, amidst the blessings of the people, who crowded round him, and plucked the hairs of the ass upon which he rode, as relics. Boniface confined him in his palace at Anagni, and after some time committed him to close custody in the castle of Fumoni, where he died in 1296, aged 81 years. Clement V. canonized him in 1313; and the religious order which he established under the name of *Celestines* still subsists. The writings attributed to him are merely collections of passages from the Scriptures, the fathers, the popes, and the canonists. Bower. Du Pin. Mosheim.

CELESTINES, in *Ecclesiastical History*, an order of religious, called also the *congregation of St. Damian*, reformed from the Bernardines in 1224, by pope Celestine V. then only Peter de Morrhone, of Isernia in Naples; and established

in 1264, by pope Urban IV. and confirmed by Gregory X. in 1274. They were introduced into France by Philip the Fair, who requested a dozen of them from the general of their order, by his ambassador at Naples, in 1300. This order still subsists in France and Italy.—It is a kind of proverb with them *Voilà un plaçant Celestin*.

CELESTINI, an excellent performer on the violin, whom the late duke of Dorset brought from Rome in the year 1770. His style was pleasing, elegant, and correct; and such were his manners and conduct: so that while he remained in England, he at once did honour to his noble patron, to his profession, and to himself.

CELETÆ, in *Ancient Geography*, a people who inhabited part of mount Hæmus and part of mount Rhodope, and who are called by Piny the most savage of all the Thracians. Livy tells us, that they fell upon Cn. Manlius, as he was returning out of Asia into Europe, and took from him great part of the booty which he had gotten by plundering some rich cities of Gallo-Græcia. Livy decad iv. lib. viii.

CELETES, or CELETÆ from κίλες, a race horse, in *Antiquity*, denote single or saddle horses, by way of contradistinction from those yoked or harnessed together, called *bigarii*, *quadrigarii*, &c.

The same denomination is also given to the cavaliers, or riders on horseback; and hence some deduce *celeres*, the name of Romulus's guard.

CELETRUM, in *Ancient Geography*, a small town of Greece, in the north of Illyria, situated on a peninsula, with its walls encompassed by a lake.

CELETTE, in *Geography*, a town of France in the department of the Loire and Cher, and district of Blois; 4 miles south of Blois.

CELEUSMA, or CELEUMA, in *Antiquity*, the shout or cry of the seamen, whereby they animated each other in their work of rowing.

The word is formed from κέλευσις, to call, to give the signal. CELEUSMA was also a kind of song or formula recited or played by the master or others, to direct the strokes and movements of the mariners, as well as to encourage them to labour. See CELEUSTES.

Aquinas, without much foundation, extends the *celeusma* to the military shouts in land armies.

When Christianity got footing, hymns and psalms were sung in vessels by way of *celeusma*, in which the words *amen* and *hallelujah* were frequently repeated.

CELEUSTES, in *Ancient Navigation*, the boatswain or officer appointed to give the rows the signal when they were to pull, and when to stop. See CELUSMA.

He was also denominated *epopus*, and by the Romans *portifculus*; sometimes simply *hortator*.

CELEUSUS, in *Ancient Geography*, a place of Germany between Germanicus and Aruena, at the mouth of a small river which runs into the Danube.

CELEZENE, a country of Asia in Armenia, according to Suidas; called *Celene* and *Celtzani* by Eusebithus.

CELIA, a town of Italy, situate in the interior of the Peucetian district, according to Ptolemy and Strabo: thought to be the present *Ceglia*.—Also a place of Italy in Campania, taken by Quintus Fabius, according to Diodorus Siculus.

CELIAC *Passion*, in *Medicine*. See COFLIAC.

CELIBATE. See CELEBATE.

CELIDA, in *Ancient Geography*, a town of Africa, placed by Ptolemy in the Cyrenaica.

CELIODOGRAPHIA, the description of the spots which appear on the faces of the sun and planets.

The word is formed from *μακρῆς*, *macula*, *spot*, and *γραφή*, *I describe*.

Signor Bianchini has published a *celidographia*, or description of the spots of the sun.

CELIMEOS, in *Ancient Geography*, an episcopal see of Asia, under the metropolis of Edessa.

CELIMIA, in the *Materia Medica*, a name given by the modern Greeks to the calamine, or *lapis calaminaris*. The Arabians called this substance *climia*, and sometimes *calimia*; and *celimia* was but a very small change from this.

CELL, *Cells*, in *Ancient Writers*, denotes a place or apartment usually under ground, and vaulted; in which were stored up some sorts of necessaries, as wine, honey, wheat, and the like; according to which it was peculiarly denominated *cella vinaria*, *oleria*, *mellaria*, *penaria*, &c.

The word is formed from *celare*, *to conceal*. See CELLS.

CELL, in *Botany*, (*loculamentum*), the hollow part of a pericarp in which the seeds are lodged. According to the number of these, a pericarp is said to be one-celled, two-celled, &c.

CELLA, in *Ancient Writers*, was used for the lodge or habitation of a common woman or prostitute, as being under ground; hence also denominated *fornicus*.

“*Intravit calidum veteri centone lupanar,
Et cellam vacuum.*” Juv. Sat. vi. ver. 124.

On which place an ancient scholiast remarks, that the names of the whores were written on the doors of their several cells, by which we learn the meaning of *inscripta cella*, in Martial, lib. xi. ep. 45.

CELLA was also applied to the bed-chambers of domestics, and servants; probably as being low and narrow.

Cicero, inveighing against the luxury of Antony, says, the beds in the very *celle* of his servants were spread with pompous purple coverlets.

CELLA is also applied to the members or apartments of baths.

Of these there were three principal, called *frigidaria*, *tepidaria*, and *caldaria*. To which may be added a fourth, called *cella assis*, a d sometimes *sudatoria*. See BATH.

CELLA was also applied to the *adyta*, or inmost and most retired parts of the temples, where the images of the gods to whom the edifices were consecrated, were preserved. In this sense we meet with *cella Jovis*, *cella Concordiæ*, &c. Pub. Victor calls them *delubra*; and Pliny, by a more comprehensive name, *ades*. Hist. Nat. lib. xxxv. cap. 10.

The Roman capitol, we are told by Dionysius, had three such *cellæ*, or chapels; the middle-most of which was sacred to Jupiter, that on the right hand to Minerva, and that on the left to Juno.

CELLA, is also used for a lesser or subordinate fort of monastery, dependant on a great one, by which it was erected and continues still to be governed. The great abbies in England had most of them *cells* in places distant from the mother-abbey, to which they were accountable, and from which they received their superiors.

The alien priories in England were *cells* to abbies in Normandy, France, Italy, &c.

The name cell was sometimes also given to rich and considerable monasteries not dependant on any other. Such was that called *cella vetus*, erected by Otho, furnished the Rich, marquis of Misnia, in the middle of the twelfth century, the most splendid abbey in that country.

CELLÆ, in *Ancient Geography*, sometimes called *Callæ*, a town of Africa, in Mauritania.—Also, another town of Africa in Byzacene, upon the Lesser Syrtis; called by D’Anville

“*Cellæ Picentinae*.”—Also, a town of Europe, in Thraee, upon the Hebrus, at a small distance E. from Philippopolis.—Also, a place in Macedonia, between Heraclea to the north, and Edessa to the south.

CELLAR, *Cellarium*, in *Ancient Writers*, denotes the same with *cella*, viz. a conservatory of eatables, or drinkables.

Cellar differs from vault, as the latter is supposed to be deeper, the former being frequently little below the surface of the ground.

In which sense, *cellarium* only differed from *penus*, as the former was only a store-house for several days, the latter for a long time. Thus it is, the Bractioperata, a sort of ancient Cynics, are said by St. Jerome to carry their *cellar* about with them. Hieron. in Matth. cap. x.

CELLARIA, in *Zoology*, a section of the *Scutularia* genus, including those species which have the stem crustaceous, inclining to the nature of stone, and composed of rows of cells: no vesicles, but small globules instead.

CELLARIUM, in *Ancient Writers*, denoted an allowance of bread, wine, oil, or other provision, furnished out of the *cella*, to the use of the governor of the province, and his officers, &c. In which sense, the word amounts to much the same with *annona*, which see.

CELLARIUS, CHRISTOPHER, in *Biography*, was born at Smalcald in 1638, and having studied at various German Universities, was invited at the age of 20, to teach moral philosophy and the Oriental languages at the college of Weisfelsens. In 1673, he became rector of the college of Weimar, and afterwards occupied the same post at Zerts and Merzburg. At the university of Halle in Saxony, founded by the king of Prussia, he was professor of eloquence and history. His assiduous application, at length, brought on the disorder of the stone, with which he was long tormented. He died at Halle in 1707, in his 69th year. His numerous publications comprised original works and editions of ancient authors. Of the former are, “*Notitia orbis antiqui*,” 2 vols. 4to. Lcips. 1701. 1706, 1731, and Camb. 1703, acknowledged the best work on ancient geography extant, which brings it down to the time of Constantine; “*Atlas Cælestis*,” fol.; “*Historia Antiqua*,” Jen. 1698, 12mo. an abridgment of ancient history; “*De Latinitate mediæ et infimæ ætatis*.” The works edited by Cellarius are “*Ciceronis Epist. ad Familiares*,” “*Plinii Epist.*,” “*Corn. Nepos*,” “*Quintus Curtius*,” “*Eutropius*,” “*Sextus Rufus*,” “*Veilius Paterculus*,” “*Duod. Panegyri. Antiqui*,” “*Lactantius*,” “*Mnucius Felix*,” “*St. Cyprian. de Vanit. Idol.*,” “*Sedulius*,” “*Prudentius*,” “*Silius Italicus*,” “*Pici Mirandul. Epist.*,” “*Zosimus*,” “*Pæranus*,” the “*Theaurus of Faber*,” with large additions. A collection of his letters, and some other pieces, was published after his death. Nouv. Dict. Hist.

CELLARS, in *Modern Building*, are the lowest rooms in a house, the ceilings of which usually lie level with the surface of the ground on which the house is built.

Cellars, and other places vaulted under ground, were called by the Greeks *hypogæa*; the Italians still call them *fundi delle case*.

As to the situation of cellars, sir Henry Wotton says they ought, unless the whole house be cellared, to be situated on the north side of the house, as requiring a cool fresh air.

In order to estimate the number of cubic yards in the digging of cellars, multiply continually together the three dimensions of length, breadth, and depth in feet, and divide the product by 27, the number of cubic feet in a yard; and the

the quotient will give the cubic yards. Suppose the length 54 feet, the breadth 28, and the depth 8; then $54 \times 28 \times 8 = 12096$; and $\frac{12096}{27} = 448$.

CELLARER, or CELLERER, Cellerius, or Cellarius, an officer in monasteries, to whom belong the care and procurement of provisions for the convent.

The denomination is said to be borrowed from the Roman law, where cellarius denotes an examiner of accounts and expences. Ulpian defines it thus: "Cellarius, id est, officio prepositus ut rationes falve fiat."

The cellarius was one of the four *obediensarii*, or great officers of monasteries; under his ordering was the *pisarium*, or bakchouse, and the *bracium*, or brewhouse. In the richer houses there were particular lands set apart for the maintenance of his office, called in ancient writings, *ad cibana monachorum*. The cellarius was a great man in the convent. His whole office in ancient times had a respect to that origin; he was to see his lord's corn got in, and laid up in granaries; and his appointment consisted in a certain proportion thereof, usually fixed at the thirtieth part of the whole; together with a furrow gown. The office of cellarer then only differed in name from those of bailiff and minister; excepting that the cellarer had the receipt of his lord's rents through the whole extent of his jurisdiction.

CELLARER was also an officer in chapters, to whom belonged the care of the temporals, and particularly the distribution of bread, wine, and money to canons, on account of their attendance in the choir. In some places he was called cellarer, in others *burser*, and in others *carrier*.

CELLE, in Geography, a town of France, in the department of the two Sevres; and chief place of a canton, in the district of Melle; 10 miles S.E. of Niort. The place contains 1102, and the canton 8263 inhabitants; the territory includes 167½ kilometres and 12 communes.

CELLE, or Marcen Celle, a town of Germany, in the duchy of Lower Stria, on the confines of Austria, with a celebrated abbey to which the empress Maria Theresia presented a silver image of the Virgin, after the birth of the emperor Joseph II.; 12 miles N. of Pruck.

CELLE sur Thiers, a town of France, in the department of the Puy de Dôme; 2 leagues E. of Thiers.

CELLEFROUIN, a town of France, in the department of the Charente, and district of La Rochefoucauld; 9 miles N. of La Rochefoucauld.

CELLENE, in Entomology. Cramer calls the Fabrician *Papilio bellia* by this name.

CELLENSIS, in Ancient Geography, an episcopal see of Africa in the Byzacene.—Also, another in Mauritania Sitionensis.

CELLEPORA, in Zoology, a genus of zoophytes, the animal of which is an hydra, or polype, and the coral somewhat membranaceous, and composed of round cells. The eight following species of cellepore are described by writers.

CELLEPORA ramulosa. This species is dichotomous, fasciculated, with round obtuse ramifications, and very crowded cylindrical tubes. Müll. Zool. Dan. Inhabits the North Sea.

CELLEPORA spongites. Frangible, with rows of tubular top-shape cells, in single layers, with marginate openings, irregularly unguis to mass. A native of the Mediterranean and North Sea, called by Linnaeus *cellipora spongites*; by Ellis and Soar *millepora spongites*; a large of Mreac; *porus sanguineus*. Imperat. Hist. Nat. *Lapis spongia*. Bell. Mus.

CELLEPORA verrucosa. With ovate cells in a round mass; mouth usually with three teeth. Fabr. *Tubipora verrucosa*. Linn. Inhabits the Mediterranean and Norway seas.

CELLEPORA pumicea. Dichotomous, very brittle; nearly erect, with gibbous mucronate crowded cells. Resembles pumice stone; inhabits the Indian, Atlantic, and European seas. Pallas, Ellis, &c.

CELLEPORA ciliata. With convex cell; mouth fringed with teeth.

Fabricius describes this species as having seven teeth in the mouth of each cell, and the like number is mentioned by Pallas; other writers speak of them as varying in point of number in different specimens. This kind is found on fuci in the Mediterranean and North Sea.

CELLEPORA hyalinata. Cells subglobular, and diaphanous; mouth oblique and simple, or unarmed. Fabr. Pn. Gron. Frequent on fuci, and shells in the Northern seas of Europe.

CELLEPORA nitida. Cells subcylindrical, pellucid, and annulated; mouth terminal and simple, or unarmed. Fabr. Inhabits the Greenland Sea.

CELLEPORA annulata. Cells oval, ventricose and annulated; mouth rimmed and armed with about four teeth. Fabr. Found attached to fuci, stones, &c. in European seas.

CELLES, in Geography, a town of France, in the department of Jemmapes, and chief place of a canton, in the district of Tournay. The place contains 1750, and the canton 12,835 inhabitants. The territory includes 157½ kilometres, and 13 communes.

CELLIER, ROMI, in Biography, a learned Benedictine, was born at Bar-le-Duc in 1658; and having cultivated in early life an attachment to literature and piety in the congregation of the Benedictines of St. Vanne and St. Hidulph, he assumed the habit of the order in more advanced age, and filled several posts in it, particularly that of titular prior of Flavigny. He died in 1761. His great work was written in French (though begun in Latin), and entitled "A general History of Sacred and Ecclesiastical Authors," in 23 vols. 4to., published from 1791 to 1793. It comes down no lower than to St. Bernard. This work is an useful compilation, but rendered tedious by its diffuseness. He also published "An Apology for the Morality of the Fathers, against Barbeyrac," 1718, 4to. His habits were studious and retired, and his temper singularly mild and condescending. *Dié. Nouv. Hist.*

CELLINI, BENEVENTO, a celebrated artist, was born at Florence in 1500; and though he discovered an early taste for design, was obliged by his father to learn music. Afterwards he was bound apprentice to a jeweller and goldsmith; but his temper being restless and ungovernable, he passed through various vicissitudes, and at length settled at Rome, where he was taken into the service of pope Clement VIII., both as a musician and goldsmith. In the latter department he practised drawing, seal-engraving, damasking steel, medalling, working in grotesque, and a variety of other ornamental arts. He was also an expert engineer, and was entrusted by the pope with the defence of the castle of St. Angelo, when Rome was sacked by the constable Bourbon. On this occasion he claims the honour of having shot the constable while scaling the walls, and of directing the cannon which killed the prince of Orange. As he was employed by Clement in making stamps for the Roman mint, the coins of that period are reckoned singularly beautiful. His medals, and jewellery works, are also highly

highly extolled as the finest specimens of the art. At the death of the pope, he returned to Florence, and was patronised by the grand duke Alexander. The coins which were struck from the heads of this duke prepared by Cellini for the mint at Florence have been held in such estimation, that they have been preserved by the curious like ancient medals. The roving disposition of this admirable artist led him to visit France; but being tired of that country, notwithstanding the gracious reception of Francis I., he returned to Italy. At Rome he was committed to prison under a charge of having robbed the castle of Angelo of considerable treasure, while the Spanish army was in that city; and though he made his escape in a wonderful manner, he was retaken, and again confined, till at length he was delivered from the hardships he endured by the intercession of the cardinal of Ferrara. On his return to France, he entered into the service of Francis, and employed himself in sculpture, and in casting large figures of metal, by which he obtained great reputation. But by his turbulent and quarrelsome disposition he incurred the displeasure of the favourite Mad. d'Estampes, and was obliged, after a residence of 5 years, to quit the country and return to Florence. In the service of the grand duke Cosmo, he displayed his astonishing genius, not only by smaller works, but by some large pieces of sculpture, particularly a statue of Perseus and Andromeda, and a crucifix, which placed him on a level with the first sculptors. In this art he had received instructions from the greatest genius of his time, Michael Angelo Buonarroti. He wrought in marble as well as in metal, and as he was a powerful competitor to the famous Baccio Bandinelli, there subsisted between them a great degree of mutual jealousy and hatred. He died at Florence in 1570. In 1568 Cellini published two treatises; one on the goldsmith's art, the other on sculpture, and the casting of metals. He also composed the history of his own life, which has been translated into English by Dr. Nugent, in 2 vols. 8vo. 1771. In this work he delineates his own character without disguising his faults, whilst he makes a boastful recital of his bravery, address, and professional skill. In the latter respect, the testimony of his contemporary, Vasari, places him among the most ingenious men of that flourishing period of the arts. Life of Benvenuto Cellini by himself. Gen. Biog.

CELLINO, in *Geography*, a town of Naples, in the province of Abruzzo Ultra; 7 miles E. of Teramo.

CELLITES, CELLITE, in *Ecclesiastical History*, an order of religious, founded at Antwerp in the beginning of the fourteenth century, whose patron was ANNIUS, a Roman; and therefore, in Italy they are called *Alessians*; but in Germany, and the Low Countries, where they have monasteries, *Cellites*, i. e. people inhabiting cells. See LOLLARDS.

CELLON, in *Ancient Geography*, a canton of Asia, in the Palmyrene territory, mentioned in the history of Judith.

CELLONÆENSES, a people of Scythia, mentioned by Pavorinus.

CELLS, CELLÆ, CELLULÆ, are little houses, apartments, or chambers; particularly those wherein the ancient monks, solitaries, and hermits, lived in retirement.

Some derive the word from the Hebrew *כלל*, i. e. a prison, or place where any thing is shut up.

The same name is still retained in divers monasteries. The dormitory is frequently divided into so many cells, or lodges. The Carthusians have each a separate house, which serves them as a cell.

The hall wherein the Roman conclave is held is divided, by partitions, into divers cells, for the several cardinals to lodge in.

CELLS are also the little divisions, or apartments, in honey-

combs, where the honey, young bees, &c. are distributed: these are always regular hexagons.

CELLULÆ ADIPOSÆ, in *Anatomy*. See CELLULAR SUBSTANCE.

CELLULÆ in the colon, a sort of spaces wherein the excrements continue some time before they are voided.

CELLULANUS, a monk inhabitant, or resident in a cell, or cella. He is also denominated *concellaneus*, and *syn-cellista*, by which are imported the relation of fellow-monks, or those who live in the same cell or convent.

CELLULAR SUBSTANCE, in *Anatomy*, or *cellular membrane*, *vel cellulosa*, or *muscosa*, of Latin writers, *tissu unguisse* of the French, is the medium which connects and supports all the various parts and structures of the body. It is composed of an assemblage of fibres, and laminæ of animal matter; connected to each other, so as to form innumerable cells, or small cavities, from which its name of cellular is derived. This substance pervades every part of the animal structure. By joining together the minute fibrils of muscle, tendons or nerve, it forms obvious and visible fibres; it collects these fibres into larger fasciuli; and by joining such fasciuli to each other, constitutes an entire muscle or nerve. It thus forms an investment common to the whole muscle, and beflows on each bundle of fibres, nay, on each fibre, down to the most minute threads, peculiar sheaths, delicate and tender in proportion to the subtilty of the fibre. It joins together the individual muscles, and is collected in their intervals. It surrounds each vessel and nerve in the body; often connecting these parts to each other by a firm kind of capsule; and in a looser form joining them to the neighbouring muscles, &c. When condensed into a firm and compact structure, it constitutes the various membranes of the body; which, by long maceration in water, may be resolved into a cellular texture. Its general condensation on the surface of the body constitutes the cutis, or true skin. In the bones, it forms the basis and groundwork of their fabric; a receptacle, in the interstices of which the earth of bone is deposited. Maceration in diluted acid dissolves this earth, and leaves, if one may use the expression, a skeleton of the bone, representing its figure, its processes, and its texture, in a kind of cellular substance. The only parts of the body in which the cellular texture seems to be wanting, are the proper substance of the brain, the crystalline lens, enamel of the teeth, and the insensible integuments of the body; viz. the epidermis, nails, and hair. As the cellular substance is entirely soluble in boiling water, it is ascribed by chemists to the peculiar modification of animal matter, termed gelatine. Its watery solution assumes, when cold, the appearance of jelly; and, after a particular mode of preparation, constitutes glue.

The interstices of the cellular substance are lubricated and moistened by a serous or watery fluid, poured out from the exhalant arteries, and again taken in by the absorbents. It thus acquires a pliancy and softness, which adapt it particularly to serve as a connecting medium for parts, which have motion on each other. The importance of this property will be best understood by observing the effects of its loss. Inflammation or abscess often causes an induration and consolidation of the cellular texture, by which the integuments are fixed to the muscles; the muscles are firmly united to each other, and to the surrounding parts; in short, a kind of ankylosis ensues, by which the motions of the whole are considerably impaired.

From the universal extent of this cellular texture, two conclusions may be drawn. 1st. It forms the basis of the whole animal fabric, in such a way, that if we conceive every part removed, except this, the form of the whole would still be expressed in cellular substance. 2^{ly}. It forms a connection

tion and passage between all parts of the body, however remote in situation, or dissimilar in structure. For the cells of this substance every where communicate; as we may collect from facts of the most common and familiar occurrence. The air in emphysema spreads rapidly from the chest to the most remote parts of the body; it has been known in such a case to gain admission into the eye-ball. (Littre in Mem. de l'Acad. des Sciences an. 1719.) A similar diffusion of this fluid may be effected by artificial inflation, which is commonly practised by butchers on the carcasses of calves. In anasarca, or preternatural accumulation of fluid in the cellular substance, the most depending parts are the most loaded; and scarifications in these drain the water off from the whole body.

The structure of the cellular substance varies considerably in different parts; it is very delicate, and possesses peculiarly short fibres, where it unites the different coats of the hollow viscera of the body; also where it joins the minute fibrils of muscular fasciculi. It is very loose in the scrotum, and integuments of the penis; and it is found in every intermediate stage. In these various states of density and looseness, it behaves on every part the required degree of firmness and strength, defines its form, and determines its mobility.

A peculiar power of contraction is attributed to the cellular substance; and is mentioned by Blumenbach, under the term *contractilitas*. (Institut. Physiol. sect. 4.) This is widely different from irritability, and consists in a slow and gradual motion, which is exemplified in the corrugation of the scrotum, and in the similar effect produced by cold on the surface of the body in general.

The cells of the cellular substance, in many parts of the body, are destined for the reception of a fluid termed fat, adips, or adipous substance. This substance is of an unctuous nature, inflammable, lighter than water, usually inodorous, and, generally speaking, similar to the vegetable oil. In addition to the carbon and hydrogen, which it possesses in common with these oils, it abounds with oxygen, and a peculiar acid termed the sebæic. It is white in young animals, and becomes yellowish as they advance in age. It is always more or less fluid in the living subject; in carnivorous animals and in man it retains much of its oily appearance after death; but in herbivorous animals it constantly assumes a concrete form. Dr. Hunter gave the name of adipous to that portion of the cellular substance which contains the fat; and distinguishes the rest by the term reticular.

As the fat is deposited in cells, it assumes, in general, a kind of granular form. It varies considerably in consistence. That of the orbit is the softest in the body. The fat about the kidneys becomes particularly hard after death, and is called suet; the globules or portions of this are very large, and it contains on the whole less cellular substance than any fat in the body. There is, generally speaking, a layer of fat under the skin; whence a *membrana adiposa* has been sometimes enumerated as one of the common integuments of the body. This is connected to the subjacent muscles by a portion of the reticular substance. Some parts of the body never contain fat: even in subjects, who have the greatest accumulation of this fluid. This is the case with the scrotum, the integuments of the penis, and the eyelids; it is obvious that the functions of these parts must be completely destroyed, if they were subject to the enormous accumulations of fat, which occur in the other parts of the body. Several of the viscera also never contain any of this substance, probably for the same reason, viz. the brain and lungs.

The quantity of fat varies according to the age, the state of health, and the peculiar habit or disposition of

the individual. It is not found in the early periods of foetal existence; and cannot be distinguished with any certainty, sooner than the fifth month after conception. In the fœtus, and for some time after birth, the fat is confined to the surface of the body; it is only found in a stratum under the skin. It begins, however, gradually to be deposited in the intervals of the muscles, and on the surface of some viscera. In old subjects, however thin they may seem on an external view, there is always much fat, penetrating even the substance of the muscles; the bones are greasy throughout; the heart is more or less loaded, as are also the parts in the abdomen. Hence a young subject should always be selected for dried anatomical preparations. There is considerable difference in the quantity of fat in different individuals; and in some there is a propensity or disposition to its accumulation. A sedentary life, copious food, and tranquil state of the mind are particularly favourable to the increase of fat, which sometimes proceeds to such a pitch, from the continuance of these causes, that it must be considered as a disease, and is attended with the greatest inconvenience to the individual. General diseases of the frame are commonly attended with an absorption of the fat from the cellular substance: acute diseases cause a very rapid emaciation. In no case is the adipous substance more completely removed from the whole body than in anasarca, where its place is supplied by a serous fluid.

Dr. Hunter thought that the fat was contained in cells peculiar to itself and different from those which are dilated by water in anasarca; and he distinguishes the two kinds of cells by the names of adipous and reticular cellular substance. C. A. a Bergen had already made a similar distinction (Diff. de Membrana Cellulosa in Haller's Disput. Anat. tom. 3.) He observes, in proof of this opinion, that fat is never accumulated in certain parts of the body, which parts are the most particularly dilated by the water of anasarca. He thinks that the cells of the adipous substance do not communicate together like those of the reticular; because the fluid fat does not drain into the depending parts like the water of anasarca: nor does the skin pit where fat is collected under it.

The same great anatomist also thought that there was a glandular apparatus for secreting the fat. "Wherever there is fat in the human body, I apprehend that there is a particular organization, or glandular apparatus super-added to the reticular membrane, consisting of vessels, or bags for lodging the animal oil, as well as vessels fitted for its secretion; so that I would compare the marrow in the bones to the glandular or follicular parts of the fat or adipous membrane; and the network of bony fibres and laminae, which support the marrow, to the reticular membrane, which is mixed with, and supports the adips." Medical Obs. and Inquiries, vol. ii. p. 35. Malpighi seems to be the first who ascribed the secretion of fat to a glandular apparatus: he has described the follicles or cells, in which this structure resides; and even tubes, which he considers as excretory ducts of his glands. (De Omento et adipsis Dactibus.) His opinions were adopted in a greater or less extent by several anatomists; as Glisson, Havers, Peirait, Fanton, Littre, and even Morgagni. It appears to us more probable, that the fat is a simple secretion from the arteries, like the serous fluid of the cellular membrane. We cannot discern any thing deserving the name of gland in the adipous substance of the body. We subscribe, in short, to the opinion of Haller: "Simplicissima et facillima secretions adiposæ hitoria.— Inter arterias, et adiposus loculus, nullum aliud receptaculum interesse. Neque oculus, aut microscopium in tenuissimis laminis cellulosis crassiorum aliquam

"aliquam particulam discernit, quam pro glandula habeat." (Elem. Physiolog. tom. i. lib. i. sect. 4.) We see preternatural collections of fat, (forming fatty tumours,) in those parts which are naturally the most free from aëps: can we suppose that glands are formed or created in this case? Is it not more congenial to our opinions on the formation of tumours in general to ascribe the phenomena to a peculiar action of the arteries?

The uses of the fat seem to be, in part, common to it with the cellular substance: it connects contiguous parts, and at the same time prevents their coalition. It admits of their moving on each other with freedom and facility. Its deposition under the integuments gives a roundness and convexity to the surface, on which the beauty of the human form principally depends. Indeed, its accumulation in particular situations immediately influences the outline of the part; viz. the orbit, the cheek, and the buttocks. The effect of its loss is most disagreeably manifested in the lank cheek and hollow eye of an emaciated patient. The fat is also said to defend the surface of the body from cold; and, indeed, it is accumulated very copiously under the integuments of such animals, as are exposed to the rigour of high northern latitudes; as the whale, the seal, &c. It has been likewise supposed that the fat, which is absorbed under certain circumstances, is applied to the nutrition of the body.

When we consider the extent and importance of the cellular substance in the animal body, we shall perhaps be surprised that there have only been ascertained within a comparatively short period of time. With the exception of a few vague notices in preceding writers, Malpighi, Ruysch, Douglas, and Winflow, gave the first correct descriptions of this substance in particular parts. It is to Haller that the merit belongs, of first shewing the great share which it has in the composition of the body in general, and particularly in the formation of membranes. The reader will peruse with advantage on the whole of this article, the 1st book of Haller's "Elementa Physiologiae." He may likewise consult "Bordeu Recherches sur le tissu muqueux et l'organe cellulaire," Paris, 1820.

CELME, in *Geography*, a town of Spain, in the province of Galicia, on the river Lima; 6 leagues south of Montefura.

CELNIUS, in *Ancient Geography*, a river of Britain, mentioned by Ptolemy, and supposed to be the river Spay, in the shire of Elgin.

CELONÆ, a town of Asia, supposed to have belonged to the Persian empire, and to have been situated towards Media.

CELONZA, in *Geography*, a town of Naples in the province of Capitanata; 5 miles N.W. of Volturara.

CELORICO, a town of Portugal, in the province of Beira, containing three churches, and about 1100 inhabitants; three leagues N.W. of Guarda.

CELOSIA, in *Botany*, Linn. gen. 289. Schreb. 405. Lam. Illus. 442. Willd. 463. Juss. 88. Vent. vol. ii. 265. Gært. 737. (Stachyragophora, Vaill. A. G. 1722. Paliavelours, Lam. Encyc.) Class and order, *pentandria monogynia*. Nat. Ord. *Holeraceæ*, Linn. *Amaranthi*, Juss. *Amaranthoides*, Vent.

Gen. Ch. Cal. Perianth of two or three leaves, lanceolate, acute, dry, shining, permanent. Cor. Petals five, lanceolate, acuminate, erect, permanent, rigid, resembling the leaves of the calyx. *Nrâ.* Surrounding the germ, quinquefid. *Stam.* filaments five, awl-shaped, conjoined at the base to the platted nectary; anthers versatile. *Pist.* Germ globular; style awl-shaped, straight, the length of the stamens; stigmas one, two, or three. *Peric.* Capsule globular, surrounded

by the corolla, one-celled, separating transversely into two parts (circumscissile). *Seeds* several, roundish, emarginate.

Ess. Ch. Calyx two or three-leaved; leaflets similar to those of the five-petalled corolla; filaments conjoined at the base to the platted nectary; capsule opening horizontally.

Obf. Jussieu, Ventenat, La Marek, and Gærtner understand the fructification differently. According to them the plants of this genus have no corolla, a five-leaved calyx, and an involucre of two or three scales resembling the leaflets of the calyx. It is nearly allied to *Amaranthus* and *Gomphrena*; differing from the former chiefly in its hermaphrodite flowers, and from the latter in having more seeds than one.

Sp. 1. *C. argentea*, Linn. Sp. Pl. 1. Mart. 1. Poiret Encyc. 1. Willd. 1. (*Amaranthus*, Mart. Cent. 7. tab. 7. *Belutta adæca manjen*, Rheed. Mal. to. tab. 38.) "Leaves lanceolate; stipules somewhat falcate; peduncles angular; spikes scarious." β . "Leaves nearly linear." *Tierra belutta*, Rheed. tab. 39. *Root* annual, whitish, fibrous. *Stems* almost woody, green, smooth, striated; branches, slender. *Leaves* alternate, narrow, often very acute, entire, smooth, narrowed into a petiole; stipules caducous, narrow. *Flowers* in a terminal, oblong spike, either simple or closely branched, of a white silvery colour, sometimes reddish at the summit; leaflets of the calyx thin, transparent, shining; anthers red. *Seeds* three or four in each capsule, small, orbicular, flattened, smooth, shining. A native of China and the coast of Malabar. 2. *C. albidula*, Willd. 2. Poiret 3. (*C. pyramidalis*, Burm. ind. 65. tab. 25. fig. 1.) "Leaves linear-lanceolate; stem without stipules; spikes egg-shaped; bracts the length of the corolla." Poiret doubts whether it be sufficiently distinct from the preceding, and suspects that by bracts Willdenow means the leaflets of the calyx. A native of the East Indies. 3. *C. margaritacea*, Linn. Sp. Pl. 2. Mart. 2. Poiret 2. Willd. 3. (*Amaranthus simplicifolius panicula*, Bauh. pin. 12.) "Leaves egg-shaped; stipules falcate; peduncles angular; spikes scarious." This also is scarcely more than a variety of *C. argentea*. It has thicker stems, broader and shorter leaves, and shorter spikes; in other respects not different. 4. *C. cristata*, Linn. Sp. Pl. 3. Mart. 3. Poiret 4. Willd. 4. Gært. tab. 128. fig. 8. Lam. Ill. Pl. 168. fig. 1. (*Amaranthus panicula conglomerata*; Bauh. pin. 22. *A. vulgaris*, Rumph. amb. 5. tab. 84.) Cock's comb. "Leaves lanceolate-egg-shaped, recurved, somewhat wavy; peduncles angular; spikes oblong, crested." *Root* annual. *Stems* angular, striated. *Leaves* alternate, acute, various in breadth in different plants, narrowed into a petiole at the base, sometimes a little curved. *Spikes* sometimes branched at the base, various in their form and size as well as colour, which is yellow, or yellowish white, red, or purple, and sometimes variegated with two or three colours. A native of Asia. 5. *C. comosa*, Willd. 5. Poiret 10. Retz. Obf. 6. p. 26. "Spikes cylindrical, comose; leaves lanceolate." *Stem* upright, naked, branched. *Leaves* quite entire, smooth. *Spikes* cylindrical, barren in the upper part, often much divided, consisting of minute, imbricated bracts. *Flowers* solitary, longer than the bracts, rising among them at some distance from each other. *Style* slightly trifid, permanent, twice as long as the petals. *Capsule* operculate, containing two seeds. A native of the East Indies. 6. *C. paniculata*, Linn. Sp. Pl. 6. Mart. 4. Poiret 7. Willd. 6. Swartz. Obf. p. 100. (*C. major farmentosa*, Brown Jan. 1799. *Blitum album majus scandens*, Sloan Jan. 49. hist. i. tab. 91. fig. 2. "Leaves ovate-oblong; stem rising, panicled; spikes alternate, terminal, remote." *Root* annual. *Stem* terete, prostrate, cylindrical,

Indical, branched. *Leaves* alternate, acuminate. *Flowers* alternate, distinct; stamens shorter than the corolla; stigma trifid." A native of dry rocky ground in Jamaica. 7. *C. nitida*, Willd. 7. Vahl. Symb. 2. p. 44. (Amaranthus fruticosus erectus, Sloan. hilt. 1. tab. 91. fig. 1.) "Leaves ovate-deltoid, attenuated; spikes terminal, branched; flowers distinct; stem somewhat shrubby." In habit resembling achyranthes farmentosa, but placed by Vahl under eclosia, on account of its calyx, corolla, and the number of its seeds. A native of the West Indies. Poirét suspects that it is one and the same plant with the preceding. But his doubt appears to have arisen from a blunder made by Willdenow, in quoting at full length, as a synonym of both, the amaranthus fruticosus erectus, spica viridi laxa & triglofa of Sloane, which belongs only to the present species; Linnaeus having referred the preceding to another of Sloane's plants. Willdenow indeed under nitida refers to pl. 91. fig. 5, not fig. 1, as it stands in Vahl, but this, as Poirét observes, must be an error of the press, there being no fig. 5 in that plate. 8. *C. coccinea*, Linn. Sp. Pl. 5. Mart. 5. Poir. 5. Willd. 8. (Amaranthus panicula incurva, Bauh. p. 121.) Scarlet or Chinese cock's-comb. "Leaves egg-shaped, stiff, not auriculated; stem furrowed; spikes manifold, erect." *Root* annual. *Stem* four or five feet high, branched. *Leaves* very large, narrowed into a petiole, ending in a long point, a little waved at the edges, smooth, entire, soon falling off. *Spikes* axillary and terminal, large, branched, tufted, of a beautiful scarlet colour; itamens shorter than the corolla. A native of the East Indies. 9. *C. castrensis*, Linn. Sp. Pl. 4. Mart. 6. Poir. 6. Willd. 9. (Amaranthus cristatus; Cam. Epit. 792. A. minor. Barrel ic. rar. tab. 1195. Bocch. Mus. 2. tab. 66.) "Leaves lanceolate-ovate, marked with lines, very much acuminate; stipules falcate; spikes erect." *Root* annual. *Stems* erect; branches axillary, almost from the bottom to the top of the stem. *Leaves* alternate, petioled, smooth, marked underneath with reddish veins; stipules two, sessile, embracing the stem. *Spikes* slender, axillary, sometimes a little branched. A native of the East Indies; less beautiful than many of the other species. 10. *C. monsonia*, Willd. 10. Poirét 10. Mart. 12. Hort. Kew. 1. p. 288. Retz. Obs. 2. p. 13. (Illecebrum monsonia; Linn. jun. Supp. 161. Amaranthoides; Pluk. alm. tab. 334. fig. 4. Amal. tab. 357. fig. 4.) "Leaves awl-shaped, whorled; stem branched, divaricate; spikes compact, cylindrical." *Root* annual. *Stems* prostrate, branched, ending in more elongated branches, a span long, and hoary. *Lower leaves* almost crowded into a tuft. *Spikes* opposite and terminal, reddish and whitish, very beautiful. A native of the East Indies. 11. *C. corymbosa*, Linn. Sp. Pl. 7. (excluding, according to Willdenow, the last two synonyms, which belong to Achyranthes corymbosa.) Willd. 11. Retz. Obs. 2. p. 13. (Paronychia; Burm. zeyl. tab. 65. fig. 2.) "Leaves linear, whorled, smooth; flowers corymbous-dichotomous." *Root* perennial. Willdenow asserts that it may easily be distinguished from achyranthes corymbosa by its stem ascending at the base, by its broader leaves and longer stipules, and by its flower; but Poirét is of opinion that the difference is very problematical. 12. *C. trigyna*, Linn. Mant. 212. Mart. 7. Poir. 9. Willd. 13. Jacq. Hort. 3. tab. 15. Lam. Illust. Pl. 168. fig. 2. "Leaves egg-shaped, acuminate, flat; stem herbaceous; raceme loose; bracts scarious; pistil trifid." *Root* annual. *Stem* a foot and half high, erect, simple, somewhat angular, striated, stiff. *Leaves* alternate, petioled, even, acute; stipules in pairs, crescent-shaped, horizontal, embracing the stem. *Flowers* in terminal racemes, a few clustered together at different distances, white, on short peduncles; bracts silvery, egg-shaped, distant; calyx two-

leaved; petals egg-shaped, acute, scarious, permanent; stamens purplish, only slightly connate at their base, shorter than the petals; germ globular; style very short; stigmata longer than the style, purple. *Capsule* globular. *Seeds* three. A native of Senegal. 13. *C. caudata*, Willd. 12. Vahl. Symb. 1. p. 21. (Achyranthes paniculata; Forst. desc. 48. "Leaves egg-shaped; racemes compound, loose, very long; pistil bifid; stem without stipules." Poirét thinks it only a variety of *C. trigyna*. A native of Arabia Felix. 14. *C. virgata*, Poir. 11. Willd. 14. Jacq. ic. 2. tab. 339. Collec. 2. p. 279. "Leaves egg-shaped, acuminate, waved; stem somewhat shrubby; raceme loose; bracts membranous; pistil trifid. *Root* perennial. *Stem* four feet high, almost woody, smooth, preserving its verdure all the year; branches slender. *Leaves* four or five lines long, petioled, alternate, quite entire; upper ones smaller, lanceolate; stipules acute, falcate. *Flowers* greenish, in short axillary and terminal spikes; bracts resembling the leaflets of the calyx, which are shorter than the corolla, whitish, and end in a blackish point; petals lanceolate, acute, a little concave. *Capsule* membranous. *Seeds* about six, lenticular. After impregnation the calyx and corolla unite and enclose the fruit, giving it a conical form. Native country unknown. 15. *C. polygonoides*, Mart. 14. Poir. 13. Willd. 15. Retz. Obs. 2. p. 12. "Leaves heart-shaped, stem bipid; raceme spiked, loose; flowers trigynous." *Root* perennial. *Stem* herbaceous, almost upright, striated. *Leaves* obtuse, petioled, alternate, scarious. *Racemes* consisting of alternate, remote, sessile, even, generally two-flowered, little chillers. *Capsule* pitcher-shaped, with a contracted mouth covered by a lid, longer than the calyx, many-seeded. 16. *C. madagascariensis*, Poir. 14. "Stems somewhat farmentous; leaves lanceolate, sinuated, obtuse; flowers raceme-spiked." *Stems* furrowed, limber; branches distant. *Leaves* petioled, alternate, smooth. *Flowers* small, cinereous white. Gathered in the isle of Madagascar by Commerçon and J. Martin, and described from a dried specimen in the herbarium of La Marek, but too imperfectly preserved to make it quite certain that the plant belongs to this genus and not to achyranthes. 17. *C. baccata*, Mart. 14. Poir. 15. Willd. 16. Retz. Obs. 5. p. 23. "Leaves heart-shaped, acuminate; racemes spiked, loose, flowers trigynous; fruit berried." *Stems* upright. *Leaves* alternate, entire. *Flowers* small, on very short peduncles; calyx leaflets two, small; petals oval, a little concave; filaments dilated at the base, entirely surrounding the germ. *Fruit* a blackish berry, not corresponding with the generic character. *Seeds* three, large, shining, convex on one side, concave on the other. A native of the East Indies. 18. *C. graphaloides*, Mart. 9. Willd. 17. Linn. jun. Supp. p. 161. "Shrubby, woolly; leaves opposite, egg-shaped, white underneath; head globular, peduncled. Found by Thouin in Brazil. Poirét suspects it to be an illecebrum. 19. *C. nodiflora*, Linn. Sp. Pl. 8. Mart. 10. Poir. 12. Willd. 18. Retz. Obs. 4. 24. n. 70. Jacq. Hort. tab. 98. (Amaranthoides; Burm. zeyl. tab. 5. fig. 2. Pluk. Almag. tab. 133. fig. 2.) "Leaves wedge-shaped, rather acute; spikes globular, lateral." *Root* annual. *Stems* angular, grooved, even. *Leaves* like those of purslane, obtuse with a point, quite entire, smooth, on very short petioles. *Spikes* solitary, peduncled; peduncles commonly shorter than the leaves. Instead of the calyx there are from one to three linear bracts; stamens fixed to the nectary at the base; stigma twin-capitate. *Seed* single; lens-shaped. It varies; 1. with oblong leaves and peduncled heads; 2. with short roundish leaves ending in a point and sessile heads; the first from Sumatra; the second from Malabar. Retz. According to this

this description it is surely an achyranthes. It is also a native of the island of Ceylon.

CELOSIA lanata, Linn. Sp. Pl. 7. See *ILLECEBRUM javanicum*.

CELOSIA procumbens; Murray Jac. See *COMPURENA interrupta*.

CELOSIA Gronov. virg. See *IRECINE celosifoides*.

CELOSIA, in *Gardening*, comprehends some flowery ornamental annual plants, as the amaranth, or cock's-comb.

The species commonly cultivated are the crested amaranth, or cock's-comb (*C. cristata*); the pearly-spiked celosia, or cock's-comb (*C. margaritacea*); the scarlet celosia or Chinese cock's-comb (*C. coccinea*); and the woolly celosia (*C. lanata*). Of the first sort there are many varieties, differing in form, magnitude, and colour, from the same seed. In the dwarf kinds, they vary, with large purple heads of flowers, with red heads, with scarlet heads, and with yellowish heads; in the giant kinds, with very large purple heads, with red heads, with scarlet heads, with yellowish heads, with white heads, and with variegated heads; and in the branching kinds, with purple, with red, and with buff-coloured flowers. And the able editor of Miller's Dictionary has raised great varieties from seeds from China and other countries, but generally found them alter in a few years, notwithstanding great care was taken in sowing the seeds. The principal colours of their heads were red, purple, yellow, and white, but he has had some whose heads have been variegated with two or three colours. He also raised some, he says, from seeds from Persia, whose heads were divided like a plume of feathers, and were of a beautiful scarlet colour, but which degenerated in a few years. Linnæus has found it to vary, with narrow and broad leaves; and Thunberg asserts that the crests or heads of flowers are often a foot in length and breadth in Japan, and extremely beautiful, but that they degenerate in other situations.

In the second sort there are varieties with oblong spikes of equal thickness, with pyramidal spikes, with entire white spikes, and with white and red spikes of flowers.

The third kind also varies, with crested spikes, with incurved crested spikes, and with plumed spikes of flowers.

Method of Culture.—It is observed that in order to produce fine flowers of this sort, it is necessary to be particularly careful in collecting the seed, so as to have it good and well ripened. In regard to the method of raising all the different sorts, it is by sowing the seeds of each separately in the early spring, as in the beginning of March, either upon a hot bed, or in pots to be plunged in one; in the first case, the surface being covered with fine, light, dry mould, four or five inches in thickness. When the plants have attained a few inches in growth they should be carefully taken up, and pricked out upon another hot-bed prepared and moulded for the purpose, at the distance of six inches; and should remain in this situation till they begin to be crowded, which is mostly the case in six or seven weeks. At this period another hot-bed should be put in readiness, with very deep frames.

Where the plants have been raised without pots on the beds, as many as are necessary should now be put in pots, care being taken to remove them from the former bed, with good balls of earth about their roots, by means of a trowel, placing one in each pot without disturbing the mould about them, filling up the spaces about them with good rich earth. Some water should then be given, and the pots be plunged to their rims in the bed, and as close together as possible, the openings between the pots being filled up well with mould to prevent the rising of steam so as to injure the plants.

And the glasses in these cases should be so managed as to preserve the heat in such a state as may keep the plants in a constant vigorous state of growth, being matted up in the nights, and having linings applied when there may be occasion for it from the state of the weather. When the weather is fine and calm, air should, however, be admitted rather freely by lifting up the ends of the frames, and water be moderately sprinkled over them as there may be occasion for it.

For the large sorts, the frames should have sufficient depth to draw them up to three or four feet in height, being raised, when necessary, as the plants advance in growth; but for the dwarf kinds the common frames are sufficient, as their heads should be constantly kept near to the glasses. See *HOT-BED* and *GARDEN-FRAME*.

As the summer advances the plants should be gradually hardened by more free admission of air, till the glasses are wholly removed, and the plants set out where they are to remain, in which it is proper to support the tall sorts by handsome sticks. In this situation water should be freely given every day, to prevent the leaves from shriveling and keep the flower-heads full and fine. It is remarked that plants of these sorts may be removed from the second hot bed into the beds, clumps, or borders; but that they never grow so strongly as in the above method.

The seeds in all the different species become in a state of perfection about the beginning of the autumn, when attention should be had to select them from the best and finest plants of each kind, sheltering the heads when necessary from rains, &c. and keeping the different sorts of seed separate and in a dry situation.

The perfection of the cock's-comb chiefly consists in its having a regular, upright, straight stem without any side branches, but well furnished all the way with leaves, and the large flower-head erect, close, and regular, in its form.

These are all plants of the fine ornamental kind, which have a good effect in the more conspicuous parts of gardens or pleasure grounds in mixture with others of the flowery kinds. The cock's-combs are well calculated to be placed in the courts and other places about the house, from the variety of effect which is afforded by their fine showy heads of flowers.

CELSA, in *Ancient Geography*, a town of Hither Spain, towards the south-west, seated on the Iberus. It was a Roman colony, and had a port on this river. Ptolemy has erroneously placed this town at the foot of the Pyrenæes.

CELSA, in *Geography*, a town of Naples, in the province of Principato Citra; 25 miles S.W. of Cangianno.

CELSIA, in *Botany*, (so named by Linnæus in honour of his friend Olaus Celsus, D.D. professor of the Greek language, and afterwards of theology in the university of Upsal). Linn. gen. 757. Schreb. 1015. Willd. 1153. Gært. 327. Juss. p. 124. Vent. vol. 2. p. 367. Clafs and order, *didymia angiospermia*. Nat. Ord. *Lurida*, Linn. *Solanæ*, Juss. Vent.

Gen. Ch. *Cal.* Perianth five-parted; segments lanceolate, permanent. *Cor.* monopetalous, wheel-shaped; tube very short; border flat; segments roundish, unequal. *Stam.* Filaments four, capillary, a little inclined, unequal, bearded; anthers roundish. *Pist.* Germ superior, roundish; style filiform, the length of the stamens; stigma obtuse. *Perr.* Capsule, roundish, compressed at the tip, acuminate, furrowed at its base by the calyx, two-valved, two-celled; partition simple, contrary to the valves. *Seeds* numerous, small, angular.

Eff. Ch. Calyx five parted, corolla wheel-shaped. Filaments bearded. Capsule two-celled.

Sp. 1. *C. orientalis*. Linn. Sp. Pl. Mart. 1. Lam. 1. Willd. 1. Gart. tab. 57. fig. 7. Lam. Iluf. Pl. 532. (Verbascum Sophis folio; Tournef. Cor. 8. Buxb. Cent. 5. p. 17. Blattaria; Buxb. Cent. 1. tab. 20.) "Leaves bipinnated." Linn. *Root* annual. *Stem* a foot and half high, upright, herbaceous, cylindrical, simple or furnished with short branches, leafy from the bottom. *Leaves* alternate, scattered, bipinnated, not bipinnate as they are described by Linnaeus in the specific character, green, entire smooth; segments slender toothed; those from the root oblong, finely divided almost to the midrib, lying flat on the ground. *Flowers* pale yellow, small, solitary, sessile, axillary; segments of the calyx narrow, sometimes bilobed or trilobed. A native of the Levant, flowering in June, sent to Paris from Armenia by Tournefort, in 1701, and cultivated in Chelsea-garden in 1739. 2. *C. arcturus*. Murray Syst. Veg. p. 469. Vahl *Symb.* 3. p. 79. Mart. 2. Lam. 2. Willd. 2. (Verbascum arcturus; Linn. Sp. Pl. V. humile creticum; Bauh. pin. 240. Alp. exot. tab. 122. Colum. ceplr. 2. p. 82. "Root-leaves lyrate; upper ones oblong; peduncles longer than the bractes; segments of the calyx linear, quite entire." Vahl. *Root* biennial. *Stem* a foot high or more, slender, weak, often simple, leafy, villous. *Leaves* generally alternate, sometimes opposite, pectioled, toothed, a little villous, dark green. *Flowers* yellow, in a loose spike on the upper part of each stem; peduncles from six to nine lines long; filaments covered with red or purple hairs. A native of Candia, first cultivated at Kew about 1783. 3. *C. cretense*. Willd. 3. Vahl *Symb.* 3. p. 79. "Root-leaves lyrate; stem ones egg-shaped; peduncles shorter than the bractes; segments of the calyx linear-oblong, quite entire. *Root* annual. *Flowers* distant, about the size of *C. arcturus*. A native of the East Indies. 4. *C. cretica*. Murray Syst. Veg. p. 467. Linn. jun. Sup. p. 281. Mart. 3. Lam. 3. Willd. 4. (Verbascum; Mill. Ic. tab. 273. Blattaria; Morif. 2. 458.) "Root-leaves lyrate; stem ones oblong; flowers nearly sessile, the length of the bractes; segments of the calyx egg-shaped, serrated." Vahl. *Root* biennial. *Stem* two feet high, herbaceous, simple, upright, cylindrical, pubescent. *Leaves* alternate, embracing the stem, wrinkled, serrated, pubescent underneath. *Flowers* large, yellow, with a ferruginous spot at the base of each of the upper divisions; in a long terminal raceme; bractes heart-shaped, acuminate, somewhat acutely serrated, one-flowered; segments of the calyx pubescent on the outside; and two upper filaments very short, with a dark purple beard, and kidney-shaped anthers; two lower ones the length of the corolla, smooth, inclined, with linear anthers. A native of Candia and the East Indies. 5. *C. betanica*. Willd. 5. Desf. atl. 2. p. 58. (Blattaria; Dodart. ic. Shaw afr. 4. 78.) "Leaves ovate-oblong, wrinkled, scolloped; bractes lanceolate, shorter than the peduncle." *Root* biennial. *Stem* two or three feet high, erect, somewhat hairy, generally branched; branches rod-like, bearing the flowers. *Leaves* alternate, smooth or slightly hairy, obtuse, often pinnated near the base; upper ones sessile, embracing the stem, lanceolate, acute, toothed. *Flowers* yellow, with a dark purple spot at the base of each of the two upper divisions; segments of the calyx egg-shaped, acute, nearly equal, serrated or entire; two upper filaments shorter, hairy; two lower ones smooth, declined, incurved upwards. *Capsule* roundish, covered with the calyx. A native of waste ground about Algiers.

CELSIA linearis and urticifolia, Jacq. and Curt. Bot. Muz. See HEMIMERIS.

Propagation and Culture.—If the seeds of the first species

be sown on a warm border as soon as they are ripe, the plants will come up and live through the winter provided the soil be poor; but in rich ground they are apt to grow rank, and are generally destroyed by the first frosts, or rotted in rainy seasons. They do not bear transplanting, and require only to be thinned, and kept free from weeds. Plants sown in the spring seldom produce ripe seeds. The second and the fourth species require the protection of the green house. Millar.

CELSINA, in *Ancient Geography*, an island situate between Italy and Sicily, according to the Itinerary of Antonine.

CELSIONUS Moss, a mountain supposed to have been in the life of Chos.

CELSIPA, a small town of Spain, in Bactica.

CELSITANI, a people placed by Ptolemy in the island of Sardinia.

CELSUS, in *Biography*, an early adversary of Christianity, is supposed to have been born towards the close of the reign of Adrian, who died A. D. 139; and he is placed by Dr. Lardner, with his friend Lucian, in the year of Christ, 176, not far from the end of the reign of Marcus Antoninus, who died in March, A. D. 180. Although he sometimes recedes to Platonic and Stoic modes of reasoning, he is expressly ranked by Lucian, who inscribed to him his "Alexander," or "Pseudomantis," as well as Origen, who wrote against him, among the Epicureans; and this supposition best accounts for the violence with which he opposed the Christian religion; for an Epicurean would of course reject, without examination, all pretensions to divine communications or powers. The book which he wrote against the Christians was entitled *κατὰ τὸν ἀληθινόν*, or "The true Word." Of this work we have no other remains besides the quotations made by Origen in his refutation of it. The extracts from his writings, preserved by Origen, have given occasion to various opinions concerning his talents as an objector to Christianity. Celsus, says Moheim, was a trifling caviller, as is manifest from the answer of Origen; nor do his writings against Christianity serve any other purpose than to shew his malignant and illiberal turn of mind. Cave observes, that Origen has powerfully refuted the futile calumnies and arguments of Celsus. On the other hand, Du Pin reckons him one of the most artful and acute of the opponents of Christianity; and Brucker says, that while the extracts of Origen prove him to have been an inveterate enemy to Christianity, they shew that he was not destitute of learning and ability. The answer of Origen was written at the desire of his friend Ambrose; and was published, as some think, in the year 246, and according to others in 249. It was greatly esteemed and celebrated, as an excellent work, not only by Eusebius and Jerome, but also by many judicious moderns, particularly Du Pin; who says, it is polite and methodical; not only the best work of Origen, but the completest and best written apology for the Christian religion, which the ancients have left us. Origen's apology consists of eight books, which have been divided by the Benedictines into sections for the convenience of perusal and reference. As Celsus, personating a Jew, undertook a laboured argument against the Christians, and wrote solutely as the time of Marcus Antoninus, when the Christians were openly persecuted, and their affairs were better known by the persecution itself, and by the apologies then made for them; we may reasonably expect to find in his work many things that are useful to us in the vindication of our religion; and his testimony to the books of the New Testament is peculiarly valuable. From several passages in Celsus, it appears, that the Jewish expectation of a Messiah was a thing well known; and that

this expectation subsided before the appearance of Jesus in the world. And, indeed, their having such an expectation in the time of Celsus, is an argument that they had it before the coming of Jesus; for they would not have taken up such a notion from his followers. Many passages are cited by Lardner from Celsus, which contain references to the books of the New Testament. To the cavils of Celsus, grounded on the passages which he has cited, Origen has given very satisfactory answers. To the facts recorded in the New Testament, Celsus has borne testimony; though he has misrepresented and perverted them. With regard to the miracles of our Lord, it is not easy to determine whether Celsus believed them or not. But it is not more easy to see how he could disbelieve them; and he was at a loss how to account for them. "I think," says Dr. Lardner, "Celsus could not or would not allow our Lord's great works to have been done by the power of God, because he would not admit the consequence, which was, that Jesus had a divine commission, and acted by authority from heaven; and rather than admit that just and necessary conclusion, he has recourse to shifts and evasions, which are absurd and inconsistent." Accordingly, Origen says, "Celsus not being able directly to deny the great works which Jesus is recorded to have done, asperse them, and calls them juggling tricks." With regard to the moral doctrine of the New Testament, it appears, from passages of Celsus, that no just exception could be made to it. Although he does not allow it to have any superior excellence above the doctrine of the philosophers, he does not deny it to be like their doctrine, and equal to that of the best part of the philosophers. From other passages it sufficiently appears, that Celsus allowed the progress and spread of the Christian religion; and that he acknowledges the sincerity and steadiness of those who embraced it amidst the difficulties and hardships to which they were subject. As to his charge of magic against the Christians, this affords an argument, that there were some uncommon things done by them at this time, as Origen and other ecclesiastical writers have often asserted, but not to the detriment of mankind, as Celsus insinuates, but for their benefit. From passages relating to Christian worship, it appears, upon the authority of Celsus, that they worshipped the one God, creator of all things, and had a high veneration for Jesus Christ; nor would they worship demons, or join in the public sacrifices and festivals of heathen people. Celsus likewise speaks of Christian preachers; though they had not then any altars, or temples, nor other sumptuous buildings to meet in. He also reproaches them with holding their religious assemblies privately, and contrary to law; nor was it without reason that they aimed at privacy; for, as he owns, they were then fought for to be put to death. Celsus appears not to have been acquainted with the absurd opinions of some who went under the Christian name; whom he introduces with a view of calling the greater reproach on those who were more rational in their belief. All the attacks of Celsus are against the more sober part of the believers: those others were fought for in order to disparage and expose them, if possible. It is well known, that, soon after the rise of Christianity, the followers of Jesus were loaded with many calumnies: they were said to kill infants, and eat them; and when the lights were put out, to practise promiscuous lewdness in their assemblies. Celsus, in whose time these charges were not extinct, seems, however, to have thought them absurd and incredible; and to mention them with any marks of countenance and approbation, he supposed would be a prejudice to his argument. But though he has omitted these, he has introduced divers in-

jurious reflections upon the Christians, and thus shown his disposition to expose them to general and public resentment. If Christians, therefore, derive any advantage from the work of Celsus, which is undoubtedly the case, and the advantage is very considerable, it is altogether beside the intention of the author; who evidently wished to disgrace Christianity, and prevent its subsistence and diffusion.

We have three summaries of the fragments of the work of Celsus preserved in Origen, in our own language, besides the copious extracts, with appropriate remarks, made by Dr. Lardner, of which we have above availed ourselves; one by Dr. Doddridge, for a summary of which, see Lardner's Works, vol. viii. p. 63, &c.; one by Dr. John Leland of Dublin, in his Answer to Christianity as old as the creation, vol. ii. ch. 5. p. 150—154; and another by Dr. Sherlock, supposed to be the ingenious author of the "Evidence of the Resurrection cleared up," p. 19 and 23, from which we shall extract the following observations. "Celsus lived at no great distance from the apostolic age, at a time when all religions were tolerated but the Christian; when no evidence was stifled, no books destroyed, but the Christian. And yet Celsus laboured under the same want of evidence, as Woolston and his auxiliaries, and had only the gospel to search (as Origen more than once observes), for evidence against the gospel. A strong proof that there never had been any books of credit in the world, that questioned the gospel facts, when so spiteful and so artful an adversary as Celsus made no use of them.

"Celsus admits the truth of Christ's miracles. The difference between him and Origen lies in the manner of accounting for them; the one ascribing them to the power of God, the other to the power of magic. So that, if the considerer will stand to the evidence of his own witness, the question will not be, whether the miracles are true in fact (for that is granted on both sides), but whether the truth of the miracles infers the divine authority of the performer. Nor can it be supposed, that Celsus would have admitted the miracles of Christ as real facts, had he not been compelled to it by the universal consent of all men in the age he lived? The truth is, that the objections of Celsus are preserved in his own language. Origen's answer is not a general reply to Celsus, but a minute examination of all his objections, even of those which appeared to Origen most frivolous. For his friend Ambrosius, to whom he dedicates the work, desired him to omit nothing. In order to this examination, Origen states the objections of Celsus in his own words, and that nothing might escape him, he takes them in the order in which Celsus had placed them. Celsus then, as it happens, is safe; and the considerer need not to lament over him any more." See also Paley's "View of the Evidences of Christianity," vol. i. p. 294, &c.

Celsus, besides his book against the Christians, wrote a piece "On the life to be led by those who meant to follow the rules of philosophy;" and another "Against Magic" is ascribed to him both by Origen and Lucian. Du Pin, vol. ii. p. 454. Brucker's Hist. Phil. by Enfield, vol. ii. p. 141. Moheim's E. H. vol. i. p. 163. Cave's H. L. vol. i. p. 96. Fabr. Bib. Grec. l. iii. c. 33. t. ii. p. 809. Lardner's Works, vol. viii. ch. xviii. p. 6—69.

CELSUS, A. CORNELIUS. The memoirs for the life of this elegant writer are very scanty. Even the knowledge we pretend to of his family, his rank in life, or of the age in which he lived, is rather probable conjecture than derived from certain information. It has been disputed whether he practised any branch of medicine; and if we determine in the affirmative, it is only because we cannot conceive that a mere amateur would have been at the pains of acquiring such

perfect knowledge as he appears to have had of the dogmas of the different sects of physicians, or would have been able to describe the diseases he treats of with so much accuracy, or laid down the most approved methods for curing them that were then known. All this he has done; it is therefore reasonable to suppose he practised the art, in which he was so complete a proficient. Friend, whose opinion we may safely follow in every thing relating to the early history of medicine, and its professors, produces, as a proof that he practised surgery, a passage from that part of his work, where he treats "De Oculorum Vitiis," reproving the method used by Heracides in curing adhesion of the eyelids; "Ego sic restitutum esse neminem memini."

Friend agrees with Le Clerc, that Celsus was a Roman by birth, probably of the Cornelian family; that he was born in the latter part of the reign of Augustus Cæsar, and was living in the time of Caligula. The work by which he has been rendered famous is entitled "De Medicina Libri Octo." The great number of editions this book has passed through sufficiently indicate the high esteem in which it is held. It contains, in an epitome, every thing that is valuable in the works of Hippocrates. In medicine he seemed to have approved and followed the doctrine of Asclepiades; but the most valuable part of the work is that which treats of surgery, in which we find methods of practice laid down, and modes of performing several operations described, in the manner still used. The language also in which the precepts are contained, is so pure and elegant, as to have contributed in no small degree to the celebrity of the work. He is said to have written on rhetoric and on other subjects, but his works on those subjects, if they ever existed, are lost. Le Clerc, Hist. de Med. Friend's History of Physic. Haller. Bib. Anat. Chir. et Med. in which most of the editions of the "De Re Medicina Lib." are noticed. The earliest was at Florence, 1478, fol. One of the best is Almeloveen's, edited at Padua, 1722, 8vo. by Vulpinus, and reprinted in 1750. There have been also translations of Celsus into French, English, and other modern languages. The short abridgment of rhetoric, which has been ascribed to him by some, was printed at Cologne in 1569.

CELTES, CONRAD, named also PROCTUCUS, and MRSSEL, a modern Latin poet of some eminence, was born at Schwelmert, in Franconia, in 1459. After having acquired a large stock of literary and scientific knowledge in his studies at Cologne and Heidelberg, he visited many of the German universities, and supported himself as a private lecturer. He was thus enabled to make a tour for improvement through all the principal cities and universities of Italy. The reputation he thus gained was the means of introducing him to the elector of Saxony; and the emperor Frederic III., to whom he was recommended by the elector, conferred upon him the poetical laurel at Nuremberg in 1491. Having terminated his rambles, he settled at Vienna; where he was made professor of eloquence and poetry, and librarian to the emperor Maximilian. Here he died in 1508. Celtes deserves to be ranked among the restorers of polite literature in Germany. Of all the various writings which he left, the poetical were the most distinguished. Whilst he possessed some vigour of imagination and brilliancy of expression, he was deficient in good taste and correct judgment. Some of the best of his pieces, containing amatory elegies, odes, epigrams, &c. were published at Stralsburgh in 1515, by the care of a literary society of which he was the founder. He wrote also a poem on the manners of the Germans, on the river Vitula, an historical account of the town of Nuremberg, the cosmography of Aristotle and Apulcius, orations, and several other pieces. Moreri. Gen. Biog.

CELTÍ, in *Ancient Geography*, a place of Spain, between Añigi and Regiana, according to the Itinerary of Antonine. Piny makes it the chief of the towns in the jurisdiction of Hippalis.

CELTIBERIA, the ancient name of a country of Spain, in the Tarragonensis, and to the east of Carpetania, according to Piny and Ptolemy. The latter places in it 18 towns. It was originally of large extent; but the wars of the Romans reduced it to a narrower compass.

CELTIBERIANS, a powerful and celebrated people who occupied the greatest part of the interior of Spam. Polybius, when he relates that T. Gracchus had subdued 300 towns in this country, seems to have exaggerated the number, in order to flatter the vanity of Gracchus, who had made this conquest in the year of Rome 575. Livy makes the same report; but Strabo very justly observes, that these authors had raised mere villages to the rank of towns. According to this author, Celtiberia produced a great number of plants, the roots of which served the purposes of dyeing. He adds, that the part of it which was near the Mediterranean abounded with vines, olives, figs, and other trees which yielded excellent fruits. Their principal towns were Castantum, Turisio, Bilbilis, Ergavica, and Valeria. The Celtiberians, according to Diodorus Siculus, were a people composed of two nations, the Iberians and the Celtes. Accordingly, the inhabitants of Celtiberia, or Spain, might be distinguished to distinguish those Celtes on that from those on this side of the Pyrenées. For thus we find Galia or Gaul divided into Cis and Trans-Alpina; and the word Iberia seems to be derived from the old Celtic and Teutonic "iber," which signifies over; and thus Spain, which is sometimes found in the plural number, was divided into Citerior and Ulterior. The Celtes and Iberians made war against one another, with a view to the possession of their respective territories; but as neither the one nor the other prevailed, they negotiated a peace on condition that they should possess both countries in common. From this condition, followed by intermarriages and various alliances, resulted the name of Celtiberians, which they assumed. These people, thus formed of two distinct people, equally valiant, and possessing a rich and fertile country, acquired great reputation by their long resistance to the Roman arms; though at length they were subdued. The cavalry of the Celtiberians, says Diodorus, are excellent; but their infantry was less distinguished. All the Celtiberians, except their chiefs, bore a "sagum" of wool so large, that it resembled the hair of a goat. Some of them were armed with a Gaulish buckler, and others with a round "cyrtæ," of the size of a buckler, and "cuissies," or armour for the legs, made of horse-hair. All of them wore helmets of iron with red plumes, a two-edged sabre of steel, and a cutlass, a foot long. The cavalry of the Celtiberians were so well skilled in the use of arms, that they fought equally well on foot or on horseback. The Celtiberians had a singular custom of washing their bodies every day, and their teeth with urine, pretending that nothing contributed so much to health. Whilst they treated their enemies with severity, they were very hospitable to strangers, and contended for the privilege of entertaining them, as the means of engaging the favour of their gods. Their food consisted of various delicacies, and their drink of a sort of sweet wine, mixed with honey. Their mules were in high estimation, and yielded them great profit. The Celtiberians regarded as impious the custom established among the Iberians of causing the bodies of those who died to be devoured by vultures. Strabo says, that these people celebrated a feast at every full moon, in honour of an anonymous god; it commenced with the beginning of the night and lasted the whole of the next day.

CELTICA,

CELTICA, a spacious country, which, according to P^lutarch, extended from the ocean and the northern climates as far as the Palus-Mæotides to the east, touching on one side on Pontic Scythia.

CELTICI, a people of Spain, who, according to Strabo and Pliny, dwelt on the confines of Lusitania.

CELTICI *Mirobrigenses*, were, according to Pliny, the inhabitants of Mirobriga, a town of Spain.

CELTICI *Nerici*, a people of Spain, placed by Pliny on the promontory of Nerium, the present Finisterre.

CELTICI *Presumarii*, a people of Spain, in whose country were the rivers Tamaris and Sars.

CELTICUM PROMONTORIUM, a name given to the promontory of Artabrum, called also Nerium, on the western coast of Spain, to the N.W., now Finisterre.

CELTIS, in *Betany*. (*Celtis*, Plin. 13. 17.) Tourn. Clafs 21. sect. 2. gen. 1. Linn. gen. 1143. Schreb. 1591. Juff. p. 408. *Ent.* vol. iii. p. 553. Gært. 487. *Lot*e or nettle-tree, Eng. *Micacoulir*, Fren. *Loto*, Ital. *Clafs* and order, *polygama monœcia*. Nat. Ord. *Scabride*, Linn. *Anticetaceæ*, Juff. Vent.

Gen. Ch. Hermaphrodite. Cal. perianth one-leafed, five-parted; segments egg-shaped, spreading, withering. *Cor.* none. *Stam.* filaments five, very short, at first concealed by the anthers, but after the shedding of the pollen growing longer; anthers oblong, thickish, quadrangular, marked with four furrows. *Pist.* germ superior, egg-shaped, at least as long as the calyx; styles two, spreading, variously inflexed, awl-shaped, pubescent, very long; stigmas simple or bifid. *Peric.* drupe globular, containing one round nut or stone, with a single kernel. Male. *Cal.* sometimes six-parted. *Cor.* none. *Stam.* filaments five. *Pist.* none.

Eff. Ch. Hermaph. Calyx five-parted. Corolla none. Stamens five. Styles two. Drupe one-seeded. Male. Calyx five or six-parted. Corolla none. Stamens five or six.

The two kinds of flowers are sometimes separate, and sometimes on the same raceme; in the former case the male flowers are situated about the others.

Sp. 1. *C. australis*, European nettle-tree, Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Pallas. *Rof.* 1. 19. (*C. fructu nigricante*, Tourn. *Enl.* p. 612. *Lotus fructu cerasi*, Bauh. *Pin.* 447.) "Leaves ovate-lanceolate, acuminate; fruit solitary." A tree. *Trunk* from 40 to 50 feet high; branches numerous, spreading, long, flexible, pubescent near the summit. *Leaves* near four inches long, and about two broad in the middle, dark green, ferrated, obliquely nerved, veined, rather scabrous above, slightly villous on both sides, especially when young; stipules rather long, linear, narrow, caducous. *Flowers* axillary all along the branches, small, of an herbaceous colour, perishing before the leaves have attained to half their size; peduncles solitary, generally simple, about three-fourths of the length of the young leaves; styles villous, divaricated. *Fruit* about the size of a small cherry, blackish, round, a little fleshy. A native of the south of Europe. The flowers open at the beginning of April. The fruit comes to maturity in the ensuing January, and continues on the tree till the sap rises in spring; it is rather astringent, and is eaten not only by birds, but by children, in Spain. Its wood is of a dark colour, remarkably hard, compact, and heavy; tough and flexible, and therefore excellent for making the shafts of carriages and hoops of barrels and tubs; next to ebony and box in durability, strength, and beauty; capable of receiving a fine polish, and, when sawed obliquely, is said to be a good substitute for the satinwood of America. The ancients used it for flutes and other musical instruments, and as it is not subject to crack, it is particularly fit for the purposes of the carver. The root is less compact than the trunk, but of a darker colour,

and suitable for the shafts of knives and other utensils. Scopoli obtained from the expr^{ss}d seeds an oil with a flavour similar to that of oil of sweet almonds. As an ornamental tree, it merits the attention of the planter, having a fine regular spreading head of a cheerful green colour, coming early into leaf, and retaining its foliage late in the autumn. It has not, however, been much cultivated in England, and is less common than the next species. 2. *C. occidentalis*, Linn. Sp. Pl. 3. Mart. 2. Lam. 2. Gært. tab. 77. fig. 3. Lam. *Illuf.* Pl. 844. fig. 1. (*C. fructu obscure purpurafcente*, Tourn. *Enl.* p. 612. *C. procera*, Gronov. *Virgin.* p. 158. *Lotus arbor Virginiana*, Rai *Hist.* p. 1917.) "Leaves obliquely egg-shaped, ferrated, acuminate; fruit solitary." β . "Leaves more slender, less acuminate." A tree. *Trunk* straight; in young trees even, and of a dark colour; in older ones rough, and lighter green; branches spreading. *Leaves* alternate, broader and shorter than those of the preceding species, tender, quite entire at the base and tip, ferrated in the middle, obliquely nerved, veined; petioles slightly villous from three to six lines long. *Flowers* opposite the leaves; segments of the calyx oblong, obtuse, concave, spreading, ciliated at the edges; filaments nearly the length of the calyx; germ conical, surrounded at its base by a ring of fine, short, whitish hairs, which continue on the young fruit. *Fruit* the size of a small cherry, oval, appearing like a berry, of a deep purple colour and sweet taste; stone globular, not dividing, white, hard, a little wrinkled. A native of Pennsylvania, first brought into England by John Tradescant; flowering in May, and ripening its fruit in October. There are many large trees of this species in the English gardens, which, in favourable seasons, ripen a great quantity of fruit; and there are few years in which the fruit is not sent from America. It comes out late in the spring, but retains its leaves longer than any other deciduous tree. Its wood is tough and pliable, and esteemed by coach-makers for the frames of their carriages. The variety β is a native of Louisiana, and was cultivated in the royal garden at Paris, but as it was killed down to the root every winter by the frost, La Marck never saw its fruit or flowers, and, therefore, could not determine whether it be merely a variety or a distinct species. 3. *C. crassifolia*, Lam. 3. "Leaves somewhat heart-shaped, ferrated, acuminate; peduncles often with two flowers." *Branches* woody, cylindrical, pubescent in the young shoots, with a reddish brown bark. *Leaves* in young plants five inches long, and three and a half broad, alternate, petioled, generally enlarged on each side with a kind of roundish ear, so as to appear somewhat heart-shaped, but, with the inequality, observable in the other species, rough on both sides, with short hairs, especially on the upper surface; petioles short, slightly villous. *Peduncles* axillary, generally two or three-flowered, longer than the petioles. *Fruit* round, smooth, about the size of a small cherry. A native of North America: cultivated at Paris; and described by La Marck from a living plant. 4. *C. americana*, Mart. 4. Plum. Cat. 18. "Leaves oblong-egg-shaped, obtuse, nerved, smooth above, golden underneath." *Trunk* near twenty feet high, covered with a grey bark, and dividing at the top into many branches. *Leaves* near four inches long, two and a half broad, rounded at their extremity, of a thick texture, very smooth on their upper surface, and on their under, of a lucid gold colour. *Fruit* round and red. Found by Plumier in the French West India islands, and by Houlton in Jamaica, and cultivated by Miller. Nearly allied to the preceding, if not the same species, differing chiefly in the surface of the leaves. 5. *C. Tournesortii*, Lam. 4. (*C. orientalis minor*, Tour. Cor. 42. Voyage, vol.

vol. ii. p. 425, with a figure.) "Leaves egg-shaped, crenate-ferrated; younger ones somewhat heart-shaped; fruit yellow." *Trunk* twenty five or thirty feet high, much branched; branches smooth, alternate, cylindrical. *Leaves* about two inches long, and sixteen lines broad, alternate, acute, obliquely truncate at the base so as to be obscurely heart-shaped, firm, rather thick, nearly smooth, green on both sides, a little feabrous on the upper surface, marked underneath by projecting branched nerves which proceed from the midrib. *Fruit* smooth, round, yellow, but tending to brown, when quite ripe, about the size of a pea; peduncles axillary, solitary, simple, more than twice the length of the petioles, beset with short white hairs on their upper part at the base of the young fruit, as in *C. occidentalis*. A native of the Levant; introduced into France by Tournefort. 6. *C. orientalis*, Linn. Sp. Pl. 2. Lam. 5. (Mallam tuddali, Rheed. Hort. Mal. vol. iv. p. 83. tab. 40. Papyrus spuria? Kämpf. Am. Æn. Exot. tab. 472. *Salvisolia* arbor, Pluk. Alm. tab. 221. fig. 4. Gheduba, Burm. Zeyl. 26. Herm. Zeyl. 14. *Baccifera indica*, Rai Hist. 1597.) "Leaves ovate-acuminate, obliquely heart-shaped at the base, finely ferrated, villous underneath; panicles axillary." Lam. A tree of a moderate size, with a smooth bark. *Branches* slightly villous. *Leaves* about four inches long, more than an inch and half broad, alternate, oblique, green, paler underneath, wrinkled on the upper surface, and rough, with stiff hairs, directed towards their summit, clothed on their lower surface more abundantly with finer and softer hairs; petioles from two to four lines long. *Flowers* small, greenish, on very short pedicels; in axillary, twice or thrice dichotomously branched racemes, forming a kind of compound corymb, furnished at the divisions with very short oval bractes. *Fruit* small, greenish, of a bitter taste. A native of the East Indies, and of the isles of France and Bourbon. This species has been confounded with the preceding by Miller and other authors. 7. *C. micrantha*, Mart. 5. Lam. 6. Hort. Kew. vol. iii. p. 437. Swartz. Prod. 53. (Muntingia, Plum. gen. p. 41. ic. vol. 6. tab. 77. Burm. amer. ic. 206. fig. 1. *Rhamnus* a ziziphus; Brown. jam. tab. 12. fig. 1. *Rhamnus micranthus* of Linnaeus is usually quoted as a synonymy, but we have the decisive authority of Dryander for stating, that, though the synonymy annexed to that plant belong to this species, the specimen in the Linnean herbarium from which the specific character, and the description in Amen. Acad. were formed, is *Boemehria ramiflora*. See Linn. Transf. v l. ii. p. 226.) "Leaves obliquely heart-shaped, ovate-lanceolate, finely ferrated, rather feabrous on the upper surface." Swartz. Very nearly allied to the preceding species. A tree of a moderate size with a cinerous bark. *Branches* very compound, pubescent towards the extremity; some vertical, others more or less horizontal. *Leaves* alternate, petioled, three or four inches long, about fifteen lines broad, green, paler underneath, beset with short stiff hairs rising from the feabrous protuberances, marked on the under surface with projecting oblique nerves proceeding from the midrib, three of them immediately from the insertion of the petiole. *Flowers* small, greenish, spreading, rarely pedicelled; in small, axillary, twice or thrice dichotomously branched corymbs, furnished with short bractes at the divisions; segments of the calyx oval, concave, villous on the outside; in the centre of the male flowers there is a tuft or circle of whitish hairs. *Fruit*, according to Plumier, red, fleshy, not bigger than the seed of a vetch. A native of the Antilles. 8. *C. lima*, Mart. 7. Lam. 7. Swartz. prod. 53? (Muntingia folio ulmi aspero, Plum. gen. 41? Burm. Am. ic. 206, fig. 2? *Loti arboris folio angustissimo*, Sloan. jam.

2, So?) "Leaves ovate-lanceolate, finely ferrated, very feabrous; racemes axillary, small." *Branches* cylindrical, cinerous, smooth; smaller ones clothed with numerous, upright, awl-shaped, short hairs, which render their surface a little feabrous. *Leaves* an inch and half or two inches long, about half an inch broad, alternate, on short peduncles, narrow, acute, coriaceous, firm, light green; sprinkled on both surfaces, but especially on the upper one, with a multitude of small whitish tubercles, each terminated by a short stiff hair, which render their surface as rough as a file or the skin of a shark; the intervals between these tubercles are smooth and shining, appearing as if they were varnished. *Flowers* very small, on short pedicels; in axillary, nearly simple racemes, either solitary, or two or three together, furnished at each of their divisions with a short bracte. *Fruit*, when young, green, smooth, surrounded at the base by the permanent calyx. Described by La Marek from a dried specimen sent from Martinique by Joseph Martin. The identity of Swartz's plant appears dubious. According to him it is fifteen feet high. *Trunk* straight, with a smooth, reddish or light brown bark, and several branches spreading towards the top. *Leaves* alternate, half an inch distant from each other, two inches long, and half as broad near the base, dark green, petioled. *Flowers* axillary, small, greenish. *Fruit* orange-coloured, not bigger than a pin's head, oval, insipid. having an orange-coloured pulp and a black round stone within. 9. *C. trinervis*, Lam. 8. "Leaves egg-shaped, ferrated, three-nerved, nearly smooth; flowers fascicled; fertile one with a longer pedicel." *Branches* cylindrical, greyish, slightly villous at the extremities. *Leaves* two inches, or two inches and a half long, little more than an inch broad, alternate, slightly acuminate, soft, thin, of a fine green colour; petioles about two lines long, pubescent. *Flowers* small, greenish; from three to six together, on a common axillary, solitary peduncle, much shorter than the petioles; generally only one fertile flower in a fascicle; stamens scarcely longer than the calyx; styles slightly villous. A native of St. Domingo. 10. *C. integrifolia*, Lam. 9. "Leaves roundish, ovate, acuminate, quite entire; styles bifid." *Branches* alternate, cylindrical, slightly villous. *Leaves* about two inches and a half long, an inch and half broad, alternate, firm, thickish, slightly feabrous above, green on both sides but paler underneath; with four or five elevated, branched, longitudinal nerves proceeding from their base; clothed, when young, with a few short hairs, which gradually disappear, and finally remain only on the nerves; petioles a quarter of an inch long, villous like the nerves, slightly chamelled on the upper side. *Flowers* small, greenish; in dichotomously branched panicles, solitary, or one or two together from the axils of the leaves; the male ones with very short pedicels. *Fruit* when young villous. Brought from Senegal by Adanson. 11. *C. aculeata*, Mart. 6. Swartz. prod. 53. (*Rhamnus ignaveus*, Jacq. amer. 74. 1. *ziziphus ignaveus*, Lam.) "Leaves cordate-egg-shaped, blunt at the tip, almost entire, very smooth; branches prickly; styles bifid." An elegant little tree. *Branches* very long, plant, reclining, not much divided, frequently with alternate, ditich branches the whole length; the upper ones gradually shorter. *Leaves* commonly three or four, sometimes eight inches long, alternate, ditlich, smooth, petioled. *Spines* in the axils of the leaves and branches, awl-shaped, very sharp, strong, and short, recurved, solitary, or in pairs. *Flowers* small, yellow; in small axillary racemes, growing one, two, or three together; segments, with hardly any tube and no scales; in the male flowers instead of the pistil, there is an oblong truncate body only half the length of the calyx. *Fruit* yellow, double the size of a pea, containing a sweet pulp

pulp which is eaten by the natives; stone or nut wrinkled, thick, bony, white, one-celled. A native of the Caribbee islands, and the neighbouring continent. Swartz observes that *Rhamnus ignavus* of Linnæus should be placed in this genus on account of its calyx without petal-like scales, its two styles, and its fruit; but he doubts whether it be the *ignavus* of Jacquin here described. It derived its trivial name from its growing in rocky places frequented by the Iguana.

Propagation and Culture. These trees are all propagated by seeds, and most of them are hardy enough to endure the open air in England, when they are become strong; but for the first two winters after they come up from seeds, they require to be protected from frost. It is best to sow the seeds in autumn soon after they are ripe; and they ought by all means to be sown in pots or boxes, that they may be shifted into different situations according to the season. In the following spring they may be removed into nursery beds prepared for the purpose, in a sheltered situation, and if possible in a gentle loamy soil. If the surface of the ground be covered with old tan or rotten dung, it will keep it moist, and prevent the drying winds from penetrating to the roots of the plants. After the plants have remained in the nursery beds two years they may be transplanted to the situations where they are intended to remain.

CELTO-GALATIA, in *Ancient Geography*, a name given by Ptolemy to Celtic Gaul; and which he divided into four provinces, viz. Aquitania, Lugdunensis, Belgica, and Narbonensis. See GALLIA.

CELTOS or CELTUS, a marsh or lake which seems to have been lost in the Euxine sea, according to Lycophron. Ortelius conjectured, that it was one of the marshes at the mouth of the Danube.

CELTS, or CELTÆ, in *Ancient History*, the name of a very ancient people, whose descendants were the aboriginal inhabitants of Gaul and Britain. It was, however, more particularly given to a part of the Gauls, whose country, called *Gallia Celtica*, was situated between the Seine and Marne and the Garonne.

The remoteness of their early history, and the obscurity in which it rests, make every effort to elucidate the first origin of the Celts of no avail. The opinions both of the ancient and the modern writers who have mentioned them, are equally vague and indeterminate; and it is perhaps enough to say, they appear to have been the most ancient inhabitants who can be traced in this quarter of the globe. Herodotus (Melpomene, xlix.) speaking of the Danube, says, "it commences with the *Celtæ*, who, except the *Cynetæ*, are the most remote people in the west of Europe.

The little knowledge which the earlier Greek and Roman writers had of the barbarous nations round them, and the small pains they took to gain accurate information about their peculiar differences and distinctions, led many of them to confound the *Celts*, the *Goths*, and the *Sarmatians*. Strabo (Geogr. lib. ii. p. 93.) particularly states, that the writers before his time were both ignorant and uncertain in all that they related of those countries which formed the more immediate residence of the Celts. Nor can we allow more credit to the writers of a later date, who have rather gushed at the ancestry of the Celts, than given authentic materials for their history. One of the earliest on the continent was Picard, whose work "De Prisca Cætopædia," appeared at Paris in 1556. The next writer of authority was Reineccius, who, in the second volume of the "Hilologia Julia," treated amply of them, as far as they were supposed to be related to the Gauls and Germans. Van Srieck was the next, who in the early part of the 17th century wrote ex-

actly on their origin. Another writer was Pezron. The hallucinations, reverses, and etymologies of the generality of those who followed, with the exception perhaps of Keyfler, appear almost to have involved their history in fable. It was rescued by Pelloutier. Yet though some of the most authentic and curious particulars in this article are obtained from his work, we cannot acquiesce in one of its leading features. This will appear presently.

The great source of mistake and confusion to many learned writers on the history of Europe has been the idea that the ancient Gauls and Germans, Britons and Saxons, were originally but one and the same people; thus confounding the antiquities of the Gothic and the Celtic nations. This crude opinion was long maintained with uncommon credulity. Cluverius, in his "Germania Antiqua," and Keyfler in the "Antiquitates selectæ Septentrionales et Cælicæ," incautiously adopted it, and even Pelloutier, in the last and best work which has appeared on the history of the Celts, has endeavoured to confirm it with great diligence and skill. In short, says bishop Percy (Pref. to the North. Antiq. p. iii.), so much learning and ingenuity have scarcely ever been more perversely or erroneously applied, or brought to adorn and support a more groundless hypothesis.

The ancient and original inhabitants of Europe, according to these writers, consisted only of two distinct races of men; the Celts and the Sarmatians. The Sarmatians, or Sarmatæ, they make the ancestors of the *Sclavonian* tribes; and represent the old inhabitants of *Gaul*, *Germany*, *Scandinavia*, *Britain*, and *Spain*, as the uniform descendants of the Celts. These last they state were all included by the ancients under the general name of Hyperboreans, Scythians, and Celts; having all the same common language, religion, laws, customs, and manners.

From Herodotus we have already shewn, that the source of the Danube, in the Black Forest, in Suabia, was originally among the *Celtæ*; and it seems probable that at that remote period the Sæcæ and the Massagætæ, the probable ancestors of the Saxons and the Goths, had not penetrated so far westward as they did afterwards. The *Regines* are spoken of by the same writer as a *Persian* people (in Clon.) It may likewise be worthy of observation, that, having mentioned the commencement of the Danube, he adds, "This river passes directly through the centre of Europe, and by a certain inclination enters Scythia." In this passage he seems expressly to distinguish the Scythians from the Celts; although it is no proof they were not confounded by subsequent historians; or, that the fluctuations of territory might prove a consideration which would in fact reconcile the different writers.

Cluverius, Keyfler, and Pelloutier have uniformly supported their hypotheses by obscure quotations from ancient authors, and arguments derived from etymology, leaving the precise and positive testimony of Cæsar relating to the Celts, and of Tacitus, relating to the Germans, almost entirely neglected. Cæsar, in the very first page of his Commentaries, expressly assures us that the Celts, or common inhabitants of Gaul, in his time, differed "in language, customs, and laws" from the Belgæ, on the one hand, who were a Teutonic people, and from the inhabitants of Aquitain on the other, who, from their vicinity to Spain, were probably of Iberian race. His words are remarkable: "Gallia est omnis divisa in partes tres; quarum unam incolunt Belgæ, aliam Aquitani, tertiam, qui ipsorum lingua *Celtæ*, nostri *Galli* appellantur. Hi omnes, lingua, institutis, legibus, inter se differunt. Celtos ab Aquitanis Garumna flumen, a Belgis Matrona et Sequana dividit." The text here quoted is Oudendorp's; but in a note subjoined, Cæsar stands corrected, and the theory of Cluverius admitted.

But in the sixth book of his Commentaries, Cæsar is still more particular; and his remarks are worth minute attention. He draws the characters of both nations at length, in an exact and well finished portrait, and states every essential difference by which the Gauls were distinguished in their laws, their customs, and their religion on the Germans; and closes with an observation, which we cannot but repeat, as we gain from it by inference that both nations had a separate origin. There was a time, he observes, when the Gauls were superior to the Germans in valour; when through the increase of their tribes or the scarcity of land they *sent colonies across the Rhine*. (Cæsar de Bello Gallico, lib. vi. c. 24.)

Such appears to be the true history of the Celts. The love of what is ancient, however, or the belief of fable, has led the historians of almost every period into the labyrinths of more remote antiquity. They have considered *Celtae* as the generic name of a vast people, known in different tracts of territory by a variety of names and characters. Of Cymmerians, Cymbrians, or *Comarians*, by which they relate them to have been sometimes called in the north of Europe, they have made *GOMERIANs*, and pretend to trace them even to *Gomer*, the grandson of Noah. (See Pezron Antiquités de la Nation et de la Langue des Celtes. Ancient Univ. Hist. vol. iv. p. 1. Svo. Davies's Celtic Researches.) The folly and the fallacy of such inquiries need hardly be exposed: they are only equalled by the *history* of their migrations from Asia to Europe; and the chronology of the *Titan princes*. They who would indulge their curiosity farther on the subject may consult Mr. D. Jones's translation of Pezron, published in this country, 1706; whence it may not only be learnt "that Saturn, the son of Uranus, was the first king of the Titans;" but "that the Titans were true *Celtae*."

In the difference of opinions which has been already mentioned, it is not easy to fix the exact boundaries which have at all times divided the Celts from the other inhabitants of Europe: it is on this account that we cannot but consider the work of Pelloutier, otherwise so excellent, as a perpetual source of mistake and confusion: in consonance with this idea he asserts (liv. i. ch. viii. &c.) not only the Germans, but all the people settled along the banks of the Danube to the Black Sea, the Goths, the Dacians, Bastarnes, (or Germans beyond the Vistula.) Visigoths, Herulians, and other tribes, to have been *Celts*. The ancient inhabitants of Greece, according to him, were either Celts or Scythians: under the same denomination he includes the Ligurians and the people between the Alps and Apennines. The Venetians, he says, were originally Gauls: and the Romans half Celts, half Greeks.

After such assertions, we shall probably err very little in confining ourselves to the testimonies of Cæsar, and a few of the more rational historians; who, without torturing etymology, afford us facts; and, though they may circumscribe the territory of the Celts, at least give us something which may be relied upon as history.

Mr. Pinkerton, in his "Dissertation on the Origin and Progress of the *Scythians* and *Goths*," has discriminated them from the Celts in a very clear and masterly manner. Cluverius, Keyser, and Pelloutier, have undoubtedly made many quotations from the ancient classics, which seemed to give their theory indisputable countenance. To produce all their authorities would be to fill a volume. From Herodotus to Cæsar, passages may be found with very little trouble, which shew the uncertain and confined ideas of the ancients, in regard to the nations which lay round them. Arrian (book 1. ch. 1.) particularly mentions the warlike

tribes on the banks of the Danube; τα μὲν πολλὰ ΚΕΛΤΙΚΑ, "and more especially the *Celts*." But he describes them in a manner which shews he included the *Tautonic* tribes; and expressly enumerates the Marcomanni and the Quadi, so particularly spoken of by Tacitus. (De Morib. Germ. cap. xlii. xliii.) Suidas also, who lived so late as the 11th century, makes Κελταί to have been the general appellation of the German tribes. There is a passage, however, in Diodorus Siculus, one of the best informed and most judicious of the Greek historians, (who not only wrote after Cæsar, but profited by his discoveries,) which the modern antiquaries on the continent ought to have consulted. He tells us (Diod. Sicul. lib. v. p. 355, edit. Wesseling.) it is particularly necessary, in describing the Gauls, to make a distinction, of which the generality of the world were ignorant. That the people who inhabited the country from above Marseilles, and at the Alps, and on this side the Pyrenean mountains, were called Celts. But that those who inhabited beyond this region and the parts towards the south, and situated on the ocean, and those toward the Hercynian mountains, and all onward, even to Scythia, were called *Gauls*; a name, he adds, which the Romans gave generally to all these nations. We give the passage in the original. Χρησίου δ' ἐστὶ διακρίσει τοὺς περὶ πολλὰς ἀγορεύουσιν τοὺς γὰρ ὑπὲρ Μασσαλίας καλαυκίας ἐν τῷ μισθῷ καὶ τῆς περὶ τῆς Ἀσίας, οὗ δὲ τῆς ἐπὶ τῆς ἐπὶ τῆς Ἰερουσαλὴμ ἡμῶν ΚΕΛΑΟΥΣ ἀνομαζοῦν τῆς ὑπὲρ ταύτης τῆς Κελτικῆς ἐπὶ τὰ πρὸς νότον κούνη μέρη περὶ τὴν ἡκεῖθεν καὶ τὸν Ἐρμῶν οὐδὲ καθύπερθε, καὶ πάντας τοὺς ἐπὶ τῆς μερῆς Σιδωνίας, ΓΑΛΑΤΙΑΣ ἀραγορεύουσιν οὐδὲ Ῥωμαῖοι πάντα πάντα ταῦτα τὰ ἐπὶ ἀλλοτρίῳ μὴ προσέχοντα τῆς λαμβάνουσι, ἀνομαζοῦσιν ΓΑΛΑΤΙΑΣ ἀπῶναι.

Diodorus, says Mr. Pinkerton, (Dissert. on the Scythia. p. 125.) no doubt knowing that the Celts were not those Gauls celebrated in Roman history, but quite a distinct people, possessing the inner or further part of Gaul, with propriety puts them as different nations. Indeed Polybius, by the very enumeration of the different tribes, by which Rome was pillaged under Brennus, convinces us that *abjct* Gauls were Belgic: and that their irruptions have nothing to do with any history of Gallia *Celtica*. Cæsar, observes Mr. Pinkerton, (Dissert. p. 125,) by shewing the Celts to be confined to such small bounds, palpably marks that other nations had gained ground on them, so as to confine them to such a contracted space. Of their *early* history then, we are still in that uncertainty which we seem to have inherited from the first writers among the Greeks and Romans; and excepting what we gain from Cæsar and Diodorus, we know but little of their manners. The region they retired at that period was small. And even in Britain, an island which may, perhaps, rank among their earliest possessions, they seem to have been in part exterminated by their Belgic neighbours. The Belgic, as Cæsar shews, had all the fourth cæd of present England. (See Cæsar de Bello Gallico, lib. v. c. 12, and Pinkerton's Dissert. p. 121.)

After these preliminaries, we proceed to their more special history, as it is detailed by Cæsar. In the account of his second expedition into Germany (lib. vi. c. 7,) he draws the contrast we have already mentioned between the Germans and the Celts: a picture which, with the addition of a few touches from the pencils of other matters, will be found the most correct, in regard to the Celts, we are possessed of. Previous to this time we have nothing that can be called authentic information.

The Gauls, says Cæsar, are every where, from provinces to families, divided into factions. On his first arrival the *Ædui*, who were the Autunois, and the *Sequani*, who lived in

in Upper Burgundy, were at variance. The latter had always been the weakest, and the former the strongest tribe: "quod summa auctoritas antiquitus erat in Aeduis." (Bell. Gall. lib. vi. c. 12.) But the Sequani, assisted by the Germans, defeated their opponents; while the Aedui sought the friendship of the Romans. Caesar changed the face of affairs. He restored the Aedui to their lost preponderance, and, by artfully employing one faction against another, was enabled to reduce them all. This, upon his own authority, is the introduction to the contrast.

Throughout Gaul, he says, (and it was the same in Britain,) there were only two orders of men in any high degree of honour or esteem: the *Druids* and the *Nobles*. The common people were nearly all upon a level: so submissive to the will, and so dependent on the power of the nobles, that their condition was little better than that of slaves. In the lowest rank, were such as had been taken in war, or by some other means reduced to actual slavery. These persons were the property of their respective masters.

The *Druids* had the supreme and sole direction in every thing relating to religion. By them, as the favourites of the Gods, and the depositaries of their councils, the people offered all their sacrifices, thanks, and prayers: they educated the greater part of the youth; were held in the highest honour; and determined all causes and controversies, whether of a public or a private nature. (See also Diod. Sic. lib. v. § 31.) If any crime was committed, or a murder perpetrated; if any disputes arose either about the division of inheritances, or the boundaries of estates; they alone dispensed both rewards and punishments. Whoever refused to submit to their decrees, whether tribes or individuals, were interdicted from the sacrifices; and the interdict of the *Druids* was most dreadful. They against whom it was pronounced, were held in universal detestation, as impious and abominable; their company was avoided as dangerous and contaminating; they were declared incapable of any trust or honour; put out of the protection of the laws; and exposed to injury of every kind.

Over all these *Druids*, one, who had the greatest authority, presided. On the demise of the Arch-*Druid*, if there was any one more eminent than the others in the ordinary class, he succeeded: but, in general, the high priest was elected from among the remaining *Druids* by a plurality of votes: though sometimes this office was an object of ambition; not obtained by the force of arms. Once in the year, at a certain appointed time, they assembled on a consecrated spot, in the country of the Carnutes (the *Pais Chabrain*), which was thought the centre of Gaul. Hither all who had law-suits came, and implicitly submitted to the decision of the *Druids*.

The doctrines of *Druidism*, it was the received opinion, had their origin in Britain; and were thence transferred to Gaul. And even in Caesar's time, they who were desirous of becoming adepts in its mysteries, went to Britain for the purpose.

The *Druids* were exempted from taxes and military services; and enjoyed many immunities. Numbers, allured by the honours and privileges of the profession, embraced the discipline of their own accord; while many more were dedicated to it by their parents. The *Druids* were said to commit an infinite multitude of verses to memory; and some of them passed no less than twenty years in becoming living repositories of their doctrines; since it was not lawful to entrust them to writing; though, in almost all other public transactions, and private accounts and computations, they made use of Greek letters.

The immortality of the soul, and its transmigration into other bodies, were among their leading doctrines; by which they excited an undaunted courage, and a sovereign contempt of death. Beside these, they entered into disquisitions and disputations in their schools, concerning the stars and their motions, the form and magnitude of the universe in general, and the earth in particular; on the operations of nature; and on the powers of the immortal gods.

The second description of men, enumerated by Caesar, were the *Nobles*, who, in war time, appear to have assumed the command of their respective tribes. They were skilled in the arts of fighting, and were readily followed by their dependants into actual service.

From the mention of these, he proceeds to the religious principles and opinions which the Celts maintained. Gaul, as a nation, he says, was addicted to superstition. They who laboured under disease, or expected to be called to battle, either offered, or promised the future sacrifice of human victims. For it was an article in their creed, that nothing but the life of man could atone for the life of man. For this purpose they used the ministry of the *Druids*. At more important times, however, they formed colossal images of wicker, filled them with victims, set fire to them, and destroyed the whole. On these occasions, such as had been guilty of theft, robbery, or other crimes, were deemed the most acceptable offerings to the gods. But when criminals were scarce, the innocent supplied their place.

Mercury, according to Caesar, was regarded as their chief deity; they honoured him with images, and esteemed him as the inventor of arts, and as the protector both of the public ways and commerce. After him, Apollo, Mars, Jupiter, and Minerva were worshipped; of whom their notions, he says, were much the same with those of other countries. They considered Apollo as the curer of diseases; Minerva as the guardian of works of art; Jupiter as the governor of heaven; and Mars as the god of war. To Mars, before they entered on a war, they usually vowed a great part of the expected spoil; and when they had sacrificed all the animals taken, they deposited the rest apart. In many of their states, says Caesar, these spoils are seen piled up in heaps in their consecrated groves. Nor did it often happen that any one neglected the performance of his vows, or secreted his share of spoil, or having once devoted it withdrew it. Such persons were punished with the severest tortures.

The Gauls considered themselves as the progeny of *Dis*, for to the common people were told by the *Druids*; and on this account they reckoned time not by days but nights. In the institutions of ordinary life, they differed materially from other nations in this respect; that till their children arrived at a manly age they were not suffered to appear in public before their parents. It was accounted a shame for a father to be seen in company with his son.

Whatever fortune the wife brought, the husband was obliged to equal; and the principal and produce of both were laid up for the survivor. The husband had power both of life and death, not only over his children but his wife. When any one of distinction died, his nearest relations were assembled, and if there appeared any cause of suspicion as to his death, they had power to put the wife to the same torture as the meanest slave, and if found guilty, she was burnt to death in the most excruciating manner. The funerals of the Gauls, he adds, considering their circumstances, were sumptuous and magnificent. It was their custom to throw into the funeral pile on which the body was burnt, those things, and even those animals, in which the deceased had most delighted; at a remote period, however, they threw into the flaming pile such of his servants and friends as had

been his greatest favourites, and all were reduced to ashes together in the same fire.

With those states which were esteemed the best administered, it was a law, that whosoever should receive intelligence from any neighbouring state, of public importance, should communicate it only to a magistrate; lest they who might be alarmed by rumours, should, by rash resolutions, raise a ferment. The magistrates concealed what part of the intelligence they pleased; informing the public of the rest. Except in the general assembly, it was not allowable to talk of state affairs.

Thus far we have the direct words of Cæsar. From a few other writers we obtain additional points of information, which throw as much, if not more light upon a large portion of the early inhabitants of Britain, as upon the *Celts* in general. The particular history of the *DRUIDS* will form a separate article hereafter. *Mefus*, according to Boxhorn (Orig. Gall. c. i. p. 11.), was the name by which Mars was worshipped by the Gauls and Britons, although there appears some reason to believe that he does not mean the *Celtic* but the *Belgic* Gauls. Dis answered to the Pluto of the Greeks. The sun is said to have been worshipped under various names, principally expressive of the nature and properties of light and heat. To this object of idolatrous worship, the circles of stones described by Dr. Stukely and others, are supposed to have been chiefly dedicated. Saturn, of the worship of whom in the western parts of Europe we have the evidence of some of the classic writers, is stated to have been another of their deities (see Henry's Hist. of Britain, vol. i. p. 107.); and others are indistinctly mentioned by Roman appellations, of whose history we have no clear intelligence. It is to be regretted that Cæsar did not give us the Celtic names of the several deities worshipped in Gaul, as well as the names in use among the Germans. In some resemblance of the attributes ascribed to *Mefus* and *Tentates*, the Greeks and Romans saw Mars and Mercury, and thence inferred that their own modes of worship extended to barbarous nations. "The Greek and Roman travellers and conquerors," says Mr. Hume (Hist. of Natural Religion), "without much difficulty found their own deities every where; and said, this is *Mercury*, that *Venus*; this is *Mars*, that *Neptune*; by whatever title the strange gods might be denominated."

What were the *hymns* either of the Gauls or Britons we are ignorant. The Druids, as we have already seen, instructed their disciples in a poetical system of divinity; but as their verses were never committed to writing, they were lost.

Their *offerings*, which constituted so important a part of their religion, have been described by Cæsar; and their *arts of divination*, with some minuteness, by Diodorus Siculus (lib. v. c. 35.). Pliny, in his Natural History (lib. xvi. c. 44), says, the Druids held nothing so sacred as the mistletoe of the oak. As it was very scarce, when any of it was discovered they went with great pomp and ceremony on a certain day to gather it. When they had got every thing in readiness under the oak, both for the sacrifice and the banquet which they made on this great festival, they began by tying two white bulls to it by the horns. Then one of the Druids, clothed in white, mounted the tree, and with a knife of gold cut the mistletoe, which was received in a white sagum. This done, they proceeded to their sacrifices and feasting. The Druids, he adds, had so high an esteem for the oak, that they did not perform the least religious ceremony without being adorned with garlands of its leaves. They believed that every thing that grew upon it came from heaven, and that God had chosen that tree above all others. There are, however, one or two circumstances which lead us to doubt whether Pliny here describes the *Celtic* Druids.

The sacred groves in which their religious ceremonies were performed, were surrounded by a ditch or mound, to prevent the intrusion of improper persons. In the centre of these, a circular area was inclosed with one or two large rows of stones. This was the temple. Close at hand was the carnedde, or sacred mound; the cromlech, on which the sacrifice was prepared; and all other things which were necessary for their worship. Stonehenge, if it really was a Druid temple, is the most magnificent of all that are remaining.

In regard to the state of society and government among the Celts, we find that both Gaul and Britain were divided into petty states, each composed of two, three, four, or even more clans or tribes. The king of which was commonly the head of the chief clan of which the state was composed. (See Henry's Hist. of Britain, vol. i. p. 161.) Those into which Britain was divided need hardly be enumerated here. The rule of succession to the throne is supposed to have been hereditary; as well among the Celtic as the Belgic Gauls. (Compare Cæsar de Bell. Gall. lib. v. c. 20. Sueton. Vit. Calig. c. 44. Tacitus Hist. lib. iii. c. 45. and Dio Cassus, l. ix.) And the chief prerogative of the Celtic kings was that of commanding the forces of their respective states in time of war. In every thing else they seem to have been inferior in their power to the Druids.

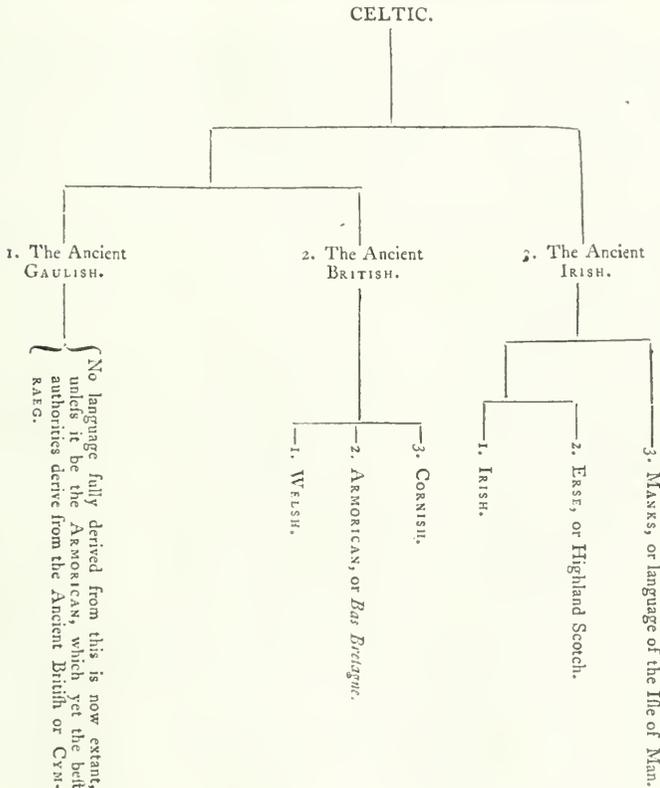

The little knowledge which we have of their theology, philosophy, and jurisprudence, is gathered with difficulty, and only from the scattered notices of ancient writers. Strabo informs us, (lib. iv. p. 197,) that it was one of their physiological opinions that the universe should never be entirely destroyed or annihilated, but should undergo a succession of great changes and revolutions, which were to be produced sometimes by the power and predominancy of fire, and sometimes by that of water. They were acquainted with a year, apparently exact enough for the purposes of life, but not fitted for astronomical calculations. Pliny (Nat. Hist. lib. xvii. c. 44) says, "they began both their months and their years not from the change, but from the sixth day of the moon." The particulars and extent of their knowledge in this part of astronomy are not farther preserved. If they used Greek letters in their ordinary calculations, as Cæsar has recorded, we must conclude they were acquainted with *arithmetic*; and the rocking-stones alone are sufficient to evince that they had some knowledge of *mechanics*. The houses of the Britons, as Cæsar saw them, are particularly described to us in the Commentaries. (De Bell. Gall. lib. v. c. 12.) They were like those of the Gauls, though little more than wretched cabins. (Zonaras, p. 189.) Their clothing was usually a skin (Bell. Gall. lib. v. c. 14), cast about the shoulders like a mantle. "Those," says Diodorus Siculus (lib. v. p. 347,) "who dwell near the promontory Belerium (or Land's end), are very hospitable, and, by their great intercourse with foreign merchants, much more civilized in their way of living than the other Britons. They dig tin ore out of their mines, and prepare it with great dexterity and art. Though this ore is naturally of a hard substance, like stone, yet it is mixed and incorporated with much earth, from which they separate it with great care, and then melt and cast it into blocks or ingots of a square form like dice." This was the only metal they were acquainted with as the produce of the island. In the *art of war* all the young men among the Celtic nations were regularly trained; and their troops, it should appear, were chiefly composed of infantry. The military cars of Britain (the *Effredæ* of Cæsar, and the *Cocini* of Tacitus) seem rather to have belonged to the Belgic than the Celtic inhabitants. War-chariots, says Mr. Pinkerton, were not known among the Celts. Their early trade was with

with the Phœnicians (the foreign merchants spoken of by Diodorus Siculus), who appear to have laboured with a very anxious care to conceal the knowledge of their commerce. A singular anecdote of their jealousy of this exclusive trade is mentioned by Strabo. Afterwards, however, the Greeks, and latterly the merchants of Gaul, obtained a share, whose information finally led to the Roman expeditions. Polybius, who was by birth a Greek, and flourished near 200 years before the Christian era, is said to have written a distinct work concerning Britain; which appears to have been first described, about 130 years earlier, by Pythias of Marseilles. What was the general medium of exchange, or what were the coins of the Celtic nations, it is impossible at this period to say. The principal of those which are acknowledged by our antiquaries as *British*, are not of Celtic but Roman origin. They have almost all the Roman letters, and many

of the Roman deities. Of the *manners*, virtues, vices, remarkable customs, or diversions of the Celts, our information is extremely scanty. Nor are we certain that the peculiar characteristics of the Britons, spoken of by Cæsar, attach either inclusively or exclusively to the Celtic population of the island.

The last subject to be mentioned here is the *language* of the Celts, which is now no longer doubted to have been one of the original dialects of Europe. What it was at a remote period we have no means to ascertain, but we are assured by Tacitus that, even in his time, the ancient British differed very little from the Gaulish. *Sermo haud multum diversus.* (Vit. Agri. cap. xi.)

Bishop Percy, in the Preface to Mallet's Northern Antiquities (p. xxv.), has given the following genealogical table of the languages descended from the Celtic.

The study of the *Welsh* language was first encouraged in this country by Henry VIII. But the best body of materials for the knowledge of the Celtic dialects will be found in Lhwyd's *Archæologia Britannica*.

CELYDNUS, in *Ancient Geography*, a river of Macedonia, in the Orellide territory. It had its source in the Cecroce-

raunian mountains, and served as a boundary between Orestides and Chaonia, according to Ptolemy.

CEMA, a mountain of the Gauls, forming a part of the chain of the Alps. "Amnis Varus," says Pliny, "ex Alpium monte Cema profusus." The mountain whence this small river flows, is at present called *Caillol*.

CEMAS, Cemas Aeliani et Herodoci, in *Zoology*, synonymous with *Antrophe Rupicapra* of modern writers. Buchart, &c. Belon conceives the Cemas, or Cemas of the Greeks to be this species.

CEMBALO, Italian, in *Musick*, at present implies a harpichord; but in the time of Boccaccio, it was the title given to the tambour de basque: *instrumento da donne*; which in the Crusca dictionary is defined, *instrumento da femine*; che è un cerchio d'asse sottile alla larghezza d'un tommeio, &c.—covered with parchment like a drum, surrounded with bells or bits of tin, and beaten with the hand. Madonna, *Pio avesse un Cembalo, in direti*, &c.

We not only meet with *Arpicordo* and *Clavicembalo* in Zarlino, 1562, but among keyed instruments, described by Ottomarius Lulemius in 1536, under the three several Latin names of *Clavichtherium*, *Clavichordium*, and *Clavicembalum*; but in the coats wooden cuts by which he represents them, the shape seems only that of a spinet or virginal; which see.

In Varchi, the contemporary of Zarlino, the harpichord is called *Gravicembalo*. And in another Italian writer of a more early period, we are told, that Titoret the painter had a daughter called *Marietta*, who, besides other accomplishments, played on the *Gravicembalo*, or harpichord, and painted extremely well. See ORGAN, HARPSICHOORD, SPINET, and PIANO-FORTE.

CEMBANI, in *Ancient Geography*, a people of Arabia Felix, who dwelt in the vicinity of the Agreans, according to Pany.

CEMBRA, in *Botany*. See PINUS *Cembra*.

CEMELANUM, CEMENELLUM, or CEMENALIUM, CEMELUM and CEMELUM, *Cimiez*, in *Ancient Geography*, a town of Gallia Narbonensis, N. N. W. of Nicea, and near it. It continued to be the capital of the Maritime Alps to the close of the 4th century, and was very considerable for the number and quality of its inhabitants, and the beauty of its edifices. The first officers of this province made this the place of their residence. It had three colleges, one of which was probably that of the priests; and a senate which allowed an assembly for deliberating on the construction of a monument in honour of M. Aurelian Maculus, president of the Maritime Alps. This Roman had supplied the city with corn in a time of famine, and re-established the ancient aqueducts, the ruin of which had occasioned a want of water. The town of Cimiez was destroyed by the Lombards towards the year 737. The inclosure of its amphitheatre is still in good preservation. It was the capital of the Veditani, and was situated on the Aurelian way. M. D'Anville discovered this ancient name in that of the church, called "Notre-Dame de Cimiez" to the right of Paillon, and $1\frac{1}{2}$ mile N. of Nice.

CEMENTATION, in *Chemistry*. *Camentiren*, Germ. This term is applied to a process in the dry way, similar to digestion in the moist, and means the exposure of any substance to a regular furnace-heat in a crucible, stratified or otherwise covered with some kind of powder which is intended to produce a chemical change. Thus iron bars are converted into steel by being cemented with a powder of bone-ash, and other materials: copper into brass by cementation, with a powder of calumne and charcoal; and the like. The powder is, in this case, called *Cement-powder*.

CEMENT-COPPER. The copper procured from the sulphat by precipitation with iron is so called. See COPPER.

CEMENTS and LUTES. Under this article may be mentioned the receipts for preparing some of the most use-

ful substances of this kind, that are required in common chemical operations.

The uses of lutes and cements are either to close the joinings of chemical vessels to prevent the escape of vapours and gasses during the processes of distillation, sublimation, and the like, or to protect vessels from the action of the fire which might crack, or fuse, or calcine them: or sometimes to repair flaws and cracks, and for a variety of other smaller purposes.

The subject of *calcareous cements*, such as mortar, terras, and other substances used to close the joinings of bricks or stones in buildings, will be mentioned in the following article.

When a lute is applied over the whole surface of a vessel, (as to a glass retort when it is intended to be heated red hot) the process is termed, *lutation* or *coating*. Iron furnaces are also *lined* or *coated* on the inside with earth, to prevent the iron from being destroyed by the constant action of the fire.

From the vast variety of receipts for lutes and cements of different kinds, the following may be selected, which will answer most of the purposes of the experimental chemist.

To prevent the escape of the vapours of water, spirit, and liquors not corrosive, the simple application of slips of moistened bladder will answer very well for glass, and paper with good paste for metal. Bladder, to be very adhesive, should be soaked some time in water moderately warm, till it feels clammy; it then sticks very well. If smeared with white of egg, instead of water, it adheres still closer.

Another very convenient lute is linseed meal, moistened with water, to a proper consistence, well beaten, and applied pretty thick over the joinings of the vessels. This immediately renders them tight, and the lute in some hours dries to a hard mass. Almond paste will answer the same purpose.

The use of the above lute is so extensive, that no other is required in closing glass vessels in preparing all common distilled liquors; and it will even keep in ammonia, and acid gasses, for a longer time than is required for most experimental purposes. It begins to scorch and spoil at a heat much above boiling, and therefore will not do as a fire lute. It is still firmer, and dries sooner when made up with milk, or lime water, or weak glue.

A number of very cohesive cements impervious to water and most liquids and vapours, and extremely hard when once solidified, are made by the union of quick-lime with many of the vegetable or animal mucilaginous liquors. The variety of these is endless. We may first mention the following, as it has been extensively employed by chemists for centuries. Take some whites of eggs with as much water, beat them well together, and sprinkle in sufficient flaked lime, to make up the whole to the consistence of thin paste. The lime should be flaked by being once dipped in water and then suffered to fall into powder, which it will do speedily with great emission of heat, if well burnt. This cement should be spread on slips of cloth, and applied immediately, as it hardens or sets very speedily. While lardening it may be of use to sprinkle over it some of the lime in fine powder. This cement is often more simply and as conveniently managed, by smearing slips of linen on both sides with white of egg, and when applied to the joining of the vessels shaking some powdered lime over it. It then dries very speedily.

Another lute of the same kind, and equally good, is made by using a strong solution of glue to the hme instead of the white of egg. It sets equally soon, and becomes very hard. A mixture of liquid glue, white of egg, and lime, makes the

the *lut d'ane*, which is so firm, that broken vessels united with it, are almost as strong as when found. None of these lutes, however, will enable these vessels to hold liquids for any great length of time. Milk or starch, with lime, make a good, but less firm lute.

A very firm and singular lute of this kind is made by rubbing down some of the poorest skimmed milk cheese with water, to the consistence of thick soup, and then adding lime, and applying as above. It answers extremely well. Lime and blood, with a small quantity of brick-dust, or broken pottery, stirred in, is used in some places as a very good water-cement for cellars and places liable to damp.

Paris-plaster, mixed with egg, milk, glue, starch, or any mucilaginous liquor, also makes a good lute.

Some artists mix other earths with the above materials. Thus a very good cement is made with equal parts of clay and lime, about $\frac{1}{2}$ of flour and white of egg; or, as is used by many of the aqua fortis-makers, a mixture of colcothar lime and white of egg.

All the above-mentioned cements, with lime, become very hard, by drying, inasmuch that they cannot be separated from glass vessels without the help of a sharp knife and some violence; and hence delicate vessels, and long thin tubes cemented with it, are apt to break, when the apparatus is taken down, and sometimes even by the mere force of contraction in setting. It is a great advantage, however, that they may be applied immediately to any accidental crack or failure of the lute already on, notwithstanding a stream of vapour is burling through; and in large distillations it is of advantage always to have some of the materials at hand.

These lutes will not confine very corrosive acid vapours perfectly, for a great length of time, but will answer for other purposes, particularly where a complicated apparatus is to be kept steadily united and air tight. They will bear nearly a red heat without material alteration.

Another kind of lute, which is the most perfect for confining acid vapours for any length of time, and which never hardens to an inconvenient degree, is the *fat lute*, as it is called. This is made by taking any quantity of good clay, tobacco-pipe clay, for example, thoroughly dry, but not burnt, powdering it in an iron mortar, mixing it gradually with drying linseed oil, and beating them together for a long time to the consistence of thick paste. Much manual labour is required, and it should be continued till the mass no longer adheres to the pestle. Then make the edges of the glass or other vessel, where it is to be used, perfectly dry, and apply the lute carefully, and it will stand the longest process without failing. This grows firm enough to retain its place, and to hold the vessels together, but may readily be separated by a knife. This lute much improves in adhesiveness by long keeping, which should be in a covered pan in a cool cellar. When wanted, it regains sufficient ductility, merely by beating for a minute or two, or by the help of a few drops more of the oil. Good glaziers putty, which is made of chalk, beat up with drying linseed oil, much resembles the fat lute in quality.

Another species of lute is that which is commonly applied round glass retorts, when distillation with a full red heat is wanted, to protect them from the sudden action of the fire, and to give them firmness, and to enable them to bear this heat without flattening or falling together, when red-hot, or melting with the fuel. A glass vessel, so prepared, with a thick earthen coating, may be considered as an earthen vessel glazed on the inside. The substance used is a mixture of sand, with just sufficient clay to make it adhere together, beat up with some kind of fibrous matter, so as mecha-

nically to increase the tenacity. A natural earthy mixture of the kind is Windsor Ham, or an equally good one may be formed with coarse sand and clay, or better with fragments of pottery coarsely ground, (the fine part being separated by sifting, and rejected,) mixed with more or less clay, according to the quality, so that it will just mould together when wet. For the fibrous matter, some use horse-dung, which appears to be the best, others chopped straw or chaff, others chopped horse, or cow-hair, or tow, all of which answer the same purpose. A small quantity of these will suffice. Beaumé recommends about an ounce of cow's hair to five pounds of the earthy mixture. A good deal of water should be added, when the materials are mixed, and much manual labour is required to diffuse the hair equally through the mixture. To apply it to a glass vessel, a retort, for example, take a sufficient quantity of the lute, spread it out flat on a table, lay the bottom of the retort on the middle of the mass, and then turn up the edges of the flat cake, and bring it over the rest of the glass, pressing it down with the fingers, till it applies uniformly and closely. By this method the lute is without seam, and is much more likely to dry in the fire without cracking. Or else, bring the lute, with sufficient water, to the consistence of thick soup, dip the retort in, and it will come out thinly coated. Turn it round before the fire, and, when dry, dip it again in the lute, to give a second coating, and so on, to the required thickness, which may be from $\frac{1}{4}$ to $\frac{1}{2}$ an inch.

A lute similar to this is used as a lining to iron furnaces, to confine the fire, and prevent the iron from consuming by the constant heat. This lute is just so fusible as to begin to agglutinate in a full red heat; and hence, if it remains found till thus hot, it will form an impenetrable coating to the glass within, from which it cannot afterwards be detached. The covers of crucibles and other vessels intended to bear fire may be luted with this earthy mixture. It is rendered still less liable to crack on the first heating, if, when thoroughly dry, it is smeared with linseed oil.

Sometimes, however, a still more fusible compound is wanted, particularly where very volatile and penetrating substances are distilled from an earthen vessel. These vessels are necessarily porous, to a certain degree, independent of any casual cracks, from which the larger earthen vessels are seldom entirely free. When phosphorus, for example, is prepared, by strongly heating charcoal and phosphoric acid in one of these retorts, the vapour of the phosphorus penetrates through the pores, when thoroughly red hot, and much of it is lost. Nor will the last-mentioned luting entirely prevent this, so that it is a great saving to cover the retort first with a thin coat of a fusible glazing, which will melt on the surface as soon as red-hot, and close every opening. This glazing may be made by a variety of fluxes added to the proper dose of clay and earth, and mixed into a thin paste and applied to the retort with a brush. The following management is recommended by Mr. Willis, a practical chemist, (Repertory, vol. i.) in distillation with large earthen retorts. Dissolve one ounce of borax in half a pint of boiling water, and add as much slaked lime as will make it into a thin paste. Spread it over the retort with a brush, and, when dry, apply over the whole a lute of slaked lime and linseed oil, beaten till it is perfectly plastic. This becomes dry in a day or two, and is then fit for use. Stone retorts may thus be used several times with safety, (always renewing the oil and lime-lute); whereas, in the common way, and even with the clay and hair-lute, they generally crack when cooling, or on being heated a second time. If, during the operation, the retort should crack, Mr. Willis advises to spread some of the oil composition thickly on the

part, and sprinkle some flaked lime over the whole, which will prevent the further escape even of the penetrating vapour of phosphorus, and may be safely applied even when the retort is red hot. When prepared somewhat thicker, it is very proper as a general lute for a variety of purposes, and will never harden so as to break the vessel.

Often a fire lute is required to join the covers to crucibles, or for similar purposes, so as to keep them air-tight when hot. A very valuable composition of the kind is made of glass of borax, brick-dust and clay finely powdered together, and mixed with a little water when used. No very great nicety is required in the proportions, but about a tenth of borax is quite sufficient to bring the earths to that state of semi-vitrification which is desired. Litharge may also be used instead of borax, but the latter is by far the best, as it promotes that thin spreading fusion which is best calculated to be equally applied over an uneven surface; and besides, if a portion of the litharge lute were to drop into the crucible it might possibly be reduced, and lead introduced into the results of the experiments.

A cement, said to be useful to stop cracks of iron vessels intended to be strongly heated, is made of six parts of clay, one of iron filings, and linseed oil enough for the mixture.

Another species of cement is what is termed by the French *Mastic chaud*, and consists of different kinds of oily and resinous substances, liquid when hot, and which become more or less solid by cooling. They are useful for a variety of miscellaneous purposes, for experiments with gasses over water or mercury, and others where only a very moderate warmth is used, and where it is of importance to keep out air and water. These will also confine acid vapours, but not the vapours of alcohol, turpentine, or essential oils, which dissolve most resinous substances. Most of them will stick very well to glass. Common sealing-wax is one of the most useful of these cements. A cheaper and less brittle cement is made simply by melting bees wax with about one eighth of common turpentine. This may be made up into sticks to be used when wanted, being first melted or spread evenly with a hot iron. A greater proportion of turpentine renders this lute softer and more fusible, but somewhat pliable.

A very firm cement is made by four parts of rosin, one of bees wax, and when melted, one part of fine brick dust, stirred in. This adheres to extreme firmness. Table knives are cemented to their handles by this mixture, and turners use a similar composition in some fine works to fix them to the lathe.

Chaptal found, after many trials, that the penetrating vapours of sulphureous acid in the manufacture of alum were completely confined in a wooden chamber lined very carefully with a mixture of equal parts of pitch, turpentine, and wax boiled till all the essential oil was dissipated (which was known by the cessation of the bubbles) applied melted to the wood, and spread with a hot trowel over the joints. Vintners stop leaks in their casks with melted suet rubbed over when cooling with sifted wood ashes, or previously mixed with the ashes in melting.

The use of gum arabic dissolved in water, for cementing paper labels to bottles, and a great variety of miscellaneous purposes, is known to every one. A still better cement for the same use is isinglass dissolved in vinegar to a pretty thick consistence when warm. This congeals on cooling, and before it is used it should be gently warmed.

Many of the varnishes and oil paints are employed in rendering vessels air and water tight. Thus when *ca vas bags* are fastened to a stop-cock tube for air-holders, the joining

is made perfectly tight by tying over it slips of cloth or bladder soaked in spirit varnish.

The following cement is said to be very useful in joining together glass or steel. Take of mallich five or six bits as big as peas, dissolve in as much alcohol as will render them liquid. In another vessel dissolve as much isinglass (previously soaked in water) in brandy or rum, as will make two ounces by measure of a strong glue, warm it, and incorporate with it by rubbing two or three small bits of galbanum or ammoniacum and then the mallich solution. Keep the cement in a bottle well stopp'd, and gently warm it before use.

Those fusible metal compounds used to unite pieces of metal form another totally distinct species of cements. These are termed **SOLDERS**, under which they will be described. See **CEMENT**.

CEMENTS, calcareous. In this article it is proposed to give an account of the various cements used in building, into which lime enters as an essential constituent part; and in order to treat the subject with a degree of clearness, in some measure corresponding to its importance, it will be advisable to arrange every kind of calcareous cement under one or other of the following three divisions: first, simple calcareous cements: secondly, water cements: thirdly, mallichs or maltha.

§ 1. Simple calcareous cements.

This section includes those kinds of mortar which are employed in buildings on land; and generally consist of lime, sand, and fresh water.

It is well known that calcareous earths are converted, by burning, into what is called quick lime, which substance being wetted with water falls into a powder with great extrication of heat, and then acquires the property of uniting with sand, and various other substances, and forming a solid mass which becomes as hard and durable as most building stones. We have no means of ascertaining by whom or at what time this valuable property of lime was discovered; but among the nations of antiquity the Romans appear to have made the most use of, and to have been most skilled in cementitious building.

The various kinds of marble, chalk, and lime-stone, as far as regards their use in cements, may be divided into two species; the first being pure or nearly pure carbonat of lime; the second containing besides from $\frac{1}{2}$ to $\frac{1}{3}$ of clay and oxyd of iron. Previous to burning or calcination, there are no external characters by which the simple lime-stones can be distinguished from the argillico-ferruginous ones; but the former, whatever may have been their colour in a crude state, become when calcined of a white colour, while the latter possess more or less of a light ochery tinge. The brown lime is by far the best for all kinds of cements; but the white varieties being more abundant, and allowing of a larger proportion of sand, are generally made use of. It was an opinion of the ancients, and is still commonly received among builders, that the hardest lime-stone, *ceteris paribus*, furnishes the best lime; thus mortar was said to grow as hard as the lime-stone of which it was composed, and hence marble was considered as superior to common lime stone, and this latter to chalk. The experiments of Dr. Higgins and Mr. Smeaton, however, show that this is entirely a mistake; common chalk, and the hardest Plymouth marble, when similarly treated, affording cements of equal firmness.

When carbonated lime has been thoroughly burnt, it is deprived of its water, and of all, or nearly all of its carbonic acid; if, in this state, it is plunged into water, and immediately taken out again, the water which it has absorbed will

will occasion the mafs to crack and become exceffively hot, and at length to fall into an impalpable powder, much of the water being carried off in the form of steam during the procefs. When lime has been thus flaked, if it is beaten up with a little water into a very stiff paffe and allowed to dry, it will be found that the white limes, whether from chalk or marble, never acquire any degree of hardnefs, that the brown limes become confiderably indurated though not fo much fo as when mixed with fand, and that fhell lime (procured by calcining fea fhells), concretes into a firm, hard cement, well qualified for dry buildings, although it falls to pieces in water.

Lime-ftone lofes about $\frac{2}{3}$ of its weight by burning, but fhinks in an inconfiderable degree; upon quenching, when fully burnt, it falls freely, and will produce fomewhat more than double the quantity of powder or flaked lime, in meafure, that the burnt lime-ftone confifted of.

Quick-lime, by exposure to the air, absorbs carbonic acid with greater or lefs rapidity, as it is of a clofe and hard, or foft and fpongy texture; thus it gradually lofes its cementing properties and at length becomes totally unfit for the purpofes of mortar. Hence, though ftone-lime and chalk-lime are equally good, when perfectly burnt, and ufed fresh from the kiln, there is an important practical difference between them, as the chalk lime absorbs carbonic acid with much the greateft facility.

A proper felection of fand is of great importance in the compofition of mortar; the fharper and coarfer it is the better; as it requires a fmall proportion of lime, and makes a ftronger cement than when fine grained and round fand is made ufe of. Sea fand requires to be well wafhed in fresh water to difsolve out the falt with which it is mixed, otherwife the cement into which it enters never becomes thoroughly dry and hard.

The moft advantageous proportions of lime and fand in the compofition of mortar is a point by no means fettled. The Roman builders were accuftomed to allow three parts of pit fand, or two parts of river or fea fand to one of lime. In general, it may be affirmed, that it will be advantageous to ufe the largeft quantity of fand that can be introduced, preferving the neceffary degree of plafticity. Mortar, in which the fand predominates, requires lefs water in preparing, and therefore fetts fooner; it is harder and alfo lefs liable to crack on drying than that in which lime prevails. Smeaton obferves, that there is fcarcely any but what, if well burnt and beaten, a load or meafure of unflaked lime will take two loads or meafures of fand. On purfuing this fubject he foon found that, by good beating, the fame quantity of lime would take in one meafure of tarraf and three of clean fand, which feems to be the greateft ufeful proportion, for on a further increafe of the quantity of fand, the mortar required fo much more beating to bring it to a proper confiftence and toughnefs, that the labour became of more value than the faving of materials. Thefe obfervations agree very nearly with the experiments of Dr. Hutton.

The weaknefs of modern mortar compared to the ancient is a common fubject of regret, and many ingenious men taking for granted, that the procefs ufed by the Roman architects in preparing their mortar is one of thofe arts which are now loft, have employed themfelves in making experiments to recover it, inftead of attending to the directions left us in the works of Pliny and Vitruvius, which, when illuftrated by the actual practice of builders in various parts of Europe, feem to leave little or no doubt on the fubject.

The characteristic of all modern artifts, builders among the reft, feems to be to fpare their time and labour as much as poffible, and to increafe the quantity of the articles they

produce, without much regard to their goodnefs; and perhaps there is no manufacture in which this is fo remarkably exemplified as in the preparation of common mortar, efpecially in London and its neighbourhood.

The peculiar badnefs of London mortar is to be attributed, both to the faulty nature of the materials, and the carelefs and hally method of ufing them. The lime employed is the foft chalk-lime of Effex and Kent, which infufficiently burnt at firft, is conveyed a diftance of ten or twenty miles and kept many days, without any precautions to prevent the access of the external air; and thus before it is ufed, it has time to abforb fo much carbonic acid as nearly to lofe its cementing properties. It has been before obferved, that though chalk, when perfectly burnt, is equally good as the hardeft lime, it poffeffes fome practical difadvantages; it will fall into a coarfe powder on the application of water, when it is only partially calcined, which ftone-lime will not, and the cores or unburnt lumps may be broken down by a blow with the fpace, and are therefore very feldom rejected as they ought to be.

Sand, which is fcarce and dear in London, is equally defective. This is pit fand, but very different from the kind recommended by Pliny and Vitruvius; inftead of being clean, large-grained, and fharp, it is compofed of fmall round grains, and foiled with a large mixture of clay. Its finenefs and fmoothernefs cannot be amended, but by wafhing it well in running water the clay might unquestionably be got rid of, and this would be no trifling improvement, for Smeaton has fhown, by direct experiment, that mortar of the belt quality, when mixed with a fmall proportion of unburnt clay, never acquires that hardnefs and drynefs which, without this addition, it would fpeedily have attained. Screened rubbish and the ferapings of the roads, confifting chiefly of gravel reduced to fine powder, are alfo ufed as fubftitutes for fand with ftill greater impropriety.

The method of preparing common mortar is alfo extremely imperfect. The lime being flaked by the addition of water, and the unburnt lime being broken down and mixed with the reft, a quantity of dirty fand is added, and the whole being incorporated by means of a fpace, is reckoned to be fit for ufe; thus the principal point in the making of mortar, namely, beating the ingredients together, fo as to mix them thoroughly, is flurred over in a hally carelefs manner, and the refult, as might be expected, is a crumbling mafs fcarcely fit for ufe. The Roman builders, on the other hand, after they had mixed together the materials, employing for this purpofe a fmall proportion of water than is customary at prefent, put the mafs into a large wooden mortar, and beat it till it ceafed to adhere to the heavy wooden or iron peftle which was ufed on the occafion; a practice, which has long been followed by the Dutch with complete fuccefs, as will be fhewn in the next fection.

Fresh made mortar, if kept under ground in confiderable mafles, may be preferved for a great length of time without injury; and the older it is before it is ufed the better; the builder taking the precaution to beat it up afresh, previous to ufig it; for it not only fetts fooner, but acquires a greater degree of hardnefs, and is lefs apt to crack. A fact related by Mr. Smeaton, remarkably illuftrates thefe points. Having had occafion to take up a large flat ftone of a clofe grain, of about five feet fquare, that had probably lain above a century at the bottom of a malt ciftern, he found that it had been well bedded in mortar, which had become coagulated to the confiftence of cheefe; but having never come to a perfect drynefs, it fo far retained its natural humidity, that he found it might, with fome pains, be beaten up to mortar

without any addition of water; and afterwards being suffered to dry in the air, it set to a stony hardness, and appeared as good mortar as any which that part of the country produced. Piny informs us, that the ancient Roman laws prohibited builders from using mortar that was less than three years old; and to this circumstance he expressly attributes the remarkable firmness of the oldest buildings in the city. A similar custom prevailed, and we believe still prevails in Vienna, requiring the mortar to be a year old before it is employed. But there is nothing which flows, in so striking a point of view, the advantage and necessity of beating mortar, and that the effect produced is owing to something more than a mere mechanical mixture of the ingredients, as the preparation of *grout*, or liquid mortar. This differs from common mortar only in containing a larger quantity of water, so as to be sufficiently fluid to penetrate the narrow irregular interstices of rough stone walls, and is generally made by diluting common mortar with water, either cold or hot. It not unfrequently happens, that this grout refuses to set, and at all times it is a long while in acquiring the proper hardness; but if, instead of common mortar, that which has been long and thoroughly beaten is employed, the grout will set in the space of a day, and soon after acquires a degree of hardness much superior to what is made in the common manner.

§ 2. *Water Cement.*

Although a well made mortar, composed merely of sand and lime, if allowed to dry, becomes impervious to water, so as to serve for the lining of reservoirs and aqueducts; yet if the circumstances of the building are such as to render it impracticable to keep out the water, whether fresh or salt, a sufficient length of time, the use of common mortar must be abandoned; for lime and sand, if mixed together in any proportions, and put, while soft, into water, will in a short time fall to pieces.

Among the nations of antiquity the Romans appear to have been the only people who practised building in water, and especially in the sea, to any great extent. The bay of Baiz, like our fashionable watering places, was the summer resort of all the wealthy in Rome; who, not content with erecting their villas as near the shore as possible, were accustomed to construct moles, and form small islands, in the more sheltered parts of the bay, on which, for the sake of the grateful coolness, they built their summer houses and pavilions. They were enabled to build thus securely in the water by the fortunate discovery, at the neighbouring town of Puteoli, of an earthy substance, which, from this circumstance, was called *pulvis Puteolanus* (powder of Puteoli.) Puteolan powder, or as it is now denominated puzzolana, is a light, porous, friable mineral, of a red colour, and is generally supposed to derive its origin from concreted volcanic ashes, thrown out from Vesuvius, near to which mountain the town of Puteoli is situated. It seems to consist of a ferruginous clay, baked and calcined by the force of volcanic fire, and when mixed with common mortar, not only enables it to acquire a remarkable hardness in the air, but to become as firm as stone, even under water. The only preparation which puzzolana undergoes, is that of pounding and sifting, by which it is reduced to a coarse powder; in this state being thoroughly beaten up with lime, either with or without sand, it forms a mass of remarkable tenacity, which speedily sets under water, and becomes at least as strong as good freestone.

It has been before observed, that a composition of pure lime and sand alone will not harden under water, but limes containing a portion of clay possess this property in a considerable degree, and are therefore generally used in water

building. The cement used by Mr. Smeaton, in the construction of the Eddystone lighthouse, was composed of equal parts by measure of flaked Aberthaw lime and puzzolana. The peculiar difficulties of this undertaking, exposed to the utmost violence of the sea, rendered these proportions advisable; but for works that are less exposed, such as locks and basins for canals, &c. the quantity of puzzolana may be considerably diminished. A composition of this kind, which has been found very effectual, is 2 bushels of flaked Aberthaw lime, 1 bushel of puzzolana, and 3 of clean sand; the whole being well beaten together will yield 4.67 cubic feet of cement.

The Dutch have practised building in water to a greater extent than any other nation of modern Europe; and to them is due the discovery of a cement admirably well adapted for this purpose, and called *tarras* or *trafs*. This is nothing more than wakke, or cellular basalt, and is procured chiefly from Bockenheim, Frankfort on the Maine, and Andenaach, whence it is transported down the Rhine in large quantities to Holland. This substance being, by grinding and sifting, reduced to the consistence of coarse sand, is used in the composition of mortar, with the blue argillaceous lime from the banks of the Scheldt, in the following method. They take of the quick-lime about the quantity which will be wanted during a week, and spread it in a kind of basin in a stratum of a foot thick, and sprinkle it with water. It is then covered with a stratum of about the same thickness of *tarras*, and the whole suffered to remain for two or three days, after which it is very well mixed and beaten, and formed into a mass, which is again left for about two days; it is then taken in small quantities, as it is wanted for daily consumption, which are again beaten previous to using. Thus is composed the celebrated *tarras* mortar with which the mounds and other constructions for the purpose of protecting the lowlands of Holland against the sea are cemented.

Tarras is frequently used in this country, being imported from Holland for that purpose. The proportions of the materials of the *tarras* mortar generally used in the construction of the best water works is the same as the Dutch practice. One measure of quick-lime, or two measures of flaked lime in the dry powder, is mixed with one measure of *tarras*, and both very well beat together, to the consistence of a paste, using as little water as possible. Another kind, almost equally good, and considerably cheaper, is made of two measures of flaked lime, one of *tarras*, and three of coarse sand; it requires to be beaten a longer time than the foregoing, and produces three measures and a half of excellent mortar. When the building is constructed of rough irregular stones, where cavities and large joints are to be filled up with cement, the pebble mortar may be most advantageously applied; this was a favourite mode of construction among the Romans, and has been used ever since their time in those works in which a large quantity of mortar is required. Pebble mortar will be found of sufficient compactness if composed of two measures of flaked argillaceous lime, half a measure of *tarras*, or puzzolana, one measure of coarse sand, one of fine sand, and four of small pebbles, screened and washed.

It is only under water that *tarras* mortar acquires its proper hardness; for if suffered to dry by exposure to the air, it never sets into a substance so firm as if the same lime had been mixed with good clean common sand, but is very friable and crumbly. Ash mortar is reckoned to be superior for works that are sometimes wet and sometimes dry, but *tarras* has the advantage when constantly under water. *Tarras* mortar when kept always wet, and consequently in a state most favourable to its cementing principle, throws out a

substance something like the concretions in limestone caverns called stalactites, which substance acquires a considerable hardness, and in time becomes so exuberant as to deform the face of the walls.

Although the cellular basalt is the only kind admitted into the preparation of Dutch terras, yet it appears from some good experiments of Morveau on the subject, that the common compact basalt, if previously calcined, will answer nearly the same purpose. Great Britain is at a considerable annual expence in purchasing terras from Holland; it may be worth while, therefore, to point out some of our domestic treasures of the same material. The compact basalt abounds in all the districts where coal is raised, and may therefore be procured easily, and calcined with the refuse coal, so as to be sold at a cheap rate. The Calton hill, adjoining to Edinburgh, consists almost entirely of cellular basalt, and being but at a short distance from the port of Leith, offers an inexhaustible abundance at a small cost.

In some parts of the Low Countries coal ashes are substituted for terras with very good effect; of which the valuable *cedrée de Tournay* is a striking instance. The deep blue argillo-ferruginous limestone of the Scheldt is burnt in kilns with a slaty kind of pit-coal that is found in the neighbourhood. When the calcination of the lime is completed, the pieces are taken out, and a considerable quantity of dust and small fragments remains at the bottom of the kiln. This refuse consisting of coal ash mixed with about one-fourth of lime dust, is called the *cedrée*, and is made into a mortar with lime in the following method. About a bushel of the materials is put in any suitable vessel, and sprinkled with water just sufficient to slake the lime; another bushel is then treated in the same way, and so on till the vessel is filled. In this state it remains some weeks, and may be kept for a much longer time if covered with moist earth. A strong open trough, containing about two cubic feet, is filled about two-thirds full with the cement in the above state, and by means of a heavy iron pestle, suspended at the end of an elastic pole, is well beaten for about half an hour: at the end of this time it becomes of the consistence of soft mortar, and is then laid in the shade from three to six days, according to the dryness of the air. When sufficiently dry, it is beaten again for half an hour as before, and the oftener it is beaten the better will be the cement; three or four times, however, are sufficient to reduce the cement to the consistence of an uniform smooth paste; after this period it is apt to become refractory on account of the evaporation of its water, as no more of this fluid is allowed to enter the composition than what was at first employed to slake the lime. The cement thus prepared is found to possess the singular advantage of uniting in a few minutes so firmly to brick or stone, that still water may be immediately let in upon the work without any inconvenience, and by keeping it dry for 24 hours, it has nothing further to fear from the most rapid current.

A composition very similar to the preceding in materials, which are coal cinders and lime, though seldom prepared with any attention, is the blue mortar, commonly used in London for setting the coping of buildings, and other works much exposed to the weather.

Ash mortar is used in some parts of England. It is prepared by slaking two bushels of fresh burnt meagre lime, and mixing it accurately with three bushels of wood ashes: the mass is to lie till it is cold, and is then to be well beaten: in this state it will keep a considerable time without injury, and even with advantage, provided it is thoroughly beaten twice or thrice before it is used.

The scales of black oxyd, which are detached by hammering red-hot iron, and are therefore to be procured at the

forges and blacksmiths shops, have been long known as an excellent material in water cements; but we believe that Mr. Smeaton was the first person who made any accurate experiments on their efficacy, compared with other substances. The scales being pulverised and sifted, and incorporated with lime, are found to produce a cement equally powerful with puzzolana mortar, if employed in the same quantity. Induced by the success of these experiments, Mr. Smeaton substituted roasted iron ore for the scales, and found that this also gave to mortar the property of setting under water; it requires, however, to be used in greater proportions than either terras or puzzolana; two bushels of argillaceous lime, two of iron ore, and one of sand, being carefully mixed, produce 3.20 cubic feet of cement fully equal to terras mortar. If the common white lime is made use of, it will be advisable to employ equal quantities of all the three ingredients.

With respect to the water used in the preparation of water cements, that of rivers or ponds where it can be had easily, is to be preferred to spring water; but for works exposed to the action of the sea, such as piers, light-houses, &c. it is usually more convenient and equally advantageous in other respects to use salt water.

Pumice stone, brick, and tile dust, are also recommended for water cements, but their only advantage seems to be an absorbent quality, which causes the mortar made with them to set sooner, and therefore acquire a greater hardness in the same time, than mortar composed of sand and lime alone, for they have no power of hardening under water.

The Lorient mortar is a composition which has acquired considerable celebrity in France, and has been employed in some large works. It was invented about 40 years ago by Mr. Lorient, who imagines that he has discovered the process used by the Romans. The principle of this invention consists in adding to any quantity of mortar made in the usual way with lime and sand, but prepared rather thinner than usual, a certain proportion of quick lime, in powder. The lime powder being well incorporated with the mortar, the mass heats, and in a few minutes acquires a consistence, equal to the best Paris plaster, and is as dry at the end of two days, as an ordinary cement after several months. It also, when the ingredients are well proportioned, sets without any cracks. The quantity of lime powder to be added, varies from $\frac{1}{4}$ to $\frac{1}{2}$ of the other materials, according to the qualities of the lime; too much burns and dries up the mass, and with too little, it loses its peculiar advantages; thus the proportions, a point of the utmost importance, can only be determined by experiment. It is its speedy desiccation which rendered the Lorient mortar useful as a water cement, for under water it has only the common properties of a composition of lime and sand of equal solidity; indeed for this purpose various substances, commonly used in cements, are recommended to be added, such as brick and tile powder, and forge scales. The following is an approved receipt. One measure of bricks exactly pounded, two measures of fine river sand, old slaked lime in sufficient quantity to make a mortar in the usual manner and sufficiently liquid to quench the lime powder which is added in about the same quantity as the pulverised brick.

It is sufficiently extraordinary, that a process, perfectly similar to that of M. Lorient, is described in a "Treatise on Building in Water, by George Sempie," printed at Dublin, 1776. In discoursing on the good qualities of the roacilime of Ireland, Mr. Sempie remarks, that, "it has some useful qualities not much known among the generality of workmen, as, for instance, our lime-stone will make exceeding good terras for water-works, for which purpose, you are

to prepare it thus. Get your roach-lime brought to you hot from the kiln, and immediately pound, or rather grind it, with a wooden maul, on a dry, boarded floor, till you make it as fine as flour; then, without loss of time, sift it through a coarse hair or wire sieve, and, to the quantity of a hod of your setting mortar, (which, on this account, ought to be poorer than ordinary,) put in two or three shovels-full of this fine flour of the roach-lime, and let two men, for expedition sake, beat them together with such beaters as the plaiter make use of, and then use it immediately. This, I can assure you, will not only stand as well, but is really preferable to any terras." The memoir of M. Lorient was published in 1774, only two years previous to this treatise of Semple, who appears to have been a man rather of practice and experience than of reading; and, besides, in the book quoted from, he expressly, though incidentally, mentions his ignorance of the French language. We are justified therefore, in stating, that the knowledge of the advantages of mixing quick lime powder in mortar was not confined to M. Lorient, though it might be an original invention in him, and he was the first who drew public attention to the process, and used it in any considerable works.

§ 3. *Maltha, or Malslich.*

Under this term we include those calcareous cements of a more complicated kind, whose hardness appears to depend on the oily or mucilaginous substances that enter into their composition. The use of these is at present very limited, at least in Europe, but they were highly esteemed by the ancients, especially for stucco. The maltha of the Greeks seems to have been more simple than that employed by the Roman architects; at least we are informed that Panæus, the brother of Pindias, lined the inside of the temple of Minerva at Elis with a stucco, in which the usual ingredients, sand and lime, were mixed up with milk instead of water, some saffron being also added to give it a yellow tinge. The Roman maltha, according to Pliny, was prepared in the following manner. Take fresh burnt lime, flake it with wine, and beat it up very well in a mortar with hog's lard and figs: this cement, if well made, is excessively tenacious, and, in a short time, becomes harder than stone; the surface to which it is to be applied is to be previously oiled, in order to make it adhere. Another kind, almost equally strong, and considerably cheaper, was prepared by beating up together fine flaked lime, pulverized iron-scales and bullock's blood.

In the preparation of malsichs, as well as of every other kind of mortar, so much depends on the manipulation, and especially on the care which is taken to incorporate the ingredients by long beating, that those countries in which labour is of the least value possess, in general, the best mortar. Hence, no doubt, principally arises the unrivalled excellence of the mortar made by the Tunisians and other inhabitants of the northern coast of Africa, which, according to Dr. Shaw, is prepared in the following manner. One measure of sand, two of wood-ashes, and three of lime, being previously sifted, are mixed together, and sprinkled with a little water; after the mass has been beaten some time a little oil is added: the beating is carried on for three days successively, and, as the evaporation in that hot climate is considerable, the cement is kept at the proper degree of softness by the alternate addition of very small quantities of water and oil. The cement being completed, is applied in the usual manner, and speedily acquires a stony hardness. The last species of maltha that we shall mention is the celebrated chunam of India, where it has been used from time immemorial. The method in which it is prepared at Madras is as follows.

Take 15 bushels of pit sand, and 15 bushels of stone-lime; flake the latter with water; and when it has fallen to powder, mix the two ingredients together, and let them remain untouched for three days. In the mean time dissolve 2c lbs. of molasses in water, boil a peck of gramm (a kind of pea), to a jelly, boil a peck of mirabolans also to a jelly, mix the three liquors, and incorporate part of the mixture very accurately with the lime and sand, so as to make a very fluid cement: some short tow is now to be beaten very well into it, and it is then fit for use. The bricks are to be bedded in as thin a layer as possible of this mortar; and, when the workmen leave off, though but for an hour, the part where they recommence working is to be well moistened with some of the above liquor, before the application of any fresh mortar. When this is used for stucco, the white of four or five eggs, four ounces of butter or sesamum oil, and a pint of buttermilk, are to be mixed up with every half bushel of cement, and the composition is to be applied immediately.

It is to be regretted, that no experiments have been instituted to ascertain the cause of the induration of calcareous cements. It is attributed by Dr. Higgins to the absorption of carbonic acid; but several circumstances contradict this supposition. In numerous instances the cement hardens long before the lime is saturated: in the different kinds of maltha the lime combines with the albumen, mucilage and oil with which it is in contact, and in all probability takes up little or no carbonic acid; and, if it be true, that the lime in old mortar cannot by burning be re-converted into quick lime, this would imply a chemical union of the ingredients; and it may reasonably be questioned whether, even in the simple calcareous cements, carbonic acid acts so important a part as is usually attributed to it.

CEMETERY, *Cameterium*, a dormitory, or sacred place set apart for the burial of the dead.

Chorier observes, that under *cameterium*, *καμητηριον*, from *καμηαι*, I sleep, anciently was comprehended, not only the strict dormitory, or place where the dead were disposed; but all the lands which encompassed the parish churches, and were contiguous to the real churches.—Perhaps it might be added, that all the church domains were comprised under *cameterium*. This will best account for that confiscation of the cemeteries, charged on Valerian.

In the early ages, the Christians held their assemblies in the cemeteries, as we learn from Eusebius and Tertullian; the latter of whom calls those cemeteries where they met to pray, *arce*. Valerian seems to have confiscated the *cemeteries* and places destined for divine worship, which were restored again to the Christians by Gallian. In the rescript of that emperor, which is preserved by Eusebius, cemeteries and places of worship are used as synonymous terms. It being here the martyrs were buried, the Christians chose those places to have church s in, when leave was given them by Constantine to build. And hence some derive that rule which still obtains in the church of Rome, never to consecrate an altar without putting under it the relics of some saint. See BURIAL.

The heathen writers frequently upbraid the primitive Christians for their meetings in cemeteries; as if they served other purposes besides those of religion. The council of Elvira prohibits the keeping of tapers lighted in *cameteria*, during the day-time; and by another canon, the women from passing the night, watching in *cemeteria*.

The practice of consecrating cemeteries is of some antiquity: the bishop walked round it in procession, with the crozier, or pastoral staff, in his hand, the holy water-pot being carried before, out of which aspersions were made.

CEMMENUS, in *Ancient Geography*, the name of a mountain;

mountain, which, branching from the Pyrenées, advanced far into Gaul, according to Strabo. It was the mafs of mountains which Ptolemy calls "Cemcni montes," and which, he fays, was inhabited by the Segufiani, found in that chain which formed the Cevennes.

CEMPSI, a people of Spain, who occupied the foot of the Pyrenées, according to Dionyfius Periegetes.

CENA, a fmall river of Sicily, which at prefent bears the name of "Fiume delle Cane."

CENABUM. See GENABUM.

CENÆUM, a promontory of the ifland of Eubœa towards the welt and oppofite to Thermopylæ, according to Strabo, Pliny, and Ptolemy, feated on the Maliaç gulf; now called Cabo Litar, or Cania. It had a temple of Jupiter Ceneus.

CENAPATAM, in *Geography*, a town of Hindooftan, in the country of Myfore; 34 miles N.E. of Seringapatam, and 28 S.W. of Bangalore.

CENCHRÆ, a town of Afia Minor, in the Troade. Suidas fays that it was the country of Homer.—Also, a town of Italy. Steph. Byz.

CENCHRAMIDIA, in *Botany*, Pluk. See *CLUSIA rofea*, and *BUBROMA Guazina*.

CENCHRAMUS, in *Ornithology*, one of the names given by authors to the fnow bunting, *EMBERIZA nivalis*.

CENCHREA, in *Ancient Geography*, a port of Corinth, fittuate on the bay of Saron. This was a fortrefs built on the frontiers of Arcadia, towards the fource of Phryxus, and S.W. of Argos. It defended the way that led from Argos to Tegea. Near this place, towards the fourth-eal, lay the tombs of thofe Argians, who, according to Paufanias, challenged an army of Lacedæmonians near Hyfæ, under the archonate of Pififtratus.

CENCHREA, a port town of Corinth, which lay towards the eaft upon the gulf. It derived its name from Cenchrias, the pretended fon of Neptune, when his brother Leches had given his name to Lecheum. There were the only two havens; and indeed the only two cities of any note, next to Corinth, that belonged to this territory. They were fo well fittuated for naval commerce, and fo near the metropolis, that they made ample compensation for the barrennefs of the foil. Thefe two naval roads, which opened a way into the Ionian and Ægean feas, might eafily have gained them a fuperiority, if not a command over all Greece; if this advantageous fittuation had not inclined them more to commerce than war. That Cenchrea was a diftinct city from Corinth, at leaft in St. Paul's time, we may infer from Acts xviii. 18, and from his epiftle to the Romans, ch. xvi. 1; though it had the epithet of Corinthiaca in the poets, from its being one of the havens of that little iftate, as Corinth had that of Binaris, from its being fo conveniently fittuated between two feas. Upon the road from Cenchrea acrofs the ifthmus there was a temple of Diana, and at Cenchrea a temple of Venus, with a fine ftatue. At the end of this road was a Neptune in bronze; and on the other fide of the port were two temples, one of Neptune, the other of Iſis. In the vicinity was a fpring of hot water, faid by Paufanias to be falt, and called the bath of Helena. The water fell from a rock, and precipitated itfelf into the fea. Along the coaft, towards the north-eaft, there was another port, mentioned by Strabo and Ptolemy. Pliny and Strabo lay, that it was fittuated in the moft feçure place of the ifthmus.

CENCHREA was alfo a name given generally to the ifthmus of Corinth, diftant 70 furlongs from it, where were celebrated the Iſthmian games: whence the apoftle in his epiftle to the Corinthians fo frequently alludes to thefe games. See 1 Epift. ix. 2 Epift. iv. 7, 8, 9.

CENCHREIS, a fmall ifland of Greece, towards the bottom of the Saronic gulf, according to Pliny.

CENCHRIS, in *Ornithology*, a name given by Gefner, Aldrovandus, and others, to the kind of hawk known in England by the title of Kellril, Stannel, or Windhover hawk, *FALCO TINNUCULUS* of Linnæus.

CENCHRIS, in *Zoology*, the name of a fpecies of BOA that inhabits South America, and which is diftinguifhed by having 265 abdominal plates, and 57 caudal. Linn.—*Bca flavescens ocellis albidis, iride grifea, Boddaert*.

Boa cenchris is a ferpent of large fize, though inferior in this refpect to either the boa constrictor, or the spotted boa. The prevailing colour is yellowifh-ferruginous, darkeft on the back, where it is marked by a continued ferief of very large blackifh circles extending from the head to the tail; the fides are marked with a number of kidney-shaped blackifh fpoats, many of which are ocellated with whitifh; the head is of a lengthened form, and is marked by a black longitudinal and two lateral bands.

CENCHRIUS, in *Ancient Geography*, a river of Afia Minor, in Ionia, which had its courfe through the territory of the city of Ephesus, according to Tacitus and Paufanias.

CENCHRUS, in *Botany*, (*xyxpo*; Theophrast. Diofcor.) Linn. gen. 1149. Schreb. 1574. Willd. 119. Gært. 503. Juff. p. 30. Vent. vol. ii. p. 102. (Panicatrelia; Mich. 31. Racle, Fr.) Clafs and order, *polygamia monœcia*, Linn. *Triandria monogynia*, Willd. Nat. ord. *Gramina*, Linn. *Gramineæ*, Juff. Vent.

Gen. Ch. Cal. involucre variously divided, often echnated, containing from two to four flowers; or, if wanting, the defect compensated by echnated calyx-glumes; calyx-glumes lanceolate, concave, acute, fhorter than the corolla, generally about two-flowered; one of the flowers often male. Cor. Glumes concave, lanceolate, acuminate, awnless; one fhorter than the other. Stam. filaments three, capillary, the length of the corolla; anthers arrow-shaped. Pist. gium roundifh; fstyle filiform, the length of the ftamens; fstyles two, hairy, oblong, fpreæding. Seeds roundifh, enclosed in the permanent corolla.

Efl. Ch. Involucre variously divided, often echnated; or, if wanting, the defect compensated by echnated calyx-glumes; fstyle one, blind.

* *With an involucre.*

Sp. 1. *C. cebinatus*, Linn. Sp. Pl. 4. Mart. 5. Poir. 2. Willd. 3. Pluk. Alm. tab. 92. fig. 3. Schreb. gram. 9. tab. 23. fig. 1. Gært. tab. 80. Lam. Illuf. tab. 838. fig. 1. (Panicatrelia americana major, Mich. gen. 36. tab. 31. Elymus caput Medusæ, Forfk. Flor. Ægypt. p. 25.) " Spike oblong, conglomerated." Root annual. Stems from eight to ten inches high, bent at the lower joints, fmooth, ftriated, compressed, almoft angular. Leaves from four to five lines broad, long, fmooth, ftriated; fheaths loofe, fmooth, flightly tomentous at their orifice. Spike two or three inches long; fimple, upright; fpiklets on fhort peduncles, fattered or alternate, at a fmall diftance from each other; involucre large, entire at the bafe, cut at the edge into feveral ftilf, awl-shaped, fetaceous, yellowifh or fomewhat violet fegments; flowers from two to four in each involucre, very fmall. Seeds almoft elliptical, flat, a little convex, without a furrow. A native of Jamaica and the coaft of Barbary, defcribed by Poiret from a living plant in the botanic garden at Paris, cultivated in England by Doody, in 1691. It is one of the moft common graffes in the open paltures of Jamaica, and is esteemed a wholefome and pleafant food for all forts of cattle. 2. *C. tribuloides*, Linn. Sp. Pl. 5. Mart.

C. paniculata, Pissacafra, Amer. Mich. Gen. 7. *Compositae*, Lam. Ox. tab. 7, fig. 4. Shan. Jam. *Compositae*, Lam. glomerated; female glumes globose, a little pointed, spinous-habited. *Linn. Root* annual. *Stems* branched, pointed, smooth, striated. *Leaves* often linear-lanceolate, palm, two or three lines broad, striated, smooth; the one a little pubescent at its upper part; orifice furnished with a tuft of fine, tereteous, whitish hair. *Spikelets* oblong, five or more frequently capitate, very close; spikelets entire, pubescent; spines linear, smooth, very pungent, spreading; calyx glumes pubescent or villous, especially towards the base, ciliated at the edges, mucronated, very hard. A native of Virginia and Jamaica. 5. *C. muricata*, Linn. Mant. 302. Mart. 3. Poir. 7. (Panicum squarulosum, Retz. Obs. tab. 1. Willd.) "Spike mucronated; scales various, sharp-pointed." *Root* annual. *Stems* from eight to ten inches high, procumbent, branched. *Leaves* of a moderate size, soft, enveloping almost the whole of the culm by their sheaths. *Spikes* on long filiform peduncles, slender, naked, almost unilateral, very close; rachis zig-zag, jointed, furnished on each side with a rather large membrane. *Flowers* sessile, scarious; involucre composed of various scales, large, stiff, sometimes a little twisted, oval or lanceolate, smooth, hard, awl-shaped or mucronate; calyx-glumes ciliated at the edges, containing one or two flowers. The disposition of the flowers gives it the habit of a tripartite. It is also in some respects allied to panicum, under which Retz and Willdenow have placed it. A native of the East Indies. 4. *C. bordiformis*, Willd. 6. Thunb. prod. 24. (C. asperifolius; Poir. 7. Desfont. flor. Atl. vol. ii. p. 388. Alopecurus hordeiformis; Linn. Sp. Pl. Mart. and p. 388. Alopecurus hordeiformis; Linn. Sp. Pl. Mart. and p. 388. Alopecurus hordeiformis; Linn. Sp. Pl. Mart. and p. 388.) "Leaves rough backwards; involucre bristle-shaped, four times as long as the flower, villous towards the bottom, white, enclosing one or two flowers." *Desf. Root* perennial. *Stems* two or three feet high, upright. *Leaves* about a line broad, rolled in, smooth, awl-shaped, stiff. *Spikes* five or six inches long, whitish, not interrupted; involucre composed of numerous silky filaments. *Flowers* sessile; rachis villous. A native of the East Indies, of the Cape of Good Hope, and of mount Atlas near Bugie. Nearly allied to *C. rufescens*, and *C. ciliaris*. 5. *C. rufescens*, Poir. 10. Desf. Flor. Atl. vol. ii. p. 388. "Leaves smooth; spike elongated; involucre crowded, bristle-shaped, rufescent, villous towards the bottom, three times as long as the flower; calyx about two-flowered." *Desf. Stems* almost procumbent, firm, jointed, rush-like. *Leaves* smooth, rolled in, rough at their edges; orifice of the sheaths furnished with a lacerated membrane. *Spike* four or five inches long, close; bristles of the involucre silky; calyx-glumes membranous; those of the corolla violet-coloured. A native of sandy soil in Barbary near Mafcal. 6. *C. ramifolius*, Poir. 11. "Stem frutescent; branches dichotomous; involucre bristle-shaped, soft, naked; spikelets about four flowered." *Poir. Stems* very high, several times branched, smooth. *Leaves* smooth, long, acute, striated, a little scarious; sheaths naked and serrated at their orifice. *Flowers* terminating the branches and forming cylindrical spikes two or three inches long; spikelets, sessile, scattered, alternate, involucre composed of numerous, fine, silky, almost silvery hairs, a little longer than the flowers; calyx-valves obtuse. A native of Egypt, described from a dried specimen in the herbarium of La Marek. 7. *C. ciliaris*, Linn. Mant. 302. Mart. 7. Poir. 12. Willd. 5. Giseke ic. tab. 23. Lam. Illuf. tab. 838. fig. 3. "Involucre bristle-shaped, ciliated, enclosing four calyxes." *Root* perennial. *Stems* a foot and half high, slender, a little bent at their joints, naked at their upper part. *Leaves* narrow, somewhat villous; sheaths striated,

ciliated. *Spike* two or three inches long, cylindrical, a little interrupted; spikelets alternate, sessile, involucre composed of fine silky hairs, of a purple colour, ciliated at their base, two or three times longer than the valves of the calyx; calyxes two-flowered, one male, the other hermaphrodite; glumes membranous, unequal; ligmas violet-colored; rachis zig-zag. A native of the Cape of Good Hope, of Barbary and Egypt. 8. *C. parviflorus*, Poir. 13. "Involucre bristle-shaped, naked; spikelets generally one-flowered, very small." *Stems* from one to two feet high, slender, filiform, smooth. *Leaves* long, narrow, very acute, rough to the touch; sheaths smooth, rather loose, naked at their orifice, furnished with a short reddish membrane, a little torn at its summit. *Spike* lanceolate, somewhat compressed, greenish or purplish; spikelets sessile; involucre composed of long, stiff hairs. A native of Porto Rico. 9. *C. purpurascens*, Mart. 11. Poir. 15. Willd. 9. Thunb. Linn. Transf. vol. ii. p. 327. (Panicum hordeiforme 7; Thunb. Jap. 38.) "Spike simple; florets surrounded with very long awns; stem erect." *Stems* about two feet high. *Leaves* longer than the culm. *Spike* six or seven inches long, loose; spikelets in two rows; peduncles as long as the spikelet; bristles of the involucre purple, five or six times longer than the flowers. A native of Japan. 10. *C. festus*, Mart. 10. Willd. 6. Swartz. prod. 26. "Spike linear-oblong; involucre bristle-shaped; interior bristles with ciliated hairs at the base; glumes even." A native of the West Indies. 11. *C. geniculatus*, Willd. 7. Thunb. prod. 24. "Raceme spiked, simple; involucre many-leaved, scarious; culm geniculated." A native of the Cape of Good Hope.

* Without an involucre.

12. *C. inflexus*, Poir. 6. "Leaves lanceolate, villous; racemes lateral, inflexed, on long peduncles; spikelets sessile, florets in a single row." *Stems* branched, cylindrical. *Leaves* entirely covering the stem, an inch and half long, about four lines broad at their base, lanceolate, almost heart-shaped, finely striated, most villous on the sheath and at the edges. *Peduncles* from the axils of the upper leaves, six or seven inches long, simple, smooth; each terminated by a spike of sessile flowers, so curved at its insertion as to make nearly a right angle with the stem; spikelets lanceolate, narrow, very acute; calyx one or two-flowered; outer valve echinate with spiny points, ciliated at its edges, very acute; inner one short, villous; corolla one-valved, much shorter than the calyx, flat, smooth, obtuse. *Seed* naked, shining, oblong, cylindrical. A native of Cayenne. Described by Poirlet from dried specimens in the herbarium of Jusseu and La Marek, but not so perfect as to make him quite certain that the plant may not more properly be referred to some other genus. On account of its one-valved corolla, it appears to us to be truly an alopecurus, and might have been placed very conveniently next to *A. monspeliensis* of Linnæus, if that plant had not been determined by Schreber and Dr. Smith to have really a two-valved corolla, and therefore removed to phleum. Its rachis resembles that of pappalum. 13. *C. ovariatus*, Poir. 8. Lam. Ill. 838. fig. 2. "Leaves quite smooth, rather firm; spike densely egg shaped." *Stems* stiff, smooth, cylindrical. *Leaves* stiff, acute, rolled in at their edges; sheath cylindrical, long, narrow, furnished at its orifice with a small tuft of fine whitish hairs. *Flowers* in a thick branched spike; outer calyx-valves echinate with stiff, whitish hairs; florets smooth, oval, mucronate; two or three in each calyx. Gathered by Sonnerat at the Cape of Good Hope, preserved in the herbarium of La Marek. 14. *C. tomentosus*, Poir. 9. "Leaves tomentous-woolly on their upper surface, striated underneath; spikes obtuse, egg shaped." *Stems* upright, smooth. *Leaves* stiff, narrow, flat, a little

a little rolled in at their edges; sheaths cylindrical, striated. Spike very close, sometimes interrupted at its base; outer valves of the calyx echinated with short, stiff, unequal points; florets three or four in each calyx, oblong; valves very acute. A native of the Cape of Good Hope, preserved in the herbarium of La Marck. 15. *C. carolinianus*, Walt. Flor. Car. p. 79. "Spike glomerated; glumes globular, mucated with spines, even."

Obf. In conformity with Poirer's ideas on the subject, we have extended the generic character so as to include the last four species, which would be excluded by it, as it was originally constructed by Linnæus; without, however, being perfectly satisfied that they may not be better otherwise disposed of. 16. *C. frutescens*, Linn. Sp. Pl. 6. Mart. 9. Willd. 10. (Arundo graminea aculeata; Alp. exot. tab. 104. Gramen orientale, spicatum fruticosum, spinosum; spicis echinatis in capitulum congestis; Tourm. cor. 39.) "Heads lateral, sessile; leaves mucronate; stem shrubby." Linn. Root perennial. A native of Armenia. La Marck asserts, on the authority of Tournefort's specimen preserved in the herbarium of the museum at Paris, that its leaves have no sheaths, and that therefore it cannot be a gramineous plant. He has no doubt, notwithstanding the singularity of its habit, of its being really an eryngium. See Encyc. vol. iv. p. 756, and vol. vi. p. 53.

CENCHRUS capitatus; Linn. Mart. Willd. Poir. See ECHINARIA.

CENCHRUS lappaceus; Linn. Mart. Willd. Poir. See PANICUM lappaceum.

CENCHRUS racemosus; Linn. Mart. Poir. See LAPPAGO.

CENCHRUS granularis; Linn. Mantissa. Mart. See MANSURIS.

As these four plants are destitute of an involucre, they were improperly placed by Linnæus under his cenchrus; and as they have not an echinated calyx glume, they are equally excluded from our second section.

CENDEVIA, in *Ancient Geography*, a marsh of Asia, in Phœnicia; placed by Pliny at the foot of mount Carmel.

CENEDA, in *Geography*, a town of Italy, in the Trevisano, belonging to the state of Venice, the see of a bishop, suffragan of Udina, destroyed by the Huns and Goths; 20 miles N. of Treviso.

CENDRILLARD, in *Ornithology*, the name given by Buffon to the St. Domingo Cuckow. *Cuculus dominicus*, Gmelin.

CENDRILLE, the cinereous Lark, *Alauda cinerea* of Gmelin, is so named by Buffon in his Nat. Hist. des Ois.

CENEGILD, in the *Saxon Antiquities*, an expiatory mulet, paid by one who had killed a man to the kindred of the deceased. The word is compounded of the Saxon *cinne*, i. e. cognatio, relation, and *gild*, solutio, payment.

CENEONLATOTI, in *Ornithology*, the name by which Nierenberg described the Polyglot or American mocking Thrush; a bird celebrated for the different modulations of its notes, which excel those of the nightingale in melody.

CENERIUM, in *Ancient Geography*, a small town of the Peloponnesus, in the Elide, according to Strabo.

CENÉSPOLIS, a name given by Polybius to a town of Spain.

CENESTAM, a town placed by Ptolemy towards the middle of the island of Corfica; which was an episcopal see.

CENETZE, a town of Venetia, N. of Tarvisium.

CENGOTTO, in *Geography*, a small island in the Mediterranean; 24 miles N.N.W. of Candia. N. lat. 36° 1'. E. long. 41°.

CENIA, in *Zoology*, (*xenos*, empty), a genus formed by Jussieu for *Cottula turbinate* of Linnæus, with the following character: *Flowers* radiate; florets four-cleft, retrandrous; ligulate ones about twenty, very short; calyx top-flapped, empty under the receptacle; border short, eight-cleft; seeds compressed; receptacle convex. See LANCIVIA.

CENIA, in *Geography*, a river of Spain, which runs into the Mediterranean, 8 miles N.E. of Peguifcola, separating in its course the provinces of Catalonia and Valencia.

CENION, a river of Britain, the mouth of which is supposed to be Falmouth haven; so called from the British word "gene," a mouth; and of which there is still some vestige in the name of a neighbouring town, Tregonny.

CENIS, in *Entomology*, *Phalana Cenis* of Cramer, is the species described by Fabricius as *Phalana cœnaria*, which see.

CENIS, in *Geography*, a summit of the Western Alps, which separates the marquise of Susa from Maurienne, and over which is the famous passage from Savoy to Piedmont. At Lafnebourg on the Savoy side of the mountain, preparations are made for crossing it, which is usually performed in about 5 hours. The inns at La Ramasse and La Grand Croix, so called from the crosses near it, which is a boundary between Savoy and Piedmont, affording but very uncomfortable entertainment, in case, by any accident, persons were obliged to spend the night on the mountain, the baggage and chaises which are here taken to pieces are forwarded upon mules and asses. The Vetturini, or carriers, have generally their chaises standing on each side of the mountain, which save the trouble and expence of taking their carriages to pieces. The horses which they take with them become by degrees as well acquainted with the road over the mountains, as the mules of the country; so that betwixt Lafnebourg and Novalese in Piedmont, one may safely give them the reins. From La Grand Croix to Novalese travellers take those carriers whom they hire at Lafnebourg. In coming from Piedmont, the journey up the steep mountain from Novalese to La Grand Croix, and likewise across to La Ramasse, where the Novalese carriers take up the travellers, and forward them to Lafnebourg, is performed on mules. Down hill the mules are not so sure-footed, neither does the rider sit so well upon them as upon an ascent, which renders it necessary to be carried by men. From Lafnebourg to the summit of mount Cenis is a league, the climbing of which takes up a full hour: the two leagues from thence to La Grand Croix, being over a plain, are travelled in an hour and a half: here commences a declivity of two leagues more; one to Fertiere, and another to Novalese. In winter, when the snow is on the ground, the plain on the top of mount Cenis is crossed on sledges, drawn by a horse and a mule. The descent from La Grand Croix to Novalese mult, at all times, and even in winter, he passed in chairs; the large stones, the winding ways full of holes, and the dangerous precipices not admitting of sledges. But the descent from mount Cenis to Lafnebourg is performed in another manner. On the spot where the declivity begins is a house called la Ramasse, from whence one is carried in a sledge down to Lafnebourg, which is about a league further, in seven or eight minutes, the rapidity of the motion almost taking away the breath. These sledges hold only two persons, the traveller, and the guide who sits forward steering with a stick. On each side he has an iron chain; which he drops like an anchor, either to slacken the course of the sledge, or to stop it. This, like the carrying in chairs, is called "Ramasser les gens, aller à ramasse." The horse-road from Lafnebourg up to the Ramasse-house is very serpentine; the mules and asses are so used to it, that they are at no loss in selecting the best tracks and avoiding the stones, so that the rider may trust himself

himself to them. That the inhabitants may not exact upon strangers, the king has issued an order to regulate the price, which is generally stuck up in the post-houses. From Lafnebourg to Novalese are two roads, the old and new; the last is the worst, but the shortest, and always chosen by those who travel on mules or in chairs. The Lafnebourg chairmen are very active and expeditious in performing their labour; but notwithstanding their alertness and the extreme fatigue that seems to attend it, they attain, in the use of the most simple diet, a considerable longevity. In order the better to secure their footing, their shoes are without heels, and the soles are rubbed with wax and rosin. The machines in which travellers are carried down hill are a kind of straw chairs, with low backs, two arms, and instead of feet a little board hanging down by a cord for resting the traveller's legs. The seat, which is made of bark and ropes twisted together, is fastened to two poles, and carried, like a sedan, with broad straps.

On the summit of mount Cenis is a plain, of rather a long uneven valley betwixt very high mountains, whose tops, even in summer, are covered with snow; and in winter and spring, when vast quantities of snow fall from the hills into the valley, the journey over mount Cenis is rendered not a little dangerous. There are huts built up and down along the mountain for the herdsmen, who come hither in summer with their cattle: fine grass and several sorts of flowers being produced here, in the months of July, August, and September. This mountain, like some other parts of the Alps, abounds with chamois, wolves, marmottes, and hares. Half-way up the mountain is a lake about a league in circumference, which is said to be in the middle almost unapproachable. In this lake is fine trout, some of which weigh 16 pounds. It is constantly supplied with water from springs issuing from the adjacent eminences, which are always covered with snow, and often with clouds; and out of it flows a river, which being augmented by other springs falls down in very delightful cascades: this river is by some called Semar, by others St. Nicholas; and near Susa it loses itself in the Petite Doire or Dura. Keyser erroneously asserts, that the mountain of Roche-melon, on the left hand of Cenis, betwixt Fertierte and Novalese, is reckoned the highest of all the Italian Alps; it is 11,977 English feet above the sea; and little mount Cenis is 9,956; whereas mount Rosa exceeds 15,500; and mont Blanc is, according to sir George Stauckborough, 15,662; and according to De Luc 15,304. Keyser's Travels, vol. i.

CENNA,BA, in *Ancient Geography*, a mountain of Africa, in Mauritania Cæsariensis.

CENNING, **CENNINGA**, or **Kenninga**, in our *Ancient Books*, denotes notice given by the buyer to him of whom he had bought, that the thing purchased was claimed by another, that he might appear and avow, or warrant his bargain.

The word is formed of the Saxon *cennan*, *auðorem advocare*, to call an author. Du-Cange.

CENO, or **ZENO**, in *Geography*, a river of Italy, which runs into the Taro; 8 miles S.S.W. of Parma.

CENOBITE. See **COENOBITE**.

CENOMANI, in *Ancient Geography*, a people of Transalpine Gaul, belonging to the Aulerci, whose country corresponded to the diocese of Mans. The Cenomani also were a people who originally came from Gaul, where they inhabited the country called by moderns le Maine, and settled themselves in Italy, a little after the year 600 B.C. Their principal towns in Italy were Brixia, Cremona, Mantua, and Verona.

CENOTAPH, compounded of $\kappa\epsilon\omicron\tau\omicron$, empty, and $\tau\alpha\zeta\epsilon\omicron\varsigma$,

tomb, an empty tomb, or a monument without a body under it; erected only by way of honour to the deceased; and distinguished from *sepulchre*, in which a corpse is actually deposited.

Cenotaphs are honorary tombs, erected either to persons buried in another place, or to those who have received no burial, and whose relics cannot be found, as being killed in battle, lost at sea, or the like. Among the ancients the same privileges and religious regard were allowed to these *cenotaphi iranis & hororarii*, as to real tombs. Card. Norris has a treatise express on the cenotaphs of th. Cæsars, Cains and Lucius, which are still seen at Pifa. Lan-pud. in Alex. cap. 63.

CENSAL, in the Mediterranean parts, denotes a regular or established broker, authorized to negotiate between merchant and merchant.

CENSER, in *Antiquity*, a kind of vessel where incense was burnt to the gods.

Censer is chiefly used in speaking of the Jewish worship. Among the Greeks and Romans it is more frequently called *thuribulum*, $\lambda\upsilon\sigma\tau\epsilon\omicron\iota\omicron\varsigma$, and *accensa*, which see.

The Jewish censer was a small sort of chafing-dish, covered with a dome, and suspended by a chain. Josephus tells us, that Solomon made twenty thousand gold censers for the temple of Jerusalem, to offer perfumes in, and fifty thousand others to carry fire in.

CENSER, the same with **ARA**.

CENSIO, in *Antiquity, the act or office of the censor. See **CENSOR**. Censio included both the rating or valuing of a man's estate, and the imposing of mulcts and penalties.*

CENSIO hostoria, a punishment inflicted on a Roman soldier for some offence, as laziness or luxury, whereby his *hastia*, or spear, was taken from him, and consequently his wages, and hopes of preferment stopped.

CENSITUS, a person censured, or entered in the censural tables. See **CENSUS**.

In an ancient monument found at Ancyra, containing the actions of the emperor Octavius, we read,

“ Quo lustro civium Romanorum
Censita sunt capita quadrages
Centum millia & sexaginta tria.”

CENSITUS is also used in the *Civil Law*, for a servile sort of tenant, who pays capitation to his lord for the land he holds of him, and is entered as such in the lord's rent-roll. In which sense, the word amounts to the same with *capite census*, or *capite censitus*. See **CAPITE CENSU**.

CENSOR, in *Antiquity, one of the prime magistrats in ancient Rome; whose business was to survey and rate the people, and to inspect and correct their manners.*

The word is derived from *censere*; because he assessed and valued every man's estate; registering their names, and placing them in a proper century, that the Romans might know their own strength; though others say, the censors were so called on account of their other office; viz. as being comptrollers or correctors of manners and policy. The censors had all the ensigns of the consuls, except the licitors.

There were two censors first created in the year of Rome 311, upon the senate's observing, that the consuls were too much taken up with matters of war, to be left at leisure for looking near enough into private affairs; so that the census had been intermitted for 17 years. The two first were Papirius and Sempronius: their authority extended over every person; and they had a right to reprehend the highest. At first they were taken out of the senate; but after the plebeians had got the consulate open to them, they soon arrived

eived at the censorship. M. Rutilius was the first; who, having been twice consul and once dictator, in the year 402 demanded the office of censor. The custom was to elect two; the one of a patrician family, the other a plebeian; and upon the death of either, the other was discharged from his office, and two new ones elected; but not till the next lustrum. In the year 413, a law was made, when Publius Philo was dictator, appointing one of the censors to be always elected out of the plebeians; which held in force till the year 622, when both censors were chosen from among the people, viz. Q. Cæcilius Metellus, surnamed Macedonicus, and Q. Pompeius; after which time, it was shared between the senate and the people.

The last censors, viz. Paulus and Planus, under Augustus, are said to have been private persons; not, indeed, that they had never borne any public office before, but by way of distinction from the emperor; all besides him being so called.

This office was so considerable, that none aspired to it till they had passed all the rest: so that it was looked on as surprising, that Crassus should be admitted censor, without having been either consul or prætor. The term of this office was at first established for five years; but that institution only lasted nine; Mæmæus Æmilius the dictator, in the year 320, made a law, restraining the censorship to a year and a half; which was afterwards observed very strictly. Thus, Rome was regularly without censors 3½ years; for the lustrum did not take place till the end of the fifth year. But this order was often interrupted, either by wars abroad, or domestic divisions, or some other particular reasons. Sometimes five years expired without the creation of any censors; on other occasions censors were created more than once during the space of a lustrum, if those who had been first chosen had not been able to complete the census.

The power of the census was at first very limited; but afterwards it became very extensive. All the orders of the state were subject to them. Hence the censorship is called by Plutarch (in Cat. Maj.) the summit of all preferments, "omnium honorum apex, vel summus;" and by Cicero (in Pif. 4.) "magistra pudoris et modestiæ." The title of censor was esteemed more honourable than that of consul; as appears from ancient coins and statues; and it was reckoned the chief ornament of nobility to be sprung from a censorian family.

The sentence of censors only affected the rank and character of persons; and it was therefore properly called "ignominia;" and in later times had no other effect besides putting a man to the blush, or, as Cicero expresses it, "nihil fore damnato afferbat præter roborem." It was not fixed and unalterable, like the decision of a court of law; but might either be taken off by the next censors, or rendered ineffectual by the verdict of a jury, or by the suffrages of the Roman people. Thus we find C. Cæta, who had been excluded the senate by the censors, A.U. 639, the very next lustrum made himself censor. Sometimes the senate added force to the feeble sentence of the censors, by their decree, which imposed an additional punishment. When the censors acted improperly, they might be brought to a trial, as they sometimes were, by a tribune of the commons. Two things were peculiar to the censors: 1. No one could be elected a second time to that office, according to the law of C. Martius Rutilius, who refused a second censorship when conferred upon him, hence surnamed "Censorinus." 2. If one of the censors died, another was not substituted in his room; but his surviving colleague was obliged to resign his office. The death of a censor was deemed ominous, because it had happened that a censor died, and another was chosen

in his place, in that lustrum in which Rome was taken by the Gauls. Before the censors began to exercise their office, they swore that they would do nothing through favour or hatred, but that they would act uprightly; and when they resigned their office, they swore that they had done so. Then going up to the treasury, they left a list of those whom they had made "ararii." A record of their proceeding was kept in the temple of the Nymphs, and is also said to have been preserved with great care by their descendants.

The business of the censors was, to register and value the effects, &c. of the Roman citizens; and to impose taxes, in proportion to what each person possessed. Cicero reduces their functions to the numbering of the people; the correction and reformation of manners; the estimating of the effects of each citizen; the proportioning of taxes; the superintendance of tribute; the exclusion from the temples, and the care of the public places. They had also a right, *senatu ejicere*, to expel from the senate such of the members as they judged unworthy of the dignity; as well as to break and calumniate the knights who failed in their duty, by taking from them the public horse, *equum adimere*.

There are many examples of senators expelled by the censors, generally for good reasons, yet sometimes through mere peevishness, envy, or revenge; but in such cases, there was always the liberty of an appeal to the final judgment of the people. So that the censorian power, properly speaking, was not that of making or unmaking senators, but of enrolling only those whom the people had made; and of inspecting their manners, and animadverting upon their vice; over which they had a special jurisdiction delegated by the people. Their rule of censoring seems to have been grounded on an old maxim of the Roman policy, enjoining, "that the senate should be pure from all blemish, and an example of manners to all the other orders of the city;" as we find it laid down by Cicero in his "Book of Laws," which were drawn, as he tells us, from the plan of the Roman constitution.

Besides the talk of enrolling the senators, and inspecting their manners, it was a part likewise of the censorian jurisdiction to let out to farm all the lands, revenues, and customs of the republic; and to contract with artificers for the charge of building and repairing all the public works and edifices, both in Rome, and the colonies of Italy. Now in this branch of their office it is certain that they acted merely under the authority of the people, and were prohibited by law to let out any of the revenues, except in the rotura, under the immediate inspection and in the very presence of the people.

In the general census and review of the city, held by them every five years, though every single citizen was particularly summoned and enrolled by name in his proper tribe, as a freeman of Rome, yet that solemn enrolment, as Cicero tells us, did not confirm any man's right to a citizenship, but signified only that he had passed for a citizen at that time; because the proper power of determining that right resided always in the people. (Cicero pro Arch. 5. Liv. x. 52. Middleton of Rom. Sen. p. 59. 68. 70. 83, &c.)

When Rome had extended her conquests, and founded many colonies, or given the freedom of the city to many of her neighbours, the functions of the censors became proportionably more extensive. Officers, who were also called censors in those colonies, and municipal cities, gave the senators of Rome an account of the condition of those cities, of the number of their inhabitants, and of their riches; and their reports were registered in the books of the censors. The power of the censors continued unpaired to the tri-

franchise of Clodius, A. U. 695, who procured a law to be enacted, ordering that no senator should be degraded by the censors, unless he had been formally accused and condemned by both censors; but this law was abrogated, and the powers of the censorship restored soon after by Q. Metellus Scipio, A. U. 702.

The office continued to the time of the emperors, who assumed the authority of it to themselves, but without the name, calling themselves, instead of censors, *morum præfæcti*; though Vespasian and his sons took a pride to be called censors, and put this among their other titles on their coins. Decius attempted to restore the dignity to a particular magistrate. After this we hear no more of it till Constantine's time, who made his brother censor: the last who seems to have enjoyed the office.

The necessity of appearing at certain times before the tribunal of the censors, to give an account of their conduct, imposed universally on all the citizens, and from which neither birth, services rendered to the state, nor the most important offices previously exercised, as those of consul and dictator, exempted any one, must have been a powerful check upon licentiousness and disorder. There are, says the author of "Considerations upon the Causes of the Greatness and Declension of the Romans," bad examples, which are more pernicious even than crimes, and more states have been ruined by corrupting their manners than by violating their laws. At Rome, whatever might introduce dangerous innovations, change the sentiments or inclinations of the good citizen, and prevent their perpetuity; in a word, all disorders of a public or private nature were reformed by the censors. If luxury and avarice, the usual causes of the ruin of states, were introduced so late at Rome; if poverty, frugality, simplicity, and moderation in the table, buildings, furniture, and equipage, were so long in honour there, this extraordinary felicity ought, without doubt, to be ascribed principally, or in a great degree, to the inexorable severity of the censors, rigidly attached to the ancient manners of their country, from which they well knew how important it was not to depart. The austerities of the censorship produced at Rome the same effect, in respect to manners, as the severity of the military discipline did in the armies with respect to the support of subordination and obedience. And these were the two principal causes of the Roman greatness and power. Whatever victories are gained, whatever provinces are subjected, if purity of manners do not prevail in the different orders of a state; if the administration of justice, and the power of the government, be not founded upon invariable equity and a sincere love of the public good, however powerful an empire may be, it cannot subsist long. (Val. Max. l. ii. c. 9.) The sanctity of oaths was no where so much respected as at Rome. This was, as Cicero remarks, (Offic. l. iii. c. 3.), because no crimes were so severely punished by the censors, as breach of faith and contempt of oaths. Upon the whole, we may observe, that upon the office of censorship depended, in a great degree, the good order, regulation, discipline, conservation of the manners, and administration of the revenues of the commonwealth. See on the subject of this article, Dion. Hal. Dion. Cassius. Livy. Cicero. Val. Max. Suetonius. Tacit. Annal. &c. &c.

The republic of Venice has at this day a censor of the manners of their people, whose office lasts six months.

CENSORS of books are a body of doctors, or other officers, established, in divers countries, to examine and give their judgment of all books, before they go to the press; and to see they contain nothing contrary to the faith, and good manners. In England we had formerly an officer of this

kind, under the title of *licencer of the press*; but since the revolution the press has been open.

At Paris, the faculty of *theology* claimed the privilege of censors, as granted to them by the pope; and it is certain they have been in possession of it for many ages: but in the year 1624, a new commission of four doctors was created, by letters patent, the sole public, and royal censors, and examiners of all books; and answerable for every thing contained therein. The faculty, however, still maintained their claim, by taking occasion, now and then, to give their approbation to books.

In the year 1750, when public censors were appointed without their consent, whom the faculty opposed, they stated the antiquity of their right to be 200 years. For they said, "It is above 200 years since the doctors of Paris have had a right to approve books without being subjected but to their own faculty, to which they assert they are alone responsible for their decisions."

Many centuries before the invention of printing, books were forbidden by different governments, and even condemned to the flames. See *Burning of Books*. Authors, at this early period, submitted their works, before they were published, to the judgment of their superiors. This was principally done by the clergy; partly to secure themselves from censure or punishment, and partly to manifest respect for the pope or bishops. This, however, does not appear to have been, on their part, a duty, but a voluntary act. In 768, Ambrosius Autpert, a Benedictine monk, sent his exposition on the book of Revelation, to pope Stephen III. and begged that he would publish the work, and make it known. On this occasion, he says expressly, that he is the first writer who ever requested such a favour; that liberty to write belongs to every one who does not wish to depart from the doctrine of the fathers of the church; and he hopes that this freedom will not be lessened on account of his voluntary submission. Soon after the invention of printing, laws began to be made for subjecting books to examination; a regulation proposed even by Plato; and which has been wished for by many since. It is, indeed, very probable, that the apprehensions of the clergy, lest publications should get abroad prejudicial to religion, and consequently, to their power, contributed not a little to hasten the establishment of book-censors. The earliest instance of a book printed with a permission from government is commonly supposed to occur in the year 1480; but professor Beckmann mentions two books, which were printed almost a year sooner than 1479, with the approbation of the public censor. The oldest mandate for appointing a book censor, that has occurred to him, is that issued by Berthold, archbishop of Metz, in the year 1486. In 1501, pope Alexander VI. published a bull, which contains several prohibitions and regulations, with regard to the printing of books, and decrees all catalogues and books before that period to be examined, and those which contained any thing prejudicial to the Catholic religion to be burned. In the council of Lateran, held at Rome in 1515, it was ordered, that in future no books should be printed but such as had been inspected by ecclesiastical censors. Beckmann's Hist. of Inventions, vol. iii.

CENSORIAL, CENSORIUS, something that relates to the office of censor. In this sense we meet with *censoria nota*, or *animadversio, censoria virgula*, &c.—*censoria lex*, denoting a law passed or enacted by the censors:—*homo censorius*, a person who has borne the dignity, and served the office of censor:—*virgula censoria*, which, among the ancient *Grammarians* and *Critics*, denoted a note or mark of reprobation, affixed to those passages of a book or writing, which the critic disapproved or condemned.

CENSORINUS, in *Biography*, a learned grammarian, is supposed to have been of the Martian family, and to have been eminent at Rome in the times of Alexander Severus, Maximian, and Gordian. In the first year of the emperor Gordian, A.U.C. 991, A.D. 238, he wrote his famous book "De Die Natali," which has been of great use to chronologers by connecting the principal æras of various events of antiquity. It was dedicated to Q. Cerellius, of the equestrian order, and has been often cited with commendation by Sidonius, Cassiodorus, Priscian, and others. This work has passed through a great number of editions. It was printed at Hamburg, in 1614, with a perpetual commentary, by Lindentrog; at Leyden, with additional notes, in 1642; at Cambridge in 1695; and by Havercamp in 1743. Censorinus also wrote a book "On Accents." Fab. Bib. Lat. vol. ii.

CENSUAL, Books, *libri censuales*, those wherein the census was taken down.

CENSUALES, in a substantive sense, denoted the clerks or public scribes who wrote the *censual* books.

CENSUALES, in *Ecclesiastical Antiquity*, denoted also a class of the *oblato*, or voluntary slaves of churches or monasteries; or those who, for procuring the protection of the church, bound themselves to pay an annual tax or quit-rent out of their estates to a church or monastery. Besides this, they sometimes engaged to perform certain services. Robertson's Ch. V. vol. i. p. 326.

CENSURE, CENSURA, is popularly used for a judgment, whereby some book, person, or action is blamed or condemned; more particularly for a reprimand made by a superior, or person in authority.

CENSURE is also a custom, in several manors in Cornwall and Devon, whereby all the tenants above the age of sixteen are called to swear fealty to the lord, to pay two-pence per poll, and a penny *per annum* ever after, as *cert-money*, or common fine.

CENSURES, *ecclesiastical*, are the public menaces which the church makes, or pains and penalties incurred by disobeying what she enjoins; or rather the pains and punishments themselves; as interdiction, excommunication, &c.

Till the time of the Reformation, the kings of England were subject to the censures of the church of Rome; but the kings of France have always maintained themselves exempt from them.

The canonists distinguish two kinds of censures; the one *de jure*, and the other *de facto*, or by sentence.

CENSUS, among the Romans, was an authentic declaration made upon oath by the several subjects of the empire, of their respective names, and places of abode, before proper magistrates in the city of Rome, called *censores*; and in the provinces, *censitores*, by whom the same were registered.

This declaration was accompanied with a catalogue, or enumeration, in writing, of all the estates, lands, and inheritances they possessed; their quantity, quality, place, wives, children, tenants, domestics, slaves, &c.

Those who neglected to conform to this regulation were deprived of their estates, beaten with rods, and publicly sold for slaves, as persons who had deemed themselves unworthy of liberty.

The census was instituted by king Servius Tullius; to be held every five years: and this prince took the census four times during his reign. Tarquin the Proud neglected this useful institution. After the expulsion of the kings, the consuls were charged with this care till the establishment of

the censors. Each census terminated with a ceremony called *lustrum*, which see.

There had been ten census, or lustra, before the first taken by the censors, which was the eleventh. See CENSOR. Servius, having by this regulation ascertained the valuation of the estates of the citizens, divided them into six classes, and each class into a certain number of *centuriaz*. See CENTURV. By thus ascertaining the number of citizens and the value of their estates, Servius undertook to ease the poor by increasing the burdens of the rich, and, at the same time, to please the latter, by augmenting their power and influence. The census was taken anciently in the forum; but after the year 320, in the villa publica, which was a place in the Campus Martius; but the census was sometimes held without the concluding ceremony of the lustrum. The census comprehended all the ranks of people, though under different names; that of the common people was called *census*, or *lustrum*; that of the knights, *census, recensio, recognitio*; that of the senators, *lectio, relectio*. Hence, also, census came to signify a person who had made such a declaration: in which sense it was opposed to *incensus*, a person who had not given in his estate, or name, to be registered.

The census among the old Romans was held, as is commonly thought, every five years; but this must not be taken to be precisely true: on the contrary, Dr. Middleton has shewn, that both the census and lustrum were for the most part held irregularly and uncertainly, at very different and various intervals of time. See LUSTRUM.

The census was an excellent expedient for discovering the strength of the state: by it they learnt the number of the citizens, how many were fit for war, and who for offices of other kinds; how much each was able to pay of taxes towards the charge of the war.

The census, according to Salsafius, was peculiar to the city of Rome. That in the provinces was properly called *profectio* and *απογραφή*. But this distinction is not every where observed by the ancients themselves.

In the provinces, the census not only served to discover the substance of each person, but where, and in what manner and proportion, tributes might be best imposed.

CENSUS was also used for the book or register wherein the professions of the people were entered. In which sense the census was frequently cited and appealed to, as evidence in the courts of justice.

CENSUS is also used to denote a man's whole substance or estate.

CENSUS *senatorius*, the patrimony of a senator, which was limited to a certain value; being at first rated at eight hundred thousand sesterces, but afterwards, under Augustus, enlarged to twelve hundred thousand. Sueton. in Cæs. cap. 41.

CENSUS *equitæ*, the estate or patrimony of a knight, rated at four hundred thousand sesterces, which was required to qualify a person for that order, and without which no virtue or merit was available. Suet. in Cæs. cap. 33. Hor. lib. i. ep. l. ver. 57, 58, 59.

CENSUS was also used for a person worth an hundred thousand sesterces, or who was entered as such in the census tables on his own declaration. In which sense, census amounts to the same with *classis*, or a man of the first class; though Gellius limits the estate of those of this class to an hundred and twenty-five thousand asses. By the Voconian law no census was allowed to give by his will above a fourth part of what he was worth to a woman. Aul. Gell. Noct. Att. lib. vii. cap. 13. Cic. in Verr. 3.

Census was also used to denote a tax or tribute imposed on persons, and called also capitation. See CAPITE *conf.*

Census dominicanus, in *Writers of the Lower Age*, denotes a rent due to the lord.

Census duplicatus, a double rent or tax, paid by vassals to their lord, on extraordinary or urgent occasions; as expeditions to the Holy Land, &c.

Census ecclesie Romanae, was an annual contribution, voluntarily paid to the see of Rome by the several princes of Europe.

Census ficus, that paid in money.

CENT, in *Commerces*, an abbreviation of the Latin *centum*, which properly signifies a hundred. It is applied when expressing the profit or loss upon any commodity.

CENT is also used in the trade of money, and signifies the benefit, profit, or interest of any sum of money which is laid out for improvement. Thus we say money is worth 3 or 5 *per cent.* upon exchange; that is, it brings four or five pounds profit for every 100*l.* laid or lent out.

CENT is also used with regard to the draughts or remittances of money, made from one place to another. Thus we say it will cost 2½ *per cent.* to remit money to such a city.

CENTA, in *Ancient Geography*, a town of Africa, in Mauritania Tingitana. Ptol.

CENTALLO, in *Geography*, a town of Italy, in the principality of Piedmont; 4 miles N. of Coni.

CENTAUREA, in *Botany*, (κένταυρος; or κενταύριον βοτανικόν, herb centaury; κενταύριον, Theophr. Dioscor.; κένταυρος, Theophr. fo called from Chiron the Centaur, who is said to have employed one of its species to cure himself of a wound accidentally received by letting one of the arrows of Hercules fall upon his foot.) Linn. gen. 984. Schreb. 1331. Willd. 1548. Class and order, *syngnesium polygamia fruticosa*. Nat. Ord. *Compositae capitata*, Linn. *Cinarocephala*, Juss. Vent.

Gen. Ch. *Cal.* common, imbricated, roundish; scales variously terminated. *Cor* compound, floscular; florets differing in form; those of the disc hermaphrodite, numerous; those of the ray fewer, looser, larger, funnel-shaped, constantly abortive; tube of the hermaphrodite florets filiform; border bellying, oblong, erect, terminated by five linear erect segments: tube of the abortive florets slender, gradually enlarging, recurved; border oblong, oblique, unequally divided. *Stam.* of the hermaphrodite florets: filaments five, capillary, very short; andthers united into a hollow cylinder, the length of the petal; of the abortive florets none. *Pist.* of the former: germ small; style filiform, the length of the filaments; stigma very obtuse, projecting in a point, in many species bifid; of the latter, germ very small; style scarcely any; stigmas none. *Seeds* of the fertile florets solitary; down in most species feathered or capillary; recept. bristly.

Eff. Ch. Receptacle bristly. Florets of the ray funnel-shaped, longer, abortive.

This extensive genus was formed by Linnaeus as a kind of common receptacle for such plants as would have been placed under some other genus of compound capitate flowers, if they had not had a ray of abortive florets, which, by the principles of his system, obliged him to place them in his third artificial order, at a distance from their natural congeners. It contains centaureum majus of Tournefort; jacea and cyanus of Tournefort and Vaillant; calcitrapa, calcitrapoides, rhaponticum, rhaponticoideis, amberboi, and crocodillum of Vaillant. Most of these have been revived by Jussieu as separate genera, with some alterations, and are retained by Ventenat.

1. *Jacea*, Scales of the calyx even, neither ciliated nor spinous. (*Centaurea*, Juss.)

Sp 1. *C. crupinea*, Linn. Sp. Pl. 1. Mart. 1. Lam. 8. Willd. 1. (*Jacea annua*, Toura. Inst. 444. *Chondrilla foliis laciniatis*, Bauh. Pin. 150. Barrel. Ic. 1139. *Centaureum eliare*, Morf. tab. 5. fig. 3.) "Calyx-flores linear-awl-shaped; leaves pinnated, serrated." Linn. "Calyces oblong; scales lanceolate; acute; leaves pinnated, finely serrated." Lam. "Calyx-flores lanceolate; leaves pinnated, scabrous; pinnules linear, acute, finely serrated." Willd. Black-seeded centaury, beard'd creeper, Ray. *Root* annual. *Stem* three feet high, striated, almost simple. *Flowers* terminal; florets in the disc three; in the ray five, quadrifid. Usually one or two seeds ripened in a flower, crowned with a black down, so stiff as to make the seeds creep when held in the hand; whence the trivial name *crupinea*, from the Dutch *cruppen*, to creep. A native of the south of Europe, the coast of Barbary, and the Levant. 2. *C. crupinoides*, Willd. 2. Desfont. Atl. ii. p. 273. "Leaves pinnated; pinnules lanceolate, 1x-tooth, obtuse, toothed; down chaffy." *Root* annual. A native of Barbary. 3. *C. arenaria*, Willd. 3. "Calyx-flores lanceolate; lower leaves pinnated; pinnules linear, quite entire; upper ones linear, simple." *Root* annual. *Stem* angularly furrowed, paneled. *Leaves* and calyxes clothed with a slight, woolly, pubescence. A native of Russia, on the banks of the Volga. 4. *C. glauca*, Willd. 4. "Calyces pubescent; scales roundish, obtuse; leaves deeply pinnatifid; lowest segments toothed." A native of mount Caucasus. 5. *C. mychata*, Linn. 2. Mart. 2. Lam. 6. Willd. 5. *Cyanus moschatuus*, G. Mart. 2. Lam. 6. Willd. 5. (*Cyanus moschatuus*, G. Mart. 2. Lam. 6. Willd. 5. *C. floridus* major, Park. 481. Tourn. 445. Rai Hist. 322.) Purple sweet fulan. "Calyces roundish, smooth; scales egg-shaped; leaves lyrate-toothed." Linn. "Calyces roundish, smooth; leaves long, pinnatifid, somewhat lyrate; flower purple, with a smell of musk." Lam. "Calyces pubescent; scales roundish, rather obtuse; leaves shortly pinnatifid; lowest segments nearly entire." Willd. *Root* annual. *Stem* two feet high, channelled, smooth, braeched. *Flowers* terminal, solitary, pale purple, red, or white. A native of Persia, brought into England from Consta: inopla, and cultivated in 1629. 6. *C. furcicolens*, Willd. 6. Yellow sweet fulan. (*C. moschata*, β, amberboi, Linn. Sp. Pl. C. amberboi, Lam. 5. C. orientalis flore luteo, Morf. tab. 25. fig. 9.) "Calyces roundish, smooth; lower leaves broad, somewhat spatulate, toothed; upper ones lyrate at the base; flower yellow, sweet-scented." Lam. "Calyces smooth; scales roundish-egg-shaped, rather obtuse, spatulate at the tip; leaves lyrate-pinnatifid." Willd. *Root* annual. *Stem* a foot and a half high. *Flowers* bright yellow; barren florets larger than those of the preceding species; calyx-flores very smooth and even. A native of the Levant. 7. *C. verbajijolia*, Willd. 7. Vahl Symb. i. p. 75. (*C. maxima*, Forsk. Def. 152.) "Leaves elliptical, tomentous; stem shrubby." *Root* perennial. Whole plant white, with down. *Branches* cylindrical. *Leaves* about seven inches long, alternate, petioled, approximate, toothed, ending in a rigid point, veined, ribbed; petiole an inch long, dilated at the base. *Flowers* violet-coloured, terminal, peduncled, two or three together; bracts an inch long, lanceolate, petioled; calyx an inch long, egg-shaped, imbricated; scales egg-shaped, brown at the tip. A native of Arabia Felx. S. C. *Crucifolia*, Linn. Sp. Pl. 3. Mart. 3. Willd. 8. (*Jacea foliis crucis*, Tourn. Inst. 444. *Amberboi*, Vaill. *Stæbe major foliis eruceis*, Bauh. Pin. 271.) "Calyx-flores lanceolate; leaves lanceolate, somewhat toothed; woolly." *Root* annual. *Stem* a foot

foot high, furrowed, rough, with hairs. *Branches* numerous, erect. *Leaves* near the bottom pinnatifid; legumes about six. *Flowers* bright purple, axillary, and terminal; peduncles long, rough with hairs, two or three-flowered; calyxes pubescent. Native country unknown. 9. *C. Lippii*, Linn. Sp. Pl. 4. Mart. 4. Lam. 7. Willd. 9. (*Ambiculi minus*, Hu. Act. 17. 9. tab. 10.) "Calyx-scalcs mucronate; leaves somewhat decurrent, lyrate-toothed. *Root* annual. *Stem* a foot high, slender, much branched, with the habit of *C. cyanus*. *Leaves* angular, few. *Flowers* faint purple, terminal, smaller than those of *C. cyanus*. Sent to Jusseu from Grand Cairo by Dr. Lippi; cultivated by Miller in 1759. 10. *C. africana*, Lam. 4. Willd. 10. Desfont. Atl. n. p. 264. (*Centaurium majus laciniatum*, Tourn. Inst. 447. *Rhapontocoides*, Vaucl. Act. 17. 8. p. 180.) "Calyx-scalcs egg-shaped, obtuse; leaves almost bipinnate; pinnæ pinnatifid, bicinate." Lam. *Root* perennial. *Stems* several, four feet high, upright, smooth, a little branched. *Root-leaves* pinnate; pinnæ large, toothed, cut smooth; stem-leaves almost bipinnate, quite smooth, green. *Flowers* bright yellow, large, terminal; calyx-scalcs very smooth, convex. A native of the north of Africa; cultivated at Paris. 11. *C. alpina*, Linn. 6. Mart. 5. Lam. 2. Willd. 11. (*Centaurium alpinum luteum*, Bault. Pin. 117. Tourn. 449. Morif. Hist. tab. 25. fig. 5. Barrel. 1c. 514.) "Calyx-scalcs egg-shaped, obtuse; leaves pinnate, smooth, quite entire; odd one serrated." Linn. *Root* perennial. *Stem* two or three feet high, cylindrical, smooth. *Leaves* rather glaucous. *Flowers* yellow, large, terminal. A native of mount Baldo. 12. *C. centaurium*, Linn. Sp. Pl. 7. Mart. 6. Lam. 1. Willd. 12. (*Centaurium majus*, solo in laciniis plures divisio, Bault. Pin. 117. Tourn. 449.) "Calyx-scalcs egg-shaped; leaves pinnate; leaflets decurrent, serrated." Linn. "Calyx-scalcs egg-shaped, obtuse; leaves pinnate, smooth; leaflets sharply double-serrate, decurrent; terminal one lanceolate." Willd. *Root* perennial, long, large, reddish within. *Stems* four or five feet high, upright, cylindrical, smooth, branched. *Leaves* large, green. *Flowers* yellow, large, terminal. A native of the Alps, supposed to be the trillia centaurea of Lucretius, the thesilla centaurea of Lucan, and the graveolentia centaurea of Virgil, by all which authors it is expressed in the plural number of the neuter gender. 13. *C. ruthenica*, Lam. 3. Willd. 13. Gmel. Sib. ii. p. 87. tab. 41. "Calyx-scalcs egg-shaped, obtuse; leaves pinnate smooth; leaflets cartilaginous, sharply serrated; terminal one oblong-egg-shaped." Willd. *Root* perennial. *Stems* three or four feet high, smooth. *Leaves* numerous. *Flowers* pale yellow. 14. *C. nana*, Willd. 14. Desf. Atl. ii. p. 296. tab. 241. "Stemlets; calyx-scalcs egg-shaped, rather acute; leaves lyrate-toothed, smooth." *Root* perennial. *Leaves* pinnate; leaflets egg-shaped. *Scapes* very short, one-flowered. *Flowers* yellow; barren florets short, trifid, or quadrifid. A native of mount Atlas, near Tlemcen.

11. *Rhapontica*. *Calyx-scalcs fœracious or dry; neither chalcid, nor spinous.* (*Rhaponticum*, Jull.)

15. *C. Bohen*, Linn. Sp. Pl. 26. Mart. 25. Lam. 12. Willd. 60. (*Behen album*, Raw. Hin. tab. 258. Garf. Exot. tab. 6. *Serratula zfinis*, Bault. Pin. 235. *Jacea orientalis patula*, Tourn. Cor. 32.) "Calyxes conical; scales quite entire; leaves coriaceous, reticularly veined; root-ones lyrate; stem-ones embracing the stem, decurrent." *Root* perennial. *Stem* a foot and a half high, smooth, leafy, with simple branches. *Root-leaves* long, petioled; stem-leaves small, smooth, obtuse. *Flowers* yellow, terminal, solitary; calyx a little coloured, but scarcely fœracious. A native of Syria, about mount Lebanon. 16. *C. repens*, Linn. Sp. Pl. 28. Mart. 29. Lam. 13. Willd. 61.

(*Jacea orientalis cyani folio*, Tourn. Cor. 32.) "Leaves lanceolate, toothed, somewhat petioled; peduncles filiform, leaflets." *Root* perennial. *Stem* angular, smooth, branched. *Leaves* smooth, rough at their edges, narrowed into a petiole. *Peduncles* the length of the leaves; calyx scales acute, entire. A native of the Levant. 17. *C. ficaria*, Willd. 62. Pallas. "Calyxes cylindrical; scales roundish, quite entire; leaves lanceolate; lower ones somewhat toothed at the base; stem pinnate; branches leafy, one-flowered." *Stem* a foot and a half high, furrowed, upright; branches flagellate. *Leaves* broad-lanceolate, rather acute, scabrous at the edges. *Flowers* purple. Found by Pallas about the Caspian sea. 18. *C. Jacea*, Linn. Sp. Pl. 29. Mart. 30. Lam. 17. Willd. 63. Flor. Dan. tab. 519. (*Jacea nigra pratensis*, latifolia, Bault. pin. 271.) *β. Jacea*, nigra angulifolia. "Calyx-scalcs egg-shaped, lacinated at the tip; leaves lanceolate, quite entire; root leaves sometimes toothed; branches angular." *Root* perennial. *Stems* from eight inches to three feet high. *Leaves* scattered, acute, often a little cottony, and whitish. *Flowers* purple, terminal, solitary; florets of the ray long, two-lipped; two inner divisions erect; three lower ones pendulous; florets of the disc unequally cut; down of the seed consisting of a few short, deciduous bristles. A native of the south of Europe. 19. *C. amara*, Linn. Sp. Pl. 27. Mart. 31. Willd. 64. (*C. Jacea γ, Lam. Cyanus repens*; Lob. ic. 548.) "Stems decumbent; leaves lanceolate, quite entire." *Root* perennial. *Stems* two or three from the same root; simple, angular, hoary with down, one-flowered. *Root-leaves* petioled, lanceolate, toothed and pinnatifid, tomentous; stem-leaves sessile, linear, usually fœcate. *Flower* only half as large as that of *C. Jacea*. A native of Italy, and the south of France. 20. *C. alba*, Linn. Sp. Pl. 30. Mart. 32. Willd. 65. (*C. Jacea β, Lam. Jacea calyculis argenteis minor*, Tourn. 444. Stæbe n. 6. Bault. pin. 273.) "Calyx-scalcs entire, mucronated; leaves pinnate-toothed; stem-ones linear, toothed at the base." Very nearly allied to *C. Jacea*. *Root* perennial. *Stem* pinnate. *Leaves* acuminate, those nearest the top quite entire. *Calyxes* terminal, egg-shaped, small; scales loose, snow-white. A native of Switzerland and Spain. 21. *C. splendens*, Linn. Sp. Pl. 31. Mart. 33. Lam. 14. Willd. 69. (*Stæbe calyculis argenteis major*, Tourn. 444. Stæbe, Bault. pin. n. 5. *Rhaponticum*, Hall. helv. n. 5.) "Calyxes egg-shaped; scales mucronated; lower leaves bipinnatifid, linear; upper ones pinnate; pinnæ linear, sometimes toothed." *Root* biennial. *Stems* two or three feet high, angular, hard, smooth, many-flowered. *Leaves* toothed, or slightly tomentous. *Flowers* purple, with a beautiful silvery calyx. A native of Switzerland, Spain, and Siberia; cultivated by Gerard in 1597. 22. *C. nitens*, Willd. 67. (*Jacea*, Buxb. cent. 2. p. 22. tab. 15. fig. 1.) "Calyxes cylindrical; scales mucronated; leaves pinnate; pinnæ linear, mucronated, quite entire." Nearly allied to the preceding, but differs in having longer branches beset with minute leaves; leaves not bipinnatifid, longer pinnæ, and calyxes twice as large. *Root* annual. A native of mount Caucaus. 23. *C. tagana*, Willd. 68. Brot. Phyt. g. Lucht. tab. 3. (*Centaurium*, Bault. pin. 117. n. 2.) "Calyx-scalcs roundish, quite entire; leaves oblong, smooth; root-ones serrate"; stem-ones sometimes slightly cut at the base." *Root* perennial. A native of Portugal. 24. *C. rhapontica*, Linn. Sp. Pl. 32. Mart. 37. Willd. 69. (*Centaurium*, Hall. helv. n. 163. *Rhaponticum*; Lob. ic. 588. Bault. pin. 17. n. 5 and 6.) "Calyx-scalcs lacinated; leaves ovate-oblong, finely toothed, tomentous underneath." *Root* perennial, thick, round, black, wrinkled, and irregular, striking deep into the ground, aromatic when dry. *Stem* from a foot and a half to four feet high. *Root-leaves* nume-

rous, somewhat heart-shaped, on long petioles; stem-leaves few, on short petiole. sometimes pinnatifid. *Flowers* purple, solitary, large, without any barren florets; La Marck on that account has discarded it from this genus, and Gærtner has referred it to *Serratula*. 25. *C. baly-nica*, Linn. Mant. 460. Mart. 3. Lam. 9. Willd. 70. (*Serratula* Babylonica, Linn. Sp. Pl. Jacea Babylonica, Bauh. prod. 1. 9. pin. 372. Centaurium Helveticum, Tourm. cor. 37. Morif. hilt. tab. 28. fig. 10.) "Calyxes conical, hard; scales ending in a patulous point; leaves somewhat tomentous; decurrent, undivided; root-ones lyrate." *Root* perennial. *Stems* six or seven feet high, simple, upright, winged, a little woolly. *Root-leaves* very large, a foot and a half long, upright, petioled; stem-leaves diminishing in size from the bottom to the top, giving the plant a pyramidal form, rough to the touch. *Flowers* yellow, nearly sessile; in a very long, upright, terminal raceme, growing in bunches three or four together along the raceme; calyx almost smooth, made rough by the little expanding points which terminate the lobes. A native of the Levant. 26. *C. alata*, Lam. 10. Mart. 69. Willd. 58. Vahl. symb. 2. 53. "Calyxes egg-shaped, smooth; scales somewhat scarious at the tip; leaves greenish, decurrent, undivided; radical ones lyrate." *Root* perennial. *Stems* four feet high, smooth, a little angular, branched near the top, forming neither a spike, nor a raceme. *Root-leaves* considerably less than those of the preceding species, nerves, very little downy; stem-leaves narrow. *Flowers* bright yellow; calyx scales slightly scarious at the tip. Willdenow attributes to it ferrated; and Vahl, ciliated calyx-scales. Described by La Marck from a living plant, in the royal garden at Paris, where it had long been cultivated, supposed to be a native of Tartary. 27. *C. glabifolia*, Linn. Sp. Pl. 33. Mart. 36. Lam. 11. Willd. 71. Curt. Bot. mag. 62. (Centaurium majus orientale, glabifolium, flore luteo, Comm. rar. tab. 39. Tourm. cor. 32.) "Leaves undivided, quite entire, decurrent." *Root* perennial, striking deep into the ground. *Stems* four feet high, greenish, a little winged with the decurrent leaves, branched at their top. *Root-leaves* shaped like those of Wood, upright, on long petioles, with prominent veins on both sides; stem leaves oblong, narrow. *Flowers* bright yellow, terminal; barren florets less than the others; calyx-scales loose, silvery, transparent. A native of the Levant. 28. *C. conferta*, Linn. Sp. 54. Mart. 37. Lam. 15. Willd. 72. (Centaurium majus incanum humile, capite pini, Tourm. 449. Jacea incana capite pini, Bauh. pin. 272. Morif. hilt. tab. 26. fig. 19. Chameleon non aculeatus; Lob. ic. 2. p. 7. Stæbe, Barr. ic. 38.) "Leaves tomentous; root ones lanceolate; stem ones pinnatifid; stem simple." *Stem* six or eight inches high, upright, striated, cottony. *Leaves* greenish above, very white and cottony underneath. *Flower* very large, purple, terminal, bracteated; calyx shaped like a pine-cone, very taper at the top, where it closely surrounds the florets which rise only a little above it; scales shining, transparent, the upper ones reddish. A native of the south of Europe. 29. *C. membranacea*, Lam. 16. Cnicus unilobus, Linn. 7. "Calyxes membranous; leaves pinnatifid, toothed." Nearly allied to the preceding. *Stem* a little taller. *Leaves* deeply pinnatifid. *Flower* large, purple; calyx shorter than in *C. conferta*; scales whitish with a pale brown tint, rounded at their summit, lacerated at their edges. A native of Siberia.

111. *Rhopontiodica*. Calyx-scales dry and scarious, ciliate-ferrated. (Rhoponticum; J. L.)

30. *C. puberrima*, Willd. 50. "Calyx scales egg-shaped, acuminate, ciliate-ferrated; leaves hoary underneath; root ones pinnatifid; stem ones lanceolate." *Root* perennial. *Stem* a foot high, quite simple, one-flowered, cylindrical,

upright, tomentous. *Root-leaves* two inches long, petioled; segments lanceolate, entire, terminal one very large; stem leaves an inch and half long, entire. *Flower* purple; the ray twice the length of the disc; lower calyx-scales brown-white; upper ones brownish. A native of the East. 31. *C. Balfanita*, Lam. 26. Willd. 51? (*Carduus orientalis costi hortensis folio*; Tourm. Cor. 32. Itin. 2. p. 439.) "Calyxes ciliate-fringed with straight, rigid, white bristles; leaves oblong, a little toothed; flower yellow, without a ray." Lam. "Scales egg-shaped, ciliate-ferrated, awned; leaves oblong, undivided, nearly entire, scabrous, nuncronated." Willd. *Stem* two feet high, striated or angular, slightly woolly, leafy; branches upright, one-flowered. *Root-leaves* oblong, acute, petioled; stem leaves scattered, sessile, lanceolate, a little toothed, whitish green. *Flowers* yellow, terminal; barren florets smaller than the fertile ones; calyx globular; scales beautifully fringed with rather long, straight, whitish bristles. La Marck, from a living plant, in the royal garden at Paris, raised from seeds gathered by M. André in Svia or Armenia. *Stem* erect, cylindrical, smooth, a little scabrous. *Leaves* scabrous, green; higher ones a little hoary; root ones oblong, acute, petioled; stem ones oblong-lanceolate; lower ones somewhat toothed, rather acute; upper ones quite entire, ending in a long bristle-shaped point. *Flowers* yellow, without a ray; calyx-scales yellowish, terminated by a long bristle, ciliate-ferrated at the edges. Willd. from a dried specimen. He quotes La Marck; but it appears dubious whether they have not described different plants. 32. *C. macrocephala*, Willd. 52. "Calyx-scales roundish-egg-shaped, ciliated; leaves oblong-lanceolate, undivided, very scabrous, acute, ferrated." *Branches* the thickness of a swan's quill. *Leaves* three inches long, an inch and a half broad at the base, embracing the stem. *Flowers* yellow, without a ray. A native of Iberia. 33. *C. calendulacea*, Lam. 31. "Calyxes ciliate-hairy; inner scales ligulate, scarious, ferrated at the tip; stem-leaves pinnatifid; those on the branches simple." *Stem* a foot and a half high, angular, striated, much branched, panicled. *Flowers* yellow, terminal; fertile florets few, small; barren ones large, ligulate, flat, four or five toothed; inner calyx-scales long, narrow, toothed at the summit; the other shorter, ciliated with long reddish hairs. A native of Armenia; discovered by M. André; described by La Marck from a living plant. 34. *C. atropurpurea*, Willd. 53. Waldt. and Kitaib. pl. rar. Hung. 2. p. 121. tab. 116. "Calyx-scales ovate-lanceolate, ferrate-ciliated; leaves bipinnatifid; segments lanceolate." *Flowers* dark purple; calyx-scales black, fringed with white. A native of Hungary among calcareous rocks. 35. *C. orientalis*, Linn. Sp. Pl. 23. Mart. 27. Lam. 44. Willd. 54. (Cyanus; Hall. Aët. Angl. 1745. vol. 43. p. 94. tab. 4.) "Calyx-scales pecuniate-ciliated; leaves deeply pinnatifid; segments linear-lanceolate." Lam. Nearly allied to *C. scabiola*, but distinguished from it by the colour of the flower, and the structure of the calyx. *Root* perennial. *Stem* a foot and a half or two feet high, striated, branched, downy near the summit. *Leaves* petioled, large, green. *Flowers* bright yellow, large, terminal; calyx scales yellowish white, roundish, downy at the base, ciliated with long pecuniate hairs. A native of Siberia and Tartary. 36. *C. strabilicea*, Mart. 72. Scop. inlutr. 38. tab. 17. "Calyxes ferrate ciliated; leaves dotted underneath, pinnated; pinnæ lanceolate, falcated, erect." Nearly allied to the preceding. *Root* perennial. *Root-leaves* entire. *Flowers* pale yellow, scutellous; calyx-scales twice as large as in *C. orientalis*, not at all downy at the base; laciniated all round; down of the seeds very apparent. 37. *C. sibirica*, Linn. Sp. Pl. 20. Mart. 21. Lam. 41. Willd. 55. Pallas it. vol. i. p. 43. Gmel. Sib. vol. ii. tab. 42. fig. 2. (Cyanus fibricus;

filiricus; Gært. vol. ii. p. 383.) "Calyx scales egg-shaped, obtuse, ciliated; leaves downy on both sides, pinnatifid and undivided; stem declining." *Root* perennial. *Stem* from six to nine inches high, quite simple, rarely furnished with a single branch, somewhat furrowed, pubescent. *Leaves* lanceolate; root ones generally pinnatifid; lobes turned upwards, entire, terminal one very large; stem-leaves mostly five or six, the uppermost generally undivided. *Flowers* purple or flesh-coloured, often single, with a large ray of barren florets; calyx swelling. A native of Siberia. 38. *C. sessilis*, Willd. 56. "Calyx-scales ciliate-ferrated; flowers sessile; leaves all pinnatifid, hoary; stem none." *Root* perennial. *Leaves* an inch and a half long, petioled; segments lanceolate, rather obtuse, quite entire in the upper part, auricled towards the base with an obsolete tooth; terminal one larger, egg-shaped, somewhat toothed. *Flowers* purple, five or six, sessile on the crown of the root, not at all peduncled; calyxes oblong. A native of Armenia. 39. *C. elongata*, Willd. 57. Schouböe Moroc. p. 199. "Calyx-scales scariosus at the tip, ferrated; leaves scabrous at the edge; root-ones oblong toothed; stem-ones lanceolate, somewhat decurrent, quite entire." *Root* perennial. *Flowers* pale violet; disc twice the length of the ray; calyx egg-shaped; lower scales toothed at the tip, mucronated; upper ones encreased with a scariosus toothed fecculate. A native of Barbary. 40. *C. trinervis*, Willd. 59. "Calyx scales ciliated; leaves linear, downy, three-nerved, quite entire; stem erect." *Stem* downy; branches few, fasciateg, one-flowered. *Leaves* an inch or an inch and a half long. *Flowers* purple. A native of Siberia. 41. *C. nigrescens*, Willd. 28. "Innermost calyx-scales scariosus; root-leaves obsoletely pinnatifid; lower stem ones somewhat toothed at the base, upper ones undivided, quite entire." *Root* perennial. It differs from *C. nigra*, in having a radiate flower, and calyx-scales ciliated, not feathery; from *C. jacea* in having a ciliated calyx, root-leaves often obscurely pinnatifid, and the lower stem ones often deeply toothed at the base. A native of Hungary and Austria.

IV. *Cyan.* *Calyx-scales ciliate-ferrated, not scariosus.* (*Cyanus* and *Jacea*; Juss.)

42. *C. Triumfetti*, Mart. 67. Willd. 29. Allion. ped. n. 579. (*Cyanus*; Triumf. Obs. 26. Misc. taur. 5. p. 68.) "Calyx ferrated; leaves sessile, downy, lanceolate, innate-pinnatifid" Willd. "Calyxes ferrated, with white cilia; leaves decurrent, deeply pinnatifid; pinnæ generally two." Allion. *Root* perennial. *Stem* simple or branched; branches one-flowered. *Leaves* two inches long. *Flowers* purple. A native of mount Cenis. 43. *C. cheiranthifolia*, Willd. 30. Phytog. 12. n. 42. tab. 7. fig. 2. (*Cyanus orientalis*, angustifolius, ineanus; flore magno, citrino; Tourn. Cor. 32.) "Calyx ferrated; leaves downy; root-ones pinnatifid; stem ones sessile, linear, somewhat toothed; stem one-flowered." *Root* perennial. *Flowers* yellow, with a large ray; calyx-scales spheclated at the edges. A native of Armenia. 44. *C. ochroleuca*, Willd. 31. (*Cyanus orientalis*, flore maximo, citrino, Tourn. Cor. 32.) "Calyx ferrated; leaves oblong, ferrated, decurrent, and undivided." *Root* perennial. *Flowers* pale yellow, twice as large as those of *C. montana*. A native of mount Caucasus. 45. *C. atrata*, Willd. 32. (*Cyanus orientalis* folio virefcente dentato; flore magno; Tourn. Cor. 32.) "Calyx ferrated, spheclated; leaves lanceolate, sessile, smooth, toothed." *Root* perennial. *Stem* seven or eight inches high. *Leaves* an inch and a half long, green; younger ones woolly at the edge. *Flowers* blue; calyx-scales black, with white teeth. A native of Armenia. 46. *C. variegata*, Lam. 29. (*C. axillaris*, Willd. 33. *C. scufana*, Villars delph. 3. p. 52. Suter helv. 2. p. 205.) "Calyxes ciliated, variegated; leaves sessile, linear,

downy; stem one-flowered." Lam. "Calyxes ferrated, leaves hoary, lanceolate, decurrent; lower ones innate-toothed at the base; peduncles axillary and terminal." Willd. *Root* perennial. *Stem* from five to seven inches high, quite simple, cottony. *Leaves* about three inches long, two lines broad, entire, a little undulated, cottony and whitish on both sides; lower ones a little flattened; upper ones shorter, more distant from each other. *Flower* fine blue, large, terminal; calyx scales smooth, green at their base, blackish at their edges, furnished with large, palmated, brilliant, silvery cilia. Lam. A native of mountains in the south of Europe. 47. *C. montana*, Linn. Sp. Pl. 13. Mart. 13. Lam. 28. Willd. 34. Pot. Mag. t. 77. (*Cyanus*, Bauh. pin. p. 273. n. 1. Boec. musc. 2. p. 20. tab. 2. Hall. helv. n. 190.) "Calyxes ferrated; leaves smoothish, lanceolate, quite entire, decurrent; stem simple." *Root* perennial. *Stems* upright, simple, when cultivated often a little branched, entire, decurrent, soft. *Flower* blue, purple, or white, resembling that of the next species, but larger, terminal; calyx-scales light green, black at the edges, with short, black cilia; those at the tip longer, brownish, a little recurved. A native of mountains in Germany, Switzerland, and the south of France. 48. *C. Cyanus*, Linn. Sp. Pl. 14. Mart. 15. Lam. 30. Willd. 35. Eng. bot. 277. Curt. Flor. Lond. Tab. 62. Mart. Flor. russ. tab. 3. (*Cyanus fegetum*, Bauh. pin. 273. n. 2. Tournef. p. 446. *Cyanus vulgaris*, Lob. ic. 546. Backw. tab. 270. Hall. helv. n. 191.) Corn blue-bottle. "Calyxes ferrated; leaves linear, quite entire; lower ones toothed; stem branched, many-flowered." Lam. *Root* annual, fibrous, black. *Stem* erect, much branched, somewhat woolly. *Leaves* linear-lanceolate, acuminate, somewhat woolly; root-leaves entire; lower stem-leaves often pinnatifid or toothed; upper ones always entire. *Flowers* terminal, solitary, peduncled; florets of the disc purplish, regular; anthers black; florets of the ray funnel-shaped, always blue when wild, but when cultivated it varies with almost all colours except yellow; calyx egg-shaped; scales lanceolate. *Seeds* even; down many-leaved, unequal, feabrous, reddish. A well known weed growing in corn fields in the south of England and many other parts of Europe, and for its beauty often cultivated in gardens. A blue water-colour is easily prepared from the expressed juice of the neutral florets, mixed with a little cold alum water; but it is not durable if exposed to the action of light. A water is also distilled from them in France, which is said to remove inflammations of the eyes. 49. *C. virgata*, Lam. 37. Willd. 36. "Calyxes ciliated, small, somewhat cylindrical; scales narrow-lanceolate, coloured at the tip; branches slender, long, rod like." Lam. *Branches* somewhat scabrous, striated. *Leaves* small, cinereous-green; lower ones half an inch long; segments narrow, linear, revolute at the edges, sometimes with one or two teeth; upper ones linear, entire. *Flowers* purple, small florets of the ray shorter than those of the disc. A native of Armenia. 50. *C. ovina*, Willd. 37. Pallas. "Calyxes ciliated; scales ovate-lanceolate, spreading at the tip; lower leaves bipinnatifid, lanceolate-linear; upper ones pinnatifid; stem branched, divaricated." An intermediate species between the preceding and following. Whole plant green, woolly-pubescent. *Florets* of the ray longer than those of the disc. A native of Mount Caucasus. 51. *C. paniculata*, Linn. Sp. Pl. 15. Mart. 16. Lam. 36. Willd. 38. Jacq. Ault. tab. 320. (*C. meranthus*, Gmel. it. 1. tab. 23. fig. 1. Steud. Bauh. pin. p. 273. n. 3. *Jacea foliis candidantibus*, Tourn. Inst. p. 444. Moril. hist. tab. 28. fig. 15.) "Calyxes ciliated, egg-shaped; scales flat, clove-pressed; lower leaves bipinnatifid; upper ones pinnatifid; stem panicled." *Root* annual. *Stem* a foot and a half high,

angular,

angular, hard, slender. *Flowers* small, purple; pistils white. A native of the south of France, Aultria, Italy, Spain, and Siberia. 52. *C. maculosa*, Lam. 35. Gmel. Sib. 2. p. 69. n. 79 and 83. Tab. 47. fig. 1, 2. "Calyxes ciliated, ovate-roundish, beautifully spotted; leaves slender, bipinnatifid; stem a little panicle." *Stem* from eight to ten inches high, striated, whitish. *Leaves* whitish, more finely cut than those of the preceding species; lower ones oblong, bipinnatifid; upper ones smaller, simply pinnatifid; segments linear. *Flowers* purple; calyxes large, short; tepals marked with brown spots at their tip. A native of the south of France. 53. *C. pinnata*, Linn. Sp. Pl. 16. Mart. 17. Lam. 38. Willd. 39. (*Jacea erecta aculeata incana*, Tourn. 445. Stæbe Ipinota, Morf. 3. p. 176. *Cyanus spinosus*, Alp. exot. tab. 162.) "Calyxes ciliated; root-leaves undivided and pinnatifid, smooth; stem-leaves downy, pinnatifid; branches spinous." *Root* perennial. *Stem* from six to eight inches high, cottony, whitish, much branched, panicle; branches diverging, stiff, terminating in stiff thorns. *Flowers* flesh-coloured, linear, oblong; scales of the calyx acute, slightly ciliated. A native of Candia. 54. *C. vaguina*, Linn. Sp. Pl. 17. Mart. 18. Lam. 32. Willd. 40. Bot. mag. 494. (*Cyanus ragulatus*, Gært. *Jacea Epidaurica*, Tourn. 445. *J. ragulina*, Zan. hill. tab. 41. Stæbe, Bar. ic. 30.) "Calyxes ciliated; leaves downy, pinnatifid; segments obtuse, egg-shaped quite entire; outer ones largest." *Root* perennial. *Stem* perennial, near 3 feet high, commonly simple, cottony. *Leaves* remaining all the year alternate, cottony, very white, soft; terminal lobe large, roundish. *Flower* yellow, large, terminal; barren flowers not larger than the others. Calyx cottony; scales acute, a little ciliated; inner ones terminated by a scarious, lacerated, ciliated appendage. A native of Ragusa and the isle of Candia. 55. *C. cineraria*, Linn. Sp. Pl. 18. Mart. 19. Willd. 41. (*C. candidissima*, Lam. 33. *Jacea montana candidissima*, Bauh. pin. 272. Tourn. 444. Morf. hist. 3. tab. 26. fig. 20.) "Calyxes ciliated; leaves downy, very white, all compound; the lowest bipinnatifid; the highest pinnate-laciniate." *Root* perennial. *Stem* about a foot high, cottony, with two or three short branches near the summit. *Leaves* petioled, soft; segments acute. *Flowers* purple, large, terminal, solitary; calyx roundish; apparently sessile, the stem being leafy to its base. According to La Muck it is the *C. Triumphi* of the royal garden of Paris. Is it specifically different from our n. 42? A native of Italy. 56. *C. cinerea*, Lam. 34. Willd. 42. (*C. cineraria*, β . Linn. *Jacea cineraria lacinata*, flore purpureo, Trium. Obs. 72. Tourn. 444. Morf. hist. 3. p. 141. n. 21. Jacq. hort. 72. Stæbe, Barr. ic. 347?) "Calyxes ciliated, leaves somewhat downy, cinereous; lower ones pinnate-laciniate; upper ones simple." *Root* perennial. The whole plant less white than the preceding species. *Stem* near a foot and a half high, angular, a little panicle in its upper part. *Root-leaves* on long petioles, smoothish above, mucous underneath; segments oblong-lanceolate, obtuse. *Flowers* purple, only half the size of those of the preceding species. A native of Italy. 57. *C. dealbata*, Willd. 43. "Calyxes ciliated; leaves downy underneath; root-leaves bipinnatifid; segments lanceolate, acute; stem-leaves pinnatifid." Willd. *Root* perennial. *Root-leaves* a foot long and a more, on long petioles, smooth and deep green above, snow-white with down underneath; stem-leaves an inch and a half or two inches long. *Flower* purple, large. A native of Iberia. 58. *C. argentea*, Linn. Sp. Pl. 19. Mart. 20. Lam. 39. Willd. 44. (*Jacea erecta lacinata*, Tourn. Cor. 32. Barr. ic. 218. Argentina. Alp. exot. 116.) "Calyxes ferrated; leaves downy; root-ones pinnate; leaves obovate." *Root* perennial. Whole plant cottony, very white.

Stem scarcely a foot high. *Root-leaves* with nearly equal egg-shaped leaflets, having only one lobe on the lower side of the base; stem-leaves simple, wedge-shaped, with an obtuse tooth on one side at the base. *Flowers* yellow, only half the size of those of *C. ragulina*. A native of Candia. 59. *C. abrotanifolia*, Lam. 42. (*Jacea tenuifolia*, hispanica, Barr. ic. 140?) "Calyxes ciliated, pale-leaves bipinnatifid, linear bristle-shaped; stem-corymbous." *Stem* a foot and a half high, upright, striated, angular, leafy its whole length; branches simple, forming a corymb. *Leaves* numerous, finely cut, like those of southern-wood (*artemisia abrotanum*); upper ones simply pinnate. *Flowers* terminal, solitary, resembling those of *C. paniculata*, but smaller. Communicated to La Mark by Jussieu, supposed to be a native of Spain. 60. *C. sempervirens*, Linn. Sp. Pl. 21. Mart. 22. Lam. 46. Willd. 45. (*Jacea luteicarpa sempervirens*, Tourn. 444. Morf. Hill. tab. 28. fig. 9. Bocc. Sicc. tab. 39. fig. 3.) "Calyxes ciliated; leaves lanceolate, ferrated; lowest tooth elongated, so as to appear like a lipule." *Root* perennial. A kind of evergreen shrub, a foot and a half or two feet high. *Stem* cylindrical, greyish; branches pubescent, thick set with leaves. *Leaves* greenish, a little pubescent, soft, toothed, and narrowed at their base. *Flowers* purple, terminal, solitary; peduncles thickened towards the base of the calyxes; calyx-leaves smooth, ciliated at the tip. A native of Portugal. 61. *C. infylacea*, Lam. 47. Mart. 70. Hort. Kew. 1. 259. (*Jacea rubra foliis utraque*, Barr. ic. 1229 2) (*Centaurea leucantha*, Poir. compare Stæbe tenuifolia, Barr. Ic. 359.) "Calyxes ciliated, nearly globular; leaves deeply pinnatifid; segments linear." 3. "Leaves narrower, downy underneath, somewhat hairy." *Root* perennial. *Stem* near two feet high, upright, hard, striated, branched. *Leaves* large, almost without hairs, rough to the touch. *Flowers* purple, flesh-coloured, or white, terminal. A native of the south of Europe, on the borders of fields, and in dry pastures. 62. *C. feabiosa*, Linn. Sp. Pl. 22. Mart. 23. Lam. 45. Willd. 47. Eng. Bot. 56. (*Scaebiosa*, Bauh. Pin. p. 269. n. 2. *Jacea vulgaris lacinata flore purpureo*, Tourn. 443. *J. nigra lacinata*, Morf. Hist. tab. 28. fig. 10. *Cyanus*, Hall. Heiv. n. 186.) Greater knapweed. "Calyx-leaves ciliated, pubescent, egg-shaped; leaves pinnatifid; segments lanceolate, sometimes toothed, a little hairy." *Root* perennial. *Stem* two or three feet high, erect, branched, furrowed. *Flowers* purple, large, terminal, solitary, peduncled; flowers of the ray elongated; segments linear, narrow; down unequal, rather scabrous. Smith. A native of England, and other parts of Europe, chiefly on a calcareous soil. 63. *C. karstschiana*, Mart. 68. Scop. Car. n. 10: 7. tab. 55. "Calyxes ciliated with spines; leaves pinnate; pinnæ sessile, lanceolate, decurrent, ending in a point. *Stem* angustate, smooth, branched. *Leaves* all pinnate; pinnæ two or three pairs; terminal one larger than the rest. *Flowers* reddish; calyx-leaves yellowish-green, striated, egg-shaped, smooth, ciliated with spines above the middle. A native of the south of Europe. 64. *C. coriacea*, Willd. 46. Waldst. and Kitab. pl. rar. Hung. "Calyxes ciliated, smooth; leaves pinnatifid, scabrous; segments oblong-lanceolate, acute; highest of the root ones sometimes cut at the base." *Root* perennial. Very nearly allied to *C. feabiosa*, but the leaves are much broader and coriaceous, the flowers larger, and the calyxes smooth. A native of Hungary. 65. *C. tatarica*, Mart. 24. Willd. 48. Linn. Jus. Sup. 385. "Calyxes ciliated; leaves scabrous underneath, pinnatifid; segments lanceolate, sometimes toothed. Nearly allied to *C. feabiosa*. *Root* perennial. *Root-leaves* oblong, entire, or to the 3, petioled; lower stem ones pinnate; leaflets petioled, lanceolate, toothed towards the base; upper ones pinnatifid; segments lanceolate, quite entire, terminal, one-toothed; uppermost lanceolate, quite entire.

ture. *Flowers* yellow; calyx-scales smooth, yellowish. A native of Tartary. 66. *C. flebe*, Linn. 24. Mart. 25. Lam. 42. Willd. 49. (Stebe, Bauh. Pin. 273. n. 7. *C. austriaca humilis*, Cluf. Hf. 2. p. 10.) "Calyx ciliated, oblong; leaves pinnatifid, linear, quite entire." *Root* perennial. *Stems* near three feet high, branched; branches slender. *Leaves* some pinnatifid, others entire and linear. *Flowers* solitary, terminal. A native of Austria. 67. *C. acutifolia*, Linn. 25. Mart. 27. Lam. 43. Willd. 110. (Jacea, Shaw Af. 342.) "Calyx ciliated; leaves lyrate; stem scarcely any." *Flower* yellow, oblong, solitary; calyx-scales with white cilia. A native of Arabia. The root is sweet and esculent, and called toffy by the Arabs.

V. *Cyanoides*. *Calyx-scales* bristly-ciliated; *bristles* recurved or erect. (Cyanus & Jacea, Juss.)

68. *C. phrygia*, Linn. Sp. Pl. 8. Mart. 7. Lam. 19. Willd. 15. (Jacea, n. 7. 8. 9. Bauh. Pin. Cyanus, Hall. Helv. n. 188.) "Calyx recurved-feathery; leaves oblong, undivided, scabrous, mucronate-ferrulate." *Root* perennial. *Stem* a foot and a half high, somewhat shrubby, angular, striated, pubescent, branched towards the summit. *Leaves* greenish, rough to the touch; root-ones long, lanceolate, toothed, narrowed into a petiole towards the base; stem-ones embracing the stem, lanceolate, toothed, with a longer tooth, appearing like an ear, at the base. *Flowers* purple, terminal, solitary; calyx-scales oblong, smooth, yellowish; ending in a brown, lanceolate lamina, twice or thrice as long as the scales themselves, with two rows of rufous cilia, having the appearance of a reflected feather. A native of Germany, Switzerland, and the south of France. 69. *C. falcifolia*, Willd. 16. "Calyx recurved-feathery, top-shaped; leaves oblong, undivided, scabrous, mucronate-ferrulate; stem simple." *Root* perennial. *Stem* a foot or a foot and a half high, furrowed, angular, woolly-pubescent above. *Leaves* with white veins; root and lower stem ones long, egg-shaped, petioled; upper ones oblong, sessile. *Flowers* few, generally two, terminal; lower scales of the calyx ciliated; upper ones recurved-feathery. It differs from *C. phrygia* chiefly in the structure of the calyx. 70. *C. austriaca*, Willd. 17. (*C. phrygia*, Jacq. Rind. 167.) "Calyx recurved-feathery; leaves egg-shaped, undivided, scabrous, grossly toothed." *Root* perennial. Easily distinguished from *C. phrygia* by its grossly toothed egg-shaped leaves; and by its roundish, scabrous, inner calyx scales. 71. *C. pedinata*, Linn. Sp. pl. 9. Mart. 11. Lam. 24. Willd. 18. (Jacea montana incana aspera, capitulis hispidiis.) "Calyx recurved-feathery; leaves mucronate-ferrate; lower stem ones sinuate pinnatifid; upper ones, and those of the branches undivided." *Root* perennial. *Stem* scarcely a foot high, angular, branched, a little woolly. *Leaves* oblong, embracing the stem, auricled at the base, lyre-shaped, slightly cottony, whitish. *Flowers* purple, terminal, solitary. A native of the south of France and Hungary. 72. *C. capillata*, Linn. 10. Mart. 8. Lam. 22. Willd. 10. (Cyanus, Act. Gott. 1. 202. tab. 6.) "Calyx recurved-feathery; lower leaves pinnate, toothed; upper ones lanceolate." *Stem* four or five feet high, hard, angular, branched. A native of Siberia. 73. *C. pulcata*, Linn. Sp. Pl. 12. Mart. 13. Lam. 27. Willd. 85. (Cyanus humilis hieracum folio, Tourn. 446. Cyanus pultatus, Gart. Jacea humilis alba, Bauh. Pin. 271. Moris. hist. tab. 28. fig. 18. Lob. Ic. 542.) "Calyx ciliated, surrounded by a whorl of long leaves; leaves lyrate, toothed, obtuse." *Root* annual. *Leaves* from the root, oblong, lyre-shaped, green, slightly villous, spreading on the ground; segments short, obtuse; terminal one almost round. *Flowers* pale purple, three or four in the centre of the leaves, at first almost sessile, but having their peduncles gradually lengthened into simple stems, a

little villous, declining, and longer than the root-leaves; calyx-scales green, bordered with black; terminated, by long yellowish, recurved-feathery cilia. When cultivated, the stem becomes two feet high, branched, and leafy. A native of the south of France, Spain, and the Levant. Willdenow has inserted this species in the next division. 74. *C. involu-crata*, Willd. 20. Desfont. Atl. 2. 295. "Calyx recurved-feathery, leafy at the base; leaves slightly toothed; root-leaves pinnatifid; stem ones lanceolate, petioled." *Stems* a foot high, several, simple, or branched, striated, pubescent, some erect, others decumbent at the base. *Leaves* pubescent; stem ones obtuse. *Flowers* yellow, solitary, terminal, sometimes axillary and sessile; barren florets larger, three or four cleft; calyx oblong, with an involucre of lanceolate leaves; scales pale yellow, linear-lanceolate, acute, sometimes brown at the edge. *Seed* oblong, even; down bristly. *Receptacle* bristly. A native of mount Atlas. 75. *C. uniflora*, Linn. Mant. 118. Mart. 9. La Marek 20. Willd. 21. (Cyanus alpinus; Tourn. 445. Hall. helv. n. 189. Boec. Mus. 2. tab. 2.) "Calyx recurved-feathery; leaves lanceolate, sometimes toothed; downy." *Root* perennial. *Stem* near a foot high, simple, cottony, one-flowered. *Leaves* narrow lanceolate, cottony, whitish, soft to the touch, some entire, others thinly toothed. *Flower* purple, large, terminal, sessile, surrounded by bracts at its base. A native of the South of Europe. 76. *C. strobilifera*, Willd. 22. "Calyx recurved-feathery; flowers without a neutral ray; leaves hairy, lanceolate, remotely toothed." *Root* perennial. *Stem* simple, one-flowered, hairy. *Leaves* an inch and a half long, not downy, but clothed on each side with numerous, short, erect hairs. *Flowers* purple. The habit of the preceding species, but differs in the leaves and flowers. A native of Italy. 77. *C. tricobcephala*, Willd. 23. Gmel. Sib. tab. 45. fig. 1. 2. "Calyx recurved-feathery, pubescent; leaves linear-lanceolate, quite entire, scabrous." *Root* perennial. *Stem* scabrous. Nearly allied to the next species, but larger. A native of Russia about the Volga. 78. *C. linifolia*, Linn. Mant. 117. Mart. 10. Lam. 21. Willd. 24. (*C. linarifolia*; Lam. 23. Jacea hispanica pumila, linearifolia; Tourn. 445. Bar. ic. 162.) "Calyx recurved-feathery, smooth, leaves linear; quite entire, hairy." *Root* perennial. *Stems* several, from six to eight inches high, more or less upright, much branched, panicled, hairy. *Leaves* acute, small, numerous, sessile, whitish, rough to the touch. *Flowers* purple, terminal, sessile, solitary. A native of Spain and Italy. The *linifolia* and *linarifolia* of La Marek appear to be the same plant. He described the former from a living, the latter from a dried specimen, and was doubtful to which the synonym from Tournefort should be referred. 79. *C. lyfopifolia*, Willd. 25. Vahl. Symb. 1. p. 75. (Stebe, Barr. ic. 366.) "Calyx recurved-feathery, pubescent; flowers without a neutral ray; leaves linear, quite entire; stem somewhat shrubby." *Root* perennial. *Stem* about half a foot high, cylindrical, somewhat scabrous, branched from the bottom. *Leaves* sessile, crowded, half an inch long, stiff, pale green, spreading at the tip, ending in a white point. *Flower* purple, egg-shaped, nearly sessile, terminal. A native of Spain. 80. *C. cernopifolia*, Linn. 25. Willd. 26. (Jacea orientalis anara coronop. folio flore luteo, Tourn. Cor. 32.) "Calyx erect-feathery; flowers without a neutral ray; lower leaves pinnatifid; upper ones linear; all quite entire; stem panicled." *Root* annual. *Stem* about a foot high, upright, slender, nearly smooth. *Leaves* clothed on both sides with short hairs. *Flowers* yellow, terminal, solitary; calyx-scales lanceolate, bristly-ciliated, ending in a long, stiffish, expanding awn. A native of Spain. 81. *C. nigra*, Linn. Sp. Pl. 11.

Mart. 12. Lam. 18. Willd. 27. Eng. bot. tab. 178. Mart. Flor. Ruft. tab. 130. Flor. dan. 996. (Cyanus niger, Gært. tab. 161. fig. 4. *Jacea nigra laciniata*, Bauh. pin. 271. Tourn. 443. Lob. ic. 541.) Common knap-weed, knob-weed, horfe-knops, or hard heads. "Calyxes erect-feathery; leaves oblong; root ones sometimes pinnatifid, stem ones entire or slightly toothed." *Root* biennial. Linn. Lam. Willd. but in England it is certainly perennial, woody, and somewhat creeping; while plant rigid, hard, scabrous. *Stem* branched, angular. *Lower-leaves* often lyrate-angular or toothed, upper ones egg-shaped, often entire. *Flowers* purple, terminal, foliary, feffile; calyx globular; scales black, egg-shaped; ciliae erect, bristle-shaped, brown; inner scales unguiculate; florets most generally equal, regular, all fertile. *Seeds* hairy; down short, confiding of numerous scales. Dr. Smith. In the north of England it is almost always without a ray of barren florets; but in the western counties it is said by Ray and other botanists, to be frequently found with it. According to La Marck it has always, in France, an evident ray of barren florets larger than the others. Are there not two distinct species, one biennial with a ray, the other perennial without one?

VI. *Stobe. Calyx-scales with palmated spines at the tip.* (Sericea; Julf.)

82. *C. Jonckifolia*, Linn. 35. Mart. 38. Lam. 49. Willd. 73. (*Carduus maritimus*, Tourn. 441. *Jacea laciniata fonchii folio*, Bauh. pin. 272. Pluk. tab. 39. fig. 1. β . Pluk. tab. 94. fig. 1.) "Calyxes palmate-spinous; spines reflexed; leaves oblong, smoothish, embracing the stem, half-decurrent, repand-toothed; teeth prickly." *Root* perennial. *Stem* a foot high, simple or sometimes a little branched, green, slightly downy near the top. *Lower-leaves* petioled, undivided, lanceolate-egg-shaped; upper ones sessile, toothed towards the base; uppermost somewhat decurrent, lanceolate. *Flower* purple, large, terminal, foliary; calyx-scales green; spines yellowish. A native of the coast of the Mediterranean. 83. *C. feridis*, Linn. 36. Mart. 39. Lam. 50. Willd. 74. (*Carduus hispanicus*, Tourn. 442. *Jacea folius feridis*, Bauh. pin. 272. J. latifolia, Pluk. tab. 38. fig. 1.) "Calyxes palmate-spinous; spines reflexed; leaves oblong, hoary, embracing the stem, half decurrent, toothed, cut at the base; teeth rather prickly." *Root* perennial. *Stems* about a foot high, inclining, a little branched. *Leaves* thick, fleshy; lower ones near a foot long, sinuated like those of dandelion. *Flowers* very large, with a purple ray and whitish disc; calyx-spires nine or more, yellowish. A native of Spain. 84. *C. romana*, Linn. 37. Mart. 40. Willd. 75. (*Jacea*, Zan. hist. tab. 42. *Cyanus*, Barr. rar. tab. 504.) "Calyxes palmate-spinous; leaves decurrent, not prickly; root ones pinnatifid, terminal lobe very large." Linn. "Calyxes palmate spinous; spines reflexed; leaves lanceolate, sessile, decurrent, hairy, scabrous, not prickly, finely toothed; root-leaves lyrate." *Root* annual, Linn. biennial, Miller; perennial, Willd. *Stems* three feet high. *Flowers* large, red; calyxes strongly armed with spines. Mill. A native of the Campania of Rome. Cultivated by Miller in 1768. 85. *C. napifolia*, Linn. 40. Mart. 43. Lam. 51. Willd. 86. (*Cyanus napifolius*, Gært. *Jacea*, Herm. par. tab. 189. Pluk. tab. 94. fig. 2. Morif. hist. tab. 26. fig. 20.) "Calyxes palmate-spinous; leaves decurrent, sinuated, somewhat prickly; root-leaves lyrate." Linn. "Calyxes palmate-spinous; stem-leaves lanceolate, toothed, decurrent; root-leaves lyrate, obtuse." Willd. *Root* annual. *Stem* three feet high, branched. *Lower-leaves* not much unlike those of a turnip, rounded at the end, cut at the base into many segments, diminishing gradually to the top of the stem, and winged. Miller. *Stem* a foot and a half high, weak,

much branched. *Root-leaves* lyrate; terminal lobe very large, roundish-oval, finely toothed; stem-leaves small, oblong, narrow. *Flowers* purple, terminal; barren florets loose, large; calyx-spires small, very weak, always reflexed. Lam. from a living plant. A native of Candia. Cultivated by Miller in 1759. La Marck is of opinion that this and the preceding are the same species, and that one is not even a variety of the other. But as both are said to have been cultivated by Miller; and as Willdenow appears to have formed his specific characters of both from living plants, we apprehend that this eminent French botanist must have fallen into an error, from having seen only one of them. 86. *C. serox*, Willd. 76. Desfont. Atl. 2. tab. 242. "Calyxes palmate-spinous; spines reflexed, larger than the calyx; leaves hoary, oblong, sessile, decurrent, pinnatifid; teeth not prickly." *Root* perennial. *Stem* procumbent. A native of the coast of Barbary. 87. *C. foliatis*, Linn. 46. Mart. 50. Lam. 59. Willd. 77. Eng. Bot. tab. 243. (*Carduus stellatus*, Bauh. pin. 387. n. 4. Tourn. 440. n. 7. Rai Syn. 196. n. 16. *Jacea*, Morif. tab. 34. fig. 29. Calceitrapa, Hall. Helv. n. 193.) St. Barnaby's thistle. "Calyxes palmate-spinous, terminal, foliary; spines straight; leaves lanceolate, decurrent, not prickly; root ones lyrate." *Root* annual. *Stem* near two feet high, alternately branched, winged by the decurrent leaves. *Leaves* slightly cottony, whitish; stem ones small, narrow, a little finuated or toothed; root-ones four or five inches long, deeply finuated or pinnatifid; with a large, more or less triangular terminal lobe. *Flowers* bright yellow, terminal, scarcely rayed; calyx, like the rest of the plant, clothed with a cotton-like web; spines yellowish; the middle one considerably longer and stronger than the others. A native of the south of Europe, very rare in England. 88. *C. verutum*, Linn. 52. Mart. 56. Lam. 60. Willd. 111. Gouan Illust. 73. Jacq. Ic. Rar. i. tab. 178. "Calyxes palmate-spinous; middle spine very long; lateral ones short; root-leaves sinuate-pinnatifid; stem ones lanceolate, quite entire, decurrent." *Root* annual. *Stem* from one to three feet high, upright, winged, with a few simple branches near the top. *Lower-stem-leaves* lyrate. *Flowers* yellow, large, terminal, foliary; calyx pubescent; spines yellowish. La Marck is inclined to consider it as only a variety of the preceding, although placed by Linnæus and most other authors in a different division. 89. *C. melitenfis*, Linn. 47. Mart. 51. Lam. 62. Willd. 78. (*Cyanus melitenfis*, Gært. *Carduus melitenfis capitulis conglobatis*, Tourn. 442. *Jacea*, Boec. Sic. tab. 35. Morif. Hist. iii. p. 145.) "Calyxes palmate-spinous; terminal ones clustered, sessile; spines straight; leaves lanceolate, scabrous, decurrent, not prickly; lower stem ones a little toothed; root ones finuated." *Root* annual. *Stem* from five to ten inches high, a little woolly, simple, or with only a few short branches. *Leaves* oblong, finuated, their terminal lobe obtuse, not angular, as in *C. foliatis*; lower stem-leaves not decurrent. *Flowers* yellow; axillary ones single; terminal ones clustered, two or three together, nearly sessile; calyx-scales brownish; the middle one not above one-third the length of that in *foliatis*. A native of Malta and the south of France. This species was cultivated in the English gardens under the name of *foliatis*, till Dr. Smith pointed out the mistake in the Linnæan Transactions, vol. ii. p. 236. 90. *C. Adami*, Willd. 79. "Calyxes palmate-spinous, foliary; spines straight; inner scales scarious at the tip; leaves downy, lanceolate, decurrent; lower ones finely toothed, pinnatifid at the base." *Root* annual. *Stem* a foot high, branched, near the top, hoary. *Leaves* hoary on both sides. *Flowers* yellow, terminal; calyx-scales egg-shaped, green; middle

middle spine longer than the others; florets of the ray shorter than those of the disc. A native of Iberia. 91. *C. fulva*, Linn. 48. Mart. 52. Lam. 63. Willd. 80. (*Carduus melitensis cruce folio*, Tourn. 442. *Jacea cichorii folio*, Boeck. Sic. 15. Morif. Hill. tab. 28. fig. 26.) "Calyxes palmate-spinous; spines spreading; leaves scabrous; stem-leaves lanceolate, a little embracing the stem, finely toothed; root ones lyrate." *Root* perennial. *Stem* a foot and a half high, angular, branched, slightly villous. *Flowers* yellow, terminal; middle spine of the calyx longer than the others, brown. A native of Sicily. 92. *C. sphaerocephala*, Linn. 38. Mart. 41. Lam. 57. Willd. 81. (*Jacea*, Morif. Hill. tab. 27. fig. 9.) "Calyxes palmate-spinous; leaves ovate-lanceolate, petioled, toothed." *Linn.* *Root* annual. *Stem* from one to two feet high, feeble, dividing at the top into a few branches. *Leaves* woolly; root ones petioled, a little sinuated or lacinated, stem ones sessile, oblong, simply toothed. *Flowers* purple, terminal, solitary, often with one or two bracts. A native of the coast of Barbary and Spain. 93. *C. cespitosa*, Mart. 75. Cyril. Bar. Neap. tab. 8. Vahl. Sym. ii. 93. "Calyxes palmate-spinous; leaves sinuate-toothed; lower ones petioled; upper ones half embracing the stem." *Root* perennial, woody, dry, perpendicular, black on the outside. *Stems* from one to two feet high, thickish, round, pubescent, striated; dividing from the bottom into numerous procumbent branches. *Leaves* slightly pubescent; teeth unneronate, but not prickly. *Flowers* purple, terminal, solitary, of a strong disagreeable smell; surrounded at the base of the calyx with an involucre of from four to six concave inflexed leaves, irregularly toothed, lanceolate-egg-shaped at the tip. A native of Italy, on the sea-coast near Naples, forming thick tufts in the sand. Willdenow supposes this and the preceding to be one and the same species. 94. *C. Injardi*, Linn. 39. Mart. 42. Lam. 52. Willd. 82. (*Calcitrapoides*, In. Paris, 1719, tab. 9.) "Calyxes palmate-spinous, foliary, sessile; leaves lanceolate, a little embracing the stem, pinnatifid-toothed." *Root* perennial. *Stem* ascending, about a foot long, commonly square, hairy, furrowed, branched. *Lower leaves* four or five inches long, scabrous, especially at the edges; lobes rather prickly; upper ones smaller, often entire, or a little toothed. *Flowers* purple, terminal; calyx egg-shaped, smooth. A native of the isle of Jersey, and other parts of the south of Europe. 95. *C. straminea*, Willd. 84. (*C. prolifera*, Vent. Hort. Celf. tab. 16. *C. glomerata*, Vahl Sym. ii. 94. *C. acaulis*, Forsk. Descript. 152.) "Calyxes palmate-spinous, terminal, sessile, glomerated; leaves petioled, pinnatifid, cut-toothed." *Root* annual. *Stem* less in its natural wild state; but when cultivated it has a short stem. 96. *C. polyantha*, Willd. 83. Calyxes palmate-spinous; leaves embracing the stem, runcinate, pinnatifid, prickly toothed; root ones lyrate." *Root* annual. *Stem* six or seven inches high, erect, slightly villous. *Root-leaves* hispid-scabrous, lyrate; segments oblong, toothed; terminal one large, roundish. *Flowers* purple; ray twice the length of the disc. Native country unknown. 97. *C. heterophylla*, Willd. 87. "Calyxes palmate-spinous; spines three; stem-leaves linear-filiform, quite entire; root ones lanceolate, toothed towards the base." *Root* probably annual, simple, perpendicular. *Stem* six or seven inches high, erect, scabrous, pubescent; branches simple. *Leaves* hispid-scabrous; root ones rather acute, lessening into a petiole; stem ones alternate, rather crowded, revolute at the edges. *Flowers* purple, rayed, terminal, solitary; calyx-scales egg-shaped, close; spines yellow, awl-shaped, spreading, equal. A native of Spain. 98. *C. aspera*, Linn. 41. Mart. 44. Lam. 48. Willd. 88. (*Stæbe squamis apricis*,

Dauh. Pin. 275. *Jacea*, Boeck. Mus. ii. tab. 26.) "Calyxes palmate-spinous; spines three or five; leaves lanceolate, sessile, toothed. *Root* perennial. *Stem* from one to two feet long, procumbent when young, reddish, striated, rough to the touch, branched, diffuse. *Root-leaves* oblong, sinuated; stem ones small, narrow, rough. *Flowers* bright purple, small; calyx-spines very small, yellowish, or reddish. A native of the south of France, Italy, Spain, and Portugal.

VII. *Calcitrapæ*. *Calyx-spines* compound or branched. (*Calcitrapa*, Jull.)

99. *C. benedictæ*, Linn. 42. Mart. 45. Lam. 54. Willd. 89. Woodv. Med. Bot. tab. 42. (*Cnicus benedictus*, Gært. tab. 162. fig. 5. *Cnicus sylvæstris hirsutus*; five carduus benedictus, Bauh. pin. 378. Tourn. 450.) Blessed thistle. "Calyxes doubly spinous, woolly, involucred; leaves half-decurrent, toothed-spinous." *Root* annual, cylindrical, whitish. *Stems* several, a foot and a half high, reddish, woolly, branched. *Leaves* oblong, toothed, villous, bright green, with a white nerve; lower ones sinuated; almost runcinate. *Flowers* yellow, terminal; involucre of ten leaves; five outer ones larger; calyx-spines pinnated; yellowish; florets of the ray small, triind. A native of the south of France, Spain, and the Levant, flowering from June to September. This plant obtained the name of benedictus, or blessed, from its supposed extraordinary medicinal virtues. It has an intensely bitter taste, and disagreeable smell; and exclusive of the qualities attributed to other bitters, was thought, when taken internally, to be peculiarly efficacious in malignant fevers, and applied externally to heal cancers and carious bones. It has now lost much of its reputation, and does not seem to be essentially different from other simple bitters. An infusion of it was formerly employed to assist the operation of emetics, but the flowers of chamomile are now substituted for it with equal advantage. In loss of appetite, where the stomach has been injured by irregularities, its good effects have been frequently experienced. Cold water poured on the dry leaves extracts in an hour or two a light grateful bitterness; by standing long upon the plant the liquor becomes disagreeable. Rectified spirit in a short time extracts the lighter bitter, but does not take up the nauseous fo easily as water. See Woodville's Medical Botany. 100. *C. epula*, Lam. 61. Willd. 92. Desfont. Atl. 2, 300. (*Carduus stellatus luteus*, capitulo minus spinosus; Tourn. 441.) "Calyxes doubly spinous, globular, small; spines small; root-leaves lyrate, obtuse; stem winged." *Linn.* *Root* annual. Whole plant pubescent. *Stem* about a foot high, branched. *Root-leaves* lyrate-pinnatifid; terminal lobe oval-obtusè; stem-leaves decurrent, oblong, rather narrow, entire or toothed. *Flowers* yellow, terminal; calyx-spines three; middle one longer, branched. A native of Italy and the coast of Barbary. 101. *C. eriophora*, Linn. 43. Mart. 46. Lam. 55. Willd. 91. (*Carduus luitanicus canescens*, Tour. 441. *Calcitrapa*, Vaill. Act. 1718, p. 212. *Cyanus eriophora*, Gært. 2, 382. tab. 161. fig. 4.) "Calyxes doubly spinous, woolly; leaves half decurrent, entire and sinuated; stem proliferous." *Linn.* *Root* annual. *Stem* eight or nine inches high, with several branches on its upper part, which often rise higher than itself. *Leaves* light green, obtuse, with a spine-like point. *Flowers* yellow, terminal, somewhat globular; barren florets four-cleft, shorter than the others; inner scales of the calyx simply acuminate; outer ones ending in a yellow, spreading spine, half an inch long, armed with prickles on each side. A native of Portugal. 102. *C. aggyptiaca*, Linn. Mant. 118. Mart. 47. Lam. 56. Willd. 92. "Calyxes doubly spinous, somewhat woolly; leaves sessile, lanceolate, entire and toothed; stem proliferous." *Root* annual. *Stem* a foot high.

diffuse, profusely branched, spreading; branches alternate, from the axis of the upper leaves. *Leaves* alternate, sessile, or embracing the stem, somewhat leabrous; jowell pinnatifid; middle ones lyrate; highest lanceolate. *Flowers* white, florets of the ray four-eft, smaller than the others; calyx-fines purplish, slender, with two brittle-flapped small fpires on each fide. A native of Egypt. 103. *C. calcitrapa*, Linn. 44. Mart. 48. Lam. 57. Willd. 93. Eng. Bot. 125. (Carduus ilectus, f. his papaveris erratic, Bauh. pin. 387. Tourn. 440. Calcitrapa, Hall. helv. n. 191. Hippophellum, Col. phyt. tab. 24. Calcitrapa hippophellum, Gært. tab. 163. fig. 2.) Common flar-thistle. "Calyx doubly spinous, sessile; leaves pinnatifid, toothed; stem divaricated, spreading, hairy." Smith. *Root* annual. *Stem* low, much branched, furrowed. *Leaves* pale green, sometimes alternate, sometimes from luxuriance clustered under the branches; teeth somewhat prickly. *Flowers* purple or white, lateral, sessile; florets of the ray scarcely longer than those of the disc, nearly regular; calyx-fines yellowish, divaricated, polished, three times the length of the scales, pinnated at their base with smaller fpires. *Seeds* with scarcely any down. A native of England and other temperate parts of Europe. The plant and root are both bitter, and are said to be sometimes used by brewers instead of hops. The leaves are eaten by the Jews with their paschal lamb. They are given by the French physicians in the way of extract, decoction, or powder in agues and fevers. A decoction of the root in the proportion of from half an ounce to an ounce in six ounces of water, is said to be useful in disorders of the bladder and kidneys. 104. *C. calcitrapoides*, Linn. 45. Mant. 49. Lam. 58. Willd. 94. (Carduus ilectus, foliis integris serratis, Magn. Monip. 292. Tourn. 446.) "Calyx somewhat doubly ferrated; leaves embracing the stem, lanceolate, undivided, ferrated." Nearly allied to the preceding, if not merely a variety. A native of the south of France, and of Syria.

VIII. *Calcitrapoidea*. Calyx-scales ciliated, terminated by a simple spine. (Calcitrapa; Jul.)

105. *C. dilata*, Mart. 71. Hort. Kew. 3. 261. "Calyx ciliated; scales acuminate, somewhat thorny; leaves oblong, pinnatifid; florets of the ray longer than those of the disc. A native of the south of Europe." 106. *C. micrantha*, Mart. 74. Willd. 95. Allion. ped. tab. 74. "Calyx ciliate-spinous at the tip; leaves oblong, embracing the stem, leabrous, undivided, quite entire; root-leaves egg-shaped, toothed." *Root* biennial. *Stems* a foot and a half high, striated, angular, alternately branched. *Flowers* yellow; calyx-fines dilated at the tip; spine short, stiff. A native of the neighbourhood of Nice. 107. *C. fupulata*, Willd. 96. Desfont. Atl. 2. tab. 244. "Calyx ciliate-spinous at the tip; leaves of the stem lyrate-pinnatifid; of the branches pubescent, lanceolate, somewhat toothed." A native of the coast of Barbary. 108. *C. hybrida*, Mart. 75. Willd. 97. Allion. ped. n. 511. "Calyx ciliate-spinous at the tip; leaves hoary, pinnatifid, quite entire; upper ones linear-lanceolate." *Root* biennial. Whole plant hoary-pubescent. *Root-leaves* pinnatifid, somewhat toothed. *Flowers* of the disc yellow; of the ray violet; calyx-fines rigid, yellow. A native of hills about Turin. It has been supposed to be a mule between *C. foliolialis* and *C. paniculata*. 109. *C. squarrosa*, Willd. 98. "Calyx ciliate-spinous, cylindrical; scales reflexed at the tip; leaves of the stem pinnatifid; of the branches linear." *Stem* a foot high or more, erect, branched, paniced; branches spreading. *Flowers* violet, solitary, or two together at the top of the branches. A native of the Levant. 110. *C. parviflora*, Willd. 99. Desf. Atl. 2. 301. (*C. diffusa*, Lam. 70. Carduus orientalis calcitrapa folio,

flor. minimo, Tourn. 31.) "Calyx ciliate-spinous, egg-shaped; scales reflexed at the tip; leaves hoary; root ones lyrate; stem ones linear." Nearly allied to the preceding. A native of the Levant, and of the coast of Barbary. 111. *C. ceruleiflora*, Willd. 100. (*C. virgata*; Cavan. ic. 3. tab. 320.) "Calyx ciliate-spinous; leaves of the stem pinnated-linear; of the branches linear." *Stem* a foot high, erect, smooth, pubescent near the top, furrowed, branched; branches few, erect. *Leaves* smoothish. *Flowers* violet; calyxes oblong; scales egg-shaped, obtuse, with a long spine; inner ones scarious at the tip. A native of Spain. 112. *C. jacobaeifolia*, Lam. 68. Willd. 101. "Calyx ciliate-spinous; inner scales scarious; root-leaves deeply pinnatifid, lacinated, tomentous; stem nearly naked, one-flowered." *Stem* six or seven inches long, simple, angular, cottony. *Leaves* from the root, or the lower part of the stem, petioled, soft, whitish. *Flowers* yellow. Described by La Marck from a specimen in the herbarium of Julieu. 113. *C. ruffula*, Lam. 67. Willd. 102. (Carduus orientalis, calcitrapa folio, flore flavescente odoratissimo.) "Calyx ciliate-spinous at the tip; fpires of the lower scales reflexed; leaves pinnated; pinnæ linear, obtuse; root-leaves bipinnated." *Stem* about three feet high, erect, angular, deeply furrowed, branched. *Leaves* large. *Flowers* yellow, large; calyx-fines egg-shaped, ending in a long, stiff, straight spine; fpires of the lower ones shorter, weaker, reflexed. A native of Armenia. 114. *C. ornata*, Willd. 103. "Calyx ciliate-spinous; fpires of the lower scales reflexed; leaves very scabrous, pinnated, linear; pinnæ linear, mucronate; root-leaves bipinnated." Nearly allied to the preceding. *Leaves* smaller, hoary; calyx-fines bristly-ciliated; inner ones with a scarious ciliated little scale at the tip, acute. A native of Spain. 115. *C. eryngioides*, Lam. 66. Willd. 104. (Carduus eryngioides, capite pinnato, Alp. Exor. 158.) "Calyx ciliate-spinous; leaves pinnated; pinnæ oblong, lanceolate, toothed, or entire, mucronate at the tip." *Root* perennial. *Stem* a foot and a half high, upright, simple, furrowed. *Flowers* purple, large, terminal; calyx-fines egg-shaped, with a strong spine half an inch long; inner ones with a small ciliated appendage at the tip. A native of the Levant. 116. *C. centauroides*, Linn. 49. Mart. 53. Lam. 64. Willd. 105. (Jacea lutea spinosa centauroides, Bauh. Pin. 27. Carduus centaurii majoris facie, capitulo longis & brevibus aculeis nunito, Tourn. Cor. 31.) "Calyx ciliate-spinous; leaves lyrate-pinnated, generally entire; terminal lobe large, toothed." *Stem* two or three feet high, angular, branched, clothed with short hairs. *Leaves* large, rough, deeply pinnated. *Flowers* yellow, large, terminal; outer calyx-fines short, round; inner ones oblong, scarious, without a spine. A native of Spain, Italy, and the south of France. 117. *C. incana*, Linn. 51. Mart. 54. Lam. 65. Willd. 106. (Jacea lutea, capite spinoso, Bauh. Pin. 472. Carduus luteus centauroides fegetum, Tourn. 441.) "Calyx ciliate-spinous; stem-leaves pinnatifid; root ones bipinnatifid; segments lanceolate." *Root* perennial. *Stem* two or three feet high, angular, nearly smooth, branched. *Leaves* large, greenish. *Flowers* yellow, rather large, terminal, solitary. La Marck thinks it scarcely more than a variety of the preceding, but its leaves are more deeply cut, and their terminal lobe is smaller. A native of Italy, Spain, and the south of France. 118. *C. raphanifolia*, Linn. 50. Mart. 55. Lam. 69. Willd. 107. (Jacea laciniata lutea, Bauh. Pin. 272. Col. Echpr. 1. tab. 35. fig. 2. Monf. tab. 8. fig. 25.) "Calyx ciliate-spinous; stem-leaves pinnated; root-leaves bipinnated; pinnæ linear-filiform." *Root* perennial. *Stem* scarcely angular, but little branched. Calyx-fines weak, shorter than the scale; inner scales scarious. 108. Nearly allied to the preceding. 119. *C. pubescens*, Willd. 108.

(*C. incana*, Desfont. Atl. 2. 361 ?) "Calyxes ciliate-spinous at the tip; stem-leaves pinnatifid, linear-lanceolate; root ones bipinnatifid; segments lanceolate, terminal one toothed." *Root* perennial. *Stem* a foot high, erect, furrowed, woolly, pubescent, a little branched. *Root-leaves* about seven inches long, rather smooth, segments short, acute, entire; stem-leaves three inches long; segments linear-lanceolate, an inch long, quite entire, acute; upper ones shorter, undivided, linear-lanceolate, quite entire. *Flowers* yellow; calyx the size of *C. eriophora*; scales pubescent, brownish at the tip. Described by Willdenow from a living plant. Native country unknown. 120. *C. jordanii*, Willd. 109. "Calyxes ciliate-spinous; stem-leaves pinnated, quite entire; root-leaves bipinnatifid." *Root* perennial. *Stem* a foot high, erect, furrowed, branched at the base. *Root-leaves* three inches long, pubescent; segments short, lanceolate, acute; pinnae of the stem-leaves linear, acute, quite entire. *Flowers* dull purple, the size of those of the preceding species. Willdenow, from a living plant. Native country unknown.

IX. *Crocodylodea*. Calyx-foles not ciliated, terminated by a simple spine. (Crocodylum, Juss.)

121. *C. jamaicensis*, Linn. 54. Mart. 57. Lam. 71. Willd. 112. (Stäube, Bauh. Pinax. p. 275. n. 1. *Jacea foliis cichoraceis flore purpureo*, Tourn. 444.) "Calyxes globular, smooth; spine very small, weak, a little reflected; leaves lanceolate, serrated, root ones lyrate; stem divaricated." *Root* perennial. *Stem* three feet high, a little villous towards the base; branches simple, long, slender, striated. *Lower leaves* soft, very hairy, runcinate-pinnatifid; terminal lobe lanceolate, large, toothed; lower ones narrow, almost linear, toothed, smooth, acute. *Flowers* purple or white, of a moderate size, terminal, solitary; barren florets four-elefit, not larger than the others. A native of the south of France and Spain. 122. *C. elegans*, Mart. 76. Allion. Ped. tab. 49. fig. 1. "Stem simple; leaves undivided, linear; flowers solitary, axillary, and terminal." *Root* annual. *Stem* a foot and a half high, cylindrical. *Leaves* linear, elliptical, hoary beneath, slightly toothed, ending in a small spine; lower ones opposite the others, alternate. *Flowers* blue. A native of Piedmont, in the vineyards. 123. *C. aurea*, Mart. 77. Willd. 113. Hort. Kew. 3. 265. B. t. Mag. 421. "Calyxes simply spinous; spines spreading; florets equal; leaves hairy; lower ones pinnatifid." *Root* perennial. *Stem* two feet high, hairy. *Leaves* sessile. *Flowers* bright yellow, large, terminal. A native of the south of Europe; cultivated by Miller in 1758. 124. *C. cichoracea*, Linn. 53. Mart. 58. Lam. 72. Willd. 114. (*Jacea*, Rai. Sup. 203. Till. Pil. tab. 27.) "Calyxes bristly spinous; leaves decurrent, undivided, serrated-spinous." *Flowers* small; calyx-spine recurved. A native of Italy. 125. *C. muricata*, Linn. 55. Mart. 59. Lam. 73. Willd. 115. (*Jacea cyanoides, ciliolato capite*, Bauh. Pin. 272. Morif. Hist. 3. tab. 26. fig. 18.) "Calyxes simply spinous, villous; lower leaves lyrate, toothed; upper ones lanceolate; peduncles very long." *Root* annual. *Stem* a foot high, or more, inclining, slightly villous, a little branched. *Flowers* purple, rayed; calyx-scales lanceolate, black at the edges; spine brown, very sharp. A native of Spain. 126. *C. peregrina*, Linn. 56. Mart. 60. Lam. 74. Willd. 116. (Centaurium, Boerh. Lugd. 1. p. 44.) "Calyxes bristly-spinous; leaves lanceolate, petioled, toothed near the base." *Root* biennial. *Flower* yellow, large. A native of the south of Europe. 127. *C. radiata*, Linn. Syst. 65. Mart. 61. Lam. 75. Willd. 117. (Xeranthemum crucifolium, Linn. Sp. Pl. Ed. 2. Gmel. Sib. 2. tab. 47. fig. 1. Pal. It. 3. p. 682.) "Calyxes scarcely spinous, somewhat awned, rayed; leaves pinnatifid." *Stem* branched towards the summit. *Leaves* as well as the stem furnished with white hairs,

toothed. *Flowers* white, almost cylindrical, terminal; inner calyx-scales long, forming a small ray. A native of Russia, on the banks of the Don. Linnæus was at a loss where to place this plant; and, after all, doubted whether it be not a species of *Zucca*. 128. *C. medialis*, Linn. 58. Mart. 62. Lam. 74. (Carduus cernitiosus, Willd. 35. *Jacea folio cernitio*, Tourn. 445. Herin. Parad. tab. 192. Barcl. ic. 1288. Boec. mu. v. 2. tab. 48.) "Calyxes bristly-spinous; leaves undivided; upper ones somewhat toothed; stem simple, nearly naked, one-flowered." *Root* perennial. *Stem* a foot high, upright, smooth, striated; furnished near the base with two or three narrow, distant y toothed leaves. *Root-leaves* egg-shaped, entire, petioled, a little hairy at the base and along the petiole. *Flower* purple, terminal; calyx-scales smooth, blackish at the tip. A native of the south of France, Spain, and Italy. 129. *C. Crocodylum*, Linn. 57. Mart. 63. Lam. 77. Willd. 118. (Crocodylum, Vail. Act. 1710. 183. *Cyrenus*, Barr. 503. good.) "Calyxes scarious, simply spinous; leaves pinnatifid, quite entire; terminal segment larger, toothed." *Root* annual. *Stem* a foot and half high, angular, rough to the touch; branches spreading, loose. *Flowers* on long peduncles; barren florets large, purple; fertile ones whitish; calyx-scales whitish or silvery green; with a brown appendage, terminated by a sharp spine. A native of Candia and Syria. 130. *C. fumilla*, Linn. 59. Mart. 64. Lam. 78. Willd. 119. (Crocodylum acaulum, Vail. Act. 1719. 103.) "Calyxes simply-spinous; leaves pinnated, toothed, villous; stem none. Similar to *C. acaulis* (n. 66.) but the calyx-scales are not ciliated. *Leaves* spreading on the ground. *Flowers* about three together, close to the root; barren florets scarcely longer than the others; calyx-scales smooth, membranous at their edges; spine short, yellowish. Found by Hasselquist in Egypt. 131. *C. singitana*, Linn. 60. Mart. 65. Lam. 79. Willd. 120. (*Cyrenus*, Hall. Goett. 370. Linn. Goett. 393. *Cnicus*, Herin. Ludg. tab. 163.) "Calyxes spinous at the edge; leaves lanceolate, undivided, serrated, somewhat spinous; stems one-flowered. Distinguished, according to Linnæus, from *Carthamus tinctorius* and *ceruleus* by its ray of barren florets; but La Marek suspects that the same plant has been assigned to two different genera. A native of the coast of Barbary about Tangier. 132. *C. galatites*, Linn. 61. Mart. 66. Lam. 80. Willd. 121. (*Carduus tomentosus, capitulo minore*, Bauh. pin. 582. *Carduus galatites*, J. Bauh. hist. 3. 54. Tourn. 441.) "Calyxes bristly-spinous; leaves decurrent, linear, spinous, downy underneath." Entirely the habit of a thistle. *Root* perennial. *Stem* a foot and a half high, branched, cottony, whitish. *Leaves* long, rather narrow, deeply pinnatifid, toothed, deep green, often variegated with white, milky veins or spots. *Flowers* purple or white terminal; barren florets large, cut into very narrow segments. A native of the south of Europe, and the coast of Barbary.

CENTAUREA *frutescens*, Linn. See *STEFELIA frutescens*.

CENTAUREA *majus*, Tourn. See *CENTAUREA*.

CENTAUREA *minus*, Tourn. See *GENTIANA, CHIRONIA*, and *CHLORA*.

CENTAUREA *minus*, Rai. Sup. See *ERANTHEMUM Capense*.

CENTAUREA, in *Gardening*, contains plants of the herbaceous annual and perennial kinds. It has been seen that the species are very numerous, but those most commonly cultivated are: the great purple century, (*C. centaurium*); the perennial blue bottle, or blue batchelors button (*C. montana*); the annual blue-bottle, or bottles of all sorts (*C. Cyrenus*); the purple sweet century, or sweet Sultan, (*C. moschata*).

The first sort has a strong perennial root, and a great number of long pinnate leaves, of a lucid green colour, spreading wide on every side proceeding from it; the peduncles are slender, but very stiff, and divide at top into many smaller peduncles. These together with the stalks, rise five or six feet high, having at each joint one small pinnate leaf of the same form with the others; each of the peduncles is terminated by a single head of purple flowers, considerably longer than the calyx, which come out in July, and in warm seasons, produce ripe seeds in this climate.

The second sort has a perennial root, running deep into the ground; the stem is commonly, single, upright, one-flowered; sometimes, especially in a cultivated state, it puts forth a branch or two; the leaves are quite entire, tomentose; and the flower large and spacious. And there are varieties, with broad leaves, with narrow leaves, and the dwarf perennial blue-bottle.

In the third the stem is from one to two feet high, angular, slightly tomentose, branched at top; the leaves are numerous, white underneath, with three parallel ribs; the branches are one-flowered, flowering from June to August. It varies with blue flowers, with blue and white flowers, with purple flowers, with purple and white flowers, with flesh-coloured flowers, with flesh-coloured and white flowers; with violet-coloured flowers, with violet and white flowers, with red flowers, with double blue flowers, with double purple flowers, and with double purple and white flowers.

The last sort is annual, and sends up a round channelled stalk near three feet high, which divides into many branches with jagged leaves, of a pale green colour, smooth, and close to the branches; from the side of the branches come out long naked peduncles, each sustaining a single head of flowers, which have a very strong odour, so as to be offensive to many people, but to others very grateful; they are purple, white, or flesh-coloured. It varies with purple flowers, with white flowers, with flesh-coloured flowers, with purple fistulous flowers, with white fistulous flowers, with fringed flowers and sawed leaves, and with bright yellow fistular flowers.

Method of Culture.—These are plants which are raised with little trouble or difficulty. The first sort is capable of being increased by parting the roots, and planting them out in the early spring months or in the autumn, in beds or borders where they are to remain. And it, as well as the annual sorts, may likewise be raised from seed, which in it and the second kind should be sown in the borders or clumps in March or the following month, the young plants being kept clean from weeds, and removed into other situations, when necessary, in the following autumn.

The two last sorts and varieties are also propagated by sowing the seeds in the open ground, where the plants are to flower, in the above season. They should be put in patches of six or seven seeds in a place, covering them lightly in to the depth of half an inch. The latter of which may also be sown in the autumn as soon as the seeds are fully ripened, by which means they will flower at a much more early period in the following year. And the last or sweet sultan kind, especially the yellow, which is rather tender, may also be rendered more forward by sowing the seeds under frames or glasses on gentle hot-beds in the early spring, removing the plants to the open ground when of sufficient growth, with balls of earth about their roots or in pots. They are all proper for ornamenting the clumps and borders of pleasure-grounds; the two first being placed more backward in them, as growing to the largest size.

CENTAURIUM *minerale*, among *Chemists*, a name given by some to the PANACEA of antimony, called also by Glau-

ber, *purgas universalis*; the preparation of which is given by Juncker.

CENTAUROIDES, in *Medicine and Pharmacy*, the same with GRATIOLA. Others give the denomination to the greater centaury.

CENTAURIOPOLIS, in *Ancient Geography*, a fortress of Greece in Thessaly; seated on Mount Ossa, near Tempe. The emperor Justinian is said to have repaired its ruined walls.

CENTAURS, in *Metaphysics*, a kind of fabulous monsters, half men, half horses. The poets seem that at the centaurs were the sons of Ixion and a cloud. The reason of which fancy was, that the call to which they retired was called Νέφος, which signifies a cloud. Pind. Pyth. Od. 2. This fable is differently interpreted.

The centaurs, in reality, were a tribe of Lapithæ, who inhabited the city Peloponnesum, adjoining to mount Pelion, and first invented the art of breaking horses; as is intimated by Virgil. Georg. lib. iii. vers. 115. Homer and Hesiod speak of centaurs. The first of these poets in his Iliad (l. i. v. 263, and l. ii. v. 742) and in his Odyssey (l. xxi. v. 207) calls them savage, or monsters covered with hair. Hesiod describes the combat of the centaurs and Lapithæ, the latter of whom had helmets and cuirasses, whereas the former fought without any defensive armour.

Pindar seems to have been the first of the poets who represented the centaurs as half men and half horses. "These monsters (says he) were the fruit of the amours of Centaurus, the son of Ixion, with the mares of Thessaly; they resembled their father in the upper part of their body, and their mother in the lower." But upon the chest of Cypselides, mentioned by Pausanias, and upon which characters were written in the year 778 B. C. in the boultrophedon form, the centaur Chiron appears half man and half horse, but represented as a man sustained upon two human legs and feet, with the croup-flanks and two hinder legs of a horse attached to his loins; so that two feet of this centaur were those of a horse; so that it resembled a man leading a horse by the bridle rather than a cavalier mounted on horseback. M. Treret (Mem. Liter. t. 23.) suggests, that the centaurs were herdsmen, who for a long time occupied with their herds the valleys of Thessaly. Their name seems evidently to be derived from κέντρον, *stimulo*, *I prick*, and ταύρος, *boves*, whence κενταύρος, *bull-prickers* or centaurs. It is of this kind of persons that Homer speaks (v. 250) as inhabiting at first the environs of mount Pelion, and who, having been driven away by Pirithous, fought a retreat in the country of the Æthiæ. Didymus, upon this and the following verses, observes, that, according to all the ancients, the centaurs of mount Pelion were of the same nation with the Perithæi. Accordingly, the centaurs were the first herdsmen of Thessaly. The more ancient sculptures represent them as persons who stood near horses to hold them; and in process of time, and by means of a poetic or picturesque licence, they came to be represented as half men and half horses.

CENTAURUS, CENTAUR, from κενταύρος, formed of κέντρον, *pringo*; and ταύρος, *bull*; q. d. *bull-pricker*, in *Astronomy*, a part or moiety of a southern constellation, being one of the 48 old constellations, in form, half man, half horse; usually joined with the Wolf. See LUPUS. According to the fable of the Greeks, this was Chiron the centaur, who was the tutor of Achilles and Æsculapius, represented as half man and half horse, because he had applied the art of medicine to the benefit both of men and of horses. Others pretend that it is the symbol of pleasure, which reduces men to the similitude of beasts: but the origin of the allegory which has placed

placed Centaurus among the constellations is unknown. His hands hold a bottle full of wine, as a symbol of the vintage, which occurs when the sun is near this constellation; and the seventh labour of Hercules is represented by his triumph on a furious animal, because the sun in the sign of Aquarius causes the minotaur monster of this constellation to disappear.

The stars of this constellation, in Ptolemy's Catalogue are 37; in Tycho's 4; and in the Britanick Catalogue, with Sharp's Appendix, 35. Among a great number of stars in the catalogue of La Caille, there is one, besides others of the first magnitude, which in 1750 had $215^{\circ} 42' 26''$ of right ascension, and $59^{\circ} 47' 8''$ of south declination. For an account of the comparative lustre of some of the stars in this constellation by Dr. Herschel, see the Phil. Transf. for 1797, p. 314.

CENTAURY. See **CHLORA**, **GENTIANA**, and **CENTAUREA**.

CENTAURY, in *Agriculture*, is the name of a weed or plant, abounding in arable or other lands, and generally called blue-bottle. It is often very troublesome to extirpate from the lands on which it has established itself.

CENTELLA, in *Botany*, Linn. See **HYDROCOTYLE glabrata**, and **villosa**.

CENTENARIENSIS, in *Ancient Geography*, an episcopal see of Africa in Numidia.

CENTENARIUS, or **CENTENIER**, in the *Middle Age*, was an officer who had the government or command, with the administration of justice, in a village, or division, containing an hundred freemen. The *centenarii* were under the jurisdiction and command of a superior officer, called the count or *comes*. We find them among the Franks, Germans, Goths, Lombards, &c. On account of the disorders that prevailed in the ninth century, and the acts of violence that were so commonly committed, as to be hardly considered as criminal, the centenarii were required to take an oath, that they would neither commit any robbery themselves, nor protect such as were guilty of that crime. Before the time of Charles the Bald, the titles of count, duke, vicar, centenier, or thungin, were not hereditary in families. They had the management of the revenue and administered justice in the provinces. They were at the same time magistrates and military men. They convoked the *ban* and *arrière-ban*, assembled and conducted the troops to the places of general rendezvous.

CENTENARIUS is also used for an officer who had the command of a hundred men, more frequently called **CENTURION**.

CENTENARIUS, in *Monasteries*, was an officer who had the superintendance of a hundred monks.

CENTENARIUS was also used for a person worth a hundred thousand sesterces; or otherwise called **CENSUS**.

CENTENIER. See **CENTENARIUS**.

CENTENIUM ovum. See **EGG**.

CENTER, or **CENTRE**, in a general sense, denotes a point equally remote from the extremes of a line, figure, or body; or the middle of a line, or plane, by which a figure or body is divided into two equal parts; or the middle point to dividing a line, plane, or solid, that some certain effects are equal on all sides of it. The word is *κεντρος*, which primarily signifies a *point*; being formed from the verb *κεντρον*, *pungere*, to prick.

CENTER, in *Architecture*. This term is used to denote a frame of timber constructed for the purpose of supporting the stones or bricks forming an arch or vault during the erection. Thus the center serves as a foundation for the arch to be built upon, which, at the completion of the

work, is struck or taken down, and then the arch will stand of itself from its curved figure.

The center of a large vault, such as that of a bridge, consists of trussed ribs, framed like those of a roof, set in parallel vertical planes; at the distance of 5, 6, 7, or 8 feet, bridged over with horizontal pulnies. In great works, a bridging is laid for every course of arch stones, with blockings between to keep them at proper distances. The vault-stones do not always immediately rest upon these bridgings: planks are sometimes put between that they may afterwards be cut away, in order to separate the center from the vaults, which must now support itself by the reciprocal pressure of its parts.

If a center is truly constructed, every point of the vault to be built ought to be supported, without giving any transverse strain to the incumbent part of the center: but this is impracticable, for, as it would require such a multiplicity of joints, and, from the shrinking of the timber, it would be less sufficient than if composed of few pieces, supporting only a certain number of points disposed at judicious distances, leaving the intervals to be supported by timbers in which the superincumbent part of the arch will act transversely, but will still present a sufficient resistance so as not to be materially bent or put out of form by the load of the arch above.

If the river over which a bridge is to be built is not navigable, the manner of constructing the center is so easy, that it would be unnecessary to give any examples here; but where the river is navigable, the center requires an opening in the middle for vessels to pass: this renders the construction more intricate by interrupting the horizontal tie, instead of which a number of ties are therefore disposed around the polygon, forming the interior part of the center; but as in many practical cases the most judicious and well-skilled theorist might be deceived as to the equilibrium of the arch to be supported, or the points on which it has the most tendency to fall in, it would, therefore, be difficult to say what are ties and what are struts; and even if the true pressure of the arch could be ascertained, the knowledge of this alone would not be sufficient; for the same parts of the vaults, in the process of execution, vary their pressure in every succeeding additional part, and what was a tie at one time, becomes sometimes a strut, and a strut, on the contrary, a tie at another, either in building, or at the completion of the vault. This ought to be well considered; and, where the pressure is doubtful, or any of the lengths of timber forming the center be ascertained to be in the two different states above mentioned, such timbers should be made to act in either case.

Though the timbers upon which the vault immediately rests cannot be supported transversely throughout, the other pieces, which support the arch from the several pressing points, may all be made to act by a judicious arrangement, in a direction of their lengths. The abutting joints, which are pressed, will be sufficiently resisted, when their shoulders are made perpendicular to the direction of their force, and with a very small tenant; but if the timbers are drawn in a direction of their length, the joints ought to be strapped.

The beauty of every truss is to have as few quadrilaterals as possible. All the openings should be triangles: the intersection of the timber should be as direct as possible. Oblique pressures exert prodigious strains, which require timbers of very large sections to withstand them, and which press upon the abutments so much as to make the whole truss sag by the compression of the intermediate joggles.

If proper attention be paid to these circumstances, and

the bearings of the timbers well ascertained, a center, constructed upon such principles, must answer its intended purpose, provided that a proper estimate be taken of the communicating forces during the execution of the vault, and that the center be well secured at its abutment.

There are several principles of constructing the ribs of centering; one of these may be that of a large truss, spanning the whole opening, having its vertex supporting the summit of the arch, and its rafters, or principal braces, supporting other subordinate trusses which refill the prellure of the arch at other intermediate points.

Of this kind is that of the bridge of Orleans, by Mr. Hupéau, one of the boldest centers ever executed in Europe. Another principle is that of two independent trusses, one supporting the sides or haunches of the arch, and the other the crown. Of this construction was the centering of the nave and transepts of St. Peter's church at Rome, by Michael Angelo, and two centers by Pitot. Another principle of centering is that of inscribed equilateral polygons, that is, the exterior beams, supporting the curve, are of equal lengths, and joined together in the form of a polygon; another polygon is formed within this, having its angles in the middle of the sides of the former, and so on, alternately until there are as many polygons inscribed as will make the centering sufficiently strong or stiff; this mode of centering may be of two kinds. One, when the angles are fixed at their junction to the sides of the last, with bolts: double king-polls are put over the angles to prevent transverse strain at that section of the beams where the two pieces meet, and to support the curve above. The other kind is, when the polygons act independently of each other: these polygons are brought into action by king-polls, which support the curve, and act upon the angular points of each other's polygon. Of this kind were the centering of the bridges of Cravant, Nogent, Mayence, and Neuilly, constructed by Perronet. Though these centerings have been executed to very large spans, the last mentioned being 120 feet, their equilibrium is by no means so secure as when the angles of the inner polygon are fastened to that immediately preceding, as is evident from the information given of the erection of these bridges by the ingenious architect who has favoured the world with a treatise on this subject. Another principle of centering is that of Westminster and Blackfriars bridges, London. They consist of a series of trusses, each supporting a point in the arch, the principal braces having their lower extremities abutting below at each end of the centering, on the striking-plates, and at the upper end, upon apron pieces, which are bolted to the curve that support bridgings for binding the pieces which compose them together at their junction. There is one disadvantage under which this mode labours; that is the frequent intersection of the principal braces with one another: they must either be halved, upon each other, otherwise they must be discontinued, and made in various lengths. Both of these diminish their lateral strength, and consequently make them much more liable to buckle than when whole; but of the two that of halving is to be preferred; as, by the braces being in one length, there can be no sagging occasioned by intermediate joggles, and the braces may be rendered sufficiently secure laterally, by running straps longitudinally across the notched part on each side, bolting these straps to the braces.

Lastly, another mode of centering may be that of a number of quadrilateral frames abutting on each other, having their joints radiating to a center, in the manner of the wedges of an arch in masonry. These frames should all be re-

solved into triangles by one or two diagonals, according to the kind of strain, keeping in view that a piece, which is a tie in one diagonal, is, in the other diagonal, of the same quadrilateral, a strut: but if the kind of strain on any frame is not well ascertained, it would be better to place two diagonals halved upon each other. The frames are to be secured to one another with keys or bolts; by this precaution each frame will be rendered quite immovable.

Having now shown the principles upon which a good center may be constructed, we shall proceed to give some of the most approved examples.

Fig. 1, Plate LXXVI of Architecture, is the manner of forming the rib for a center by two independent trusses; in this form of centering there is no occasion for bridges, or double king-polls, as in those of Pitot, of the same construction.

Fig. 2 The manner of forming a center by two polygons, of which the interior one is secured to the exterior: in this there is no occasion for double king-polls, as the parts of the inscribed polygon either act as struts, or ties to that of the circumscribing one.

Fig. 3, is the manner of constructing a center with three polygons, which are all secured to each other. In this, king-polls become necessary, otherwise the angles of the inner polygon would bend the sides of that next to it.

Fig. 1, Plate LXXVII, is the manner of constructing a center according to Perronet, with four polygons, independent of each other, but with this improvement, that the lower extremities of each ring of polygons are framed into the two abutments; this gives a much firmer base than if they were all to meet at the same place, and renders the center much stronger, by making the angles more acute. In this it becomes also necessary to have double king-polls, otherwise the exterior polygon would only be effective.

Fig. 2, is the manner of forming a center, as used at Westminster and Blackfriars bridges, by independent trusses, consisting of two rafters. Whoever considers the principle of this center, must evidently see that there is no occasion for the double king-polls, as the pressure is directed to the abutments, or to two opposite of the arch in the same level. In this example, the intersections are all supposed to be halved together, and firmly strapped across the notchings.

Fig. 3, is the manner of constructing a center with separate frames, the sides of which radiate to a center, as has already been intimated.

Fig. 1, Plate LXXVIII, is the design of a center; its principle is that of two roofs intersecting each other. In this example, the forces which are communicated to the various parts of the frame are resisted longitudinally, either by compression or extension; and no force is exerted transversely on any part, excepting the curved pieces in contact with the boarding supporting the arch stones.

Fig. 2, is the design of a center: it is first framed in one large truss, like a common roof, with two principal rafters, and a collar beam: each of the rafters becomes a tie for the two small trusses above which are framed in the manner of a roof with queen-polls and braces. The lower angles of the principal rafters are braced from the lower queen-polls to the polls. This truss is free from transverse strains in all its parts, except the curve, which support the arch stones; and, if well secured at the abutments, an arch of an immense weight may be erected upon it.

Fig. 3, is the celebrated center used at Blackfriars bridge. The names of the timbers are as follows:

- A, Timbers which support the centering.
- B, C, Upper and lower striking-plates cased with copper.
- D, Wedge

- D, Wedge between striking-plates for lowering the center.
- E, Double king-poils to confine braces.
- F, Apron pieces to strengthen rib of center.
- G, Bridings laid on the back of the ribs
- H, Blocks between bridgings to keep them at equal distances.
- I, Small braces to confine the ribs tight.
- K, Iron straps bolted to king-poils and apron-pieces.
- L, Ends of the beam at the feet of king-poils.
- M, Principal braces.

In striking the center of a large arch, the best method is to let it down a little at a piece, by easing some of the wedges; it is there left to rest for a few hours or days, to try if the arch makes any efforts to fall, or any joints open or stones crush or crack, that the damage may be repaired before the center is entirely removed, which is not to be done till the arch ceases to make any visible efforts.

CENTER of Attack, in French *centre d'attaque*, or *attaque du centre*, in *Military Language*, is an attack on an extensive front, from the second parallel upon the works of a strong place that is besieged, according to the rules or principles of a regular attack.

CENTER of Attraction. See *CENTER of Gravitation*.

CENTER of abajision, in *Fortification*, is the middle point of its gorge, or angular point of the interior polygon, or the point where the two adjacent curtains would meet when produced.

CENTER, or CENTRE, of a battalon on parade, in *Military Language*, is the middle of it, where an interval is left for the colours; and so on.

CENTER of cavity, in a *ship*, is the center of that part of the ship's body which is immersed in the water; and which is also the center of the vertical force exerted by the water to support the vessel. See *BALLAST*.

CENTER of a circle is a point in the middle of a circle, or circular figure, from which all lines drawn to the circumference are equal.

Euclid demonstrates, that the angle at the centre is double to that at the circumference; i. e. the angle made by two lines drawn from the extremes of an arch to the center, is double that made by two lines drawn from those extremes to a point in the circumference.

CENTER of a conic section is the middle point bisecting any diameter, or the point in which all the diameters intersect and bisect one another.

This point, in the ellipsis, is within the figure; and in the hyperbola, without, or between the conjugate hyperbolas; and in the parabola, it is at an infinite distance.

CENTER of conversion, in *Mechanics*, a term first used by M. Parent. Its signification is thus conceived: if a stick be laid on stagnant water, and drawn by a thread fastened to it, so that the thread always makes the same angle with the stick; the stick will be found to turn on one of its points which will be immovable; which point is termed the *center of conversion*. For the greater ease the thread may be conceived fastened to one end of the stick.

This effect arises from the resistance of the fluid, and the manner wherein it divides: for, imagine the first moment of traction, it is certain, here, the resistance of the parts of the fluid to be displaced tends to turn the stick around the point to which the thread is fastened, as on a center; so that in the present instance, the staff would describe precisely the quadrant of a circle: after which the fluid would no longer bear the stick lengthwise; but in a particular motion, in such manner, as that the free end of the stick, and the parts nearest it, would describe larger arcs of circles than the rest, and have a greater velocity. The resistance, therefore, of the fluid, which tends to impress a circular motion on the stick, around the point to which the thread is fast-

ened, tends to impress a greater velocity on the parts next to the other extremity; or, which is the same thing, those parts require a greater velocity to surmount the resistance of the fluid, so that the stick will not have that circular motion around the point to which the thread is fastened; or the resistance of the fluid is greater towards the free extreme of the stick, and still lessens towards the other extreme. Now all the columns, or threads of water, which resist the stick, must be supposed of the same length or the same mass. One may therefore find on the stick such a point, as that taking a great number of those threads on that side which resists the least, and a less number on that side where they resist the most, there will be an exact compensation, and the forces be equal on each side: this point is the center of conversion. And as the foregoing reasoning has place in all motions of traction made in the same manner, this center is always the same point. The grand question here arising is, to know precisely in what point the center of conversion is found: this M. Parent has determined by much laborious calculation. If the stick drawn by one extremity be a straight line divided into twenty parts, reckoning from the thread, the center of conversion he finds will be nearly on the 13th. If it be not a line, but a surface or a solid, there will be some change in the situation of the center of conversion, according to the surface, or the solid. See *Mem. of the Acad. of Sciences*, abridged, vol. i. p. 191.

If in lieu of a body swimming in a fluid, we suppose it laid on a rough uneven plane: the resistance of this plane to the motion of the body will always be divided in the same manner, and determine the same center of conversion. This resistance is, precisely, what we call *friction*, so prejudicial to the effects of machines. See *CENTER of rotation*.

CENTER of a curve, of the higher kind, is the point where two diameters concur.

When all the diameters concur in the same point, sir Isaac Newton calls it the *general center*. M. l'Abbé de Gua, in his "Usages de l'Analyse de Descartes," has given a method for finding the general centers of curves, and suggested some important remarks on the definition of general centers given by Newton. The ingenious abbé calls the general center of a curve a point of his plane, such that all the right lines which pass thither have on one side or other of this point equal portions terminated by the curve; and he observes: 1. That this definition corresponds with sufficient exactness to the ordinary acceptation of the word center:—2. That the definition of Newton is comprised in his own: and 3. That by adhering to his definition he has arrived at those conditions which Newton assigns to curves, which, according to him, have a general center; and hence it seems to follow, that Newton had in view the definition of M. l'Abbé de Gua rather than his own, when he determined these centers. M. Cramer, in his "Introduction à l'Analyse des Lignes courbes," gives a very exact method for determining these general centers.

CENTER of a dial, is that point where its gnomon or style, which is placed parallel to the axis of the earth, intersects the plane of the dial; and from thence, in those dials which have centers, all the hour lines are drawn. If the plane of the dial be parallel to the axis of the earth, it can have no center at all; but all the hour-lines will be parallel to the style, and to one another; the center being, as it were, at an infinite distance.

CENTER of an ellipsis, is that point where the two diameters, the transverse and the conjugate, and also all other diameters, intersect each other.

CENTER of the equant, in the *Old Astronomy*, a point in the line of the aphelion; being as far distant from the center

of the eccentric towards the aphelion, as the sun is from the center of the eccentric towards the perihelion.

CENTER of equilibrium, is the same with respect to bodies immersed in a fluid, as the center of gravity of two bodies in free space; or it is a certain point on which, if the body or bodies be suspended, they will rest in any position. More generally, in a system of bodies, it is the point about which they will be in equilibrium; or it is a point such that if the system of bodies were suspended or supported by it, the said system would remain in equilibrium. Thus, the fulcrum of a lever is its centre of equilibrium. For a method of determining the centre of equilibrium, see Emerson's Mechanics, pp. p. 92, p. 131.

CENTER of friction is that point in the base of a body, on which it revolves, into which, if the whole surface of the base and the mass of the body were collected, and made to revolve about the center of the base of the given body, the angular velocity destroyed by its friction would be equal to the angular velocity destroyed in the given body by its friction in the same time.

To find the center of friction. Let FGH (Plate IV. Mechanics, fig. 21.) be the base of a body revolving about its center C, and suppose about a, b, c , &c. to be indefinitely small parts of the base, and let A, B, C, &c. be the corresponding parts of the solid, or the prismatic parts, having a, b, c , &c. for their bases; and P the center of friction. It is manifest, that the decrement of the angular velocity must vary as the whole diminution of the momentum of rotation caused by the friction directly, and as the whole momentum of rotation or effect of the inertia of all the particles of the solid inversely; the former being employed in diminishing the angular velocity, and the latter in opposing that diminution by the endeavour of the particles to persevere in their motion.

Hence, if the effect of the friction varies as the effect of the inertia, the decrements of the angular velocity in a given time will be equal. Now as the quantity of friction does not depend on the velocity, the effect of the friction of the elementary parts of the base a, b, c , &c. will be as $a \times aC, b \times bC, c \times cC$, &c. and also the effect of the inertia of the corresponding parts of the body will be as $A \times aC^2, B \times bC^2, C \times cC^2$, &c. Now when the whole surface of the base and mass of the body are concentrated in P, the effect of the friction will be as $a + b + c + \&c.$

$\times CP$, and of the inertia as $\frac{A + B + C + \&c. \times CP^2}{\&c.}$; consequently $a \times aC + b \times bC + c \times cC + \&c. : a + b + c + \&c. \times CP :: A \times aC^2 + B \times bC^2 + C \times cC^2 + \&c. : A + B + C + \&c. \times CP^2$; and hence

$$CP = \frac{A \times aC^2 + B \times bC^2 + C \times cC^2 + \&c. \times a + b + c + \&c.}{a \times aC + b \times bC + c \times cC + \&c. \times A + B + C + \&c.} = (\text{if } S = \text{the sum of the products of each particle into the square of its distance from the axis of motion. } T = \text{the sum of the products of each part of the base into its distance from the center, } s = \text{the area of the base, } t = \text{the solid content of the body}) \frac{S \times s}{T \times t}.$$

See Vince on the motion of bodies affected by friction, in the Philof. Transf. for 1785, vol. lxxx p. 186.

CENTER of gravitation, or attraction, in Physics, is that point to which bodies tend by gravity; or that point to which a revolving planet or comet is impelled or attracted by the force or impetus of gravity.

CENTER, in Masonry, denotes a wooden mould by which to turn an arch. See CENTER in Architecture.

CENTER of gravity, in Mechanics, is a point within a body,

through which if a plane pass, the segments on each side will be equidistant, i. e. neither of them can move the other. Hence, if the descent of the center of gravity be prevented, or if the body be supported by its center of gravity, it will continue at rest in equilibrium, in any position. The whole gravity, or whole matter, of a body may be conceived united in its center of gravity; and therefore, in demonstrations, it is usual for the body to substitute the center.

Through the center of gravity passes a right line, called the diameter of gravity: the intersection, therefore, of two such diameters determines the center. The plane whereon the center of gravity is placed is called the plane of gravity: so that the common intersection of two such planes determines the diameter of gravity.

In homogeneous bodies, which may be divided lengthwise into similar and equal parts, the center of gravity is the same with the center of magnitude. If, therefore, a line be bisected, the point of bisection will be the center of gravity.

The center of gravity of a parallelogram, or cylinder, or any prism whatever, is in the middle point of the axis: and the center of gravity of a circle, or any regular figure, is the same as the center of magnitude. Also, if a line can be drawn as to divide a plane into equal and similar parts, that line will be a diameter of gravity, or will pass through the center of gravity; and it is the same as the axis of the plane. Thus, the line, drawn from the vertex perpendicular to the base of an isosceles triangle, is a diameter of gravity; and thus also the axis of an ellipse, or a parabola, &c. is a diameter of gravity. The centre of gravity of a segment or arc of a circle is in the radius or line perpendicular bisecting its chord or base. Likewise, if a plane divide a solid in the same manner, making the parts on both sides of it perfectly equal, and in all respects similar, it will be a plane of gravity, or will pass through the center of gravity. Therefore, as the intersection of two such planes determines the diameter of gravity, the center of gravity of a right cone, or spherical segment, or conoid, &c. will be in the axis of the same. See the sequel of this article.

To find the center of gravity of a body. Let A, B, C, D, &c. (Plate IV. Mechanics, figs. 22.) be particles of the body, and finding the centers of equilibrium, p and q , of A and B, C and D respectively (see BALANCE and LEVER); let A + B be placed in p , and C + D in q , and their center of equilibrium, G, will be the center of gravity of the particles A, B, C, D, &c. Because the force of gravity acts upon the particles in parallel directions, the efficacy of A to communicate motion to G is A \times AG, and that of B is B \times BG, or A \times Ap + pG, and B \times Bp + pG, which are equivalent to them, or A + B \times pG, since A \times Ap and B \times Bp are equal and opposite, and consequently destroy each other. The sum of the momenta of C and D is found, by a similar process, to be the same as if they were placed in q ; and consequently G, which is the center of gravity of A + B and C + D, placed in p and q respectively, is the center of gravity of A, B, C, D, placed at the points A, B, C, D, &c.

Hence it follows, that the particles of the body cannot be in equilibrium about any other point except G; for, if possible, let X be such a point, and it is plain that the efforts of A and B to move X = A + B \times pX, and of C and D = C + D \times qX; consequently the point X is kept in equilibrium by two forces, A + B \times pX, and C + D \times qX, not acting in opposite directions, which is impossible. Moreover, in every situation of the body composed of the particles A, B, C, D, &c. if the point G be supported, the body will be at rest; for the force of gravity acting always in parallel directions upon the particles, their momenta, or efforts to move

C, will always be as $A \times \Delta G, B \times B G, \&c.$ which, by the process used in this proposition, will always be reduced to two forces that are equal and opposite. Farther, if $A + B + C + D, \&c.$ be equal to Q , and the pressure of each in parallel directions be equal to g , a force, as $Q \times g$, acting at the point G in a direction opposite to that in which the particles press, will remove their pressure. Or, if $A, B, C, \&c.$ be destitute of gravity, and only resist the action of a force by their inertia, a force at P acting at G will communicate equal velocities to every particle; because their resistances, being exerted in directions opposite to that of P , and therefore parallel to each other, vary as their distance from G , and consequently the sums of the resistances on each side of G are equal. And, vice versa, if Q be moving and without gravity, a force applied at G (the center of inertia) equal to the momentum of Q , will destroy all motion.

The center of gravity of a ship is always before the point, which is the middle of her absolute length; for the fore part, having greater capacity than the after part, must of course have also greater weight: and, therefore, it carries the center of gravity forward in proportion to its greater weight (which in large ships is from 50 to 80 tons), and also to the interval between every center of gravity of each particular part, both forward and aft. When a ship is at sea, and loaded, the center of gravity may well be supposed not to change, unless the cargo be moved. But experience shews, that the fore or after part of the bottom of a ship plunges and labours more and more, in proportion as the wind acts with more or less force on the sails: because ships are generally not masted according to the "point velique;" so that a ship which has the center of the effort of her sails ill placed, draws always more water forward or aft, when the impulse of the wind upon her sails is very powerful, than when she is at ease under her burden. Obf. From the center of gravity of the floating line of a ship let a perpendicular be raised, and continued till it be intersected by the direction of the impulse of the water on the bows, in sailing directly before the wind; and, where these two lines cut each other, that point is the "point velique," and where the center of effort of all the sails should be placed.

CENTER, common, of gravity of two bodies, is a point so situated, in the right line joining the centers of the two bodies, as that, if the point be suspended, the two bodies will equiponderate, and rest in any situation. Thus, the point of suspension in a common balance, or in a Roman steelyard, where the two weights equiponderate, is the common center of gravity of the two weights.

When any number of bodies move in right lines with uniform motions, their common center of gravity moves likewise in a right line with an uniform motion; and the sum of their motions estimated in any given direction, is precisely the same as if all the bodies, in one mass, were carried on with the direction and motion of their common center of gravity. Nor is the center of gravity of any number of bodies affected by their collisions or actions on each other.

1. If one or more of the bodies, $A, B, C, \&c.$ (Plate IV. *Mechanics*, fig. 23.) move uniformly in the same right line, with velocities equal to $a, b, c, \&c.$ their common center of gravity will move uniformly. For, let A and B move uniformly in the same or an opposite direction, P be their center of gravity, and D their distance; then, because the motions of A and B are uniform, D either continues the same, or increases and decreases uniformly; but $AP = \frac{D \times B}{A + B}$, and consequently varies as D , and P moves uniformly. If another

body, C , move uniformly in the same right line, and R be the center of gravity of A, B, C , the distance, CP , either continues the same, or increases and decreases uniformly, because C and P move uniformly; but $PR = \frac{CP \times C}{A + B + C}$; and consequently varies as CP , or R moves uniformly. Hence it follows, that the velocity of the center of gravity is equal to $\frac{Aa \pm Bb \pm Cc}{A + B + C}$; for, let p, r, a, b, c , be contemporary positions of P, R , and the bodies, and (by what we shall demonstrate in the sequel of this article) $A \times \Delta p$, or $\times Aa + ap - B \times Bp$ or $\times bp \pm Bb = A + B \times Pp$, and $Pp = \frac{A \times Aa \pm B \times Bb}{A + B}$, because $A \times ap - B \times bp = a$. And, placing $A + B$ in P , and repeating the above process, it appears that $Rr =$ the velocity of $R = \frac{A \times Aa \pm B \times Bb \pm C \times Cc}{A + B + C}$. Hence again it is in-

ferred, that the velocity of R is uniform; because Aa, Bb, Cc , are constant, and consequently their sum, or difference, multiplied into the same given quantities, or the velocity of R , is always the same. Moreover, because $A + B + C \times Rr = A \times Aa \pm B \times Bb \pm C \times Cc$, the velocity of the center of gravity is such as would be communicated to the sum of the bodies acted upon by a force equal to $A \times Aa \pm B \times Bb \pm C \times Cc$.

2. If one or more bodies, $A, B, C, \&c.$ (fig. 24.) move uniformly in right lines, either in the same or different planes, their common center of gravity, S , will move uniformly in a right line. Let B describe Bb uniformly in the time T , and P, Q be the centers of gravity of A and B ; and $A + B : B :: AB : AP :: Ab : AQ :: Bb : PQ$ (Eucl. I. vi. pr. 5.), and PQ is parallel to Bb , and equal to $\frac{Bb \times B}{A + B}$, and varies

therefore as Bb , or uniformly. Let A describe Aa uniformly in the time T , either in the same plane with Bb , or not, and R be the center of gravity of A , and B placed at b ; and QR , the path of the center of gravity, will appear, by the same process with the above, to be parallel to Aa , and equal to $\frac{Aa \times A}{A + B}$, and consequently it varies as Aa , or increases uniformly. When both bodies move at the same time, the point P will have two motions, PQ and QR ; and will consequently describe the diagonal PR uniformly in the time T . Let a third body be added, and the common center of gravity be S , and CS produced will pass through the center of gravity of A and B . Then, from the nature of the center of gravity, $A + B + C : A + B :: CP : CS :: CQ : CT :: QP : ST$; and $ST = \frac{A + B \times QP}{A + B + C}$,

and varies as QP , or uniformly; and for the same reason TV , the motion of T arising from A 's motion, is equal to $\frac{QR \times A + B}{A + B + C}$, and therefore varies as QR , or uniformly. When A and B move together, the motions ST, TV , will be combined into one, SV ; and if C describe Cc uniformly in the time T , the common center of gravity will describe VY , and this new motion, combined with SV , will make it describe SY uniformly in the time T .

This proposition may be otherwise demonstrated in the following manner. *Case 1.* Let two bodies move, in the same plane, in the directions $D E, A B$, (fig. 25.); and let D and A, E and B be contemporary positions, and H, K , the centers of gravity in those positions, respectively; and taking

BP = AD, joining EP, and drawing DL parallel to HK, DE : AB in the given ratio of the motions of the bodies; and, because the angle EDP is given, all the angles of the triangle EDP are given, and DP is to PE in a given ratio; and, because all the angles of the triangle DPL are given, the angle PDL is given, and L is always in DL. By the nature of the center of gravity, DA : DH :: EB : EK :: PB or DA : LK; therefore DH = LK, and DHKL is a parallelogram, HK is parallel to DL, and the angle BHK is given, and the center of gravity K is always in the right line HK given in position. And, because all the angles of the triangles DPL and DLE are given, the lines DP, DE, DL, that is, A, B, DE, HK, are in a given ratio, and consequently the point K moves uniformly in HK. The demonstration is the same if one of the bodies moves from B towards A.

Case 2. Let the paths of the bodies, A B and D E, (fig. 26.) be in different planes; and through A B draw a plane Bde parallel to DE, and through DE draw the plane Dde perpendicular to Bde; produce BA to d, and let Dd, Ee, be perpendicular to de, and the planes dAa, EeB, will be perpendicular to the plane edB. Let A and D, B and E, be contemporary positions of the bodies. If the body at D were to move in de, the center of gravity would move uniformly in some line HK (case 1.); though H K erect the plane HKkb perpendicular to HBK. From similar triangles, and the nature of the center of gravity Ab : dD :: AH : Hd :: BK : Ke :: Bk : ke; therefore hk is the path of the center of gravity of the bodies moving in A B, D E. And, because Dd : Hb :: Ad : Aa :: Be : BK :: Ee or Dd : Kk, Hb = Kk, and kb is equal and parallel to HK; therefore the center of gravity of the bodies, moving uniformly in A B, D E, moves uniformly in hk.

Case 3. The common center of gravity of two bodies and a third body is either at rest, or moves uniformly in a right line; for two may be placed in their common center of gravity, which was proved to move uniformly, and the center of gravity of the three or more bodies is proved, by the same process as before, to move uniformly.

From what has been above demonstrated, it is evident, that the path of the center of gravity, arising from the motion of any one body, is always parallel to that of the moving body: PQ and ST (fig. 24.) are parallel to Eb; QR and TV are parallel to Aa, and VY to Cc. Moreover, the centers of gravity of two, three, &c. bodies will describe polygons or curves similar to that of the moving body to which their motion is owing; and if the velocity of the body be variable, the velocity of each center will be variable according to the same law. Also, the velocity of the center of gravity of two, three, &c. bodies is the same as if they were placed in it, and acted upon by forces equal to the momenta of the moving bodies, in their respective planes and directions: for $B \times Bb = \bar{A} + \bar{B} \times PQ$, and $A \times Aa = \bar{A} + \bar{B} \times QR$; and if A + B were placed at P, and acted upon by forces equal to $B \times Bb$ and $A \times Aa$ in the planes and directions of Bb and Aa, they would describe the diagonal PR.

3. *The common center of gravity of two or more bodies is not affected by any action of the bodies upon each other.* For, let A and B (fig. 27.) be two bodies in a fyltem, acting upon each other, G their common center of gravity, and Aa, Bb, the velocities lost by A and gained by B respectively in opposite directions; and $A \times Aa = B \times Bb$, or $A : B :: Bb : Aa :: BG : AG :: Gg : aG$, or $A : B :: B's \text{ distance from the center of gravity} : A's \text{ distance from it; and con-$

sequently the same point, G, is still the center of gravity of A and B, or it has been immovable. What is proved of these two is true of every two bodies, and therefore of all. Hence, if two parts of a fyltem, A and B, attract or repel each other, or moving with unequal rectilinear motions, disturb each other's motion by the force of their inertia, the center of gravity will not be affected by their mutual action.

CENTER OF GRAVITY, LAWS OF THE. 1. *In two bodies, whose masses of matter are equal, the center of gravity is equidistant from their two respective centers.* For there are like two equal weights suspended at equal distances from the point of suspension; and in this case they will equiponderate, and rest in any position.

2. *If the centers of gravity of two bodies, A and B, (Plate IV. Mechanics, fig. 28.) be joined by the right line AB, the distances, BC and CA, of the common center of gravity, C, from the particular centers of gravity, B and A, are reciprocally as the weights B and A.* See this demonstrated under BALANCE and LEVER.

Hence, if the gravities of the bodies A and B be equal, the common center of gravity, C, will be in the middle of the right line, A B. Again, since $A : B :: BC : AC$; it follows that $A \times AC = B \times BC$; whence it appears, that the powers of equiponderating bodies are to be estimated by the product of the mass, multiplied into the distance from the center of gravity; which product is usually called the *momentum of the weights*.

Further, since $A : B :: BC : AC$, $A + B : A :: BC + AC : AC$ (or AB) : BC; or $A + B : B :: BC + AC : AC$ (A B) : AC. Therefore the common center of gravity, C, of two bodies, will be found, if the product of one weight, A, into the distance of the separate centers of gravity, A B, be divided by the sum of the weights, A and B. Suppose, e. g. $A = 12$, $B = 4$, $AB = 24$; therefore $BC = 24 \times 12 \div 16 = 18$; and $AC = 6$. If the weight, A, be given, and the distance of the particular centers of gravity, A B, together with the common center of gravity, C; the weight of B will be found = to $A \times AC \div BC$; that is, dividing the momentum of the given weight, by the distance of the weight required from the common center of gravity. Suppose, $A = 12$, $BC = 18$, $AC = 6$; then $B = 6 \times 12 \div 18 = 4$.

3. *To determine the common center of gravity of several given bodies or points, a, b, c, d, (fig. 29.) in the same right line, A B.* Find the common center of gravity of the two bodies, a and b, which suppose in F; conceive a weight, a + b, applied in F; and in the line, FE, find the common center of the weights, a + b and c; which suppose in G. Lastly, in BG, suppose a weight a + b + c applied, equal to the two a + b and c; and find the common center of gravity between this and the weight d, which suppose in H; this H will be the common center of gravity of the bodies, a, b, c, d. And in the same manner might the common center of gravity of any greater number of bodies be found. Otherwise: take the distances of the given bodies from some fixed point, as V (fig. 30.), calling the distance VA = a, VB = b, VC = c, VD = d, and the distance of the center of gravity VS = x; then SA = x - a, SB = x - b, SC = x - c, SD = d - x; and by the property of the lever, $A \times x - a + B \times x - b = C \times x - c + D \times d - x$; hence $Ax + Bx + Cx + Dx = Aa + Bb + Cc + Dd$, and $x = \frac{Aa + Bb + Cc + Dd}{A + B + C + D} = VS$, the distance sought; which is consequently equal to the sum of all the momenta, divided by the sum of all the weights in the bodies. Or

Or thus: when the bodies are not in the same straight line, connect them with the lines, AB, CD ; then find, as before, P , the common center of A and B , and Q the common center of C and D ; and conceiving A and B united in P , and C and D united in Q , find S , the common center of P and Q , which will be the common center of the whole. Or, the bodies may be all reduced to any line, VAB . &c. drawn in any direction whatever, by perpendiculars, $BB', CC', \&c.$ and then the common center in this line, found as before, will be at the same distance from V as the true center is; and consequently, the perpendicular from s will pass through S , the real center. From the preceding general expression, viz. $x = \frac{Aa + Bb + Cc}{A + B + C}$, &c. for the center of

gravity of any system of bodies, we may deduce a general method for finding that center; for $A, B, C, \&c.$ may be considered (as above stated), to be the elementary parts of any body, whose sum or mass is $M = A + B + C, \&c.$ and Aa, Bb, Cc , are the several momenta of all these parts, viz. the product of each part multiplied by its distance from the fixed point, V . Hence then, in any body, find a general expression for the sum of the momenta, and divide it by the content of the body, and the quotient will be the distance of the center of gravity from the vertex, or from any other fixed point, from which the momenta are estimated. The application of this principle will appear in the sequel of the article. M. Lhuilier has, in the fourth volume of the New Acts of the Academy of Peterburg, given the demonstration of a very general theorem concerning centers of gravity; the following expression is a particular example of the general proposition: Let A, B, C be the centers of gravity of three bodies; a, b, c , their respective masses; and Q their common center of gravity. Let right lines, QA, QB, QC , be drawn from the common center to that of each body, and the latter be connected by right lines, AB, AC , and BC ; then $QA^2 \times a + QB^2 \times b + QC^2 \times c$

$$= \frac{\Lambda B^2 \times \frac{ab}{a+b+c} + AC^2 \times \frac{ac}{a+b+c} + BC^2 \times \frac{bc}{a+b+c}}$$

4. Two weights, D and E , (fig. 31.) being suspended without their common center of gravity in C , to determine which of them preponderates, and how much. Multiply each into its distance from the center of suspension; that side on which the product is greatest will preponderate; and the difference between the two will be the quantity wherewith it preponderates. Hence, the momenta of the weights, D and E , suspended without the center of gravity, are in a ratio compounded of the weights, D and E , and the distances from the point of suspension. Hence, also, the momentum of a weight suspended in the very point, C , will have no effect at all in respect of the rest, D, E .

5. To determine the preponderation where several bodies, a, b, c, d , (fig. 32.) are suspended without the common center of gravity in C . Multiply the weights, e and d , into their distances from the point of suspension, CE and CB ; the sum will be the momentum of their weights, or the ponderation towards the right; then multiply the weights, a and b , into their distances, AC and CD . the sum will be the ponderation towards the left; subtracting, therefore, the one from the other, the remainder will be the preponderation required.

6. Any number of weights, a, b, c, d , being suspended without the common center of gravity in C , and preponderating towards the right; to determine the point, F , from whence the sum of all the weights being suspended, the ponderation still continues the same as in their former situation.

Find the momentum wherewith the weights, e and d , preponderate towards the right; since the momentum of the sum of the weights to be suspended in F is to be equal to it, the momentum now found will be the product of CF into the sum of the weights: this, therefore, being divided by the sum of the weights, the quotient will be the distance, CF , at which the sum of the weights is to be suspended, that the preponderation may continue the same as before.

7. The sum, or difference, of the products, which results from multiplying each particle, A, B, C, D , into its perpendicular distance from any plane, L, N , as they are on the same or different sides of the plane, is equal to the product of all the particles multiplied into the distance of their center of gravity, G , from that plane. See figs. 33, and 34. Let P and Q be the centers of gravity of A and B, C and D , and drawing right lines through P, Q, G , parallel to the plane, which intersect the perpendiculars drawn from those points respectively; and $A : B :: BP : AB :: Pn$ or $Bb - Pp : Am$ or $Pp - Aa$; and $A \times \frac{Pp - Aa}{AB} = B \times \frac{Bb - Pp}{AB}$, or $A \times \frac{Aa + B \times Pb}{AB} = \frac{A + B \times Pp}{AB}$. By a similar process it appears, that $C \times Cc + D \times Dd = \frac{C + D \times Qq}{AB}$. But $A + B : C + D :: QG : PG :: Gv$ or $\frac{Cg \mp Qq}{Qq} : Pn$ or $Pp - Gg$, and $A + B \times \frac{Pp - Gg}{AB} = \frac{C + D \times Gg \pm Qq}{AB}$; or, by transposition and substitution of equals, $A \times Aa + B \times Bb \pm C \times Cc \pm D \times Dd = \frac{A + B + C + D \times Gg}{AB}$; in which expression the higher or lower signs are to be used, as the bodies are on the same, or a different, side of the plane.

Hence it appears, that, if the particles be placed upon the same right line, or, (as in fig. 35.) Aa, Bb, Cc, Dd, Gg become Ag, Bg, Cg, Dg, Gg respectively, $A \times Ag + B \times Bg \pm C \times Cg \pm D \times Dg = \frac{A + B + C + D \times Gg}{AB}$; i.e. the sum, or difference, of the products resulting from the multiplication of each particle into its distance from any point, g , as they are on the same, or a different side of that point, is equal to the product of their sum multiplied into the distance of their center of gravity from that point. Moreover, the whole momentum of a body, acting upon a lever, being equal to that of every particle, or to the sum of the products which results from the multiplication of each particle into its distance from the center of motion, is equal therefore to the product of the whole body into the distance of the center of gravity from the center of motion, and is consequently the same as if it were collected in the center of gravity. The demonstration of this proposition obtains therefore when A, B, C, D are collections of particles or bodies, whose centers of gravity are the points A, B, C, D . And to find the center of gravity of a system of bodies, it is evident that in the proposition, introducing this article, bodies, whose centers of gravity are $A, B, C, D, \&c.$ may be substituted for particles. Farther, if A, B, C, D (fig. 33 and 34) be bodies acting upon any plane, L, N , in parallel directions, the sum of their efforts to move it is the same as if they were collected in their center of gravity; for, if A, B, C, D be the respective centers of gravity of each body, this sum is equal to $A \times Aa + B \times Bb \pm C \times Cc \pm D \times Dd = \frac{A + B + C + D \times Gg}{AB}$; or, if they be placed upon a lever, the sum of their efforts to make it revolve is the same as if they were placed at G . When the center of gravity, therefore, is in the plane, or at the fulcrum of the lever, the plane and lever are quiescent. And if any point, Z , be taken in N, L , $A \times aZ + B \times bZ + C \times cZ + D \times dZ = \frac{A + B + C + D \times gZ}{AB}$; for if a plane pass through Z , the proof is the same as that of this proposition. Also, the

distance

distance of any plane from the common center of gravity of A, P, C, D, &c. or G_g is equal to $\frac{A \times Aa + B \times Bb \pm C \times Cc + D \times Dd}{A + B + C + D, \text{ \&c.}}$; and its distance from a plane passing through any point, Z, is equal to $\frac{A \times Za + B \times Zb \pm C \times Zc \pm D \times Zd}{A + B + C + D}$, in which expression the lower signs are to be used for the bodies that are not on the same side of Z with A and B. It follows, that a right line drawn from A (fig. 36.) through the center of gravity, G, of any number of bodies, A, B, C, D, &c. will pass through the center of gravity of the remainder; for $B \times Bb + D \times Dd = C \times Cc$; and consequently the center of gravity of B, C, D is in the plane passing through A, G; and if this plane revolve, their center of gravity is always in the plane passing through A, G, and consequently it must be in the line A, G produced, which is the common intersection of the planes. If A be this center, $B + C + D \times Gr = A \times A, G$, and if the bodies be equal, and their number, A, G = $n - 1 \times Gc$. It appears farther, that if a circle or sphere be described about the center of gravity, G, of any number of bodies, A, B, C, &c. (fig. 37.) and any point, P, be taken in the periphery of the circle or surface of the sphere, $PA^2 \times A + PB^2 \times B + PC^2 \times C, \text{ \&c.}$ is a given quantity; for, drawing G, P, and the perpendiculars to it Aa, Bb, Cc, $A \times Ga = B \times Gb + C \times Gc$, or by substitution of equals,

$$A \times \frac{GA^2 - PA^2 + GP^2}{2GP} = B \times \frac{PB^2 - BG^2 - GP^2}{2GP} + C \times \frac{PC^2 - GP^2 - GC^2}{2GP}, \text{ or, } A \times PA^2 + B \times PB^2 + C \times PC^2 = A \times GA^2 + GP^2 + B \times GB^2 + GP^2 + C \times GC^2 + GP^2; \text{ and this side of the equation is invariable in whatever point of the periphery or surface P be placed.}$$

8. If A, B, C, D, &c. (fig. 38.) be particles of a body acted by forces in parallel directions, whose magnitudes are Aa, Bb, Cc, &c. the sum of their weights is equal to the weight of A + B + C, &c. acted upon by a force whose magnitude is Gg. For the weights of A, B, C, &c. being A × Aa, B × Bb, C × Cc, &c. the sum of their weights will be equal to A + B + C, &c. × Gg; but this product is the weight of A + B + C, &c. acted upon by the force Gg. Hence, if the forces Aa, Bb, Cc, &c. be equal to each other, Gg is equal to one of them, or if the particles A, B, C, &c. be acted upon by the same force, their weight is the same as if they were collected in their center of gravity, and acted upon by that force. The tendency, therefore, of a body to descend is the same as if it were collected in its center of gravity, and, consequently, if a line drawn from that center perpendicular to the horizon fall within the base of that body, it cannot fall; and if without the base, it cannot stand. See GRAVITY.

9. If any number of bodies, A, B, C, &c. (fig. 39.) move in parallel directions with any velocities, the center of gravity will describe a right line parallel to them. Let A and B, a and b, be contemporary positions of the bodies A and B, and G, g, their centers of gravity, and through g draw a line, x, y, parallel, and consequently equal, to A, B. From the nature of the center of gravity, A : B :: P, G : A, G :: b, g : y, g : x (by similar triangles); and the point g divides the parallel and equal lines A, B, x, y, in the same ratio, and G, g

is a right line parallel to Aa or Bb. If H be the center of gravity of A, B, C, it is proved in the same manner that it cuts the parallel and equal lines, G, C, &c. in the same ratio, and H, G is consequently a right line parallel to G, g. Hence, if any number of bodies, A, B, C, &c. (figs. 38.) ascend or descend in parallel right lines, the sum of the products resulting from the multiplication of each body into the space described by it is equal to the product of their sum, and the space described by their center of gravity; for, let a, b, c, &c. be contemporary positions of A, B, C, G, and, drawing any plane N, L, $A \times Am + B \times Bn + C \times Cc = A + B + C \times Gb$; and $A \times am + B \times bc + C \times cc = A + B + C \times Gb$; and consequently by addition $A \times Aa + B \times Bb + C \times Cc = A + B + C \times Gg$. Moreover, if any number of bodies move in parallel directions with any unequal velocities, or they be placed upon the lever X, Y (figs. 39. and 40.), and receive unequal impulses from any force at the same time in parallel directions, the center of gravity will, in the beginning of its motion, move uniformly in a right line parallel to them, and its velocity is equal to the products of each body into its velocity, divided by the sum of the bodies; for the spaces Aa, Bb, Cc, Gg are described in the same time, and vary as the velocities; and Gg, or velocity of G, = $\frac{A \times Aa + B \times Bb + C \times Cc}{A + B + C}$.

See Parkinſon's System of Mechanics, &c. ch. ix.

10. To find the center of gravity in a right line A, B (Pl. VI. Mechanics, fig. 41.) All the particles that compose this line may be considered as so many very small weights, each equal to x, which is therefore the fluxion of the weights, or of the line denoted by x. Multiplying therefore the small weight x by its distance from A, viz. ax, and xx will be the momentum of that weight x; or, in other words, xx is the fluxion of all the momenta in the line A, B or x; and, therefore, its fluent $\frac{1}{2}x^2$ is the sum of all those momenta; which, being divided by x the sum of all the weights, gives $\frac{1}{2}x$ or $\frac{1}{2}A, B$ for the distance of the center of gravity C from the point A; that is, the center of gravity of an homogeneous line is in the middle of that line. In any body, having found a general expression for the sum of the momenta of all the parts, if this be divided by the content of the body, the quotient will be the distance of the center of gravity from the vertex, or from any other fixed point, from which the momenta are estimated.

11. To find the center of gravity in a parallelogram and parallelepiped. Draw the diagonals A, D and E, G; (fig. 42.) likewise C, B and H, F; since each diagonal, A, D and C, B, divides the parallelogram A, C, D, B into two equal parts, each passes through the center of gravity; consequently, the point of intersection, I, must be the center of gravity of the parallelogram. In like manner, since both the planes, C, B, F, H, and A, D, G, E, divide the parallelepiped into two equal parts, each passes through its center of gravity; so that the common intersection, I, K, is the diameter of gravity, the middle whereof is the center.

After the same manner may the center of gravity be found in prism, and cylinders; it being the middle point of the right line that joins the center of gravity of their opposite bases.

The center of gravity of a parallelogram, &c. may be very easily found by the method of fluxions. Let the axis or length A, B of the parallelogram (fig. 43.) be = x, and its breadth D, E = b; and if d, e be drawn parallel and indefinitely near to D, E, the arc d, D, E, e = b² will be the fluxion of all the weights, which multiplied by its distance x from

from the point A gives $b \times \dot{x}$ for the fluxion of all the moments, and consequently the fluent $\frac{1}{2} b x^2$ is the sum of all those moments themselves; which, being divided by $b \times$ the sum of all the weights, gives $\frac{1}{2} x = \frac{1}{2} A B$ for the distance of the center C from the extremity at A, and is therefore in the middle of the axis, as we have above shewn. The process and conclusion will be precisely the same for a cylinder, or any prism whatever, making b to denote the area of the end or of a transverse section of the body.

12. In regular polygons, the center of gravity is the same with the center of the circumscribed parallelogram.

13. To find the center of gravity of a cone and a pyramid. The center of gravity of a cone is in its axis AC (fig. 44.) If then AP = x , AC = a , CD = r , the periphery of the base = p , and PN = y , we shall have, by the well known property of circles, $r : p :: y : \frac{p y}{r}$ = the periphery of the

circle, whose diameter is MN, which being multiplied by $\frac{y}{2}$ will give $\frac{p y^2}{2r}$ = the area of the same circle. But, by

similar triangles, $y : x :: r : a$, therefore $y = \frac{r x}{a}$, and $y^2 = \frac{r^2 x^2}{a^2}$; consequently the area of the circle, whose radius

is PN, becomes equal to $\frac{p r x^2}{2 a^2}$; and therefore $\frac{p r x^2 \dot{x}}{2 a^2}$ will be the fluxion of the mass, or of the content of the cone at the term MN, and $\frac{p r x^3 \dot{x}}{2 a^2}$ will be the fluxion of the momentum, whose fluent is $\frac{p r x^4}{4 a^2}$, which, being divided by

$\frac{p r x^3}{6 a^2}$, the fluent of $\frac{p r x^2 \dot{x}}{2 a^2}$, the fluxion of the mass, will give $\frac{2}{3} x = \frac{2}{3} A P$, for the distance of the center of gravity of the portion AMN from the vertex A; and when AP becomes equal to AC, x will be equal to a ; and therefore the center of gravity of the whole cone is distant from the vertex $\frac{2}{3}$ of AC. And in the same manner is found the distance of the center of gravity from the vertex of the pyramid $\frac{3}{4}$ AC; and therefore all pyramids of the same altitude have the same center of gravity.

14. To determine the center of gravity in an isosceles triangle BAC (fig. 45.) Draw the right line AD, bisecting the base BC in D which will be also perpendicular to it; since $\triangle BAD = \triangle DAC$, each may be divided into the same number of little weights, applied in the same manner on each side to the common axis AD; so that the center of gravity of the $\triangle BAC$, will be in AD. To determine the precise point in that, let AD = a , BC = b , AP = x , MN = y ; then will AP : MN :: AD : BC; or, $x : y :: a : b$.

Hence, $y = \frac{b x}{a}$. Consequently $y x \dot{x}$, which represents the fluxion of the mass at the term MN, divided by $y \dot{x}$ expressing the fluxion of the area AMN, will be equal to $\frac{b x^2 \dot{x}}{a} \div \frac{b x \dot{x}}{a} = \frac{x^2 \dot{x}}{x \dot{x}}$; the fluent of which quantity will be $\frac{\frac{1}{2} x^3}{\frac{1}{2} x^2} = \frac{2 x}{3}$, and at the term BC, when $x = A D$, $\frac{2}{3} A D$; and therefore the distance of the center of gravity of the \triangle from the vertex, will be found $\frac{2}{3} a$.

In the very same manner the center of gravity of any other plain triangle will appear to be at $\frac{2}{3}$ of a line drawn from one angle to bisect the opposite side, or the diameter of gravity, from the vertex.

The same center may be otherwise ascertained without fluxions, thus. Since a line drawn from any angle to the middle of the opposite side passes through the center of gravity, the point of intersection of any two such lines will be that center: so that the center of gravity is in the line AD, (fig. 46.) and it is also in the line CG bisecting AB; and consequently in the point of their intersection, S. In order to determine the distance of S from any angle, as A, produce CG to meet BH parallel to AS in H; then the two triangles AGS, BSH are mutually equal and similar, because the opposite angles at G are equal, and also the alternate angles at H and S, and at A and B, and the line AG = BG; therefore the other sides BH, AS are equal. But the triangles CDS, BSH are similar, and the side CB = 2 CD; therefore BH or its equal AS = 2 DS; that is AS = $\frac{2}{3}$ AD, the same as before. And in like manner CS = $\frac{2}{3}$ CG.

15. To determine the center of gravity of a trapezium. Divide the figure (fig. 47.) into two triangles by the diagonal AC, and find the centers of gravity E and F of these triangles; join EF, and find the common center G of these two by this proportion, viz. ABC : ADC :: FG : EG, or ABCD : ADC :: EF : EG. In a similar manner, the center of gravity may be found in any other figure, whatever be the number of sides, by dividing it into several triangles, and finding the center of gravity of each; then connecting two centers together, and finding their common center as above; then connecting this and the center of a third, and finding the common center of these; and so on, always connecting the last found common center to another center, till all are included in the process; and thus the last common center will be that which is required.

16. For the center of gravity in a parabola (fig. 48.) Let AE = a , SH = b , AP = x , PN = y . Then will $2 y \dot{x}$ be the fluxion of the whole weight; but from the nature of the parabola, and the parameter being a constant quantity, $1 x = y^2$; whence $x^{\frac{1}{2}} = y$, and $x^{\frac{1}{2}} \dot{x} = 2 y \dot{y}$: substituting $2 x^{\frac{1}{2}} \dot{x}$ instead of $2 y \dot{y}$ in the above expression, we shall have $2 x^{\frac{1}{2}} x \dot{x}$ for the fluxion of the mass, whose fluent $\frac{4 x^{\frac{3}{2}}}{3}$ will be the mass itself. Then, multiplying $2 x^{\frac{1}{2}} x \dot{x}$ by x , we shall have $2 x^{\frac{1}{2}} x^2 \dot{x}$ or $2 x^{\frac{5}{2}} \dot{x}$ for the fluxion of the momentum, whose fluent $\frac{4 x^{\frac{7}{2}}}{5}$ will be the momentum itself. Divide this by the whole weight, and the quotient $\frac{1}{5} x^{\frac{5}{2}} - \frac{2}{3} x$, will be the distance of the center of gravity of the space NAZP from the vertex A; and when AP becomes equal to AE, or $x = a$, $\frac{2}{3} a$, or $\frac{2}{3} A E$, will be the distance of the center of gravity of the whole parabolic space from the vertex A. Now $y^m = 1 x$, being a general equation for all kinds of parabolas, we shall have $y = x^{\frac{1}{m}}$, and therefore $x^m \dot{x}$ will be

the fluxion of the whole mass, and $x^{\frac{1}{m} + 1} \dot{x}$ the fluxion of the momentum: the fluent of this last expression, viz.

$$\frac{m}{2m+1} x^{\frac{1}{m} + 2}$$

, being divided by the fluent of $x^{\frac{1}{m}} \dot{x}$ or

$$\frac{m}{m+1} x^{\frac{1}{m} + 1}$$

will give $\frac{m+1}{2m+1} x$, for the distance of the center of gravity of the space ZAN from the vertex A, and $\frac{m+1}{2m+1} a$ will be the distance of the center of gravity of the whole parabolic space from A. When $m = 2$, as in the common

common parabola, this expression will be $\frac{2}{3}a$. If $m = 3$, as in the cubical parabola, then the expression will be $\frac{2}{3}a$; when $m = 4$, as in a biquadratic parabola, we shall have $\frac{2}{3}a$ of the axis for the distance; and in a surfolid parabola, when $m = 5$, the expression will give $\frac{2}{3}a$ for the required distance. If $m = \frac{1}{2}$, which is the property of the concave or supplemental space, then the axis becomes a tangent to the vertical point, and $\frac{2}{3}a$ will be the distance required. In the exterior parabola $A S T$, as may be easily found, by reasoning on similar principles, the center of gravity is at the distance $A L$, equal to $\frac{2}{3}A Q$. In the cubical parabola, $\frac{2}{3}A Q$. In a biquadratic parabola, $\frac{2}{3}A Q$. In a surfolid parabola, $\frac{2}{3}A Q$.

17. The center of gravity of the arc of a circle, as ABD (fig. 49.) considered as a physical line, having gravity.

It is evident that the center of gravity, G , of the arc, will be somewhere in the axis, or middle radius BC , C being the center of the circle, which is considered as the point of suspension. Suppose F indefinitely near to A , and FH parallel to BC . Put the radius BC or $AC = r$, the semi-arc $AB = z$, and the semi-chord $AE = x$; then $AH = \dot{x}$, and $AF = \dot{z}$, the fluxion of the weights, and therefore $CE \times \dot{z}$ is the fluxion of the momenta. But by similar triangles, AC or $r :: AF$ or $\dot{z} :: AH$ or \dot{x} ; therefore $r \dot{x} = CE \times \dot{z}$, and consequently $r \dot{x}$ is also the fluxion of the momenta; the fluent of which is rx , and this, divided by z , the weight, gives $\frac{rx}{z} = \frac{AC \times AE}{AB} = \frac{AC \times AED}{ABD}$ = CG , the distance of the center of gravity from the center C of the circle; and it is manifestly a fourth proportional to the given arc, its chord, and the radius of the circle. When the arc becomes the semi-periphery ABK , the above expression becomes $\frac{IC^2}{IB}$ or $\frac{r^2}{1.5708r} = \frac{r}{1.5708} = .6366r$ viz. a third proportional to a quadrant and the radius.

18. Let $A B D C$ (fig. 49.) be a circular sector; and the center of gravity will be somewhere in the axis or middle radius, BC , as in the former case. With any lesser radius describe the concentric arc $L M N$, and put the radius AC or $BC = r$, the arc $ABD = a$, its chord $AED = c$, and the variable radius, CL , or CM , = y ; then $r : y :: a : \frac{ay}{r}$ = the arc $L M N$, and $r : y :: c : \frac{cy}{r}$ = the chord $L O N$; and also by the last article the distance of the centre of gravity of the arc $L M N$ is $\frac{CM \times LON}{LMN} = \frac{CM \times AED}{ABD}$

= $\frac{y^2}{a}$: hence the arc $L M N$ or $\frac{ay}{r}$ multiplied by y gives $\frac{a^2 y^2}{r}$, the fluxion of the weights, and this multiplied by

$\frac{r y}{a}$, the distance of the common center of gravity, gives

$\frac{a^2 y^2}{r}$ the fluxion of the momenta; the fluent of which, viz.

$\frac{a^2 y^3}{3r}$ divided by $\frac{ay^2}{2r}$, the fluent of the weights, gives $\frac{2cy}{3a}$

for the distance of the center of gravity of the sector $C L E N$ from the center C : and when $y = r$, it becomes

$\frac{2cr}{3a}$ = CG for that of the sector $C A B D$ proposed; being

$\frac{2}{3}$ of a fourth-proportional to the arc of the sector, its chord, and the radius of the circle. Hence, when the sector becomes a semi-circle, the last expression becomes

$\frac{4r^3}{3a} = \frac{2IC^2}{3IB}$, or $\frac{2}{3}$ of a third proportional to a quadrant

arc and the radius: or, it is equal to $\frac{4r}{3p} = .4244r$ from the center C , where $p = 3.1416$.

19. To find the center of gravity of an hemisphere, $A B O$, (fig. 50.) Put the axis or radius $AD = a$. $DP = x$, and MP , parallel to the base, = y . Then $PM D$ being a right-angled triangle, we have $MP^2 = MD^2 - DP^2$, i. e. $y^2 = a^2 - x^2$. And putting c for the circumference of a circle whose diameter is unity, the circumference of a circle whose diameter is ME , or $2y$, will be $2cy$, and its area will be $2cy \times \frac{1}{2}y$, viz. cy^2 , or (by substituting for y its value as above found, i. e. $a^2 - x^2$) $c a^2 - c x^2$; and this is a section of the hemisphere parallel to the base. Then, $c a^2 - c x^2 \times \dot{x}$ is one of the infinitely small weights into which the hemisphere is supposed to be divided; and its

fluent $c a^2 x - \frac{c x^3}{3}$ is the sum of all those weights. Also,

$\frac{c a^2 - c x^2}{2} \times x \dot{x}$ is the fluxion of the momentum of the small weight; the fluent of which, viz. $\frac{c a^2 x^2}{2} - \frac{c x^4}{4}$ is the

sum of all the momenta. And, when x is equal to the whole axis AD , those two fluents become $(c a^3 - \frac{c a^3}{3}) = \frac{2c a^3 - c a^3}{3}$

= $\frac{2c a^3}{3}$; and $(\frac{c a^4}{2} - \frac{c a^4}{4} = \frac{2c a^4 - c a^4}{4} = \frac{c a^4}{4}$.

Then, dividing the latter fluent by the former, we have $\frac{c a^3 \cdot \frac{2c a^3}{3}}{4 \cdot \frac{c a^4}{4}} = \frac{3c a^3}{8c a^3} = \frac{3}{8}a$: so that the center of gravity is distant from the point D , $\frac{3}{8}$ ths of the axis, or of the radius AD .

The centers of gravity of other bodies may be found in a similar manner. Thus the altitude of the segment of a sphere, or spheroid, or conoid, being x , the whole of the axis itself being a , the distance of the center of gravity in each of these bodies from the vertex will be as follows: viz.

$\frac{4a - 3x}{6a - 4x} x$ in the sphere or spheroid.

$\frac{2}{3}x$ in the semi-sphere or semi-spheroid (as above).

$\frac{4a + 3x}{6a + 3x} x$ in the hyperbolic conoid.

These, and such cases, however, are more obscure, and also more uncommon, and we shall therefore refer for a more ample account of the center of gravity to writers on this subject; among whom we may reckon Archimedes, Pappus, Guldinus, Wallis, Casatus, Carré, Hays, Wolfius, Hodgson, Simpson, &c. &c.

To find the value of any surface or solid by means of the center of gravity; see CENTROBARIC Method.

20. To determine the center of gravity in any body mechanically. Lay the given body $H I$ (fig. 51.) on an extended rope, or on the edge of a triangular prism $F G$, bringing it thus and that way, till the parts on either side are in equilibrio; the plane, whose side is $K L$, passes through the center of gravity. Balance it again on the same, only changing its situation; then will the chord, or the side $M N$, pass through the center of gravity; so that the intersection of the two lines $M N$ and $K L$ determines the point O in the surface of the body required.

The same may be done by means of a horizontal table (as near the

in two positions, lengthwise and breadthwise : the common intersection of the two lines contiguous to the edge will be its center of gravity. Or it may be done by placing the body on the point of a stylé, &c. till it rest in equilibrio. It was by this method that Borelli found the center of gravity in a human body to be between the nates and pubes ; so that the whole gravity of the body is there collected, where nature has placed the genitals : an instance (says Wolfius) of the wisdom of the Creator, in placing the membrum virile in that place which of all others is the most convenient for copulation ; nevertheless, this law does not take place in the greater number of animals.

Or thus. Suspend the body by any point ; then a plumb-line hung over the same point will pass through the center of gravity ; because that center will always descend to the lowest point when the body comes to rest, which it cannot do except when it falls in the plumb-line. Therefore, marking that line upon it, and suspending the body by another point, with the plummet, to find another such line, the intersection of the two will give the center of gravity.

Otherwise. Hang the body by two strings from the same tack or nail, but fixed to different points of the body ; then a plummet, hung by the same tack, will fall on the center of gravity.

CENTER of gyration, is that point of a body revolving about an axis, into which, if the whole quantity of matter were collected, the same moving force would generate the same angular velocity in the body. This point differs from the center of oscillation, because, in this latter case, the motion of the body is produced by the gravity of its own particles ; but in the case of the center of gyration, the body is put in motion by some other force acting at one place only. Let a body, p , revolve about C, (Plate VII. *Mechanics*, fig. 52.) and let a force act at D to oppose its motion. Then the momentum of p varies, as $p \times$ its velocity, or as $p \times p C$, which may be considered as a power acting at p , in opposition to the force at D ; but this power acting at the distance, $p C$, from the center of motion, its effect to oppose a force at D must (by the property of the lever), be as $p \times p C \times p C = p \times p C^2$. This effect of p to persevere in its motion, or, which is the same, to prevent any change in its motion, is called its "inertia."

To find the center of gyration of a body. Let a body be conceived to be made up of the particles A, B, C, &c. whose distances from the axis are $a, b, c, \&c.$ and let x be the distance of the center of gyration from the axis ; then, by the preceding observation, the inertia of A, B, C, &c. will be as $A \times a^2, B \times b^2, C \times c^2, \&c.$ and the inertia of all the matter at the distance x , will be as $A + B + C + \&c. \times x^2$: and as the moving force is the same in both cases, the inertia must be the same when the same angular velocity is generated ; hence, $A + B + C + \&c. \times x^2 = A \times a^2 + B \times b^2 + C \times c^2 + \&c.$; therefore, $x = \sqrt{\frac{A \times a^2 + B \times b^2 + C \times c^2 + \&c.}{A + B + C + \&c.}}$: that is, if \dot{s} be the fluxion of the body at the distance z from the axis,

$$x = \sqrt{\frac{\int \dot{s} u. z^2 \dot{z}}{s}}$$

E. G. 1. Let the straight line, CA, (fig. 53.) revolve about C ; to find O the center of gyration. Put $z = Cp$, then $s = z$, and $\dot{s} = \dot{z}$, and therefore $z^2 \dot{z} = z^2 \dot{z}$, whose fluent is $\frac{1}{3} z^3 =$ (when $z = CA$) $\frac{1}{3} CA^3$; hence, $CO = \sqrt{\frac{1}{3} CA^3}{CA} = CA \sqrt{\frac{1}{3}}$. 2. Let a circle, AB, (fig. 54.) revolve in its own plane about its center C ; to find O, its center of gyration. Put $p = 6.28318$, &c. the circumference of a circle

whose radius = $r, z = Cp$; then the circumference $p \dot{z} = p z$, and $p z \dot{z} = \dot{z}$; hence, the fluent of $z^2 \dot{z}$, or of $p z^2 \dot{z}$ is $\frac{1}{3} p z^3 =$ (when $z = CA = r$) $\frac{1}{3} p r^3$. Also, the area of the circle = $\frac{1}{2} p r^2$; hence, $CO = \sqrt{\frac{1}{2} p r^3}{r} = r \sqrt{\frac{3}{2}}$. The same must be true for a cylinder revolving about its axis ; as it is true for every section parallel to the end. 3. Let R A D B be a sphere revolving about the diameter, R D ; to find O, its center of gyration. Draw C A perpendicular, and $s p r$ parallel to R D ; put $Cr = r, Cp = z$, then $p r = \sqrt{r^2 - z^2}$; and if $p = 6.28318$, &c. the surface of the cylinder, generated by $s r$ revolving about R D, is $p z \times z = \sqrt{r^2 - z^2}$; hence $\dot{z} = 2 p z \dot{z} \sqrt{r^2 - z^2}$, and $z^2 \dot{z} = 2 p z^2 \dot{z} \sqrt{r^2 - z^2}$. In order to find this fluent, put $r^2 - z^2 = y^2$, then $z^2 = r^2 - y^2$, and $z^2 \dot{z} = r^2 - 2 r^2 y^2 + y^4$; therefore $z^2 \dot{z} = - r^2 y \dot{y} + y^3 \dot{y}$; hence, $2 p z^2 \dot{z} \sqrt{r^2 - z^2} = 2 p \times \frac{r^2 y^2 \dot{y} + y^3 \dot{y}}{y}$, whose fluent is $2 p \times -\frac{1}{3} r^2 y^3 + \frac{1}{4} y^4$; and when $z = 0$, the fluent ought to vanish, but y is then $= r$; and the fluent becomes $2 p \times -\frac{1}{3} r^3 + \frac{1}{4} r^4$; hence, the correct fluent is $2 p \times \frac{r^3}{4} - \frac{1}{3} r^3 + \frac{1}{4} r^4$; and the whole fluent, when $z = r$ (in which case $y = 0$), will be $\frac{1}{4} p r^4$. And as the content of the sphere = $\frac{4}{3} p r^3$; hence, $CO = \sqrt{\frac{1}{3} p r^4}{\frac{4}{3} p r^3} = r \sqrt{\frac{3}{4}}$. Vince's Principles of Fluxions, p. 98, &c.

CENTER of heavy bodies is, in our globe, the same with the center of the earth towards which all heavy bodies at or near the surface have a kind of tendency. It should be observed, however, that the tendency of heavy bodies towards the center is strictly applicable only to the earth, considered as perfectly spherical ; but as the earth is flatted towards the poles, or an oblate spheroid, heavy bodies will not be found to tend exactly towards the same point. Nevertheless, as the figure of the earth does not differ much from that of a sphere, the deviation of the tendency of heavy bodies from the same point is not very considerable ; and in common language the center of the earth may be regarded as the center of heavy bodies.

CENTER of an hyperbola, is a point in the middle of the axis, or of any other diameter ; being the point without the figure, in which all the diameters intersect one another ; and it is common to all the four conjugate hyperbolas.

CENTER of the magnet, and Magnetic center. See MAGNET.

CENTER of magnitude, is that point which is equally distant from all the external parts of a body. In homogeneous bodies that can be cut into similar and equal parts, according to their length, as in a cylinder or prism, it is the same with the center of gravity.

CENTER of motion, is a point round which one or more heavy bodies, that have one common center of gravity, revolve ; v. gr. If the weights, P and Q, (fig. 55.) revolve about the point, N, so that when P descends, Q ascends, N is said to be the center of motion.

It is demonstrated in mechanics, that the distance, I N, of the center of gravity of any particular weight, from the common center of gravity, or the center of motion, N, is perpendicular to the line of direction, I P.

The center of motion of a ship is the point upon which a vessel oscillates or rolls, when put in motion.

CENTER of oscillation, is that point, in the axis or line of suspension of a vibrating body, into which, if the whole was contracted, the angular velocity, and the time of vibration, would remain unaltered. Hence, in a compound pendulum, its distance from the point of suspension is equal to the length of a simple pendulum, whose oscillations are isochronous with those of the compound one.

CENTER of oscillation, laws of. From what we shall demonstrate

monstrate under CENTER of percussion it will appear, that in the case of two bodies connected together, the product of the body on one side of the center of oscillation multiplied by both its distance from the point of suspension and its distance from the center of oscillation is equal to the product of the body on the other side of the center of oscillation, multiplied both by its distance from the point of suspension, and its distance from the center of oscillation. The reasoning from which this theorem is deduced may also be applied to a pendulum consisting of more than two bodies connected together, or to the different parts of the same pendulous body; and hence may be deduced the following general law: viz. if the weight of each part of a simple or compound pendulum be multiplied both by its distance from the center of suspension, and its distance from the center of oscillation (or percussion), the sums of the products on each side of the center of oscillation will be equal to each other. In order to illustrate this law, and the mode of applying it, let a pendulum consist of any number of parts or small bodies A, B, C, D, E, joined together; let a, b, c, d, e represent their respective distances from the point of suspension, and let x be the distance of the center of oscillation from the point of suspension. The distances of those parts or bodies, from the center of oscillation, will be $a-x, b-x, c-d-x, e-x$; D and E being supposed to be farther from the point of suspension, than the center of oscillation is. By multiplying every one of those bodies, both by its distance from the center of suspension and its distance from the center of oscillation, we have, agreeably to the above-mentioned law, the equation $Aax - Aaa + Bbx - Bbb + Ccx - Ccc = Ddx + Ddx + Eex - Eex$; which, by transposition and division, is resolved into the following; viz.

$$x = \frac{Aaa + Bbb + Ccc + Ddd + Eee}{Aa + Bb + Cc + Dd + Ee}$$

Should any of the bodies, as for instance A and B, in the preceding instance, be situated above the center of suspension, then their distances will be negative, viz. $-a, -b$, though their squares aa, bb , are always positive. In this case the value of x is $= \frac{Aaa + Bbb + Ccc + Ddd + Eee}{-Aa - Bb + Cc + Dd + Ee}$

Since the center of gravity of a body, or system of bodies, is that point wherein all their matter may be conceived to be condensed, therefore the product of all the matter or sum of the different weights A, B, C, D, E, multiplied by the distance of the common center of gravity from the point of suspension, is equal to the sum of the products of each body multiplied by its distance from the point of suspension. Hence the above stated value of x becomes $\frac{Aaa + Bbb + Ccc + Ddd + Eee}{Aa + Bb + Cc + Dd + Ee}$ divided by the product of the whole body or sum of the weights, multiplied by the distance of the center of gravity from the point of suspension. And being expressed entirely in words, it forms the following general

Rule 1. " If all the bodies or parts of a body, that forms a pendulum, be multiplied each by the square of its distance from the point or axis of suspension, and the sum of the products be divided by the product of the whole weight of the pendulum, multiplied by the distance of the center of gravity from the point of suspension; the quotient will be the distance of the center of oscillation or percussion from the point of suspension."

The situation of the centre of oscillation may also be found by means of another rule, which we shall likewise lay down, and shall demonstrate; since in some cases this rule will be found preferable to the first.

Rule 2. " If the sum of the products of all the parts or weights, multiplied each by the square of its distance from

the center of gravity, or from a line passing through the center of gravity parallel to the axis of vibration, be divided by the product of the whole mass or body, multiplied by the distance of the center of gravity from the point of suspension, the quotient will be the distance of the center of oscillation from the center of gravity; which being added to the distance of the center of gravity from the point of suspension, will be the distance of the center of oscillation from the point of suspension."

Let C A B (Plate VII. *Mechanics*, fig. 56.) represent any sort of body regular or irregular, suspended at C; O its center of oscillation; G its center of gravity; COB its axis or right line, passing through the point of suspension, and centers of gravity and oscillation. This body may be conceived to consist of an indefinite number of extremely small parts or weights. Let W be one of those small weights; join WC and WG, and from W drop WF perpendicular to CO. Then the product of W, by the square of its distance from C, is $W \times C^2$. But (Eucl. p. 47, B. i.) $CW^2 = WF^2 + CF^2$; and $GW^2 = GF^2 + WF^2$ (Eucl. p. 7. B. ii.) $CG^2 + GF^2 = 2CG \times GF + CF^2$; and by transposition $CF^2 = GF^2 + CG^2 - 2CG \times GF$. Then by substitution (viz. by putting instead of CF^2 , its equal $GF^2 + CG^2 - 2CG \times GF$) the above stated equation becomes $CW^2 = WF^2 + GF^2 + CG^2 - 2CG \times GF = (WF^2 + GF^2) + CG^2 - 2CG \times GF$. And multiplying both sides by W, we have the sum of all the products $W \times CW^2 =$ the sum of all the $W \times GW^2$ + all the $W \times C^2 -$ the sum of all the $W \times 2CG \times GF$.

But by the nature of the centre of gravity the sum of all the $W \times GF$ is 0; for those which are on one side of the axis will balance those which are on the other side; and of course all the $W \times 2CG \times GF$ also become = 0. Therefore there remains the sum of all the $W \times CW^2 =$ sum of all the $W \times GW^2$ + sum of all the $W \times C^2$ = sum of all the $W \times GW^2$ + the whole body $\times C^2$. Or, (taking away the sum of all the $W \times GW^2$ from both sides of the equation) the sum of all the $W \times C^2 =$ the whole body $\times C^2$.

$$\text{Then } CO = \frac{\text{sum of all the } W \times C^2}{\text{whole body} \times C} \text{ (by rule the 1st)} = CG + \frac{\text{sum of all the } W \times GW^2}{\text{the whole body} \times C}$$

$$GO = CO - CG = \frac{\text{sum of all the } W \times GW^2}{\text{the whole body} \times C}$$

which is rule the 2d. In the application of the above-mentioned rules, it is frequently very difficult to find the sum of the products of all the weights multiplied by the squares of their respective distances. The method of fluxions is undoubtedly the most extensive, as it may be applied to all such figures or bodies as have some regularity of shape, or such as may be expressed by an algebraical equation. But in some cases the irregularity of form is so very great, that the center of oscillation can only be found out by means of the mechanical method subjoined.

In order to find the sum of the weights, &c. you must consider an indefinitely small part, or increment, or fluxion, of the figure, as being a small weight, and multiply it by the square of its distance from the center of suspension or axis of vibration, according to rule the 1st, or else multiply it

by the square of its distance from the center of gravity, or from a line passing through the center of gravity, and parallel to the axis of vibration, according to rule the 2d.; then the fluent of that expression will be the sum of the products of all the weights, multiplied by the squares of their respective distances, either from the axis of vibration, or from the center of gravity, &c. Lastly, this fluent must be divided by the product of the whole body (to be had by common mensuration) multiplied by the distance of the center of gravity, from the point of suspension; and the quotient will be the distance of the center of oscillation either from the point of suspension, or from the center of gravity, according as the operation was performed either by rule the first, or rule the second. Before we proceed to state and apply another method for investigating the center of oscillation, it will be necessary to premise the following lemma.

Suppose two exceeding small weights, C and P, acting on each other by means of an inflexible line (or wire), P C, to vibrate in a vertical plane, R O P C M, about the center O; and it is required to determine how much the motion of one is affected by the other. Let C H and P Q (Plate VII. Mechanics, fig. 57.) be perpendicular to the horizontal line O R; and let P B and C S be perpendicular to O P and O C respectively. If the force of gravity be denoted by unity, the forces acting in the directions C S and P B, whereby the weights, in their descent, are accelerated, will, according to the resolution of forces, be represented by $\frac{O H}{O C}$ and $\frac{O Q}{O P}$. Moreover, since the velocities are always in the ratio of the radii O C and O P, if the aforesaid forces were to be in that ratio, or that of P was to become $\frac{O H}{O C} \times \frac{O P}{O C}$, instead of $\frac{O Q}{O P}$, in that case it is plain, that the weights would continue their motion without affecting each other, or acting at all on the line of communication P C (or P B). Whence, the excess of $\frac{O Q}{O P}$ above $\frac{O H}{O C} \times \frac{O P}{O C}$ must be the accelerative force whereby the weight, P, acts upon the line (or wire), O C, in the direction P B; which multiplied by the weight, P, gives

$P \times \frac{O Q}{O P} - \frac{O H \times O P}{O C^2}$ for the absolute force in that direction; which, therefore, in the perpendicular direction N B, is $P \times \frac{O Q}{O P} - \frac{O H \times O P}{O C^2} \times \frac{O P}{O B}$; whereof the part acting upon C being to the whole as O B to O C, is truly defined by $P \times \frac{O Q}{O C} - \frac{O H \times O P^2}{O C^3}$. If Phc supposed to act upon C by means of P C (instead of P B) the conclusion will be in no respect different. For, let F denote the force $\left(P \times \frac{O Q}{O P} - \frac{O H \times O P}{O C^2} \right)$ in the direction P B, found above; then the action thereof upon P C (according to the principles of mechanics) will be expressed by $F \times \frac{\text{Radius}}{\text{Cof. } \angle C P B}$; which, therefore, in the direction S C, perpendicular to O C, is $F \times \frac{\text{Radius}}{\text{Cof. } \angle C P R} \times \frac{S. P C O}{\text{Radius}} = \frac{S. P C O}{\text{Cof. } \angle C P B} = \frac{S. P C O}{S. O P C} = F \times \frac{O P}{O C}$, the same as before.

To determine the center of oscillation of a body. Let L M S (fig. 58.) be a section of the body by a plane, perpendicular to the horizon and the axis of motion, passing through the center of gravity, G, and the point of suspension, O; and

suppose all the particles of the body to be transferred to this section, in such places of it as they would be projected into (orthographically) by perpendiculars falling thereon. (Nor does this supposition at all affect the conclusion, the angular motion continuing the same.) Moreover, let C be the center of oscillation, or that point in the axis, O S, where a particle of matter (or a small weight) may be placed so as to be neither accelerated nor retarded by the action of the other particles of matter situate in the plane. Then, if from C, and any other point, P, in the plane, L M S, two perpendiculars, C H and P Q, be let fall upon the horizontal line, O R, the force of a particle (or weight) at P to accelerate the weight at C, will (according to the preceding lemma) be

represented by $P \times \frac{O Q}{O C} - \frac{O H \times O P^2}{O C^2}$: which, supposing G N perpendicular to O R, will also be expressed by $P \times \frac{O Q}{O C} - \frac{O N}{O G} \times \frac{O P^2}{O C^2}$, or its equal $P \times \frac{O Q \times O G}{O C^2} \times \frac{O C - O N \times O P^2}{O G}$. In the same manner the force of any other particle, P', will be represented by $P' \times \frac{O Q' \times O G \times O C - O N \times O P'^2}{O C^2 \times O G}$, &c. &c. Consequently, the forces of all the particles destroying each other (by hypothesis), the sum of all the quantities $P \times \frac{O G \times O Q \times O C - O N \times O P^2 + P' \times O G \times O Q' \times O C - O N \times O P'^2}{O C^2 \times O G}$, &c. &c. must be equal to nothing. Whence

$P \times O G \times O Q \times O C + P' \times O G \times O Q' \times O C$, &c. &c. = $P \times O N \times O P^2 + P' \times O N \times O P'^2$, &c. &c. and consequently $O C = \frac{O N}{O G} \times \frac{P \times O P^2 + P' \times O P'^2 + \&c.}{P \times O Q + P' \times O Q' + \&c.}$ But the sum of all the quantities $P \times O Q + P' \times O Q' + \&c.$ is equal to the content of the body, multiplied by the distance, O N, of the center of gravity, G, from the line L M, (perpendicular to O C); whence O C is also = $\frac{O N}{O G} \times \frac{P \times O P^2 + P' \times O P'^2 + \&c.}{O N \times \text{the body}}$ = $\frac{P \times O P^2 + P' \times O P'^2 + \&c.}{O G \times \text{the body}}$; which expression continuing the same in all inclinations of the axis, O S, the point, C, thus determined, is a fixed point, agreeable to the definition; and appears to be the same with the CENTER of percussion.

Hence it follows, that if P D, P' D', &c. be perpendicular to O S, the numerator of the fraction, found above, will become $P \times O G^2 + G P^2 - 2 O G \times G D + P' \times O G^2 + G P'^2 + 2 O G \times G D' + \&c. \&c.$ (since $O P^2 = O G^2 + G P^2 - 2 O G \times G D$, &c.); which, because all the quantities $P \times - 2 O G \times G D + P' \times 2 O G \times G D'$, &c. or $P \times - G D + P' \times G D'$, &c. (by the nature of the center of gravity) destroy one another, and be barely = $P \times O G^2 + G P^2 + P' \times O G^2 + G P'^2 + \&c. \&c.$ = $P + P' + \&c. \times O G^2 + P \times G P^2 + P' \times G P'^2 + \&c.$ = mafs $\times O G^2 + P \times G P^2 + P' \times G P'^2 + \&c.$ Whence it is evident, that O C is, also, $\left(\frac{\text{mafs} \times O G^2 + P \times G P^2 + P' \times G P'^2 + \&c.}{\text{mafs}} \right) = O G + \frac{P \times G P^2 + P' \times G P'^2 + \&c.}{\text{mafs} \times O G}$; and consequently

$$C G = \frac{P \times G P^3 + P' \times G P'^3 + \&c. \&c.}{m a l s \times O G} .$$

Whence it appears, that, if a body be turned about its center of gravity, in a direction perpendicular to the axis of the motion, the place of the center of oscillation will remain unaltered; because the quantities $P \times G P^3$, $P' \times G P'^3$ are no way affected by such a motion of the body. It also appears, that the distance of the center of gravity from that of oscillation (if the plane of the motion of the body remains unaltered) will be reciprocally as the distance of the former from the point of suspension. Consequently, if that distance be found when the point of suspension is in the vertex, or so posited, that the operation may become the most simple, the value thereof in any other proposed position of that point will likewise be given by one single proportion.

In order to shew how these conclusions may be reduced to practice, let it be observed, that the product of any particle of the body by the square of its distance from the axis of motion is (here) called the force thereof, (its efficacy to turn the body about the said axis being in that ratio). According to which, and the first general value of $O C$, it appears that, if the sum of all the forces be divided by the product of the body into the distance of the center of gravity from the point of suspension, the quotient thence arising will give the distance of the center of percussion, or oscillation, from the said point of suspension.

In the following examples, let the distance of the center of gravity from the point of suspension be g , and the distance of the center of percussion, or oscillation, from the same point, be C .

1. To find the center of oscillation of a right line, OS , (fig. 59.) suspended at one of its extremes. If the part, OP , considered as variable, be denoted by x , the force of x particles, at P , will be expressed by $\dot{x} \times x^2$; and $\frac{1}{2} x^3$, the fluent of this quantity will express the force of all the particles in OP , or the sum of all the products, under each particle, and the square of its distance from O , the point of suspension. This quantity, when x becomes OS , being divided by $OS \times \frac{1}{2} OS$, according to the rule above stated, will give $\frac{\frac{1}{2} OS^3}{\frac{1}{2} OS^2} = \frac{2}{3} OS$ for the value of C , the true distance of the center of oscillation (or percussion) from the point of suspension.

2. Let AB , (fig. 6c.) be a line, vibrating in a vertical plane, having its two extremes, A and B , equally distant from the point of suspension, O . If OG , perpendicular to AB , be put $= a$, and $GP = x$, the force of x particles at P , will be denoted by $\dot{x} \times a^2 + x^2 = \dot{x} \times OP^2$; and the fluent of this quantity, divided by ax , or $PG \times OG$, will give $\frac{a^2 x + \frac{1}{3} x^3}{ax} = a + \frac{x^2}{3a} = OG + \frac{BG^2}{3OG} = C$, when x becomes $= GB$.

3. Let $APSQ$ (Plate VIII. Mechanics, fig. 61.) be a circle, vibrating in a vertical plane; any diameter of which is PQ . Thus $OP^2 + OQ^2$ being $= 2 OG^2 + 2 PG^2$, the sum of the forces of two particles at P and Q (putting $OG = a$, and $AG = r$) will be $= a^2 + r^2 \times 2$; whence the sum of all the particles, in the whole periphery, will be expressed by their number, multiplied by $a^2 + r^2$, or by $a^2 + r^2 \times$ periphery $APSQ$; which, if p be put $= 3.141$, &c. will be $= a^2 + r^2 \times 2 p r = 2 p a^2 r + 2 p r^3$. Hence the force of the circle itself is also given, being equal to the fluent of $2 p a^2 r + 2 p r^3$ which $= p a^2 r^2 + \frac{1}{2} p r^4 = a^2 + \frac{1}{2} r^2 \times$ circle $APSQ$. If the two expressions thus found be divided by $a \times$ periphery $APSQ$, and $d \times$ cir-

cle $APSQ$ respectively, we shall have $a + \frac{r^2}{a}$, and $a +$

$\frac{r^2}{2a}$, for the two corresponding values of C .

4. Let $AHBE$, (fig. 62.) be a circle, having its plane (al-ways) perpendicular to the axis of suspension GO . Let AGB be that diameter of the circle which is parallel to the axis of motion RS ; and let EF be any chord parallel to AB and RS ; whose distance, GP , from the center of the circle may be denoted by x ; and put $OG = a$, and $AG = r$. Then, by the nature of the circle, $EF = 2 \sqrt{r^2 - x^2}$, whose distance, OP , from the axis of motion, RS , is also given $= \sqrt{a^2 + x^2}$. Hence it appears, that the force of all the particles in the line, EF , will be represented by $\dot{x} \times a^2 + x^2 \times 2 \sqrt{r^2 - x^2}$. Consequently, $\dot{x} \times a^2 + x^2 \times 2 \sqrt{r^2 - x^2}$ is the fluxion of the force of the plane $AHBE$; whose fluent, when $x = r$, is $= a^2 r + \frac{1}{2} r^3 \times$ area $A E F B C$; which, if p be put for the area of the circle whose radius is unity, will be $= a^2 r + \frac{1}{2} r^3 \times \frac{1}{2} p r^2$; whereof the double ($p a^2 r^2 + \frac{1}{2} p r^3$) is the force of the whole circle $A E F H$; whose fluxion, $2 p a r \dot{x} + p r^3 \dot{x}$ (supposing r variable), being divided by r , we likewise get $2 p a^2 r + p r^3$ ($= a^2 + \frac{1}{2} r^2 \times$ periphery $A E F H$) for the force of the periphery $A E F H$. But the center of gravity, whether we regard the circle itself or its periphery, is in the center of the circle; therefore the distance of the center of oscillation from the point of suspension will, in these two cases, be exhibited by

$a + \frac{r^2}{4a}$ and $a + \frac{r^2}{2a}$ respectively. If the circle, instead of being perpendicular to GO , either coincides, or makes a given angle with it, the value of C will be exactly the same, provided that the diameter, AB , still continues parallel to the axis of motion, RS .

5. Let the proposed figure be a curve, $A E F$, (fig. 63.) moving, as it were, flatwise, so that the plane described by the axis OAS may be perpendicular to that of the curve. Here, putting $AP = x$, $PN = y$, $AN = z$, the area AMN will be expressed by $2 y + d + x^2$. Consequently the fluent of $2 y \dot{x} \times d + x^2 \dot{x}$ will be as the whole force of the plane, NAM (or $A E F$, when $x = AS$), and, consequently,

$$C = \frac{\text{Flu. } d + x^2 \times y \dot{x}}{\text{Flu. } d + x^2 \times y \dot{x}} ;$$

which, therefore, when the point of suspension is in the vertex A , will become $C = \frac{\text{Flu. } y x^2 \dot{x}}{\text{Flu. } y x \dot{x}}$.

Let this value be denoted by v ; then, the distance of the centers of gravity and oscillation being $v - a$, we have

$$g . a :: v - a : \frac{a \times v - a}{g},$$

the distance of the same centers, when the point of suspension is at O ; and consequently,

$$C, \text{ in that case, } = g + \frac{a \times v - a}{g};$$

which form will be found in most cases more commodious than the foregoing. After the same manner the value of C , with respect to the arc, $A E F$, will appear to be $= \frac{\text{Flu. } d + x^2 \times \dot{z}}{\text{Flu. } d + x^2 \times \dot{z}} = g + \frac{a \times v - a}{g}$,

$$\text{supposing } v = \frac{\text{Flu. } x^2 \dot{z}}{\text{Flu. } x \dot{z}}$$

The preceding theorem may be exemplified in the following instances. First, let EAF be considered as an isosceles triangle; in which case AP (x) and PN (y) being in a con-

a constant ratio, we have $y = \frac{b x}{c}$ (supposing $S F = b$, and $\Lambda S = c$). Hence, $C = \left(\frac{\text{Flu. } \overline{d+x}^2 \times y \dot{x}}{\text{Flu. } \overline{d+x} \times y \dot{x}} \right) = \frac{\text{Flu. } d^2 x \dot{x} + 2 d x^2 \dot{x} + x^3 \dot{x}}{\frac{1}{2} d^2 + \frac{2}{3} d x + \frac{1}{4} x^2} = \frac{\text{Flu. } d x \dot{x} + x^2 \dot{x}}{\frac{1}{2} d + \frac{1}{3} x} = \frac{6 d^2 + 8 d x + 3 x^2}{6 d + 4 x}$; or, according to the second form,

because $v = \left(\frac{\text{Flu. } y x^2 \dot{x}}{\text{Flu. } y x \dot{x}} \right) = \frac{3 x}{4}$, and a is known to be $= \frac{2 x}{3}$, we have $C = \left(g + \frac{a \times v - a}{g} \right) = g + \frac{x^2}{18 g}$, where $g = (d + a) = d + \frac{2}{3} x$. Again, because \dot{z} and \dot{x} are in a constant ratio, we also have $\frac{\text{Flu. } \overline{d+x}^2 \times \dot{z}}{\text{Flu. } \overline{d+x} \times \dot{z}} = \frac{\text{Flu. } \overline{d+x}^2 \times \dot{x}}{\text{Flu. } \overline{d+x} \times \dot{x}} = \frac{d^2 + d x + \frac{1}{3} x^2}{d + \frac{1}{3} x}$; whence the center of oscillation of the lines $E H$ and $A F$ is given.

Secondly, let $E A F$ be supposed a parabola of any kind, whose equation is $y = \frac{x^n}{c^{n-1}}$, then, according to the second form, we shall first have $v = \left(\frac{\text{Flu. } y x^2 \dot{x}}{\text{Flu. } y x \dot{x}} \right) = \frac{\text{Flu. } x^{n+2} \dot{x}}{\text{Flu. } x^{n+1} \dot{x}} = \frac{n+2 \times x}{n+3}$; whence, a being $= \frac{n+1 \times x}{n+2}$, we also obtain $C = \left(g + \frac{a \times v - a}{g} \right) = g + \frac{n+1 \times x^2}{n+2 \times n+3 \times g}$;

where $g = d + \frac{n+1 \times x}{n+2}$. But with respect to the arc of the curve, $v = \left(\frac{\text{Flu. } x^2 \dot{z}}{\text{Flu. } x \dot{z}} \right) = \frac{\text{Flu. } x^2 \dot{x} \sqrt{c^2 n^2 - 2}}{\text{Flu. } x \dot{x} \sqrt{c^2 n^2 - 2}}$;

from which value found by infinite series, and even without it in some cases, that of C will also be given.

6. Let the proposed figure be a curve vibrating edgewise, so that the motion of the axis may be in the plane of the curve. Then the force of all the particles in the line $P N$ (fig. 63) being defined $O P^2 \times P N + \frac{1}{2} P N^2$, or $\overline{d+x}^2 \times y + \frac{1}{2} y^2$ (retaining the notation above) we have $C = \frac{\text{Flu. } \overline{d+x}^2 \times y \dot{x} + \frac{1}{2} y^2 \dot{x}}{\text{Flu. } \overline{d+x} \times y \dot{x}}$; which, when the point of suspension is in the vertex A , will become $\frac{\text{Flu. } y x^2 \dot{x} + \frac{1}{2} y^2 \dot{x}}{\text{Flu. } y x \dot{x}}$. Denote this, when found, by v ; then it appears from the preceding case, that the general value of C will also be represented by $g + \frac{a \times v - a}{g}$.

In the same manner, the value of C , with respect to the arc $E A F$, will be expounded by $\frac{\text{Flu. } \overline{d+x}^2 + y^2 \times \dot{z}}{\text{Flu. } \overline{d+x} \times \dot{z}}$, or by $g + \frac{a \times v - a}{g}$, supposing $v = \frac{\text{Flu. } x^2 + y^2 \times \dot{z}}{\text{Flu. } x \dot{z}}$.

E. G. Let the equation of the given curve be $y = \frac{x^n}{c^{n-1}}$, then $v = \left(\frac{\text{Flu. } y x^2 \dot{x} + \frac{1}{2} y^2 \dot{x}}{\text{Flu. } y x \dot{x}} \right) =$

$$\frac{\text{Flu. } c^{1-n} x^{n+2} \dot{x} + \frac{1}{2} c^{1-2n} x^{2n} \dot{x}}{\text{Flu. } c^{1-n} x^{n+1} \dot{x}} = \frac{n+2 \times x}{n+3} + \frac{1}{2} \frac{c^{1-2n} x^{2n+1} \times n+2}{n+2 \times c^{1-2n} \times x^{2n-1}} = \frac{n+2 \times x}{n+3} + \frac{3 n+1 \times c^{1-n} x^{n+1}}{3 \times 3 n+1} = \frac{n+2}{n+3} \times x + \frac{n+2}{3 \times 3 n+1} \times \frac{y^2}{x}$$

From which the value of C is also given; and from whence it appears, that if n be expounded by o , v will become $= \frac{2 x}{3} + \frac{2 y^2}{3 x} = \frac{2}{3} \times \frac{x^2 + y^2}{x}$; in which case the figure will degenerate into a rectangle: but, if n be denoted by 1 , the figure $E A F$ will then be an isosceles triangle, and $v = \frac{3 x}{4} + \frac{y^2}{4 x}$; and, lastly, if n be taken $= \frac{1}{2}$, the curve will be the common parabola, and $v = \frac{5 x}{7} + \frac{c}{3}$.

7. Let the figure $A E F H$ (fig. 64.) be a solid, generated by the rotation of a curve $E A F$ about its axis ΛS ; having its base $H H$ parallel to the axis of motion $B O C$. It appears from Art. 4. (above) that the force of all the particles in the circular section $h h$, parallel to $H H$, will be expressed by $O P^2 + \frac{1}{2} P N^2 \times$ circle $h h$, or $O P^2 \times P N^2 + \frac{1}{2} P N^2 \times p$ (p being $= 3.1415$, &c.) which, in algebraic terms, is

$$\frac{\overline{d+x}^2 \times y^2 + \frac{1}{2} y^4}{\text{Flu. } \overline{d+x}^2 \times y^2 + \frac{1}{2} y^4 \times p} \times p. \text{ Hence we have } C = \frac{\text{Flu. } \overline{d+x}^2 \times y^2 \dot{x} + \frac{1}{2} y^4 \dot{x}}{\text{Flu. } \overline{d+x} \times p y^2 \dot{x}} = \frac{\text{Flu. } \overline{d+x}^2 \times y^2 \dot{x}}{\text{Flu. } \overline{d+x} \times y^2 \dot{x}} + \frac{\frac{1}{2} y^4 \dot{x}}{y^2 \dot{x}}. \text{ Which, when the point of suspension is in the}$$

vertex A , becomes $\frac{\text{Flu. } y^2 x^2 \dot{x} + \frac{1}{2} y^4 \dot{x}}{\text{Flu. } y^2 x \dot{x}} = v$; and consequently, $C = g + \frac{a \times v - a}{g}$, as in the preceding cases.

But with regard to the superficies of the solid, it is found (Art. 4. above) that the force of the particles in the periphery $M b N b$ is expressed by $O P^2 + \frac{1}{2} P N^2 \times$ periph. $M b N b = \overline{d+x}^2 \times 2 p y + p y^2$. Hence the fluent of $\overline{d+x}^2 \times 2 p y + p y^2 \times \dot{z}$, divided by that of $\overline{d+x} \times 2 p y \dot{z} = \left(\frac{\text{Flu. } \overline{d+x}^2 \times 2 y \dot{z} + y^2 \dot{z}}{\text{Flu. } \overline{d+x} \times 2 y \dot{z}} \right)$ will give the true value of C with respect to the curve surface $E b A b F$: which, putting $v = \frac{\text{Flu. } 2 y x^2 \dot{z} + y^2 \dot{z}}{\text{Flu. } 2 y x \dot{z}}$, is likewise expressed by $g + \frac{a \times v - a}{g}$.

E. G. 1. Let $E A F$ be considered as a cone: then, putting $\Lambda S = f$, $S F = b$, and $\Lambda F = c$, we have $y = \frac{b x}{f}$, and $z = \frac{c x}{f}$; and, therefore, $C = \left(\frac{\text{Flu. } \overline{d+x}^2 \times y^2 \dot{x} + \frac{1}{2} y^4 \dot{x}}{\text{Flu. } \overline{d+x} \times y^2 \dot{x}} \right) = \frac{20 d^3 + 30 f d + 12 f^2 + 3 b^2}{20 d + 15 f}$, when $x = f$. But with respect to the convex superficies, C will be found $= \frac{12 d^3 + 16 d f + 6 f^2 + 3 b^2}{12 d + 8 f}$.

T. G. 1. Let E A F be considered as a sphere, whose center is S, and radius A S = r; in which case, y² being = 2 r x - x², we have $\phi = \frac{\text{Flu. } y^2 x^2 \dot{x} + \frac{1}{2} y^4 \dot{x}}{\text{Flu. } y^2 x \dot{x}} = \text{Flu. } \frac{r^2 x^2 \dot{x} + r x^3 \dot{x} - \frac{2}{3} x^3 \dot{x}}{2 r x^2 \dot{x} - x^3 \dot{x}} = \frac{\frac{1}{2} r^2 + \frac{1}{2} r x - \frac{2}{3} x^2}{\frac{2}{3} r - \frac{1}{3} x}$; whence C also is given. But when x = 2 r (or the whole sphere is taken) $\phi = \frac{2 r^2}{5}$; therefore, a being = r, and g = O S, in

this case, we have $C = \left(g + \frac{a \times \phi - a}{g} \right) = g + \frac{r \times 2 r}{5 g} = g + \frac{2 r^2}{5 g}$.

S. Let the figure proposed be a solid (as before), but with its axis A G parallel to the axis of motion O R S (fig. 65). Then, if R P (O G) be put = g, . . . 1470 &c. = p, A P = x, the force of the particles in the circle N M (parallel to E F) will be exhibited by $\frac{p^2 + \frac{1}{2} y^2 + p y^2, \text{ or } p g^2 y^2 + \frac{1}{2} p y^4 (\Delta r t. 3)}{\text{Flu. } p g^2 y^2 \dot{x} + \frac{1}{2} p y^4 \dot{x}} = \frac{\text{Flu. } p g^2 y^2 \dot{x}}{g \times \text{Flu. } p y^2 \dot{x}}$

Hence $C = \frac{g \times \text{solid}}{g \times \text{Flu. } p y^2 \dot{x}} = g + \frac{\text{Flu. } \frac{1}{2} y^4 \dot{x}}{g \times \text{Flu. } y^2 \dot{x}}$. With respect to the superficies, the force of the particles in the periphery of the said circle M N being 2 p g² y + 2 p y³, we have, in this case, $C = \frac{\text{Flu. } 2 p g^2 y \dot{x} + 2 p y^3 \dot{x}}{g \times \text{Su-}} = \frac{\text{Flu. } 2 p g^2 y \dot{x} + 2 p y^3 \dot{x}}{g \times \text{Flu. } y^2 \dot{x}} = g + \frac{\text{Flu. } y^4 \dot{x}}{g \times \text{Flu. } y^2 \dot{x}}$

E. G. 1. Let E A F be a segment of a sphere, whose radius is r; then y² being = 2 r x - x², we shall have $C = \left(g + \frac{\text{Flu. } \frac{1}{2} y^4 \dot{x}}{g \times \text{Flu. } y^2 \dot{x}} \right) = g + \frac{\text{Flu. } 2 r^2 x^2 \dot{x} - 2 r x^3 \dot{x} + \frac{1}{2} x^4 \dot{x}}{g \times \text{Flu. } 2 r x \dot{x} - x^2 \dot{x}} = g + \frac{\frac{2}{3} r^2 x + \frac{1}{2} r x^2 + \frac{1}{10} x^3}{2 r x - x^2} = g + \frac{20 r^2 - 15 r x + 3 x^2}{30 r - 10 x} \times g$.

This quantity, when x is denoted either by r or 2 r, becomes = $g + \frac{2 r^2}{5 g}$, for the true value of C, as the hemisphere, or the whole sphere, is taken. But, with regard to the center of oscillation of its superficies, we have $\frac{r \dot{x}}{\sqrt{2 r x - x^2}} = \frac{r \dot{x}}{y}$; and, therefore, $g + \frac{\text{Flu. } y^4 \dot{x}}{g \times \text{Flu. } y^2 \dot{x}}$

= $g + \frac{\text{Flu. } 2 r x - x x \times r \dot{x}}{g \times \text{Flu. } r \dot{x}} = g + \frac{r x - \frac{1}{2} x^2}{\frac{2}{3} g}$; which, when x = r, or x = 2 r, becomes $g + \frac{2 r^2}{3 g}$.

E. G. 2. Let the solid, E A F, be a paraboloid, whose generating curve is defined by the equation $y = \frac{x^n}{c^{n-1}}$; then

$C = g + \frac{\text{Flu. } \frac{1}{2} y^4 \dot{x}}{g \times \text{Flu. } y^2 \dot{x}} = g + \frac{\text{Flu. } \frac{1}{2} x^{4n} \dot{x} \times c^{4-n}}{g \times \text{Flu. } x^{2n} \dot{x} \times c^{2-n}} = g + \frac{2n+1 \times y^3}{4n+1 \times 2g}$. Here, taking n = 0, the figure will become a cylinder, and C = $g + \frac{y^3}{2g}$; but if n be expressed by 1, the figure will be a cone, and C = $g + \frac{3 y^3}{10g}$. If n be taken = $\frac{1}{2}$, the figure will be the solid generated from the common parabola, and

$C = g + \frac{y^3}{3g}$.

E. G. 3. Let the body be a cylinder, and the axis of vibration pass through C perpendicular to its plane (fig. 66). Put G A = r, C G = d, G O = x, and $\phi = 6, 283, \&c.$ Then ϕx = the circumference $\phi x z$, and the fluxion of the sum of all the particles multiplied into the square of their distances from C = $\phi x \times x^2 \times \dot{x}$, whose fluent, when x = r, is $\frac{\phi r^3}{2}$; and the area of the circle $\times d = \frac{\phi r^2}{2} \times d$; hence

$C O = d + \frac{r^2}{2d}$. If C coincide with A, then C O = $\frac{2}{3} r$.

Hence it follows that the same must be true for a cylinder, whose axis is parallel to the axis of vibration. See Simpson's Fluxions, vol. i. p. 214, &c. Hodgson's Fluxions, p. 434, &c. Vince's Principles of Fluxions, section 5. Cavallo's Elem. of Nat. and Exp. Philos. vol. i.

Mr. Huygens, in his "Horologium Oscillatorium," was the first person who shewed how to find the center of oscillation. Merfennus, he says, first proposed the problem to him, when he was very young, requiring him to resolve it in the cases of sectors of circles suspended by their angles, and by the middle of their bases, both when they oscillate side-ways and flat-ways; as also for triangles and the segments of circles, either suspended from their vertices, or the middle of their bases. But, as he proceeds to observe, not having immediately discovered any thing that would open a passage into this business, I was repulsed at first setting out, and stopped from the further prosecution of it; till, being farther incited to it by adjusting the motion of the pendulums of my clock, I surmounted all difficulties, going far beyond Descartes, Fabri, and others, who had done the thing in a few of the most easy cases only, without any sufficient demonstration; and solving not only the problems proposed by Merfennus, but many others that were much more difficult, and shewing a general way of determining this center in lines, superficies, and solids. In the Leipzig acts for 1691 and 1714, this doctrine is discussed by the two Bernouillis; and the same is also done by Hermann, in his treatise "De Motu Corporum Solidorum et Fluidorum." But it has been since more amply investigated in various treatises on the inverse method of fluxions, in which it is introduced as one of the examples of that method by Hayes, Carré, Wolfius, Simpson, &c. &c. A specimen of the application of this method to several cases has been given above; from which it appears, that in a right line, or rectangle, or cylinder, or any other prism, whose constant section is y, or the constant quantity a: then $y x^2 \dot{x}$ is $a x^2 \dot{x}$, whose fluent is $\frac{1}{3} a x^3$; also $y x \dot{x}$ is $a x \dot{x}$, whose fluent is $\frac{1}{2} a x^2$; and the quotient of the former $\frac{1}{3} a x^3$ divided by the latter $\frac{1}{2} a x^2$, is $\frac{2}{3} x$ for the distance of the center of oscillation below the vertex in any such figure; namely, having every where the same breadth or section, that is, at two-thirds of its length. In like manner, the centers of oscillation are found for various figures, vibrating flat-ways, and are as they are expressed in the subjoined summary:

Nature of the figure, when suspended by the vertex.	
Hofceus triangle	$\frac{2}{3}$ of its altitude
Common parabola	$\frac{2}{3}$ of its altitude
Any parabola	$\frac{2m+1}{3m+1} \times$ its altitude;
m being 2 in the common parabola;	3 in the cubic parabola;
4 in the biquadratic.	

The investigation of the center of oscillation in figures moved laterally or side-ways, or edge-ways, that is, about an axis perpendicular to the plane of the figure, is somewhat difficult; because all the parts of the weight in the same horizontal plane, on account of their unequal distances from the point of suspension, do not move with the same velocity;

city: as is shown by Huygens, in his Horol. Oscill. He found, in this case, the distance of the center of oscillation, from the axis; in a circle, to be $\frac{2}{3}$ of the diameter: in a rectangle, suspended by one of its angles, $\frac{3}{4}$ of the diagonal: in a parabola, suspended by its vertex, $\frac{5}{8}$ of its axis, and $\frac{1}{4}$ of the parameter; suspended from a point in the middle of the basis, $\frac{3}{8}$ of the axis, and $\frac{1}{2}$ the parameter: in the sector of a circle, $\frac{2}{3}$ of a right line, which is to the radius as the arc to the subtense: in a cone, $\frac{2}{3}$ of the axis, and $\frac{1}{2}$ of the third proportional to the axis, and a semidiameter of the base: in a sphere (as is usually the case in pendulums) $\frac{2}{3}$ of a third proportional to two quantities composed of the semidiameter and length of the thread, and the semidiameter itself: in a cylinder, $\frac{2}{3}$ of the altitude, and $\frac{1}{2}$ a right line, which is to the semidiameter of the base, as that is to the altitude. See the preceding part of this article.

To find the center of oscillation mechanically or experimentally. Let the body be made to oscillate about its point of suspension; and hang up also a simple pendulum of such a length that it may vibrate or just keep time with the other body: then the length of the simple pendulum is equal to the distance of the center of oscillation of the body below the point of suspension. Or it may be still better found in the following manner: Suspend the body very freely by the given point, and make it vibrate in small arcs, counting the vibrations it makes in any portion of time, as a minute, by a good stop-watch; and let that number of oscillations made in a minute be called n ; then shall the distance of the center

of oscillation be $SO = \frac{140850}{n^2}$ inches. For, the length

of the pendulum vibrating seconds, or 60 times in a minute, being $39\frac{1}{2}$ inches, or more accurately 39.1196 inches, and the lengths of pendulums being reciprocally as the squares of the number of vibrations made in the same time; therefore $n^2 : 60^2 :: 39\frac{1}{2} : \frac{140850}{n^2}$, the length of the pendulum

which vibrates n times in a minute, or the distance of the center of oscillation below the axis of motion. Or again: divide 50 seconds by the number of vibrations performed by the pendulous body in question in one minute; and the quotient is the time of one vibration. Square this time, and multiply its square by the length of the pendulum that vibrates seconds, viz. by 39.1196 inches, and the last product shews the distance in inches of the center of oscillation or percussion from the point of suspension in the proposed pendulum.

E. G. 1. Let a cylindrical stick about a yard long be suspended by one extremity, and caused to vibrate. Let the number of its vibrations be 70 in a minute; divide 60 seconds by 70, and the quotient, or $0''.79$ (79 hundredths of a second), is the time in which the proposed pendulum performs one vibration. Then, the lengths of pendulums being as the squares of the times of vibration, lay, as the square of one second, *i. e.* unity, is to the square of $0''.79$, viz. 0.6241 , so is the length of the pendulum which vibrates seconds, viz. 39.1196 , to the length sought; therefore multiply 39.1196 by 0.6241 , and the product, 24.4 , is the distance sought: so that the center of oscillation in the stick is 24 inches and 4 tenths distant from its extremity by which it is suspended; that is, about $\frac{2}{3}$ of its length.

E. G. 2. Let an irregular body, suspended by one end, perform 20 vibrations in a minute; and the time of one vibration is $\frac{60}{20} = 3$ seconds; the square of this is 9, and $39.1196 \times 9 = 352.0764$ inches, or nearly 29 feet, the distance of the center of oscillation from the point of suspension.

CENTER of percussion, in a moving body, is that point

where the percussive force is the greatest, in which the whole percussive force of the body is supposed to be collected: or about which the impetus of the parts is balanced on every side: so that it may be stopped by an immovable obstacle at this point, and rest on it, without acting on the center of suspension: or, the center of percussion is that point in the axis of a vibrating or revolving body, which, striking against an immovable obstacle, causes the whole motion, estimated in the plane of the body's motion, to be destroyed. It is obvious, that if the obstacle be opposed to the moving body at different distances from the point of suspension, the stroke or percussion will not be equally powerful: and it is evident, that this center of percussion does not coincide with the center of gravity. Let the body, AB, (*Plate VIII. Mechanics, fig. 67.*) consisting of two equal balls fastened to a stiff rod, move in a direction parallel to itself, and it is evident that the two balls must have equal momentums, since their quantities of matter are equal, and they move with equal velocities. Now if in its way, as at N. II. an obstacle C be opposed exactly against its middle E, the body will thereby be effectually stopped, nor can either end of it move forwards, for they exactly balance each other, the middle of this body being its center of gravity. Now should an obstacle be opposed to this body, not against its middle, but nearer to one end, as at N. III. then the stroke being not in the direction of the center of gravity, is in fact an oblique stroke, in which case, agreeably to the laws of congress, a part only of the momentum will be spent upon the obstacle, and the body advancing the end A, which is farthest from the obstacle, as shewn by the dotted representation, will proceed with that part of the momentum which has not been spent upon the obstacle; consequently in this case the percussion is not so powerful as in the foregoing. Therefore there is a certain point in a moving body which makes a stronger impression on an obstacle than any other part of it. In the present case, indeed, this point coincides with the center of gravity; because the two ends of the body before the stroke moved with equal velocities. But in a pendulum the case is different; for let the same body of *fig. 67.* be suspended by the addition of a line AS, *fig. 68.* which line we shall suppose to be void of weight and flexibility, and let it vibrate round the point of suspension S. It is evident that now the two balls will not move with equal velocities; for the ball B, by describing a longer arc than the ball A in the same time, will have a greater momentum; and of course the point where the forces of the two balls balance each other, which is the center of percussion, lies nearer to the lower ball B; consequently this point does not coincide with the centre of gravity of the body AB; but it is that point wherein the forces of all the parts of the body may be conceived to be concentrated. Hence the center of oscillation and the center of percussion coincide; or rather they are exactly the same point, whose two names only allude, the former to the time of vibration, and the latter to its striking force.

If in *fig. 67.* the balls A and B be not equal, their common center of gravity will not be in the middle at E, but it will lie nearer to the heavier body, as at D, supposing B to be the heavier body; so that the distances, BD, AD, may be inversely as the weights of those bodies. Now when the above-mentioned body is formed into a pendulum, as in *fig. 68.* though the weights A and B be equal, yet by their moving in different arcs, viz. with different velocities, their forces or momentums become actually unequal; therefore in order to find the point where the forces balance each other, so that when an obstacle is opposed to that point, the moving pendulum may be effectually stopped,

and no part of it may preponderate, in which case the obstacle will receive the greatest impression; we must find first the momentums of the two bodies A and B, then the distances of those bodies from the center of percussion n, or of equal forces, must be inversely as those momentums. Thus the velocities of A and B are represented by the similar arcs which they describe, and those arcs are as the radii SA, SB. Therefore the momentum of A is the product of its quantity of matter multiplied by SA, and the momentum of B is the product of its quantity of matter multiplied by SB; consequently AD must be to BD, as the weight of B multiplied by SB is to the weight of A multiplied by AS. Then D is the center of percussion. And since, when four quantities are proportional, the product of the two extremes is equal to the product of the two means; therefore if the weight of A multiplied by AS, be again multiplied by AD, the product must be equal to the product of the weight of B multiplied by BS, and again multiplied by DD.

CENTER of percussion, locus of the.—1. *The center of percussion is the same with the center of oscillation*, where the percussive body revolves round a fixed point; and is determined in the same manner. viz. by considering the impetus of the parts, as so many weights applied to an invisible right line, void of gravity; i. e. by dividing the sum of the products of the forces of the parts, multiplied by their distances from the point of suspension, by the sum of the forces. What, therefore, has been above shewn of the *center of oscillation*, will hold of the *center of percussion*, where the percussive body moves round a fixed point: e. g. that the center of percussion in a cylinder is at $\frac{2}{3}$ of its length from the point of suspension; or that a $\frac{2}{3}$ of a cylindrical figure, supposing the center of motion at the hand, will strike the greatest blow at a point about two-thirds of its length from the hand. See *CENTER of oscillation*.

2. *The center of percussion is the same with the center of gravity*, if all the parts of the percussive body be carried with a parallel motion, or with the same celerity: for the momenta are the products of the weights into the celerities. Wherefore, to multiply equiponderating bodies by the same velocity, is the same thing as to take equimultiples; but the equimultiples of equiponderating bodies themselves equiponderate; therefore, equivalent momenta are disposed about the center of gravity: consequently the center of percussion in this case coincides with that of gravity; and what is shewn of the one, will hold of the other.

To find the center of percussion of a body. Let A B D (fig. 69.) be a plane passing through the center of gravity G of the body, and perpendicular to the axis of suspension which passes through C; and conceive the whole body to be projected upon this plane in lines perpendicular to it, or parallel to the axis: then, as each particle is thus kept at the same distance from the axis, the effect, from the rotatory motion about the axis, will not be altered, nor will the center of gravity be changed. Let O be the center of percussion, and draw *pnv* perpendicular to *pC*, and *Osw* perpendicular to *pw*; also *pv* perpendicular to *Cn*. As the velocity of any particle *p* is as *pC*, the momentum of *p* in the direction *pv* is as $p \times pC$, it being as the velocity and quantity of matter conjointly; and by the property of the lever, the efficacy of this force to turn the body about O is as $p \times pC \times Osw =$ (because *On* : *Ow* :: *pC* : *vC*) $p \times vC \times On = p \times vC \times CO - Cn = p \times vC \times CO - p \times vC \times Cn =$ (as *Cn* : *Cp* :: *Cp* : *vC*) $p \times vC \times CO - p \times Cp^2$. Now that the efficacy of all the particles to turn the body about O may be = ϵ , we

must make the sum of all the quantities $p \times vC \times CO -$ sum of all the quantities $p \times Cp^2 = 0$; hence $CO =$ sum of all the $p \times Cp^2 \div$ sum of all the $p \times vC$, these two denominators being equal from the property of the center of gravity. Although the body by striking at O may have no tendency to move in the plane of its previous motion, and this only is included in the common definition here adopted, yet it may have a tendency to revolve about A O. If therefore the center of percussion were defined to be that point where the whole motion would be destroyed, we must find the plane parallel to A B D, such that the sum of all the forces to turn the body about the line joining the center of percussion and the axis of vibration in that plane, is also = 0. But this is a problem of more difficult solution. As the force acting at O destroys the motion, let us suppose a force to act at O and to generate the motion back again; then it is manifest, that the body would begin to return under all the same circumstances in which its motion ceased; that is, it would begin its motion by revolving about C. In this case C is called the *CENTER of spontaneous rotation*; making therefore the point at which a force acts upon a body that can move freely the center of percussion, the center of spontaneous rotation coincides with the center of rotation corresponding to that center of percussion. Vince's Principles of Dynamics, p. 102. Parkinson's System of Mechanics, &c. p. 194.

CENTER of a parallelogram, the point wherein its diagonals intersect.

CENTER of position, denotes a point of any body, or system of bodies, so selected, that we may properly estimate the situation and motion of the body or system by those of this point. It is evident that, in mechanical discussions, the point, by the position of which we estimate the position and distance of the whole, must be so determined, that its position and distance, estimated in any direction whatever, shall be the average of the positions and distances of every particle of the mass, estimated in the same direction. Accordingly this will be the case, if the point be so selected that, when a plane is made to pass through it in any direction whatever, and perpendiculars are drawn to this plane from every particle in the body or system, the sum of all the perpendiculars on one side of this plane is equal to the sum of all the perpendiculars on the other side. If there be such a point in the body, the position and motion of this point are the average of the positions and motions of all the particles. For if P (Plate IX. Mechanics, fig. 70.) be a point so situated, and if Q R be a plane (perpendicular to the paper) at any distance from it, the distance Pp of the point from this plane is the average of the distances of all the particles from it. For let the plane A P B be passed through P, parallel to Q R. The distance CS of any particle C from the plane Q R is equal to DS - DC, or to Pp - DC. And the distance G'I of any particle G, lying on the other side of A P B, is equal to H'I + G'H, or to Pp + G'H. Let *n* be the number of particles on that side of A B which is nearest to Q R, and let *o* be the number of those on the remote side of A B, and let *m* be the number of particles in the whole body, and therefore equal to *n* + *o*. It is evident that the sum of the distances of all the particles, such as C, is *n* times Pp, after deducting all the distances, such as DC. Also the sum of all the distances of the particles, such as G, is *o* times Pp, together with the sum of all the distances, such as G'H. Therefore the sum of both sets is $n + o \times Pp +$ sum of G'H - sum of DC, or $m \times Pp +$ sum of G'H - sum of DC. But the sum of G'H, wanting the sum of DC, is nothing, by

by the supposed property of the point P. Therefore $m \times Pp$ is the sum of all the distances, and Pp is the m th part of this sum, or the average distance.

Now suppose that the body has changed both its place and its position with respect to the plane Q R, and that P (fig. 71.) is still the same point of the body, and a P β a plane parallel to Q R. Make $\beta \pi$ equal to βP of fig. 70. It is plain that $P\beta$ is still the average distance, and that $m \times P\beta$ is the sum of all the present distances of the particles from Q R, and that $m \times \pi \beta$ is the sum of all the former distances. Therefore $m \times P \pi$ is the sum of all the changes of distance, or the whole quantity of motion eliminated in the direction πP . $P \pi$ is the m th part of this sum, and is therefore the average motion in this direction. The point P has therefore been properly selected; and its position, and distance, and motion, in respect of any plane, is a proper representation of the situation and motion of the whole.

It follows from the preceding discussion, that if any particle C (fig. 70.) moves from C to N, in the line C S, the centre of the whole will be transferred from P to Q, so that P Q is the m th part of C N; for the sum of all the distances has been diminished by the quantity C N, and therefore the average distance must be diminished by the m th part of C N, or $P Q$ is $= \frac{C N}{m}$.

But it may be doubted whether there is in every body a point, and but one point, such that if a plane pass through it, in any direction whatever, the sum of all the distances of the particles on one side of this plane is equal to the sum of all the distances on the other.

It is easy to shew that such a point may be found, with respect to a plane parallel to Q R. For if the sum of all the distances D C exceed the sum of all the distances G H, we have only to pass the plane A B a little nearer to Q R, but still parallel to it. This will diminish the sum of the lines D C, and increase the sum of the lines G H. We may do this till the sums are equal.

In like manner we can do this with respect to a plane L M (also perpendicular to the paper), perpendicular to the plane A B. The point wanted is somewhere in the plane A B, and somewhere in the plane L M. Therefore it is somewhere in the line in which these two planes intersect each other. This line passes through the point P of the paper where the two lines A B and L M cut each other. These two lines represent planes, but are, in fact, only the intersection of those planes with the plane of the paper. Part of the body must be conceived as being above the paper, and part of it behind or below the paper. The plane of the paper therefore divides the body into two parts. It may be so situated, therefore, that the sum of all the distances from it to the particles lying above it shall be equal to the sum of all the distances of those which are below it. Therefore the situation of the point P is now determined, namely, at the common intersection of three planes perpendicular to each other. It is evident that this point alone can have the condition required in respect of these three planes.

But it still remains to be determined whether the same condition will hold true for the point thus found, in respect to any other plane passing through it; that is, whether the sum of all the perpendiculars on one side of this fourth plane is equal to the sum of all the perpendiculars on the other side. Therefore

Let A G H B (fig. 72.), A X Y B, and C D F E, be three planes intersecting each other perpendicularly in the point C, and let C I K L be any other plane, intersecting the first in the line C I, and the second in the line C L. Let P be any particle of matter in the body or system.

Draw P M, P O, P R, perpendicular to the first three planes respectively, and let P R, when produced, meet the oblique plane in V; draw M N, O N, perpendicular to C B. They will meet in one point N. Then P M N O is a rectangular parallelogram. Also draw M Q perpendicular to C E, and therefore parallel to A B, and meeting C I in S. Draw S V; also draw S T perpendicular to V P. It is evident that S V is parallel to C L, and that S T R Q and S T P M are rectangles.

All the perpendiculars, such as P R, on one side of the plane C D F E, being equal to all those on the other side, they may be considered as compensating each other; the one being considered as positive or additive quantities, the other as negative or subtractive. There is no difference between their sums, and the sum of both sets may be called 0 or nothing. The same must be affirmed of all the perpendiculars P M, and of all the perpendiculars P O.

Every line, such as R T, or its equal Q S, is in a certain invariable ratio to its corresponding Q C, or its equal P O. Therefore the positive lines R T are compensated by the negative, and the sum total is nothing.

Every line, such as T V, is in a certain invariable ratio to its corresponding S T, or its equal P M, and therefore their sum total is nothing.

Therefore the sum of all the lines P V is nothing; but each is in an invariable ratio to a corresponding perpendicular from P on the oblique plane C I K L. Therefore the sum of all the positive perpendiculars on this plane is equal to the sum of all the negative perpendiculars, and the proposition is demonstrated, viz. that in every body, or system of bodies, there is a point such, that if a plane be passed through it in any direction whatever, the sum of all the perpendiculars on one side of the plane is equal to the sum of all the perpendiculars on the other side.

The point P, thus selected, may, with great propriety, be called the center of position of the body or system.

If A and B (fig. 73.) be the centers of position of two bodies, whose quantities of matter (or numbers of equal particles) are a and b , the center C lies in the straight line joining A and B, and A C : C B = $b : a$, or its distance from the centers of each are inversely as their quantities of matter. For let $\alpha C \beta$ be any plane passing through C. Draw A α , B β , perpendicular to this plane. Then we have $a \times A \alpha = b \times B \beta$, and $A \alpha : B \beta = b : a$, and, by similarity of triangles, C A : C B = $b : a$.

If a third body D, whose quantity of matter is d , be added, the common center of position E of the three bodies is in the straight line D C, joining the center D of the third body with the center C of the other two, and D E : E C = $a + b : d$. For passing the plane $\delta E \chi$ through E, and drawing the perpendiculars D δ , C χ , the sum of the perpendiculars from D is $d \times D \delta$; and the sum of the perpendiculars from A and B is $a + b \times C \chi$, and we have $d \times D \delta = \frac{a + b}{d} \times C \chi$; and therefore D δ : E C = $a + b : d$.

In like manner, if a fourth body be added, the common center is in the line joining the fourth with the center of the other three, and its distance from this center and from the fourth is inversely as the quantities of matter; and so on for any number of bodies.

If all the particles of any system be moving uniformly, in straight lines, in any directions, and with any velocities whatever, the center of the system is either moving uniformly in a straight line, or is at rest.

For, let m be the number of particles in the system. Suppose any particle to move uniformly in any direction. It is evident from the reasoning in a former paragraph, that

the motion of the common center is the *m*th part of this motion, and is in the same direction. The fame must be said of every particle. Therefore the motion of the center is the motion which is compounded of the *m*th part of the motion of each particle. And because each of these was supposed to be uniform and rectilinear, the motion compounded of them all is also uniform and rectilinear; or it may happen that they will compensate each other that there will be no diagonal, and the common center will remain at rest.

Cor. 1. If the centers of any number of bodies move uniformly in straight lines, whatever may have been the motions of each particle of each body, by rotation or otherwise, the motion of the common center will be uniform and rectilinear.

Cor. 2. The quantity of motion of such a system is the sum of the quantities of motion of each body, reduced to the direction of the center's motion. And it is had by multiplying the quantity of matter in the system by the velocity of the center.

The velocity of the center is had by reducing the motion of each particle to the direction of the center's motion, and then dividing the sum of those reduced motions by the quantity of matter in the system.

By the selection of this point, we render the investigation of the motions and actions of bodies incomparably more simple and easy, freeing our discussions from numberless intricate complications of motion, which would frequently make our progress almost impossible. That there is in every body such a point has been demonstrated in the manner above stated by Dr. Robison (after Boolevich) in his Elements of Mechanical Philosophy, &c. 8vo. 1834, p. 79, &c.

CENTER of pressure, in Hydraulics, is that point of a surface, against which any fluid presses, in which the whole pressure may be conceived to be united; or, as Mr. Cotes has defined it, it is that point, to which, if the total pressure on any plane were applied, its effect upon the plane would be the same as when it was distributed unequally over the whole; or again, it is that point to which, if a force were applied, equal to the total pressure, but with a contrary direction, it would exactly balance or null in the effect of the pressure, and keep the surface at rest. Thus if *abcd* (*PLATE IX. Mechanics, fig. 74.*) be a vessel for water, and the side *ac* be pressed upon with a force equivalent to 20 pounds of water, this force is unequally distributed over *ac*; for the parts near *a* being at a lesser depth, are less pressed upon than the parts near *c*, which are at a greater depth, and therefore the efforts of all the particular pressures are united in some point as *z*, which is nearer to *c* than to *a*, and that point *z* is what may be called the centre of pressure. If to that point a force equivalent to 20 pounds weight be applied, it will affect the plane *ac* in the same manner as before by the pressure of the water distributed unequally over the whole; and if to this same point we apply the same force with a contrary direction to that of the pressure of the water, the force and pressure will balance each other, and by contrary endeavours destroy each other's effects. Suppose at *z* a cord *zpw* were fixed, which passing over the pulley, *p*, has a weight, *w*, of 20 pounds annexed to it, and that the part of the cord *zp* were perpendicular to *ac*; the effort of the weight *w* is equal, and its direction contrary to that of the pressure of the water. Now if *z* be the center of pressure, these two powers will be in equilibrium, and mutually defeat each other's endeavours.

To find the center of pressure of a plane surface. Let *ABCD* (*fig. 75*) be the surface of the fluid, *VW* the plane, in which produced, let *cd* be its intersection

with the surface, *P* the center of pressure, and *G* the center of gravity; and conceive the whole plane to be divided into an indefinite number of indefinitely small parts, of which one is *x*; draw *PQ*, *Gg*, *xx*, perpendicular to the surface, and *Pa*, *Gn*, *xxm*, perpendicular to *cd*; and join *Qa*, *gn*, *vm*: then it is manifest that the triangles *PQa*, *Ggn*, *xxm*, are similar. Now the pressure on *x* perpendicular to *VW* is as *x* \times *xv* (being as the particle or number of particles \times the depth); and its effect to turn the plane about *cd* is as *x* \times *xv* \times *xm*; but, by similar triangles,

$$Gn : Gg :: xm : xv = xm \times \frac{Gg}{Gn} : \text{hence the effect of}$$

the pressure at *x* to turn the plane about *cd* is as *x* \times *xm*² \times $\frac{Gg}{Gn}$; therefore the whole effect is as the sum of all the

$$x \times xm^2 \times \frac{Gg}{Gn}. \text{ But if } A = \text{the area of } VW, \text{ the pres-}$$

sure on *VW* is as *A* \times *Gg*; therefore the effect of that pressure at *P* to turn the plane about *cd* is as *A* \times *Gg* \times *Pa*. Hence *A* \times *Gg* \times *Pa* = the sum of all the *x* \times *xm*² \times $\frac{Gg}{Gn}$; Consequently *Pa* = $\frac{\text{Sum of all the } x \times xm^2}{A \times Gn}$.

Hence it appears, that *P* is at the same distance from *cd* as the center of percussion is, *cd* being the axis of suspension. They do not, however, in general lie in the same line, that is, in the line *NG*; for the efficacy of the pressure at *x*, to turn the plane about *NG*, is as *x* \times *xv* \times *mn*, or (since *xv* varies as *xm*) as *x* \times *xm* \times *mn*; but the sum of all the *x* \times *xm* \times *mn* is not generally = 0; therefore the whole pressure will not necessarily balance itself upon the line *NG*. The situation of the line *AP* must therefore be determined, by making the sum of all the *x* \times *xm* \times *mn* = 0. The centers of pressure and percussion do not therefore in general coincide, taking the center of percussion in its usual acceptation. Obs. The center of percussion has always been defined to be that point in the line *NG* at which all the motion of the body would be destroyed, eliminating the motion of the body about the line *cd*; and the computations have been always made upon this principle. But the body, after its action against that center, may still have a tendency to turn about the line *NG*. If, therefore, we were to define the center of percussion to be that point at which the whole motion of the body would be destroyed, the centers of pressure and percussion would not, in general, coincide; in which case, the position of the line *AP* must be computed on the above principle. Cotes's Lectures on and Pneumatics Lectures, p. 49, &c. Vince's Principles of Hydrostatics, p. 10.

CENTER of a regular plane, or circular body, is the same as that of the inscribed or circumscribed circle or sphere.

CENTER of rotation, is that point about which a body, otherwise at liberty, revolves or tends to revolve, when it is acted upon unequally at different parts, or by a force, the direction of which does not pass through its center of gravity. M. I. Bernoulli was the first who published any thing on this subject; and he first found the point about which a body at rest would begin to revolve, when struck by another body, and he called this point the spontaneous center of rotation, to distinguish it from the center of fixed rotation. He observes, however, that D. Bernoulli had discovered the same: he has also mentioned the curve described by that point in the progressive motion of the body, and has directed a method of inquiry by which the velocities of the bodies may be found after the stroke. Two years afterwards D. Bernoulli published a paper on progressive and rotatory motion, containing nothing more than what I. Bernoulli had before given. Euler has also investigated the velocities of the

the bodies after impact in a manner somewhat different, but he has rendered it much more intricate by a fluxional calculus. Mr. Vince has treated this subject much at large and with great perspicuity in the Philosophical Transactions, vol. lxx. (for 1780) p. 546, &c. He begins with the most simple cases, and then proceeds to those that are more complicated; and he comprehends the whole in a variety of distinct propositions.

1. Let A and B (*Pl. IX. Mechanics. fg. 76.*) be two indefinitely small bodies connected by a lever void of gravity; and suppose a force to act at any point D perpendicularly to the lever; and it be required to find the point about which the bodies will begin to revolve.

By the property of the lever, the effort of the force acting at D on the body is to the effect on B :: BD : AD; and therefore the ratio of the spaces Am, Bn, described by the bodies A and B in the first instant of their motion will be as $\frac{BD}{A} : \frac{AD}{B}$; join mn, and produce it if necessary, and also AB to meet in C, and this will be the point about which the bodies begin to revolve. Hence from similar figures BC : AC :: $\frac{AD}{B}$ (Bn) :: $\frac{BD}{A}$ (Am) :: A × AD : B × BD; or DC - DB : AD + DC :: A × AD : B × BD; and consequently DC = $\frac{A \times AD^2 + B \times BD^2}{B \times BD - A \times AD}$; and therefore D is the center of percussion or oscillation to the point of suspension C. Hence, whatever be the magnitude of the stroke at D, the point C will remain the same. Moreover, if the force acts at the center of gravity, G, the bodies will have no circular motion; for in this case B × BD - A × AD = 0; and therefore DC becomes infinite. Further, if the force acts at one of the bodies, the center of rotation, C, will coincide with the other body. Also, if the lever had been in motion before the stroke, the point C, at the instant of the stroke, would not have been disturbed.

2. Let a given quantity of motion be communicated to the lever at D, to determine the velocity of the center of gravity, G. The space Am is as $\frac{DB}{A}$; and CG = CD - DG = CD -

$$AG + AD = \frac{A \times AD^2 + B \times BD^2}{B \times BD - A \times AD} - AG + AD = \frac{B \times BD \times BG + A \times AD \times AG}{B \times BD - A \times AD}; \text{ also } CA =$$

$$CD + DA = \frac{A \times AD^2 + B \times BD^2}{B \times BD - A \times AD} + DA =$$

$$\frac{B \times BD \times AB}{B \times BD - A \times AD}; \text{ hence we have } \frac{B \times BD \times AB}{B \times BD - A \times AD}$$

$$(A'C) : \frac{BD}{A} (mA) :: \frac{B \times BD \times GB + A \times AD}{B \times BD - A \times AD}$$

$$\times AG (CG) : \frac{B \times BD \times GB + A \times AD \times AG}{A \times B \times AB}$$

or Gv , the velocity of the center of gravity; hence if the motion be communicated at G, the velocity becomes as $\frac{B \times GB^2 + A \times AG^2}{A \times B \times AB}$.

Let the motion, supposed to be actually communicated to the rod at D, be equivalent to the motion of a body whose magnitude is G, and moving with a velocity v; then, if that motion be communicated at G, the velocity of the center of gravity is well known to be = $\frac{G \times v}{A + B}$; hence $\frac{B \times BG^2 + A \times AG^2}{A \times B \times AB}$;

$$\frac{B \times BD \times BG + A \times AD \times AG}{A \times B \times AB} :: \frac{G \times v}{A + B}$$

$$\frac{G \times v}{A + B} \times \frac{B \times BG \times BD + A \times AD \times AG}{B \times BG^2 + A \times AG^2} =$$

the velocity of the center of gravity, when the same motion is actually communicated to any point D. Now BD =

$$BG + GD, \text{ and } AD = AG - GD; \text{ hence } B \times BG \times BD + A \times AD \times AG = B \times BG^2 + A \times$$

$$AG^2 + GD \times B \times BG - A \times AG \times GD = (because B \times BG - A \times AG = 0) B \times BG^2 + A \times AG^2;$$

consequently, the velocity becomes $\frac{G \times v}{A + B}$; and hence

the center of gravity moves with the same velocity, wherever the motion is communicated.

3. Let a given elastic body P, moving with a given velocity, be supposed to strike the lever at the point D, in a direction perpendicular to it; and it be required to determine the velocity of the center of gravity G after the stroke. Suppose, first, the body to be non-elastic, and let v be the velocity of the center of gravity after the stroke, and V the velocity of the

striking body: then CG : CD :: v : $\frac{v \times CD}{CG}$ = the

velocity of the point D, after the stroke, or of the body P;

for the same reason $\frac{v \times CA}{CG}$ and $\frac{v \times CB}{CG}$ equal the veloci-

ties of A and B respectively. Now, because in revolving bodies, their distance from the center of rotation and velocity conjointly, remain the same after the stroke as before, we

shall have $P \times V \times DC = \frac{v \times CD^2 \times P}{CG} + \frac{v \times CA^2 \times A}{CG}$

+ $\frac{v \times CB^2 \times B}{CG}$, and therefore $v = \frac{P \times V \times DC}{P \times V \times CG + A \times$

$$\frac{A \times CA^2 + B \times CB^2}{A + B \times CG + P \times DC^2}$$

hence if P be supposed an elastic body, we shall have

$$\frac{A \times CA^2 + B \times CB^2}{2 \times P \times V \times CG + A + B \times CG + P \times DC}$$

for the velocity of the center of gravity after the stroke, in *ipso motus initio*.

4. Let a motion be communicated to the lever obliquely, and it be required to determine the point about which the bodies begin to revolve. Let FD (*fig. 77.*) represent the force communicating the motion at the point D, and resolve it into two others, FH, HD, the former FH parallel to the lever, and the latter HD perpendicular to it. Let C be the point about which the bodies would have begun to revolve, if the force HD alone had acted, which may be found by

Art. 1; and suppose in this case mg n to have been the next position of the lever after the commencement of the motion, or that the bodies A, B, and center of gravity G, had been carried to $m, g,$ and n , respectively. But as the force FH acts at the point D at the same time in the direction of the rod, if we take $Gg : G_2$ as FH : HD, then whilst the center of gravity would have moved from G to g in consequence of the force HD, it will by means of the force FH be carried in the direction of the lever from G to g_2 , and also every other point of the lever will be carried in the same direction with the same velocity; take therefore Ap and Br each equal to Gg_2 , and complete the parallelograms A g_2 , G v and Bb, and the bodies A, B, and center of gravity G will, at the end of that time, be found at a, b, and v respectively, and avb will be the position of the lever. Now it is evident, that C is not the point about which the bodies begin to revolve, for

(considering the lever to be produced to C) that point must have moved over a space Cc equal to Gg , when the lever is come into the position awb : draw CO perpendicular to C, B , and GO perpendicular to Cc , and O will be the center of rotation at the commencement of the motion. For conceive CO to be a lever, then the lever ABC has a circular motion about C , whilst that point is moving from C to c , and consequently the point O is carried forward in a direction parallel to Cc by this motion; but as the lever CO is carried by a circular motion about C in a contrary direction, it is evident that that point of the lever CO must be at rest where these two motions are equal, as they are in contrary directions. Now the velocity of C in the direction Cc : velocity of G about C :: Gg : Gc :: (by sim. triang.) CO : CG , and the velocity of the point G about C : velocity of the point O about C :: CG : CO ; hence *ex æquo* the velocity of C in the direction of Cc , or of O in the direction OP parallel to Cc , is equal to the velocity of the same point O in a contrary direction arising from its rotation about C , and consequently O being a point at rest, must be the center of rotation in *ipso motu initio*. Also, because ma is equal and parallel to nb , ab must be equal and parallel to mn , therefore the angular velocity is just the same as if the force FH had not acted. The center O of rotation at the beginning of the motion being thus determined, every thing relative to the motion of the bodies, after they are at liberty to remove freely, may be determined as in the preceding propositions.

Cor. 1. Hence it appears, that whatever be the magnitude or direction of the force communicating the motion, or the point at which it acts, the center of gravity will move in a line parallel to the direction of the force, for the triangles FHD , Gqw being similar, Gw must be parallel to FD .

Cor. 2. The same is manifestly true for any number of bodies; for let (*fig. 78.*) E be a third body, and conceive it to be connected with the other two bodies A and B in their center of gravity G ; then if FD represents the force acting at the point D , it is evident from the last Corol. and the second Prop. that the center of gravity moves with the same velocity and in the same direction, as if the same motion had been communicated at G in a line RG parallel to FD , and that the center of gravity has the same velocity communicated to it, as if the two bodies had been placed at G ; conceive therefore the bodies A and B to be placed at G , and let the force act at D , and then from the last Corol. the center of gravity G , of the three bodies, will move in a line parallel to the direction of the force communicated. In the same manner it may be proved for any number of bodies.

The method here used for determining the point of rotation in *ipso motu initio*, when a single force acts at any point D , may be applied, when any number of forces act at different points at the same time. For let (*fig. 76.*) α, β, γ , &c. represent the forces acting on the lever at the points D, E, F , respectively, &c. then from the same principles the effect of all the forces on A : the effect on B ::

$$\frac{\alpha}{AD} + \frac{\beta}{AE} + \frac{\gamma}{AF} + \&c. : \frac{\alpha}{BD} + \frac{\beta}{BE} + \frac{\gamma}{BF} + \&c.$$

which quantities put equal to P and Q respectively, and then $\frac{P}{A} : \frac{Q}{B} :: Am : Bn :: AC : BC$, from whence

$$\text{it appears, that (putting } GC + GA = AC \text{ and } GC - GB = BC) \text{ the distance } GC = \frac{A \times Q \times AG + B \times P \times BG}{B \times P - A \times Q}.$$

The same conclusion might have been deduced from this consideration; that if any number of forces act on a lever, the effect on any point of that lever is just the same as if a force, equivalent to the sum of these forces, had acted at their common center of gravity; and therefore their common center of gravity, and conceive a force equivalent to them all to be communicated to that point, and the problem is reduced to the case of the first proposition. If any of the forces had acted on the opposite side of the lever, such forces must have been considered as negative.

If there be any number of bodies placed on the lever, and a single force acts at D , it will appear from the same principles that the point C , about which they begin to revolve, will be the point of suspension to the center of percussion D ; and the same conclusion will be obtained, if the bodies be not situated in a straight line.

5. If a force acts upon a body in any given direction not passing through the center of gravity; to determine the plane of rotation, the direction in which the center of gravity begins to move, and its motion after. Conceive a plane $AyBZ$ (*fig. 79.*) to be supported upon a line AB passing through its center of gravity G , and suppose a force to act at any point D in that line, and in a direction perpendicular to the plane; then it is manifest, that such a force can give the plane no rotatory motion about AB . Imagine now the support to be taken away whilst the force is acting at D , then it is evident, that as the plane had no tendency to move about AB as an axis, and the taking away of the support can give it no such motion, it will, by Cor. 2. Art. 4. begin its progressive motion in the direction in which the force acts; and as the force is supposed not to act at the center of gravity, it must at the same time have a rotatory motion about some axis, which, as it has no motion about AB , must be somewhere in the plane, and perpendicular to AB ; and consequently in *ipso motu initio* the plane of rotation must be perpendicular to the plane $AyBZ$. Let LCM , perpendicular to AB , be the axis about which the plane begins to revolve, and p, q be two equal particles of the plane similarly situated in respect to AB , also qb, pa perpendicular to LCM . Now the centrifugal force of p , or its force in the direction ap is $p \times ap$, and that of q in the direction bq is $q \times bq$; to determine now how these forces will affect the motion of the plane, we may observe, in the first place, that the force $p \times ap$, acting at a in the plane, must tend to give it a motion about an axis perpendicular to the plane; but as an equal force $q \times qb$ acts at q to give it a motion in a contrary direction, it is evident that the two forces will destroy each other, so far as they tend to generate any motion in the plane about an axis perpendicular to it; and hence it is manifest, that if the parts of the plane AyB, AZB , be similar, and similarly situated in respect to AB , the plane, after the commencement of the motion, will have no tendency to revolve about an axis perpendicular to it. Also, as the centrifugal force of each particle acts in a direction parallel to AB , it can give the plane no tendency to revolve about that line as an axis, and consequently the plane of rotation will be preserved as in *ipso motu initio*. Conceiving therefore the plane on each side the line AB to be similar, and similarly situated, suppose another plane to be fixed upon this, whose parts on each side AB are similar, and similarly situated, and the force to act as before, then it is manifest, that as each plane endeavours to preserve the same plane of rotation, the

two planes connected will also continue to move in the same plane of rotation, for the action of one plane on another, on each side the plane of rotation, being equal, cannot tend to disturb the motion in that plane; and as this must be true for any number of planes thus similar and similarly situated, it is evident, that if a force should act upon a body, and each section, perpendicular to the direction of the force, should be similar on each side the plane passing through the direction of the force, and the center of gravity of the body, that that plane would be the plane of rotation in which the body would both begin and continue its motion. It appears also, from what has been proved, that if every section on each side that plane had not been similar, the plane of rotation would not necessarily have continued the same after the commencement of the motion. Hence all bodies, formed by the revolution of any plane figure, will have the axis about which they were generated, a fixed axis of rotation; to determine, however, every other axis of a body about which it would continue to revolve, would be foreign to the present subject. Supposing therefore the plane of rotation to continue the same, imagine all the particles of the body to be referred to that plane orthographically, which supposition not affecting the angular motion of the body, the centrifugal force of all the particles, to cause the body to revolve about an axis perpendicular to that plane, will remain unaltered. Let LMNO (fig. 80.) be that plane, and suppose a force to act at A in the direction PA lying in the same plane, which produce until it meets LN, passing through the center of gravity G, perpendicularly in D; then by Cor. 2. Art. 4. the center of gravity G will begin its motion in a line parallel to PA, or perpendicular to LN; and consequently the center C, about which the body begins to revolve, must lie somewhere in the line LN. Now the centrifugal force of any particle p is $p \times pc$; let pa perpendicular to LN, then the effect of that force at C, in a direction perpendicular to LN, will be $p \times pa$, and in the direction CL it will be $p \times Ca$; but as the sum of all the quantities $p \times pa = 0$, and the sum of all the quantities $p \times Ca =$ the body multiplied into CG, it follows from the same reasoning as in Art. 3. that the point G will continue to move in a direction perpendicular to LN; and also, as the forces $p \times Ca$ act in a direction perpendicular to that in which the center of gravity moves, its motion must be continued uniform. In the following proposition, therefore, we suppose the axis of the body, after the commencement of the motion, to continue perpendicular to the plane passing through the direction of the force and the center of gravity of the body, and that the body itself is orthographically projected upon that plane; also in the case of the action of two bodies on each other, the plane passing through the direction of the striking body and point of percussion is supposed to pass through the centers of gravity of each body; that the axis of each body after it is struck continues perpendicular to that plane, and that each body is reduced to it in the manner above described.

6. To determine the point about which a body, when struck, begins to revolve. Let LMNO (fig. 80.) represent the body, G the center of gravity, and PA the direction of the force acting at A, which produce till it meets LN, passing through G, perpendicularly in the point D; draw pb perpendicular to pc , on which (produced if necessary) let fall the perpendicular Dw ; C being supposed the point about which the body begins to revolve, and which, from the last proposition, is somewhere in the line LN. Because the body, in consequence of the force acting at D, begins to revolve about C, and consequently if immediately

after the beginning of the motion a force were applied at D equal to it, and in a contrary direction, the motion of the body would be destroyed, it is evident, that the efficacy of the body revolving about C, to turn the body about D, should any obstacle be opposed to its motion at that point, must be equal to nothing; for were it not, the body, when stopped at D, would still have a rotatory motion about that point, and consequently two equal and opposite forces applied at D would not destroy each other's effects, which would be absurd. Now the force of a particle p , in the direction pc , being $p \times pc$, its efficacy to turn the body about the point D is $p \times pC \times Dw$; but by sim. trian.

$$Dw : Db :: aC : pC, \therefore Dw = \frac{Db \times aC}{pC}, \text{ and consequent-}$$

ly the efficacy to turn the body about D = $p \times Db \times aC = p \times Ca \times DC - Cb = p \times Ca \times DC - p \times pC^2$; hence the sum of all the $p \times Ca \times DC - p \times pC^2$; the sum of all the $p \times PC^2 = 0$, and consequently $CD =$ sum of all the $p \times PC^2$, therefore D is the center of percussion of all the $p \times Ca$

the point of suspension being at C.

For further particulars relating to this subject, see Vince's paper above referred to. See also Parkinson's System of Mechanics. &c. p. 187, et seq.

For an account of the position of the center of rotation, and the changes to which the angle of rotation is subject in the theory of working ships; see the Elements and Practice of Rigging and Seamanship, Vol. ii. p. 249, &c.

CENTER of a sphere is a point from which all the lines drawn to the surface are equal.

The centre of the semicircle, by whose revolution the sphere is generated, is also that of the sphere. See SPHERE.

Hermes Trismegistus defines God an intellectual sphere, whose center is every-where, and circumference no-where.

CENTER division, column, or squadron of a fleet, that which is under the immediate orders of the commander in chief, or admiral of the fleet; and its position is between the van and the rear divisions, which are under the command of their respective admirals. The ships of each division are distinguished by the position of their colours; those of the front or center squadron carry their pendant at the main-top-gallant-mast head; the ships of the second division carry their pendants at the fore-top-gallant-mast head; and those of the third division at the mizen-top-mast head. Each squadron ought, as nearly as possible, to consist of the same number of ships, and to be of the same force, in order that each may be equally able to attack, or repulse the enemy, and when in a line, the several parts will be equally strong. When the fleet is very numerous, each squadron is sometimes divided in a similar manner into three divisions of center, van, and rear. The term is also applied to that column in the order of sailing, which is between the weather and the lee columns.

CENTER-wheel of a watch. See WATCH-work.

CENTERING, in Carpentry. See CENTER in Architecture.

CENTERING of an optic glass, the grinding it so as that the thickest part is exactly in the middle.

M. Cassini the younger has a discourse expresses on the necessity of well centering the object glass of a large telescope, that is, of grinding them so, that the center may fall exactly in the axis of the telescope. Mem. Acad. Sc. an. 1710, p. 259, seq.

One of the greatest difficulties in grinding large optic glasses is, that in figures so little convex, the least difference will put the center two or three inches out of the middle. Dr. Hook notes, that though it were better the thickest

part of a long object glass were exactly in the middle, yet it may be a very good one when it is an inch or two out of it. Phil. Trans. N^o 4. p. 57. Id. ibid. p. 64. seq. See OBJECT GLASS.

CENTESIMA usura, in *Roman Antiquities*, that wherein the interest in an hundred months became equal to the principal; i. e. where the money is laid out at one per cent. per month, answering to what in our time would be called 12 per cent. for the Romans reckoned their interest not by the year, but by the month.

CENTESIMUM, in *Ancient Geography*, a place of Italy, in Umbria, S.W. of Nuceria. Its name indicates its distance from Rome.

CENTESIMATION, in *Ancient Military History*, a punishment resorted to in cases of mutiny, desertion or the like, by which every one hundredth man only was executed or punished with death.

CENTESM, the 100th part of any thing.

CENTGRAVIUS, in *Middle Age Writers*, the same with CENTENARIUS,

CENTIARE, in *French Superficial Measure*, 100 square metres, or 948.31 square feet. See MEASURE.

CENTIBAR, in *French Measures of Capacity*, the hundredth part of a bar, called also decal, containing 10 cubic decimetres of water, and weighing 20.444 French pounds. See MEASURE.

CENTICADE, or a bushel, 10 cubic decimetres, or 10 $\frac{1}{2}$ Paris pints, or .789 Paris bushel. See MEASURE.

CENTIGRAVE, or dram, the hundredth part of a Grain, weighing 2 gros, 44.41 grains. A piece of silver coin weighing a centigrave, is denominated a *Franc* of silver, and, according to the former standard, will be worth 40 sols 10 $\frac{1}{2}$ deniers.

CENTIGRAVET, contains .00001 cubic decimetre, and weighs 0.18841 grain.

CENTILOQUIUM, from *centum*, a hundred, and *loquor*, I speak, denotes a collection of an hundred sentences, opinions, or sayings.

CENTIME, in *French Money*, the hundredth part of a livre. See MONEY.

CENTIMETRE, in *French long Measure*, is the hundredth part of a metre or 4.474 lines. A cubic centimetre of water is named a *Gravel* or *Muille*, and weighs 18.841 grains.

CENTINEL or *Centry*, in *French Sentinelle*, is a soldier from a guard, placed at any post for the security of the said guard, or any other body of troops, for watching the enemy, preventing surprisals, and stopping those who might wish to pass without orders, and without making themselves known. All centinels ought to be very vigilant on their posts, should avoid singing, smoking, making any noise themselves, or suffering any to be made near them by others. They should keep their arms in their hands during the whole time they are on duty, should not sit down, or on any account go to sleep, as on their attention and watchfulness depend the lives of many; but should keep moving about, if the weather will permit them. They ought never to move farther from their posts in any directions, than to distances from which they can have distinct views of them, as well as of the intervening and interjacent spaces. And should the weather be ever so bad, they ought not to go under any other cover than that of their centry boxes. Not one of them should be allowed to quit his post without leave from his commanding officer. And in order to prevent desertion, marauding, or other irregularities; they should be strictly charged to let no soldier pass them.

CENTINEL perdu, in *French Sentinelle perdue*, is a soldier placed at a very hazardous post, or in a situation where he

is in constant danger of being attacked, taken, or killed by the enemy without any prospect of aid, help (help) or relief. Hence the phrase *forlorn help*, commonly pronounced *forlorn hope*.

CENTINEL, *Great and Little*, in *Geography*, two islands in the Indian Sea: the former six leagues from the Great Andaman; and the latter seven leagues N. W. from the Little Andaman.

CENTINODIUM, an official plant, popularly called *best-crafs*; by the botanists *polygonum*; reputed an alstringent and vulnerary.

CENTIPES, **CENTIPEDES**, in *Entomology*. See SCOLOPENDRA.

CENTIUM PUTEI, in *Ancient Geography*, a place of Asia in Syria, situated on a large plain, and surrounded by mountains.

CENTLANCES, in *Military Language*, a name given to a Scottish company of gendarmie, established in 1422 by Charles VII. of France.

CENTLIVRE, **SUSANNA**, in *Biography*, a dramatic writer, was the daughter of Mr. Freeman, a gentleman of Lincolnshire, who, being attached to the parliamentary cause, took refuge in Ireland at the restoration. She is supposed to have been born in Ireland about the year 1667. Discovering an early propensity to poetry and a romantic disposition, and being ill-treated by those who had the care of her after the death of her mother, she resolved on a visit to London; and in the course of her journey, which she performed on foot, she was met by Anthony Hammond esq. then a student at the University of Cambridge. This gentleman caused her to assume a boy's garb, and took her with him to college, where she spent some months in his company; but fearing a discovery, he persuaded her to go to London, where, being in her 16th year, she married a nephew of sir Stephen F. x. Having in about a year lost her husband, she soon after married Mr. Carrol, an officer in the army, whom she lost in a duel about a year and a half after their union. She then commenced her course as a dramatic writer, and made her first attempt in tragedy. Accordingly in 1700 her "Perjured Husband" was performed at Drury-lane. She afterwards wrote several comedies, which were chiefly translations from the French, and which obtained temporary success. One of them, entitled "The Gamester," was honoured with a prologue by Rowe. She also made some trial, without rising to any great reputation, as an actress. Under this character, however, she performed before the court on the stage at Windsor, and captivated the heart of Mr. Joseph Centlivre, yoman of the mouth to queen Anne, whom she married in 1706. Of the number of her comedies, which she produced with great fertility, we may reckon "The Busy Body," performed in 1708; "The Wonder, a Woman keeps a Secret," in 1714; and "A bold Stroke for a Wife," in 1717. The licentiousness which at that time characterized the English stage is too apparent in her productions. She lived, however, on terms of friendship and familiarity with most of the wits of that period, as Steele, Rowe, Farquhar, and Budge; but upon incurring the displeasure of Pope, she was introduced into the Duciad. Her person was handsome, her conversation sprightly, and her disposition friendly and benevolent. She died in 1723. Her dramatic works were printed in 1761, in 3 vols. 12mo. Her verses and letters were collected and published by Mr. Boyer. Biog. Brit.

CENTNER, or *Decimassie HUNDRED*, in *Metallurgy and Assaying*, is a weight divisible, first into an hundred, and thence into a greater number of other smaller parts; but though the word is the same, both with the assayers and metallurgists,

metallurgists, yet it is to be understood as expressing a very different quantity in their different conception of it. The weights of the metallurgists are easily understood, as being of the common proportion, but those of the assayers are a thousand times smaller than these, as the portions of metals or ores examined by the assayers are usually very small.

The metallurgists, who extract metals out of their ores, use a weight divided into an hundred equal parts, each part a pound; the whole they call a *centner* or *hundred weight*; the pound is divided into thirty-two parts, or half ounces; and the half ounce into two quarters of ounces, and these each into two drams.

These divisions and denominations of the metallurgists are easily understood; but the same words, though they are equally used by assayers, with them express very different quantities; for as the centner of the metallurgists contains a hundred pounds, the centner of the assayers is really no more than one dram, to which the other parts are proportioned.

As the assayers' weights are divided into such an extreme degree of minuteness, and are so very different from all the common weight, the assayers usually make them themselves, in the following manner. out of small silver, or fine folder plates, of such a size, that the mark or their weight, according to the division of the dram, which is the decimatic, or assaying centner, may be put upon them. They first take for a basis one weight, being about two thirds of a common dram: this they mark (6*z*lb.) Then having at hand some granulated lead, washed clean, well dried, and sifted very fine, they put as much of it in one of the small dishes of a fine balance, as will equipoise the 6*z*lb. (as it is called) just mentioned: then dividing this granulated lead into very nice halves, in the two scales, after taking out the first silver weight, they obtain a perfect equilibrium between the two scales: they then pour the granulated lead out of one dish of the scales, and instead of it put in another silver weight, which they make exactly equiponderant with the lead in the other scale, and mark it (3*z*lb.) If this second weight, when first put into the scale, exceed by much the weight of the lead, they take a little from it by a very fine file; but when it comes very near, they use only a whetstone to wear off an extremely small portion at a time. When it is brought to be perfectly even and equal to the lead, they change the scales to see that no error has been committed, and then go on in the same manner till they have made all the divisions, and all the small weights. Then to have an entire centner, or hundred weight, they add to the 6*z*lb. (as they call it) a 3*z*lb. and a 4*z*lb. and weighing against them one small weight, they make it equal to them, and mark it (10*z*lb.) This is the decimatic, or assaying centner, and is really one dram. Cramer, Art. Afl. p. 108.

CENTO, in *Poetry*, a work wholly composed of verses, or passages, promiscuously taken from other authors; only disposed in a new form, or order: so as to compose a new work, and make a new meaning.

The word is Latin, *cento*, which primarily signifies a cloak made of patches, and that from *cento*.

Aufonius has laid down the rules to be observed in composing centos. The pieces, he says, may be taken either from the same poet, or from several; and the verses may be either entire, or divided into two; one half to be connected with another half taken elsewhere; but two verses are never to be taken running, nor is much less than half a verse to be taken. Agreeably to these rules, he has made a pleasant nuptial cento from Virgil.

Proba Falconia has written the life of Jesus Christ in centos taken from Virgil: the like is done by Alex. Ross, in his

Christiados; and by Stephen de Pleurre, canon regular of St. Victor at Paris.

CENTOBROCA, in *Ancient Geography*, a town of Spain, in Celtiberia.

CENTON, a fortress of Thrace, in Lower Mysia, the walls of which were repaired by Justinian. Procopius.

CENTONARE. In Italy, a plagiarist in musical composition, where melody and harmony are mere patch-work, is said to *centonare*. Sometimes an opera consisting of airs selected by the Maestro, or by the singers themselves from the works of various composers, is called a *cento*. See PASTICCIO.

CENTONARI, in *Antiquity*, a sort of officers or operators, whose business was to make centones, or coats patched of leather and cloth, wherewith to cover the *vineæ*, under which the besiegers made their approaches, as well as the towers and machines used to batter the place, and prevent their being set on fire by the enemy. In the Theodosian code we have a title *De centonariis & dendrophoribus*. And in ancient inscriptions, the centonarii are joined with the *signarii*, or carpenters, *ferrarii*, or smiths, &c. who made but one company, under the denomination of *collegium fabriarum & centonariorum*.

CENTONIER, *French*. See CENTONARE, *Ital*.

CENTO-POZZI, in *Geography*, a town of Naples, in the province of Bari; three miles N. of Matera.

CENTORBI, the ancient *Centuripa*, a city of Sicily, mentioned by Cicero in his oration against Verres. It is seated on five points of rocks, and resembles a star-fish; being very difficult of access, and incommodious for habitation. Yet, in the time of the Romans, it was very populous; but it retains no vestige of its ancient splendour, except a few ruins. Its long suburbs, terminated in a point, are miserable and depopulated; and it is destitute of money and commerce. The convent of the reformed Augustines is a large building, but in as depopulated a state as the town. To the westward of the town there are considerable ruins of baths, built with beautiful masonry, lined with marble in the Roman style, like that of the baths of Baize. To the east of the town is the ruin of a castle, called the castle of Conradin. Frederic, the grandfather of this Conradin, destroyed Centorbi about the beginning of the 13th century, and razed its foundations. It was, however, again rebuilt, with the castle; for in 1268, after the defeat of Conradin, Conrad Capetian, aspiring to become king of Sicily, and finding himself abandoned by the Sicilians, who declared for Charles of Anjou, shut himself up in this fortress. Montfort, having forced him to surrender, put out his eyes, and afterwards hanged him; and then destroyed the city. A greater number of gold and silver coins, precious stones of every kind, vases, statues, cinerary urns, &c. have been found at Centorbi than in any other place in Sicily. A considerable part of the riches of the museum of the prince of Biscaris has been furnished by this town. The number of inhabitants in this ancient and once large city is now reduced to 3000, who are very poor and wretched. The neighbouring country, planted chiefly with vineyards, produces an indifferent wine; and there are soft rocks of an imperfect free-stone, mixed with a marine tufa, even to the summit of the mountain. The soil in one part of the town is formed of marine concretions, mixed with shells; and under the vegetable earth lies tufa, with the fore-mentioned concretions, and gritty stone; and at a greater depth, scorize and lava, beneath which is a fresh bed of grit. The lava probably forms the basis of the mountain, and indicates, by being covered with marine concretions to the depth of 600 feet below the present level of the sea, the antiquity of the

the volcano that produced it. De Non's Journey in Sicily and Malta, p. 85.

CENTORES, in *Ancient Geography*, a people of Scythia, mentioned by Valerius Placcus.

CENTORIO, ASCANIO, in *Biography*, an Italian writer of the 16th century, originally of Rome, and after his expulsion from this city, a resident at Milan. His profession was military; but in the interval of peace he composed "Military and Historical Memoirs," collected from his own knowledge and from the information of others. They were published at Venice in 1565 and 1569, in 2 vols. 4to. The first part contains an account of the wars of Transylvania; the second, of those of his own time. They are held in high estimation. *NOV. DICTION.*

CENTRAL, something relating to a centre, or CENTRE. Thus, we say, central eclipse, central forces, central rule, &c.

CENTRAL eclipse, is that in which the centers of the luminaries exactly coincide, and are directly in a line with the eye of the observer. See ECLIPSE.

CENTRAL forces, are the forces which tend to or from some point or center; or they are forces which cause a moving body to tend towards the center of motion, or to recede from it. Accordingly they are divided into two kinds, with regard to their different relations to the center, viz. the centripetal and the centrifugal.

The doctrine of central forces, a very considerable branch of the Newtonian philosophy, has been much cultivated by mathematicians, on account of its extensive use in the theory of gravity, and other physico-mathematical sciences.

In this doctrine it is supposed, that a body at rest never moves itself; and that a body in motion never of itself changes the velocity or the direction of its motion; but that every motion would continue uniform, and its direction rectilinear, unless some external force or resistance affected it. Hence, when a body at rest always tends to move, or when the velocity of any rectilinear motion is accelerated or retarded continually, or when the direction of a motion is continually varied, and a curve line is described; these changes are supposed to proceed from the influence of some power that acts incessantly; which power may be measured either by the pressure of the quiescent body against the obstacle that hinders it to move, in the first case; or by the degree of acceleration or retardation of the motion, in the second; or by the flexure of the curve described, in the third case; due regard being had to the time in which these effects are produced, and other circumstances, according to the principles of mechanics. Effects of the power or force of gravity of each kind fall under our constant observation near the surface of the earth; for the same power which renders bodies heavy while they are at rest, accelerates them when they descend perpendicularly, or retards them when they ascend, and bends the course of their motion into a curve line when they are projected in any other direction than that of their gravity. But we can judge of the forces or powers that act on the celestial bodies by effects of the last kind only. And hence it is that the doctrine of central forces is of so much use in the theory of the planetary motions.

Sir Isaac Newton has treated of central forces in book i. § 2. of his Principia; and has demonstrated this fundamental theorem respecting them, viz. that the areas which revolving bodies describe by radii drawn to an immovable center, lie in the same immovable planes, and are proportional to the times in which they are described. Princip. lib. i. prop. 1. A late eminent mathematician observes, that this law, which is originally Kepler's, is the only general principle in the doctrine of centripetal forces; but since this law, as Sir Isaac Newton himself has proved, cannot hold whenever a body

has a tendency by its gravity or force to any other than one and the same point, there seems to be wanting some law that may serve to explain the motions of the moon and satellites which have a gravity towards two different centers. The law he lays down for this purpose is as follows; namely, that where a body is urged by two forces tending constantly to two fixed points, it will describe, by lines drawn from the two fixed points, equal solids in equal times, about the line joining those fixed points. See MACHIN, on the laws of the moon's motion, in the preface. This short treatise is published at the end of the English translation of Sir Isaac Newton's Principia. See a demonstration of this law by Mr. W. Jones in the Phil. Transf. vol. lix. art. 12. p. 74. &c. The same subject has been elaborately discussed, when the motion respects, not two centers only, but several centers, by many ingenious authors; and practical rules have been laid down for computing the places, &c. of planets and satellites; as by La Grange, La Place, Waring, &c. &c. See Berlin Memoirs: those of the Academy of Sciences at Paris; the Philosophical Transactions of the Royal Society of London; and various treatises of astronomy.

M. de Moivre has given elegant general theorems relating to central forces in the Phil. Transf. and in his Méth. Analyst. p. 231.

Let MPQ (Plate X. *Mechanics*, fig. 81.) be any given curve in the perimeter of which a body moves; let P be the place of the body in the curve at any time; S the center of force, or the point to which the central force acting on the body is always directed; PG the radius of concavity or curvature at the point P; and ST the perpendicular drawn from the center of force to the tangent PT of the curve in P, then will the centripetal force be every where proportional to the quantity $\frac{SP}{PG \times ST}$.

Monsieur Varignon has also given two general theorems on this subject in the Memoirs of the Acad. Scienc. an. 1700, 1701, and has shewn their application to the motions of the planets. See also the same Memoirs, ann. 1706, 1710. Mr. Mac-Laurin has also treated the subject of central forces very fully in his Fluxions, from art. 416 to 493, where he gives a great variety of expressions for these forces, and several elegant methods of investigating them.

CENTRAL forces, *laws of*. 1. The following rule, for which we are obliged to the marquis de l'Hôpital, is very clear and comprehensive. Suppose a body of any determinate weight to move uniformly round a center, with any given velocity; find from what height it must have fallen to acquire that velocity; then, as the radius of the circle it describes is to double that height, so is its weight to its centrifugal force.

Let b represent the body, or its weight or quantity of matter, v its velocity, and r the radius of the circle described, and g be = $16\frac{1}{2}$ feet, the space fallen through in the first second of time, and $2g$ will express the velocity acquired; then, since the squares of the velocities are as the spaces (see ACCELERATION) $4g^2 : v^2 :: g : \frac{v^2}{4g}$, or the height pertaining to the velocity v ; and $r : \frac{v^2}{2g} :: b : \frac{v^2 b}{2gr} = f$ the centrifugal force. Hence, if the centrifugal force be equal to the gravity, the velocity acquired is equal to that acquired by falling through half the radius.

2. The central force of a body moving in the periphery of a circle, is as the versed sine of the indefinitely small arc, A E, or as the square of the said arc divided by the diameter, A B: or, as the square of the arc, A E, directly, and the diameter

meter, A B inversely, (*Plate X. Mechanics, fig. 82.*) Let this arc be the distance which the body describes in a given particle of time; then, from the nature of the circle (A E being very small, and consequently nearly equal to its chord)

$$A E^2 = A B \times A M, \text{ and therefore } A M = \frac{A E^2}{A B}. \text{ Now}$$

A M is the space through which the body is drawn from the tangent in the given time; and though 2 A M is the proper measure of the central force, yet when the forces compared are all computed in the same manner, from the nascent, or indefinitely small subtenses of contemporaneous arcs, it is of no consequence whether we consider those subtenses, or their doubles, as the measures of the forces, since the ratio is in both cases the same. Since then a body, by an equable motion, in equal times describes equal arcs A E; the central force by which the body is impelled in the periphery of the circle is constantly the same.

3. If two bodies describe different peripheries by an equable motion, their central forces are in a ratio, compounded of the duplicate ratio of their velocities directly, and the reciprocal ratio of their diameters: that is, the ratio of the velocities is in this case the same with that of the arcs or spaces described in the same time; and the velocities are evidently in the subduplicate of the products of the diameters multiplied

$$\text{by the forces. Thus, } F : f :: \frac{V^2}{D} :: \frac{v^2}{d} :: \frac{V^2}{R} :: \frac{v^2}{r}; \text{ for,}$$

by the last article, the force is as $\frac{A E^2}{A B}$ or $\frac{A E^2}{D}$, and the

velocity v is as the space A E uniformly described. Hence, if the velocities be equal, the central forces will be reciprocally as their diameters; and if the diameters A B and H L be equal, i. e. if each moveable proceed in the same periphery, but with unequal velocities, the central forces will be in a duplicate ratio of the velocities. Hence, if the radii or diameters be reciprocally in the duplicate ratio of the velocities, the central forces will be reciprocally in the duplicate ratio of the radii, or directly as the 4th powers of the velocities: that is, if $V^2 : v^2 :: r : R$, then $F : f :: r^2 : R^2 :: V^4 : v^4$; for $V^2 R = v^2 r$, and $F : f \left(:: \frac{V^2}{R} :: \frac{v^2}{r} :: \frac{V^2 \times V^2 R}{R} : \frac{v^2 \times v^2 r}{r} \right) :: V^4 : v^4$.

If the central forces of the two bodies moving in different peripheries be equal, the diameters of the circles A B and H L will be in a duplicate ratio of the celerities. For in

$$\text{this case, } \frac{V^2}{R} = \frac{v^2}{r} \text{ and } V^2 r = v^2 R; \text{ therefore } R : r :: V^2 : v^2.$$

4. The central forces are in a ratio compounded of the direct ratio of the diameters, and the reciprocal one of the squares of the periodic times. For the diameters are as the peripheries, which are the spaces run in the periodic times; and these are in the compound ratio of their times and velocities directly: therefore, representing the times by T, t; the velocities by V, v, and the diameters by D, d; D : d ::

$$V \times T : v \times t; \text{ consequently, } \frac{V^2 \times T^2}{D^2} = \frac{v^2 \times t^2}{d^2}, \text{ and}$$

$$\frac{F}{d} : \frac{T^2}{D} :: \frac{V^2}{D} : \frac{v^2}{d}; \text{ and therefore by Art. 3, the central}$$

forces are in the proportion required; i. e. $F : f \left(:: \frac{V^2}{D} : \frac{v^2}{d} \right)$

$:: \frac{r^2}{d} : \frac{T^2}{D} :: r^2 \times D : T^2 \times d$. And when the circles are equal, the central forces are reciprocally as the squares of the times, D being = d.

5. If two bodies, equal in weight, describe peripheries of unequal circles in equal times, their central forces are as their diameters A B and H L. For $F : f :: r^2 \times D : T^2 \times d$; but $T^2 = r^2$; $\therefore F : f :: D : d$; or $R : r$. And hence, if the central forces of two bodies, describing peripheries of two unequal circles, be as their diameters, they pass over the same in equal times. For $V d = f D$, and $V T^2 \times d = f \times r^2 \times D$; \therefore by equal division, $T^2 = r^2$ and $T = t$.

6. If two bodies, moving in unequal peripheries, be acted on by the same central force, the time in the larger is to that in the smaller, in a sub-duplicate ratio of the greater diameter A B, to the less H L; for F being = f, $T^2 \times d = r^2 \times D$, and $T^2 : r^2 :: D : d$, and $T : t :: D^{\frac{1}{2}} : d^{\frac{1}{2}}$; wherefore, $T^2 : r^2 :: D : d$, that is, the diameters of the circles in whose peripheries those bodies are acted on by the same central force, are in a duplicate ratio of the times. Hence also the times wherein similar peripheries or arcs are run over by bodies impelled by the same central force, are in proportion to their velocities.

7. If the times wherein the bodies are carried through the same entire peripheries, or similar arcs, be as the diameters of the circles, the central forces are reciprocally as the same diameters. For $T : t :: D : d$, and $T^2 : r^2 :: D^2 : d^2$; $\therefore F : f \left(:: \frac{d}{r} : \frac{T^2}{D} \right) :: \frac{d^2}{d} : \frac{D^2}{D} :: d : D$.

8. If a body move uniformly in the periphery of a circle, with the velocity it acquires by falling the height A F; the central force will be to the gravity, as double the altitude A F to the radius C A. If, therefore, the gravity of the body be called G, the centrifugal force will be 2 A F \times G \div C A. See Art. 1.

9. If a heavy body move equally in the periphery of a circle, and with the velocity which it acquires by falling through a height equal to half the radius; the central force will be equal to the gravity. And again, if the central force be equal to the gravity, it moves in the periphery of a circle, with the same gravity which it acquires in falling a height equal to half the radius.

10. If the central force be equal to the gravity, the time it takes up in the entire periphery, is to the time of its fall through half the radius, as the periphery to the radius.

11. If two bodies move in unequal peripheries, and with an unequal velocity, which is reciprocally in a subduplicate ratio of the diameters; the central forces are in a duplicate ratio of the distances from the center of the forces, taken reciprocally. For $F : f :: d^{\frac{1}{2}} : D^{\frac{1}{2}}$, and $F : f :: \frac{V^2}{D} : \frac{v^2}{d}$; $\therefore F : f \left(:: \frac{d}{D} : \frac{D}{d} \right) :: d^2 : D^2$ or $r^2 : R^2$.

12. If two bodies move in unequal peripheries, with velocities which are reciprocally as the diameters or distances from the center; their central forces will be reciprocally as the cubes of their distances from the center, or directly as the cubes of the velocities. Thus, if $V : v :: r : R$, $F : f \left(:: \frac{V^2}{R} : \frac{v^2}{r} :: \frac{r^2}{R^3} : \frac{R^2}{r^3} \right) :: r^3 : R^3$, or $V^3 : v^3$.

13. If the velocities of two bodies, moving in unequal peripheries, be reciprocally in a subduplicate ratio of the diameters, or central distances; the squares of the times wherein they pass the whole peripheries, or similar arcs, are in a triplicate ratio of the distances from the center of the forces; wherefore, if the central forces be reciprocally in a duplicate ratio of the distances from the center, the squares of the times wherein the entire peripheries, or similar arcs, are passed over, are also in a triplicate ratio of the distances. If $V : v :: d^{\frac{1}{2}} : D^{\frac{1}{2}}$; or $V^2 : v^2 :: d : D$; then $T^2 : t^2 :: D^3$

nearer to the poles, perform circles smaller than those which lie nearer to the equator; though they are all performed in the same interval of 24 hours. Hence, the periodical times being equal, or the same, the central forces are as the radii of the circles, and as in different latitudes the radii are equal to the sines of the latitudes, we may use the following proportion; viz. as the radius is to the cosine of a given latitude, so is the centrifugal force of bodies situated at the equator to the centrifugal force of bodies at that given latitude. Now as the sines decrease in length the nearer they approach the poles, so the tendency of bodies to fly off from the surface of the earth is greatest at the equator, but diminishes in approaching towards the poles; and hence we perceive why the earth has been found, by means of unquestionable measurements and other observations, to be an oblate spheroid, whose polar diameter is the shortest. This circumstance furnishes a convincing evidence of the earth's daily rotation about its axis.

For another example of the application of the theory of central forces above stated, we may suppose A to be a ball of one ounce, whirled about the center C, so as to describe the circle ABE (fig. 82.), each revolution being made in half a second; and the length of the cord AC = 2 feet. Here $t = \frac{1}{2}$, $r = 2$; and as it has been already found that

$$c \sqrt{\frac{2R}{g}} = T \text{ is the periodical time at the circumference}$$

of the earth, when the centrifugal force is equal to gravity; hence then, (by Art. 4.) $\frac{R}{T^2} : \frac{r}{t^2} :: F \text{ or } t : f$; and this

$$\text{proportion becomes } \frac{g}{2^2} : \frac{r}{t^2} :: 1 : \frac{2^2 r}{g t^2} = \frac{16g^2}{g} =$$

$$\frac{16 \times \sqrt[3]{14103}}{16 \frac{g}{T^2}} = 9.819 = \text{the centrifugal force, or that}$$

by which the string is stretched, viz. nearly 10 ounces, or 10 times the weight of the ball. This central force may be called centripetal or centrifugal, according as it is applied to the tenacity of the parts of the string, or to the force of the body; so that the body is said to be retained by a centripetal force 9.8 times as great as the force of terrestrial gravity; or it may be said, that the centrifugal force of the revolving body stretches the string as much as if a weight of 9.8 pounds were simply suspended to it.

Again, suppose the string and ball to be suspended from a point, D, (fig. 83.) and to describe in its motion a conical surface, ADB; thus, putting DC = a, AC = r, and AD = b; and F = 1, the force of gravity as before; the body will now be acted by three forces, viz. gravity acting parallel to DC, a centrifugal force in the direction CA, and the tension of the string, or force by which it is stretched, in the direction DA: hence these three powers will be as the three sides of the triangle ADC respectively;

and, therefore, as CD or a : AD or b :: 1 : $\frac{b}{a}$ the tension of the string as compared with the weight of the body.

Also, CD or a : AC or r :: 1 : $\frac{2^2 r}{g t^2}$, the general expression for the centrifugal force above found: hence $g t^2 = 2ac^2$, and consequently $t = c \sqrt{\frac{2a}{g}} = 1.108 \sqrt{a} =$

the periodical time.

16. When the force by which a body solicited towards a point is not every where the same, but is either increased or diminished, in proportion to some power of the distance from the center; several curves will thence arise in a certain

proportion according to that power. If the force decreases in an inverse ratio of the squares of the distances from that point, the body will describe an ellipse, which is an oval curve, in which there are two points called foci, and the point towards which the force is directed, falls upon one of them; so that in every revolution the body once approaches to, and once recedes from it: and the eccentricity of the ellipse is greater or less, according to the projectile force: and when the eccentricity is nothing, the curve becomes a circle, which may also be described, in certain circumstances, by a moving body. The body may also (by supposing a greater degree of velocity in certain proportions, describe the two remaining conic sections, viz. the parabolic and hyperbolic curves, which do not return into themselves: on the contrary, if the force increases with the distance, and that in a ratio of the distance itself, the body will again describe an ellipse; but the point to which the force is directed is the centre of the ellipse; and the body, in each revolution, will twice approach to, and again twice recede from, that point. In this case also a body may move in a circle, for the reason above mentioned.

In order to explain these particulars more at large, let ACD (fig. 84.) represent a circular orbit, A z S an elliptical, A r E a parabolic, and A K F a hyperbolic orbit; and let the bodies be supposed to move with certain velocities under the influence of a force at N, which is the center of the circle, and the focus of the conic sections. Let AB, perpendicular to AD, represent the velocity which is necessary to retain the body in the circular orbit, and let it be denoted by 1; as the standard with which the other degrees of velocity may be compared. Also, let a body be projected from A in the direction AI with any other degree of velocity n. It is now proposed to determine the nature of the curve, which will be described with this other velocity n, or rather to ascertain what the value of n must be in order to produce each particular conic section. Draw mK parallel to AI, intersecting the circle as well as the other curves. Let AN be denoted by d; the semi-transverse axis of any of the conic sections by a; the semi-conjugate by b; and Am (= BC = Gz = Hr = IK) by x. Then the ordinate mC in the circle will be = $\frac{2dx - xx^2}{a}$; but the ordinate m z of the ellipse, and mK of the hyperbola, may both be represented by $\frac{b}{a} \times \sqrt{2ax \mp xx^2}$. The fluxions of these ordinates are

$$\frac{d\dot{x} - x\dot{x}}{2dx - xx^2} \frac{1}{a} \text{ and } \frac{b}{a} \times \frac{a\dot{x} \mp x\dot{x}}{2ax \mp xx^2} \frac{1}{a}$$

respectively; which fluxions are to each other as the velocities in every point of their respective curves in the direction AI; and in the like proportion are the quantities $\frac{d - x}{2d - x}$, and $\frac{b}{a} \times \frac{a \mp x}{2a \mp x}$; these quantities being the abovementioned fluxions divided by the same quantity, $\frac{\dot{x}}{x^2}$. Now, when the point in the

curve approaches the point A so near as to coincide with it, then Am vanishes, or x = 0; and the above expressions become $\frac{d}{2a}$, and $\frac{b}{a} \times \frac{a}{2a}$; so that at the point A the velocity which retains the body in the circular orbit is to the velocity which retains the body in the ellipse or the hyperbola, as $\frac{d}{2a} : \frac{b}{a} \times \frac{a}{2a} :: d^{\frac{1}{2}} : \frac{b}{2a} \frac{1}{2} :: 1 : n$; therefore

$$n d^{\frac{1}{2}} = \frac{b}{2a} \frac{1}{2}; \text{ and } n n d = \frac{bb}{a}, \text{ or } a n n d = bb. \text{ When}$$

$x = d = AN$, then d the parameter, and (the parameter being a third proportional to the transverse and conjugate diameters) $2a : 2b :: 2b : 2y$, or $a : b :: b$

$$y = \frac{bb}{a} = \frac{b}{a} \times \frac{2ax \mp xx}{2} = \frac{b}{a} \times \frac{2ad \mp dd}{2} =$$

$$\frac{2ab'd \mp b'd^2}{2a}$$
; which equation being squared, becomes

$$\frac{2ab'd - b^2d^2}{a^2} = \frac{b^4}{a^2}$$
 for the ellipse, and $\frac{2ab'd + b^2d^2}{a^2} =$

$$\frac{b^4}{a^2}$$
 for the hyperbola. And being divided by $\frac{b^2}{a^2}$, these ex-

pressions become $2ad - d^2 = b^2 = ann$ for the ellipse, and $2ad + d^2 = b^2 = ann$ for the hyperbola. Consequently,

In the ellipse	$\left\{ \begin{array}{l} \text{the semi-transverse axis is } a = \frac{d}{2 - n^2} \\ \text{the semi-conjugate axis is } b = \frac{nd}{2 - nn} \end{array} \right.$

Having determined these values of the transverse and conjugate diameters, in which n is the only indeterminate value, we may, by introducing certain substitutes instead of n , ascertain what its values must be in order to produce one curve or another. Thus, by making $n = 1$, each of the above values becomes equal to d ; therefore the two diameters become equal to each other, and the curve is of course a circle: and, accordingly, the velocity, which retains the revolving body in a circular orbit, has been denominated 1, or unity.

If we make $n = \sqrt{2}$, then $a = \frac{d}{2 - nn} = \frac{d}{2 - 2} =$

$\frac{d}{0}$, which is an algebraical expression of infinity: and all the other expressions will likewise become infinite: so that the transverse and conjugate diameters in that case becoming infinite, the curve is the parabola.

If we make n equal to a quantity less than the square root of 2 (viz. less than the square root of twice that velocity which is required to retain the body in a circular orbit); then

the values $\frac{d}{2 - n^2}$ and $\frac{nd}{2 - nn}$, viz. of a and b , will be posi-

tive; whereas, by the same substitution, the value $\frac{nd}{nn - 2}$ becomes impossible; which shews, that when n is less than the square root of 2, the curve can only be the ellipse.

But if we make n equal to any thing greater than the square root of 2; then the values of a and b for the hyperbola become positive: whereas those for the ellipse become impossible; and, therefore, in this case, the curve must be the hyperbola. Cavallo's Elem. of Nat. and Exp. Philos. vol. i. Simpson's Fluxions, vol. i. sect. 12. See CENTRIFUGAL FORCE.

CENTRAL Rule, is a rule or method discovered by our countryman Thomas Baker, rector of Nympton in Devon, for finding the center of a circle designed to cut the parabola in as many points as an equation to be constructed hath real roots. See the article BAKER.

Its principal use is in the construction of equations; and he has applied it with good success as far as biquadratics.

The central rule is chiefly founded on this property of the parabola: that if a line be inscribed in that curve perpendicular to any diameter, a rectangle formed of the segments of this line is equal to a rectangle made of the intercepted part of the diameter and the parameter of the axis.

The central rule has the advantage over Cartes's and De L'Hospital's methods of constructing equations, as both these are subject to the trouble of preparing the equation by taking away the second term. This we are freed from in Baker's method, which shews us how to construct all equations not exceeding the fourth power, by the intersection of a circle and parabola, without the omission or change of any terms. See Phil. Trans. N^o 157.

CENTRALIS RETINÆ, in *Anatomy*, an artery, which is sent from the ophthalmic, and is chiefly distributed to the retina. See ARTERIES and EYE.

CENTREVILLE, in *Geography*, the chief town of Queen Anne's county, and on the east side of Chesapeake bay in the state of Maryland, in America. It lies between the forks of Corlica creek, which runs into Chester river; 18 miles S. of Chester; 34 S.E. by E. of Baltimore; and 95 S.W. by S. of Philadelphia, N. lat. 39^o 6'.

CENTRIFUGAL FORCE is that whereby a body revolving round a centre or another body endeavours to recede from it.

It is one of the established laws of nature, that all motion is of itself rectilinear; and that the moving body never recedes from its first right line, till some new impulse be super-added in a different direction: after that new impulse, the motion becomes compounded, but it continues still rectilinear, though the direction of the line be altered. To move in a curve, it must receive a new impulse, and that in a different direction every moment; a curve not being reducible to any number of finite right lines. If then a body continually drawn towards a center be projected in a line that does not go through that center, it will describe a curve; in each point whereof, A (*Plate X. Mechanics, fig. 82.*) it will endeavour to recede from the curve, and proceed in the tangent A D; and, if nothing hindered, it would actually proceed to it; so as in the same time wherein it describes the arc A F, it would recede the length of the line D E, perpendicular to A D, by its centrifugal force. The centrifugal force, therefore, is as the right line D E, perpendicular to A D; supposing the arch A E indefinitely small.

The effect of the centrifugal force is such, that a body obliged to describe a circle, always describes the largest it possibly can; a greater circle being, as it were, less circular, and less distant from a right line, than a small one. A body therefore suffers more violence, and exerts its centrifugal force more, when it describes a little circle than a large one: that is, the centrifugal force is always proportional, other circumstances being alike, to the circumference of the curve in which the revolving body is carried round.

It is the same in other curves as in circles; for a curve, whatever it be, may be esteemed as composed of an infinity of arcs of indefinitely small circles, all described on different radii; so that it is at those places where the curve has the greatest curvity, that the little arcs are most circular, other circumstances being equal: thus in the same curve, the centrifugal force of the body that describes it varies according to the several points wherein it is found.

The doctrine of centrifugal forces was first suggested by Huygens, at the close of his "Horologium Oscillatorium" published in 1673; and demonstrated in the volume of his "Polithumous Works" and also by Guido Grando; where

he has given a few easy cases in bodies revolving in the circumferences of circles. But the doctrine was still fully discussed, especially in its reference to the conic sections, by Sir Isaac Newton. He was succeeded by several other writers upon the same subject; as Leibnitz, Varignon in the *Mém. de l'Acad.* Keil in the *Phil. Trans.* and in his "Phyſics," Bernoulli, Hermann, Cotes in his "Harmonia Mensurarum," Maclaurin in his "Geometria Organica," and in his "Fluxions," and Euler in his book "De Motu," where he considers the curves described by a body acted on by centripetal forces tending to several points. The subject has also been illustrated by various writers on mechanics and astronomy. See CENTRIFUGAL FORCE, and CENTRAL FORCE.

CENTRIFUGAL Machine, a curious machine invented by Mr. Etkine, for raising water by means of a centrifugal force, combined with the pressure of the atmosphere. This machine consists of a large tube of copper, &c. in the form of a cross, placed perpendicularly in the water, and resting at the bottom on a pivot. At the upper part of the tube is an horizontal cog-wheel, which touches the cogs of another in a vertical position; so that by the aid of a double winch, the whole machine is moved round with very great velocity. Near the bottom of the perpendicular part of the tube is a valve opening upwards; and near the two extremities, but on the contrary sides of the arms, or cross part of the tube, are two other valves opening outwards. These two valves are kept shut, by means of springs, till the machine is put in motion; when the centrifugal velocity of the water forces them open, and discharges itself into a cistern or reservoir placed there for that purpose. On the upper part of the arm are two holes, which are closed by pieces that serew into the metal of the tube. Before the machine can work, these holes must be opened, and water poured in through them, till the whole tube be full; by these means all the air will be forced out of the machine, and the water supported in the tube by means of the valve at the bottom. The tube being thus filled with water, and the holes closed by their serew-caps, it is turned round by the winch; when the water in the arms of the tube acquires a centrifugal force, opens the valves near the extremities of the arms, and flies out with a velocity nearly equal to that of the extremities of the said arms.

A perspective view of the centrifugal machine erected on board a ship, is exhibited in Pl. XI. *Mechanics*, fig. 93. ABC is the copper tube; D an horizontal cog-wheel, furnished with 12 cogs; E a vertical cog-wheel, having 36 cogs; FF the double winch; *a* the valve near the bottom of the tube; *b, b*, the two pivots on which the tube turns; *c* one of the valves in the cross piece; the other at *d*, but invisible, as it is on the other side of the tube; *e, e* the two holes through which the water is poured into the machine; G H the cistern or reservoir; I I part of the ship's deck. The distance between the two valves, *e, d*, is 6 feet; the diameter of these valves is about 3 inches; and that of the perpendicular tube is about 7 inches.

If the men who work the machine be supposed to turn the winch round in 3 seconds, the machine will move round its axis in one second; and consequently each extremity of the arms will move with a velocity of 18.8 feet in a second. A column of water, therefore, of three inches diameter will issue through each of the valves with a velocity of 18.8 feet in a second; but the area of the aperture of each of the valves is 7.14 inches; which, being multiplied by the velocity in inches = 125.6, gives 1610.784 cubic inches, the quantity of water discharged through one of the apertures in one second; so that the whole quantity discharged in that space of time through both the apertures is = 3221.568

inches; or 197204.08 cubic inches in one minute. But 60812 cubic inches make a tun beer-measure; consequently, if we suppose the centrifugal machine to revolve round its axis in one second, it will raise nearly 3 tons 44 gallons in one minute; but this velocity is too great, at least to be maintained for any considerable time; so that, when this and other deficiencies in the machine are allowed for, two tuns are nearly the quantity that can be raised by it in one minute. As the water is forced up the perpendicular tube by the pressure of the atmosphere, it is evident that this machine cannot raise water above 32 feet high.

An attempt has been made to substitute this machine in place of the pumps commonly used on ship board; but the labour of working was found to be so great as to render the machine inferior to the chain-pump; which see. The machine might be improved by loading with a weight of lead the ends of the tubes through which the water issues; and thus the machine would be made to turn with much greater ease, as the centrifugal force of the lead would in some measure supply the place of a fly.

CENTRIFUGAL Wheel. See WHEEL.

CENTRINA, in *Ichthyology*, the specific name of a shark. See *SQUALUS Centrina*. The fish described by Ray, Aldrovandus, and various old writers, under the name of CENTRINA and CENTRINE is of this species. This shark has been also called *Porcus Piscis*, from its somewhat triangular figure, and elevated back, which rising into a ridge, bears a remote resemblance to that of a hog.

CENTRINA, a synonymous name of *CHIMAERA Monofrosta*. *Centrina prima*, *Centrina vera*, *Simia marina Danica*. Aldrovandus.

CENTRINES, in *Physiology*, a species of insects hatched in the wild fig-tree, and used in CAPRIFICATION.

CENTRIPETAL FORCE is that by which a moving body is perpetually urged towards a center, and made to revolve in a curve, instead of a right line. Thus, the body impelled in the right line AG, (*Plate X. Mechanics* fig. 82.) is perpetually drawn out of its rectilinear motion, and solicited to proceed in a curve. The centripetal force, therefore, is as the right line DE; supposing the arc, AE, indefinitely small. Hence, when a body revolves in a circle, the two forces, viz. the centrifugal and centripetal, are equal and contrary to each other, since neither of them gains upon the other; the body being, as it were, equally balanced by them. But when, in revolving, the body recedes farther from the center, then the centrifugal force exceeds the centripetal; as is the case in a body revolving from the lower to the higher apsis in an ellipse, and respecting the focus as the center. And when the revolving body approaches nearer to the center, the centrifugal force is less than the centripetal; as while the body moves from the farther to the nearer extremity of the transverse axis of the ellipse. For the proportion of the one to the other, see the sequel of this article.

In the first or nascent state of circular motion, the projectile force infinitely exceeds the centripetal force. For, let the circle AEB, (*fig. 82.*) represent the orbit of the body A, moving uniformly along its circumference; this body, A, is impelled by a projectile force in the direction AG, perpendicular to AC, and is at the same time constantly acted upon by an attractive or impelling force, in a direction towards the center. C: these two forces being so adjusted, or bearing such proportion to each other, as to keep the body in the circular orbit, AEB. In the very small arc AE, the line AD is to the line AM (= DE) as the force of projection is to the centripetal force at the distance AC; for whilst AD represents the uniform or equal

CENTRIPETAL FORCE.

equilibrium: movement which arises from the projectile force in a certain time, DF represents the deviation from that centre, or the force whereby the body is drawn towards the centre of force in the same time. Now, DE (= AM) : AE :: AE : AB; and when the arc AE becomes indefinitely small, or is in its nascent state, then the diameter AB becomes infinitely greater than AE: and of course AE or AD (which in the state here supposed is nearly equal to it) becomes infinitely greater than DE or AM; i. e. the projectile force infinitely greater than the central or centripetal force. If a body move in a curve line, and in such a manner that the radius CB (fig. 85.) drawn from it to the fixed point C, placed in the same plane, describes areas BAC, BCE, &c. proportional to the times, or equal in any given time, it is solicited towards the point C by a centripetal force. And also, if a body proceed according to the direction of the right line AD, and be solicited by a centripetal force towards a fixed point C, placed in the same plane; it describes a curve, whose cavity is towards C, and whose several areas, comprehended between the two radii AC and CB, are proportional to the times. Moreover, the velocity of a revolving body, at any point, Q or R, (fig. 86.) is inversely as the perpendicular SP or ST, falling from the center of force, upon the tangent at that point. For, let two other bodies, m and n, be supposed to move uniformly from Q and R, along the tangents QP and RT, with velocities respectively equal to those of the revolving body at Q and R; then the distances Qm and Rn, gone over in the same time, will be to each other as those velocities; and the areas QSm and RSn, will be equal, being equal to those described by the revolving body in the same time (see QUADRATURE): whence Qm × SP being = Rn × ST, it follows that Qm : Rn :: ST : SP :: $\frac{1}{SP} : \frac{1}{ST}$.

1. To determine the law of the centripetal force tending to a given point C, (fig. 87.) by which a body may describe a given curve AQH. Let QP be a tangent to the curve at any point Q: upon which, from the center C, fall the perpendicular CP: put CQ = s, CP = u; and let the velocity of the projectile at Q be denoted by v. Since v² is always as $\frac{1}{u^2}$ (by the preceding article), it is evident that if we take the fluxions of both quantities, v \dot{v} will also be as $\frac{-\dot{u}}{u^3}$. But the centripetal force, whether the body moves in a right line or a curve, is always as $\frac{-v\dot{v}}{s}$ (see CENTRAL force): consequently the centripetal force is likewise as $\frac{\dot{u}}{u^2 s}$. Otherwise, let the ray of curvature QO be denoted by R; then, because the centripetal forces in circles are as the squares of the velocities directly and the radii inversely (see CENTRAL forces); it follows that the force, tending to the point O, by which the body might be retained in its orbit at Q, or in the circle whose radius is QO, will be defined by $\frac{1}{u^2} \times \frac{1}{R}$; whence (by the resolution of forces) it will be CP (u) : CQ (s) :: $\frac{1}{u^2 R}$ (the force in the direction QO) : $\frac{s}{u^2 R}$, the force in the direction QC, which, because R = $\frac{s^2}{u}$ (see Radius of EVOLUTE), will be ex-

pressed by $\frac{\dot{u}}{u^2 s}$. Hence it appears, that as the force, tending to the point C, is universally as $\frac{CQ}{CP^2 \times QO}$ (or $\frac{s}{u^2 R}$) the force to any other point s will, by the same argument, be as $\frac{eQ}{cp^2 \times QO}$. Consequently, the forces to different centers C and e (about which equal areas are described in the same time) are to each other in the ratio of $\frac{CQ^2}{CQ}$ to $\frac{eQ^2}{eQ}$ inversely. Moreover, the ratio of the velocity at Q to the velocity by which the body might revolve in a circle about the center C, at the distance CQ, is easily deduced from hence: for, since the velocity at Q is that by which the body might revolve in a circle about the center O, and the forces tending to the centers, O and C, are to each other as u (CP) and s (CQ); it therefore follows, that the ratio sought be assumed as v to w, that $\frac{w^2}{QO} = \frac{v^2}{QC} :: a : s$ (see CENTRAL forces): whence also v² : w² :: u × $\frac{QO}{uR}$ (uR) : s × QC (s²); and consequently, v : w :: $\sqrt{\frac{uR}{s s}}$: 1 :: $\sqrt{\frac{u}{s}}$: $\sqrt{\frac{u}{u}}$ (because R = $\frac{s^2}{u}$).

It appears farther, that if OL be made perpendicular to QC, QL will be ($= \frac{CP \times QO}{CQ}$) = $\frac{uR}{s}$, and $\frac{CL}{CQ} = \frac{uR}{s}$; and therefore v : w :: QL^{1/2} : CQ^{1/2}; which is another proportion of the proposed celerities. Hence, if the law of the centripetal force be given, the nature of the trajectory may be found; for since the force (F) is universally defined by $\frac{u}{u^2 s}$, it is evident that $\frac{F}{2u^2 s}$ will be = the fluent of F s; which, when F is given in terms of s, will become known; and then the relation between u and s being given, the curve itself is known.

E. G. Let it be required to find the law of the centripetal force, by which a body, tending to the focus C, is made to revolve in the periphery of an ellipse AQDB (fig. 88).

From the other focus, F, draw FK parallel to CP, meeting the tangent PQ (or right angles) in K, join F, Q; putting the transverse axis AB = a, the semi-conjugate OD = $\frac{1}{2} b$, and the parameter ($\frac{b^2}{a}$) = p; then, CQ and CP being denoted as before, we have FQ (= AB - CQ), by property of the ellipse) = a - s; whence, by reason of the similar triangles CQP and FQK, it will be s : u :: a - s : FK = $\frac{a - s \times u}{s}$. But FK × CP is = OD² (by the nature of the curve). Hence we get $\frac{a - s \times u^2}{s}$ = $\frac{1}{2} b^2$; and consequently $\frac{1}{u^2} = \frac{4a}{b^2 s} - \frac{1}{b^2}$; the fluxion of which being $-\frac{2\dot{u}}{u^3} = -\frac{4a\dot{s}}{b^2 s^2}$, we obtain $\frac{\dot{u}}{u^3 s}$ (as before) = $\frac{2a}{b^2} \times \frac{1}{s^2} = \frac{2}{p s^2}$, and $\sqrt{\frac{u\dot{s}}{s u}} = \sqrt{\frac{2 \times \frac{a - s}{a}}{a}} = \sqrt{\frac{2(a - s)}{a^2}}$.

CENTRIPETAL FORCE.

$\sqrt{\frac{FQ}{AO}}$. Hence it appears, that the centripetal force is, in this case, as the square of the distance inverfly; and the velocity at Q is to that by which the body might describe a circle at the distance CQ, every where in the ratio of $FQ^{\frac{1}{2}}$ to $AO^{\frac{1}{2}}$. If the curve had been an hyperbola; then $\frac{a+s}{s} \times u^2$ (instead of $\frac{a-s}{s} \times u^2$) would have been $= \frac{1}{2} b^2$; and fo $\frac{\dot{u}}{u^{\frac{3}{2}}} = \frac{2a}{b^2} \times \frac{1}{s^2} = \frac{2}{\rho s^2}$, as before. If the curve had been a parabola, the equation would have been $\frac{a+s}{s} \times u^2 = \frac{3}{2} b^2$, or $\frac{u^2}{s} (= \frac{b^2}{4a}) = \frac{1}{2} \rho$; and the force, still, as $\frac{2}{\rho s^2}$. But the measure of the velocity ($\sqrt{\frac{u \dot{s}}{s \dot{u}}} = \sqrt{\frac{2a-2s}{a}}$) in this case becoming barely $= \sqrt{2}$, it follows that the velocity in a parabola is to that by which the body might describe a circle at the same distance from the centre, in the constant ratio of $\sqrt{2}$ to unity.

2. To determine the ratio of the velocities of bodies revolving in different orbits, about the same, or different centers; the orbits themselves, and the forces by which they are described, being given. Let AQH (fig. 89.) be any orbit, described about the center of force C, and let the force itself at the principal vertex be denoted by F; also let r stand for the semiparameter, or the ray of curvature at the vertex, and let CP be perpendicular to the tangent QP. Then, the celerity at A being, always, as \sqrt{rF} (by CENTRAL forces), we have CP : CA :: \sqrt{rF} (the velocity at A) to $\frac{CA \times \sqrt{rF}}{CP}$, the velocity at Q (by a preceding article). This answers in all cases, let the values of A, C, r and F be what they may.

Hence, if the centripetal force be as the square of the distance inverfly, or F be expressed by $\frac{1}{AC^2}$, the velocity at Q will become $\frac{AC}{CP} \times \sqrt{\frac{r}{AC^2}}$, or $\sqrt{\frac{r}{CP}}$: whence the velocities, in different orbits, about the same center, are in the subduplicate ratio of the parameters, and the inverse ratio of the perpendiculars from the center of force to the tangents, conjunctly. Farther; if the celerity at Q be denoted by Qq, and Cq be drawn; then, Qq being as $\sqrt{\frac{r}{CP}}$, it follows that \sqrt{r} is as CP \times Qq, or as the triangle QCq. Consequently, the areas described about a common center of force in a given time, are in the subduplicate ratio of the parameters.

Moreover, since the area of the curve AQHB, &c. when an ellipse, is known to be as $(AO \times OD) AO \times \sqrt{r} \times AO$ (supposing O to be the center), if the same be applied to \sqrt{r} , expressing the area described in a given part of time (by the last article), we shall thence have $AO \times \sqrt{AO}$, or $AO^{\frac{3}{2}}$, for the measure of the time of one whole revolution. Whence it appears that the periodic times, let the species of ellipse be what it may, are in the sesquipedial ratio of their principal axes.

3. The centripetal force, tending to a point C, being as the square of the distances reciprocally, and the direction and velocity

of a body at any point Q being given; to determine the path in which the body moves, and the periodic time, in case it returns, (fig. 90.) The trajectory AQB is a conic section, having the point C for one of its foci. Let F be the other focus, and upon the tangent PQK let fall the perpendiculars CP and FK, and let CQ and FQ be drawn: also, put the semitransverse axis AO = a, the given focal distance CQ = d, and the sine of the angle of direction CQP (to the radius 1) = m; and let the given velocity at Q be to that by which the body might revolve in a circle about the center C, at that distance, in any given ratio of n to unity; then it will be n : 1 :: $FQ^{\frac{1}{2}} : AO^{\frac{1}{2}}$ (see a preceding article); therefore $n^2 : 1^2 :: FQ(2a-d) : AO(a)$; whence

$AO(a)$ is given = $\frac{d}{2-n^2}$. Moreover, since CP = m \times CQ, and FK = m \times FQ, we have OD² (= CP \times FK = m² \times CQ \times FQ) = $\frac{m^2 n^2 d^2}{2-n^2}$; whence the semi-conjugate axis (OD) is given likewise. Lastly, it will be (by a preceding article) as CT² : AO³ :: P to the periodic time in any given circle, whose radius is CT, to $(\frac{AO^{\frac{3}{2}}}{CT^{\frac{3}{2}}} \times P)$ the required time of one revolution, when the orbit is an ellipse; that is, when n² is less than 2; for

if n² be = 2, the curve (as its axis $\frac{2d}{2-n^2}$ becomes infinite)

will degenerate to a parabola; and if n² be greater than 2, the axis being negative, it is then an hyperbola; whose two

principal diameters are equal to $\frac{2d}{n^2-2}$ and $\frac{2mn d}{\sqrt{n^2-2}}$. Hence

it follows, that, since neither the value of A, O, nor that of the periodic time, is affected with m, the principal axis, and the periodic time, will remain invariable, if the velocity Q be the same, let the direction at that point be what it may.

The same solution might be obtained by first finding the principal parameter; for it is evident, that the area described by the body about the center C, in any given time, is to the area described, in the same time, by another body revolving in a circle at the distance CQ, as mn to unity; hence it will be, $1^2 : m^2 n^2 :: d : m^2 n^2 d$, the semiparameter: from which (proceeding as above) we get $a \times m^2 n^2 d (= OD^2) = m^2 \times 2ad - d^2$; and consequently $a = \frac{d}{2-n^2}$, as before.

4. To find expressions for the centrifugal and centripetal forces, and to determine their proportion to each other. Let S (fig. 91) be the center of force, PK the curve described, PT a tangent to it, SY perpendicular to PT, and PQ an indefinitely small arc; draw Qsw perpendicular to SP, and with the center S describe the circular arc Qs; and let RQ be parallel to SP, and PV be the chord of the circle of curvature. Let PQ represent the motion of the body in the curve in a given time; then Psw will represent that part of the motion which is directed towards the center, and by which alone the body would be found, at the end of the given time, at the distance Sw; but on account of the motion wQ, it is found at the end of the same time at the distance SQ or Sx; so that the perpendicular motion wQ has made the body to recede from S through a space equal to w \times x, which therefore represents the centrifugal force; and the centripetal force is represented by QR.

Now $w \times x = \frac{xQ^2}{2 \times S}$ ultimately: but xQ^2 varies as $\frac{\text{area } SxQ^2}{S^2}$;

therefore $w \times x$ varies as $\frac{\text{area } SxQ^2}{2 \times S^2}$, which varies as

$\frac{2 \times S P \times V}{S P^2}$ ultimately. Hence, in the same curve, the centrifugal force varies as $\frac{1}{S P^2}$, the area $S P Q$ described in a given time being given. And in different curves, if the distance is the same, the centrifugal forces are as the squares of the areas described in a given time. Hence, the centripetal force in the curve is the centrifugal force :: $Q R : x \omega ::$

(because $Q R = \frac{Q P^2}{P V}$, and $x \omega = \frac{x Q^2}{2 Q S} = \frac{x Q^2}{2 P S}$)
 $\frac{Q P^2}{P V} : \frac{x Q^2}{2 P S} ::$ (since by similar triangles $Q P^2 : Q x^2 ::$
 $S P^2 : S Y^2$) $\frac{S P^2}{P V} : \frac{S Y^2}{2 P S} :: 2 S P^2 : S Y^2 \times P V$.

E. G. Let the curve be an ellipse whose greater axis is $2a$, and the eccentricity $= \omega$, and the body be at the greatest distance from the center of force, which is supposed to be in the focus; then the centripetal force : centrifugal :: $S P : \frac{1}{2} P V :: a + \omega : \frac{a^2 - \omega^2}{a} :: a : a - \omega$.

Let $V P A$ (*fig. 12.*) be an ellipse whose focus is S and center C ; $V W$ a curve to be constructed, that $S p$ may be always equal to $S P$, and the angle $V S p$ to $V S P$ in a given ratio $G : F$; then the areas $V S p$, $V S P$ will be in the same given ratio. Let a body revolve from V to P about the center of force S , in the same time in which another body revolves from V to p . Then as the area $V S P$ varies as $V S p$, and the area $V S P$ varies as the time, the area $V S p$ varies as the time; consequently the body describing $V p$ is urged by a force tending to S . Let $P v$ be the chord of curvature. Since the centrifugal forces of the two bodies are as $G^2 : F^2$, or as $\frac{G^2}{S P^2} : \frac{F^2}{S p^2}$, let them be represented by these quantities; hence the difference of the centrifugal forces is $\frac{G^2 - F^2}{S P^2}$. Now if p recede from the center by a centrifugal force which is greater by $\frac{G^2 - F^2}{S P^2}$ than that by which P recedes, it is manifest that p must be acted upon by a centripetal force which is greater by the same quantity, in order to destroy it, so that the bodies may keep at the same distance. Now $S Y^2 \times P v : 2 S P^2 :: \frac{F^2}{S P^2}$ (the centrifugal force is the ellipse at P):

$\frac{2 F^2}{S Y^2 \times P v}$ the centripetal force in the ellipse at P ; hence, the force in the orbit $V W$ at $p = \frac{2 F^2}{S Y^2 \times P v} + \frac{G^2 - F^2}{S P^2}$.

But $S Y^2 = \frac{A C \times R \times S P^2}{C D^2}$, and $P v = \frac{2 C D^2}{A C}$, R being half the latus rectum, and $C D$ the semi-conjugate diameter to $P C$: hence, the force at $P = \frac{F^2}{R \times S P^2}$, and at $p = \frac{F^2}{R \times S P^2} + \frac{G^2 - F^2}{S P^2}$; therefore the ratio of these forces is $\frac{F^2}{S P^2} : \frac{F^2}{S P^2} + \frac{R G^2 - R F^2}{S P^2}$. See Vince's Astronomy, vol. ii. chap. 31. Simpson's Fluxions, Vol. i. Section 12.

CENTRISCUS, in *Ichthyology*, a genus of Branchiostegous fishes, distinguished by the following characters: Head produced into a very narrow snout: mouth without

teeth: lower jaw longer than the upper: aperture of the gills broad and flat: body compressed: abdomen emarginated: ventral fins united.

CENTRISCUS *Solefax*, trumpet, or orbweils fish, of Ray, is an inhabitant of the Mediterranean sea, and has been recently discovered on the coast of Cornwall. (Donov. Brit. fishes). It is specifically described as having the body fealy and rough: tail straight, and extended.

This is a small fish measuring commonly from four to five, or six inches in length, or rarely seven. The body is much compressed laterally; and is entirely covered with hard pointed scales: the colour red, or reddish, darkest or inclining to purple on the back, and silvery on the belly, and the same surface glistened with a tinge of gold. The first dorsal fin consists of four strong bony rays, the anterior one of which is moveable, very strong, jagged or denticulated on each side, and with the rest of the fin is situated in a small hollow on the side of the back. This spiny ray is the only defensive weapon with which nature has furnished this species. The French call this fish *Beaufin*, the Germans *Meerblauschiff*. In the north of Europe, where it is not unfrequently taken, it is esteemed as a delicate fish; the flesh is tender, of a good flavour, and easy digestion.

CENTRISCUS *Sutinus*. Back covered with a smooth bony shell. Bleach, &c. This species has the body so much compressed as to resemble a lamina, particularly on the abdomen, where it is membranaceous: the back is covered with smooth, golden, and closely united plates: sides pellucid, yellowish, and silvery; beneath tortoiseshell, marked with transverse white lines: pectoral and ventral fins yellowish, the rest brown.

Klein calls this fish *Amphiscien*; *Ikan Pasfan*, *Mejswisch*, Valent. *Ikan Peixe*, Ruysch. Length from six to eight inches: inhabits the Indian seas, and subsists on marine worms, and small crabs.

CENTRISCUS *Valutaris*. Body oblong lanceolate, rough, with small recumbent bristles at the nostrils. Linn. Pallas, &c. A native of Amboyna. Length two inches: body silvery; above, yellowish grey: before the ventral fins a triangular emargination: back protected by a rhombic shield, marked by four oblique lines, in the middle a recumbent, slightly moveable, fubulate, acutely pointed spine, which is rather serrated at the edge, and grooved beneath; and below this another smaller spine situated in a hollow of the back: ventral fin broad: tail slightly rounded.

CENTRISCUS is also the name given by Klein to two or more species of the Linnæan genus *Gasterosteus*, as for example, *Centriscus duobus* in dorso areolato aculeis, &c. *Gasterosteus aculeatus*; *Centriscus aculeis quindecim* in dorso, &c. *Gasterosteus spinachia*.

CENTRITES, in *Ancient Geography*, a river of Asia in Armenia, which sprung from the mountains S.W. of the lake Artifla, and running to the south-west, discharged itself into the river Nicephorus. Diodorus Siculus says, that this river flowed between Armenia and Media; and in the account of Xenophon's famous retreat, it is said to have separated Armenia from the country of the people called *Carduchi*. The Greeks, under the command of this general, were obstructed by this river, 200 feet wide, in their progress to the Armenian plains, and lodged one night near its banks, refreshing themselves with the plenty and variety which the country yielded, and flattering themselves that the hardships which they had endured were just terminating. But on the following morning they were alarmed by the appearance of an army of horse and foot, drawn up in hostile array on the other side of the river, on an eminence about three or four hundred

hundred feet from it, who seemed determined to oppose their passage. These were Armenians, Mygdonians, Chaldeans, and other auxiliaries, hired by Orontas, governor of that province. The only road which the Greeks could discover led upwards, and seemed to have been made by art: and the breadth of the river inducing them to believe it fordable, they attempted to pass it there; but they had not proceeded far before they found themselves obliged to return, and encamp on the banks of the river.

CENTRO-BARYC METHOD, from *κέντρον* and *βαρῦς*, heavy, in *Mechanics*, is a method of measuring or determining the quantity of a surface or a solid, by considering it as formed by motion, and multiplying it into the way of its center of gravity.

The doctrine is comprised in the following theorem, with its corollaries.

Every figure, whether superficial or solid, generated by the motion of a line or figure, is equal to the product of the generating magnitude into the way of its center of gravity, or the line which its center of gravity describes.

Demonst. For suppose the weight of the whole generating magnitude collected in the centre of gravity; the whole weight produced by its motion will be equal to the product of the weight moved into the way of the center of gravity. But when lines and figures are considered like homogeneous, heavy bodies, their weights are as their bulks; and therefore the weight moved is the generating magnitude; and the weight produced that generated. The figure generated, therefore, is equal to the product of the magnitude into the way of its center of gravity. Q. E. D.

This kind of proof, furnished by Wolfius, is very vague and unsatisfactory. But it is not difficult to supply one that is much better. Accordingly, let us suppose a lever loaded with two weights, and a fixed point in this lever. It is well known that the sum of the products of each weight by its distance from this point is equal to the product of the sum of the weights by the distance of their center of gravity from this point: then, if we imagine the lever to revolve round this fixed point, the circumferences will be proportional to the radii, and the sum of the products of each weight by the path or circumference which it describes will be equal to the product of the sum of the weights by the circumference described by the center of gravity. This demonstration, comprehending two weights, may be easily applied to any number of weights at pleasure.

Corol. 1. Since a parallelogram ABCD (*Plate XI. Mechanics, fig. 94.*) is described, if the right line AB proceed according to the direction of another AC, with a motion still parallel to itself; and the way of the center of gravity E is equal to the right line EF, perpendicular to CD, that is, to the altitude of the parallelogram: its area is equal to the product of the base CD, or the describing line into the altitude EF. On this corollary we may observe, that AC is not, strictly speaking, the directrix of AB, although AB moves along AC; but this directrix is properly the line EF, which measures the distance of AB from CD; and the way of the center of gravity, by which we multiply the describing line, AB (or CD) is not the absolute way of this center, but its way estimated with respect to the directrix or the way it describes in a line perpendicular to the describing line. This remark is necessary in order to prevent those paralogisms which might occur, in applying without precaution the foregoing rule to the measure of surfaces and solids.

Corol. 2. In the same manner it appears, that the solidity of all bodies, described by a plane descending according to

the direction of any right line AC, is had by multiplying the describing plane by the altitude.

Corol. 3. Since a circle is described, if the radius CL, (*fig. 95.*) revolve round a center C and the center of gravity of the radius CL be in the middle F, the way of the center of gravity is the periphery of a circle X, described by a subduple radius: consequently the area of the circle is equal to the product of the radius CL, into the periphery described by the subduple radius CF.

Corol. 4. If a rectangle ABCD (*fig. 96.*) revolve about its axis AD; the rectangle will describe a cylinder, and the side BC the superficies of a cylinder. But the center of gravity of the right line BC is in the middle, F; and the center of gravity of the generating plane in the middle, G, of the right line EF. The way of this latter, therefore, is the periphery of a circle described by the radius EG, and that of the first the circumference of a circle described by the radius EF. Wherefore, the superficies of the cylinder is the product of the altitude BC into the periphery of a circle described by the radius EF, or the base. And the solidity of the cylinder is the product of the generating rectangle ABCD into the periphery of a circle described by the radius EG, which is subduple of EF, or of the semidiameter of the cylinder.

Suppose, v. gr. the altitude of the describing plane, and therefore of the cylinder BC = a; the semidiameter of the base DC = r; then will EG = $\frac{1}{2}r$; and supposing the ratio of the semidiameter to the periphery = 1 : m, the periphery described by the radius $\frac{1}{2}r$ = $\frac{1}{2}mr$. Therefore multiplying $\frac{1}{2}mr$ by the area of the rectangle AC = ar; the solidity of the cylinder will be = $\frac{1}{2}mar^2$. But $\frac{1}{2}mar^2$ = $\frac{1}{2}r \times mr \times a$; and $\frac{1}{2}mr^2$ is the area of the circle described by the radius EG. It is evident, therefore, the cylinder is equal to the product of the base into the altitude.

Corol. 5. In like manner since the center of gravity of the right line AB (*fig. 97.*) is in the middle M, and the surface of a cone is described, if the triangle ABC revolves about its axis; if PM = $\frac{1}{2}$ BC; the superficies of the cone will be equal to the product of its side AB, into the periphery described by the radius PM, or the subduple of the semi-diameter of the base BC.

Suppose, v. gr. BC = r, AB = a, the ratio of the radius to the periphery 1 : m; then will PM = $\frac{1}{2}r$, and the periphery described by this radius = $\frac{1}{2}mr$. Therefore multiplying $\frac{1}{2}mr$ into the side of the cone AB, the product is the superficies or $\frac{1}{2}amr$. But $\frac{1}{2}amr$ is also the product of $\frac{1}{2}a$ and mr : therefore the surface of the cone is the product of the periphery into half the side.

Corol. 6. If the triangle ACB (*fig. 98.*) revolve about its axis, it describes a cone; but if CB be bisected in D, and the right line AD be drawn, and AO = $\frac{2}{3}$ AD; the center of gravity will be in O. The solidity of the cone, therefore, is equal to the product of the triangle CAB into the periphery described by the radius PO; but AD : AO :: BD : OP; and AO = $\frac{2}{3}$ AD, and DB = $\frac{1}{2}$ CB. Therefore, OP = $\frac{2}{3}$ BD = $\frac{1}{3}$ CB.

Suppose, v. gr. BC = r, AB = a, the ratio of the radius to the periphery = 1 : m. Then will OP = $\frac{1}{3}r$, the periphery described by this radius $\frac{1}{3}mr$; the triangle ACB = $\frac{1}{2}ar$; and, therefore, the solidity of the cone $\frac{1}{3}mr \frac{1}{2}ar$ = $\frac{1}{6}amr^2$. But $\frac{1}{6}amr^2$ = $\frac{1}{3}r \times \frac{1}{2}ar \times \frac{1}{3}a$: Or, the product of the base of the cone into the third part of the altitude. See TRIANGLE.

Corol. 7. Let the semicircle DCA (*fig. 99.*) revolve about the diameter AD, and describe the surface of a

sphere. If there be taken $DC : FC :: FC : FH = \frac{FC^2}{DC} = \frac{4r^2}{c}$, putting r for the radius, and c for the whole circumference; H will be the center of gravity of the arc DCA ; and consequently $r : c :: FH : 4r =$ the line or circumference described by H the center of gravity: and by the general rule $DCA \times 4r = \frac{1}{2} c \times 4r = 2rc =$ the surface of the sphere = the circumference into the diameter: as it ought to be by other principles. For the solidity of the sphere, we shall have $\frac{1}{2} c : 2r :: \frac{3}{2} r : \frac{3r^2}{3c} =$ the distance

FH of the center of gravity of the semicircle $DCAD$ from the diameter AD ; which is two-thirds of the distance of the center of gravity of the arc DCA from the same diameter DA , in the former case: consequently, the line described by the center of gravity in this case will be two-thirds of that in the former: but the describing line in the former case is to the describing space in this as 1 is to $\frac{1}{2} r$; therefore $1 : \frac{3}{2} \times \frac{1}{2} r ::$ surface of the sphere: solidity $= \frac{3}{2} r \times$ surface. Hence it follows, that the circumference of the circle whose radius is the distance of the center of gravity of the semicircumference of any circle from its center, is equal to four times the radius of that circle.

Corol. 8. For the solidity of a parabolic spindle, put $b =$ the base, and $a =$ the altitude or axis of the generating parabola, and $n = .785398$. It is known that $\frac{2}{3} a$ is the distance of the center of gravity from the base, and consequently $\frac{1}{3} a =$ the line described by the center of gravity; but $\frac{2}{3} ab$ is = the revolving area; therefore $\frac{1}{3} a \times \frac{2}{3} ab = \frac{2}{9} a^2 b$ will be the content, which is $\frac{2}{9} n$ of the circumscribed cylinder.

Corol. 9. For the paraboloid, let the notation be as in the last example; and $\frac{2}{3} b$ will be the distance of the center of gravity of the semi-parabola from the axis; consequently $\frac{1}{3} b \times 8n \times \frac{2}{3} ab = 2abnn =$ the solidity = half the circumscribed cylinder.

This elegant theorem, which may be ranked among the chief inventions in geometry of the last age, was taken notice of long ago by Pappus; but the jesuit Guldinus was the first who set it in its full light, and exhibited its use in a variety of examples. Several other geometers, after Pappus and Guldinus, have also used it in measuring solids, and surfaces generated by a rotation round a fixed axis; especially before the late invention of the integral calculus: and it may still take place in some cases where the integral calculus would be more difficult. M. Leibnitz has observed, that the method will hold, though the axis or center be continually changed during the generative motion.

CENTRON, in *Geography*, a village of Savoy in the Tarantaise, formerly a capital town of a people, called *Centrons*; 3 miles E.N.E. of Nonfrier.

CENTRONES, in *Ancient Geography*, a people of Belgic Gaul, placed by Cæsar in dependence on the Nervians. Some authors place them in the territory of Gand, others in that of Courtray, &c. D'Anville has not mentioned them.—Also, an ancient people of the Gauls, placed by Ptolemy in the Grecian Alps; and mentioned both by Cæsar and Pliny. Many authors have supposed, and not improbably, that the Acitavones, on the Alps, were the Centrones.

CENTRONIA, in *Zoology*, the name by which Dr. Hill distinguishes the crustaceous vermes called Sea-eggs, and by Naturalists, Echini. See **ECHINUS**.

CENTRUM, in *Geometry, Mechanics, &c.* See **CENTER**.

CENTRUM phonicum, in *Acoestics*, is the place where the speaker stands in polysyllabic and articulate echos.

CENTRUM phonoacousticum, is the place, or object, that returns the voice in an echo.

CENTRUM tendinosum, in *Anatomy*, a name applied to the tendon of the diaphragm, which occupies the center of the part. See **DIAPHRAGM**.

CENTRY BOX, a sort of box or hut for sheltering centinels in bad weather. It is commonly made of wood. But in fortifications with revetements or demi-revetements of masonry, they are often made of stone, and usually in a circular form.

CENTUM-CELLÆ, in *Ancient Geography, Civita Vecchia*, a sea port town of Italy, in Etruria. Trajan made this the place of his residence, where he entertained his friends and the great men of his court, with music, plays, and banquets, not sumptuous but moderate. In process of time, he gave it importance by erecting a harbour, which he called after his own name, and which is the present port of Civita Vecchia, where the pope keeps his galies. The harbour was formed by running out two piers into the sea, and constructing in the interval between them a mole or little island, which served to break the violence of the waves, and to secure the ships in the inner basin from storms and bad weather.

CENTUM-MORBIA, in *Botany*, a name used by some authors for the common money-wort or nummularia, from its supposed virtues.

CENTUM-PUTEA, in *Ancient Geography*, a place of Dacia Trajana.
