COLLISION.

COLLISION, from the Latin *Collisio*, a breaking, knocking, or dashing together, in *Philosophy* and in *Mechanics*, means the meeting, mutual striking, or congress, of two or more bodies, one of which at least is in motion. The collisions of bodies, and the results arising from those collisions, form by far the greatest part of the operations of nature, as well as of artificial mechanics; hence the industry of man has spared no pains in the investigation of the laws which regulate those motions, and in the performance of experiments tending to confirm and to illustrate the same. In the theory of collision or percussion, the simplest cases are considered first, and such, indeed, as cannot actually take place in nature; for instance, two bodies are supposed to move equally (that is, each of them, or one at least, to run through equal lengths in equal portions of time) in non-resisting mediums, and those bodies are farther supposed to be either hard, or soft, or elastic. A hard body is that whose parts retain their respective situation or figure in all cases, not yielding to any stroke or percussion. A soft body is that whose parts yield to any stroke, and have no power to recover their original situation; and lastly, an elastic body is that whose parts yield to any stroke, but presently regain their original form and situation. Now, in nature, (as far as we know) there are no bodies perfectly elastic or perfectly unelastic; including under the latter name both those that are perfectly hard and those that are perfectly soft. All the bodies we are acquainted with are partially elastic, but in various degrees; nor can their motions take place without meeting with some obstruction. Yet the laws of collision, under the above-mentioned suppositions, being demonstratively deduced from the general laws of motion, which are justly assumed as axioms, determine the pheno-

mena which would take place if those suppositions were real; it being afterwards more easy and practicable to estimate, and to allow for those deviations of practical results from the abstract theory, which arise from the imperfect elasticity of bodies, from resistances of mediums, from friction, &c.

The theory of collision is derived from sir Isaac Newton's third law of motion, which says, that action and re-action are always equal and contrary to each other. See *Laws of motion*.

Definition 1. *The respective velocities or celerities of bodies are proportional to the spaces which they describe in a given time.* Thus, if a body, A, passes through an extension of 10 feet in one second of time, whilst the body, B, runs through an extension of 100 feet in the same time, then the respective celerities of those bodies are said to be as 10 to 100; or as one to ten.

Def. 2. *The bodies are said to strike directly against each other, when in striking, there occurs no reason why they should turn towards one side rather than towards another; so that both before and after the stroke, the motion is in the same straight line, unless it be all destroyed.*

Def. 3. *In every other case the stroke is said to be oblique.* The principal proposition belonging to this theory, considers two bodies that strike directly against each other, and the result is concisely expressed by sir Isaac Newton in the following words: "the quantity of motion, that is gathered by taking the sum of the motions made towards the same part, and the difference of those made towards the contrary parts, is not altered by the action of bodies amongst themselves." For the sake of perspicuity we shall endeavour to demonstrate this proposition, by considering the two cases separately.

B

*THEOREM

THEOREM I.

If a body, A, (Plate XV. *Mechanics*, fig. 1.) strike directly against another body, B, which is either at rest, or moving in the same direction, but slower; the sum of the motions in both the bodies towards the same parts, will remain the same after the stroke, as it was before that stroke.

Let CD express the motion of the body A, and EF the motion of the body B; viz. that whilst A moves from C to D, B moves from E to F. Therefore, the sum of the motions is CD plus EF. Now, since it moves with greater velocity than B moves with, it necessarily follows, that A must overtake, and strike against B. And it will appear, that after the stroke the sum of the motions is the same as it was before, viz. CD plus EF. For since action and re-action are equal (3d law of motion), if A, by striking on B, communicates to it the additional motion FG; it must lose as much itself; viz. DK (equal to FG) must be subtracted from CD. So that after the stroke, CK is the motion of A, and EG that of B; and the sum of those motions is CK plus EG, equal to CD plus EF; for, since FG is equal to DK, add EF and CK to both, and it will be FG + EF + CK equal to KD + CK + EF; viz. EG + CK = CD + EF.

The various cases of this proposition are as follow: If FG is equal to CD, then K and C coincide, and CK vanishes or becomes equal to nothing (as in fig. 2.); hence, after the stroke, A will be at rest.

If FG exceed CD; then K will fall beyond C; and the motion of A will become retrograde or negative (as in fig. 3.) Therefore, the sum of the motions towards the same part is the difference between EG and CK; viz. EG minus CK.

If B stand at rest, then its motion becomes equal to 0, and in that case the sum of the motions is reduced to CD.

THEOREM II.

If two bodies, moving towards contrary parts, strike directly against each other, the sum of their motions towards the same parts (which is the difference of their motions towards contrary parts) before and after the stroke, will always remain the same towards the same parts.

Let the body, A (fig. 4.), move from C towards D, and let C D represent its motion, whilst the body, B, moves in a contrary direction from E towards F, and let EF represent its motion.

Make DH equal to EF; then CH is the difference of the motions towards the contrary parts, and is, at the same time, the sum of the motions towards the same part; viz. towards G. Now, after the stroke, the same, CH, will be as the sum of the motions towards the same part, viz. towards G.

Let the motion of B, after the stroke, be towards G, and let it be represented by EG. Therefore, the force communicated to B is FE plus EG, that is, FG. But (by the 3d law of motion) making DK equal to FG, DK will represent the motion lost by A; so that if DK be subtracted from CD, the remainder, CK, will be the motion of A towards G. Now, since DK is equal to FG, and DH is equal to FE; it will be DK minus DH, (viz. KH), equal to FG minus FE (viz. EG). Therefore, since KH is equal to EG; KH will represent the motion of B after the stroke, and CK will represent the motion of A; so that CK plus KH is equal to CH, and is the sum of the motions of both the bodies towards G.

If FG is equal to CD (as in fig. 5.); then K and C coincide, consequently the motion of A becomes equal to 0.

If FG exceeds CD (as in fig. 6.) K will fall beyond C, and the motion of A will be retrograde; but (since FG is equal to DK, and FE to DH) KH will be equal to EG; therefore, taking CK from both, CH will be equal to EG minus CK. But CH was as the sum of the motions towards G before the stroke, and EG minus CK is as the sum of the motions towards the same part; namely, as the difference of the motions towards the contrary parts after the stroke. Therefore, the sum of the motions towards the same part will be the same both before and after the stroke.

Having demonstrated the two simplest theorems belonging to the doctrine of collision, wherein the equality of the motions before and after the stroke has been considered, it is now necessary to examine the direction, the velocity, and the momentum of the bodies alter the stroke; and for this purpose the properties of the centre of gravity must be recollected.

But, that property of the centre of gravity, which is more immediately concerned with the present subject, is briefly expressed in the following lines:

If bodies, moving in the same straight line, strike against each other, the state of their common centre of gravity will not thereby be altered; viz. it will either remain at rest, or it will continue to move in the same straight line, exactly as it moved before the stroke. See CENTER OF Gravity.

THEOREM III.

Let there be two non-elastic bodies (viz. either perfectly hard or perfectly soft); and if one of them move in a straight line, whilst the other is at rest in that line, or is moving in the same direction, but at a slower rate, or is moving in the contrary direction; then those bodies must strike directly against each other, and after the stroke they will either remain at rest, or they will move on together, conjointly with their common centre of gravity.—Their momentum, after the stroke, will be equal to the sum of their momentums before the stroke, if they both moved in the same direction; but it will be equal to the difference of their momentums if they moved in contrary directions.—Their velocity, after the stroke, will be equal to the quotient that arises from dividing the sum of their momentums, if they both moved the same way, or the difference of their momentums, if they moved contrary ways, by the sum of their quantities of matter.

That, after the stroke, the two bodies must either remain at rest or move on together, is evident; for, since they are not elastic, there exists no power that can effect their separation. With respect to the momentum, it must be observed, that where the bodies meet (by the 3d law of motion), whatever part of the momentum is lost by one of the bodies, must be acquired by the other; therefore, if before the stroke the bodies moved the same way, their joint momentum, after the stroke, will be equal to the sum of their momentums before the stroke. If one of the bodies was at rest, then, as its momentum is equal 0, the joint momentum will be equal to the momentum of the other body before the meeting. If the bodies moved towards each other, then their momentum, after the meeting, will be equal to the difference of their former momentums; and if in this case their momentums are equal, then their difference vanishes; that is, the bodies will remain at rest after their meeting.

The last part of the theorem is evident; for the momentum of a body in motion is equal to the product of the velocity multiplied by the quantity of matter. See MOMENTUM. The

The weights and velocities of the two bodies before their meeting being given, the velocity, after the meeting, may be determined by the following method, which is applicable to the four cases of *figs.* 7, 8, 9, and 10. Let A and B be the two bodies, C their common centre of gravity, and D the place of their meeting. Make DE equal to DC, so that the point, D, may be between C and E; then DE will represent the velocity after their meeting; for, since the bodies, after their meeting, move together conjointly with their common centre of gravity; and the centre of gravity has the property mentioned immediately before the third theorem; it follows that the velocity of their common centre of gravity after their meeting, must be equal to its velocity before the meeting; *viz.* DE must be equal to CD, and is the same as the velocity of the two bodies after the meeting, because, then, they move together with the centre of gravity.

Fig. 7. shews when the bodies move the same way. *Fig.* 8. shews the body, B, at rest before the stroke, in which case B and D coincide. In *fig.* 9. the two bodies move towards each other; and *fig.* 10. shews the two bodies moving towards each other with equal momentums, in which case they will remain at rest after the meeting. In all those four figures, the respective velocities of the bodies are represented by AD and BD, and AB is their difference. The respective momentums are represented by the product of the weight of A multiplied by AD, and of the weight of B multiplied by BD. The momentum after the meeting is represented by the weights of both the bodies multiplied by DE.

Example of the computation of the first case, fig. 7.—Let A weigh 10 lb. and move at the rate of 4 feet per minute. Let B weigh 6 lb., and move at the rate of 2 feet per minute, and let the distance AB be 32 feet. The centre of gravity is found by saying $16 : 32 :: 10 : BC = \frac{32 \times 10}{16} = 20$ feet; hence AC = 12 feet. Put BD = x , and AD will be equal to $32 + x$. Then the time employed by A in moving from A to D, is equal to the quotient of the space, $32 + x$, divided by its velocity; *viz.* $= \frac{32 + x}{4}$. And the time employed by B in moving from B to D, is equal to the quotient of the space, x , divided by the velocity of B, *viz.* $= \frac{x}{2}$. But, since the bodies meet at D,

those times must be equal; that is, $\frac{32 + x}{4} = \frac{x}{2}$; and by the resolution of this simple equation, we have $64 + 2x = 4x$; and $x = 32 = BD$.

Then DE = DB + BC = $32 + 20 = 52$ feet; *viz.* after the meeting, the two bodies will move from D to E, which are 52 feet apart, in as much time as each of them employed in going to D; *viz.* 16 minutes. Therefore, in order to find how many feet per minute the bodies will run over after the meeting, divide 52 by 16, and the quotient, $3\frac{1}{4}$, is the answer.

The magnitude or quantity of the stroke is deduced from the third general law of motion, and from the nature of the momentum of a body in motion, which is equal to the product of the quantity of matter, or weight of the body, multiplied by the velocity, consequently in the same body the momentum is proportionate to the velocity. The particulars relative to the magnitude of the stroke, are expressed in the following theorem.

THEOREM IV.

If a body in motion strike directly against another body, the magnitude of the stroke is proportional to the momentum lost, at the concurrence, by the more powerful body. Also, when the latter body is at rest, the quantity of the stroke is proportional to the velocity of the former body.—If the second body be moving in the same direction with the first, but at a slower rate, the magnitude of the stroke will be the same as if the second body stood still, and the first impinging upon it with a velocity equal to the difference of their velocities.—And, lastly, if the bodies move directly towards each other, the magnitude of the stroke is the same as if one of the bodies stood at rest, and the other struck it with the sum of their velocities.

Thus much may suffice with respect to the congress or collision of non-elastic bodies. It is now necessary to state the particulars belonging to the congress of elastic bodies; *viz.* of those whose parts yield to any impression, but frequently recover their situation, by re-acting the contrary way with a force, which, in bodies perfectly elastic, is equal to the impression or stroke received. There are innumerable degrees of elasticity. See ELASTICITY.

THEOREM V.

When two bodies, that are perfectly elastic, strike directly against each other, their relative velocity (by which is meant the excess whereby the velocity of the swifter body exceeds that of the slower) will be the same before and after the stroke; viz. they will recede from each other with the same velocity with which they approached before the stroke.

The magnitude of the stroke (Theor. IV.) is proportional to the respective velocities. And in bodies that are perfectly elastic, the restoring force is equal to the compressing one; therefore, if the momentums of the bodies produced a certain compression, the elastic force must re-act on the bodies with equal power; hence the bodies will be forced to recede from each other with the same velocity with which they approached each other.

From what has been stated above, the results arising from the congress of bodies that are perfectly elastic, may be easily deduced in all the variety of cases in which the two bodies may be conceived to meet. The particulars upon which those results more immediately depend, are, first, that the distances of two bodies from their common centre of gravity are inversely as their weights; (see *CENTER of Gravity* and its properties); secondly, that the state or the uniform motion of the centre of gravity of bodies is not altered by the mutual action of those bodies on each other; thirdly, that in bodies that are perfectly elastic, the restoring is equal to the compressing force; and fourthly, that the distances of the bodies from each other, and from their common centre of gravity, are equal in equal times taken before and after the stroke; for in those two cases they move with equal velocities.

All the cases of direct congress of two perfectly elastic bodies are delineated in the figures 11, 12, 13, 14, 15, 16, 17, 18, and 19, in which A and B represent the two bodies; C is their common centre of gravity, D the place where they meet. A D expresses the velocity of A, BD the velocity of B, and C D that of the centre of gravity. Hence by inspecting the figures it will be easily discerned when both the bodies are in motion, or one of them is at rest; also their directions, &c. Then the rule for determining the velocities after the stroke is as follows:—Take a point E in the line AB, produced if necessary, so that the distance CE be equal to CD; then, after the stroke, the right line EA will
B 2
express

express the velocity of the body A from E towards A, and the right line E B will express the velocity of B from E towards B.

In *fig. 11*, B is larger than A, (which is plainly indicated by the situation of the centre of gravity C), B is at rest, and A strikes against it. In this case, after the stroke, both the bodies will recede from the point D, with the velocities EA and EB.

In *fig. 12*, A, the larger body, runs against the body B, which is at rest. In *fig. 13*, the body A is larger than B, and they are both in motion the same way. In *fig. 14*, A is less than B; the rest as in the preceding case. In *fig. 15*, A and B meet at D, where A remains at rest. In *fig. 16*, A and B are equal; and after the stroke they recede with interchanged velocities. In *fig. 17*, the bodies are proportional to their velocities; hence the points C, F, D, and E, coincide. In *fig. 18*, A remains stationary at the place of congress D. Lastly, in *fig. 19*, though the bodies A and B meet at D between the points A and B, yet after the stroke they both move towards F.

The numerical computation of those cases may be easily comprehended by the following example, which is adapted to the case of *fig. 13*.

A and B are two elastic bodies. A weighs 2 lb., and moves at the rate of 8 feet per second. B weighs 1 lb., and moves the same way at the rate of 5 feet per second. The distance AB is 12 feet.

1. To find the place of the centre of gravity C, we have $A + B : B :: AB : CA$; *viz.* $3 : 1 :: 12 : 4$; so that $AC = 4$, and $CB = AB - AC = 8$.

2. To find the distance BD, put $BD = x$; and since the distances AD and BD are run over in the same time, the former at the rate of 8, and the latter at the rate of 5 feet per second; therefore we have $\frac{x}{5} = \frac{x + 12}{8}$; hence $8x = 5x + 60$; and $3x = 60$; or $x = 20 = BD$.

3. If the distance BD; *viz.* 20, be divided by the velocity of B (*viz.* by 5); the quotient 4, is the number of seconds, during which the bodies moved from their respective places A and B, to the place of their congress D.

4. $EC = CD = CB + BD = 8 + 20 = 28$; and $EA = EC - AC = 28 - 4 = 24$; which being divided by 4 (the number of seconds found above) gives 6 for the velocity of A after the stroke, in the direction from E towards A. Also $EB = EC + CB = 28 + 8 = 36$; which being divided by 4 (the number of seconds, &c.) gives 9 for the velocity of B after the stroke in the direction from E towards B. So that after the stroke, the bodies A and B will both continue to move the same way, but the former at the rate of 6, and the latter at the rate of 9 feet per second.

It is now necessary to apply the above theory to those cases which really occur in nature, and in the first, since all known bodies are partially elastic, we must shew how to estimate the results of the collision of such bodies. Thus, let A and B, *figs. 20* and *21*, be two bodies imperfectly elastic, C their common centre of gravity, and D the place of their meeting. Divide AC in *a*, so that AC may be to aC, as the force compressing the body, A, is to the force whereby it is restored itself. Also divide BC in *b*; so that BC may be to bC as the force compressing the body B is to the force whereby it is restored itself. Take CE equal to CD; then the right line Ea will express the velocity of A after the stroke, in the direction from E towards a, and the right line Eb will express the velocity of B after the stroke in the direction from E towards D.

In the foregoing paragraphs the distances have been reckoned from the centres of the bodies; but since the bodies must strike with their surfaces, and not with the centres, therefore, when great accuracy is required, the thicknesses of the bodies must be deducted from the distances. However, when the distances are considerable, and the sizes of the bodies proportionately very small, it is immaterial whether the distances be reckoned from the centres or from the surfaces of the bodies; the difference becoming insignificant.

When more than two bodies move in the same straight line, the computation of the velocity of each body after the various strokes cannot be expressed under any general rules; the variety of cases being too great, and often very intricate: yet when any particular case presents itself, the preceding rules will be found sufficient to determine the particulars; observing to apply the computation to the two bodies which, from the circumstances of the case, appear to strike first, then to one of those and the next, and so forth. But sometimes the equality of the bodies, their being contiguous to each other, and other favourable particulars, render the calculation pretty easy and obvious. Thus, if any number of equal and perfectly elastic bodies be at rest, contiguous to each other in the same straight line, and another body, equal to one of them, strike the first of them in the same straight line, with any velocity; then after the stroke the striking body and all the rest will remain motionless, and the last body only will move on with the velocity of the striking body.

If the movements, instead of being equable, as we have hitherto supposed, be either accelerated or retarded, the momentum for each single small portion of time, must be reckoned such as belongs to the velocity acquired at that particular moment. In curvilinear movements, the direction of the motion in each point is the same as that of the tangent to the curve at that point. Lastly, if the movements, either accelerated or retarded, be likewise curvilinear (as in the vibration of pendulums;) the momentum for each single point must be deduced from the degree of acceleration and from the direction of the tangent, at that particular point.

Hitherto we have considered the collision of bodies, which strike directly against each other; that is, in a direction perpendicular to their surfaces, and in the direction of their centres. It is now necessary to treat of oblique collision; for which purpose the doctrine of the composition and resolution of forces, or of movements, must be previously known. See *Composition and resolution of FORCES.*

THEOREM VI.

If a body, perfectly elastic, as A, fig. 22, strike obliquely at C on the firm obstacle BE, then, after the stroke, this body will be reflected from that obstacle in the direction CE, in such a manner as to form the angle of reflection ECF, equal to the angle of incidence ACB.

The oblique force, AC, being resolved into two forces, *viz.* DC perpendicular to the obstacle, and AD parallel to it; the effect on the plane is the same as if the body had advanced towards it directly from D, and (according to the laws already stated) the body A, after the stroke, would be sent back in the direction CD. But of the two forces into which the original force of A was resolved, this body retains the one represented by AD, since this force was not concerned in striking the obstacle; therefore, after the stroke, the body, A, is actuated by two forces, *viz.* one represented by CD, equal to AD, equal to EF; and the other represented by CF, equal to DA, equal to DE; hence it must move in the diagonal CE; and since the lines CF,

FE, are respectively equal to the lines CB, BA, and the angles at B and F are equal, being right angles; therefore the triangle, EFC, is in every respect equal to the triangle ACB; consequently the angle of reflection, ECF, is equal to the angle of incidence ACB.

It evidently follows, from this proposition, that the force of an oblique stroke is to that of the same stroke coming in a perpendicular direction, as the sine of the angle of incidence is to radius.

If the body, instead of striking upon a plane strikes upon a curve surface, the effect is the same as if it struck on a plane, tangent to that surface at the striking point.

This being premised, the application of the foregoing rules to the oblique collision of bodies will be illustrated by the following examples.

Let two non-elastic bodies A and B, *fig. 23*, move, the former in the direction AC, the latter in the direction BD, and let them meet at CD. Draw the line, MG, through their centres, and through the point of contact. From A and B, *viz.* the original situation of those bodies, drop AM and BN perpendicular on M G. Then the force of each body may be resolved into two forces, *viz.* that of A into AM and MC, and that of B into BN and ND. Of its two forces, A retains the force AM whilst MC is exerted against the other body. Of the two forces of the body B, the force BN is retained by it, whilst the force ND is exerted against the other body. Therefore, the actions of those bodies upon each other is exactly the same as if they moved directly one from M and the other from N; hence the above stated rules of direct collision, will serve to find out whether the bodies, after the stroke, will proceed both the same way, or different ways, and at what rate. But when their velocities have been thus determined; for instance, if it be found, that had the bodies moved directly from M and N after the stroke, the body, A, would have moved as far as O, whilst the body, B, would have moved as far as G; then it must be recollected, that, in the present case of oblique collision, the body, A, has retained the force AM; therefore, after the stroke, the body, A, is actuated by two forces, *viz.* one equal and parallel to AM, and another which is equal and parallel to CO, in consequence of which this body must run a compound course, which is found thus: Through the centre, C, draw CI equal and parallel to AM; through I, draw IE equal and parallel to CO, then the diagonal CE exhibits the velocity and the direction of the body, A, after the oblique concourse. With respect to the body, B, it has been said, that at the concourse this body retains the force BN, and that, if the bodies had moved directly towards each other, B would, after the stroke, have moved from D to G. Therefore, through D draw DH equal and parallel to BN, and through H draw HF equal and parallel to DG; and, lastly, the diagonal, DF, will represent the velocity and the direction of the body, B, after the oblique concourse.

If the bodies be perfectly elastic, then suppose it be found (by the rules for elastic bodies) that, after the supposed direct concourse, the body, A, would have been sent back to Q, in the same time that B would have been sent back to R; it follows, that after the oblique stroke, the body, A, will be actuated by two forces, *viz.* one equal and parallel to AM, and the other equal and parallel to CQ. The body, B, will likewise be actuated by two forces, *viz.* one equal and parallel to BN, and the other equal and parallel to DR; therefore, in *fig. 24*, draw QZ through Q, equal and parallel to AM; also through Z draw IZ equal and parallel to CQ; then the diagonal, CZ, represents the

direction and the velocity of the elastic body, A, after the oblique stroke.—Again, through R draw the line, RX, equal and parallel to BN, and through X draw the line, XY, equal and parallel to DR, then the diagonal, DX, will represent the velocity and the direction of the elastic body, B, after the oblique stroke.

Amongst all the cases of collision, we have hitherto omitted to mention the striking of a body upon an immovable obstacle. This has been done merely because the particulars belonging to it may be easily derived from the consideration of the foregoing cases; it being only necessary to consider this case as if it were that of the collision of two bodies, either elastic or non-elastic, or partially so, and to suppose that one of the bodies, which represents the immovable obstacle, is infinitely great.

There is a difference between the stroke of an elastic body, and that of a non-elastic one, which, not being very obvious, deserves to be mentioned. This is, that the effect of the blow of an elastic body upon another body, as upon a plane, is double to that of a non-elastic body, their masses and velocities being equal. This arises from the elasticity of the former, which, after the stroke, by endeavouring to recover its original figure, acts upon the plane with a force equal to the first impression; whereas a non-elastic body acts only with the first impression. See the article PERCUSSION. Also, if the reader wish to see the original investigation of the laws belonging to the collision of bodies, together with any analytical and experimental illustration of the same, he may peruse Dr. Wallis's paper in the Phil. Transf. No. 43; Mr. Huygens's paper, Phil. Transf. No. 46; Sir Christ. Wren's paper, Phil. Transf. No. 45; Gravelande's Mat. Ele. of Nat. Phil. edited by Descaguliers; Gregory's Mechanics, vol. i. chap. v.; and all the best works on mechanics.

COLLIUS, PETER, in *Biography*, of the college of Milan, flourished at the beginning of the seventeenth century, and was the author of a curious treatise entitled "De Animalibus Paganorum," printed at Milan in two vols. 4to. in the years 1622-3. In this work he decides without hesitation on the future happiness or misery of many virtuous and truly illustrious characters of the Pagan world. His conclusions were founded on conjectures, deduced from a comparative view of their means of divine knowledge, their lives and manners, their opinions and writings, united with the testimony of sacred and profane history. He published also a treatise "De sanguine Christi," and a quarto volume entitled "Conclusiones Theologicæ." In them all is a great display of singularity, accompanied with a good share of talents. *Nouv. Dict. Hist.*

COLLIWILLY, in *Geography*, a town of the island of Ceylon; 50 miles W. of Trincomaly.

COLLMEN, or CULLMEN, a town of Germany, in the circle of Upper Saxony, and circle of Leipsick; 6 miles E. N. E. of Mutfchen.

COLLOBRIERES, a town of France, in the department of the Var, and chief place of a canton, in the district of Toulon; 18 miles N. E. of Toulon. The place contains 1509, and the cañon 2933 inhabitants; the territory includes 322½ kilometres, and two communes.

COLLOCOCCUS, in *Botany*, Sloan. See *Cordia Collococca*.

COLLON, in *Geography*, a post and fair town of the county of Louth, Ireland, which is neat and well built; and which has improved considerably under the auspices of the late lord chief baron Foster, and his son the right honourable John Foster, the much respected speaker of the Irish house

of commons, when the union took place. It is 29 Irish miles N. from Dublin.

COLLONGE, a town of France, in the department of Lèman, and chief place of a canton, in the district of Genève; the place contains 1178, and the canton 8,947 inhabitants: the territory comprehends $212\frac{1}{2}$ kilometres, and nine communes.

COLLOPS, in *Ancient Geography*, an appellation distinguishing two towns of Africa; the one called "Collops Parva," appears to have been the same with *Cullucitana*, situate E. of the Sinus Numidicus; the other, called "Collops Magna," was, according to Ptolemy, the same with *Callu*, and situated N.W. of the same gulf.

COLLOQUIA, in *Ecclesiastical History*, a name given in Switzerland to assemblies of the protestant Grison clergy. Each league is divided into a certain number of districts, the ministers of which assemble twice every year; and these assemblies are called *colloquia*. Each colloquium has its president, and each league a superintendent, called a dean. The supreme authority in spiritual concerns is vested in the synod, which is composed of the three deans, and the clergy of each league; the synod assembles every year alternately in each of the three leagues. Candidates for holy orders are examined before the synod. The necessary qualification for admission into the church, ought to be the knowledge of Hebrew, Greek, and Latin; but many are ordained without the least acquaintance with either of these languages. Formerly Latin was solely used, as well in the debates of the synod, as for the purpose of examining the candidates; but at present that tongue is more and more disused, and German is employed in its stead. See **GRISONS**.

COLLOQUIUM, in *Læv*, (*a colloquendo*), a talking together, or affirming of a thing, laid in declarations for words in actions of slander, &c.

COLLUCIANISTÆ, in *Church History*, a designation given to the Arians, from the martyr Lucian, a presbyter of Antioch.

COLLUM, in *Anatomy*. See **NECK**, and **CERVIX**.

COLLURIO, in *Ornithology*, the name given by Brisson to the *Lanius Collurio* of the Linnæan *Fauna Suecica*; red backed shrike of English writers.

COLLURIO madagascariensis, of Brisson, the hook-billed shrike, *lanius curvirostris*.

COLLUSION, a secret understanding between two parties, who plead, or proceed, fraudulently against each other, to the prejudice of a third. This collusion is either apparent, when it shows itself on the face of the act; or more commonly, it is secret and artfully concealed by a show of honesty. This is a practice which the law abhors; and, therefore, when detected, it makes void all things dependent upon it, though otherwise in themselves good. Co. Litt. 109. 360. Plowd. 54. Collusion may sometimes be tried in the same action, wherein the covin is, and sometimes in another action, as for lands aliened in mortmain by a *quale jus*; and where it is apparent, the proof of it is unnecessary; but when it is secret, it must be proved by witnesses, and found by a jury like other matters of fact. 9 Rep. 33. The statute of Westm. 2. 13 Ed. 1. c. 33. gives the writ *quale jus*, and inquiry in these cases; and there are several other statutes relating to deeds, made by collusion and fraud. The cases particularly mentioned by the statute of Westm. 2. are of *quare impedit*, *assise*, &c. which one corporation brings against another, with intent to recover the land or advowson, for which the writ is brought, held in mortmain, &c. See **FRAUD**.

In the canon law, collusion, in matters of benefices, va-

cates the benefice, and incapacitates the person from holding any benefice at all.

COLLUTHIANS, in *Ecclesiastical History*, a religious sect, which rose about the beginning of the fourth century; on occasion of the indulgence shewn to Arius by Alexander, patriarch of Alexandria.

Several people being scandalized at so much condescension; and, among the rest, Colluthus, a priest of the same city; he hence took a pretence for holding separate assemblies, and by degrees proceeded to the ordination of priests, as if he had been a bishop; pretending a necessity for this authority, in order to oppose Arius. To his schism he added heresy; teaching, that God did not create the wicked; that he was not author of the evils that befall men, &c.—He was condemned by a council held at Alexandria by Osius, in the year 330.

COLLUTHUS, in *Biography*, a presbyter of Alexandria, was founder of the temporary Christian sect, at the beginning of the fourth century, above-mentioned. By the decrees of the council held by Osius, Colluthus was deposed of the episcopal honours with which he had invested himself, and the presbyters whom he had ordained were degraded. Colluthus submitted to the decree, and returned quietly to the duties of his office as a parochial presbyter; his followers likewise re-united themselves to the orthodox church. Noniv. Dict. Hist.

COLLUTION, *Collutio*, in *Medical Writers*, is sometimes used for the washing of the mouth, particularly, when done to clean or fasten bad or loose teeth; or free the gums, &c. from ulcers.

COLLUVIES, a term which Calcott and other writers on the universal deluge have applied to the fluid mafs, into which, according to their opinion, the strata of the antediluvian earth were dissolved, and their constituent corpuscles separated. See **DELUGE**.

COLLYBUS, $\kappa\omicron\lambda\lambda\upsilon\beta\omicron\varsigma$, in *Antiquity*, the same with what is now called the rate of exchange.

COLLYRÆ, or **COLLYRIDES**, a certain ornament of hair, worn by women on their necks. It was made up in the form of the small, roundish, cakes, called $\kappa\omicron\lambda\lambda\upsilon\rho\alpha\iota$, *collyre*.

COLLYRIDIANs, in *Church History*, a sect, towards the close of the fourth century, denominated from a little cake, called by the Greeks $\kappa\omicron\lambda\lambda\upsilon\rho\iota\delta\iota\alpha\iota$, *collyridia*, which they offered to the Virgin Mary.

This sect, it seems, consisted chiefly of Arabian women, who brought it from Thrace to Arabia, and who, out of an extravagance of devotion to the Virgin, met on a certain day in the year, to celebrate a solemn feast, and to render divine honours to Mary as to a goddess; eating the cake which they offered in her name.—St. Epiphanius, who relates the history of this superstitious ceremony, ridicules it. They sprung up in opposition to the Aatidico-Marianites.

COLLYRIUM, $\kappa\omicron\lambda\lambda\upsilon\rho\iota\omicron\nu$. This term was formerly applied, to any medicament, solid, or liquid, employed to restrain fluxions; but it is now entirely confined to wet applications, topically applied for this purpose in complaints of the eyes.

COLLYRIUM is also a name given to unguents used for the same purpose; as unguent of tully, and several others.

COLLYRIUM is also a denomination given, though improperly, to some liquid medicines used against venereal ulcers.

COLLYRIUM Samium. See **SAMIA terra**.

COLLY-WESTON Slate, a whitish kind of micaceous grit

grit stone, which splits into very thin lamina, and is much used for slating of buildings in the eastern and some of the midland counties of England; it is the produce of a stratum situated not far in the series from the Oalite or Ketton stone, so well known to builders. In this stratum, particularly near Stonesfield, in Oxfordshire, bones of animals of some unknown kind are frequently found lodged. See SLATE.

COLM, in *Geography*, a small island of Scotland, in the Frith of Forth, six miles S.E. of Dumferline.

COLMAN, GEORGE, in *Biography*, an English writer, was the son of Mr. Thomas Colman, British resident at the court of the duke of Tuscany. He was born at Florence about the year 1733. He received his school education at Westminster; and was entered as student at Christ-church, Oxford, where he engaged with Bonnet Thornton, in writing "the Connoisseur," a periodical paper of considerable merit, which was afterwards published in four volumes, 12mo. This work is remarkable for the humorous delineations of the manners of the age, and displays classical reading and taste. On leaving the university he entered at Lincoln's Inn, and was in due course called to the bar, but never followed his profession. In 1760, he produced two dramatic pieces which were received with great success, the first was entitled, "Polly Honeycombe," and the other "the Jealous Wife;" this last still keeps its place on the stage. In 1764, lord Bath died and left Mr. Colman a handsome annuity, which was increased on the death of general Pulteney, in the year 1767. In conjunction with Garrick, he brought out the "Clandestine Marriage," a comedy of great merit, and which maintains an undiminished reputation. In 1768, he purchased a share of the Covent Garden theatre; this, however, he soon disposed of, and purchased Mr. Foote's theatre in the Haymarket, which he held till his death in 1794, though he had for the five preceding years been incapable of any business, owing to a paralytic stroke with which he was seized in 1789, and which affected his understanding in such a manner as to bring on derangement and idiocy. Mr. Colman translated Terence's plays into a sort of blank verse: also "Horace's Art of Poetry," which added to his reputation as a classical scholar. In 1787, he collected, in three small volumes, a variety of pieces which he had published at different times, under the title of "Prose on several occasions, accompanied with some pieces of verse." Gen. Biog.

COLMAR, in *Geography*, a town of Germany, in the duchy of Holstein, five miles S.E. of Gluckstadt.

COLMAR, a large and well built town of France, and capital of the department of the Upper Rhine, seated on the river Recht, and surrounded by a wall, flanked with towers. It has a prefect and four courts of justice. The town contains 13,376, and the canton 14,429 inhabitants; the territory includes 55 kilometres, and two communes; 10½ leagues N. of Bâle. The principal trade of the inhabitants of Colmar, who are said to be very industrious, is in corn, and wine; and their chief manufactures are those of woollen cloth, callico prints, stockings, hardware, and gun-powder. The district consists of 142 communes or townships, distributed into 13 cantons, and comprehending a population of 144,821 inhabitants. Its whole territory includes 1680 kilometres. It has silver, copper, lead, antimony, arsenic, and beautiful crystal mines; and also a manufacture of gold and lace. N. lat. 48° 4' 44". E. long. 7° 22' 11".

COLMARS, a town of France, in the department of the Lower Alps, and chief place of a canton, in the district of Castellane; 22 miles N. of it. The place contains 898, and the canton 3585 inhabitants; the territory includes 285 kilometres and five communes.

COLMBERG, or KOLBERG, a town of Germany, in

the circle of Franconia, and principality of Anspach; 9 miles N.W. of it.

COLME, LA, a river of France, branching from the river, AA, at Watte, in the department of the Straits of Calais.

COLMENAR, a town of Spain, in Old Castile, on the confines of New Castile; 7 leagues N.W. of Talavera de la Reina.—Also, a town of Spain in New Castile, five leagues N.E. of Elcurial.

COLMITZ, a town of Germany, in the archduchy of Austria, four miles S.S.W. of Drossendorf.

COLMWORTH, a rectory in the county of Bedford, and hundred of Barford: the lofty spire of its steeple forms a very conspicuous object to the surrounding country. In the Government Trigonometrical Survey in 1799, its situation was determined by observations from Lilly-Hoe station, distant 97 617 feet, and bearing 0° 12' 52" S.E. from the parallel to the meridian of Greenwich; and from Lidlington station 75,944 feet; whence is deduced its latitude 52° 12' 49".3 N. and its longitude 22' 27", or 1^m 29'.8 W. of Greenwich.

COLN, a river of England, which passes by Uxbridge and Cobnook, and runs into the Thames, near Staines, separating the county of Middlesex from Buckinghamshire. The clearness and purity of the water of this river, issuing almost entirely in springs out of the chalk hills of Hertfordshire, have always been proverbial. This circumstance probably occasioned the cutting, at some distant periods, of two channels many miles in length, for diverting part of its waters across Hownlow-heath to Twickenham, and into Bushey-park; and a very principal part of the design of the Paddington branch of the Grand Junction Canal, in latter times, was for diverting part of its limpid streams, in order to supply the metropolis with water, to which purpose it is admirably adapted.

COLN, a river of Essex, which is navigable from the mouth of the Thames at Mersey island up to the town of Colchester. See CANAL.

COLN, a river which runs into the Thames at Cricklade.

COLNBROOK, a town of England, in the county of Bucks, on the river Coln, with a weekly market on Wednesday, three miles E. of Windfor, and 17 W. from London.

COLNE, a considerable market-town of Lancashire, England, is advantageously situated on a dry and elevated ridge. This place, says Dr. Whitaker, "is unquestionably the *colonia* of the anonymous Ravennes, and was probably never abandoned entirely, in the long and obscure period of Saxon history." At this place, there have been several Roman coins, and other antiquities found. The church is a spacious structure, and appears to have been "referred about the time of Henry VII or VIII." Here are a market on Wednesday, and two annual fairs. Colne is 218 miles N. of London, and contains 782 houses, with 3626 inhabitants. This town is situated in the hundred of Blackburn, near to the grand ridge on its western side, and also to the Leeds and Liverpool canal, and to the famous Foulridge tunnel upon it. It was once an object of contemplation to conduct a branch of the Rochdale canal to this town; but it was never accomplished. Whitaker's History of Whalley, 4to. See CANAL.

COLNUD, *de Cayenne*, of Buffon, in *Cornitology*, the bare-necked crow, *corvus nudus*.

COLOMBAUDE, the name given by Buffon to *motacilla atricapilla*, or black cap.

COLO, in *Geography*, a town of Poland, in the palatinate of Kalisch, 20 miles N. of Kalisch.

COLO, in *Ancient Geography*, a Roman colony, near the city

city of Constantina, in the kingdom of Algiers, in Africa: the ruins of it now remain, having a castle on a very high rock towards the sea-coast, with a garrison, under the command of an aga; under the protection of which is a small French factory, that deals with the Moors for hides, wax, and wool. The mountains of Colo abound with a large and fierce kind of monkeys, which the Moors have the art of catching with great facility.

COLOBI, a people of Africa, placed by Ptolemy in the Tr. *godytic* tract.

COLOBIUM, *Kolobos*, from *kolos*, I mutilate, among the *Andarts*, an upper garment, without sleeves, longer than the tunic.

COLOBOMA, in *Medical Writers*, is used for the preternatural growing together of the lips, or eyelids, or for the adhesion of the ears to the head.

COLOBON PROMONTORIUM, in *Ancient Geography*, a promontory of Ethiopia, near Egypt, placed by Strabo and Ptolemy in the Arabic gulf.

COLOBONA, a town of Spain, in Bætica, placed by Pliny in the district of Hispætis: now Trebuxena.

COLOBRASUS, a town of Afiæ, situate in the interior part of Cileæ Montana, which, according to Ptolemy, was a country of Pamohyia.

COLOCASIA, in *Botany*, Clus. See *Arum Colocasia*.

COLOCASITES, in *Ancient Geography*, an island of the Red sea, on the coast of Azania, a country of Ethiopia, according to Pliny.

COLOCOLO, in *Ornithology*, a name given by the people of the Philippine islands, to a bird called also there *castil*, and by some authors the *water raven*, *corvus fluviatilis*. This bird, as it is described in the Philosophical Transactions (n. 285), "is of the shape of a common raven, but is truly an amphibious bird, living more of its time under water than in the air; it is black in colour; its neck is remarkably long, and it feeds on fish, which it hunts under water, as they do one another; it feeds likewise on frogs, serpents, and shell-fish. It is common to see it under water in clear rivers, where it seems perfectly at ease, and runs about with great swiftness; at times it comes up to the surface, and dries its wings in the air and sunshine." It is understood by naturalists pretty generally, that the colocolo of the Philippines is no other than the common corvorant, *pelecanus carbo*, a bird known to inhabit moist parts of the world, and to delight especially in maritime situations, or in marshes, and other watery places, near the sea-coast.

COLOCYNTHIS, *COLOCYNTHIDA*, *Bitter Apple*, in the *Materia Medica*. The colocynth is a species of gourd (*cucumis colocynthis*, Linn.) brought from Aleppo and Cyprus, of a globular shape, about the size of the fist, white, smooth, of a fungous texture, divided internally into large cells, which contain a number of oblong seeds.

The pulp, which is the part used medicinally, is intensely bitter, nauseous, and acrid. It contains a remarkably large portion of mucilage so as to render slimy a considerable quantity of water when boiled with it; and, on this account too, the spirituous tincture is too thick to pass through a paper filter.

The colocynth, taken in substance, without any mixture or preparation, is one of the most violent purgatives that we are acquainted with, producing, when in a large dose (that is, when more than eight or ten grains), very severe griping pains, and often a discharge of blood, and leaving for some days symptoms resembling those of dysentery. It is said, too, to act upon the bowels when applied externally to the abdomen.

The activity of the colocynth renders it a valuable medi-

cine, when used with caution. It is seldom or never employed by itself, but is mix'd with aloes, and other purgatives, and much adds to their efficacy.

The only preparation of it retained in the London Pharmacopœia, is the extract (*extractum colocynthis composium olim est catharticum*), which is prepared by digesting in proof spirit, colocynth, aloes, scammony, and cardamom seeds, and afterwards evaporating the tincture to the proper consistence. This is one of the most certain and powerful purgatives we are acquainted with, and generally operates without much griping or inconvenience. It may be properly combined with calomel, if necessary, or, in cases of spasmodic pain of the bowels, with opium.

COLOCYNTHIS, in *Botany*. Tourn. Bauh. Pin. Ray. Moris. See *Cucumis colocynthis*.—Plum. See *TRICHOSANTHES amara*.

COLOCZA, in *Geography*, a town of Hungary, on the Danube, the see of an archbishop. This was formerly an important place, but it is now sunk into decay, in consequence of repeated wars; 136 miles S.E. of Vienna. N. lat. 46° 33'. E. long. 18° 36'.

COLODI, a town of Italy, in the republic of Lucca; 7 miles from Lucca.

COLOE, in *Ancient Geography*, a marsh of Ethiopia, according to Ptolemy, which, he says, was the source of the river Aitapis.—Also, a town, situated, according to Ptolemy, in the interior of Ethiopia; but, according to Arrian, it was a maritime town, and carried on a considerable commerce in ivory.

COLOEPHRYGES, a people of Greece, in Bœotia, called also *Anticondyles*, according to Steph. Byz.

COLOEPHRYX MONS, a mountain of Bœotia, Hefychius.

COLOES, *Enli Gheli*, a lake of Asia Minor, in Lydia, according to Strabo; called *Gigæa* by Homer. It was two leagues, or 40 stadia, to the N.E. of Sardes. Diana, furnished by the tombs of the kings of Lydia, and, among others, that of Aliattes, described by Herodotus, and compared by him with the grandest works of the Babylonians and Egyptians.

COLOGENAR, a town of Asia, situate near the Euphrates, and the town of Edessa.

COLOGNA, in *Geography*, a town of Italy, in the Paduan; 15 miles from Vicenza.

COLOGNE, PETER DE, in *Biography*, a protestant minister at Metz, in the 16th century. He was born at Ghent, and educated at Paris, from whence, at the advice of Robert Stevens, he retired to Geneva, to avail himself of the instructions of John Calvin, who persuaded him to devote his life to the work of the ministry. He embarked in the protestant cause with great zeal and ardour, and the superiority of his talents above those of his contemporaries, recommended him to the peculiar friendship of Calvin and Beza. He commenced his ministerial functions at Metz, in the year 1558, where he continued in the exercise of them either openly, or from house to house, in a private way, during the reigns of Francis II. and Charles IX. In the performance of his duty, he was occasionally subjected to the miseries of imprisonment and exile, until the dispersion of the protestant church at Metz, in 1659. From this town he went to Heidelberg, where he undertook the charge of a congregation, and where he died while he was a young man. He was the author of some original works, and translated others from the German into the French language, but as they were mostly on temporary subjects, it is not necessary to enumerate them. *Nouv. Dict. Hist.*

COLOGNE, in *Geography*, an archi-episcopal electorate of Germany, in the circle of the Lower Rhine, divided into several districts by other estates, and deriving its name from the city of Cologne. It was a bishopric in the year 314, and, in 799, was erected into an archbishopric by Charlemagne. In the ancient constitution of Germany, the archbishop assumed the title of born legate of the holy see, and arch-chancellor of the sacred empire for Italy. He gave his vote after the elector of Treves, and sat at the right hand of the emperor, at assemblies held in his own diocese, in Gaul, or in Italy. The metropolitan church, and chapter, which is composed of 25 canons, and 36 dignities, are at Cologne. Since the French revolution, and the subsequent arrangement of its territories, Cologne is a district of Roer, or Roor, comprehending 10 cantons, *viz.* Cologne, Bergheim, Brühl, Dormagen, Eifen, Juliers, Kerpen, Lechnich, Weyden, Zulpich, which include 204 communes, 1375 kilometres, and 137,215 inhabitants. Although this electorate is reckoned one of the most fertile countries of Europe, the bigotry, ignorance, and idleness of its inhabitants, who are mostly Roman Catholics, prevent its deriving those advantages from its productions, and particularly its commerce, which might reasonably be expected.

COLOGNE, the capital of the archbishopric above mentioned, and formerly one of the free and imperial cities of Germany, in the circle of Westphalia. It was taken possession of by the French in 1794, and is now the capital of the district that bears its name in the French department of Roer, and is said to contain 38,344 inhabitants. Cologne is situated, in the form of a crescent, on the banks of the Rhine, and fortified in the ancient manner; but its walls are in so decayed and tottering a state, that they are incapable of affording it any defence. The whole of its length, along the river, is about $\frac{3}{4}$ miles, two-thirds of which space is uninhabited; several of the squares and streets more resembling a field, or an uncultivated garden, than parts of an inhabited city. In traversing its environs one may observe more than 150 miserable farm-houses, with gardens, which furnish the city with all sorts of greens, butter, cheese, milk, &c. The streets are narrow, winding, and gloomy, and most of the houses are very high, old, and ruinous; and yet this city is said to contain, within its compass, more churches, chapels, and monasteries, than there are days in the year. The Roman Catholic university scarcely merits the appellation. The number of beggars that disgrace its police is very great, and it is said, that the propensity to idleness, gluttony, and begging, which prevails through the city and adjacent country, is sanctioned and encouraged by the example of the different orders of monks; whose chief object is to keep the people, who, with the exception of a few Protestant families, are Roman Catholics, in a state of ignorance and superstition. Two thirds of the inhabitants are either professed beggars, or ecclesiastics. The other third consists of a few patricians, merchants, and mechanics, on the produce of whose exertions and industry the rest live.

Cologne, upon the whole, is at least two centuries behind the other parts of Germany, with regard to improvement in the arts and sciences. Although no city in Germany is more favourably situated for commerce, the natural bigotry and idleness of the inhabitants lead them to forego the benefits which their situation affords them; and their trade has dwindled away to the manufacture of a few ribbands, stockings, lace, and tobacco. The vessels that may be always seen in the port of Cologne are very numerous; the quay, more than $\frac{1}{2}$ mile long, is continually crowded with ships; but the goods on board are almost wholly the property of foreign merchants. About a fortnight before

the fair at Frankfort begins, there is a great concourse of these merchants at Cologne, who repair daily from thence to Frankfort, by means of two commodious vessels containing from 150 to 200 passengers, which perform this voyage every other day during the fair. The Jews were expelled from Cologne in the year 1485, and from that remote period not one of them has ever obtained leave to settle there, or dared even to enter the city without permission of the magistrate. Under the old police, if a Jew came into the city, he was accompanied by a guard during his stay, and obliged to pay a duet for every hour of his continuance there. In the year 1618, the Protestants were all expelled, but some years after they obtained permission to return. The magistrates indeed gave them leave to erect a place of worship, which was destroyed by the infuriated mob as soon as it was finished. Since that event they have erected for themselves several handsome churches at Mulheim, three miles from Cologne, on the right bank of the Rhine. The trifling commerce of Cologne has been confined to a few Protestant families ever since the period of their return, who, it is observed, are the only opulent inhabitants of the place. The wealth of the churches at Cologne, at least before it was taken possession of by its new occupiers, was immense, particularly that of the cathedral. These churches are repositories of various relics that are held in high estimation by the superstitious catholics. The theatre is a roomy building, but not elegant. The town-house is an irregular stone edifice, awkward and in a ruinous state. The arsenal occupies part of a very narrow street; its contents are chiefly ancient arms, not proper for modern use; and the building itself is in a state of decay. The dealers of Nuremberg and Augsburg bring their toys in large quantities to Cologne for exportation to Holland, England, and America. The Spaniards and Portuguese carry on a very profitable trade with them in both the Indies. The inhabitants of Cologne derive a very considerable advantage from the importation of coals out of the adjacent countries of Berg, the electorate of Treves, the principalities of Saarbruck, and duchy of Deuxponts, which come by the Saar down the Moselle and the Rhine, and supply the want of wood-fuel, that is very scarce about Cologne. Some of these coals are round and large, and another sort consists of dust, which is mixed with clay and water, and formed into small cakes, manufactured in summer; and which, being gradually hardened by the heat of the sun, are stored up in large magazines erected for that purpose. These coal-cakes are sold at 15 shivers (about 1s. English money) per hundred; and it is said, that 100 of them will go as far as three bushels. Near this city some pseudo-volcanic remains have been traced, which are thought to be such as are mentioned by Tacitus at the close of the 13th book of his *Annals*, the effects of subterranean fire which ravaged the country of the Juhones. N. lat. $50^{\circ} 35' 21''$. E. long. $6^{\circ} 55'$.

COLOGNE, a town of France, in the department of Gers, and chief place of a canton, in the district of Lombes; six leagues E. of Auch. The place contains 769, and the canton 6096 inhabitants; the territory comprehends 117 $\frac{1}{2}$ kilometres, and 17 communes.

COLOGNE Earth, a substance used in painting, as a water colour, much approaching to amber in its structure, and of a deep brown. It has generally been esteemed a genuine earth, but has since discovered to contain a great deal of vegetable matter, and, indeed, it is a very singular substance.

It never constitutes an entire stratum in the earth, but is lodged among other strata in large flat detached masses. It is moderately dry, while in the earth, and of a soft

crumbly texture. When dried, it is of a deep, dusky brown, of a very close, compact, and fine texture, and very remarkably light; it is of a smooth, even surface, dry, but not harsh to the touch, crumbles easily to pieces between the fingers, and slightly stains the hands; it adheres firmly to the tongue, but not at all resembling the albugency of the boles, or any thing else of the mineral kingdom, but plainly resembling the taste of oak bark. It makes no effervescence with acids; if thrown into water, it swims on the surface, till thoroughly wetted; and if brought into contact with burning coals, it takes fire and burns of itself, till reduced to yellowish ashes.

It is easy to discern from this account, that, though this is generally esteemed an earth, and known to the world by no other name, it is no pure native fossil, but contains more vegetable than mineral matter, and owes its origin to the remains of wood which has been long buried in the earth. It is dug in Germany and France; the quantities consumed in painting, in London, are brought from Cologne, where it is found very plentifully; but our own kingdom is not without it, it being found near Birmingham, and on Mendip hills in Somersetshire; but what has been yet found there is not so pure or fine, as that imported from Cologne. Hill's Hist. of Fossils, p. 64. and Da Costa's Hist. of Fossils, p. 121.

COLOGNOLI, in *Geography*, a town of Italy, in the duchy of Tuscany; 6 miles E. of Leghorn.

COLOKITIA, or **KOLOKITIA**, a town of European Turkey, on the southern coast of the Morea, in a gulf to which it gives name: 25 miles S.E. of Mistra. N. lat. 36° 47'. E. long. 22° 34'.

COLOMAY, a town of Poland, in the palatinate of Red Russia; 5 miles N.E. of Halez.

COLOMBA, in the *Materia Medica*. See **COLUMBO**.

COLOMBEL, **NICOLAS**, in *Biography*, a French painter who was born in 1646, at Sotteville near Rouen, and became the scholar of Le Sueur, under whom he studied several years; he then went to Italy, where he assiduously copied the works of Raffaele and Nicolo Poussin; but though he enjoyed every advantage of education, and laboured to form his style upon the model of those great masters, the poverty of his genius ever appeared; and his pictures, though correctly drawn and carefully finished, generally wanted that elevation of thought and striking expression, which can alone give value to historic painting. However, in 1682, he sent four pictures which he had painted at Rome to Paris, and thereby gained sufficient reputation to cause his being chosen a member of the Academy upon his return to Paris in 1694. One of his most esteemed pictures is an "Orpheus playing on his Lyre," in the apartment of the menagerie in the royal palace. He died in the year 1717. D'Argenville.

COLOMBES, in *Geography*, a town of France, in the department of Paris, and chief place of a canton, in the district of St. Denis; 1½ league N.W. of Paris.

COLOMBEY, a town of France, in the department of the Meurthe, and chief place of a canton, in the district of Toul; 15 miles S.W. of Nancy. The place contains 858 and the canton 12,887 inhabitants; the territory includes 315 kilometers and 32 communes.

COLOMBIEN, **DE**, in *Biography*. See **VALENTINE**.

COLOMBIER, in *Geography*, a town of France, in the department of the Upper Saone, and chief place of a canton, in the district of Vesoul; four miles N. E. of Vesoul.

COLOMBIER, a town of Switzerland, in the principality of Neuchatel; two miles S.W. of Neuchatel.

COLOMBIERE, **CLAUDE DE LA**, in *Biography*, a

celebrated French Jesuit, was born near Lyons, in which city he prosecuted his studies, devoting most of his time to rhetoric and theology. Of the former branch of science he became a professor, and in the latter he was distinguished as a popular and impressive preacher. In this character he was noticed at the court of the duke of York, afterwards James II, of England, being made chaplain and confessor to the duches, until he was banished under suspicion of being engaged in a conspiracy. He returned to his native country in the year 1682, where he died at the age of 41. Colombiere published six volumes of sermons, which are elegant, pious, and simple; they have been often reprinted. He published also a "Collection of Orations" in Latin, delivered by the author as professor of rhetoric; a volume of "Moral Reflections;" two volumes of "Spiritual Letters;" and "A System and Office for the Solemnity of the Worship of the Heart of Jesus," which the Jesuits employed a considerable time in every Catholic country, as a powerful instrument in favour of the papal cause. Patru, a well known writer, describes Colombiere as one who thoroughly understood the nicest refinements of the French language. Nouv. Dict. Hist.

COLOMBINI, **COSIMO**, an engraver of Florence, who engraved a great part of the portraits of painters inserted in the magnificent work of the "Museum Florentinum." He flourished about 1754. Strutt. Heineken.

COLOMBONI, **DON ANGIOL MARIA**, a very celebrated painter of miniature and natural history, was born at Gubbio in the year 1608, and at a very early period of life became a monk of the order of Mount Oliveto. He made considerable progress in literature, and in the mathematics, and published at Bologna, in the year 1699, a book on Sundialling, entitled "Pratica Gnomonica, ovvero Tavole, colle quali ciascuno agevolmente puo far da se gli Orologi da Sole." But he was not less admired for his miniatures, and for his excellent drawings of herbs, flowers, and birds, which he drew with such taste and correctness, and finished with such extraordinary delicacy and softness, that he was styled the Giovanni da Udine of his time, and the great Guercino used to call him the Raffaele of his profession. He left two volumes of these drawings of birds, in which not only the beautiful colours and the delicacy of the plumage were admirably represented, but, what was more extraordinary, each appeared exactly in the attitude most usual to it or most characteristic. He spent great part of his life in Bologna, highly esteemed, and died in the place of his nativity in the year 1672. Bildinucci.

COLOMBRARO, in *Geography*, a town of Naples, in the province of Basilicata; 4½ miles S.S.W. of Turfi.

COLOMIES, **PAUL**, in *Biography*, was born at Rochelle; he embraced the Protestant religion, and followed his friend Isaac Vossius into England, where he attached himself to the cause of episcopacy, and even attacked the party among whom he had been educated, in a work entitled "Theologorum Presbyterianorum Icon," which raised him many enemies. He was, however, rewarded by being made librarian at Lambeth, and reader at the episcopal French church in London. Here he died in January 1692, leaving the reputation of great skill in bibliography. He was author of "Gallia Orientalis," in 4to. which was an account of Frenchmen eminent for oriental learning; of a similar work respecting Italy and Spain, with many others of considerable note at the time in which he flourished. Bayle.

COLOMNA, **FABIUS**. See **COLUMNA**.

COLON, in *Anatomy*, from *κολος*, *holos*; is a name applied to the greater part of the large intestine. See **INTESTINE**.

COLON, in *Grammar*, a point, or character, formed thus (:) serving to mark a pause, and to divide the members of a period. See POINTING. See also PERIOD, COMMA, and SEMICOLON.

Grammarians generally assign the use of a colon to be to mark the middle of a period; or to conclude a sense less perfect than the dot, or period; but a sense less perfect than the period, is an expression extremely vague and indeterminate.

Others say, a colon is to be used when the sense is perfect, but the sentence not concluded; but neither is this sufficiently clear and express. Add to this, that in practice, our best writers confound the colon with the semicolon.

F. Buffier attempts to fix the use of the colon; but he does not much distinguish it from the semicolon: he prescribes the use of either, indifferently, and calls them by a common name, *intermediate pointings*; as being mediums between the comma, and full point, or period. Their use, according to this author, is to distinguish the supernumerary members of a period. By supernumerary members are meant such as the precedent ones do not raise any expectation of; *i. e.* such parts as have indeed a dependence on what goes before, even though what goes before has a complete sense, independent hereon: *v. gr.* "the Augustan age was so eminent for good poets, that they have served as models to all others; yet did it not yield any good tragic poets;" where the supernumerary member, and the use of the colon, are obvious. The most obvious and sensible use of the colon, he adds, is, when the supernumerary member is distinguished by some conjunction; as, "notwithstanding, however, but, except that, unless, inasmuch as, yet, since, the rather as, provided that," &c. Some, indeed, use the colon in the middle of long periods, without any regard to supernumerary members: which custom was probably introduced to mark, that the breath is here to be taken almost as much as in a common period, in the place where the supernumerary period commences. But this, at best, is arbitrary; and the intermediate pointings may always be omitted in a period, if there be no supernumerary member, *i. e.* if there be no subsequent member, but what is expected from the precedent. As to the occasions where the colon is to be used, rather than the semicolon, there is nothing precise to be said of it; except that the colon shews the supernumerary member more detached, and sets it at a greater distance from the rest; and therefore marks a longer pause than the semicolon.

Accordingly, it seems preferable to use the semicolon before conjunctions adverbial, restrictive, conditional, &c. as, "nevertheless, but, excepting that, however, otherwise, provided that." Again, where the supernumerary phrase is not only supposed the precedent, but depend on them for their regimen, and are, as it were, new parts thereof; there the semicolon seems preferable to the colon: *v. gr.* "You are regardless of the goodness of God, who first chose you; a God who is only jealous of your heart for your own happiness; a God who could be equally glorious in destroying you by his justice, as in saving you by his mercy." Or thus: "The discourse consisted of two parts; in the first was shewn the necessity of fighting; in the second, the advantages that would redound from it." But this difference, it must be owned, has a dependence on something that influences all the points, and sways the whole doctrine of punctuation; *viz.* the length, or shortness, of the members and periods: for, when the phrases are long, we point higher than when short.

A later author, in an ingenious discourse, "De Ratione Interpungendi," marks the office of the colon, and its difference from the semicolon, &c. more precisely; a colon, on

his principles, serves to distinguish those conjunct members of a sentence, which are capable of being divided into other members, whereof one at least is conjunct. Thus, in this sentence, "as we cannot discern the shadow moving along the dial-plate, so the advances we make in knowledge are only perceived by the distance gone over;" the two members being both simple, are only separated by a comma: in this, "as we perceive the shadow to have moved, but did not perceive it moving; so our advances in understanding, in that they consist of such minute steps, as are only perceivable by the distance;" the sentence being divided into two equal parts, and those conjunct ones, since they include others, we separate the former by a semicolon, and the latter by commas: but in this, "as we perceive the shadow to have moved along the dial, but did not perceive it moving; and it appears the grass has grown, though nobody ever saw it grow: so the advances we make in knowledge, as they consist of such minute steps, are only perceivable by the distance." The advancement in knowledge is compared to the motion of a shadow, and the growth of grass; which comparison divides the sentence into two principal parts: but since what is said of the movement of the shadow, and likewise of the growth of grass, contains two simple members, they are to be separated by a semicolon; consequently a higher pointing is required to separate them from the other part of the sentence, which they are opposed to; and this is a colon.

Bishop Lowth observes, that a colon distinguishes a member of a sentence, whether simple or compounded, which of itself would make a complete sentence, and so requires a greater pause than a semicolon, yet is followed by an additional part, making a more full and perfect sense. He adds, that a colon may be also used, when a semicolon has preceded, and a greater pause is still necessary, though the sentence be incomplete; and that it is commonly used, when an example, or a speech, is introduced. *Introd. to Eng. Gram. ed. 1772. p. 207.*

COLONA, in *Botany*, Bosc. *Nouv. Dict. Hist. Nat. Cavan. tab. 370.* Class and order, *polyandria monogynia.*

Gen. Ch. *Cal.* five-leaved; leaves linear, coloured on the inside, caducous. *Cor.* Petals five, with a nectareous scale at the base. *Stam.* Filaments numerous, inserted into the top of a pentagonal column. *Pist.* Germ placed at the top of the column, in the centre of the stamens, tetragonous-globular; style longer than the stamens; stigma simple. *Peric.* Drupe globular, with four wings, opening into four parts. *Seeds* oval, two in each division of the drupe. Nearly allied to *Grewia*, and differing chiefly in the structure of the pericarp.

Sp. C. *dentata.* A tree. *Leaves* alternate, almost sessile, oval, toothed, very large. *Flowers* reddish, in axillary, solitary racemes, which sometimes form a panicle. A native of the Philippine islands.

COLONE, in *Ancient Geography*, a town of Asia Minor, in the Troade, placed by Strabo at the distance of 140 stadia from Ilium, in the territory of Lampascus; it was a colony of Milesians.—Also, a town of the same name, placed by Strabo near Chrysa; by d'Anville, S. of Troas.—Also, a town, mentioned by Anaximenes, cited by Strabo, and placed in Erythraea.—Also, a town of Greece, in Messenia; according to Ptolemy; now *Griffo*.—Also, a town of Greece, in the Phocide.—Also, the name of a rock, on the bank of the Thracian Bosphorus, over against the Cyanan island, at the entrance of the Euxine sea.—Also, a town of Greece, in Thessaly.—Also, a promontory near the river Lycus.

COLONEL, the officer who has the chief command of a regiment of horse, foot, dragoons, or artillery. The lieutenant.

tenant-colonel commands it in chief in the absence of the colonel, to whom he is subordinate, as the other officers are in like manner to him, when he is present.

COLONEL of a regiment of horse, is the first officer in it, and commands it when present. His duty consists chiefly in keeping the regiment complete; in having it composed of men and horses that are fit for service; in taking care to have them well exercised and instructed in the different evolutions, so that they may be able, on all occasions, to form themselves suitably to the ground they occupy or act on, or to the manner in which they may wish either to make or receive an attack. In France, Spain, and some other southern nations of Europe, colonels of horse have been usually called *maitres de camp*. But in Germany, and most northern nations, they are called *ritmeisters*.

COLONEL of dragoons. His principal functions are the same as those of a colonel of horse. But he ought to be also in some measure acquainted with the duties of a colonel of infantry, as his men are liable to act either mounted or dismounted.

COLONEL of foot, or infantry. His functions are more extensive and diversified than those of a colonel of horse, as the infantry are employed for a greater variety of purposes, and on a greater diversity of services. Colonels of infantry should be well acquainted with fortification, and with field-engineering (which, however, they seldom or ever are); since such a thorough and comprehensive knowledge of their principles, as enables an officer to apply them expeditiously and judiciously, is the best and safest guide to the proper formation and arrangement of troops in various situations, and to the advantageous occupation of ground and positions. A colonel of infantry should be particularly careful to maintain union and harmony among his officers, and contentment among his men; to acquire the esteem and confidence of both, and to make himself be respected by them; to which nothing contributes more than a steady, uniform, and impartial enforcement of subordination and discipline. He should likewise be peculiarly attentive to the health and comfort of his men.

COLONEL of Artillery; the commander of a battalion of artillery. His duties, when properly understood and attended to, are various and laborious, both in war and peace, and require, in order to be well performed, not only abilities, but also application, knowledge, and experience. He ought to be an able mathematician and mechanic, and should be acquainted with all the duties of an engineer, that are connected with the use and application of artillery in different situations, and to different purposes; the construction of batteries, platforms, field-works, the occupying of positions with artillery, to the best advantage, both as to direct and flanking fires, &c. Whatever situation he may be placed in, or on whatever service he is going, he should understand thoroughly what nature and species of ordnance is best adapted to it. He should be acquainted with all the best and most useful experiments, that have been made with artillery in the different nations of Europe; he should know the greatest distance at which walls can be battered in breach effectually; the different charges of powder, best adapted for different services, and different distances. And he should not only be well acquainted with the wide differences between the ranges of cannon-shot and shells in the air, and those which the parabolic theory gives for them *in vacuo*, but also be able to approximate, nearly to the truth, the distances to which projectiles will go in the air, thrown with given charges of powder, and given degrees of elevation. In short, he ought to know a variety of things, which few officers of artillery actually do know.

COLONEL of Engineers. See the article **ENGINEER**.

COLONEL, Lieutenant, is, as has been already observed the second officer belonging to a regiment, and commands it in the absence of the colonel.

COLONEL General of the French Infantry, or **COLONEL General d'Infanterie Francoise**: an appointment of great trust and authority, which took its birth, or originated, under Francis I. in 1544. It became an immediate gift of the crown, under Henry III. in 1584. It was at last suppressed, because it gave too many prerogatives, and too much power to the person who was invested with it. Under Louis XV. however, it was re-established in 1711, in favour of Louis, the first duke of Chartres. This officer had originally the right of nomination to every commission and place of trust in the infantry. He could order courts martial, and enforce the sentences awarded by them, without any suspension of his power in that respect, by an appeal to a superior tribunal; and he had a company in every regiment of infantry, which was called the colonel general's company.

COLONEL Général d'Infanterie de Suisses et Grisons. This appointment was not held of the crown; but it was almost always given to a prince. It took its rise in right of office under Charles IX. in favour of the son of the countess of Montmorency, killed at the battle of St. Denis. All the Swiss and Grison troops were subordinate to the colonel general, the company *des cent Suisse de la garde* excepted. He appointed colonels and captains. The lieutenants at last assumed, or refused, this right of nomination. But he still retained the right of naming and presenting to the king the officers of the nation, to be included in the promotion of general officers, and enjoyed several other prerogatives.

COLONEL Général de la Cavalerie légère et étrangère. This charge, or employment, was created in right of office under Charles IX. It was, however, known before his time, in 1449, under the title of "capitaine general de la cavalerie Albanoise." Under Louis XIII. there were two such colonels general, one of the French cavalry, and the other of the German cavalry. Though these general officers enjoyed great honours and prerogatives, the generals of the Roman cavalry, under the emperors, were persons of still greater importance. For they had the same authority over the troops and militia, that the kings and dictators had. The emperors treated them in their regulations and constitutions, as seignors of the highest rank, eminence, magnificence, and celebrity. They enjoyed an authority almost absolute, over all military people.

COLONEL General des Dragons, colonel general of dragons. This appointment was created in 1688, by Louis XIV. It was, like the preceding ones, favoured with an attribution of great honours and particular prerogatives.

COLONEL de Troupes Légères, colonel of light troops. This officer ought to be well instructed, both by study and experience, in the art of petty warfare, and the management of detachments. For, as he is almost always responsible for the corps confided to his charge, and forced to take advanced positions in an enemy's country, he is of consequence more exposed to be surprized, taken, or at least beaten.

COLONELLE, COMPAGNIE, the first company in a French regiment.

COLONI, ADAM, called the Old, in *Biography*, a painter who was born at Rotterdam, in 1634, but afterwards resided and died in London, in 1685. The subjects of his pictures were generally wakes, country fairs, rural subjects, and cattle; besides which, he made several copies from the pictures of the Bassans, with success. He had a son called **ADRIAN COLONI** the young, who received instructions from

from his brother-in-law, Van Dyck, in addition to the lessons bestowed on him by his father. He frequently painted the figures in the landscapes of Van Dyck, as well as in those of other masters; and sometimes imitated the touch of Salvator Rosa. At other times he produced pictures of history, but more generally those of cattle, conversations, or landscapes. Adrian died in the year 1701, aged 33. Pilkington.

COLONIA, *Caps*, in *Geography*, lies on the W. coast of Asiatic Turkey, N. of the gulf of Smyrna. N. lat. 39°. E. long. 26° 36'.

COLONIA, in *Ancient Geography*, an episcopal town of Asia, under the metropolis of Sebaste; situate in the first Armenia, and called also *Taxara*.—Also, an episcopal town of Asia, in Cappadocia.—Also, a town of Italy, in Etruria.—Also, a town of the Isle of Albion, in the route from Londinium to Lugwallium ad Vallum, between Cæsaromagus and Villa Faustini, according to the Itinerary of Antonine. Although our antiquarians are divided about the situation of Colonia, it seems, upon the whole, to be most probable that it was at Colchester, on the river Colne, from whence it derived its name.—Also, a town of the Damulii, according to Ptolemy, which some, as Camden and Baxter suppose, to have been Coldingham in the Mers, but which was more probably situated at or near Lanark, in Clydesdale. See COLDINGHAM.

COLONIA, in *Geography*, a town of Istria; five miles S.S.E. of Rovigno.

COLONIA Agrippina Ubiorum, in *Ancient Geography*, a town seated on the banks of the Rhine; now COLOGNE. It was built by the Ubii, when they left Germany to establish themselves in Gaul. Agrippina, the mother of Nero, fixed a colony of veterans in this place, and gave it her name in honour of the place of her birth.

COLONIA Equestris, a town of Gallia Belgica, assigned by Pliiny to the Helvetians; but by Ptolemy to the Sequani. The Itinerary of Antonine marks it under the name of "Equestris," between Bantua and Læca Laufanio. It was also called "Noiodunus," or "Niviodunum;" but when it became a colony, the Romans called it "Colonia Equestris." It is now *Nion*.

COLONIA Flavia, the town called CÆSAREA of *Palestine*.

COLONIA Julia, a town and Roman colony of Germany; now *Bonn*.

COLONIA Julia Celsi, a town of Spain, which was a Roman colony; now a village called *Xelsi*.

COLONIA Julia Hispania, a town and Roman colony of Italy, in Umbria; now *Spello*.

COLONIA Marcia, a town of Spain, which had the title of Roman colony; now *Marchara*.

COLONIA Senensis, a town of Italy, in Etruria, which was a Roman colony; now *Sienna*.

COLONIA Septimanorum Juniorum, a town of Gaul, with the title of colony; now *Béziers*.

COLONIA Trajana, now *Keln*, or *Keln*, was situated at a small distance from the Rhine, and about a mile from *Cleves*.

COLONIA Ulpia, is now *Cleves*, which see.

COLONIDES, called *Colone*, by Ptolemy, a town of Messenia, seated on an eminence on the coast which bore northwards to the west of the gulf of Messenia. Its inhabitants are said to have been conducted under the direction of an oracle, by a person named Colonus, from Attica to this country. In process of time they assumed the manners and language of the Dorians. The mountain Temathæ, called by Pausanias Temathia, commenced towards Colonis, and extended itself towards the north-west, as far as mount Egealcus.

COLONIS, an island of Greece in the Argolic gulf, according to Pliiny.

COLONNA, GIOV. PAOLO, Maestro di Capella di San Petronio di Bologna, in *Biography*, was the son of Antonio Colonna, alias del Corno, a celebrated organ builder of Brescia. He composed but few operas; indeed, we know of but one, *Amleir* in Cipro, for the theatre of Bologna, 1632; but he published about the latter end of the last century many excellent works for the church, of which P. Martin has given a list, to the amount of twelve, in the second volume of his *History of Music*.

It was the opinion of the late Dr. Boyce, that Colonna was Handel's model for choruses accompanied with many instrumental parts, different from the vocal. But it must, however, be owned, that Handel has greatly surpassed his model in energy, fire, and vigour of genius. The psalms of Colonna in eight real vocal parts, published at Bologna in 1694, have been very justly admired for their masterly composition. Paolucci has inserted the hymn, "Pange lingua," set in plain counterpoint of four parts by him, in a manner sufficiently simple and syllabic for the most zealous reformers of church music. His "Sacre lamentationi della settimana santa, a voce sola," published 1689, contain many pleasing and elegant fragments of pathetic recitative, which we should have admired much more if we had not previously been acquainted with the works of Carissimi, who had anticipated not only all the thoughts of Colonna in this species of music, but almost all those of every composer of the present century. The airs of these lamentations are too short to make much impression on the hearer.

Colonna had a controversy with Corelli in 1685, concerning the consecution of fifths in the first movements of the third sonata of his Opera 2da. Every lover of music will be sorry that the charge against Corelli should be well-founded; but it must be owned that the base is indefensible in the passage which has been condemned by Colonna, and was not likely to have passed uncorrected, even in an age much more licentious than that of Corelli.

Antimo Liberati, with whom Colonna was in correspondence at the time of this controversy, seems to defend Corelli's violation of the known rule against the consecution of fifths, in a letter written 1685. "Sopra un teguito di quinte," in which he reasons thus: "If a quaver rest, or even a fermiquaver, were not sufficient to satisfy the rule against fifths and eighths, a composer writing in many parts would have very narrow limits for the expansion of his genius and fancy, or for varying the harmony." But with due respect for the authority of Antimo Liberati, and with peace to the ashes of the gentle Corelli, the passage is unwarrantable, and seems the more inexcusable, as several better bases were easy to find, without altering his design, or distorting the effect of his trebles. It appears that the excellent theorist Berardi had a reverence for the professional erudition of Colonna, by his dedicating to him the seventh chapter of his "Miscellanea Musicale."

COLONNA, MICHAEL ANGELO. See ANGELO.

COLONNA, MARC-ANTONIO, bore arms from an early age in the service of the Spaniards, and rose to great military reputation. He was appointed by pope Pius V. general of his galleys, and served in the famous battle of Lepanto, gained against the Turks in 1571. On his return he pope honoured him with a triumphal entry after the manner of the ancient Roman conquerors. He possessed several high civil posts, as constable of Naples, and viscount of Sicily, and died in Spain in 1584. Moreri.

COLONNA, ASCANIO, was son of Marc Antonio, and educated under his father's roof by the celebrated Murcius.

He

He accompanied his father into Spain, and studied at the universities of Alcalá and Salamanca. Philip II. gave him an abbacy, and he was made cardinal by Sixtus V. At the death of the king his patron, he delivered a funeral oration, which he printed. He was himself a promoter of literature, and collected a magnificent library. Owing to his great skill in canonical law, and the support which he gave to the claims of the Catholic king, he was made viceroy of Catalonia. He afterwards wrote a canonical defence of the pope's conduct in his dispute with the republic of Venice. This and some other letters and harangues he published, and died at Rome in 1628. Moreri.

COLONNA, FÆLIUS. See COLUMNA.

COLONNA, FRANCESCO, was born about the middle of the sixteenth century, probably at Venice, and entered young into the order of Dominicans. The work by which he is chiefly known is "*Hyperotomachia di Poliphilo*," which signifies *the combat of Love in a dream, and the Lover of Polia*. It consists of fable, history, allegory, architecture, mathematics, &c. and is written in a language compounded of words taken from six or seven different languages. It was printed by Aldus in 1499, and a French translation was published in 1549, and has been several times re-printed. The original and translation have been in great request among collectors of books, as well on account of their rarity, as for the sake of the beauty of the numerous wooden cuts with which the work is decorated. Colonna died at an advanced age, at Venice, in the year 1527.

COLONNA, PROSPERO, a distinguished military commander, was younger son of Anthony prince of Salerno, and born about the year 1452. He engaged in the service of Ferdinand king of Naples, and after his death, in that of Charles VIII. king of France. When that prince undertook the conquest of Naples, Colonna, with his cousin Fabrizio, rendered him some signal services, but upon a change of politics, they returned to their former allegiance. Prospero assisted in the recovery of the kingdom of Naples: he was at the battles of Barletta and Garigliano, at which the French were worsted; and he signalized his valour and conduct at a variety of sieges and other military actions. In the year 1515, while attempting to defend the passage of the Adriant, he was made prisoner, and carried to France, but being liberated, he resumed his profession in order to revenge the disgrace that attached to him while a captive. He died in 1523, aged seventy-one, leaving behind him a very high character as a general; he was rather prudent and cautious than formed for remarkable enterprises. Though slow and inactive, he was, by constant vigilance, generally secured from surprize. He was the friend and patron of learned men. Moreri. Robertson's Hist. ch. v. vol. ii.

COLONNA, POMPEO, was brought up by his uncle Prospero, and destined by him for literary pursuits. The young man inclined to the profession of arms, and distinguished himself as a military man till he was compelled to assume the ecclesiastical character. He was made bishop of Rieti, and obtained many lucrative benefices. He was, however, little attentive to the duties of his sacred office, and so regardless of the decorum that ought to be attached to it, that he accepted a challenge, and tore his cassock to pieces that he might not be prevented from fighting. On a false report of the death of pope Julius II. in 1512, Pompeo joined in raising the cry of liberty, and took possession of the capital. For this he was deprived of his benefices, but by the interest of his uncle, matters were again accommodated, and in 1517, he was elevated to the rank of cardinal. Still, however, inclined to turbulent measures, his conduct gave

his enemies the opportunity of charging him with the intention of putting the pope to death, in order that he might succeed to that high dignity: he was accordingly deprived of his offices, in which he was reinstated on account of some important services which he rendered to the reigning pontiff. He was afterwards viceroy of Naples, where he died in 1532. He was esteemed a patron of literature, and wrote a poem "*D. laudibus mulierum*," chiefly in praise of Vittoria Colonna. Moreri. Robertson's Hist. ch. v. vol. ii.

COLONNA, VITTORIA, a learned lady and poetess, was born at Marino in 1490. At the age of seventeen, she married Ferdinand Francis D'Avalos, marquis Pescara, who, by her influence, was dissuaded from accepting the kingdom of Naples, which was offered him after the victory of Pavia, in order to detach him from the service of the emperor Charles V. After his death, which happened in 1525, she lived in retirement, devoting herself to poetry; she kept up, with much credit to herself, a friendly and learned correspondence with some of the most celebrated literary characters of the age. In 1541, she retired to the monastery at Orvieto, and from thence she went to St. Catharine in Viterbo, but in 1547, she returned to Rome, where she died. Her poems have passed through many editions, and have been printed with the commentaries of learned men. Moreri.

COLONNA, in *Geography*, a town of European Turkey in Dalmatia; 24 miles N. of Spalatro.—Alto, a town of Italy, in the Campagna di Roma; 12 miles from Rome.—Alto, a cape of Naples, on the E. coast of Calabria Ultra. N. lat. 35° 6'. E. long. 17° 26'.

COLONNADE, the name given to any range of insulated columns. See PORTICO.

COLONNE, in *Geography*, a town of France, in the department of the Jura, and chief place of a canton in the district of Poligny; 2 leagues W. N. W. of Poligny.

COLONNI, a cape on the coast of the Morea, in the Mediterranean. N. lat. 37° 32'. E. long. 24 11'.

COLONOSSIS, in *Ancient Geography*, a place of Asia, in Lycæonia.

COLONSAÏ, in *Geography*, one of the islands of Scotland, called the Hebrides. It belongs to Argyllshire, and as it is separated from Oranfay, merely by a narrow channel, which is dry at low water, Colonsay and Oranfay may be considered but one island. Although the eminences of the former cannot correctly be termed mountains, they are high, rugged, and covered with heath. The arable land, which consists of about 3000 acres, produces early and tolerable crops, as the soil is light and mixed with sand along the shores; part of this land has lately been converted into pasture, and numbers of black cattle are fed on the two isles. A monastery of Cistercian monks formerly flourished in Colonsay, and the remains of the walls of the abbey gave place some years past to a farm house; a priory attached, stood in Oranfay, where the ruins still remain, and are considered superior to any other religious building in the Hebrides, with the single exception of Icolmkill; there are besides fragments of several chapels in Colonsay. The inhabitants make large quantities of kelp from the seaweed found on the coast; and the banks which surround the islands produce plenty of fine coral. The population is estimated at about 720, and the duke of Argyll is the principal proprietor.

COLONSAÏ, *Little*, an island, and one of the Hébrides, situated between Gometra and Staffa. There are several specimens of basaltic pillars in the Lesser Colonsay, but it has no other inhabitants than one family who attend a few sheep.

COLONUM, a place of Greece, in Attica. Here was a forest

a forest consecrated to the Eumenides. Sophocles, according to Suidas, was born in this place.

COLONUS, an husbandman, or villager, who was bound to pay yearly a certain tribute, or at certain times of the year, to plow some part of the lord's land; and from hence comes the word *colonus*, who is called by the Dutch *boor*.

COLONY, *COLONYA*, is properly a number of persons of all sexes and conditions, transported into a remote province, with a view of remaining there, and for the purpose of cultivating and inhabiting it; but among commercial nations, the term is used in a larger but less proper sense, and applied to the temporary residence of merchants and agents in another country. The word colony originally signified no more than a *farm*, i. e. the habitation of a peasant, *colonus*, with the quantity of land sufficient for the support of his family; "quantum colonus unus arare poterat." It is derived from the Latin word *colos*, I till or cultivate; hence *colonus*, a husbandman, and *colonia*, a body of farmers, sent to cultivate the ground in a distant country, and, by metonymy, the place itself. From the Latin the word has passed, with scarcely any alteration, into the modern languages of the west of Europe.

We may distinguish, generally, four kinds of colonies; *viz.*
 1. Those that serve to ease or discharge the inhabitants of a country, where the people are become too numerous, so that they cannot any longer conveniently subsist together.
 2. Those established by victorious princes and people, in the middle of vanquished nations, to keep them in awe and obedience.
 3. Those that are formed by emigrants, driven from their native country by oppression and persecution to seek a foreign settlement, and to subsist first by agriculture, and afterwards by commerce.
 4. Those that may be called "colonies of commerce;" because trade is the sole occasion and object of them.

To the *first* class we may refer the colonization which took place in the earlier ages of the world, and which served to disseminate the human race, first through the various regions of the east, and afterwards through other more remote parts of the globe. At this early period colonization was of course more frequent than it is at present. The increase of a tribe beyond the limits of a comfortable subsistence upon the lands which were occupied, would be a sufficient motive for inducing the younger members of the society to remove from the prospect or actual pressure of want, to some unoccupied territory. Some authors, however, are of opinion that soon after the deluge, when the descendants of Noah became numerous, a division of the ancient continent and its adjacent islands was made, probably by lot, among the heads of the several families. This opinion seems to be in some measure supported by the authority of Moses, who says, (Gen. x.) on mentioning the children of Eber, that the name of one of them was "Peleg" (division), for in his days was the earth divided." (See DISPERSION.) However this be, the gradual extension of the habitations of mankind must have corresponded with their increase; and it seems to have been unrestrained by claims made upon the uncultivated spots. But this unlimited right of dispersion has long since ceased in most parts of the world; and hence it has become necessary for colonists, who seek new scenes for their labours, either to unite with the natives as friends, or to subdue them by conquest, if the colony is founded upon hostile principles. At a subsequent period, the different states of ancient Greece, such were Athens, Sparta, Corinth, and Argos, possessed territories of very limited extent; and the increase of population gave rise to various emigrations from all those states. The colonies of the Dorians resorted chiefly to Italy and Sicily, which, in

the times preceding the foundation of Rome, were inhabited by barbarous and uncivilized nations; those of the Ionians and Eolians, the two other great tribes of the Greeks, to Asia Minor and the islands of the *Ægean* sea, the inhabitants of which seem at that time to have been pretty much in the same state as those of Sicily and Italy. The emigrations now mentioned, and some others of a similar nature, were undertaken by private individuals, with no authority from the government; and as they were generally directed towards distant and transmarine settlements, they retained but a slight connection with their original countries. The parent state, indeed, considered the colony as a child, at all times entitled to great favour and assistance, and owing in return much gratitude and respect; but, moreover, considered it as an emancipated child over whom no direct authority or jurisdiction was claimed. The colony settled its own form of government, enacted its own laws, elected its own magistrates, and made peace or war with its neighbours as an independent state, which had no occasion to wait for the approbation or consent of the parent city. The colonists, indeed, remembered the land of their fathers with filial affection and respect; they honoured its gods, by offerings of first-fruits to their temples; they retained a predilection for its customs and laws, as well as its religion and language; they yielded to its citizens the place of distinction at public games, and to its priests the holy honour of first inspecting the entrails of sacrifices. In war they generally followed the fortunes of the metropolis, as allies upon equal terms; but as they were perfectly independent, received no protection from her, and often equalled her in resources, they always refused to come forward as auxiliaries, when unfair terms were proposed. Thus, the Sicilian colonies refused to admit an Athenian army into their territories, for the purpose of selling, on an expedition; and, in the Persian war, the republic of Syracuse, when intreated by the Lacedæmonians to aid the common cause, refused to send any assistance, unless their chief magistrate, Gelon, were allowed to command the united forces. Sometimes the parent country, conscious of her superiority and strength, attempted to exact from the colonies, as matter of right, the usual marks of filial attachment. Thus, Corinth was despised by her colony at Corcyra, for her inferiority of wealth and trade; and she endeavoured to obtain by force, the usual tokens of remembrance. The colonists appealed to Athens, who took their part, and retained them as useful allies, especially during the Peloponnesian war. Potidæa, another Corinthian settlement, took the part of Athens, until her impolitic tyranny urged it to throw off the yoke, and appeal to Sparta and Corinth. After a long and severe struggle, the Athenians were successful; sent new colonies to occupy the confiscated and vacant lands; continued their oppressive government; and retained their dominion over Potidæa, until the invasion of Philip. When the progress of Cyrus exposed the Asiatic colonies of Greece to extreme danger, they in vain applied to Sparta for assistance; and, being soon conquered by the Persian monarch, they remained in subjection, until the victories of Platæa and Mycale restored them to freedom; but despairing of long maintaining their independence, they formed a strict alliance with Athens, who availed herself of the opportunity of a general alarm, to propose an universal contribution from all her colonies and allies, for the great purpose of resisting the Persian power. We might cite many other instances to exemplify the independence of the Grecian colonies on the states from which they originated. Nevertheless, the benefits in point of civilization resulting to barbarous countries from colonies of private adventurers, migrating

grating from countries more advanced in the knowledge of those arts which meliorate the condition of human life, have entailed honour on those who imparted them, and claimed returns of respect and gratitude from those on whom they were bestowed. From this mode of colonization, reciprocal advantages have been derived. The natives already in possession of the country, to which colonies have migrated, are benefited by the introduction of new arts; while, at the same time, the adventurers receive the reward of their knowledge, valour, and conduct, by the superior degree of influence which they acquire beyond what they would have possessed if they had remained in their own country. Thus individual adventurers, who have fitted out expeditions at their own charge, and conducted colonies to a permanent settlement by their own skill and valour, have, in some memorable instances, attained even to supreme authority. This seems to have been the case with regard to the colonies anciently established by Ægialeus in Sicily, by Inachus in Argos, by Cærops in Attica, by Janus in Italy, and by Cadmus at Thebes in Greece. From the veneration in which the memory of these adventurers, who were mostly of Egyptian origin, were held, it is evident that they had imported into the countries where they settled great and important improvements. The great literary renown which Athens acquired in progress of time has rendered us better acquainted with its early history; so that we can form some idea of its primitive laws. The regulation of the connexion between the sexes is recorded as being due to Cærops; from whence some etymologists, as Eustathius, deduce the origin of the appellation *Ætes*, by which he was distinguished. The collection of the inhabitants into towns and villages, is said to have been an improvement of his immediate successors, who, it is probable, also introduced the regulation of local jurisdictions, and the division of the land in property among the then existing heads of families, to be inherited by their descendants. This seems to be, in fact, the main foundation of perfect civilization, by introducing this inequality of condition, as some of the families increased or prospered more than others, which, notwithstanding the reveries of some speculative politicians, is absolutely necessary to civilized life. This mode of colonization is seldom attempted in more modern times, because the maritime nations of Europe have laid claim to all heathen lands which their subjects discovered, and have prevented even their own subjects from endeavouring to ameliorate the condition of these countries, by attempting the formation of independent Christian states. The Jesuits had, indeed, formed a considerable establishment for the improvement of the natives in South America; but it gave umbrage to the Portuguese government, and the neglect of military affairs rendered the overthrow an easy undertaking. The Moravian brethren have similar settlements in the most northern parts of America and Europe, where the inhospitality of the climate is such, that the country is not worth contending for. The establishment of the Macedonian dynasties in Asia and Egypt; and, in later times, that of the northern tribes in the southern parts of Europe and of Asia, are signal examples of this mode of colonization. It is notorious, that it was for the establishment of colonies, referred to the first class above-mentioned, that, during the declension of the Roman republic, those torrents of barbarous nations, issuing, for the generality, out of the north, over-ran the Gauls, Italy, and the other southern parts of Europe; and, after several bloody battles, divided it with the ancient inhabitants, and blended their own habits and manners with those of the nations which they subdued, or in which they obtained either temporary or permanent settlements.

To the second class of colonies belong those of a military nature, which served as guards or garrisons, for the maintenance of a conquered country. The Romans recurred to this mode of colonization more frequently than any other nation; and added, to the original motive, that of providing retreats for the aged and worn-out soldiers; as also for the settlement of the poorer classes of Roman citizens. Nor were the interests of the rich forgotten, in the establishment of Roman colonies. The spirit of the Roman laws having restrained the mercantile classes to their proper rank in society, the capital accumulated by their commanders, during the long continued and widely extended successes of the Roman republic, was of course invested in land. The extent of Italy was too small for the capital, thrown, by this means, into agriculture; and the capitalists were therefore obliged to seek new lands, on which it might be employed. It appears that the eastern shores of the Mediterranean sea were, at the time of their falling under the Roman dominion, in the highest possible state of cultivation. The provinces seated on these shores, were, therefore, the scenes of oppression rather than of improvement, and the plunder accumulated there, was transferred to Gaul, and other western provinces, to be employed in the purchase and improvement of land, or in loans to those who resided there. The high rate of interest allowed by the Roman laws, made it also far better to employ money in loans than in commercial speculations, which cannot be supposed, in the restricted and degraded state of Roman commerce, to have yielded the same profit as the former. Seneca, the philosopher, is said to have had, at the time of his death, no less than 600,000 *l.* sterling due to him from the colonists in Britain; the sudden calling in of which produced a rebellion. Besides Rome, like most of the other ancient republics, was originally founded upon an Agrarian law, which divided the public territory in a certain proportion, among the different citizens who composed the state. The course of human affairs, by marriage, by succession, and by alienation, necessarily deranged this original division, and frequently threw the lands, which had been allotted for the maintenance of many different families, into the possession of a single person. To remedy this disorder, a law was made restricting the quantity of land which any citizen could possess to 500 jugera, or about 350 English acres. This law, however, was neglected or evaded, and the inequality of fortunes went on continually increasing. The greater part of the citizens had no land, and without it the manners and customs of those times rendered it difficult for a freeman to maintain his independency. The people, therefore, became clamorous to get land, and the rich and great, we may readily imagine, were determined not to give them any part of theirs. To satisfy the unquiet and clamorous people, it was frequently proposed to send out a new colony. Accordingly, Rome assigned them lands, generally in the conquered provinces of Italy, where, being within the dominions of the republic, they could never form any independent state; but were, at best, merely a sort of corporation, which, though it had the power of enacting by-laws for its own government, was at all times subject to the correcton, jurisdiction, and legislative authority of the mother city. The sending out of a colony of this kind, not only gave some satisfaction to the people, but often established a sort of garrison, too, in a newly conquered province, of which the obedience might otherwise have been doubtful and precarious. Some of these colonies were of a civil, and others of a military nature. In their manners and internal policy, the colonies formed a perfect representation of their great parent; and they were soon endeared to the natives by the ties of friendship and alliance; they effectually disused a reverence for the Roman name, and a desire, which was seldom

dom disappointed, of sharing, in due time, its honours and advantages. A Roman colony, whether we consider the nature of the establishment itself, or the motives for making it, was altogether different from a Greek one. The words, accordingly, which, in the original languages, denote those different establishments, have very different meanings. The Latin word, *colonia*, signifies simply a plantation. The Greek word *κωλονια*, on the contrary, signifies a separation of dwelling, a departure from home, or a going out of the house. In conformity to this distinction of names, we may observe, that the colonial settlements of the Greeks were placed in distant countries, and amongst barbarous tribes. They were established, not in Greece, or in the states immediately in the neighbourhood, which had already been well peopled, but in Gaul, Sicily, and the south of Italy; in Cyrene and Egypt; in Illyria and Asia Minor. The Roman colonies, on the other hand, were at first planted in the immediate vicinity of Rome. During the second Punic war, the city was surrounded by no fewer than 30 establishments of this kind; which served as so many garrisons or advanced posts for her defence. Ancient authors mention no less than 164 colonies settled in Italy, from the foundation of Rome to the death of Augustus; whereas those planted in all the provinces were only 199. From this consideration it appears, that the Italian colonies were materially different in their constitution and uses from the colonies of the provinces. The emigrations from Rome to the conquered towns and lands of Italy, and afterwards of the foreign provinces, were the operations of war and plunder. Whenever an Agrarian division of conquered territory was proclaimed, the discontented citizens presented themselves in a body; and if a sufficient number did not offer to form a legion for retaining the conquest, which they called a colony, the deficiency was supplied from all the tribes by lot. As this system of conquering policy was effected slowly, until the whole of Italy had been subdued, no emigration ever took place to any transmarine, or transalpine countries. Among the Romans there were two kinds of colonies; those sent by the senate, and those that were military, consisting of old soldiers, broken and disabled by the fatigues of war, who were thus provided with lands, as the reward of their services. The colonies sent by the senate were either Roman or Latin, i. e. they were composed of Roman or Latin citizens. The colonies of Roman citizens had the right of suffrages, and could reclaim the rights of citizens whenever they chose to remove to the capital. The Latin colonists lost their rights for ever, nor had they any right of suffrages without an express permission. According to Ulpian (lib. i. D. de Cens.), there were other colonies, which had little more than the name; only enjoying what they called *jus Italicum*, i. e. they were free from the tribute and taxes paid by the provinces; such were the colonies of Tyre, Berytus, Heliopolis, Palmyra, &c. Between all the Roman colonies and the metropolis, there subsisted the closest connexion. The form of colonial government was modelled upon that of Rome. The laws, if not changed at once, were gradually moulded by the spirit of the Roman jurisprudence; the officers were almost all sent from the capital; the mandates of the republic were more promptly obeyed in the provinces than in the city itself;—in a word, the establishments which have been called colonies, and, compared to those of modern times, or of the Greeks, were military stations; garrisons, placed in conquered countries; advanced posts of a great army, of which the commander in chief held his head quarters in Rome, and occasionally made a progress through the different cantonnments. From these settlements taxes were levied, according to a census;

and, after paying the expences of their own government, they transmitted a revenue to the Roman treasury. Men were raised for the Roman army according to a muster-roll. When the grandeur of the Roman name extended across the ocean and the Alps, the rights of citizenship became valuable, as the title to power, honours, and plunder. The allies, or colonial and provincial settlements of Italy, then demanded the communication of this privilege; and the refusal produced that "Social war," which may be justly deemed the end of the regular republican constitution. In consequence of the Julian law, which terminated this war, and of other laws afterwards passed, all the states of Italy, whether allies, colonies, or prefectures, obtained the full rights of Roman citizens. Until the year U.C. 640, no colony but one, which never flourished, had been planted beyond the confines of Italy. The military colonies, introduced by Sylla, and much favoured by Augustus, were remarkable only for a form of government more entirely military than that of the other settlements. All were equally subordinate to the central government, and equally obedient to its decrees.

The first foreign colony which the Romans planted was in Carthage, A.U.C. 710, when Julius Cæsar formed the plan of restoring that deserted city by means of a colonial establishment. The first colony planted in Italy was that of Capua, A.U.C. 4. The practice of sending Roman colonies to the provinces, where they did not enjoy all the privileges of the Italian colonists, was very common after the experiment of Julius Cæsar. He himself transplanted 80,000 citizens in this manner. (Sueton. in Jul. Cæs. c. 42.) After the time of Augustus, who planted 28 colonies in Italy (Suet. in Octav. c. 46.), the custom of planting Italian colonies seems to have been abandoned. His successors did not plant so many as 20; and preferred forming those settlements beyond seas. Livy does not even mention a transmarine or transalpine colony; although he constantly relates the foundation of those in Italy, Dacia and Britain, the most difficult and insecure of the Roman conquests, had only, the former four, and the latter five, Roman colonies. Twenty-five colonies were settled in Spain; and Africa, the most peaceable of all the Roman possessions long before the downfall of the commonwealth, received, after the usurpation of Julius Cæsar, no less than 57 colonies, exclusive of Egypt. From these circumstances we may be led to conclude, that the Italian establishments were founded with different views, and in a different age of the Roman history, from the settlements in the provinces.

M. Vaillant has filled a volume in folio with medals struck by the several colonies, in honour of the emperors who founded them. The ordinary symbol they engraved on their medals was either an eagle, as when the veteran legions were distributed in the colonies; or a labourer holding a plough drawn by a pair of oxen, as when the colony consisted of ordinary inhabitants. On all the medals are seen the names of the Decemviri, who held the same rank, and had the same authority there as the consuls had at Rome.

In the political relations of the Roman settlements with their parent city, there is some resemblance to the political relations of modern colonies with their mother countries. But in the policy of a state so neglectful of every thing, except war, we cannot expect to find any parallel to those commercial views, by which the plantation of modern colonies has been undertaken, and their connexion with the European governments maintained. The objects of the Romans, in planting their colonies, were conquest and plunder; so that detachments of emigrants incorporated with, and governed, the old possessors of the soil. In modern

den times the chief objects have been trade and agriculture; the most important settlements have been made in desert countries, or districts, whose ancient inhabitants were extirpated by the first settlers. In this respect then, the Roman colonies rather bear a resemblance to the Asiatic establishments of modern Europe; but they differ from these too, in the structure of their government. The constitution of the Italian colonies was formed upon the Roman model, and varied with its changes. The provincial governments of Hindoostan, and the islands of the Indian ocean, very little resemble those of their European masters, and are rather allied to the spirit of the oriental legislation. The provincial governments of the Roman transmarine territories bore, in every respect, the same kind of relation to the metropolis, which the East Indian establishments do to the states of Europe. The inhabitants retained, in a great degree, their own laws; they were ruled and oppressed by a Roman magistratus, and an army, composed partly of Roman, partly of native troops; their country was the scene of every criminal excess in politics and manners, and the source of large supplies to the plunderers of the world.

The species of colonies now described is not restricted to the Romans, but it has been adopted by almost every nation, both ancient and modern, with very little variation. To it we may refer the establishment of the Normans in England, and of the English in Ireland. In a still later period, the Portuguese and Dutch have established themselves in India; but the English East India company have, on the contrary, repressed, as far as possible, the colonization of the countries they possess there, as these directors observe that "the energy or the European character becomes obliterated in the course of a few generations."

The commerce of Carthage, together with her extensive continental possessions, enabled her to provide for her increasing population at home. The want of an outlet for inhabitants formed no part of the motives that induced the Carthaginians to settle foreign colonies. Their colonial establishments, indeed, were most probably founded in the same manner with the transmarine and transalpine provinces of the Romans—conquered countries, retained in subjection, from ambition and pride, by means of a Carthaginian governor, and a few followers; prompted by idleness, or the love of change, or the desire of distinction to follow in his retinue. However, the relations of the new establishments with the mother country were different, in several respects, from the relations which connected the distant parts of the Roman dominions with the metropolis. The Carthaginian colonies were, in reality, trading correspondents to the mother country; and should have found a place under the 4th class of colonies rather than here, if they had not been immediately connected with the Roman. It is probable that the Carthaginians received the surplus of the rude produce of Sicily, Sardinia, and Spain, which Africa did not yield, and exported thither those manufactures, which would naturally be raised in a country fully peopled, and long habituated to traffic. From the superiority of their navigation too, the skill of the Carthaginian merchants, their connexions long established with the Levant, more particularly with the great emporiums of the East, Tyre and Smyrna, and from the greater trading capitals of those rich merchants; they would most likely furnish the colonies or provinces with Asiatic commodities, of which Carthage would be the natural entrepôt for the countries to the west of the Mediterranean. History has preserved two traces of commerce and navigation between the Carthaginians and Romans, conceived in the true spirit of the modern colonial policy; for which see Polyb. l. iii. c. 22, or Brougham's Colonial Policy, &c. vol. i. p. 21, &c.

In this connection we might mention another species of external colonies, produced by the dispossession of weaker states by those who are stronger, in order to extend their borders, or to possess some advantageous situations for trade, or for war. The bigotry of the Europeans, at the time of the discovery of the West Indies, led them to look upon the natives of those countries in a very unfavourable and contemptuous light, on account of their being heathens and idolaters, and made them heedless as to the measures they adopted for their own security, so that they could but obtain the object of their wishes. The great disproportion also in the numbers of the invaders and of the natives, in some measure, impelled the Europeans to adopt the most severe methods, to perpetuate the terror which the natives had originally manifested at the effects of their fire-arms. The consequence of those ferocities was, that the natives of most of the islands were soon exterminated, except in some very small ones which the Europeans left unnoticed. On the continent, however, the natives still exist, as they have there sufficient space to retire from the neighbourhood of their visitors.

To the *third* class belong those colonies that have been formed by refugees from countries, in which they were oppressed or persecuted. Thus the emigrants, who fled from the religious broils in which France, the Low Countries, and Germany have been involved, found safety in England, and introduced many of these manufactures and arts, which have contributed to the commercial superiority of Great Britain. Norwich, Canterbury, and even some of the most populous districts of the metropolis, have owed the industry and productions of their inhabitants to these colonies; and, in like manner, part of Pembrokehire, in South Wales, has been peopled by a colony from Flanders. The colonies of North America were originally planted by men who had quitted their native country, either from a love of civil and religious liberty; or from a desire to better their fortunes, by laying out a small capital in the improvement of land; or from the necessity of finding employment in a country where labour bore a high price. Anxious only to live in peace and freedom, with a competency for themselves and their families; these men centered all their views in the spot to which they removed their fortunes and persons; they gave up for ever the thoughts of returning to the countries which they left behind them; and transferred to their new homes all those ties which had formerly bound them to Europe. The woods of the northern continent were cleared by men of small capital content with a living profit, attached to the soil, which owed its cultivation to their labours, and entertaining no idea of removing from it. By degrees the influence of local attachment binds them to a spot, which necessity had made the object of their choice; and in process of time the desire of depositing their bones in a country which had received and cherished them, succeeded to the obliterated partiality for the place of their birth. The first settlers of all the colonies of N. America were men of irreproachable characters, though not very enlightened in their views, or polished in their manners. Many of them fled from persecution; others on account of an honourable poverty; and all of them with their expectations limited to the prospect of a bare subsistence in freedom and peace. The greater part of them viewed their emigration beyond the Atlantic, as a taking up of the cross; and bounded their hopes of riches to the gifts of the spirit, and their ambition, to the desire of a kingdom beyond the grave. A set of men more conscientious in their doings, or simple in their manners, never founded any commonwealth. It is, indeed, the peculiar glory of N. America, that, with a very few exceptions, its empire was originally founded in clarity and peace. In process of time, however, new emigrants

grants flocked to this extensive country, as it became more open and improved, whose views, principles, and character were very different from those of the first settlers. Many of them were persons in very indigent circumstances; they were of different sects, or of no perceptible religion at all; and of different nations, though the English greatly predominated. Some of them were convicts, who after confinement in goals were banished for their crimes; many of them persons of desperate fortunes, to whom every place was equally unwelcome; or men of notoriously abandoned lives, to whom any region was acceptable, that offered them a shelter from the vengeance of the law, or the voice of public indignation. But a change of scene would naturally produce some salutary effect upon characters the most dissolute. This mixture of various population was soon blended, by the influence of those simple manners that are formed by an agricultural life, into one nation of husbandmen, whose character has communicated itself, in a great degree, to the most profligate of those whom compulsion or despair from time to time introduced. While purity of manners was in this way preserved, that firmness of principles in religion and politics was maintained, which had so eminently contributed to the establishment of the colonies. Sentiments of freedom might find an asylum in America; when, even in Switzerland, it could no longer be lawful to think beyond the rules. Nevertheless, the circumstances of the N. American colonies produced some other effects not quite so favourable, upon the taste, and in what, in common conversation, we call the manners of the people. The solitary nature of agricultural labour, and the seclusion of the husbandman's residence, surrounded only by his own family and servants, are very inimical to all sorts of refinement, and to every ornamental accomplishment; whilst the settlers of the new colonies were occupied with the useful, they neglected the agreeable arts of life; and voluntarily threw themselves back some centuries, in most branches of civilization, instead of prosecuting the improvements of those branches, from the point to which the mother country had brought them at the era of their emigration. In consequence of their peculiar circumstances and occupations, the Americans have always possessed a numerous, virtuous, and athletic peasantry; but they have numbered few fine artists, or accomplished orators; and, indeed, an ingenious writer, to whom we are much indebted in the compilation of this article, proceeds so far as to observe, with a latitude of expression scarcely allowable, that "the word American has never yet (so far as I know) been coupled with either poetry, or painting, or music." The history of manners in N. America, says this writer, is the general history of manners in every new community, of which agricultural industry forms the basis. The peculiarities (perhaps accidental), which marked the situation and habits of the first settlers, have likewise produced some effect upon those of their descendants, without in the least modifying their character as an agricultural nation. The love of civil and religious freedom was connected with an anxious attention to all matters of controversy, whether in politics or in faith; and as the settlers were equally incapable of understanding either, so they were chiefly captivated with the more abstruse of the two sciences; and affected great depth in the things appertaining to grace, spirit, incarnation, and all the sublime mysteries of the Christian dispensation. These fruitless speculations were the only literary inheritance which they transmitted to their children. But although they had left the old world for the sake of liberty of conscience, they too soon manifested what they understood by liberty of conscience. By that term they meant (like many other advocates of liberty) the propagation of

their own peculiar tenets; and they shewed that they only wanted the power to propagate their creed (like their European oppressors) by that method of mental perfusion which consists in burning the body. They allowed every man entire liberty of conscience, provided that he used that liberty in adopting their own standard of faith. Accordingly, while in Old England the spirit of fanaticism was operating the downfall of government, and minging itself with every pursuit of the age, to the universal debatement of manners and sentiment; in New England, the heterodox were persecuted by the impulses of the inward light; or parties were formed, and armies marshalled, and millions led by the subtle principles of a metaphysical theology. But the Falklands and Sydneys had no parallels to temper the unclassical rage of the American bigots; and even the Cromwells and Bradshaws found but poor representatives in the stupid fanatics of Bolton and Salem. Long after the mother country had relinquished, for ever, the acts of persecution, they found votaries in the constituted authorities of the colonies; and the northern states at the end of the 17th century, afforded the disgraceful example of that spiritual tyranny, from which their territories had originally served as an asylum. The century, which has just elapsed, moderated this odious spirit; but to this day, the northern states are chiefly distinguished from the others, by a taint of religious bigotry;—as the character of the middle states is modified by the greater mixture of different nations, which have contributed to people them;—and that of the southern provinces, by the admixture of negro slaves. In the middle states, the mercantile spirit has gained more ground than in any of the rest: the diversities of race have rendered the sentiments of patriotism, and the love of liberty, less ardent; while the variety of religions has prevented the introduction of that fanaticism, of which we have traced the effects in the north. In the southern states the contrast of servitude has mingled an aristocratical spirit with the manners of simple husbandmen; and the climate, by promoting the growth of an article, belonging to the class of luxuries, has given rise to a species of agriculture bordering upon the great gains and uncertain prospects of commercial speculation. In all the colonies, however, of the northern continent, a respectable national character may be said to prevail. If their intercourse with the mother country would have had no tendency to civilize or adorn her, it could certainly have in no degree contributed to the corruption, either of her moral or political habits; and the most rapid interchange of population could only have tended to embellish the American society and to vary its accomplishments, while it rendered a service to the British manners, by the intercourse of a more simple and virtuous people. Unfortunately, the very circumstances which necessarily laid the foundation of those habits and that national character insulated the population of the country from that of the old world. The colonies were stationary for the same reason that they were respectable; and the circulation of its inhabitants, with all its effects upon both parts of the empire, has been maintained and accelerated in other colonies, placed in circumstances which rendered those effects unfavourable, at least to the mother country. For the change that has taken place with regard to the principles and manners, the religion and liberty of the several colonies of N. America, since they have acquired a new government, and been formed into the *United States*; see this article, and also an account of the several states themselves under their appropriate titles.

The fourth class of colonies comprehends those that are denominated *commercial*, and which have been established at different periods, by the English, Dutch, French, Spaniards,

Portuguese, and other nations; and which are still maintained, in a greater or less degree, with a view of keeping up a regular intercourse with the natives, or of cultivating the ground, by planting sugar-canes, rice, indigo, tobacco, cotton and other commodities. See *CHARTER Governments*.

The principal of this kind of colonies are those that have been established in North and South America; particularly Peru, Mexico, Canada, Virginia, New England, Carolina, Louisiana, Hudson's bay, the Antilles islands, Jamaica, Domingo, and the other islands of the West Indies; also, in Africa, Madagascar, the cape of Good Hope, cape Verd, and its islands, and all the coasts extended thence as far as to the Red sea; and likewise in Asia, the famous Batavia of the Dutch, and Ceylon; Goa, Diu, of the Portuguese; and some other less considerable places of the English, French, Danes, and other nations, in the East and West Indies.

The establishment of the European colonies in America and the West Indies, if we except those of North America to which we have already alluded, did not originate in necessity; but it was the result of ambitious and interested views. The Dutch, indeed, may plead in favour of the extension of their own settlements and commerce, that the colonial system is necessary to their subsistence and prosperity. Their territory is small, and generally undistinguished by its fertility; and therefore they have recurred for the necessities of life to the ports of more fruitful and less populous countries. Habituated to industry, and excelling other nations in nautical skill, instead of confining themselves to the exchange of their own manufactures for the rude produce, or the manufactures of other nations, they employed themselves in circulating the produce and manufactures of other countries; and, more attentive to this occupation than to the arts of working up the produce which they imported or raised, they became a nation, not of farmers or manufacturers, but of fishermen, merchants, and sailors. Constrained by other circumstances belonging to their country, when compared with other nations, they were obliged, by the disadvantages of their situation and the oppression of their Spanish masters, to put forth every possible effort of fortitude and perseverance. By industry, frugality, and labour, these people not only soon outstripped all their contemporaries in riches and naval skill, but amassed a much greater share of wealth, and gained a more formidable influence over the destinies of the world, than so small a tribe ever acquired in any age. Their steady attachment to the principles of freedom and toleration served as a concurring mean of their advancement and prosperity. The necessary consequence of extensive opulence, acquired by a people who have not a proportionably great territory, is, that the means of advantageously employing their capital will become gradually more and more difficult; the profits of its employment more confined, and its accumulation more slow. Such a people will naturally seek some new opening for settlement or commerce, by acquiring territory in distant quarters of the globe. Should they fail in this way, the overflowing wealth of the nation must infallibly emigrate, as it were, into the service of foreign countries, where the profits are greater than they are at home. Hence we find that the Dutch became, in a sense, the brokers of Europe; and that they advanced sums to foreign states and their subjects, which were enormous. It is probable, says an ingenious and accurate writer, (Mr. Brougham), that the Dutch have frequently been creditors, at one time, to the amount of much more than 300 millions sterling to their own government, and to foreign states, of which we may reckon two-thirds in foreign loan: an immense sum of surplus capital to have been accumulated by a nation possessed of no greater territory than the principality of Wales, without

any good harbours, or any natural produce fit for exportation; a territory, 120 times less extensive than the European dominions of Russia, which is constant y running in debt with all the world! A people possessed of such an overflowing capital, was, of all people, that which stood the most in need of foreign colonies; and this for two reasons:—in order to obtain a new opening, of whatever kind, for the stock which could not be employed at home, or which, for want of this employment, was drawn into the service of foreigners; and in order to secure the possession of this opening at all times under its own command. The acquisition of colonial possessions is the only means by which the United Provinces can possibly avoid the decline of its mercantile prosperity and political importance, and supply their natural deficiency of territory, the cause of their instability, as it was the cause of their rise and progress. An opening for capital may then be obtained always under the command of the state. The possession of colonies must be as advantageous to the community of the United Provinces, as agreeable to individual capitalists and adventurers. It has certainly preserved the commercial excellence of the republic for a long series of years, and enabled this ancient state to retain its place among the great powers of Europe instead of being swallowed up by its neighbours, or reduced to a few fishing villages. No nation of Europe depends so much upon colonial policy as Holland; nor is any so liable to be affected, in every member, by the slightest variation of colonial affairs. See *Dutch East India Company* and *Dutch West India Company*. The whole return of the Dutch colonies, above 20 years ago, was calculated (says Mr. Brougham) at 24 millions of florins—exported in 150 vessels, navigated by 4000 men, and paying, in freight, 4 millions 5 hundred thousand florins—in commission and insurance, 2½ millions. The Dutch merchants exported to them merchandize (including negro slaves) to the value of 6 millions. The most unfortunate circumstance in the colonial policy of the Dutch has always been their bad treatment of slaves. (See *NEGROES AND SLAVES*.) The colonies of Holland have also suffered, in general, from the importation of negroes being too scanty to answer the demands of the proprietors. Upon the whole, it is observed by the writer so often cited in this article, that in no country is there so great a demand for new colonies as in the United Provinces. To no part of Europe are colonial possessions so valuable; none would be so irretrievably ruined by their loss; none would be so much benefited by their extension.

The views of Spain in its colonial establishments were directed from the beginning of their connection with America to the pecuniary advantages likely to result from them. In consequence of the representation of Columbus, the council of Castile determined to take possession of countries of which the inhabitants were incapable of defending themselves. The pious purpose of converting them to Christianity sanctified the injustice of the project. But the hope of finding treasures of gold there was the sole motive which prompted them to undertake it; and to give this motive the greater weight, it was proposed by Columbus, that the half of all the gold and silver which might be found there should belong to the crown. This proposal was approved of by the council. The tax was easily paid whilst the defenceless natives were plundered; but as they were stripped of all that they had, which, in St. Domingo, and the other countries discovered by Columbus, was completely done in six or eight years; and when it became necessary to dig for it in the mines, it was impossible to pay the tax. The rigorous exaction of it occasioned first the total abandonment of the mines of St. Domingo, which have never been wrought since; and it was afterwards reduced, by successive defalcations, to a 20th part of the produce of the gold mines.

mines. The tax upon silver, which was a fifth of the gross produce, was reduced to a tenth in the course of the last century. All the other enterprises of the Spaniards in the New World, subsequent to those of Columbus, seem to have been prompted by the same motive. It was the sacred thirst of gold that carried Ojeda, Nicuesa, and Vasco Nunez de Balboa, to the isthmus of Darien, that carried Cortez to Mexico, and Almagro and Pizarro to Chili and Peru. Impelled by the prospect of immense gain to establish colonies in America, the first object of the Spanish monarchs was to secure the productions of these colonies to the parent state, by an absolute prohibition of any intercourse with foreign nations. They took possession of America by right of conquest; and, having reason to apprehend the loss of their infant settlements, on account of their feebleness, their extent, and the reluctance with which the vanquished nations submitted to their dominion, they guarded, by every possible method, against the intrusion of strangers. As their possessions were extended, the spirit of jealousy and exclusion increased; and, in order to their greater security, a system of colonizing was introduced, to which the history of mankind afforded no parallel. In the ancient world, as we have already seen, colonies were of two kinds; either migrations from a country overstocked with inhabitants, or military detachments, stationed as garrisons in a conquered province. The colonies of some Greek republics, and the swarms of northern barbarians which settled in different parts of Europe, were of the first kind; and the Roman colonies were of the second kind. In the former, the connection with the mother country quickly ceased, and they became independent states; in the latter, the dependence continued, because the separation was not complete. The Spanish monarchs, in their American settlements, took what was peculiar to each, and studied to unite them. By sending colonies to regions so remote, by establishing in each a form of interior policy and administration, under distinct governments, and with peculiar laws, they disjoined them from the mother country. By retaining in their own hands the rights of legislation, as well as that of imposing taxes, together with the power of nominating the persons who filled every department, civil or military, they secured their dependence. At first, as we have already observed, the precious metals were the only objects that attracted their attention. Afterwards they sought for such productions of the climate as, from their rarity or value, were of chief demand in the mother country; and they forbade the establishment of several species of manufacture, that were likely to interfere with those of the mother country. Their clothes, furniture, instruments of labour, luxuries, and even a considerable part of the provisions which they consumed, were imported from Spain. In return, the colonists supplied the produce of their mines and plantations, which was conveyed only in Spanish bottoms. The commercial intercourse of one colony with another was either absolutely prohibited, or limited by many jealous restrictions. All that America yields flows into the ports of Spain; all that it consumes must issue from them. No foreigner can enter its colonies without express permission; no vessel of any foreign nation is received into their harbours; and the pains of death, with confiscation of moveables, are denounced against every inhabitant who presumes to trade with them. Thus the colonies are kept in a state of perpetual pupillage; and by the introduction of this commercial dependence, a refinement in policy, of which Spain set the first example to the European nations, the supremacy of the parent state hath been maintained over remote colonies, during 2½ centuries. Several maxims were also adopted and enforced

with regard to the restrictions of settlers, the state of property, and the ecclesiastical policy of the colonies, which served very much to discourage emigration from Europe, and the increase of population in America. If we advert to the state of Spain, and compare it with that of Holland, we shall soon perceive, that the Spaniards, possessing a country fifteen times more extensive than Holland, of incalculably greater fertility, enjoying all the benefits of the finest climate in the world, surrounded with natural barriers of defence, and blessed with every advantage of situation which can facilitate commercial intercourse, and yet maintaining not much more than one-fourth of the Dutch population, are evidently independent of colonial possessions. All the industry, skill, and capital of the natives, may find ample employment in raising, manufacturing, and circulating the produce of the soil, or in exchanging the superfluous part of that produce for the commodities which abound in other countries. But, though it would have been sounder policy in the Spanish government to have promoted a spirit of industry at home, than to have established distant colonies, yet it cannot be denied, that she has received very great benefits from them, and such, in their nature and value, as more than counterbalance the injury they have occasioned. At the period of their first establishment, the interior industry and manufactures of Spain were so prosperous, that, with the product of these, she was able both to purchase the commodities of the New World, and to answer its growing demands. Under the reigns of Ferdinand and Isabella, and Charles V., Spain was one of the most industrious countries in Europe. Her manufactures in wool, and flax, and silk, were so extensive, as not only to furnish what was sufficient for her own consumption, but to afford a surplus for exportation. When a market for them, formerly unknown, and to which she alone had access, opened in America, she had recourse to her domestic store, and found there an abundant supply. By this new demand, furnishing answerable employment, the spirit of industry must have been enlivened and encouraged; and the manufacture, population, and wealth of Spain might have gone on increasing in the same proportion with the growth of her colonies. However, by the great and sudden augmentation of power and revenue, which the possession of America brought into Spain, sober plans of industry were overturned, and opulence, rapidly acquired, produced a taste for what is wild and extravagant, and daring in business or in action. The genius of Charles V. in some measure counteracted the pernicious influence of this inundation of wealth and of the subsequent interruption of it; but under Philip II. its effect, both on the monarch and the people, became conspicuous. Philip, possessing an extravagant opinion of his inexhaustible resources, and, at the same time, an ambition connected with moderate talents, thought himself equal to any undertaking. Accordingly he waged open war with the Dutch and English, encouraged and aided a rebellion in France, conquered Portugal, and maintained armies and garrisons in Italy, Africa, and both the Indies. Thus Spain was drained both of men and of money. Under the weak administration of his successor, Philip III., the vigour of the nation declined, and the bigotry of the monarch expelled near a million of his most industrious subjects; so that early in the 17th century, Spain felt such a diminution in the number of her people, that from inability to recruit her armies, she was obliged to contract her operations. Her flourishing manufactures were fallen into decay. Her fleets, which had been the terror of all Europe, were ruined. Her extensive foreign commerce was lost. Agriculture was neglected, and one of the most fertile countries in Europe hardly raised what was sufficient

for the support of its own inhabitants. In proportion as the population and manufactures of the parent state declined, the demands of her colonies continued to increase. The rage of emigration prevailed, and the strength of the colonies was augmented by exhauling that of the mother-country. The emigrants depended upon Spain for almost every article of necessary consumption. But Spain, thinned of people and destitute of industry, was unable to supply their increasing demands. She had recourse to her neighbours; and the manufactures of the Low Countries, of England, of France, and of Italy, which her wants called into existence, or animated with vivacity, furnished in abundance whatever she required. In a short time not above one twentieth part of the commodities exported to America was of Spanish growth or fabric. All the rest was the property of foreign merchants, though entered in the name of Spaniards; so that the treasure of the New World may be said henceforward not to have belonged to Spain. Before it reached Europe, it was anticipated as the price of goods purchased from foreigners. Thus the possessions of Spain in America have not lived as a source of population and of wealth to her, in the same manner as those of other nations. From the close of the 16th century she was unable to supply the growing wants of her colonies; and the pernicious effects of this disproportion between their demands and her capacity of answering them, were farther aggravated by the mode in which she endeavoured to regulate the intercourse between the mother-country and the colonies. Such was the monopoly at which she aimed, and which she wished to maintain, that she did not vest her trade with her colonies in an exclusive company; a plan which had been adopted by nations more commercial, and at a period when mercantile policy was an object of greater attention, and ought to have been better understood. The Dutch gave up the whole trade with their colonies both in the East and West Indies, to exclusive companies. The English, French, and Danes, have imitated their example with respect to their East-Indian commerce; and the two former have laid a similar restraint upon some branches of their trade with the New World. The wit of man cannot, perhaps, devise a method for checking the progress of industry and population in a new colony, more effectual than this. From this error in policy Spain was preserved, probably by the high ideas which the early formed concerning the riches of the New World. Gold and silver were commodities of too high value to vest a monopoly of them in private hands. The crown retained this alluring branch of commerce; and in order to secure it, enjoined the cargo of every ship fitted out for America to be inspected by officers at Seville, and then to receive a licence for the voyage; and on its return, that a report of the commodities which it brought should be made to the same board, before it should be permitted to land them. By this regulation all the trade of Spain with the New World centered in the port of Seville, and was brought into a form, in which it has been continued with little variation, almost to our own times. See GALEONS and FLOTA.

The trade of Spain with her colonies being thus restricted, was conducted on the same principles which directed that of an exclusive company; and the whole of it was exported by a few wealthy houses, formerly in Seville, and since the year 1720 in Cadiz; these, by combinations easily formed, prevent that competition which preserves commodities at their natural price; and, by acting in concert, to which mutual interest prompts them, they may raise or lower the value of them at pleasure. This restraint of the American commerce to one port, not only affects its domestic state, but limits its foreign operations. In these circumstances, and

whilst the evils resulting from them found no effectual remedy, Spain, with dominions more extensive and more opulent than any European state, possessed neither vigour, nor money, nor industry. At length the violence of a great national convulsion roused the slumbering genius of Spain. As soon as the Bourbons acquired possession of the throne, it was the first object of Philip V. to prohibit the admission of foreign vessels into any port of Peru and Chili; and a Spanish Squadron was employed to clear the South Sea of intruders, whose aid was no longer necessary. After the treaty of Utrecht, which terminated the war, new embarrassments occurred in consequence of the assistance, or contract for supplying the Spanish colonies with negroes, conveyed to Great Britain, as the price of peace; (See *ASSISTENTE*) and the additional privilege of sending annually to the fair of Porto-Bello, a ship of five hundred tons, laden with European commodities. By the operations that succeeded these grants, and by the activity of private interlopers, almost the whole trade of Spanish America was engrossed by foreigners. Guarda costas, and regillar ships were introduced. (See each of these articles). Since the reign of Philip V., sentiments with regard to commerce, more liberal and enlarged, began to spread in Spain. At length Charles III. in 1764, appointed packet-boats to be dispatched on the first day of each month, from Corogna to the Havannah or Porto-Rico. From thence letters are conveyed in smaller vessels to Vera-Cruz and Porto-Bello, and transmitted by post through the kingdoms of Terra-Fermé, Granada, Peru, and New Spain. Other packet-boats sail regularly once in two months, to Rio de la Piata, for the accommodation of the provinces to the east of the Andes. With this new arrangement for conveying speedy and regular intelligence, a scheme of extending commerce has been more immediately connected. Each packet boat is a trading vessel, and is used for facilitating the exchange of Spanish products, for an equal quantity of that of America. This was soon followed by a greater degree of enlargement. In the year 1765, Charles III. laid open the trade to the windward islands, Cuba, Hispaniola, Porto-Rico, Margarita, and Trinidad, to his subjects in every province of Spain. He reduced the duties on goods exported to America, to the moderate tax of six in the hundred, on the commodities sent from Spain. He allowed them to return to any port at pleasure. This ample privilege was afterwards extended to Louisiana, and to the provinces of Yucatan and Campeachy. Such have been the benefits experienced from the relaxation of the ancient system of commerce between the mother-country and her colonies, that Spain has been induced to permit a more liberal intercourse of one colony with another. In 1774 Charles III. published an edict, granting to Peru, New Spain, Guatemala, and Granada, the privilege of a free trade with each other. The towns to which Spain has granted the liberty of trade with any of her colonies, are Cadiz and Seville, for the province of Andalusia; Alicante and Carthagena, for Valencia and Murcia; Barcelona, for Catalonia and Arragon; Santander, for Castile; Corogna, for Galicia; and Gijon, for Asturias. These are either the ports of chief trade in their respective districts, or those most conveniently situated for the exportation of their respective productions. Prior to the allowance of free trade, the duties collected at the Custom-house at the Havannah, were computed to be 104,208 pesos annually. During the five years preceding 1774, they rose at a medium to 308,600 pesos a year. In Yucatan, the duties have risen from 8,000 to 15,000. In Hispaniola, from 2,500 to 5,600. In Porto-Rico, from 12,200 to 7,000. The total value of goods imported from

Cuba

C O L O N Y.

Cuba into Spain, was reckoned, in 1774, to be 1,500,000 pesos. From another statement, it appears, that the exports to Spanish America in 1778, were made in 170 ships; were worth about 74 millions of reals vellon, and paid above $3\frac{1}{2}$ millions of duty. The imports from thence, in the same year, were made in 130 ships, valued at $74\frac{1}{2}$ millions, and paid nearly 3 millions duties. In 1788, the value of the exports had risen to above 300 millions, and that of the imports to above $804\frac{1}{2}$ millions. The duties upon both exports and imports exceeded 55 millions. This rapid increase can be ascribed to nothing but the effects of the free trade; and notwithstanding all the clamours raised by the Cadiz merchants, we find that this city was the first to enjoy the advantage of the change; for the imports of Cadiz from America in 1788, were three-fourths of the whole colonial imports; and the exports of Cadiz thither were considerably above two-thirds of the whole colonial exports. Spain has likewise directed particular attention to the interior government of her colonies. For an account of the Philippine colony, see ACAPULCO and MANILA.

The revenues which Spain derives from America, arises from taxes of various kinds, which may be divided into three capital branches. The first contains what is paid to the king, as sovereign of the New World; to this belongs the duty on the gold and silver raised from the mines, and the tribute exacted from the Indians; the former called "the right of signory," and the latter "the duty of vassalage." The second branch comprehends the numerous duties upon commerce, which are very minute and oppressive. The third includes what accrues to the king, as head of the church, and administrator of ecclesiastical funds in the New World. In consequence of this he receives the first-fruits, annats, spoils, and other spiritual revenues, levied by the apostolic chamber in Europe; and is entitled likewise to the profit accruing from the bull of *Crusado*, which see. The whole amount of the net public revenue of Spain, raised in America, is stated by Dr. Robertson as not exceeding a million and a half sterling. Spain and Portugal are the only European powers which derive a direct revenue from their colonies, as their quota towards defraying the general expence of government. All the advantage, that accrues to other nations from their American dominions, arises from the exclusive enjoyment of their trade; but, besides this, Spain has brought her colonies to contribute towards increasing the power of the state, and, in return for protection, to bear a proportional share of the common burden. The amount of the Spanish revenue, above stated, comprehends only the taxes collected there, and is far from being the whole of what accrues to the king from his dominions in the New World. The heavy duties imposed on the commodities exported from Spain to America, as well as what is paid by those which she sends home in return; the tax upon negro slaves, with which Africa supplies the New World, together with several smaller branches of finance, bring larger sums into the treasury, the precise extent of which Dr. Robertson cannot pretend to ascertain. But if the revenue which Spain draws from America be great, the expence of administration in her colonies bears proportion to it.

The total amount of the public revenue of Spain from America and the Philippines, from the most recent information stated by Dr. Robertson, is as follows:

Alexavalas (excise) and aduanas (customs), &c.	2,500,000
in pesos fuertes, - - -	3,000,000
Duties on gold and silver, - - -	1,000,000
Bull of <i>Crusado</i> , - - -	2,000,000
Tribute of the Indians, - - -	300,000
By sale of quicksilver, - - -	300,000

Paper exported on the king's account, and sold in the royal warehouses, - - -	300,000
Stamped paper, tobacco, and other small duties, - - -	1,000,000
Duty on coinage of, at the rate of one real de la Plata, for each mark, - - -	300,000
From the trade of Acapulco, and the coasting trade from province to province, - - -	500,000
Affitto of negroes, - - -	200,000
From the trade of <i>Mahé</i> , or herb of Paraguay, formerly monopolized by the Jesuits, - - -	500,000
From other revenues formerly belonging to that order, - - -	400,000
Total	12,000,000

Total in sterling money £ 2,700,000

Deduct half, as the expence of administration, and there remains net free revenue, £ 1,350,000

From the above detail, and upon a general view of the subject, it appears to be absurd to deny, that Spain has derived very great benefits from her colonial possessions. Nevertheless, many very enlightened men have maintained, that the downfall of the Spanish power has been owing, in a great measure, to the extension of dominion which followed the discovery of America. To this purpose an appeal has been made to the authority of Dr. Smith, the well known and much approved author of the "Wealth of Nations." "That the monopoly," he observes, "of the trade of populous and thriving colonies is not alone sufficient to establish, or even to maintain, manufactures in any country, the examples of Spain and Portugal sufficiently demonstrate. Spain and Portugal were manufacturing countries before they had any considerable colonies. Since they had the richest and most fertile in the world, they have both ceased to be so." However, Mr. Brougham has remarked, that the tenor of this observation is confined to the statement of a fact which cannot be denied, that the period of the decline which the Spanish and Portuguese manufactures have experienced, coincided with the period of the Spanish and Portuguese colonial greatness. But the whole argument proceeds upon a view of the subject, formerly discussed, that colonial monopolies in general have been hurtful, from their effects on the wealth of the mother-country. Mr. Brougham has accurately examined this subject; and in the prosecution of his inquiry, he has shewn, in what manner the prosperity of Spain has been influenced by the discovery of America; and he has investigated the question, whether the acquisition of rich and extensive colonies can be charged with having caused the decline of the mother-country, and whether, in short, any bad consequence whatever is imputable to this augmentation of empire.

By those who have maintained, that Spain has been materially injured by her colonies, it has been alleged, that by an immoderate extension of territory, the Spaniards have been led to the neglect of the territory, which they formerly possessed. But although Spain, and also Portugal, may have severely suffered in this respect, it is seldom, if ever, that, from the nature of colonial power, any such consequences can arise to the mother-country from the possession of the most widely spread colonial dominions. In the case of Spain especially, whatever neglect there may have been in the management both of the mother-country and the colonies, the mal-administration of both those parts of the empire must evidently have arisen from other causes besides their being united under one crown. Farther, the vast outlet to population which the Spanish colonies

lonies afford has been thought by many to be detrimental to the mother-country. They allege that the population of Spain has been drained by the demands and temptations for men which the colonies afford. Our author suggests a variety of considerations that tend to invalidate this objection. The indolent and adventurous, the nobles and soldiers of fortune, and men of considerable property, were the principal emigrants at the first settlement of the Spanish colonies in America; as conquest or plunder, and mining in search of the precious metals were the only modes in which wealth was then sought. Besides, the drain of emigration has been chiefly confined to the population of the maritime provinces of Spain; and the whole amount of the emigration, at different periods, cannot be estimated very high. It has been said that the rage for emigration to America was so much abated in a short time after the discovery, chiefly by the ruin of many who flocked thither, that in the year 1550, there were not above 15 thousand Spaniards in all the New World. From other documents it has been inferred, that the whole amount of those who have emigrated to the Spanish colonies, during a period of three centuries, does not exceed 500,000. The drain of the Spanish population must therefore be wholly inadequate to account for the decline of the Spanish resources, and the slow progress of the Spanish population. It is no less chimerical to imagine that the capital which has been drawn to the colonial agriculture and mining, can have impoverished the mother-country in any considerable degree, than to suppose that the colonial emigration can have drained her population: and it is, therefore, to causes different from the emigration of inhabitants, and of capitals, that we must ascribe the depopulation, the indolence, and the poverty of Spain. In order to account for the depopulation of Spain we may recur to the ravages of the plague, which, during three years in the middle of the 14th century, carried off two-thirds of the whole population of the peninsula, and which about three centuries afterwards, destroyed 200,000 persons in the southern provinces;—to the destruction occasioned by death and famine;—to the cruel and insane policy of Ferdinand, who, as an expression of gratitude to God for the successes of his arms, expelled from his dominions the whole tribe of Israel;—to the still more bloody and impolitic measures of his successor, who, about a century afterwards, drove out all the Moorish race;—and to the constant persecutions and rebellions of these two classes during the interval between the great and general expulsions, which produced the effect of suddenly eradicating from the kingdom all the industry and skill which had raised it to such a pitch of opulence and glory. The number of the Jews, who, in the year 1492, were butchered or driven out, is reckoned by some authors at 800,000 persons, by others at 800,000 families; and the number of the Moors driven away by the edict of 1609, cannot be computed at less than a million. The best informed writers state the loss to the country at these two periods, and intervening intervals, to have amounted to between two and three millions; consisting of the most useful and valuable part of the community. We might enumerate other causes of the decline of Spain, arising from restrictions and imposts, and a miserable system of law and police, both at home and in the colonies, which operated much more fatally than the acquisition of colonial dominions, and which, indeed, counteracted any benefit they might otherwise have afforded. It is surely a proof, says Mr. B., that the downfall of a country was not caused by its colonial possessions, but by some evil in the national policy common to all its branches, when we find that the æra of adversity was common to both the contiguous and remote provinces, and that the same circumstances which raised up the colo-

nies, and increased their beneficial effects upon the wealth of the parent state, have elevated the parent state also, rescued her from inactive obscurity, and placed her in the career of general improvement, in which her neighbours are engaged in both quarters of the globe.

The Portuguese, incited by a spirit of discovery, and by a view to the great profits accruing to the Venetians from their commerce, during the 14th and 15th centuries, made several attempts, in the course of the 15th century, to find out a way by sea to the countries from which the Moors brought them ivory and gold dust across the desert. In process of time they discovered the Madirias, the Canaries, the Azores, the Cape de Verd islands, the coast of Guinea, that of Loango, Congo, Angola, and the Cape of Good Hope. They also extended their views to the East Indies, and afterwards to America. During the 16th century, the empire of Portugal was more extensive than any over which the dominion of other states has ever prevailed; and the territories that composed it, though almost all held by the right of recent discovery and conquest, were not, like those of Spain and Russia, subdued and retained with ease; nor were they tracts of useless country, thinly peopled, possessed only of unimproved natural resources, and inhabited by a few tribes of wandering savages mingled here and there with nations somewhat more civilized. The Portuguese conquests were gained with difficulty from nations far advanced in refinement and capable of resistance; the extension of their territory obtained from right of discovery, that is, seized from less civilized nations, was equal to the most opulent of the dominions possessed by Spain, and possessed by tribes much more warlike than the Mexicans or Peruvians; and the length of sea-coast, with various convenient ports, which bounded the eastern dominions of Portugal during this brilliant period, was sufficient to insure the most important commercial advantages from their intercourse with the metropolis. The whole western coast of Africa, with the greater part of the east coast and the Cape of Good Hope, was subject to the dominion of the Portuguese, and occupied at favourable intervals by their garisons and factories. They also possessed the whole southern coast of Asia, together with as many of the Indian islands as they chose to settle in, from the gulf of Persia to China and Japan, where they had a few important commercial stations. This unparalleled extent of naval territory gave them the undisputed command of all those seas, and enabled them to carry into execution the ordinary schemes of the mercantile system with uncommon vigour and success, by confining all intercourse with Asia and Africa to their own European territories. The power, adds the writer whom we are now citing, which they possessed over the interior of those vast and opulent regions, supported their commercial establishments, and enabled them to gratify with unexampled licence that tyrannical spirit which has always, though in different degrees, signalized the intercourse of European states with the refined and amiable inhabitants of their Oriental provinces. Such, during the whole of the 16th, and the greatest part of the 17th century, was the magnificent outline of the Portuguese empire in Africa and Asia. The romantic descriptions of their own authors, corroborated by the testimony of other nations, their rivals and enemies, are sufficient to prove that the achievements and wealth of their nation in the provinces of the Eastern empire were superior to any which it could boast of elsewhere; and the remains of the Portuguese dominions in Africa, where at this day 15 kings are tributary to the court of Lisbon, together with the glittering fragments of the Asiatic empire, corrupted by bad policy, as well as dismembered by

foreign conquest, may convince us of the important relations which the provincial wealth and power of this nation must have formerly borne to its whole resources. The East Indian possessions of Portugal, during the 16th century, threw into their hands the whole commerce of Asia, which, long before the discovery of the passage by the Cape of Good Hope, had formed one of the greatest trades carried on between any two parts of the world; had enriched and refined the whole European empire of Rome, and raised the inconsiderable republic of Venice to a degree of power formidable to all the great nations of the continent. The same commerce, divided among several states, has, since the downfall of the Portuguese dominions, sensibly enriched all those nations, and continues to form a very great part of their extended trade. We may judge, in some degree, of the extent of the trade carried on by the Portuguese in their Asiatic settlements, some time after their eastern empire had begun to decline from the completion of the English and Dutch, by a single fact. In the year 1611, the English company's servants, in one of their voyages to Surat, saw a single Portuguese merchant fleet, consisting of 240 sail, bound for one place, and destined only for the commerce of the northern and most thriving settlements. (Anderson's *Hist. of Commerce*, ii. 245, 263.) The African and Asiatic provinces, however, must be considered as conquered territories, held in subjugation by a few troops and squadrons of ships; not as colonies peopled by emigrants from the mother country, or by a race in which those emigrants and their descendants bore a considerable proportion. Of these vast dominions the Portuguese were nominal possessors; the treasure and blood of the metropolis were wasted in wars with the native powers, and the relations of commerce were on every occasion postponed for those of conquest and dominion. These circumstances have eventually proved fatal to the Portuguese dominion in the East, which has at length been transferred to other powers of superior policy and strength.

The Portuguese trade with India, though rigorously confined to the subjects of the mother country, was never put into the hands of an exclusive company, incorporated by charter, except for a short time, about the year 1731, when the experiment was unsuccessfully tried. The sovereign granted, from time to time, privileges of fitting out vessels, under limitations, to private co-partners and individuals, who thus enjoyed a monopoly of the supplies required both by the Asiatic and European provinces. The monopoly had been generally velleid in the crown, until the year 1752, when it was said to be abolished; but several important articles still continued subject to the royal privileges, and could only be bought in India and sold in Europe on the king's account. From the splendid pre-eminence which the Portuguese trade with India once possessed, it has sunk to a few annual voyages, in consequence of the reduction of the Portuguese empire in the East, and the bad management of the trade and settlements that still remain. With a view to its revival, new exclusive grants have been made to mercantile adventurers in Europe, and an exclusive company has been established at Goa (the chief East Indian settlement) for the management of the whole trade with China. These absurd managements have taken place since the year 1752, when the evils perceived to arise from monopolizing policy, induced the sovereign to abandon several of his exclusive rights, and to pretend that the East Indian commerce was thrown open. While the Portuguese conquests were rapidly pursuing each other in the East, the discovery of Bengal, opened a new field of exertion in the West. Brazil, however, compared

with Asiatic conquests, was regarded with indifference, and slowly peopled by malefactors, and by those whom the persecuting spirit of the times drove, from the mother-country. Among the emigrants of this period, sacrificed to the cruel bigotry of the inquisition, was a great body of Jews, who carried over with them to the colony the skill and industry with which they had enriched and strengthened the European dominions of Portugal. Under their cultivation the natural wealth of this fruitful territory began to appear, and by degrees to attract the attention of government. All the Portuguese subjects, who chose to settle in Brazil, were permitted to subdue large tracts of country, and to hold them as fiefs of the crown, with absolute power over the natives whom they had conquered, and with all the prerogatives of royalty, except capital jurisdiction, coinage, and tithes, which were invariably reserved to the sovereign. These great territorial lords thus acquired an almost absolute authority, over domains often extending 40 or 50 leagues along the sea-coast; and generally leased out parts of their possessions to sub-vassals for terms of 2 or 3 lives. This arrangement immediately attracted to the colony a number of adventurers and opulent persons from the mother country. The importance of this colony, in consequence of the whole territory of Brazil, and the cultivation of various useful articles, gradually increased; and its traffic with the parent state, would have proved a great mutual benefit; if an erroneous policy had not confined it to a few ports in each part of the empire. Annual fleets from Lisbon and Oporto alone were permitted to carry on this rich commerce, under regulations similar to those of the Spanish flotas and galleons. Four emporiums, *viz.* Olinda, St. Salvador, Paraiba, and Rio Janeiro, were appointed for the destination of those squadrons, and the supply of the whole colony. The 18th century opened with a discovery of gold and diamond mines; and since that period many regulations have been adopted, which have proved pernicious both to the colonies and to the parent state. Companies were established at Peru, Pernambuco, and Maragan, which did not long survive the downfall of Pombal, the Portuguese minister: these have ceased to exist above 20 years, after proving highly injurious to both the mother country and the colony during an equal period of time. A new and more liberal system has been introduced; but the royal monopolies still exist in their full force, and obstruct the growth, as well as the circulation, of the most valuable staple produce which Brazil supplies. Since Portugal has experienced the irretrievable loss of her rich East Indian commerce, and a diminution of the traffic formerly carried on with Africa, Brazil is of great importance to her. This colony is better governed and peopled than any of the Spanish dominions; its proximity to Africa and connection with the Portuguese settlements there, afford great facility in the increase of its cultivation, by means of negroes; the possessions of Brazil gives Portugal considerable weight in the continental politics; and the possession of this noble colony, besides yielding a clear revenue to the mother-country (above one-fourth of the whole national income) is the source of a great proportion of her whole commerce;—the imports from them being nearly equal to the whole imports from the other countries of Europe.

The colonies of Sweden and Denmark, are too insignificant to influence, in any considerable degree, the prosperity of the parent states, and bear a less proportion to the whole imperial resources than those of any other nation. The exclusive companies, which for a long series of years monopolized all the colonial trade of both these countries, have been peculiarly injurious. See *COMPANY, Danish and Swedish*.

For an account of the colonies of France and England, the limits of our article oblige us to refer to the articles FRANCE and ENGLAND, WEST INDIES, EAST INDIES, and COMPANY, and the several individual islands of the West Indies.

There are some other kinds of colonies, besides those above enumerated, of which we shall give a brief account. Conquered subjects or prisoners of war have been sometimes removed to particular and select places, either for safe custody, or for the cultivation of waste lands. The ancients more frequently practised this species of colonization than the moderns, who prefer exchanging the prisoners on each side. The Romans, in particular, were constantly accustomed to remove the more active and daring nations to a distance from their native abodes, and to oblige them to reside in some select place which was probably less defensible than their own country, and where, of course, they would be more under command. We are not, however, without some examples of this kind, even in our own times. The Maroons, or remnant of the Spanish slaves, who had been relinquished by their masters, and left on the island of Jamaica, when the Spaniards were expelled by the English, after having long gallantly resisted the forces brought against them, at last submitted to one of his majesty's officers, upon condition of not being sent off the island. To this submission they were induced by the fear of a new species of warfare with which they were threatened, *viz.* the use of blood-hounds to discover their retreats. But the legislative assembly of the island not only refused to pay the Spanish police-runners their stipulated bounty, but also took advantage of some unavoidable delays in the performance of the treaty to annul it altogether, and to transport the Maroons to Nova Scotia, whence they were afterwards removed to Sierra Leone. On account of this flagrant act of injustice the commanding officer of his majesty's troops indignantly refused a handsome sword, which the assembly offered him for his services in putting an end to a war which had been so long protracted. See MAROONS.

Another kind of colonization is the removal of convicted criminals, or of debtors, to some desert spot, in order to work the mines, or break up the land, and thus prepare it for more respectable colonists. The Russians use this mode of colonizing their vast lands in Siberia. But the most interesting colony of this description, particularly to Englishmen, is that of New HOLLAND, which see.—Also, BOTANY BAY, and New South WALES.

Great sums of money have been, and still are, annually expended on this colony, but it has hitherto languished; partly from the disproportionate number of the sexes, and the idle habits of the convicts, but still more from some radical defects in its administration, many parts of which render it more like a mere job for contractors and agents, than a well regulated system for the gradual reformation of the criminals, and for rendering them useful subjects in future. The dissensions also which have taken place among the officers there, cannot but have tended to injure the colony. These dissensions seem to have originated in some measure from the governor being always a naval officer. The absurdity, for such we must esteem it, of a naval officer commanding in chief on shore, merely because he went to the place by sea is fully equalled by several others, which demonstrate how inadequate the undertaking were the framers of the system by which the colony is regulated.

During the first ten years, *viz.* from 1787 to 1797 inclusive, the number of convicts sent to New South Wales

was 5765 men and women, and 93 children, being in all 5858 persons. The expence of transporting, feeding, and governing them, during that period, amounted to 1,087,230*l.* being above 177*l.* for each, exclusive of the expences previous to their embarkation.

The number of convicts remaining was as follows:

Men convicts in the settlement	-	2175
Women	-	939
Convicts sent out in 1796 and 1797,		
Not arrived	-	695
Total	-	3802

So that a loss of 2049 convicts had been sustained in this short period; an evident proof of the most glaring mismanagement. On the first of September, 1796, the agricultural state of the colony was as follows:

	On account of government.	In possession of private persons.
Acres of land in cultivation	1700	3719
Horses	14	43
Black cattle	150	77
Sheep	191	1340
Goats	111	1316
Swine	59	1810

The later accounts which have been received are equally unpromising. The spirit of dissension has increased, and spread itself to every rank: so also has the depravity of the convicts, in consequence of their not being separated, and placed under the controul of steady persons who have an interest in watching over their moral improvement. Indeed, the viciousness of the convicts increased by fellowship, and even many of the free settlers have, from the force of evil example, acquired the same bad habits. The quantity of land cultivated on the public account is too great, and the numerous public works absorb the labour of the convicts, and leave but few of them to be hired out to settlers. These circumstances, together with the ill selection of the convicts, and of the settlers, as to their former employments, contribute to the want of success in the colony.

It certainly is not improper to send, as matter of favour, criminals to remote and desert places to procure their own livelihood, furnishing them at first with a few necessaries, and then leaving them to their own industry, or to supply the free settlers in those places with convicts for servants, in order to free them from the heavy expence incident to their procuring servants from a distance. But the idea of transporting large bodies of criminals to an immense distance, and employing them, under a strong guard, in public works, where few such works can possibly be wanted, and in cultivating land in the produce of which they have no interest, does not seem to have been happily chosen, or very promising, even in theory; and we may add, that practice, upon a very extensive scale, has completely shewn its futility.

The Romans, it is true, transplanted their prisoners of war to distant countries, and employed them on public works; but these works were carried on in well inhabited countries, and were designed for the facilitation of the intercourse between the several parts of the empire, or for adorning the cities with marks of the Roman grandeur.

We believe, however, that the colony of New South Wales might be made to answer much better, if a few simple regulations were adopted, and particularly if the employment of so many convicts on account of government was abolished, and the convicts left more to their own industry.

It was formerly observed in Virginia, that the colony languished so long as the cultivation of the ground, &c. was carried on as a public concern, but that it immediately began to flourish when the lands were divided, and every one left to shift for himself.

The want of capital and experience among the majority of the convicts, forms no objection; as, by furnishing those accustomed to husbandry, gardening, or useful trades, with the necessary seeds and tools, and "a very sparing allowance of provisions, to be gradually diminished," there can be no doubt but that, in a very short time, they would not only be able to repay the advances made them, with interest, but also to pay a gradually increasing rent. As to those bred to no profession useful in the colony, they might be let out by auction, for a year at a time, until they had acquired sufficient experience: and a fourth part of their wages might be deducted and laid by, to form a stock when they were capable of using it, another part being paid into some benefit society.

Hitherto we have spoken of external colonies, or those in which the colonists recede from their mother-country, and establish themselves in foreign land, without, however, submitting to their form of government.

It now remains to treat of those colonies in which large communities of foreigners are, for some particular reasons, permitted to enter and settle in a country; which colonies differ from those founded by private adventurers, only because they do not so strongly affect the political system of the country.

The Russian government, having immense tracks of waste lands, some of which are advantageously situated for mines or for commerce, has, as we have already said, bestowed great attention in endeavouring to people these tracks, as well by foreigners as by natives. The Prussian government has also bestowed the same laudable attention to the improvement of the waste lands in its possession; and it even went so far as to require from the Poles a tribute of marriageable virgins, with a stipulated portion for each.

To this species of colony belongs what is usually called the Babylonish captivity of the Jewish nation, and which is erroneously supposed to have been a removal of the whole nation in a state of slavery; whereas it evidently appears, from their own records, that it simply meant the residence of the Jewish chiefs, and of their priests, at the court of the king of Babylon. The number of persons carried off by the king himself, was (2 Kings, xxiv.) only 10,000; a number surely applicable only to the higher classes. The officers which many of them held in the Babylonian court, and subsequently in the Persian, are a proof, that although they were, for obvious political reasons, required to reside at court, their situation there was perfectly honourable. It is probable, however, that their removal might occasion the gradual emigration of a number of other families, who followed them for the sake of employment, and spread over the Babylonian dominions; as their number was found to be greatly increased, when they were allowed by the Persians to return. They then amounted (Nehemiah, vii. Ezra, iii.) to 49,697 persons.

Many other instances may be found, both in ancient and modern history, of this importation of people. The conquered Greeks filled the capital of the Roman empire, and, by the versatility of their talents, acquired the same influence over the masters of the world, as the modern French (who frequently boast of their Greek origin) have over the fashionable part of our own country. By means of this influence, they introduced among the Romans all the vices for which they were notorious; and to the baneful

effect of their influence, we may justly attribute, in great measure, the downfall of the empire, since they introduced a love of dissipation, and of showy, but trifling acquisitions, instead of the more solid attainments which were required, before they contaminated the public mind.

The importation of slaves into a country, may be regarded as a kind of internal colony of the most important, because dangerous nature. When the slaves are numerous, they are not only retained in subjection with difficulty, (being in general far superior in bodily strength) but they are also of very doubtful fidelity, and ever ready to join any invader, or to flock to the standard of any military adventurer. There is yet still greater danger if an independent state exists in the neighbourhood, and particularly if it should consist of revolted slaves (as has lately happened in St. Domingo), because the greater energy of an independent government enables it to prosecute any ambitious designs of conquest with decided advantage over a delegated authority.

It is, therefore, highly impolitic that slavery should be constantly permitted in any country; and, although, for the sake of bringing labourers to any particular spot, it may be tolerated at first, it is the bounden duty of every state to take decisive measures to convert the slaves, by degrees, into free subjects, and to put a stop to the importation, as soon as the colony has obtained a certain population, and further to take some steps in order to liberate the slaves already imported, or at least to make their offspring free at a certain age. Thus it will be requisite for the colonist to attend to the welfare of his present stock, and to introduce talk-work, whereby he will be changed, in time, from a commercial capitalist, or a needy planter, into a landed gentleman. He will then be solicitous only for his rents, and deprecate the idea of keeping more land in hand than is necessary for the support of his establishment, or to serve as an example of perfect cultivation and grazing to his tenants, to the most industrious of whom he might furnish capital and favourable leases, in order to enable them to improve his own land.

To a neglect of this salutary precaution, we may attribute the present dangerous state of the Dutch and English colonies in the West Indies, since, notwithstanding the length of time that they have been established, the state of society in them is as crude and semi-barbarous as it was at the time of their being first settled.

It was probably owing to a similar neglect that the western provinces of the Roman empire were so speedily subdued by the northern adventurers. The Roman provincials, like the planters in the West Indies, seem to have had little repugnance to a change of masters; partly because the resident planters were thus relieved, at least for some time, from the claims of their creditors; partly because the agents were enabled, in many cases, to convert the plantations to their own benefit; and, lastly, because both were equally afraid that, in case the war was protracted, they should lose their slaves. See SLAVES.

As to their intrinsic nature, colonies are either *agricultural*, which grow within themselves the principal articles of their food and subsistence; or they are *commercial*, which depend upon other countries for the necessaries of life, and devote themselves to the traffic of a few staple commodities. The northern states of America and the Bermuda island are so many instances of agricultural colonies; while the West-Indian islands, together with Virginia and Maryland on the continent, are examples of commercial colonies.

In respect to the advantages or disadvantages of external dependent colonies, no person has more thoroughly consid-

dered the subject than Mr. Brougham, in his elaborate treatise "On the Colonial Policy of the European Powers." The adoption of all the positions advanced by that ingenious writer, may indeed be somewhat hazardous; especially if we consider the great degree of doubt and uncertainty which hangs over all political speculations, on account of the difficulty, and still more the danger of making experiments on those subjects; to say nothing of the want of means for ascertaining whether the effects are ascribed to the right causes, when (as is usual in human affairs) so many causes concur in producing those effects.

The first advantage arising from colonies dependent upon any country, is the extension of the home trade; for such in fact the trade between the mother-country and the colony may fairly be considered, because the whole of the profits is retained within the state; whereas in foreign trades, one of the profits, either that of the buying, or of the selling merchant, goes to enrich a foreign state. The trade of a colony also produces a considerable augmentation of the mercantile navy of the mother-country, and, at the same time; as the ships and their crews are constantly retained within the power of the state, there is far less danger of the sailors being enticed into foreign service, than if part of their time was spent in foreign ports. The European nations have anxiously endeavoured to confine the trade of their colonies to the merchants of the mother-country by positive regulations; but Mr. Brougham thinks this solicitude is absurd and even nugatory. Merchants will, in all countries, prefer dealing with their own countrymen, with whose language, laws, and habits of thinking they are acquainted. And this is more especially the case in commercial colonies, as they require in general such large advances of capital, that few persons would be inclined to invest sums upon private foreign security.

But the greatest utility of colonies, is the affording an opening for the employment of the superfluous population of the mother-country, which must otherwise either emigrate to the neighbouring foreign nations, or die of want at home. The inhabitants, indeed, of agricultural colonies, are in general stationary, and, as it were, lost to the mother-country; but these colonies only attract those who cannot get employment at home, or in the commercial colonies, or those who are in such desperate circumstances that they are obliged to fly from home to avoid the importunities of their creditors. Commercial colonies, on the other hand, have for the most part only a temporary population, as the colonists, after spending a part of their time in the colony, generally return home with their fortunes improved, and carry with them, to the mother-country, the same spirit of improvement to which they owed their success in the colony.

Commercial colonies have a further advantage, in furnishing employment for those large capitals which would otherwise be employed upon the more distant foreign trades, or lent to foreign states.

We shall now say a few words respecting the disadvantages arising from the possession of colonies; these are so great that the economists have loudly declaimed against the utility of forming such establishments; but they have committed a fundamental error, in considering colonies as foreign states. They ought rather to be considered as mere extensions of the parent state, into regions adapted to the production of articles which cannot be raised at home. A circulation of inhabitants is kept up by the commercial intercourse between the colony and the mother-country, and also by the weakness incident to parts remote from the seat of government. So that, as the colonies require, at all times, the fostering care of the mother-country, they are

generally filled with the troops of the parent state and their followers, and the ports are constantly resorted to by its shipping, both mercantile and warlike. It were needless to insist upon the powerful attractions resulting from their common origin, their identity of language, and their similarity of habits in thinking; as the effect of these, in producing a good understanding among nations, must strike the most inattentive observer.

One of the principal disadvantages of colonies, is the wars into which they seem to draw the nations which possess them. But although it is certainly true that external commercial colonies do, in the present times, generally become the seat of warfare between such of the belligerent powers as possess them, it cannot be allowed that they are the causes of the war; for as they increase the frontier to be defended, those nations which possess them will be less ready to engage in hostilities; and it is the weakness of the colonies, (on account of their deficient population preventing the raising of regular troops in them), that is the principal cause of the enemy chusing rather to invade them, than to force his entry into the parent state. The want of a powerful landed interest, in colonies of this nature, tends also to attract the hostilities of the enemy, as the possession of them is seldom disputed with the obstinacy which marks the resistance to invasion in old settled countries; the defence being limited to the small number of troops which the parent state can spare without endangering her own safety, and whose exertions are impeded by the mixture of an ill-disciplined militia, and of volunteers, unaccustomed to service, and deploring their fate in being freed from their own homes.

This unfittedness of external colonies, which are always understocked with inhabitants, to contribute supplies of men for the general defence of the state, is usually considered as a disadvantage; but it cannot in reality be esteemed to be one of much consequence. Even in the parent state itself, it is only in those manufacturing districts that produce articles, the demand for which is variable, that the recruiting service meets with success; in those where agriculture prevails, or in which a staple commodity is manufactured, that service is in general unsuccessful. It cannot, however, be of any consequence, in regard to the general population of the empire, whether the mother-country supplies soldiers, or whether they are raised in the colony, and their place supplied by fresh settlers.

It is only the total want of system, both in the planting and subsequent management of the English colonies, that rendered them at first, and still keeps several of them expensive burthens to the mother-country; as those of other countries not only pay, in general, their own expenses, but also furnish a surplus revenue for the service of the empire.

It will appear, from what we have already said, that a great difference of political strength subsists between agricultural and commercial colonies. The former are much stronger internally, and capable of affording, with their own resources, a more obstinate defence to the attacks of the enemy. But this strength renders them refractory, and difficult to be controlled; hence they require either early restraint, and the observance of a strict discipline, or they must be relinquished as dependencies, and incorporated into the mother-country, as has recently been found necessary in respect to Ireland. On the other hand, although the weakness of commercial colonies renders them much more dependent on the state to which they belong, yet, from the debts with which they are in general loaded, they are ever ready to submit to any invader; especially if the change can be made to a state, where the merchants possess larger

larger capitals than those of the state to which they have already been subjected; as this affords them a hope, not only of being released for some time from the claims of their ancient creditors, but also gives them reason to suppose they may be able to procure still greater credit from their new masters. Every person acquainted with West Indian affairs must acknowledge the truth of this remark; and with respect to other parts, we have, ourselves, twice experienced the facility and even eagerness with which the Cape of Good Hope was surrendered to us.

The want of mercantile capital which our enemies in the West Indies do not as yet possess, is the principal security we have that those colonists will rather chuse to remain under our dominion than fall into the hands of other powers, as they would, in that case, be obliged to diminish their cultivation in consequence of the diminution in the advances made by the merchants upon their future crop. And as to any attempts at independence, the mother-country has a considerable security in the precarious situation of the inhabitants, in consequence of the number of their slaves and the discontent that generally prevails among them. This latter circumstance, might, by those who think the possession of colonies, and the monopoly of their trade, are of great benefit to a nation, be thought to afford a good argument against the abolition of the slave trade, as tending indirectly to lessen the dependency of the colonists. But we may remark, that the greater strength of the colonies, arising from their internal improvement in consequence of the abolition of the slave trade, would more than counter-balance the danger of their revolt, as they would, in consequence of such strength, run less hazard of falling into the hands of an enemy. And the event of the American war has fully proved, that even in the case of the colonies revolting, when they had acquired sufficient strength, the commercial intercourse between the two countries would continue, and probably rapidly increase; so that the government would, at the worst, lose only an expensive incumbrance. It can only be by the influx of foreigners, belonging to a mercantile nation, in such numbers as to acquire a preponderance in the state, so as to alter the fundamental laws and language of the colony, that any great change in its commercial relations would be effected.

The most serious disadvantage of colonies, is that they divert the capital of the nation from the improvement of the mother-country; although this improvement is certainly the most advantageous employment in which the capital of any nation can be engaged. It has indeed been asserted, that the labour of one man on the continent of America, produced more to the state than four at home; but this must be regarded as the mere rant of visionary politicians, being totally unfounded and absurd in the highest degree; for the subjects at home being directly taxed, must yield far more revenue than those in the colonies, who are in general only indirectly taxed to the common service of the empire, by the customs levied upon the commercial intercourse of the two countries. The same persons asserted that each white person in Virginia and Maryland, took off from ten to twelve pounds a year of the growth or manufactures of the mother-country. But the custom-house books are sufficient evidence that this calculation was much over-rated; for the exports to those colonies were never more than 300,000*l.* a year, and therefore, allowing them to contain, as was stated, 120,000 white persons, the consumption of each person was only 1*l.* 13*s.* 4*d.* a head. The whole of the exports to America, when at the highest, was only about 834,000*l.* a year: and this tends to show that it is better to retain the industry of the inhabitants of any coun-

try within its own sphere, and encourage the cultivation of the waste lands, than to divert it to distant colonization. It may, however, be sometimes necessary, as a measure of precaution, to secure the possession of distant places, when it is known, or suspected, that the usual enemies of the state intend to colonize them; but it is extremely imprudent to foster these distant colonies at the expense of the mother-country, as is done in respect to the British colonies. When an old settled country is improved to the highest, then, and then only, can it be necessary to provide outlets for the employment of the surplus capital of its subjects, by conquering, or purchasing some poor country, with a view to its improvement.

As to internal colonies, the encouragement of foreigners, and especially the importation of foreign slaves, must, in general, be regarded as errors in politics. The procuring of a stock of labourers in the first stage of breaking up a new and uninhabited colony, the introduction of new manufactures, or of new commercial relations, can alone justify such measures. And surely it is far better to endeavour to attain these ends by other means. The removal of idle and disorderly persons from great cities, the sending out intelligent travellers into other countries, the encouragement of experimental philosophers and chemists, together with the apprenticing of clever youths to merchants in foreign countries, would probably be equally efficacious. See Smith's *Wealth of Nations*, B. iv. chap. 7. Robertson's *Hist. of America*, vol. iii. Brougham's *Inquiry into the Colonial Policy of the European Powers*, 1803, vol. i. and ii. passim. Paley's *Principles of Moral and Political Philosophy*, vol. i. p. 381. Edwards's *West Indies*, vol. ii.

COLONY of Bees. See HIVE.

COLOONY, in *Geography*, a small post-town of the county of Sligo, Ireland, remarkable for the check given to the progress of the French troops under general Humbert, in September, 1798, by the gallantry of lieutenant-colonel Vereker with about 300 men chiefly of the city of Limerick militia. Though col. Vereker was obliged to retreat in consequence of the number of the enemy, yet he saved the town of Sligo, and by the delay he occasioned, enabled marquis Cornwallis to come up with and entirely subdue the French force. Colony is 98 Irish miles N.W. from Dublin, and five S. from Sligo.

COLOOR, or COLORE, a town of Hindoostan, in the circar of Guntoor, which possesses a diamond mine on the southern bank of the Kistnah, and not far from Condavir.

COLOPENA REGIO, in *Ancient Geography*, a country of Asia in Cappadocia; Sebastopolis and Sebaste are towns of this country.

COLOPHON, a town of Asia Minor now *Atolofco*, or according to others, *Belvidere*. It was one of the chief cities of the Ionian league, seated near the sea, and not, as Piny calls it, an inland city, in the small river Halefus, N.W. of Ephesus and S.E. of Smyrna. It was founded by Mopsus, grandson of Tiresias, and, in process of time, Damafichtlon and Promether, sons of Codrus, conducted a colony hither. It was destroyed by Lyfimachus, and its inhabitants were sent to people Ephesus; but after his death it was rebuilt in a more convenient situation. The Colophonians were such excellent horsemen, that those, for whom they declared themselves, were sure of victory; whence the trite proverb "*Τον Κολοφωνα ιππευεις, colophonem addere*," i. e. to put the last hand to a work, or successfully to terminate it. Colophon was the birth-place of Nicanor, and one of the seven cities that claimed Homer, who lived there some time, as Herodotus informs us. The ancients mention a famous grove and temple of Apollo Darius in the neighbourhood

bourhood of this city; whence some have said that he derived this appellation, though others say that he was called from a mountain bearing that name. The small town of "Notium," on the same coast, often mentioned by Livy, belonged to the Colophonians, and the Romans allowed it the same privileges, which they granted to Colophon itself. Pliny informs us, that they collected in the vicinity of Colophon, a resin of a yellowish red colour, which being bruised, emitted a strong odour; and hence some have derived the name of *Colophony*, now frequently called "Spanish wax," or "Grecian resin," as it is brought from one or the other of those countries. Its episcopal see was subject to the metropolis of Ephesus.

COLOPHON, a town of Greece in Epirus.

COLOPHONIA, in *Botany*, Commers. See *BURSERA pariculata*.

COLOPS, in *Geography*, the name given by Dion to a river of Pannonia, called *Colapis*, by Strabo.

COLOQUINTIDA, in the *Materia Medica*. See *COLOCYNTHIS*.

COLOR, in the *Ancient Music*. See *COLOURS*.

COLOR *Indicus*. See *INDICUS Color*.

Color nero e rosso, Ital. black and red, in *Music*. We have seen in Bene's college, Cambridge, old music books of Henry VII's time, in which some of the notes were black, and some red.

COLORADO, in *Geography*, a river of New Mexico, in the south-western part, which flows into the northern part of the Vermilion sea, or gulf of California, called by D'Anville *Colorado de los maytzes*. The course of this river, which is generally from N. E. to S. W. sometimes W. may be computed at 600 British miles. It is called Rio Colorado, or Red river, because the waters acquire that colour from the red clay on which the rains fall. Its stream is deep and copious, and is capable of considerable navigation. The neighbouring savages, who swim across it by a peculiar artifice, are denominated *coconiaropas*, which see. This river is joined from the east by a large river, called Gila, which, however, is everywhere fordable. The country between these rivers is said to be an upland desert, without water or pasture. On the other side of the Colorado, the country is said, on the contrary, to be very fertile, and the natives rather fond of cultivation. It is thought that considerable rivers also join the Colorado from the west, flowing from the same chain of mountains that supply the sources of the Rio Bravo, in lat. 40°. Among these the Zaguuanas is the most lengthened stream, and may therefore be regarded as the Colorado itself. On the west of the Colorado, the river of Maityrs, and that of Pyramids, have umbraceous terminations, perhaps in the same lakes, or, perhaps in the Colorado. In lat. 39° W. long. from Madrid, 110° 3', there is a large lake without a name, which receives two considerable rivers from the east, one of which is called Euenara. From lat. 42° to 43°, and under the same meridian, extends another lake, which, though not fully explored, seems to be that of Imperices, where the factors Velez and Escalante terminated their discoveries, and the same fit inland knowledge of the Spaniards. If, indeed, the Spaniards have explored that part of the country, they conceal their in ornament.

On the east of the same chain, from which springs the Rio Bravo, arise two rivers, which probably join the Mississippi; and it appears that the eastern river of Colorado has been confounded with another river of the same name, with the epithet of Nuevas, which probably joins the Atkanza or Akasala. See *COLORADO* or *Riviere Rouge*, infra.

COLORADO, a river of New Mexico, which runs into the Bay of St. Bernard, in the gulf of Mexico.

COLORADO, *Riviere Rouge*, or *Red River*, a river of North America, in Louisiana, which runs into the gulf of Mexico, or rather joins the Mississippi river, before it falls into this gulf, some miles above New Orleans.

COLORADOS, *Los*, a numerous cluster of small islands or rocks, near the N. W. coast of the island of Cuba.

COLORATURA, in the *Italian Music*, is used to denote all sorts of variations, trillos, diminutions, &c. that can render a song agreeable.

COLORBASIANUS. See *COLARBASIANUS*.

COLOREDO, in *Geography*, a town belonging to the state of Venice, in the country of Friuli; seven miles N. W. of Udina.

COLORETTI, MATTEO, in *Biography*, was born at Reggio, in the year 1611, and is spoken of by Tirabochi and the abbé Lanzi, as a most excellent painter of portraits.

COLORIFIC earths, in *Mineralogy*, a class or tribe of earths, in the arrangement of Kirwan, described by him as strongly staining the fingers. Of these he enumerates four families, viz. red, yellow, black, and green; the red is the reddle, or rubrica fossilis. Rothel. Laffi, o. 973. Of dark cochineal red colour, or intermediate between brick and blood red, having neither lustre nor transparency; fracture, earthy, sometimes conchoidal; fragments, 1; hardness, 4; sp. gr. inconsiderable; adhering pretty strongly to the tongue; feeling rough; assuming a polish from the nail; strongly staining the fingers; falling immediately into powder in water, and not becoming ductile; not effervescing, nor easily dissolving in acids. When heated to redness, crackling and growing black; at 150° the specimen (Lefke, o. 973) melted into a dark greenish yellow frothy enamel. It differs from red ochres only by containing more argill. The red colour proceeds from oxygenation, and the absence of acid. The mere air of water is expelled by heat, the browner it grows. The yellow, Gellebard, Lefke, o. 1093, is of an ochre yellow colour; as to lustre, externally it often hath some gloss, but internally none; transparency, 0; fracture earthy, often inclining to the conchoidal; fragments, 0; hardness, 3; sp. gr. inconsiderable; adheres strongly to the tongue; feels smooth, or somewhat gray; takes a high polish from the nail; strongly stains the fingers; in water it immediately falls to pieces with some hissing; and afterwards to powder, without diffusing itself through it; does not effervesce with acids, nor is easily soluble in them; heated to redness, it crackles, hardens, and acquires a red colour, and gives a reddish break. At 156°, Mr. Kirwan melted the specimen, Lefke, (o. 1093) into a liver brown porous porcelain mass. This yellow earth differs from ochres only in containing a greater proportion of argill; the yellow colour proceeds from the calc of iron, highly oxygenated, and probably containing both water and acid. Those earths which contain a large proportion of iron, have rather an orange colour. According to the analysis of M. Sage of Paris, who has the merit of preserving to his countrymen the immense gains acquired by the Dutch from converting this yellow earth into what is there called "English red," it contains 50 per cent argill, 40 oxyd of iron, 10 water, acidulated by vitriolic acid. Mem. Par. 1773, 313. The 3d family, or black, black chalk. Schwartz, Krude, Z. chen, Schifer, Lefke, 3, 972; Pierre noire of Briffon, p. 16, is of a greyish black colour; lustre, 0; transparency, 0; fracture imperfectly curved slaty; fragments 1, partly flat, partly long subultry; hardness, 5; sp. gr. 2, 114. by Kirwan's trial by Briffon, 2 186 before absorption of, 2, 277 after absorption of water; adheres slightly to the tongue, feels smooth, assumes a polish from a knife; gives a black break, and marks black; in wa-

ter does not readily moulder, but if taken out cracks in a short time; does not effervesce with acids, nor easily dissolve in them; heated to redness, it crackles and becomes reddish grey; and contains somewhat vitriolic. The 4th family, green earth. Lefke, o. 1013, is of a greyish green colour; found generally in lumps in the cavities of other stones, or externally investing them; lustrous, o; transparency, o; fracture, earthy, fragments uneven, sometimes verging to the conchoidal; fragments, 2; hardness, from 6 to 7; sp. gr. 2.637; sometimes feels smooth, does not assume a polish from the knife, nor adhere to the tongue, nor stain the fingers, nor mark while dry, and when wet but slightly, in water it often crumbles after standing about half an hour; does not effervesce with acids, nor is easily soluble in them; heated to redness, it crackles and becomes of a dark reddish green colour; at 147°, the specimen (Lefke, o. 013) melted into a black compact glass, resembling that of basalt; which shews it to consist of silice, argill, iron not much oxidated, and oxyd of nickel, from which the green colour is derived, besides water. Kirwan's Elem. of Mineralogy, vol. i.

COLORINA, or COLARINA, in *Ancient Geography*, a town of Arabia Felix. Ptolemy.

COLORISATION, or COLORATION, in *Pharmacy*, a term applied to the several changes of colour which bodies undergo in the various operations of nature, or art; as by fermentation's, lotions, coctions, oxydations, &c.

COLORITES, in *Ecclesiastical History*, a congregation of Angulin monks, instituted about 1530, and so called from *Colorita*, a mountain near Morano, in Calabria, where a church was erected to the Virgin Mary.

COLORNO, in *Geography*, a town of Italy, in the Parmesan; 7 miles N. of Parma.

COLOS, a town of Transylvania; 4 miles N. of Colosvar.

COLOSER SALT MINE, in Hungary; the stratum of rock salt in this famous mine, is of the enormous thickness of 60 fathoms; the diameter of the excavation made therein by the miners, is 50 fathoms. "Boni's Hungary," p. 140, 143.

COLOSVAR. See **COLOSVAR**.

COLOSSAL COLUMN. See **COLUMN**.

COLOSSE, in *Ancient Geography*, now *Chonos, or Konos*, a city of Phrygia Major, in that part called Pacatiana, seated on an eminence, on the south side of the Meander. It was built by the river Lycus, near the place where, according to Herodotus (l. vii. c. 50.) it begins to run under ground, as it does for five furlongs before it rises again, and flows into the Meander. This city was situated at an equal distance between Laodicea and Hierapolis, and to this place Xerxes came in his expedition against Greece. All these three cities perished by an earthquake, says Eusebius, in the 10th year of Nero, or about two years after St. Paul's epistle was sent to the Christians at Colosse. The government of this city was democratic, and its first magistrate bore the title of archon and praetor. This city, having been forcibly transferred to the Persians by the Macedonians, passed afterwards to the Sacerdotes. After the defeat of Antiochus III. at the battle of Magnesia, it became subject to Eumenes, king of Pergamus. And when Attalus, the last of his successors, bequeathed his dominions to the Romans, this city, with the whole of Phrygia, formed a part of the proconsular province of Asia, which division subsisted till the time of Constantine. After the reign of this prince, Phrygia was divided into Phrygia Pacatiana, and Salutaris, and Colosse was the sixth city of the first division. It afterwards took the name of Chonos, or Konos.

COLOSSIANS, Epistle to the, in *Biblical History*, a canonical epistle, addressed to the Christians at Colosse by the apostle Paul, and conveyed to them by Tychicus and Onesimus, towards the close of St. Paul's first imprisonment at Rome, which was about the year of our Lord 63, or the 9th of the emperor Nero. As Timothy joins with the apostle in the salutation at the beginning of this epistle, he was still at Rome, and not yet sent away to Philippus; and hence Dr. Lardner concludes, that this epistle was written about the same time with that to the Philippians, in the year 62, and some time before the end of it. Although it appears from this epistle, that a Christian church was established at Colosse; we have no account by whom, or at what time, it was founded. Some have concluded from chap. ii. 1. that St. Paul had never been there himself. It is not, however, improbable, though no mention occurs of this fact in the history of the Acts, that the Colossians might have been converted while Paul resided at Ephesus, considering more especially that he spent no less than three years in that city, and preached with so much success, that St. Luke tells us, (Acts, xix. 20.) that "all they who dwell in Asia heard the word of the Lord, both Jews and Greeks." (See Acts, ch. xvi. 6. xviii. 23.) Dr. Lardner, arguing from the testimony of Theodoret (tom. iii. p. 342, 343.), who lived in the 5th century, alleges a variety of considerations, inducing him to think, that the churches of Colosse and Laodicea, had been planted by St. Paul, and that the Christians there were his converts. Of these we shall only select the three following, viz. that the apostle was twice in Phrygia, in which were Colosse, Laodicea, and Hierapolis (Acts, xvi. 6.); that he does in effect, or even expressly say, that he had dispensed the gospel to the Colossians (Epi. ch. i. 21—25); and that from several passages which occur in this epistle, it appears, that the apostle is not writing to strangers, but to acquaintance, disciples, and converts.

The Christians of the church at Colosse seem, from the honourable testimony that is born to them in this epistle, to have maintained an honourable character for their party, and the zeal they discovered for the gospel; nevertheless, we find, from the cautions addressed to them in the second chapter, that they were in some danger of being drawn aside by the subtleties of the Heathen philosophers, and the insinuations of certain Jewish zealots, who insisted upon the necessity of conforming to the ceremonies of the Mosaic law. Accordingly, the grand design of this epistle is to excite the Colossians, by the most persuasive arguments, to a temper and behaviour worthy of their sacred character, and to secure them from the influence of those Pagan sophists, or Jewish bigots, who would seduce them from the purity of the Christian faith.

COLOSSUS, a statue of enormous or gigantic size.

The most eminent of this kind was the colossus of Rhodes, one of the wonders of the world, a brazen statue of Apollo, so high, that ships passed with full sails betwixt its legs. It was the workmanship of Chares, a disciple of Lysippus; who spent twelve years in making it: it was at length overthrown by an earthquake, B. C. 224. after having stood about sixty-six years. Its height was a hundred and five feet: there were few people who could encompass its thumb, which is said to have been a fathom in circumference, and its fingers were larger than most statues. It was hollow, and in its cavities were large stones employed by the artificer to counterbalance its weight, and render it steady on its pedestal.

On occasion of the damage which the city of Rhodes sustained by the above-mentioned earthquake, the inhabit-

ants sent ambassadors to all the princes and states of Greek origin, in order to solicit assistance for repairing it; and they obtained large sums, particularly from the kings of Egypt, Macedonia, Syria, Pontus, and Bithynia, which amounted to a sum five times exceeding the damages which they had suffered. But instead of setting up the colossus again, for which purpose the greatest part of it was given, they pretended that the oracle of Delphos had forbidden it, and converted the money to other uses. Accordingly the colossus lay neglected on the ground for the space of 894 years, at the expiration of which peridi, or about the year of our Lord 653, or 672, Moawvas, the 6th caliph or emperor of the Saracens, made himself master of Rhodes, and afterwards sold their statue, reduced to fragments, to a Jewish merchant, who loaded 900 camels with the metal; so that, allowing 800 pounds weight for each load, the brass of the colossus, after the diminution which it had sustained by rust, and probably by theft, amounted to 720 thousand pounds weight.

Some critics observe, that the colossus of Rhodes gave its own name to the people among whom it stood; and that many, at least among the ancient poets, call the Rhodians *Colossians*: hence they advance an opinion, that the Colossians in scripture, to whom St. Paul directs his epistle, are, in reality, the inhabitants of Rhodes. Of this sentiment are Suidas, Calepine, Munster, &c.

The basis that supported it was of a triangular figure: its extremities were sustained by sixty pillars of marble. There was a winding stair-case to go up to the top of it; from whence one might discover Syria, and the ships that went to Egypt, in a great looking-glass that was hung about the neck of the statue. This enormous statue was not the only one that attracted attention in the city of Rhodes. Pliny (l. xxxiv. c. 37.) reckons 100 other colossuses not so large, which rose majestically in its different quarters. Besides these, here were to be seen five others, the work of Briaxis, and representing divinities. Among the antiquities of Rome, there were seven famous colossuses: two of Jupiter, as many of Apollo, one of Nero, one of Domitian, and one of the Sun.

COLOSTRUM, or **COLOSTRA**, in *Medicine*, the first milk of any animal after bringing forth young, called in common *breastmilk*.

It is remarkable that this milk is generally cathartic, and purges off the meconium; thus serving both as an aliment and medicine.

The same name is likewise given to a disease which this thick coagulated milk sometimes occasions.

An emulsion prepared with turpentine, dissolved with the yolk of an egg, is sometimes also called by that name.

COLOSVAR or **CLAUSENBURG**, in *Geography*, the *Zemlja* of the ancients, by the Hungarians called *Kolofovar*, and in Latin *Claudicopolis*, a town of Transylvania, seated on the first branch of the river Samos, and surrounded by an ancient thick wall, where the states of the province usually assemble. The university was suppressed in the year 1782. The Unitarians, who formed one of the sects received in Transylvania, established their principal seat in this place: 255 miles E.S.E. from Vienna, and 45 N.N.E. from Belgrade. N. lat. 46° 57'. E. long. 22° 21'.

COLOT, **GERMAIN**, in *Biography*, a famous lithotomist, of the 15th century, practised surgery at Paris, during the reign of Lewis IX., from the year 1461 to 1480, and was in great favour with that prince. He was the first regular bred surgeon who practised lithotomy. The operation before his time had been enquired by persons practising no other part of surgery. Regular practitioners had

probably been deterred from interfering in the business, from reverence to the authority of Hippocrates, who obliged his disciples to swear they would not perform the operation, "Nec vero calculo laborantes fecabo." He ingratiated himself with some of the itinerant practitioners, saw them perform the operation, and began with cutting dead bodies. Having communicated his ideas to the physicians of the court, they obtained leave from Lewis, that he might operate on a condemned criminal, who was attacked with the stone in the bladder. The criminal consented, on the condition promised, that he should be pardoned the crime he had committed. The operation was successfully performed, the patient recovering, it is said, in fifteen days. Colot obtained great reputation by the cure, which was rewarded by a pension from his sovereign. The time of his death is not known. Eloy, Dict. Hist.

COLOT, **LAURENCE**, a descendant of Germain, from whom he acquired the art of cutting for the stone, was in great reputation, in the early part, and to the middle of the 16th century, for his skill in performing the operation, by what is called the greater apparatus. By this method the urethra and neck of the bladder are necessarily cut through, which subjected the patients, not infrequently, to fistula, and other inconveniences, yet by his dexterity in operating these accidents were often avoided, which gave him so much credit, that he was sent for to visit patients in Flanders, and other distant countries. To retain him in France, Henry II. made him his surgeon in ordinary in the year 1550, rewarding him with a pension, adequate to the loss he sustained, by being prevented visiting patients in foreign countries. He also created for him the post of lithotomist to the royal family, which was continued to three of his descendants. Philip, the last of them, died in 1656, aged sixty-three years.

COLOT, **FRANÇOIS**, son of Philip, appears to have inherited, with the name, the skill and dexterity of his ancestors, in performing the operation of lithotomy. He left a treatise on the operation, which was published in 1727, under the title of "Traite de l'Operation de la taille, avec des observations sur la Formation de la Pierre, et les Suppressions d'Urine," 12mo. Paris. In this work he gives a short history of the method of operating by the greater apparatus. It was invented, he says, by John de Romanis, a physician of Cremona, in Italy, in 1525, and by him communicated to Marianus Sanctus, who instructed Oétavian de Vila, a surgeon at Rome. Marianus published, in 1535, "Libellus Aureus, de lapide e Vesica per incisionem extrahendo," 8vo. Venet. Of Oétavian de Vila, who was several times called to France, to perform the operation, Laurence Colot is supposed to have obtained some valuable information on the subject, which contributed much to the celebrity he afterwards enjoyed. The method of operating by the greater apparatus has been long since abandoned for a more simple and easy operation, therefore called, by the lesser apparatus, first discovered, Mr. Sharp says, by Mr. Foubert, an ingenious French surgeon, but much improved by Mr. Cheselden, in which the urethra and neck of the bladder are avoided by the operator: with Francis Colot, the celebrity of the family, seems to have been extinguished. Eloy, Dict. Hist.

COLOUR, or **COLOR**, from the Latin, *color*, in *Philosophy*, means that property of bodies which affects the sight only; thus the grass in the fields has a green colour, blood has a red colour, the sky generally appears of a blue colour, and so forth; nor can those colours be distinguished by any of our other senses, besides the sight. The variety of colours, as they are presented to us by the substances that surround

surround us, is immense, and from them arises the admirable beauty of the works of nature in the animal, in the vegetable, and in the mineral kingdom, or, more properly speaking, in the universe. The science, which examines and explains the various properties of the colours of light and of natural bodies, and which forms a principal branch of optics, has been properly denominated *chromatics*, from the Greek word, *χρῆμα*, which signifies *colour*. We shall, however, state this theory in the present article, as being much more obviously recurred to by those persons who wish to be informed on the subject. A distinct idea of what is meant by the word *light*, may be easily formed by its contrast with darkness, which is a privation of light. With our eyes shut we have darkness; if we open our eyes, whatever we perceive through them is occasioned by the agency of light, and the various colours of bodies are parts of that light.—It has sometimes been pretended by certain ignorant persons, that they could distinguish colours by the touch; but the testimony of divers intelligent persons, who have had the misfortune of being blind, in consequence of which their touch has, from necessity, become very exquisite, has constantly contradicted those vain assertions. Besides, it will appear from the following theory of colours, that to discriminate colours by the touch is utterly impracticable. There are indeed certain pigments of common use in painting, which, either from their roughness, smoothness, unctuousity, or other quality, may affect the touch, and with a little practice a person may learn to distinguish the feel of vermilion which looks red from that of sap-green, which looks green, and so forth; but this is not the art of distinguishing colours by the touch. It is only the art of distinguishing certain peculiarities of surface. In fact if two pigments exactly of the same texture (and several such there are) but of different colour, be presented to the fingers of a man with his eyes shut, he will pronounce them to be exactly of the same colour.

The questions which naturally occur to the human mind in the contemplation of colours, are, whence do they derive their origin?—Are they produced by the coloured bodies themselves, or by something external?—Do they move from the coloured bodies to our eyes, and strike upon them, or enter them; or are they owing to some medium interposed between the various bodies of the universe?—Are they material or not?

The ideas entertained by the ancients concerning the nature of colours, were mostly wild and absurd; nor has the present theory, imperfect as it is, been formed without an innumerable variety of experiments, observations, and the concurring investigations of a great many ingenious persons. The followers of Pythagoras called colour the superficies of bodies; Plato considered it as a flame issuing from them; Zeno called it the first configuration of matter; and Aristotle said it was that which rendered bodies actually transparent. We need not add a formal refutation of those extravagant ideas, which were the mere offspring of the imagination, unsupported by experience and by reason. The philosophers of those times paid little or no regard to experiments; hence they made no discoveries or improvements worthy of being recorded. A long and unprofitable period of nearly 2000 years elapsed, from the commencement of philosophical studies in Greece, until about the time of Descartes, when the revival of learning in Europe renewed with additional vigour the enquiries concerning the nature of light and colours. And it is curious to observe by what small steps, and what circuitous ways, any useful discoveries were made. See Priestley's history of vision, light, and colours. Descartes considered colour as a modification of light, and he attributed the difference of colour to the prevalence of the

direct or rotatory direction of light. Grimaldi, Dechales, and others, supposed that a certain elastic medium of a peculiar kind filled the universe, and that the differences of colour depended upon the quick or slow vibrations of that medium. Rohault imagined that the different colours were produced by the rays of light entering the eye at different angles with respect to the optic axis. And Dr. Hook imagined that colour is caused by the sensation of the oblique or uneven pulse of light; which being capable of no more than two varieties, he concluded there could be no more than two primary colours. Such were the ideas of philosophers respecting the nature of colours, when Sir Isaac Newton began to examine the subject in his cautious experimental manner, by which means, about the year 1666, he discovered the foundation of a theory of colours, which has been justly adopted and admired by his contemporaries, as well as by the present succeeding generation.—Rays of light issuing from a luminous object, proceed in straight lines as long as they pass through a uniform medium. If they meet with a transparent medium of different density, they will also proceed through it in straight lines, provided they enter that medium in a direction perpendicular to its surface, otherwise they are caused to bend their course, so that beyond the abovementioned surface they proceed in straight lines also; but these straight lines form a certain angle with the straight lines of their direction before they entered the last medium. The bending of the rays is called the *refraction* of light, and the angle that has been just mentioned is called the angle of refraction. See REFRACTION. Newton, having presented a glass prism, or kind of wedge, to the light of the sun, which entered a dark room through a small hole, found not only that the rays were bent from their course, *viz.* refracted, but he likewise observed that the image of the sun was thereby considerably elongated; and this elongated image instead of appearing of a uniform bright white light, was resolved into a series of colours, which exactly resembled the colours of the rainbow. This elongation of the solar image thus formed, is called the dispersion of light. These colours pass from one to the other by very small, and altogether imperceptible gradations; so that it is impossible to say where one begins and the next ends. Various methods have been tried for the purpose of rendering the colours of this prismatic spectrum more limited and distinct; none, however, has been attended with complete effect. The following seems to be the best method. Let the light of the sun pass through a hole of about one-tenth of an inch in diameter, into a dark room. Place a screen at a little distance from the hole (for instance six or seven inches) within the room, and let the middlemost part of the light pass through a similar hole in the screen; the object of which is to prevent, in great measure, the scattered light or penumbra, on the sides of the spectrum. Let the light then fall perpendicularly upon a convex lens; at the distance of about 10 feet, by which means a defined image of the sun will be formed upon a screen placed at the focal distance of the lens. Now, if a prism be placed close to the lens, so that the light, after having passed through the lens, may pass through, and be refracted by, the prism; then a coloured spectrum will be formed upon the screen. The long sides of this spectrum are very well defined; but its narrow terminations are semicircular, and its whole length consists of circular coloured images of the sun intermixed with each other, especially about the middle or axis of the spectrum; yet the most predominant colours are more distinguishable from each other, especially towards the sides of the spectrum, so that their boundaries may be marked with tolerable accuracy. The glass prism fit for this experiment must be well formed,

COLOUR.

and free from veins, scratches, bubbles, &c. Those principal colours are seven in number, *viz.* red, orange, yellow, green, blue, indigo, and violet. They do not occupy equal spaces in the spectrum; but for the proportion of their breadths, and likewise for a more accurate description of the prismatic experiments on light, see the article REFRACTION.

The above described experiment with the glass prism gave Sir Isaac Newton reason to conclude that the white light of the sun consisted of seven colours, which had different powers of being refracted, so that the red rays were refracted less, the orange a little more, the yellow still more, and so on; hence the image of the sun was converted into an oblong variegated spectrum. In confirmation of this theory Newton instituted a variety of other experiments, which were attended with remarkable results, and the principal of them are as follows:

If the light which has been refracted and dispersed by a prism, be received again upon another prism which must be situated in a direction perpendicular to that of the former; the spectrum will by that means be removed from its original situation into a lateral one; but its breadth and its colours will remain unaltered. Now if the elongation of the beam of white solar light, and its resolution into different colours, were a modification of light produced by the prism only; then the second prism ought to expand the spectrum in breadth, so as to form a quadrilateral figure of equal sides; but instead of that we find that the colours and their breadths remain unaltered.

If the refracted and dispersed beam of solar light, be received upon a concave reflector, the different coloured rays will be reflected to a focus, where they will form a white or colourless image of the sun. But if any of the colours be stopped by the interposition of a wire, or other slender and opaque body between the prism and the reflector, then the image will become coloured with some mixture of colours. This proves that white light consists of coloured rays, intermixed in a certain proportion, and that by a mixture of the rays of the seven primary colours in that due proportion, white light is produced. Therefore, white arises from a certain mixture of colours, and blackness arises from a stoppage or absorption of all colours. This property of light and colours, may be familiarly illustrated by the following experiment: Divide the flat surface of a wheel, or the upper flat surface of a top, such as boys use, by means of lines going from the centre to the circumference, into seven parts, having the same proportion that the breadths of the colours have in the prismatic spectrum, and let those portions be pointed respectively with the seven colours. This done, if you spin the wheel or the top, so as to cause it to turn very fast, in the light of the sun; you will find that the painted surface will look white; for by the quick motion of the wheel, the impressions of the colours in the eye become mixed, and of course they form a white light. Stop the wheel, and the seven colours will appear very distinct.

If, when a spectrum is formed by the light which has passed through a prism upon a screen, a small hole be made through the screen, and the ray of one colour only be permitted to pass through it on the other side of the screen; then whatever is viewed in that homogeneous light, will appear of that particular colour. Thus, if the red light only has passed through the hole, then blood, or grass, or milk, &c. viewed in that light behind the screen, will all appear red; excepting that the blood will appear of a stronger red colour than the grass or the milk. If the blue light only has been transmitted through the hole; then the above-mentioned substances will all appear blue; and the like may

be understood of the other homogeneous colours. This proves that the colours, which seem to proceed from coloured bodies in general, do not belong to those bodies; but they are the component parts of the white light, in which those bodies are viewed, and that certain bodies have the property of absorbing some of those coloured rays of the white light which falls upon them, and of reflecting others. Thus, grass reflects the green rays and absorbs the rest, hence, the green rays coming to our eyes, render the appearance of grass green; thus blood absorbs every other coloured ray excepting the red, and so forth. Black bodies absorb all the seven coloured rays, and white bodies reflect them all.

If two holes, at about a foot distance from each other, be made in the shutter of a dark room, and two prisms be used, *viz.* a prism be placed to receive the light at each hole, two spectrums will thereby be formed upon the screen; and by turning the prisms gently round their axes, the spectrums may be caused to fall one upon the other. Let the yellow of one spectrum fall upon the blue of the other, and at that place the mixture of those two colours will appear green. Let a small hole be made exactly at that place, and that green light will pass through the hole behind the screen, and will form a green circular image upon another screen placed to receive it. Now, if exactly behind the perforation of the first screen, you fix the refracting angle of a prism, then the image upon the second screen will not only be moved from its place, but will appear oblong, with a yellow border at one extremity, and a blue border at the other extremity; for that spot or image of the sun consists of two primitive colours of different refrangibilities. The same thing must be understood of any other colour formed from a mixture of any two primitive prismatic colours; for any two of those colours will form, or rather will look like an intermediate colour; thus, red and yellow form an orange, blue and violet form an indigo, and so forth.

If the experiment be performed with one solar spectrum: *viz.* a single prismatic colour; for instance the green be permitted to pass through a hole in the screen, and be then received upon another screen, the image will be of the same colour as in the preceding experiment, *viz.* green, and circular. Now, by placing a prism behind the perforation of the first screen, the green image will be moved from its place, but it will not be elongated nor altered in colour, because this image consists of one uniform primitive colour. (Newton's Opt. b. i. p. ii. prop. iv.) This remarkable experiment shews, that though a green may be formed from a combination, or any other prismatic colour may be formed from a combination of the two adjacent colours; yet each of those colours in the prismatic spectrum, is a primitive uniform or homogeneous colour.

Notwithstanding the conviction which naturally attends the result of the above mentioned experiments, several persons have supposed that the primitive colours of light are not seven, but three only; namely, red, yellow, and blue; and they have been led to this supposition, by observing that the painters can produce all the other colours, by mixing either all those three colours together, or two of them, in due proportion.

A recent writer of eminence in the philosophical world, (M. C. A. PIERRE) has started another theory. He thinks that the primitive colours, (*viz.* the components of white light) are three in number; but he supposes them to be the red, the green, and the violet; and that the other colours of the spectrum are formed from a mixture of those; that is the yellow from the red and the green, the blue

from

from the green and the violet, &c. See *L'Annale de Chimie*, Sept. 1806.

Hitherto we have treated of the formation of colours by refraction; from which it appears that the white solar light consists of coloured rays; that whenever that light enters a transparent medium in an oblique direction, it is caused to deviate from its rectilinear course; and at the same time its component coloured rays, are separated in consequence of their different refrangibility. The next series of facts, upon which the theory of colours depends, relates to the *inflection* of light, it having been found, that the rays of light are bent in their course, and resolved into their component colours, not only by refraction, but likewise by merely passing by the surfaces of bodies. It seems that the rays of light are attracted by bodies, when they come within a certain distance of their surfaces, and that the coloured rays of white light being attracted more or less, are separated from each other. A great variety of experiments relating to this inflection of light, were originally made by Newton, and have, since his time, been instituted by other able philosophers. But, though several remarkable facts have been discovered; yet the present state of knowledge does not admit of their being reducible to a single principle, or to any general and comprehensive laws.

In order to give our readers some idea of this property of light, we shall now subjoin an experiment related by a recent anonymous writer; referring, then, the reader to the article *Inflection of Light*, for a full account of whatever belongs to it.

"Across a beam," says the above-mentioned author, "of solar light, admitted into a dark chamber, through a small hole in a thin piece of lead, nearly $\frac{1}{8}$ of an inch wide, I interposed a hair of a man's head, and receiving the beam on a screen, or sheet of white paper at a distance, and with an obliquity convenient for the purpose, I noted the following appearances.—At the termination of what may be considered as, and therefore may be called, a shadow, whose intensity or darkness was not considerable; the following orders and distinctions of colours appeared. First, and nearest to the dark or black parts of the shadow, might be seen a diluted blue, changing into a breadth of white light, followed by breadths of yellow and red. To these succeeded an interval of diluted shade, then breadths of diluted violet, blue, diluted green, yellow, red; then green diluted yellow, red; diluted green, red; white, diluted red; and finally white light. These are the more general orders of the colours. Of these orders, the three first were sufficiently obvious and distinct; the last evanesced and requiring accommodation of circumstances to produce, and attention to perceive them." Observations concerning the Inflection of Light, &c. London 1799.

The last set of facts that remains to be mentioned, as relating to colours, consists of the phenomena exhibited by thin transparent bodies, especially by those of variable thickness. Every person must recollect to have seen the bubbles of a solution of soap, or of other thickening substance, exhibit a variety of colours similar to those of the solar spectrum, or of the rainbow. These bubbles are nothing more than thin vesicles of the solution, whose thickness varies continually. But a variety of thin solid substances exhibit the like phenomenon, such as plates of muscovy glass, or of talc; thin plates of glass; metallic and glass plates moistened with a variety of fluids, &c. Newton took two object glasses of telescopes, one of which was a plane convex, and the other a double convex one. He laid the latter on the flat side of the other, and pressed them

point of contact, which increased and decreased both in number and in size, according as the lenses were more or less forcibly pressed against each other. The central spot was black, and circles of colours appeared round this spot, which were brighter near it than farther off. Their order, commencing from the black spot, was blue, white, yellow, red; violet, blue, green, yellow, red; purple, blue, green, yellow, red; green, red; greenish, blue, red; greenish, blue, pale red; greenish, blue, reddish, white. (Newton's Optics, b. ii. p. 1. Observ. iv.) Experiments similar to the above have also been performed with flat glasses, lenses of various curvatures, and other substances, by other philosophers, such as Moraldi, Grimaldi, Delisle, Mairan, Mazoes, Du Tour, Muschenbroeck, &c. See an account of their experiments in "Priestley's Hist. of Vision, Light, and Colours." p. 6. sect. 6. After the above succinct account of the principal experiments that have been instituted, and the various important discoveries that have been made, concerning the nature of light and colours; it is proper to observe, that the subject is not only very far from being exhausted; but that the theory arising from those experiments and discoveries is doubtful in almost all its parts. The number of primitive colours distinct from one another, if such do really exist, is not quite determinate; the attraction between the rays of light and other bodies is an hypothesis not clearly understood; for it is a prevailing opinion with several philosophers, that the rays of light are attracted within a certain distance, and repelled beyond that distance. The reflection of coloured rays from the surfaces of bodies is likewise involved in much uncertainty; it being unknown whether the reflection takes place at the very surface, or at a little distance beyond it by some power inherent in bodies, or, lastly, from some other surface a little within the bodies, which supposition is founded upon the hypothesis that all bodies are transparent, as far as a very small part of their bulk, which hypothesis is founded upon the observation that several dense and opaque bodies, when much attenuated, become, in some measure, transparent; and such is the case with gold leaf, which, when placed against the light, appears of a greenish cast.

Notwithstanding this uncertainty respecting the theory in general, the following particulars seem to be sufficiently established; namely, that by refraction and inflection the white light of the sun is resolved into coloured light. Here it may be naturally asked whether the light of other luminous objects is not resolved, by the like means, into the same colours? The observations made in relation to this particular are not so numerous, nor so exact as might be wished; it appears, however, that some luminous objects emit rays of particular colours more abundantly than of other colours. The abbé Rochon having placed a prism before an achromatic telescope, observed through it the light of the stars; and found that the white light of Sirius was resolved into an oblong spectrum, which consisted almost entirely of three colours, *viz.* red, green, and violet. An indication of yellow was barely discernible between the two first, and a slight degradation between the two last. Through Dr. Herschel's powerful telescopes most of the fixed stars seem tinged with peculiar colours, *viz.* some evidently incline to a green, others to a red, and so forth. The light yielded by particular combustibles is also tinged with peculiar colours, and the flame of spirit of wine is a strong instance of this nature; for if common salt be mixed with the spirit, the light of its flame seems to be entirely destitute of red, yellow, and violet, and it is owing to this peculiarity that children frequently play with it in order to give a ghastly appearance to the luminous

company. When baryt (ponderous earth) is mixed with spirit of wine, its flame is yellow; boracic acid renders it green, and strontian earth gives it a purple colour.

The phenomena of coloured bodies, as they occur to us, in general, may be distinguished into five classes, *viz.* 1st. The colours that arise from evident refraction, such as the colours of the rainbow, of the bubbles of a solution of soap, &c. 2^{ly}. Those of opaque bodies that are fixed. 3^{dly}. The colours of transparent bodies formed by the light passing through them. 4^{thly}. The colours that are changeable, according to the situation of the eye, like the colours of certain fisks, feathers, flowers, thin laminae, &c.; and 5^{thly}. Those which are changeable in consequence of a chemical alteration of the nature of the body. We shall now add a few observations respecting each of those five classes.

1. That in passing through a transparent medium, like the drops of rains, the thin pellicle of a bubble of soap, a thin lamina of talc, &c. the light should be decomposed or rather resolved into colours, is easily understood, after the above-mentioned properties of the prismatic spectrum; but the only circumstance which may require explanation is, that we perceive the colours, &c. not when the refracting body is between us and the luminous object, but when both our eyes and the luminous object are on the same side. With respect to this, it must be observed, that a transparent body, like a plate of glass, a drop of water, &c. reflects with both its surfaces at the same time that it lets part of the light pass quite through its substance. Direct your eyes to the surface of a common glass plate so as to see the reflection of an object, as in a looking glass, and if you observe attentively you will perceive two reflected images close to each other, *viz.* one from the anterior, and the other from the posterior, surface. In most looking glasses, if you place a lighted candle on one side, and view the reflected image of it from the other side, you will generally see a succession of images of the candle fainter and fainter, in proportion as they recede from the principal image. The reason of this appearance is, that since both surfaces reflect, the image formed by the reflection of the posterior surface is partly transmitted to the eye of the spectator, and partly reflected from the anterior surface to the posterior one, the latter of which is again reflected, and so on. Now, in the case of the drops of rain, when they form the rainbow, the light of the sun falling obliquely on the surface of the drop is refracted and resolved into colours, in which state it proceeds through the drop to its farther surface, from which it is partly reflected to the eyes of the spectator. The same explanation is evidently applicable to the colours of the bubbles of soap, thin transparent laminae, and the like. See RAINBOW.

2. The fixed colours of opaque bodies are in all probability owing to their absorbing some of the coloured parts of white light and reflecting others; their immense variety arising from a mixture of the reflected primitive colours in various number and proportion; but it is impossible to say at present whether that reflection is effected at the very surface, or at some distance from it, either within or without the body; also to what cause the disposition of reflecting certain colours in preference to others may depend upon. Mr. Delaval's experiments seem to indicate that the colour of opaque bodies arises from the light that has passed through a thin layer of transparent coloured particles, and is then reflected by the smooth surface immediately under them.

3. The greatest number of accurate experiments, concerning the colours of transparent bodies, was made by

Edward H. Delaval, esq. F.R.S. (See his Paper in the Memoirs of the Lit. and Philos. Society of Manchester, vol. ii.) His experiments were performed with an immense variety of liquors differently tinged by metallic solutions, decoctions, and infusions of flowers, resins, gums, woods, mineral and animal matters. Those liquors he placed in phials of first glass, of a parallelleiped form, with an oblong cylindrical neck. "I covered," he says, "the bottom, and three of the sides of each of these phials, with a black varnish; the cylindrical neck and the anterior side, except at its edges, were left uncovered."

In order to examine what colour those liquors would exhibit, either by transmitted or by reflected light, he viewed them through the neck of the phials, or looked into the phial through the side which had been left uncovered by the varnish. But with respect to this latter case, he says, "the uncovered side of the phial should not be placed opposite to the window, through which the light is admitted; because in that situation the light would be reflected from the farther side of the phial, and would be transmitted through the coloured liquor; and it is observable that smooth black surfaces reflect light very powerfully. Now, as it is a principal object in the experiment that no light be transmitted through the liquors, this will be accomplished by placing the uncovered side of the phial in such a direction that it may form a right angle with the window."

All the coloured liquors, which Mr. Delaval tried in the above-mentioned manner, appeared tinged with their peculiar colours, when viewed through the necks of the phials; but when he looked on that part of the liquor which filled the body of the phials, he perceived no colour whatever, the whole appearing black; which proves an important fact, namely, that transparent coloured liquors do not yield any colour by reflection, but by transmission only. "If these liquors," he observes, "are spread thin on any white ground, they appear of the same colours which they had exhibited when viewed in the necks of the phials; as the light reflected from the white ground is, in this case, transmitted through the coloured medium. But when they are spread upon a black ground they afford no colour. The black ground, however, should not be a polished body; as the light reflected thereby would be transmitted through the thin medium on its surface, and be tinged by passing through it."

Next to the above, Mr. Delaval relates various other experiments which he made with transparent solids, *viz.* with coloured glasses, which he made on purpose, by tinging the substance of the glass with metallic and other matters, in imitation of real gems. These coloured glasses exhibited phenomena similar to the coloured fluids. "Having," this author says, "formed pieces of such glasses, about two inches thick, I inclosed all their sides with black cloth, except at their farther and anterior surface. Each of these pieces of glass vividly exhibited its colour, when viewed by transmitted light; but when the transmitted light was intercepted, by covering the farther surface, the anterior surface afforded no colour, but appeared black. When plates of transparent coloured glass, somewhat thicker than window glass, are viewed by transmitted light, it is well known that they exhibit their several colours. I intercepted the light, which was transmitted through such coloured plates, by fixing a piece of black cloth contiguous to their farther surface. The plates, thus prepared, when placed in such a direction that they form a right angle with the window, appear perfectly black; which shews that the coloured particles do not reflect any light."

It is hardly necessary to observe that wherever light is transmitted through any coloured transparent body, a greater part of it is lost, than when that body is quite colourless; for by transmitting one sort of coloured rays more copiously, it stops a great part of the oppositely coloured rays.

Besides these transparent coloured bodies which have been just noticed, there is a vast gradation of others between them and those that are perfectly opaque. These, which are called semipellucid, or semitransparent, exhibit a vast variety of phenomena arising from the various proportion of the opaque and the transparent particles which enter in their composition. Thus some appear of the same colour, whether viewed by transmitted, or by reflected light, others exhibit one colour by transmitted and another by reflected light; others again appear of various colours, according to their thickness, &c. See Newton's Opt. l. i. p. ii. prop. x.

4. The last paragraph may, in some measure, tend to illustrate the nature of those coloured silks, feathers, &c. which change their colour according to the angle in which they are viewed, and in which the light falls upon them; other circumstances, however, are concerned in the phenomena of those bodies. Thus the surfaces of some of them are very irregular, in consequence of which they reflect with some of their particles, whilst they absorb most of the light with other particles; hence, when by a lateral view, the former or the latter are placed out of the direction of the eye, the colour of the whole appears different from what it does in another point of view. Certain bodies of this sort may likewise be transparent to a certain small depth, in which case they become visible partly by reflected and partly by refracted (consequently decomposed white) light; hence the eye of the spectator must, according to its situation, see some coloured rays in preference to others. The phenomena of those changeable bodies, meaning with respect to colour according to situation, are far from being clearly understood; it is most probable, however, that in them all, the three principal properties of light are concerned, namely, its reflection, refraction, and inflection.

5. In the practice of various arts, wherein colours are concerned, such as in dyeing, enamelling, painting in oil or water colours, &c. a change in colour of most of the materials is commonly observed, which is evidently produced by the action of the air, the fire, the oil, or other agent to which the colouring materials are exposed, and by which they undergo different degrees of chemical alteration in their nature. This observation, and a desire of investigating the nature of those changes, with a view of improving the practical arts dependent upon them, induced several persons to try a variety of experiments, and Mr. Delaval, the same above-mentioned gentleman, who investigated other branches of the present subject, became one of the greatest labourers in this field of inquiry. Were we acquainted with the nature of those particles in bodies which reflect or refract the coloured rays, and had we a sufficient knowledge of the alterations produced on those particles by the action of different agents or menstra, be they oils, acids, air, alkalis, &c. a just idea might perhaps be formed of the changes in colour, which must arise from certain combinations; but as the present state of knowledge does not admit the formation of such a theory, the whole must rest upon conjecture, and the practical part must depend upon the result of particular experiments.

Sir Isaac Newton thought, that bodies reflect and refract light, by the same power in different circumstances.

Also, that the forces of bodies to reflect and refract light, are very nearly proportional to the densities of the same bodies, excepting that unctuous and sulphureous bodies refract more than others of the same density. In support of this assertion he relates several experiments, the result of which he expresses in a table, wherein the proportion of the sines which measure the refractions of the several bodies, the densities of the bodies estimated by their specific gravity; and their refractive powers in respect of their densities are stated in separate columns. Mr. Delaval conceived that the denser substances ought, by their greater refractive powers, in like circumstances, to reflect the less refrangible rays; and that substances of less density, should reflect rays proportionably more refrangible, and thereby appear of several colours in the order of their density. Agreeably to this supposition he gives instances of natural bodies, which differ from each other in density, though circumstanced alike in other respects, excepting in their colour, which colour follows the order of their density; the densest being red, the next in density orange, the next to that yellow, then green, &c. In support of this hypothesis Mr. Delaval made several experiments with glass tinged by metallic particles, in which the colour of the glass, in a great measure, corresponded to the density, or to the specific gravity, of the metal concerned. But this series of experiments is not extended to that degree, nor is it conducted with that caution, which a confirmation of the hypothesis demanded. Mr. Delaval also instituted similar experiments with coloured liquors, in which he endeavoured to shew, that by an incrustation or an attenuation of their particles, their colours may be changed in one order or in the reverse. His mode of attenuating those liquors was accomplished, as he supposed, by the addition of acids, and that of incrustating, by the addition of alkalis. But however specious this hypothesis may at first sight appear, a strict examination of facts will easily shew the fallacy of it in almost all its parts, and several writers have pointed out some of its defects, but none better than Dr. Bancroft, F.R.S. in his "Experimental Researches, concerning the Philosophy of permanent Colours," vol. i. chap. i. In this excellent work, Dr. B. shews that Mr. Delaval has not noticed the change of nature, as well as of specific gravity, which the metals undergo by their being exposed to different degrees of heat, together with the glass. He also observes, that if, according to Mr. Delaval's hypothesis, the densest bodies are of a red colour, or approximating to it, platina, the heaviest of all known metals, ought to be red; whereas it is white, like tin, and the lightest metals. Also gold, the heaviest metal next to platina, is much farther removed from the red colour than copper, which is much lighter. With respect to Mr. Delaval's experiments on coloured liquors, Dr. Bancroft says, "instead of choosing and employing mechanical means, which alone are suited to produce those effects, and only those effects, he has recourse to mere chemical agents, whose actions in the ways which he supposes must have been almost doubtful, though their powers of producing other, and very different effects from what he supposes, is most certain. Mr. Delaval, however, adopting Sir Isaac Newton's supposition, that acids always attenuate, and alkalis always incrustate, prepared what he considered as a dissolving or attenuating liquor; which consisted of water with about $\frac{1}{10}$ part of aquafortis: and when he wanted to lessen the dissolving force of this liquor, instead of weakening it by the addition of water (which would certainly have been the most obvious and unexceptionable expedient), he chose to do it, as he says, by adding a small quantity of a solution of pot-

ash, or some other alkaline liquor, and thereby produced a new composition, the effects of which mult, in many cases, prove different from those of a mere diminution of the supposed dissolving power of the former liquor. And on the other hand, when he wanted to increase the force of his acid liquor, instead of doing it by a farther addition of aquafortis (obviously the most proper expedient), he recurs to an addition of oil of vitriol, an acid possessing very different properties, and producing very different effects, on a great variety of substances, and particularly on colouring matters; of which we could easily allege hundreds of instances, but shall content ourselves with only mentioning what is well known, that even the strongest and most concentrated oil of vitriol (used to dissolve indigo for dyeing the Saxon blue, &c.) does not destroy, or even weaken, its blue colour, though a very weak nitrous acid, or aquafortis, will wholly destroy it, and convert the indigo to a dirty brown mass, of no use whatever." For farther observations of Dr. Bancroft on Mr. Delaval's Theory of Colours, we refer our readers to his above-mentioned work. But with respect to the practical part of the subject, viz. the art of colouring glass, porcelain, &c. or the methods of forming pigments, they are requested to consult the articles, PAINTING, ENAMELLING, DYEING, STAINING, CRAYONS, and PIGMENTS.

COLOUR of the clouds, is thus accounted for by Sir Isaac Newton. Concluding from a series of experiments, that the transparent parts of bodies, according to their several sizes, reflect rays of one colour, and transmit those of another, he hence observes, that when vapours are first raised, they are divided into parts, too small to cause any reflection at their surfaces, and therefore do not hinder the transparency of the air; but when they begin to coalesce, in order to form drops of rain, and constitute globules of all intermediate sizes, these globules are capable of reflecting some colours, and transmitting others, and thus form clouds of various colours, according to their sizes. Mr. Melville controverts this doctrine, in its application to the red colour of the morning and evening clouds. "Why," he says, "should the particles of the clouds become at that particular time, and never at any other, of such a magnitude as to separate these colours? And why are they rarely, if ever, seen tinged with blue and green, as well as red, orange, or yellow? Is it not more credible, that the separation of rays is made in passing through the horizontal atmosphere, and that the clouds only reflect and transmit the sun's light, as any half-transparent colourless body would do? For since the atmosphere reflects a greater quantity of blue and violet rays than of the rest, the sun's light transmitted through it ought to incline towards yellow, orange, or red; especially when it passes through a long tract of air: and thus it is found, that the sun's horizontal light is tinged with a deep orange, and even red; and the colour becomes still deeper after sun set." Hence he concludes, that the clouds, according to their different altitudes, may assume all the variety of colours at sun-rising and setting, by barely reflecting the sun's incident light as they receive it. Edinb. Ess. vol. ii. p. 75. Priestley's Hist. of Vision, p. 446, &c.

For the distinct properties, &c. of the several colours, see BLACK, WHITE, BLUE, &c. See also RAINBOW, &c.

COLOUR, and COLOUR Making, in Calico-Printing. The preparation of colours for calico-printing, constitutes one great branch of that beautiful art, and involves in it a series of interesting and important processes. As an art, its operations are more dependent than almost any other, on those minute differences and changes in the constitution of bodies, which it is the business of chemistry to investigate. Hence

that liability to error and uncertainty which, in the hands of the ignorant, pervades many of its processes, though conducted according to long established and approved formulae. Our present volume would scarce suffice for the various receipts in which the art abounds; yet, in the following article, we shall endeavour to lay down general principles, rather than more practical directions; convinced, that by presenting our readers with a clear and concise theory, deduced from such practical illustrations, as may be necessary for this purpose, we shall render them a more acceptable service.

The term *cola*, in calico printing, is applied not only to those vegetable, animal, and mineral solutions, which impart their own colour to the cloth on which they are applied, but also improperly to those earthy or metallic solutions, which, possessing little or no tingent properties themselves, yet retain or fix the colours of other substances, when afterwards applied to the cloth. Thus the acetite of alumine, or printers' red liquor, when pure, is almost colourless, and only becomes red by the process of dyeing, as will be explained hereafter. The acetite of iron, or iron liquor, in like manner, when used of a determinate strength, is called *black colour*, and when weaker *purple colour*, though the cloth impregnated with these solutions becomes black or purple, only as being raised, like the other, in the dye-copper.

1. The colours produced by means of these earthy or metallic solutions (which, in the language of science, are called *mordants*), form the most valuable and important series, whether considered with regard to the almost infinite variety of shades, or to their solidity and durability. These colours, from the mode in which they are produced, (the mordant being first applied to the cloth, and the colour afterwards raised by dyeing), are called *dye colours*.

2. Sometimes the mordant is previously mixed with a solution of colouring matter, and in that state applied to the cloth, so as to paint or stain it, at one operation, and without the process of dyeing. Thus, another class of colours is produced, many of them possessing great brilliancy indeed, but much inferior to the former in durability. The colours called chemical, by calico printers, belong chiefly to this class.

3. In the third and last class, we may place all those where the colouring matter is simply held in solution by an acid or alkali, and in this state applied to the cloth, without the intervention of any mordant. To one or other of the foregoing classes, may be referred all the colours used in calico printing; with the exception, however, of those systems of colours which have been produced by calico printers in this country, within a short period, by processes, and upon principles which have hitherto not been made known.

Class I.

The colours of this, as has been already observed, are produced, by first impregnating the cloth with an earthy or metallic solution, or mordant, and raising the colour afterwards by dyeing. In this article we shall confine ourselves to the preparation of the different mordants, and the enumeration of colours they afford, with different colouring substances. The operations of the dye-house, and the mode of raising the colours in the dye-copper, will be detailed hereafter.

The two great and most important mordants used in calico printing, are those that we have a ready noticed, viz. the solution of iron in acetic acid or vinegar, called iron liquor, and the acetic solution of alumine, or the earth of alum, called red liquor, or red colour, and sometimes yellow liquor.

With these two solutions, either separately applied, and

of various strengths, or mixed together, and in various proportions, an infinite variety of shades of colour are produced. Almost all the hues in nature may be obtained by raising them, and their various combinations with different colouring substances. From madder, with the acetite of alumine, or red liquor, we obtain various shades of red, from the darkest blood colour to a pink. From weld and quercitron bark, yellows, varying in intensity from a deep orange to a pale straw colour, according to the strength of the mordant employed. From logwood, various shades of violet; from cochineal, Brazil, and Hicaragua wood, pink and crimsons of different hues; and, in short, from almost every different colouring substance, a different shade of colour. With the acetate of iron, or iron liquor, of different strengths, we obtain from madder all the intermediate hues between black and pale purple, or lilac. From weld and bark, olives, browns, and drabs, of various hues; from sumac, logwood, galls, and other astringent substances, all the varieties of grey, from the palest shades to the deepest, in which all the minute differences of hue are lost till they approach to black. These various shades are further modified by applying two or more colouring substances to the same mordant, as madder and weld, for example, to the acetite of alumine, which produces orange, light cinnamon, nankeen, &c.; and again still further, by mixing the mordants themselves in various proportions, and raising them with either one or more of the different colouring matters. By these means shades, and varieties of colour, may be produced from a few substances only, which baffle description, and for which language has no precise or definite terms.

The acetite of iron, or iron liquor, is variously prepared. In this country it is chiefly made with the pyrologneous acid, which Fourcroy has proved to be identical with the aceticus. Malt acid is preferred by many on account of its being free from volatile oil and resinous matter, with which the other abounds; but the great difference in price, and the facility with which it is obtained, has brought the acid of wood almost into general use. A series of casks filled with scraps and turnings of iron upon which the acid is poured, is almost the only apparatus necessary for making iron-liquor; yet when the consumption is great, or when it is prepared for sale, vats capable of holding several hundred gallons are substituted for casks, and the acid is kept in a state of circulation through the iron by means of pumps. The saturation is much accelerated by this motion, which prevents any deposition on the surface of the iron which might defend it from the action of the acid, and also brings fresh portions of unsaturated acid more frequently in contact with the metal. In a few weeks, sooner or later in proportion to the strength of the acid, the saturation is completed, and the liquor is then removed from the vat into casks for use, and fresh acid poured upon the iron as before. This is an easy and simple mode of making iron liquor, and as it requires but little trouble and attention, is the one most generally in use. The precautions necessary to be observed are, that the acid, if it be the pyrologneous, should not be used too soon after its preparation. It holds much essential oil and resin in solution, part of which separates on being kept a few weeks, and the clear acid may then be drawn off. It may be still further freed from resin by boiling; a portion of essential oil is thus thrown off, and the resin, if held suspended, is precipitated after standing some time. We shall have occasion to recur to this subject again, when we come to treat of the pyrologneous acid, and its formation, under the article *Dissillation of Wood*. It is necessary also, that the iron should be perfectly clean and all of it malleable. Cast iron is not soluble in aceticus acid. Hoop iron

cut into lengths of from eight to ten inches is preferable to any other. It is readily cleaned and more easily taken out of the vat, and returned into it again than misshapen masses fold under the name of old iron. When malt acid is employed, simple heating and washing is sufficient to free it from any foulness it may have contracted in the vat; but when the pyrologneous acid has been used, it becomes so coated with resin on its upper surface after a second or third solution, as to prolong the period of saturation to twice or thrice its usual length. In this state it must be removed from the vat and heated to redness in oven, through which there is a current of air. The resin is consumed, and the iron by heating is freed from any remains of carbonaceous matter that may adhere to it, and is again ready for the vat.

The only objection to this mode of making iron liquor is the time required to saturate the acid, which to those, whose consumption is very great, or who manufacture it for sale, is oftentimes of importance. Different processes have therefore been devised to remedy this inconvenience, in many of which the saturation is accelerated by means of heat which is applied in various ways, as best suits the convenience of the manufacturer; but the most expeditious mode is that of presenting the iron to the acid in a state of oxydation, by which means the solution is effected immediately. Calico printers have long been in the habit of using an extemporaneous acetite of iron, formed by mixing together solutions of acetite of lead and sulphate of iron. A very pure acetite of iron may be obtained by this means, but the price of acetite of lead renders this mode too expensive for general use. By forming a solution of lead, however, in pyrologneous acid and decomposing it with sulphate of iron or copperas, an iron liquor may be obtained sufficiently cheap to render this process advantageous in many cases, though still more expensive than the ordinary mode. A patent was lately taken out for making iron liquor by a process somewhat similar to this, which, however, we understand has not answered the expectation formed of it. A solution of lead in pyrologneous acid is digested on clear metallic iron. The iron becomes oxydated at the expense of the lead and is dissolved, whilst the lead is precipitated in the metallic state, and may again be used for a fresh solution. All these modes are evidently more expensive than the ordinary one of simple solution of metallic iron in pyrologneous acid, and the only consideration with the manufacturer is, whether this extra expense is counterbalanced by the economy of time or not.

The process adopted some years ago by Mr. Thomson, is perhaps the most expeditious, and next to the common mode, the most economical of any yet in use. It consists in saturating the pyrologneous acid with quicklime, and pouring the clear boiling solution on as much sulphate of iron or copperas as will precipitate the whole of the lime. A cask of iron liquor may be made by this mode in a few hours, and when care has been taken rightly to proportion the ingredients so as to produce complete decomposition, it is inferior to no solution whatever in any of its properties.

The properties of the aceticus solution of iron fit it eminently above all others for the purpose of the calico printer, and having detailed its preparation we shall endeavour to point out in what this superiority consists.

The acetite of iron exists in two states, dependent on the quantity of oxygen combined with the iron. When pure, and recently prepared, it is of a pale greenish hue, but by exposure to air soon becomes tinged with brown. In this state the iron is at its lowest point of oxydation, strongly attractive of oxygen, and if precipitated by an alkali, of a deep green colour. By exposure to the atmosphere, and conse-

quent absorption of air, the solution passes to a deep red brown, and, if concentrated, deposits orange oxyd of iron, and becomes strongly acidulous. With this excess of acid, the solution now becomes permanent; the iron is almost wholly at the maximum of oxydation; and, when precipitated, of a dark red colour.

The same takes place only in a less degree, and more slowly with the sulphuric and muriatic solutions of iron. Of a pale greenish hue in their recent state, they gradually attract oxygen from the atmosphere, and become slightly red, deposit red oxyd of iron and pass to a state of acidity, at which the solution becomes permanent, and the oxydation of the iron proceeds no further.

If the solutions, properly thickened with gum or flour, are applied to cloth, the same change takes place, but with more rapidity, from their diffusion over a thin surface, and more complete exposure to the air. The aqueous and volatile part of the solution speedily evaporates, and as the oxydation goes on, the oxyd of iron is deposited on the cloth, and a portion of acid set free. When this acid is volatile, as is the case with the acetous, and also in a great degree with the muriatic, it is dissipated. The oxydation of the iron then goes on, fresh portions of acid are again liberated and drawn off till the whole of the solution is decomposed, and the oxyd of iron deposited in the cloth. When the acid is not volatile, however, as is the case with the sulphuric, the slight portions of acid that are liberated not being drawn off, the oxydation proceeds more slowly till the excess of acid becomes so great as wholly to interrupt it, and great part of the iron in the operation of rinsing is again carried off the cloth. Another and more serious inconvenience attending the use of the sulphuric solution is its action on the cloth itself. The disengaged acid being in a state of great concentration acts upon its fibres, weakens, and at last destroys them. The same takes place with the muriatic solution also, for though the excess of acid is slowly dissipated, yet it has sufficient time and concentration to act very powerfully, and is, if possible, still more destructive than the sulphuric, since its action is not confined to the part on which it is applied, but from its volatility extends over the whole surface of the cloth.

It is necessary, therefore, that the acid should be not only volatile, but harmless in its action on the vegetable fibre, which conditions are more completely fulfilled by the acetous than by any other solution whatever. From the preceding observations on the properties of the acetite of iron, and the changes it undergoes on the surface of the cloth, may readily be deduced the reasons for that exposure to heat and air which calico printers have, from long experience, found necessary to goods printed with this solution. By exposure to air the iron becomes oxygenated and deposited on the cloth, whilst the heat favours the liberation of the acid, and accelerates the process. From what has gone before it may also be inferred, that the acetite of iron should be used in its recent or green state, since in that state the acetous acid is capable of holding a greater quantity of oxyd of iron in solution, and that consequently after its saturation and removal from the iron, it should not be too much exposed or agitated in contact with the air. On this account, also, it is wrong to pump the liquor in the vats too much when it approaches the point of saturation, since the oxygenated iron is almost all precipitated, and fresh portions immediately dissolved, so that the liquor might in time be rendered quite thick with precipitated oxyd of iron.

The preceding ideas are at variance with the general opinion respecting the state in which the acetite of iron should be employed. All the speculative writers, and even

many well acquainted with the processes of calico printing, recommend the oxygenation of the solution by exposure to air and removal from the iron, as essential to the goodness of the iron liquor. Even Berthollet, in the last edition of his "Elements of the Art of Dyeing," has fallen into the same mistake, the source of which, and the facts which seem to countenance it, we shall point out in a future article.

It is an object of importance to the calico printer to know the precise strength of his iron liquor, and to be able to ascertain this at all times, with little trouble or chance of error. Great mischief and inconvenience often arises from uncertainty in this respect, especially in the pale shades of purple, which are obtained from madder, with diluted acetite of iron. The hydrometer has been objected to, as indicating not merely the quantity of iron in a solution, but also the essential oil, resin, and mucilage which these impure solutions often contain. This objection, however, only applies where the same instrument and graduation is employed to ascertain the relative strengths of iron liquors, prepared with different acids, as the pyroigneous which contains much essential oil and resin, and malt acid which abounds in mucilage. In this case the hydrometer may indicate great differences in solutions containing equal quantities of acid and iron, but varying in the quantities of mucilage, oil, or resin. Iron liquor, however, prepared constantly by the same process, and from the same acid, varies so little in the relative proportion of its ingredients, that the hydrometer may be used to ascertain its strength in preference to any other mode whatever; provided the necessary precautions are used to correct any error arising from variation of temperature.

In a work of this kind, not illustrated by actual specimens, and without reference to some particular kind of iron liquor, it is impossible to point out the specific gravities of the different solutions required for producing the various shades, we have enumerated. An acetite of iron, of specific gravity 1.047, with madder or logwood, will produce a black, and with weld or sumac an olive, and diluted with six, eight, or ten times its bulk of water, various shades of purple, drabs, or olives, according to the colouring matter employed. A standard solution of iron once obtained, the necessary strength for producing the different varieties of colour is easily ascertained by actual experiment, and to this we must refer our readers.

When thickened with flour or gum, and tinged with a decoction of logwood or Brazil, the better to enable the workman to observe the progress and state of his work, it forms, as we have before observed, the printers black colour, a purple colour, &c. according to the strength of the solution and the purpose it is intended for. Various ingredients were formerly added to iron liquor, to improve its quality, or vary the hue of colour it produced. Verdigris and coppers were added to the solution intended for black; and sal ammoniac or nitre to the diluted solutions for purple. These are, however, now almost universally laid aside, as being for the most part useless, and often hurtful: the simple acetite of iron being found to answer every purpose of the more complicated and heterogeneous solutions.

The acetite of alumine, or red liquor, is always prepared by the decomposition of alum, by an earthy or metallic salt, since the aluminous earth is not soluble in acetous acid, except in its newly precipitated and minutely divided state. The purest solution, and that which is generally used for the finest and most delicate colours, is produced by decomposing alum with Dutch sugar of lead, generally in the proportion of two parts by weight of the former, to one of the latter. The proportion of the two salts, and also the quantities of each gallon, as used by different calico printers, vary yet

with little difference in effect. The alum in general predominates so far as completely to saturate the liquor. The printers' aluminous mordant therefore is a compound solution. It is an aceto-sulphate of alumine, consisting of a saturated solution of common alum, and more or less acetite of alumine, according to the quantity of sugar of lead employed. In the neighbourhood of London, the proportions are 6lb. of alum, and 3lb. of sugar of lead to a gallon of water: when these are completely dissolved, one ounce of Spanish white is added, and the whole briskly stirred till the effervescence has in great measure subsided. In a few hours the solution becomes clear, and forms a standard liquor from which, by greater or less dilution, may be obtained all the various shades of red, yellow, &c. already enumerated. In the above formula the proportion of alum is somewhat too great, a part of it remains undissolved, or immediately recrystallizes, and falls to the bottom along with the precipitated lead. This excess of alum is however strongly insisted on by many calico printers, as essential to the purity of the mordant, from an idea that the *purcell* part of the alum only is taken up in the solution. This fact however may be readily disproved by employing this undissolved or recrystallized alum in the formation of fresh solutions, whose purity will be found in no respect inferior to the former. The purity of the alum and sugar of lead, and especially their being free from iron, is of great importance in the preparation of this mordant, and on this account the Dutch sugar of lead is preferred; but its high price renders it too expensive except for the pale reds of light chintz, and other kinds of work, whose great delicacy in the red tints is required. A substitute for it has been found in the solution of litharge in vinegar, or pyroigneous acid, which is afterwards decomposed by the addition of alum, and the excess of acid neutralized by Spanish white as in the former case. Great part of the acetite of alumine manufactured and sold under the name of red liquor is prepared in this manner. It is in general used for yellows, dark shades of red, and for those compound mordants into which the acetite of iron enters, and when its purity is of course of little consequence. The acetite of lime has long been substituted with great advantage by the writer of this article for the solution of lead, and its use is becoming daily more known and extended. When carefully prepared, it is scarce inferior to the best sugar of lead, and the impure solutions answer equally with the best, for the compound mordants before mentioned. The theory of these processes is the same in all. The object being to obtain a solution of alumine or earth of alum in acetic acid. On mixing acetite of lead, and sulphate of alumine together, a change of base takes place; the sulphuric acid unites with the lead, and falls down in the form of a white heavy precipitate, whilst the earth of alum combines with the acetic acid, and remains in solution. The same takes place with the solution of litharge in pyroigneous acid, which is indeed an impure acetite of lead, and when the acetite of lime is employed instead of lead, the sulphuric acid and lime unite and form an insoluble powder, which subsides, though less quickly than the other, whilst the acetite of alumine remains in solution above; the addition of the Spanish white is necessary to saturate a small excess of acid which exists in the solution. This excess is taken up by the lime, and immediately converted into acetite of alumine, by the decomposition of a fresh portion of alum.

The acetite of alumine when pure, is almost colourless. It has a slight acetic smell, and when boiling throws off acetic acid in great abundance, and deposits a portion of alumine. When evaporated it acquires a thick gummy con-

sistence, but does not crystallize a property which gives it a decided advantage over common alum as a mordant. It unites readily with gum, but when concentrated and holding much alum in solution, forms with flour a watery pulpy kind of paste, which has little adhesion, and from which the fluid soon separates. The sulphuric salts have indeed all a disposition to injure the thickening quality of flour.

The affinity of cotton for the earth of alum, is so strong as to separate it from its combinations even with the mineral acids. When a solution of common alum properly thickened is applied to cloth, a portion of alumine unites with it, and the acid, which held it in solution, is set free. When this is accumulated to a certain degree, it prevents any further decomposition, and in rinsing carries off the greater part of the earth again. When the acid however is volatile, like the acetous, and is dissipated as soon as disengaged, there being no longer any obstacle, the decomposition goes on till the whole of the acid is driven off, and the alumine combined with the cloth. In the infancy of calico printing, and before the theory and constitution of the different mordants was properly understood, a variety of substances were added to the solution, some of which are retained to this day. Verdigrise in the proportion of two ounces to a gallon, is recommended by many as tending to exalt the hue of yellows, and may in some cases be useful. Corrosive sublimate has been but lately laid aside, and the nitro-muriate of tin was long thought to give fixity and brilliancy to reds, when used in a small proportion with the aluminous mordant. In general, however, the aceto-sulphate of alumine is found adequate to every purpose of the calico printer; we shall not, therefore, perpetuate error by detailing any of those unmeaning mixtures which are still retained by the ignorant and prejudiced. These two mordants, the acetites of iron and alumine, and their various combinations, are those only in general use in calico-printing, for producing colour of the first class. This application is so extensive, and at the same time so simple, as to supersede the necessity of any other. The solutions of copper are sometimes used as mordants, but they afford colours of little solidity. The solutions of tin have also been employed, but we shall speak of these and other earthy and metallic solutions which have been used with partial success, when we come to treat of mordants in general.

Class II.

In this class the colours are produced by combining a solution of colouring matter with some earthy or metallic salt, capable of giving it fixity when applied to the cloth. The mordant and colouring matter are here applied at once, and the cloth is painted, as it were, or stained, with the colour it is intended to retain, and requires, in general, no farther operation than that of rinsing, to free it from the paste or gum with which it was thickened.

The colour of this class possesses, as we have before observed, in general great brilliancy, but wants that solidity and fixity which characterize the colours of the former class. The union of the mordant with the cloth is weakened by its previous combination with the colouring matter, and not being favoured by heat, as in the former case; the triple combination of vegetable fibre, mordant, and colouring matter, wants that solidity which is so necessary to constitute what is called a fast colour.

Many of these, however, are sufficiently durable to be partially introduced, and intermixed with other colours of greater durability, and some are indispensably necessary, as no better mode has yet been devised of producing them. When the

chemist's art shall have discovered means of giving fixity to colours thus typically applied, the art of calico printing will have arrived at perfection. Systems of colours may then be combined, which are at present incompatible, and the tedious operation of dyeing and bleaching, with their attendant difficulties, be banished from the art. Nor is the hope so chimerical as might at first be imagined; several of the most useful and permanent colours are of this description, as will be shewn hereafter.

We shall content ourselves with describing the leading and most useful colours of this class, giving, at the same time, the theory of their constitution. The mere enumeration of all the varieties that have or may be formed, would be endless, and foreign to our purpose.

Chemical Black.

This is the most useful colour of the class, and one of indispensable necessity in certain combinations of colours, where, for instance, it is mixed with drab, olive, and yellow, raised in the dye-copper with weld-quercitron bark, or any similar colouring matter, and where the presence of any substance, such as logwood or madder, capable of producing a full black, would be ruinous to the other colours. A deep olive, approaching to black, might, indeed, be produced, by employing a strong iron liquor, as mordant, and using sumac in the dye-copper; yet as this would bear no comparison in point of intensity with the madder or logwood black, and as the force of the colouring in such course of work greatly depends on contrast, the topical or chemical black, which has all the intensity required, is almost constantly employed. The constitution of this black is pretty nearly the same in all the different formulæ in use. It consists always of a solution of iron combined with a solution of colouring matter generally of an astringent nature. On the right proportion of these two solutions, and on their due specific gravity or strength depends, in a great measure, the goodness of the black.

1. If to a decoction of Aleppo galls, in five times their weight of water, made into a paste with flour, a solution of iron in nitrous acid of specific gravity 1.25 be added, in the proportion of one measure of nitrate of iron to eighteen or twenty of the former, a black will be formed fit for almost all the purposes of calico printing, and possessing the chief requisites of this colour, namely, tolerable fixity, and a disposition to work well with the black.

2. In lieu of nitrate of iron, some calico printers employ copperas, in the proportion of one pound to a gallon of the decoction of galls. Half the copperas is directed to be dissolved in the gall-liquor before it is thickened with flour; the remaining half, dissolved by heat in as much aquafortis as will cover it, is added afterwards. This black has tolerable fixity, but does not work so well as the preceding.

3. Copperas dissolved in various proportions of from four to twelve ounces per gallon, will form, with decoction of galls or logwood, blacks of less solidity indeed than the former, yet applicable, nevertheless, in many cases where the others are not.

The constitution of the two last-mentioned blacks differs somewhat from the first. We shall point out this difference, and explain, as concisely as possible, the rationale of the foregoing processes.

When a solution of iron in nitrous acid is added to a decoction of galls, as in the first example, the solution is decomposed, the iron unites with the gallic acid and tanning principle, whilst the nitrous acid is disengaged. This is proved by the blackness which the solutions assume immediately on

being mixed. The disengaged acid, however, shortly re-acts on the new compound, the blackness gradually disappears, and in a few days, if the nitrate of iron has been added in proper quantity, the paste, instead of black, is of a dirty olive green. If the proportion of nitrate of iron be greater than $\frac{1}{7}$, this change will be effected sooner; and if to 10 lb as $\frac{1}{15}$, the paste, when applied to the cloth, will be a bright orange, like the acetite of iron. By exposure to heat and air, this colour generally deepens, becomes grey, and at last a full black. In this state it is permanent, and adheres powerfully to the cloth. These changes of colour depend on the solution of the tannate and gallate of iron in the disengaged nitrous acid, and the evaporation of the acid when exposed to heat and air on the cloth. This solution of the tannate and gallate of iron is indeed an essential requisite in the goodness of the chemical black. If the disengaged acid is not sufficient to effect this, or if it is in too great a state of dilution, the colour has but a feeble adherence to the cloth; it is not presented in a state favourable to its union with it, since the combination into which the iron has entered is insoluble in water. It lies merely on the surface, but does not penetrate its fibres, and yields readily in the various operations to which it is subjected. The chemical black, therefore, of the first example is a solution of the tannate and gallate of iron in nitrous acid.

The black of the second, but more particularly of the third example, differs from the preceding in the circumstance of the iron in the solution being in a less oxygenated state. We may consider this black in its recent state as a mixed solution of green sulphate of iron, and gallic acid, and tanning principle; for the decomposition of the sulphate is not complete till by exposure to air on the cloth the iron becomes fully oxygenated. When this black is recently applied to the cloth, it is of a pale greyish colour, has little fixity, simple rinsing in cold water being sufficient to fetch nearly the whole away. By gradually absorbing oxygen, it becomes deeper, and at last black. The sulphuric acid has no longer any action on it, and is removed in the first operation in which it is immersed in water.

The decoction of galls used for chemical black is variously prepared. Many calico printers infuse the galls cold in casks of vinegar, or pyroligneous acid, suffering them to remain several months, occasionally drawing off the lower part, and returning it on the galls. Others steep them in wine. Both these modes are vicious, particularly the last. Simple boiling in water, till all the soluble matter is extracted is sufficient, taking care to inclose the galls in a sack, that when lost they may not render the decoction thick.

Grey.

By diluting the chemical black of the first example with once, twice, thrice, &c. its bulk of water, and thickening the solution with gum, various shades of grey are obtained, which require rinsing off in water only, and the deeper shades of which have tolerable permanence.

The theory of these mixtures is the same as of the black, from whence they are deriv'd. On the addition of water to the olive-green solution, mentioned in the preceding article, the colour instantly becomes deep purple, approaching to black. This is occasioned by the dilution of the free acid, which being no longer able to hold the tannate and gallate of iron in solution, sets part of it at liberty, which instantly regains its colour. For the reason already assign'd, this has less adherence to cloth than that in which the solution is more perfect. The addition of a small quantity of nitrous acid effects this. The olive-green colour of the solution is restored,

COLOUR.

which, by exposure to the air, and consequent evaporation of the acid, disappears, and leaves the tannate and gallate of iron more firmly fixed on the cloth. The complete precipitation of the combination is afterwards effected in the operation of rinsing off in water.

Yellow.

The false or chemical yellows are generally prepared with decoctions of French or Turkey berries, and sometimes with quercitron bark. The latter substance produces pale yellows or straw colour, but does not afford the deep bright orange yellow of the berries. Dr. Bancroft, to whom the public is indebted for the introduction and knowledge of this most useful dyeing drug; and indeed, asserts the contrary in his work on "Permanent Colours;" and has given a receipt for the bark-yellow, which has, however, never succeeded in our hands.

Berry-yellow. Boil two pounds of good berries, slightly bruised, in a gallon of water during three hours, taking care to replace, from time to time, the evaporated water with liquor obtained from the second boiling of a former quantity of berries. When the liquor is cool, add to it eight ounces of alum, and if it is intended for the block thicken it with flour. If it is meant for those small objects in printed goods, which are generally touched with the pencil, two ounces of sugar of lead should be added with the alum, and the colour thickened with gum dragon. This yellow is generally passed through lime water as the first part of the operation of rinsing; by this means the greater part of the earth of alum, which would otherwise have been carried off in the operation, is precipitated on the cloth, and the colour considerably heightened.

When this operation of liming cannot be performed without injury to some other colour, a greater proportion of sugar of lead should be added. This decomposes the alum, and forms an acetite of alumine, which being more readily decomposed by the colouring matter and the cotton than sulphate of alumine, does not require the assistance of an alkaline solution to precipitate it on the cloth.

The proportion of berries above directed is for a full yellow; one fourth or one-third less will form, with the same quantities of salts, yellows of great brightness. Some calico printers add a small quantity of nitrate of copper to the yellows intended to be simply rinsed off without liming. This heightens the colour, but what is gained in intensity is lost in brightness; for if the solution of copper be added in sufficient quantity to produce any very perceptible effect, it imparts a dulness to the hue which is very detrimental. This is the invariable effect of copper in any shape, whether the acetite, sulphate, or nitrate of copper be employed.

Bark yellow. For a lemon or straw colour, it will be sufficient to make a decoction of bark by boiling from four to six pounds in as much water as is necessary during two hours, and after evaporating down the decoction to one gallon, add to it two ounces of sugar of lead, and eight ounces of alum. If not limed, the proportion of sugar of lead should be doubled. For strong yellows, Dr. Bancroft directs the addition of both nitrate of copper and nitrate of lime in quantities so great, as near seven ounces of the former to a gallon of colour. Experience, however, though it has done justice to the merits of Dr. Bancroft's discovery of the use of quercitron bark, has not verified the expectations he had formed of it as a substitute for the Turkey berries in the topical or chemical yellow.

The constitution of these colours, whether formed with

the sulphate and acetite of alumine, or with the solutions of copper is the same. Alumine, or the earth of alum, and the oxyd of copper, have an affinity both for colouring matter and vegetable fibre. They form the connecting link between these substances, which would otherwise counteract a feeble union. When a solution of alum is added to a decoction of berries or of bark, a slight precipitation takes place by the union of a portion of colouring matter with the earth; the greater part however remains suspended or held in solution by the acid of the alum. When applied to the cloth the farther decomposition of the salt is aided by the affinity of this substance for alumine, and, when the acid is volatile, as the acetous for example, by its consequent evaporation. The same takes place with the solutions of copper. The operation of rinsing farther aids the precipitation of the colouring matter and alumine, by thus largely diluting with water; and lastly, when the goods are previously passed through the lime tube, the decomposition is complete, the salt portions of earth or oxyd are precipitated, and the colour thereby considerably exalted.

The solutions of tin are capable of forming very bright and beautiful yellows, with decoctions of different yellow colouring substances; but the excess of acid which these solutions necessarily contain, and their powerful action on the cloth, renders their application less general than the preceding. The solution of tin most proper for yellows is the mumatic, and is formed by digesting, in a low heat for several days, the common muriatic acid, or spirits of salt, on fine grain tin. This solution forms, with bark, a pale and lively yellow, and with berries a yellow bordering more on orange. The spirit yellows, however, as they are improperly called, are seldom used except upon dyed grounds, and of this preparation for such purposes we shall treat at large under the head of *Discharged Work*.

Blue.

The only blue belonging to this class is that produced by combining the colouring matter of logwood with the oxyd of copper. It is but seldom used since the mode of dipping China blue has become generally known; and indeed its want of durability renders it of little value. It may be produced by combining almost any of the solutions of copper with a decoction of logwood.

1. Boil two pounds of logwood in a gallon of water, and to the decoction, thickened with gum, add eight ounces of sulphate of copper.

2. To a decoction of logwood as above, add two ounces of sulphate of copper, and two ounces of verdigrise.

Their colours may either be rinsed off or limed, as best suits the style of work. The theory of these combinations is the same as the preceding.

Green.

The chemical or false green is a compound colour, and consists of a mixed decoction of logwood and berries, or bark, and a solution of copper. Though fugitive, its use is in some degree authorized by the impossibility of obtaining a green of greater durability that can be applied in figures with the block. The fast green of the calico printers is the product of two operations, and is of course limited in its application, and tedious in its use. The production of a fast green at one operation, or rather by one application to the cloth, either with the pencil, block, or press, is one of the great desiderata of calico printing.

1. One pound of logwood and two pound of berries boiled together during two hours, and strained whilst hot

upon two ounces of sulphate of copper, and two ounces of verdigris, and thickened with gum, form a good and lively green, the hue of which may be varied at pleasure by the increase or diminution of the proportion of logwood. To this some calico printers add two ounces of common salt, and two ounces of sal enixion or acidulous sulphate of potash.

2. To one measure of blue of the first example in the preceding article, add two, three, four, &c. measures of a decoction of bark, made by boiling six pounds as before directed for the yellow, and to which, when reduced to one gallon, two ounces of sulphate of copper, and two ounces of verdigris have been added. The tone of the green depending on the relative proportions of blue and yellow, it is, in general, best to keep the two decoctions separate, to be mixed, when wanted, in such proportions as may best suit the purpose required. The theory of these mixtures is the same as of the blue and yellow already described. To the eye of the mere speculative chemist, the addition of common salt and acidulous sulphate of potash in the first example, may appear unnecessary and unmeaning. They indeed affect little, either the hue or fixity of the colour, but experience has proved that this addition facilitates its working with the block, more especially when thickened with gum dragon. The cause of this, in the particular instance before us, is perhaps not very clear. The sulphuric salts in general, such as the sulphates of alumine, iron, and copper, are all unfavourable to working, as their solutions, especially when concentrated, neither thicken well with flour nor gum. A saturated solution of copperas cannot be thickened with flour, nor can a strong solution of the aceto-sulphate of alumine, in which the alum is in great excess; even with gum it unites with difficulty. But if to a solution of copperas, which refuses to form a paste with flour, a small portion of nitrate of iron be added, the whole forms a good and substantial paste that works admirably with the block; and half a pound of common salt added to the aceto-sulphate of alumine has a similar effect. In the instance more particularly before us, the addition of common salt forms a muriate of copper by the decomposition of the sulphate; but this last is in too small a quantity to affect the working of the colour very sensibly. The cause of these effects is to be sought for in the very complicated play of affinities, which exist in such compounds, and which future investigation and discovery may perhaps unfold. The speculative philosopher, who is ignorant of the minute details of an art, that involves in it consideration and difficulties, unsuspected in the laboratory, will hence learn to suspend his judgment in deciding on the merits of a formula, till experience shall have proved the inutility of those ingredients which theory would reject as absurd.

But to return to our subject, there is a wide field open for experiment and discovery in the production of greens, into which logwood does not enter. A calico printer near London, celebrated for his ingenuity and invention in colours of this class, has long employed a green which, from its beauty and durability, when compared with the foregoing colours, indicate the presence of indigo as a constituent part. Prussian blue in a minutely divided state, and mixed with bark or berry-yellow has been employed; but the blue in this case has so little adherence to the cloth, that mere mechanical force, the operation of rinsing and washing is sufficient to disengage it. With one or other of these substances, however, it is likely that greens much superior in beauty, and probably also in durability to those ge-

nerally in use, might, by a series of patient and well conducted experiments, be readily obtained.

Pink.

The pale, and more delicate shades of red, belonging to this class, are chiefly sought after in calico printing. They are employed in giving relief or effect to other admixtures of a more sober cast, and all the skill of the colour-maker is exerted in giving them brilliancy and richness of tint. They are chiefly produced from decoctions of Brazil, Nicaragua, or peachwood, and cochineal, red and fixed on the cloth with solutions of tin, rarely with the aluminous mordants, though delicate and lively colours may be produced this way.

The nitro-muriate of tin is chiefly employed, though the relative proportion of the two acids, and their degree of saturation with tin, varies almost with every calico printer. The solution itself, made according to established rules, and with the same properties, varies so considerably at different times, as wholly to alter the nature of its compounds, without any apparent cause of failure. The source of this discordance is to be sought for in the constitution of the solution itself, which, from causes that we shall endeavour to explain, is subject to considerable variation.

First, from the strength or concentration of the acids employed, which are seldom uniform or constant; muriatic acid from the same manufacturer varying often in specific gravity from 1.12 to 1.18, and nitrous acid not less than from 1.15 to 1.23, without reference to the common distinction of single and double aquafortis.

When the specific gravity of the acids is neglected, as is but too generally the case, these differences occasion serious inconveniences in the use of solutions, whose properties often depend on the accuracy of their proportions, and on determinate degrees of saturation.

Secondly, from the impurity of the acids. The muriatic acid of commerce always contains iron and sulphuric acid; if the former exist in any notable proportion, it is unfit for the solution of tin; the presence of the latter is of less importance, though, on the whole, unfavourable to delicate colours. The nitrous acid varies considerably in its purity, being subject to greater or less admixture with the muriatic; the more it is made from being seldom free from marine salt. The aquafortis of commerce is, in fact, an aqua regia. This variation of the proportion of muriatic acid in the nitrous, is of the utmost importance, since the properties of the solution eminently depend upon this. With muriatic acid only, tin forms a colourless and permanent solution, one of whose distinguishing properties is, its strong affinity or attraction for oxygen. With decoction of cochineal, it forms a deep and dull purple-coloured precipitate, which, however, gradually absorbs oxygen, and becomes crimson, especially when exposed on the filtre. With decoctions of Brazil and peachwood, it affords crimson precipitates, varying in intensity with their saturation with tin. It decomposes all the combinations of iron with colouring matter, deoxygenating the iron which it carries off, leaving the tin in combination with the colouring matter. Thus a madder black becomes a red on the application of muriate of tin. On this property is founded the art of printing on dyed grounds, of which we shall treat hereafter. With nitrous acid, unless very dilute, tin contracts a very feeble union, and is generally precipitated as soon as dissolved, in a state fully saturated with oxygen. The addition of a small quantity of muriatic acid renders this solution more permanent, provided it be not fully saturated with tin, and the addition

COLOUR.

of larger portions approximates the solution still more to the nature of the former, and renders it capable of supporting a greater degree of saturation. The properties of the solution depend greatly on the proportion of muriatic acid, and consequently of muriate of tin contained in it. When small, the precipitate with cochineal is bright carmine scarlet. It does not decompose the combinations of iron with colouring matter, unless the solution be far from saturation, and this effect is then due to the disengaged acid only.

The purity of the tin is another requisite which should be carefully attended to. The fine tin of Cornwall, commonly called grain tin, should be employed. If alloyed with lead, it is wholly unfit for these purposes.

In lieu of muriatic acid, sal ammoniac and common salt are sometimes employed to form an aqua regia with nitrous acid. The solution differs little from that formed by a mixture of the two acids, the allowance being made by the portion neutralized by the alkali of the neutral salt.

From this short outline of the history of the substances employed in the formation of the solutions of tin, and of the properties of the solutions themselves, may be deduced such general ideas as will elucidate and explain many anomalous effects in their combinations with different colouring matters, and seem to direct future experiment in the discovery of those minute, but often important, conditions necessary to the formation of particular shades of colour.

The following examples of spirit tints, as they are improperly called by calico printers, will illustrate some of the preceding observations, and may be considered as specimens of the most beautiful and brilliant colours it is possible to form upon cotton.

1. Prepare an aqua regia by dissolving two oz. of sal ammoniac in one pound of nitrous acid of specific gravity 1.25. To this add two ounces of fine grain tin; decant it carefully off the sediment, and dilute it with $\frac{1}{4}$ its weight of pure or distilled water.

To one gallon of water add one pound of cochineal, ground as fine as flour; boil half an hour; then add two ounces of finely pulverized gum dragon, and two ounces of cream of tartar, and stir till the whole is dissolved. When the liquor is cool, add one measure of the preceding solution of tin, to two of the cochineal liquor, and incorporate well by stirring. Apply this with the pencil or block, suffer it to remain in the cloth six or eight hours, then rinse off in spring water. This colour will be a bright and beautiful scarlet.

2. Boil 12 pounds of Brazil chips during an hour in as much water as will cover them. Draw off the decoction, and pour on fresh water, and boil as before. Add the two liquors together, and evaporate slowly down to one gallon. To the decoction whilst warm add four ounces of sal ammoniac, and as much gum dragon or senegal as will thicken it for the work required. When cool, add one of the solution of tin before described, to four, six, or eight of the Brazil liquor, according to the colour wanted. Suffer it to remain from 18 to 24 hours on the cloth, then rinse off in spring water as before. The colour will be a pale and delicate pink. If it is required deeper, the decoction must be made stronger, and used in the proportion of three or four to one of the solution of tin. Nicaragua or peachwood, though not so rich in colouring matter as Brazil, yields a colour, however, which is, if possible, more delicate and beautiful. The fine pinks produced by certain hoeses, which have for years been the envy and admiration of the trade, are afforded by this fine dye-wood.

These colours require no lining, simple affusion with water being sufficient to precipitate the colouring matter in combination with the tin. The theory of these mixtures is the same as the preceding. They require, however, a greater excess of acid to hold the colouring matter in solution. A decoction of cochineal poured into a saturated solution of tin, occasions an instant precipitate which is not redissolved, and the greater part of which, if applied to cloth, would come off in the operation of rinsing. It is sometimes necessary to add a small quantity of muriatic acid to prevent this precipitation, or to correct it when it happens, and sal ammoniac is supposed to have the same effect, probably by engaging the water of the solution.

With the aluminous salts, the decoction of cochineal and Brazil forms colours less brilliant than those we have just described, but which are applicable in cases where the excess of acid in the solutions of tin is attended with inconvenience.

1. To one gallon of water, add eight ounces of finely ground cochineal, and two ounces of bruised galls; boil half an hour, strain the liquor whilst hot through a fine cloth, upon four ounces of cream of tartar and four ounces of gum, and thicken with gum dragon. This colour requires lining.

2. Upon Oils. of Brazil and 2 oz. of galls, pour one gallon of water, let them soak some time, then boil two hours, replacing the evaporated liquor with fresh water. Strain through a fine cloth upon 4lb. of gum senegal, and add one pint of the acetite of alumine, described in a former part of this article.

The addition of galls in the two preceding formulæ is supposed to impart solidity to the colours in some way analogous to the operation of galling in silk and cotton dyeing, of which we shall have occasion to speak hereafter. Their constitution is otherwise the same as the berry and bark yellows, and most others of this class of colours.

Purple.

1. If the solution of tin directed for the pink in the last article be mixed with six times its bulk of a decoction of logwood poured whilst hot upon four ounces of sal ammoniac, and 2½ lbs. gum senegal, a bright and lively purple will be obtained, the hue of which varies with the strength of the decoction and the proportion of solution of tin employed.

2. If instead of the solution of tin, the acetite of alumine before alluded to, be used in various proportions of one sixth, eighth, &c. purple's differing in shade and intensity will be formed, applicable in some cases, but possessing less solidity than most of the colours already described.

The constitution of these compounds is the same as the preceding.

Olive.

Olives are variously compounded, according to the colour required.

1. By mixing chemical black in various proportions with berry or bark yellow. The depth and fulness of the olive depends on the quantity of black.

2. By a decoction of logwood added in greater or less quantity to the bark or berry yellow.

3. By the addition of coppers or nitrate of iron to decoctions of yellow or altringer colouring matters, such as bark, sumac berries, weld, &c. each of these produces a different hue, varying from the green olive to a drab or cloth colour. By mixing these decoctions in different proportions, and by varying their strength, and the quantities of coppers

nitrate of iron added to each, a multiplicity of shades may be produced, of which it is impossible to convey any precise or definite ideas.

These colours may be indifferently thickened with flour or gum, as best suits the work required, but when nitrate of iron is added to solutions containing gum, the instant coagulation that takes place must be counteracted by the addition of a portion of free nitrous acid. This effect arises from the strong action exerted by metallic oxids, at the maximum of oxydation, on mucilage or gum. When the decoction is very concentrated, and contains sufficient colouring matter to engage the whole of the iron, this effect takes place in a less degree, but with solutions adapted to the production of the foregoing colours, a coagulation invariably takes place, unless counteracted by the presence of a portion of free acid. Of this action of metallic oxys on the solution of gum we shall further treat under the article Gum.

Class III.

In this class, the colouring matter is simply held in solutions, by an acid or alkali, and in that state applied to the cloth without the intervention of any mordant.

The most important of these colours, is the alkaline solution of indigo which forms the topical or.

Pencil Blue.

1. Prepared solution of pot-ash, by boiling together 7½ lbs. of quick lime, and 1½ lbs. of pot-ash, in 10 gallons of water. Decant off the clear liquor, and separate the remainder from the lime by means of the filter. To one gallon of this solution, add 1 lb. of red arsenic, or orpiment, and 1 lb. of fine indigo, both previously ground together in a mill with sufficient water to form a thick paste. Bring them up gradually to a boil, stirring carefully all the time, and then withdraw the fire. Thicken the solution with the best gum fucagel, and for the pale shades of blue, dilute with one, two, &c. measures of gum-water.

The quantities and relative proportions of pot-ash, orpiment, and indigo in a gallon of pencil blue vary considerably with different calico printers, and within certain limits, it appears, that the accuracy of these proportions is not of great importance. Hansman, an intelligent French printer, employs 1½ lbs. of pot-ash, 6 lbs. of orpiment, and 8 lbs. of indigo, to 12 gallons of water; and Oberkampff, proprietor of the celebrated manufactory of Tony, a still greater proportion of indigo. Some printers add brown sugar, and Baneroff has proposed to substitute this for the orpiment, but without success.

The solution, when recently made, is a yellowish green, but by exposure to air, becomes gradually deeper, and at last blue. In this state, it is wholly unfit for use, it contracts no union with the cloth, and is detached from it in the first operation of rinsing.

Of the peculiar nature and properties of indigo, we shall have occasion to treat hereafter, under its proper head, at present it will suffice to observe, that it owes its colour and insolubility in alkalies, to a portion of oxygen intimately combined with it. To render it soluble, therefore, it must be deprived of this oxygen, by the action of a substance having a more powerful affinity for it, and the sulphuret of arsenic, or orpiment, is used for this purpose. Sulphate of iron, has a strong affinity for oxygen, and is employed in de-oxygenating indigo for certain purposes; but the oxyd of iron not being soluble in alkalies, the solutions of indigo, formed by it, become quickly regenerated by the absorption of oxygen, and cannot even be transferred from one vessel

to another. The sulphuret of arsenic, on the contrary being very soluble in alkalies, presents the double advantage of de-oxygenating the indigo, and of retaining it a while in that state, till on its application to cloth, it becomes exposed to completely to the action of atmospheric air, as to regain its oxygen, colour, and insolubility; and becomes fixed in its original or blue state.

The copper coloured pellicles, which forms on the surface of pencil blue, and is renewed immediately on its removal, arises from the absorption of oxygen, which, in spite of the action of the orpiment, is continually taking place. Hence arises that disposition to unevenness, which is the great disadvantage of this blue; the unavoidable exposure to air of small portions of the colour during its application with the pencil, receiving greater or less portions of indigo, and considerably reducing its strength.

Most calico printers boil up the quicklime with the other ingredients, thinking its presence not less necessary than the pot-ash and orpiment; by this means a considerable portion of the solution of indigo is taken up by the sediment, which careful washing does not wholly separate. As the action of the lime is confined merely to the alkali, which it renders caustic, and capable of acting with greater force on the other ingredients; it is certainly much more economical to render the pot-ash caustic before its addition to the indigo. A considerable waste of colour is by this means prevented, and the solution may be thickened the moment the ebullition has ceased without waiting for the deposition, which in the old mode takes place.

Orange.

The oxyd of iron, when dissolved in acetous acid, forms one of the most useful and important mordants, as we have already shewn in the former part of this article. It is also capable of imparting a very pleasing and permanent colour itself to cotton, when applied in solutions of tolerable strength and purity, and forms the orange, buff, and gold colour of the calico printers.

1. The solutions of iron in vinegar, strengthened by the addition of coppers may be used, but the purest and brightest gold colours are obtained from coppers and sugar of lead, in the proportion of 5 lbs. of the former, and 1 lb. of the latter, to a gallon of water. When thickened with gum, and employed undiluted, it affords, when limed, a full strong gold colour, and with two, four, six, &c. times its bulk of water, various shades of orange and buff, which resist the action of air, alkalis, and soap; and are rather exalted than impaired by frequent washing. The addition of sugar of lead, is to increase the strength of the solution. A gallon of water dissolves about 4 lbs. of coppers. The addition of a pound of sugar of lead, enables it to take up another pound nearly, and the strength of the solution may be still further increased by equal additions of the two salts. The operation of liming is a simple precipitation of the oxyd of iron on the cloth, and in cases when this cannot be performed, the proportion of sugar of lead must be increased to nearly that of the coppers. It is only the paler shades of orange, however, which are to be obtained this way. The deep gold colour before named, is not to be procured without the aid of a precipitant. Spanish brown is sometimes added to a solution of iron, and employed in such a case, but it contracts no union with the cloth, and is readily removed by simple washing and beating. When the orange, or gold colour, is thickened with flour, a small portion of nitrate of iron must be added to the paste, for reasons we have assigned on a former occasion.

2. A beautiful, but fugitive orange, is obtained by boil-

ing half a pound of annotta with 1lb. of caustic pot-ash in a gallon of water, and thickening the liquor with gum. This colour acts powerfully on the sieves and blocks, which it very soon destroys, and on this account, and also from its want of permanence is seldom used. It may either be simply rinsed off, or first passed through water rendered slightly acidulous with sulphuric acid, or what is still better through alum-water. This operation is the very reverse of liming, for here the colouring matter to be precipitated, being held in solution by an alkali, an acid must be employed for that purpose. The colour by this means is considerably heightened, and when applied with the pencil, is useful in some cases where the other colours will support the action of alum-water without injury.

Borax, and even spirits of wine, are sometimes added to the alkaline solution of annotta, and are supposed to contribute to its strength and fixity, though on what principle it is not easy to discover.

Green.

The oxyd of copper, dissolved in volatile alkali, affords a pale and delicate green, which is sometimes employed intermixed with other colours. Turnings of copper, or verdigrise, which is more generally used, may be digested in a low heat with spirits of sal ammoniac. Care must be taken that the heat be very moderate, and the vessel in which the solution is made, well stopp'd, the ammoniac will otherwise be driven off, and lost. When the alkali has taken up as much copper as it can dissolve, the solution must be thickened with gum, and applied with the block or pencil. In a few days the ammoniac evaporates and leaves the oxyd of copper on the cloth, which must be rinsed to free it from the gum and superfluous colour.

The blues produced by alternate immersion in coppers and lime, and also in the solution of indigo, by the same substances, properly come under this class of colour, as they are solutions of colouring matter in lime and alkalis. As the processes by which they are applied, differ however very materially from all those that we have been treating of, they claim a separate and distinct notice. For the details of these operations, and the mode of preparing the pallets for bark and pale blue dipping, and the colours for China blue, we must therefore refer our readers to the article *Dipping BLUE*.

COLOURS, in Dyeing.—There are five simple, primary, or mother colours, used by the dyers: from the mixture whereof all the other colours are formed; these are blue, red, yellow, black, and brown colour; each of which fee under their proper head, *BLUE, RED, &c.*

Of these colours, mixed and combined, other colours are formed, which are infinitely various, according to the proportion of the different ingredients that are employed, or the processes by which they are blended. Thus a mixture of *blue and yellow* forms *green*, which is distinguished by dyers into a variety of shades, according to the depth of the shade, or the prevalence of either of the component parts. Hence we have *sea-green, grass-green, pea green, &c. &c.* *Blue and red* form different shades of *violet, purple, and lilac*. A mixture of *yellow and red* produces *orange*. Mixtures of *black* with other colours constitute *greys, drabs, and browns*. For a more particular account of these and other colours; and the method of procuring and applying them; see the article *DYEING*. See also the preceding article.

The greatest perfection in the art of colours would be to find the means of preparing the finest colours without the use either of acid or alkaline salts, which usually subject the colours to change, or else are apt to prey upon the

cloth, canvas, &c. as we see in verdigrise, the blue and green crystals of copper, &c. It appears highly probable, that the Indians, for making the fine bright and durable colours, wherewith their chintzes and callicos are stained, make use of metalline solutions; for some stained callicos, brought from thence, having been kept 40 or 50 years, the bright colours have been observed to eat out the cloth, exactly in the same manner as acid spirits, which dissolve metals, are found to do.

Since these, then, are the inconveniences attending such colours, we ought to search for menstrums with which to extract colours, which are neither acid nor alkaline; and for such metalline oxyds, precipitates, or powders, as will not lose their colours, by being well washed to get out their salts; to prepare certain metalline matters, by mere calcination, or the bare assistance of fire; and lastly, to look out for native colours, wherein no saline matter abounds.

Mr. Geoffroy has given a very curious process for making two clear, spirituous, inflammable liquors, which differ very little in taste and smell, and being mixt together give a fine carnation colour, without any sensible fermentation.

To make the first of these liquors, put a small handful of dried red roses into a glass bottle; pour on them rectified spirit of wine, till it covers them an inch; let this stand in a cold infusion four or five hours; then pour off the liquor, which will be clear and colourless, as when put on. The second liquor is made by dropping into rectified spirit of wine, so much oil of sulphur, by the bell, or spirit of vitriol, as will be borne in it without giving it any very sensible acidity when tasted. When these liquors are thus prepared, let a small quantity of the latter be dropped into some of the former, and the whole will become of a fine carnation colour, though there is no fermentation, nor any other change perceived in it, but barely that of colour. If instead of this last liquor, there be added to the first a few drops of the spirit of sal ammoniac, the whole will become green.

Make a slight infusion of galls in water, so as not to colour the water; make also a weak solution of green vitriol in water, so that it may appear colourless; mix these two colourless liquors together, and an inky blackness is immediately produced; add to this black liquor a little oil of vitriol, and the liquor becomes pellucid and colourless again; then add to this a little salt of tartar, and the whole is black again.

Put a little bruised camphor into rectified clear oil of vitriol; shake the mixture, and it will become black, and the camphor will be dissolved; add to this a little water, and the liquor becomes clear, and the camphor is found separated at top, in its own form, and native whiteness.

Infuse liqum nephriticum in cold water, and pour off the clear liquor. This held up against the light, appears of a fine yellow, but viewed from the light, of a beautiful blue; a little spirit of nitre put to this liquor makes it lose the power of reflecting the blue rays, and a little oil of tartar, afterwards added, recovers that power again.

Logwood, infused in water, gives a red colour. Put to this a little spirit of urine, and it becomes of a fine purple; and drop in afterwards a little spirit of salt, and it becomes of a pale red.

A beautiful blue tincture may be made from filings of copper, by digesting them in spirit of urine, hartshorn, or the like. The addition of oil of vitriol destroys the blue colour; and a little spirit of salt turns it green.

Pellucid oil of vitriol, mixed with pellucid oil of turpentine, produces a thick red balsam. And common oil, mixed with fair water, by means of a little wax, and continued rubbing,

rubbing, turns into a thick white balsam, called cold cream.

Oil of vitriol, distilled from quicksilver, leaves a white powder behind, which, if water be poured on it, becomes yellow.

Dissolve quicksilver in spirit of nitre, and to part of it add spirit of urine, and a white powder is precipitated; to another part of the solution add oil of tartar, and a yellow powder falls to the bottom.

Drop a new pen in spirit of vitriol, and write with it on common blue paper, and the letters will appear red.

A pelucid solution of saccharum saturni being written with on paper, becomes invisible when dried; but the base fumes of an infusion of quick lime, and opiment, in water, will render the invisible writing black and legible.

Volatile salt of sal ammoniac, which is white, mixed with crystals of copper, which are green, produce a fine purple.

The original and simple, as well as the mixt. colours are producible by mixture. Thus, if the sun's rays pass through two pieces of glass, the one blue, and the other yellow, and be afterwards received upon a white paper, the colour there seen is green. The dyers make cloth blue with woad, and then turn it green by the yellow herb called isoteola, or dyers' weed. To a yellow solution of gold in aqua regia add a blue one of copper in spirit of urine, and the mixture becomes green. The painters every day practise this art of producing new colours by mixture.

Metallic and mineral matters are reducible to a considerable degree of subtlety, or smallness of parts by fire, or dry calcination, so as to leave them durably possessed of their native or adventitious colours. Thus lapis lazuli, by being calcined, becomes the fine rich blue called ultramarine; light ochre, by the same treatment, becomes a light red, or flesh colour, the most useful flesh-colour in painting. Lead, by calcination, becomes durably red, and iron durably brown; but a proper method seems wanting for the dry calcinations of the nobler metals, gold and silver; though, for the uses of gilding, these are easily prepared by dipping linen rags in their respective solutions, and then drying, and burning them to ashes, whereby a dry and fine metallic powder is procured.

COLOUR, in *Heraldry*, the heraldic colours are nine, and were anciently expressed by the word *insigne*, viz. or, argent, azure, gules, sable, vert, purpure, tenney, and sanguine, and also by precious stones and planets; the a-morial colours are blazoned in different terms, according to the rank and dignity of the person whose arms are described, as follows:

Colours.	For Commoners by Tinctures.	For Peers by Precious Stones.	For Emperors, Kings, and Princes, by Planets.
Yellow,	Or,	Topaz,	Sol.
White,	Argent,	Pearl,	Luna.
Blue,	Azure,	Sapphire,	Jupiter.
Red,	Gules,	Ruby,	Mars.
Black,	Sable,	Diamond,	Saturn.
Green,	Vert,	Emerald,	Venus.
Purple,	Purpure,	Amethyst,	Mercury.
Orange,	Tenney,	Jacinth,	Dragon's head.
Dark red,	Sanguine,	Sardonix,	Dragon's tail.

For a fuller account of each, see under the respective heads.

Or, and argent are metals, and it is an invariable rule in heraldry not to put colour upon colour, or metal on metal;

that is if the field be of a colour, the charge or bearing must be of a metal.

C O U R S E, in *Law*, is a probable or plausible plea; though in reality false at bottom; and only calculated to draw the trial of the cause from the jury to the judge; and, therefore colour ought to be matter of law, or doubtful to the jury.

In pleading it is a rule, that no man be allowed to plead, especially, such a plea as amounts only to the general issue; but in such case he shall be driven to plead the general issue in terms, by which the whole question is referred to a jury. But if a defendant in an assise or action of trespass, be desirous to refer the validity of his title to the court rather than to the jury, he may state his title specially, and at the same time give colour to the plaintiff, or suppose him to have an appearance or colour of title, had indeed in point of law, but of which the jury are not competent judges. As if his own true title be that he claims by feoffment, with livery from A. by force of which he entered on the lands in question, he cannot plead this by itself, as this plea amounts to no more than the general issue. But, he may allege this specially, provided he goes farther and says, that the plaintiff claiming by colour of a prior deed of feoffment, without livery, entered, upon whom he entered; and may then refer himself to the judgment of the court, which of the two titles is the best in point of law. (Doctour and Student. 2. c. 53.) Every colour ought to have the following qualities.

1. It is to be doubtful to the *Jury-gens*, as in case of a deed of feoffment pleaded, and it is a doubt whether the land passeth by the feoffment, without livery or not. 2. Colour ought to have continuance though it wants effect. 3. It should be such colour, that, if it were effectual, would maintain the nature of the action, as in assise, to find colour of freehold, &c. (10 Rep. 83, 90, and 91.) Colour must be such a thing, which is a good colour of title, and yet it is not any title. (Cro. Jac. 122.) If a man justifies his entry for such a cause as binds the plaintiff or his heirs forever, he shall not give any colour; but if he pleads a defect in bar, he must give colour, because this binds the possession, and not the right; so that when the matter of the plea bars the plaintiff of his right, no colour must be given. When the defendant entitles himself by the plaintiff; where a person pleads to the writ or to the action of the trial; he who justifies for titles; or where the defendant justifies as servant; in all these cases no colour ought to be given. (10 Rep. 91. Lutw. 1343) Where the defendant doth not make a special title to himself or any other, he ought to give colour to the plaintiff. (Cro. Eliz. 76.) In trespass for taking and carrying away twenty loads of wood, &c. the defendant says, that A. B. was possessed of them, *ut de bonis propriis*, and that the plaintiff claiming them by colour of a deed after made, took them, and the defendant took them; and adjudged that the colour given to the plaintiff makes a good title to him, and consecuteth the interest in him. (1 Lil. Abr. 275.)

Thus, e. gr. in an action of trespass for taking away the plaintiffs heath, the defendant urges, that before the plaintiff had any interest in them, he himself was possessed of them, as his proper goods; and delivered them to A. B. to deliver to him again, when, &c. and A. B. gave them to the plaintiff; and the plaintiff, supposing the property to be in A. B. at the time of the gift, took them, and the defendant took them again from the plaintiff; whereupon the plaintiff brings his action.—This is a good colour, and even a good plea. Dict. and Stud.

COLOUR of office, is when some unjust action is done under countenance of office or authority. See BRIBERY and EXTORTION.

To COLOUR *strangers goods*, is when a free man allows a foreigner to enter goods at the custom house in his name.

COLOURS, *camp*, are a sort of small colours planted on the right and left of the parade of a regiment when in the field. They are about 18 inches square, and of the colour of the facing of the regiment, with the number of the regiment marked on them. The poles, to which they are fixed, should be about 7 feet 6 inch long; except those of the quarter and rear guards, which ought to be about 9 feet long.

COLOURS, *field*. See FIELD.

COLOURS, *guard*. See GUARD.

COLOURS used in the drawings of fortifications and military works, are chiefly Indian ink, carmine, verdigrise, sap green, gum bouché, Prussian blue, Indigo, smalt, ultramarine, amber, gum water, which articles see separately, as well as the article FORTIFICATION.

COLOURS, *Colores*, in the Ancient Music, was used to signify the musical species belonging to a genus.

In this sense the chromatic genus was said to have three colours; and the diatonic two. The enharmonic, having no subordinate species, had but one colour. Hence the ancients reckoned three genera, and six colours, in music; that is, in many different divisions of the diatessaron, or fourth.

COLOURS, *diatonic, or musical scale of*.—In the course of Sir Isaac Newton's experiments on the properties of light, (Optics, book i. part ii. prop. 3.) he discovered the remarkable fact, that the spectrum of the sun's image, formed by refracted light, let into a darkened room, is longitudinally divided by the points separating the different colours, viz. violet, indigo, blue, green, yellow, orange, and red, into spaces which are respectively equal to $\frac{1}{10}$, $\frac{1}{10}$, and $\frac{1}{10}$ parts of the double length of the spectrum, as, suppose the spectrum to be 360 parts in length, then $\frac{360}{10}$, $\frac{360}{10}$, and $\frac{360}{10}$, will represent the length of each colour respectively, and adding these successively in the reverse order, to $\frac{360}{10}$, we have $\frac{492}{10}$, $\frac{648}{10}$, $\frac{816}{10}$, $\frac{984}{10}$, $\frac{1152}{10}$, $\frac{1320}{10}$, which, in their lowest terms, are $\frac{123}{25}$, $\frac{162}{25}$, $\frac{204}{25}$, $\frac{246}{25}$, $\frac{288}{25}$, and 1, and appear to be the diatonic ratios answering to the octave, minor seventh, major sixth, fifth, minor fourth, minor third, major second, and E note; or, to VIII, 7th, VI, V, 4th, 3d, II, and key, represented in the gamut by c, bB, A, G, F, bE, D and C.

From the experiments of Henry Brougham, jun. esq. Philosophical Transactions, 1796, it appears, that not only by refraction, but by inflection, deflection, and reflection, the rays of light may be separated on a chart or screen: and he mentions numerous experiments, wherein the limits of the several colours on the spectrum were carefully marked with the point of a needle, after which the papers thus marked were put away, and a fresh paper substituted for other experiments: the measurement or comparison of the lengths of the intervals occupied by each colour on the different papers, being purposely deferred, until the whole course of experiments was completed, in order to prevent any preconceived opinions from operating, in making the experiments: the results are represented as agreeing, in the spaces $\frac{1}{10}$, $\frac{1}{10}$, occupied by the violet, indigo, blue, green, yellow, orange, and red colours, being the very same, as to arrangement, as those by refraction above-mentioned.

It is observable, that the notes composing the octave thus produced, do not answer to the major-key of bB as it might seem to do, although some writers on musical intervals have asserted, that nature produces only the major-key or division of the octave, and that the minor third bE or $\frac{3}{2}$ is

nowhere to be found in nature. If we were to consider the *colorific ratios* $\frac{1}{10}$, $\frac{1}{10}$, $\frac{1}{10}$, $\frac{1}{10}$, $\frac{1}{10}$, $\frac{1}{10}$, $\frac{1}{10}$, and 1, found above as a minor octave, and to belong to the notes in the gamut a, G, F, E, D, C, B and A; and find the ratios answering to the octaves of C and B, viz. $\frac{1}{2}$, and $\frac{2}{3}$, or c and b; then, if from each of the above ratios we deduct the ratio $\frac{1}{2}$ (or multiply by $\frac{1}{2}$), we obtain, $\frac{1}{20}$, $\frac{1}{20}$, $\frac{1}{20}$, $\frac{1}{20}$, $\frac{1}{20}$, $\frac{1}{20}$, $\frac{1}{20}$, and 1, for the notes in the octave c, b, a, G, F, E, D, and C, but which is not a major diatonic octave, because those principal notes, the V and 4th, or G and F, have not the ratio of $\frac{3}{2}$ and $\frac{4}{3}$ as they ought to have. Thus we see, that the eight notes answering to a colorific minor-key, do not hold the proper relation between themselves, for forming a major-key, by merely assuming the third of the first key, as the new key-note: and strictly speaking, the same may be observed of any other transposition or modulation whatever, upon eight diatonic notes, or even upon any 12 notes composing an octave, taking all the concord into account; although most of the keyed instruments, as organs, harpsichords, &c. in use, are made and played upon, and the notation or writing of music itself is founded upon this supposition, which is far from being correct.

COLOUR, in *Painting*, is applied both to the drugs, and to the tints produced by those drugs, variously mixed and applied.

The principal colours used by painters, are red and white lead or cerul; yellow and red ochres; several kinds of earth, as amber, &c. besides orpiment, black lead, emmabar, gamboge, lake, bice, verditer, indigo, vermilion, verdgris, ivory black, billre, lamp black, smalt, ultramarine, and carmine; each of which, with the manner of preparing them, their uses, &c. see under their respective heads.

Of these colours, some are used pure and in oil, others only in fresco, others in water, and others only for miniature.

COLOURS, in an *Ecclesiastical Sense*, are used both in the Latin and Greek churches, to distinguish several mysteries and feasts celebrated therein.

In the Latin church are only regularly admitted five colours, viz. white, red, green, violet, and black: the white is for the mysteries of our Saviour, the feasts of the Virgin, those of the angels, saints, and confessors: the red for the mysteries and solemnities of the holy sacrament, the feasts of the apostles and martyrs; the green for the time between Pentecost and Advent, and from Epiphany to Septuagesima; violet in Advent, Christmas, in vigils, rogations, and in votive masses in time of war: lastly, black for the dead, and the ceremonies thereto belonging. Cloths of gold and silver, and embroidery, serve indifferently for all solemnities.

In the Greek church the use of colours is almost obliterated, as well as among us: red, among them, was the colour for Christmas, and the dead, as black is still for the last among us.

COLOURING, in *Painting*, one of the great component and essential parts of painting, is the art of giving to every object in a picture its true and proper hue, as it appears under all the various circumstances or combinations of light, middle-tint, and shadow; and of so blending and contrasting the colours, as to make each appear with the greatest advantage and beauty, at the same time that it contributes to the richness, the brilliancy, and the harmony of the whole.

It likewise possesses powers which, when judiciously applied, render it highly conducive to the character and expression of the subject represented.

A noble author, lord Lansdown, "says, that verification is in poetry, what colouring is in painting, beautiful ornament;" but the comparison is ill-founded. Verification is, indeed, an ornament, and so is colouring; but the former is merely an ornament, whereas the latter is necessary to the painter to enable him to make his imitation or representation complete. "Should the most able master in design," says Mr. Webb, "attempt by that alone a rose or grape, we should have but a faint and imperfect image; let him add to each its proper colours, we no longer doubt, we shall the rose, we touch the grape."

Colouring, like chiaro-scuro, may therefore be divided into kinds; that which is necessary for rendering the imitation just and intelligible, and that which is *expedient or ornamental*, as contributing to make the work at once more impressive to the imagination, and more harmonious and delightful to the eye. Truth in the local tints is alone required in the first kind; the second demands choice in their selection and distribution. For illustration, let us suppose the principal figure in a piece to be dressed in sky-blue, and another figure near it, of less consequence in the story, to be represented in scarlet, with an under-vestment of bright yellow, and let the light be made to strike equally on both: in such a case, it would be utterly impossible to give an effect agreeable or harmonious to the picture; although each of these objects should be painted with the utmost exactness and truth; nay, the combination, though found in nature itself, would excite feelings of disgust and aversion; whereas, if the principal figure were dressed in scarlet and white draperies, and the figure next to it in blue of not too light or bold a tint, the effect would be harmonious and pleasing; and another point of great importance would be gained, as the eye would then be attracted by the principal figure, which could not have been the case in the former instance, where the gaudy combination of yellow and red met intolably, as is natural with all warm colours, have first obtruded itself into notice. However, as the eye has the same intuitive abhorrence of unharmonious combinations of colours, that the ear has of discordant sounds: it is, therefore, not surprising if we so seldom meet with enormities like the one above supposed, even in the works of those artists who least of all can lay claim to the scientific arrangement of colours: to produce effects not unharmonious, or disagreeable requires no great exertion of talent; but to perform all that can be done by the most skilful application of the various powers of the art is the lot of few.

In treating of chiaro-scuro, we have observed, that the part of it to which we have given the appellation of necessary or natural chiaro-scuro, was in a greater or less degree understood and practised from the earliest period of the restoration of painting: the same was the case with respect to what we have termed necessary colouring, or truth in the local tints.

The oldest painters of Florence, Giotto, Buffalmacco, and others; and still more so, Simone Memmi, Ambrogio Lorenzetti, and the rest of Senechal's school of the same period, made frequently not unsuccessful attempts at truth and even beauty in the tints of the flesh and other parts of their pictures; and sometimes produced a distribution of colours by no means ungracious in the whole; though the prodigal use of gold grounds and gold ornaments bid defiance to an effect truly harmonious. Malpino da Panicale, Maffaccio, Domenico Ghirlandajo, and Pietro Perugino, went much further, and we rarely find a want of delicacy of colouring

in the parts of their pictures, or of harmony in the general effect. But still this was the result of a happy natural feeling for what was beautiful rather than of an approved and well-founded theory. It was not till the period when Leonardo da Vinci laid the foundation of an improved system of chiaro-scuro, that the Bellini's of Venice began to discover the beautiful effects resulting from a skilful combination or opposition of colours, at the same time that they attained a richness and truth in their local tints, far exceeding any thing hitherto practised. In both these qualities, however, they were soon far surpassed by their scholars, Giorgione da Castel Franco, and Titiano Vecelli, who, superadding to the most astonishing richness of colour, the powerful light and shade of da Vinci, produced works which, in their way, have baffled all future attempts at improvement. The tone of colour of their pictures is not that of nature in her every day garb; it is ideal, like the chiaro-scuro of Coreggio or Rubens; that which may be supposed, but which, perhaps, is seldom or ever found in nature: the depth and mellowness of their tints can scarcely be accounted for but by the supposition of a tranquil but vigorous light shining through the heated atmosphere of a summers evening. The world was astonished at this new style, and it is no wise surprising that Tintoretto, Paolo Veronese, and others who followed, being unable to do better, should attempt something different; the manly, the sober senatorial dignity of Giorgione and Titian, was changed for magnificence, for show, for glitter, and for ornament; invention, composition, design, and expression, were all made subservient to the inordinate desire of effect of colour; the subject of the work could in many instances with difficulty be discovered, and their pictures may, in most cases, be compared to bewitching nonsense uttered by the silver tongue of the woman we love; to the sweet but fatal song of the Syren. There seems to be nothing in the colouring of Giorgione and Titian, incompatible with the greatest purity of design, sublimity of composition, or propriety of expression; but the splendid extravagances, the caded fluffs, the gaudy trappings of the more modern Venetians, are wholly inconsistent with true grandeur, and too frequently seem to resemble the wretched effort of poverty to personate opulence, or the despicable attempt of the lacquey or courtizan to outvie by their tinsel apparel the dignity of the nobleman, or the simple elegance of the woman of distinction.

Whilst the two great founders of the Venetian school enraptured the sight by their transcendent and novel effects of colour, the Roman and Florentine painter, though principally applying their talents to the attainment of still higher objects, were not wholly unmindful of this part of the art. Many of the frescos of Raphael in the stanzas of the Vatican, and in particular the dispute of the sacrament, the St. Peter delivered out of prison, the maids of Boffena, and the Hierodorus, are severally coloured with the richness of Venetian tint, or with the pearly hue of Parma. However, from the latter works of this great master, it should appear that he did not at all times consider this branch of painting as worthy his attentive regard. Fra Bartolommeo di San Marco, in his madonnas and apostolic figures, united grandeur of design and breadth of chiaro-scuro to a tone of colour at once dignified, tranquil, and harmonious; and Andrea del Sarto, except in some of his last works, where he in some degree adopted the gay and frivolous style then beginning to be in vogue, painted with a strength and sobriety of tint every way adapted to give increased interest and expression to the devotional or sacred subjects which he generally treated.

At this period, as if nature then made holiday, and was prodigally lavish of her gifts, the great Coreggio appeared, and by his astonishing frescos in the cupolas, and other works at Parma, seemed to cast a new radiance on the world of art. In him the very soul of harmony resided, and the magic of his pictures so irresistibly intrances the sight, as to render us almost incapable of discriminating, whether the astonishing effect is most the result of the breadth and softness of his chiaro-scuro, or the beautiful combinations and transitions of his colours. However, delicacy of tint seems to have been the aim of Coreggio; richness and luxuriance of colour that of the Venetians. And it has been observed of the great artist of Parma, that the flesh in his pictures seems generally of too firm a texture, and to want that humid appearance, the result of insensible transpiration, which forms one of the particular characteristics of human bodies, and which Titian and Giorgione succeeded so admirably in representing.

These are the great masters of colouring amongst the Italians. After this period a corrupt and frivolous style for some time predominated, and more particularly in the Roman and Florentine schools of painting. With them it was not uncommon to see yellow draperies shaded with purple, red ones with blue, or green with some other tint; as if it had been the intention to represent changeable fluids; and the eye seemed gradually to have become accustomed to the most unharmonious, the most gaudy and absurd combinations. Baroccio indeed made an effort to stem the torrent of this dastard taste. After having assiduously studied the works of Coreggio, he attempted to adopt his principle, and so far succeeded, that he deservedly had, and still has his admirers. But in the works of Baroccio, the red, the blue, and the yellow are too ostentatiously displayed, and want blending; which seems to justify the same critique on them that was made upon the works of Parrhasius, that his figures looked as if they had fed on roses.

The Venetian painters it is true, never entirely lost sight of the genuine principles of colouring; but even in this respect they fell far short of the great founders of their school above-mentioned, and the general frivolity of their taste, too frequently occasions even their merits to be passed by unregarded.

Coreggio had few followers; his divine spirit found not, like that of Donatello, a kindred place of abode amongst his successors; nevertheless, the Lombards preserved a certain richness and harmony of tint, which still, in this particular, entitled them to a higher rank than their contemporaries of lower Italy. The Carracci, towards the latter part of the 16th century, rescued the art from the degeneracy into which it had fallen; and by uniting, as far as they were able, the different beauties of the Roman, Florentine, Lombard, and Venetian schools, produced a new style, and gave their name to an academy eminent for the various talents which it called forth. Their colouring, however, is not so rich as the Venetian, nor so harmonious as that of Coreggio; but it is exempt from glaring defect, simple and tranquil, and well suited to the sobriety and dignity of history painting.

Of Caravaggio, their rival at Rome, it was hyperbolically said, that he dipt his pencil in flesh itself: but we have to regret that the black and opaque shadows which pervade his pictures, probably occasioned in some degree by the perishable nature of some colours which he used, destroy much of that truth of effect, which, from the praises bestowed on him in his life-time, we have grounds for supposing they originally possessed.

The pencil of Guercino is broad, and his tints fresh and vigorous, but his effect is generally more the result of

chiaro-scuro than of any remarkably skillful arrangement of his colours.

The pictures of Guido, in his first manner, possess considerable force of tint; but he afterwards abandoned this style for a mode of colouring weak and insipid: nevertheless, his grace, his knowledge of expression, and his unparalleled freedom of pencilling, gained him innumerable followers; till at length, that which ought to have been considered one of his greatest faults, was numbered amongst his beauties. It is true, that shortly after this period, landscape was carried to the highest pitch of perfection by the Poussins, Salvator Rosa, and Claude Lorraine; the former giving to their pictures a style of colouring at once solemn and impressive, the latter a truth of aerial tint, never before or since attained. Nevertheless, a slight and flimsy manner of colouring became one of the characteristics of the Italian schools, and the deserted daughter of Iris sought an asylum in the less congenial climes of Flanders and Holland.

Amongst the Flemish painters, Rubens undoubtedly holds the first place; and his works, as sir Joshua Reynolds observes, "have that peculiar property always attendant on genius, to attract attention, and enforce admiration, in spite of all their faults." This, however, is not the place for a general inquiry into his merits. With respect to his colouring, we have to observe, that it evinces that exuberance and boldness of genius, which in every other part of the art peculiarly characterises him. It possesses neither the sober richness of Titian, nor the delicate harmony of Coreggio, but seems frequently, by the gorgeous assemblage of tints, to vie with the gaudy of the chaplet or nosegay. It is perhaps, however, a matter worthy of investigation, whether the great variety of colours, introduced by Rubens in the draperies and other parts of his pictures, has not, by the too great equality of their distribution, upon some occasions proved detrimental, rather than advantageous, to the richness and splendour of effect, which at all times seems to have been his principal object; and whether that object would not have been more effectually attained, had he followed the practice of the early Venetians, in giving to two or three colours a more decided pre-eminence.

The style of Vandyke is more pure and chaste. The modest tenderness of his tints gently but irresistibly persuade; and his numerous portraits, by their delicacy and truth of expression, still captivate and interest the beholder, even where the personages they represent have been long buried in oblivion.

Rembrandt is, as Mr. Fuseli observes, a genius of the first class in every thing which relates not to form; but though as a colourist he certainly holds a pre-eminent rank, the effect of his pictures is, perhaps, as we have said of Guercino, more the consequence of his astonishing chiaro-scuro, than of the freshness and vigour of his tints. His works present not the gorgeous combinations of colour found in those of Rubens, or that humid mellowness of tint in the flesh, so much admired in the pictures of Titian and Giorgione; nevertheless, they evince a most powerful conception of harmony, a beautiful gradation of tint, and great solemnity of tone. His lights have a brilliancy peculiarly his own; scarcely more owing to the powerful opposition of his chiaro-scuro, than to the extraordinary method which he used of painting the luminous parts of his pictures with a very great body of colour in almost a dry state; whilst his broad masses of shadow possess a magic transparency, making as it were darkness visible.

It would be endless to enumerate the many admirable colourists of Flanders and Holland, who successively trod the

footsteps of the great artists above-mentioned: indeed, there are few painters of those schools whose works may not be studied with advantage as to this part of the art; the richness and harmony of their tints, the beauty and strength of their chiaro-scuro, and the delicacy of their penciling, comprising their chief excellence. Sir Joshua Reynolds, the great colourist of the last century, fully appreciated their merits: and by combining somewhat of their principle with the different styles of Titian and Coreggio, has succeeded in producing, in not a few instances, a richness and brilliancy of colour, inferior, perhaps, to neither, and, at the same time, different from all. Happy for his reputation, if from an insatiable desire of surpassing, he had not, in so many of his pictures, indulged himself in the use of colours and varnishes, which, like the more delicate blossoms of nature, are the earliest subject to decay.

We have been the more diffuse in our attempt to characterize the principal masters eminent for colouring, as we are aware that so little can be said upon the preceptive part of this branch of art, which, more peculiarly than any other, seems to depend upon the delicacy and perfection of the organs of vision, and the nice discriminations of feeling and judgment. The great artist last-mentioned was perhaps the only colourist who ever wrote upon colouring, and we shall therefore have recourse to the assistance of his admirable discourses, in our attempt to give some idea of the leading principles of this part of the art.

It has already been observed, that chiaro-scuro may exist in the greatest perfection, independently of colours; but colouring, without the aid of lights and shadows, would present us nothing more than the geographical chart or the harlequin's coat; and the study of it must therefore necessarily imply some previous knowledge of chiaro-scuro.

In the commencement of this article we have, for the sake of distinction, divided colouring into two kinds; the *necessary*, and the *expedient or ornamental*: the *necessary* that which denotes truth in the local tints of the objects represented; the *expedient or ornamental*, that upon which the distribution of the parts, and the harmony of the whole, depends. Although it might, upon first consideration, appear difficult to say, which of these two kinds or divisions of colouring requires the greatest exertion of talent; yet there seems little doubt but that examples of a very high degree of truth in the local tints in pictures, are more rarely met with than an equal measure of beauty in the general arrangement of the colours. To this truth of local tint, therefore, the utmost effort of the artist should be directed: nature will be his best guide, and next to her the works of Giorgione, Titian, and Giacomo Bassano in figures, and those of Claude and some of the Dutch school in landscape, and the other inferior departments of painting.

That species or division of colouring, which we have termed the *expedient or ornamental*, is of a very extended range, and may be compared to rhetoric which gives additional lustre to truth, and enables the orator, even where proof is wanting, to support his argument upon specious though fallacious grounds. By a judicious opposition of one colour to another, the skillful painter is enabled to give to each an increased delicacy or an additional splendour; and by the same means a colour may be made to appear different from that which it really is; and thus a semblance of truth in the local tint may be frequently attained, even where that truth is in reality very far from existing. If the tint of the flesh be of too warm a hue, a yellow drapery placed next it, restores it to harmony; if too red, a crimson or a scarlet mantle takes away or diminishes the imper-

fection; if it appear cold, blue or purple opposed to it gives it a proportionable degree of warmth: and thus by contrasting one colour with another, the painter is enabled to give to each the degree of value he desires, according as his subject and the general effect of his work requires. It was the custom of Rubens, when he wished to give brilliancy to the principal figures in his picture, to oppose to the flesh, a map of scarlet drapery, and another of pure white; by these means the tints of the naked parts acquired wonderful air of truth, at the same time that a splendid and harmonious effect was produced.

The balance of cold and warm colours in a picture seems to bear a strong affinity to the gradation or contrast of the chiaro-scuro, and demands equal attention. "A certain quantity of cold colours," says Sir Joshua Reynolds, "is necessary to give value and lustre to the warm colours;" he adds, "that the masses of light in a picture be always of a warm mellow colour, yellow, red, or a yellowish-white; and that the blue, the grey, or the green colours be kept almost entirely out of these masses, and be used only to support and set off these warm colours; and for this purpose a small proportion of cold colours will be sufficient." "Let this conduct be reversed;" continues this excellent writer, "let the light be cold, and the surrounding colours warm, as we often see in the works of the Roman and Florentine painters, and it will be out of the power of art, even in the hands of Rubens or Titian to make a picture splendid and harmonious. The illuminated parts of objects are in nature of a warmer tint than those that are in the shade: what I have recommended therefore is no more than that the same conduct be observed in the whole, which is acknowledged to be necessary in every individual part. It is presenting to the eye the same effect as that which it has been accustomed to feel, which in this case, as in every other, will always produce beauty; no principle therefore in our art can be more certain, or is derived from a higher source."

We have treated of the doctrine of reflections in our observations on chiaro-scuro; (see *CLAIR, Obscure*) it is proper, however, in this place to observe, that the body which receives a reflected light, receives, together with that light, somewhat of the colour of the object which gives the reflection; and this, in proportion to the strength of light on the body reflecting, and the vicinity of such body to that receiving the reflection. The skillful management of reflections is so indispensable a part of colouring, that it cannot employ too great a share of the student's attention: an excellent insight into the principles of it will be afforded him by the works of Rubens and Jordans; not perhaps the less so from these masters having marked the reflections in their pictures with a precision and distinctness, perhaps even beyond what is warranted by the appearances of nature herself.

With respect to the application of colouring, it should always be remembered, that like the other parts of the art, it is of a nature powerfully to contribute to the sentiment and expression of a picture; when the style adopted is in strict conformity with the character of the subject represented. This conformity is therefore the first thing to be considered. If the subject is awful or melancholy, a grave sombre tone of colour will be appropriate; if gay or magnificent, the most brilliant and gorgeous tints may be freely used. The dark hue given by Michelagnolo Buonarroti to his celebrated group in the boat, in the last judgment, with the cold light behind it, renders it perhaps not less a masterpiece of colour, than the Venus and Adonis of Titian, or the sleeping Nymphs of Rubens.

The following remarks of the author before cited seem highly applicable to the present purpose. "To give a general air of grandeur at first view, all trifling or artful play of little lights, or an attention to a variety of tints is to be avoided; a quietness and simplicity must reign over the whole work; to which a breadth of uniform and simple colour will very much contribute. Grandeur of effect is produced by two different ways, which seem entirely opposed to each other. One is, by reducing the colours to little more than chiaro-scuro, which was often the practice of the Bolognian schools; and the other, by making the colours very distinct and forcible, such as we see in those of Rome and Florence; but still the prevailing principle of both those manners is simplicity. Certainly nothing can be more simple than monotony; and the distinct blue, red, and yellow colours which are seen in the draperies of the Roman and Florentine schools, though they have not that kind of harmony which is produced by a variety of broken and transparent colours, have that effect of grandeur which was intended. Perhaps these distinct colours strike the mind more forcibly, from their not being any great union between them; as martial music, which is intended to rouse the nobler passions, has its effect from the sudden and strongly marked transitions from one note to another, which that style of music requires; whilst in that which is intended to move the softer passions, the notes imperceptibly melt into one another."

It is not our intention here to detail the various modes adopted by artists in mixing their colours and varnishes, or the modes of preparing the different kinds of grounds used for painting on. Every school, and, more or less, every individual differs in his practice from another; and works of so high a class have been produced by each of these different methods, that we must conclude them all to be right, when rightly applied. However, in one point, the best colourists seem to agree, that the light parts of a picture should be painted with a strong body of colour, and the shadows with as much transparency as possible; and this is the more natural as well the easiest mode of procedure, as all the light colours, and particularly white, are opaque; whereas all the dark colours are in a greater or less degree transparent.

COLOURING of Glass. See GLASS.

COLOURING of Earthenware. See GLAZING.

COLOURING Matter. For a general account of the nature of colouring matter, see DYING, *the art of*; for the principal colouring materials, such as cochineal, indigo, madder, &c. see these articles respectively.

COLOURING of Porcelain. See PORCELAIN.

COLOURING of Spirits. See SPIRITS.

COLPE, in *Ancient Geography*, a town of Asia Minor, built, according to Pliny, in the place of *Archeopolis*.

COLPEDI, or **COLPIDICI,** a people of Thrace, who inhabited the environs of *Aenos*. Steph. Byz.

COLPISCIS, a name given by some to the *felix Venetorum*, or sickle-fish, commonly called the marmot fish by the people of Venice. See FALX.

COLPODA, in *Zoology*, a genus of animalcules (*vermes infusoria*) distinguished by being of a simple form, pellucid, flat, and sinuate.

These worms are invisible to the naked eye. They have been discovered and examined, chiefly by Müller, Adams, Joblot, and other curious writers, whose attention has been particularly devoted to microscopical investigations. Of the genus *colpoda*, seven species only appear to be described.

LAMELLA. Elongated, membranaceous, and bent on the anterior part.

This resembles a long, narrow, pellucid membrane, which is narrower and obtuse behind, curved towards the upper part, and has a ridge or fold passing through the middle. It is found in water, and when it moves is observed to proceed on the edge instead of flat surface. Found in common water.

ROSTRUM. Oblong, and hooked on the anterior part.

Discovered in water more pure than the former. The posterior part of this species is obtuse, and one of the edges from the top to the middle is dilated, thick, and apparently triangular.

MELLAGRIS. Changeable, with the anterior part hooked, and the posterior folded up.

Lives in water impregnated with vegetables, and is of a variable form, the anterior part clear, the posterior full of molecules, with the margin sinuous.

CUCULLUS. Ovate, ventricose, with an incision beneath the tip.

Generally oval, and containing from eight to twenty-four bright molecules, the margin irregular. Common in a variety of vegetable infusions.

REN. Thick, and sinuate in the middle.

Described by Joblot, who discovered it in the infusions of hay. The form is slightly kidney-shaped, of a yellow colour, opaque, and filled with molecules.

PYRUM. Convex, oval, the tip produced into a beak.

The body is transparent, of a pale colour, and filled with molecules.

HIPPOCREPIS. Thick, narrow in the middle, semilunar, and greenish. Found in stagnant meadow water.

COLPUSA, in *Ancient Geography*, one of the ancient names of *Chalcedon*, according to Pliny.

COLSA, a town of Asia, placed by Ptolemy in Armenia.

COLSIR, in *Geography*, a town of Asia, in the country of Thibet; 50 miles N.E. of Harachar-Hun.

COLT, in *Zoology*, See FOAL and HORSE.

COLT'S foot, in *Botany*. See *Tussilago Farfara*.

COLT'S foot, alpine. See *CACALIA Petajites*.

COLTHENA, in *Ancient Geography*, placed by Ptolemy near the Araxes, and N. of Saducena.

COLTIE, among the *Timber Merchants*, a word used to express a tree which has a defect in some one of its annual circles, which renders it unfit for many of the uses it might have been otherwise fit for. In this case some one of the annual circles near the centre is perceived by the eye to be thicker than the rest, and its sap vessels larger. It has an appearance much different from that of the others, and is so loosely connected both to its investient, and investient circles, that, on sawing a transverse piece of the trunk off, it will slip out from the others, and so leave the heart loose, and the rest hollow, seeming to have been only fitted, not connected, to the others. In splitting the wood for other uses, it yet more readily drops out, and the timber of such a tree is therefore much less fit for general use than that of others.

It is not easy to say to what accident, in the growth of the tree, this is owing, but it seems probable that it exposes the tree to other accidents; in particular Bobart seems to think, that among the trees which were split by the hard frost, in the year 1683, while other trees of the like sizes and kinds escaped, this *coltiness* might be the occasion of the mischief, as well as of their being wind-shaken, or lagged. Philol. Trans. N^o 165.

COLUBÆ, in *Ancient Geography*, a people of India, placed by Ptolemy on the other side of the Ganges, and near to it.

COLUBER, in *Zoology*, a genus of serpents distinguished

griffed by having plates on the belly, and scales on the under parts of the tail.

The species of this genus are numerous. Linnæus describes, upon the testimony of various writers, above ninety; and that number even has been considerably augmented by naturalists since his time. The species differ greatly in size and habit; some, as the vipers having the head large, flat-tail, and semi-concated, with the body and tail of a moderate length, or rather short; while others, as the greater part of the harmless serpents, have small heads, with the body and tail much longer in proportion. In some, exclusive of the nital scales under the tail, are a few scuta or undivided lamellæ, either at the beginning or towards the tip of the tail. The best works on this tribe of reptiles are "Synopsis methodica animalium Quadrupedum et Serpentinæ generis," of Ray. "Synopsis Reptilium," &c. of Laurenti; and those of Seba and Catesby. The observations of Boddaert, "Specimen novæ methodi distinguendi Serpentina." Nov. Act. Acad. Nat. Cur.; and "Bechereibungereiner Schlange," &c. of Siegel. The papers of Mr. Ellis, and another by Dr. Gray in the Philosophical Transactions, relative to venomous serpents, are also interesting. Several of those described by count La Cèpede deserve particular attention. Professor Pallas mentions some new kinds observed in Russia and Siberia; others are mentioned by Sparman, and a number of the viper tribe occur in the "History of the Indian Serpents," published by the late Dr. Ruffell.

Linnæus considered the number of abdominal plates and scales under the tail as a characteristic distinction of the different species of this genus; such, however, is the inconsistency of this criterion that, in describing the same species, scarcely two writers agree. Characters taken from the number of those plates and scales in the serpent tribe, like those from the number of rays in the fins of fishes, are not to be relied upon. The colours are liable to some variation; but the peculiar form and disposition of the spots, lines, and other markings, afford, in general, a character by which the different species may be distinguished.

Species.

VIPERA. Somewhat ferruginous, spotted with brown; beneath whitish; tail short and mucronated.

Abdominal scuta 118, subcaudal scales 22. Linn. Haffselg. Aët. Upf. 1750. *Apis Cleopatrac*, Laurenti.

This is the common viper of Egypt. Hasselquist, who appears to have first described the species with accuracy, informs us, that it is imported in considerable quantities every year to Venice for the use of the apothecaries. Its size is somewhat smaller than that of the common viper; the head not so flat on the top, but very protuberant on each side; snout very obtuse. The body is thick towards the middle, and somewhat quadrangular, but thin, and cylindrical towards the head and tail, which last is short, slender, conical, and terminated by a slightly incurved horny point or tip. The scales on the upper parts are oval and carinated. Hasselquist describes this species as being about two spans in length, exclusive of the tail, which measures only an inch. This is supposed by some to be the asp, by the bite of which the celebrated Cleopatra is supposed rather to die than submit to be carried captive to Rome, to grace the triumph of Augustus. Mr. Bruce, on the contrary, considers the Cerastes to be the species employed on that momentous occasion. Schneider is of opinion, that the Egyptian viper (*C. vipera*) must be the true *aspis* of the ancients, a reptile which was popularly reported to kill by occasioning the most excessive thirst.

VARIEGATUS. Above chestnut, variegated with grey and white; beneath, and on the sides, pale yellow. *Apis variegata*, Laur. Amph. Seba, &c.

Considered as a native of America, and resembles the last.

VENOSUS. Reddish ash, with white transverse veins; head long. *Apis vesella*, Laur. Amph. Seba.

A native of America, and is probably only a variety of *C. vipera*.

INTESTINALIS. Body equal, slender, with a lateral and longitudinal dorsal line, the last furcated near the eyes. Laur. Amph. Seba.

Inhabits Africa, and like the former is perhaps merely a variety of *C. vipera*.

LEBUS. On the head a bilobate spot; body above cinereous (or reddish) with a black flexuous zig-zag stripe down the back, and belly purplish. *Calyx lebus*, abdominal scuta 146, subcaudal scales 72. Linn. Fu. Succ. Amoen. Acad. 148—42. We gel Abh. der Halb. 177—86. Scop. *Vipera*. Gæfner Aldr.

This is the common English viper, and which is not only frequent in this country, but appears to be generally diffused over the rest of Europe, and some parts of Asia. If the varieties, described by Gmelin, are of the same species, it extends also as far as India. The var. β of this author has the spots on the top of the head roundish, and somewhat confluent or running into a stripe; the sc on near the tail transverse. This inhabits India. 1. Reddish with the head variegated; neck slender. A native of St. Eustace. 2. The arch of the hind head intercepting a white spot. Inhabits India. 3. Spot on the head multipartite. Inhabits the Celebes. The whole of those varieties are described and figured in the works of Seba.

Though the viper varies considerably in colour from a pale cinereous or yellowish ferruginous to deep or dull brown, the varieties agree in being marked with a continued series of confluent rhomboid blackish spots, extending from the head to the tail. The head is broad, and somewhat flattened, and is more or less protuberant on each side at the back part; the front of the head is blackish, and on the upper part is a large divided and somewhat heart-shaped spot, the obtuse divisions of which are directed backwards; the lips are somewhat barred or variegated with black and light grey, and along each side of the body runs a row of roundish subtriangular dusky spots, continuing to the end of the tail. The scales on the upper part of the body are carinated, the under parts of a blackish colour, with a blueish gloss somewhat resembling that of polished steel. The general length of the viper is from eighteen inches to two feet, and it is affirmed by some writers to grow even to the length of three feet. The fangs of the viper, like those of other poisonous serpents, are situated on each side the fore part of the upper jaw, and are generally two in number, with a few smaller ones situated behind. The poison, as usual, lies in a receptacle at the base of the fangs, and being perforated, when the animal bites, the compression of those receptacles forces out a drop of the poisonous fluid, which passing through the aperture of the fangs is immediately injected into the wound. The tongue is forked, and being soft and flexible is susceptible of great extension: it may be perhaps superfluous to add that this tongue is altogether incapable of inflicting any wound, or injecting poison, as some ancient writers credulously affirm; it may assist the animal in the capture of its insect prey. The French naturalists are inclined to believe it is intended by nature to supply some defect of transpiration in the skin.

Hitherto the viper has been considered the most poisonous of

of the European serpents, and many instances are recorded of the fatal effects resulting from its bite. That the bite of this serpent is always productive of pain and temporary inflammation in the parts bitten is very evident; sometimes also the symptoms may become alarming, or, in a few instances, through neglect or injudicious treatment of the wound, may even prove fatal; but upon the whole the bite of this creature does not appear pregnant with all those dangers which the terrors and prejudices of the vulgar lead them to suppose. In England the bite of the viper is rarely attended with fatal consequences. Fontana seems to doubt whether any well attested instance can be adduced of the viper having killed any person by its bite, even in the warm climate of Italy. The testimonies of authors, both as to the nature of the poison itself, and its effects on the animal frame are, however, confessedly at variance. According to Dr. Mead, and his associates in the experiment, the poison of the viper, diluted with a little warm water, proved sharp and fiery when tasted with the tip of the tongue, as if the tongue had been struck through with something scalding or burning. This sensation went off in two or three hours; but one gentleman, who would not be satisfied without trying a large drop undiluted, found his tongue swelled with a little inflammation; and the forelegs lasted two days. On the contrary, abbé Fontana and some others describe it as of no particular acrimony of taste, but rather resembling oil or gum, and Dr. Russell, in his work on Indian serpents, affirms the same even of the poison of the cobra de capello. Boerhaave is of opinion that the poison of the viper may be taken into the stomach without danger, and quotes the case of Jacob Sozzi, who, at the court of the duke of Tuscany, is said to have swallowed three drams of this poison without experiencing any ill effects. This poison, says Boerhaave, is rendered inactive by digestion in the stomach and bowels, so that it will not afterwards exert its sad effects upon the blood; for a whole ounce of the venom taken by the mouth will not kill an animal, when, at the same time, a small needle only, dipped in the same fluid, taking up perhaps no more than a hundredth part of a drop, and then thrust into the blood of the living animal, almost infallibly kills. Fontana, on the contrary, affirms, that though the poison of the viper administered internally may not produce the same violent symptoms as the bite, that it cannot be taken with impunity. The opinion, pretty generally entertained among the ancients, seems to be in favour of the assertions of Boerhaave.

The symptoms which follow the bite of the viper (according to Dr. Mead) when it falls either one or both its greater teeth or fangs in any part of the body, is an acute pain in the part wounded, with a swelling at first red, but afterwards livid, which, by degrees, spreads further to the neighbouring parts, and occasions great faintness, and a quick, though low and sometimes interrupted pulse; great sickness at the stomach, with bilious, convulsive vomitings, cold sweats, and sometimes pain about the navel; and if the cure be not speedy, death itself, unless the strength of nature prove sufficient to overcome those disorders: and though it does, the swelling still continues inflamed for some time; nay, in some cases, more considerably upon the abating of the other symptoms than at the beginning; and often from the small wound runs a sanious liquor, and little pustules are raised about it: the colour of the whole skin, in less than an hour, is changed yellow, as if the patient had the jaundice. These mischiefs (although different climates, seasons of the year more or less hot, the greater or less rage of the viper, the animal itself being of a larger or smaller size, and consequently able to communicate more or less

venom, the wound made deeper, in a part more nervous or tendinous, and therefore receiving more of the poisonous liquor, and the like circumstances may variously heighten or abate them,) yet usually discover themselves much after the same manner in all; unless the bite happen not to be accompanied with the effusion of this liquor, which is the main instrument and cause of this violent and shocking disturbance." Dr. Mead caused several animals, as dogs, cats, and pigeons to be bitten by an enraged viper, which animals generally died, some in a longer and others in a shorter space of time; but it was observed that, immediately after being bitten, they all exhibited signs of acute pain as if affected with sickness, faintings, and convulsions. The venomous properties of the poisonous fluid of the viper is not destroyed even by the death of the animal, as was proved by Dr. Mead; he took the head of a large viper that lay three hours after it was cut off, and was perfectly flaccid and without motion, and wounded a pigeon on the thigh by the fangs of the head; the bird presently became convulsed, and died seven hours after. The Scythians, as Pliny relates, must have been aware that the poison of the viper would retain its venomous properties after being taken from the animal and dried, for they were accustomed to dip their arrows into its poison; this they previously prepared by mixing it with human blood.

From the following experiment it would seem that no very material difference takes place in the appearance of an animal killed by the bite of the viper, than if its death were occasioned by any other cause. To ascertain this fact, a viper, being enraged by the members of the Tuscan academy, and then suffered to bite the nose of a strong bull, the animal expired in a short time, and being opened by the most expert anatomists, no uncommon alteration could be perceived either in the solid or fluid parts of the beast.

The viper, though so much dreaded on account of its bite has been very highly esteemed both by the ancients and moderns as a restorative and strengthening diet. The ancients used the flesh of this snake in leprosy and other cases. The Greek physician Craterus, cured, as Porphyrus relates, a miserable slave, whose skin, in a strange manner, fell off from his bones, by advising him to feed on viper's flesh in the manner of fish. Galen says, that those afflicted with elephantiasis are wonderfully relieved by eating viper's flesh dressed like eels, and relates very remarkable cures of this disease performed by means of viper wine. In France and Italy, the broth, jelly, and flesh of vipers is in much esteem as a restorative medicine. In England we have to instance the well known circumstance of sir Kenelm Digby, who caused his wife lady Veneta to feed on capons fattened with vipers to recover her from a consumption. According to Dr. Lewis, the dried flesh of the vipers possesses none of the nutritious properties of the recent animal, and is totally insignificant. A volatile salt was formerly drawn from vipers and sold at a great price as a sovereign remedy against the bites of vipers, and other poisonous animals, but it is now found not to be materially different from the volatile alkaline salts procured by distilling other animal substances.

The viper abounds most in dry, stony, and chalky countries, or in the low herbage or underwood in thickets. It casts its skin twice in the year, namely, in spring and autumn, and is said to attain its full size at the age of six or seven years, but are capable of engendering when two or three years old. They copulate in May, and go about three months with young. "The viper (says Mr. White) is viviparous, producing its young towards the close of summer. On the 4th of Aug. 1755, we surprized
a large

a large female viper, which seemed very heavy and bloated as it lay on the grass, basking in the sun. When we came to cut it up, we found that the abdomen was crammed with young, fifteen in number; the shortest of which measured full seven inches, and were about the size of full grown earth worms. This little fry shewed into the world with the true viper spirit about them, showing great artfulness as soon as disseparated from the belly of the dam: they twisted and wriggled about, and set themselves up, and upon very wide, when touched with a stick, showing a marked degree of menace and defiance, though as yet they had no manner of fangs that we could find, even with the help of our glasses." In the month of May a female viper was opened, which had in it a chain of eleven eggs, about the size of those of a black bird, but not so far advanced as to show the rudiments of the young. Several intelligent folks (adds Mr. White) assure me that they have seen the viper open her mouth, and admit her helpless young down her throat on sudden surprizes, just as the opossum does her brood into the pouch under her belly upon the like emergencies; and yet the London viper catches itself on it to Mr. Burington that no such thing ever happens.

Sir Thomas Brown seems inclined to believe this circumstance: the young, he observes, supposed to break through the belly of the dam, will, upon any fright, for protection, run into it; for then the old one receives them into her mouth, which way, the fright being past, they will return again, which is a peculiar way of refuge, and although it seems strange is avowed by frequent experience and undeniable testimony. The same is asserted by some other writers of no mean respectability.

The enemies of the viper are numerous, the herons in particular destroy vast numbers. Their prey consists of frogs, toads, lizards, mice, and various small quadrupeds. The viper is capable of supporting a very long abstinence; it being known that some have been kept in a box without food for six months, and yet did not abate of their vivacity. They feed only for a short period annually, and as a viper has been known to be a whole month devouring and digesting a frog or toad, two such meals would be sufficient to support it for a twelve month. It is remarked, that they never eat during confinement, for if mice, their favourite food be thrown into their box, though they will kill they never eat them. The violence of their passion decreases in proportion to the length of their confinement. Vipers, when at liberty, remain torpid throughout the winter, but when confined have never been known to take their annual repose. The best method of catching them is by putting a cleft stick on or near the head, then seizing them by the tail, and instantly dropping them into a bag. The viper catchers are frequently bit, but it is seldom the wound proves fatal: oil of olive, or fluid oil, is said to be the most effectual remedy. M. Sonnini seems fully satisfied of the efficacy of *eau de luce* as an antidote to the poison of vipers as well as other venomous serpents, the good effects of which he tells us he has experienced on several occasions, and particularly at Guiana, where snakes are equally numerous and formidable. In his travels through Greece and Turkey, M. Sonnini mentions an instance of a child he saw at Sifour, three or four hours after it had been bitten by a viper or venomous snake, in the small of the leg. Both the leg and foot were much swelled, very hard, and of a bluish colour: the child suffered great pain, the wound no longer appeared, and the place was not distinguished but by a larger swelling, and by pains more acute, which were occasioned by touching it. He made the child swallow a few drops of *eau de luce* in half a glass of wine, and after

some scarifications on the part bitten applied to it, a compress, steeped in this same water, which is known to be composed of volatile alkali and oil of amber. The result of this treatment was, that four hours after, the swelling was considerably diminished; the child no longer felt any pain, and became tranquil; the compress of *eau de luce* was renewed, and the child left in a fair state for recovery. The same application is recommended by Sonnini in all snake bites; he observes, that the swelling of the wounded part is speedily diminished, and the pain entirely removed by the means; but the *eau de luce* must be taken internally, according to this writer, as well as applied to the wound externally, in order to produce the desired effect. The remedies which the Greeks commonly employ for curing the bite of snakes, as Sonnini affirms, consist in cauterizations of excellent plants, calculated to promote suppuration. Sore throats is reckoned among them to possess, particularly, a specific virtue against this sort of venom. But this treatment, he adds, is very long; it frequently lasts two months, and never less than one; neither is it always successful, and does not very frequently carries off the patient from the torments which this mode of treatment causes him to suffer.

PREFTER. Black, with deep black, dentated, dorsal line. *Coluber prester*, abdominal teata 152, subcaudal scales 32. *Linn. Fa. Suec.* 287. *Lapech Icon. Colubr. viperæ anglicanæ*, Laur. *Viperæ anglicæ nigricanæ*, Petiv. Mus.

This is the black viper of English authors, and which so completely resembles the common viper in every particular, except the colour, that we are strongly inclined to admit it as a mere variety of that species. The black viper of Austria appears from a series of experiments made by Laurenti to be innocuous, since pigeons and chickens exposed to its bite were no otherwise injured than by mere puncture without suffering any symptoms of poison, but it is not entirely certain that the kind described by Laurenti is of the same species as the black viper generally found in Europe, and which is almost universally allowed to be as poisonous as the common viper.

Prestor inhabits the northern parts of Asia as well as Europe.

CAECOPHON. Deep black; head broad and tumid; body thick. *Black viper*. Catby, Car 1.

This kind is about the size of the common viper, but of a much thicker form, and entirely of a rusty black colour; it is slow in its motions, and, when irritated, quarts the head, which is naturally large, to a surprising width, and threatening at the same time with a horrid hiss; the fangs are large, and the animal is said to be as dangerous as the rattlesnake.

It is a native of Carolina, inhabiting chiefly the higher grounds.

CHERSEA. Dusky-bay, with black flexuous dorsal band, and the head oval, and whitish beneath. *Coluber chersæa*, abdominal teata 150, subcaudal scales 34. *Linn.*

Inhabits the woody parts of Sweden, and is said to be most frequent in the province of Smoland, where it is greatly dreaded by the inhabitants, who consider its bite as mortal, unless the part bitten be immediately cut out. In the "Memoirs of the Swedish Academy" is an account of a young man, a labourer, bit by this animal on the toe of the left foot. In the space of six hours, the whole leg and thigh were red and swelled; the pulse intermitted, and the patient was oppressed with pains in the head and bowels. The first day the patient drank a glass of the juice expressed from ash-leaves mixed with wine every half hour, and had besides a cataplasm of the bruised leaves applied

to the wound; in the evening also, he took a glass of warm olive oil. By these means the patient was greatly relieved, slept well during the night, and found the swelling much reduced by the next morning; but neglecting to repeat the remedies the first symptoms returned, and were again dissipated by the same applications, and in two or three days the patient recovered. Linnæus attempted to cure a woman wounded by the bite of a viper of this kind by means of olive oil, but his endeavours were unsuccessful, and his patient died.

The *Coluber chersæa* resembles the common viper, but still more the common asp, though inferior in size, not often exceeding a span in length. The colour is a dusky rufous brown, with a fuscous dorsal band of a deeper colour; the head ovate, of a pale colour, and marked with a heart-shaped dusky spot, the divisions of which are directed backwards, and the body is round.

SCYTHA. Deep black above, beneath milk white, and polished. *Coluber scythæ*, abdominal scuta 153, subcaudal squamæ 31. Pallas It.

Inhabits woods in the mountainous parts of Siberia, where it was observed by Dr. Pallas. This species is not esteemed very poisonous, and is of a small size, seldom exceeding nine inches in length, or the thickness of a finger; the head is somewhat heart-shaped.

REDI. Head imbricated with very minute scales; body ferruginous, with a quadruple transverse dorsal series of short brown streaks. *Coluber redi*, abdominal scuta 152, subcaudal squamæ 33. Cmel. *Vipera francisci redi*, Laur. Oter, Meyer Thiere.

Allied to the common viper, but esteemed more poisonous; it differs in being marked throughout the whole length of the upper parts, with a quadruple series of short, transverse, alternate streaks, of which the intermediate ones are often confluent. The colour of the underparts is rufous, especially towards the head and tail. This kind is found in Austria and Italy near the sea.

CERASTES. Sub-ferruginous, with brown transverse spots, and horned eye-lids. *Coluber cerastes*, abdominal scuta 150, subcaudal scales 25. Hasselq. Act. Ups. 1750. Linn. *Cerastes ex hybia*, Aldr. *Cerastes*, Bellon, Ellis Puil. Transf. *Cerastes*, Bruce's Travels Append. *La vipère céreste*, La Cépède.

The cerastes viper grows to the length of eighteen inches or two feet, and is distinguished by a pair of horns, or curved processes situated above the eyes and pointing forwards; these horns have nothing analogous in their structure to those of quadrupeds, neither are they to be considered as weapons either offensive or defensive, but they contribute to give the animal an appearance of more than ordinary malignity. The cerastes is a native of many parts of Africa, and is found principally in sandy deserts and dry places. In Syria and Arabia it is particularly frequent, and is also found in many parts of Egypt.

The general colour of this snake is a pale yellowish or reddish brown, with darker spots disposed at a distance from each other, and in a somewhat transverse direction along the back, and near the sides, the belly is blueish, or of a pale lead colour, and some writers say occasionally almost white. In its manners the cerastes bears a very great affinity to the common viper, but is still more to be dreaded than that species, as its bite is very dangerous, and the animal is said to spring suddenly to a considerable distance, and assail without provocation those who happen to approach it.

According to Mr. Bruce, the cerastes inhabits the greatest part of the eastern continent, especially the desert sandy part of it. It abounds in the three Arabias, and in Africa,

I never saw (says Mr. Bruce) so many of them as in the Cyrenaicum, where the jerboa is frequent in proportion. He is a great lover of heat; for though the sun was burning hot all day, when we made a fire at night, by digging a hole and burning wood to charcoal in it for dressing our victuals, it was seldom we had fewer than half a dozen of these vipers, who burnt themselves to death by approaching the embers. The general size of the cerastes from the extremity of its snout to the end of the tail, Mr. Bruce tells us, is from thirteen to fourteen inches; in the British Museum, however, is a specimen measuring rather more than two feet, and in that of Paris another still larger. The head is triangular, very flat, but higher near where it joins the neck than towards the nose. The length of its head, from the point of the nose to the joining of the neck, is ten-twelfths of an inch, and the breadth nine-twelfths of an inch; between its horns is three-twelfths. The opening of its mouth, or rictus oris, is eight-twelfths; its horns in length three-twelfths; its large canine teeth summing more than three-twelfths and a half; its neck at the joining of the head four-twelfths; the body, where thickest, ten-twelfths; its tail, at the joining of the body, two-twelfths and a half; the tip of the tail one-twelfth; the length of the tail an inch and three-twelfths; the aperture of the eye two-twelfths, but this varies according to the impression of light. The cerastes has sixteen small immovable teeth, hollow, crooked, inwards, and of a remarkably fine polish, white in colour, inclining to blueish; nearly one-fourth of the bottom are strongly fixed in the upper jaw, and folds back like a clasp knife, the point inclining inwards, and the greatest part of the tooth is covered with a green soft membrane, not drawn tight, but, as it were wrinkled, over it, immediately above this, is a slit along the back of the tooth, which ends nearly in the middle of it, where the tooth curves inwardly. From this aperture, Mr. Bruce imagines, and not without reason, that the cerastes sheds its poison, instead of from the point, where, with the best glasses he could never perceive an aperture; so that the tooth is not a tube, but hollow only half way; the point being calculated for making the incision, and by its pressure occasioning the venom in the bag at the bottom of the fang to rise in the tooth, and spill itself through the slit into the wound. By this flat position of the tooth along the jaw, and its being defended by the membrane, it eats in perfect safety; for the tooth cannot press the bag of poison at the root, while it lies in this position, nor can it rise in the tube to spill itself, nor can the tooth make any wound so as to receive it; but the animal is supposed to eat but seldom or only when it is with young. This viper has only one row of teeth. The poison is very copious for so small a creature, being fully as much as a drop of laudanum dropped from a phial by a careful hand; it is of a yellow colour, and viewed through a glass is not perfectly transparent or pellucid.

During the day time the cerastes hides itself in the sand, where it lives in dens similar to those inhabited by the jerboa. Mr. Bruce kept two of the cerastes in a glass jar, such as is used for keeping sweetmeats in, for the space of two years, without having given them any food; they did not sleep that he observed in winter, but call their skins the last days of April. The cerastes moves with great rapidity, and in all directions, forward, backward, and sideways. When he inclines to surprize any one, who is too far from him, he creeps with his side towards the person, and his head averted, till judging his distance, he turns round, springs upon him, and fastens upon the part next to him. Mr. Bruce saw one of them in a house at Cairo crawl up the side of a box in which there were many, and there lie still as if hiding nim-

self; till one of the people who brought them to us, came near him, and though in a very disadvantageous posture, kicking, as it were, perpendicular to the side of the box, he leaped near the distance of three feet, and fastened between the man's fore-finger and thumb, so as to bring the blood. The man shewed no sign of either pain or fear, and Mr. Bruce and his party kept him with them full four hours without his applying any sort of remedy, or seeming inclined so to do. To make himself assured that the animal was in its perfect state, Mr. Bruce made the man hold the cerastes by the neck, so as to force him to open his mouth, and lacerate the thigh of a pelican, a bird he had tamed as large as a swan. The bird died in about thirteen minutes, though it was apparently affected in about fifty seconds, and this even can scarce be considered as a fair trial, because a few minutes before it had bit the man, and so discharged part of its virus, and it was made to scratch the pelican by force, without any irritation or action of its own.

It appears not only on the testimony of the above circumstance, but on the relations of travellers in general of the greatest respectability, that the natives of the countries infested by the cerastes, have a method of charming, or rather stupefying these and other serpents to prevent their biting, or to render their bite innocuous, however irritated the animal may be. Some pretend to possess preternatural powers over those reptiles, while others say, they have certain preparations with which they anoint themselves to obviate the fatal consequences of their bite, and which is never ineffectually employed. Mr. Bruce speaks at some length on this interesting topic (a long dissertation (says this writer,) would remain on the incantation of serpents. There is no doubt of its reality, the scriptures are full of it, all that have been in Egypt have seen as many different instances as they chose. Some have doubted that it was a trick, and that the animals so handled, had been first trained and then disarmed of their power of hurting; and, fond of their discovery, they have rested themselves upon it without experiment, in the face of all antiquity. But I will not hesitate to aver that I have seen at Cairo, (and this may be seen daily without trouble or expence) a man who came from above the catacombs, where the pits of the mummy birds are kept, who has taken a cerastes with his naked hand, from a tumber of others lying at the bottom of the tub, has put it upon his bare head, covered it with the common red cap he wears, then taken it out, put it in his breast and tied it about his neck like a neck-lace; after which it has been applied to a hen and bit it, which has died in a few minutes; and, to complete the experiment the man has taken it by the neck, and beginning at the tail has ate it as one would do a carrot, or stock of celery, without any seeming repugnance."

"We know from history, that where any country has been remarkably infested with serpents, there the people have been secured by this secret. The Pfylli and Marmarides of old, undoubtedly were defended in this manner."

"Ad quorum cantus mites jacuere carastæ."

Sil. Ital. lib. iii.

"To leave ancient history, I can myself avouch, that all the black people in the kingdom of Senaar, whether Fungee, or Nuba, are perfectly armed against the bite of either scorpion or viper. They take the cerastes in their hands at all times, put them in their bosoms, and throw them at one another, as children do apples or balls, without having irritated them by this usage so much as to bite. The Arabs have this secret naturally, but from their infancy they acquire an exemption from the mortal consequences attending

the bite of these animals, by chewing a certain root and washing themselves, (it is not anointing) with an infusion of certain plants, in water. One day when I was sitting with the brother of Shekh Adelan, prime-minister of Senaar, a slave of his brought in a cerastes, which he had just taken out of a hole, and was using with every sort of familiarity; I told him my suspicion that the teeth had been drawn, but he assured me they were not, as did his master, Kitton, who took it from him, wound it round his arm, and, at my desire, ordered the servant to carry it home with me. I took a chicken by the neck and made it flutter before him, his seeming indifference left him, and he bit it with signs of anger, the chicken died almost immediately;—I say his seeming indifference, for I constantly observed that however lively the viper was before, yet, upon being seized by any of these barbarians, he seemed as if taken with sickness and feebleness, frequently shut his eyes, and never turned his mouth towards the arm of the person who held him. I asked Kitton how they came to be exempted from this mischief? He said they were born so, and so said the grave and respectable men among them. Many of the lighter and lower sort talked of enchantments by words and by writing, but they all knew how to prepare any person by medicines, which were decoctions of herbs and roots. I have seen many thus armed for a season, do pretty much the same feats as those who possessed the exemption naturally; the drugs were given me, and I several times armed myself, as I thought, resolved to try the experiment; but my heart always failed me when I came to the trial; because, among those wretched people, it was a pretence that they might very probably have sheltered themselves under that I was a Christian, and that it had no effect upon me. I have still remaining by me a small quantity of this root, but never had an opportunity of trying the experiment."

Among the writers of antiquity we find abundant mention of the Pfylli, or serpent-eaters; men who pretended to possess the inherent power of charming serpents, and of devouring them without danger. Lucan speaks of the practice of the Pfylli, or African tribes, and informs us they were employed by Cato to attend his expedition through the Lybian deserts, for the recovery of his soldiers bitten by serpents. Strabo tells us the Pfylli, or men of Crene, possessed a secret antidote against the poison of those reptiles. It appears equally certain that there are tribes of men in the East, who, to this day practise the same arts. Savary relates that when at Rosetta, he was present at the festival of Sidi Ibrahim, in which the rear of a procession composed of the different trades, and chiefs, or priests of the country, bearing the standard of Mahomet, was brought up by a troop of these modern Pfylli. Those men, says Savary appeared frantic, with naked arms, their eyes wild, and enormous serpents in their hands, which twined round their bodies and endeavoured to escape. They seized the serpents forcibly by the neck, avoided their bite, and, regardless of their hisses, tore them with their teeth and eat them alive, while the blood streamed from their defiled mouths; other Pfylli struggled with them to free away their prey, for the contention was who should devour a living serpent!—The astonished populace followed, and cried—a miracle!

The remarks of Sonnini, one of the latest writers on this subject, may not prove uninteresting in conclusion. "The East, says he, was at all times the country of magicians: men boasting to have the power of charming serpents, of braving their bite, and their venom, of rendering them docile to their voice; they formerly existed there under the name of Pfylli, and there are still to be found, people who pretend

pretend to have inherited their secrets. I knew one of those versed in this kind of fascination; he was certainly the most ignorant, and most foolish of the Greeks: his secret consisted chiefly in thirteen words, which it was necessary to pronounce in sight of the serpents. He told me also, that, in order to guard against the bite of these reptiles, it was necessary to try to take one alive with the precaution of seizing it strongly by the neck so as to prevent it from biting, and not to concern myself about the body and tail, the twistings of which lightly squeeze the arm. You must then slip round its neck a running knot made with coarse thread, and draw it tight by degrees till the animal is strangled. When it is on the point of dying, you open it and take out its fat, with which you rub your hands; then said my modern Pylus to me, you have nothing more to fear from the bite of every species of serpent."

The figure of cerastes, occurs frequently among the hieroglyphic characters inscribed upon remains of Egyptian antiquity.

NASICORNIS. Somewhat olivaceous yellowish, variegated with black; flexuous, lateral band pale, and two horns on the snout. *Coluber nasicornis*, horn-nose snake. Shaw Gen. Zool.

This remarkable snake was first described by Dr. Shaw in the *Naturalist's Miscellany*. The most striking peculiarity of his species are the two large sharp pointed horns, situated on the top of the nose, or anterior part of the upper jaw. These horns stand nearly upright, but incline slightly backwards, and a little outwards on each side, and are of a substance somewhat flexible; their shape is rather triangular. The length of these horns is about half an inch, and at the base of each stands an upright strong scale, of nearly the same shape with the horn itself, and thus giving the appearance of a much smaller pair of horns. The mouth is furnished with extremely large and long fangs, or poisonous teeth, two of which appear on each side of the mouth; the hinder pair being smaller. The length of this animal is about thirty-five inches. Its colour is yellowish, olive-brown, very thickly sprinkled all over with minute blackish specks. Along the whole length of the back, extends a series of yellowish-brown oblong spots, or marks, each of which is imbedded in a patch of black; and on each side of the body from head to tail runs an acutely flexuous, or zig-zag line, or narrow band of an ochre colour, which is bounded beneath by a much deeper or blacker shade, than on the rest of the body. The belly is a dull ochre colour or cinereous yellow, freckled with blackish spots and markings, and besides these a number of black spots of various sizes are sparingly dispersed over the whole animal; the tail is somewhat thin and short in proportion to the body. The scales are hard, stiff and strongly carinated, the head is covered with small scales, and is marked on the upper-part by a longitudinal patch of brown, running out into pointed processes at the sides, and bounded by a space of dull lead colour or cinereous. The shape of the head is broad and flattened, the cheeks varied with black and yellow marks. The horned snake is supposed to be a native of the interior parts of Africa. The specimen above described, was obtained from the master of a Guinea vessel by the Rev. Edward Charles Jenkins of Charlestown in South Carolina.

ASPIS. Nose terminated by an erect wart; body rufous, with alternate, roundish, dusky, distinct, and confluent spots; beneath steel blue dotted with yellow. *Coluber aspis*, abdominal scuta 146, subcaudal scales 46. Gmel. 146—34,

Strom. Sondm. Col.—*Vipera mofis charas*. Laur. Amph. p. 100. n. 219.

Considered by some as a variety of coluber vers: it is a native of Dauphiny, Lyons, and Poitiers. Ceppe describes a snake that inhabits the northern parts of France under the name of L'Alpic, but which, according to Latreille, is not the true coluber aspis of Linnæus, as its name may imply. This kind, Ceppe informs us, is about three feet in length, of which the tail measures three inches and eight lines. The head is rather large, and covered with small carinated scales, the body larger, of similar structure, the colour, pale rufous grey, and along the upper parts are three longitudinal ranges, of roundish dark rufous spots, bordered with black, and which unite or become confluent near the tail, and thus exhibits the appearance of a zig-zag band, similar to that of the common viper. The under-parts of this snake, are of a dusky colour, marbled with dull yellow; its fangs resemble those of the common viper, and it is reputed equally poisonous with that species. We introduce this snake under the species aspis, conceiving it may be hereafter ascertained to be of the same individual species, although writers are not agreed on this point at present.

AMMODYTES. Brown or pale bluish, with a dentated black dorsal band: nose terminated by an erect wart. *Coluber ammodytes* abdominal scuta 142, subcaudal scales 32. Linn. Amoen. Ac. Weigel Abh. *Vipera illyrica*, Laur. Amph. *Drinnus*, Bell. *Ammodytes*, Aldr.

Inhabits the East, and mountainous parts of Illyria. This species is greatly allied to the viper, from which it is distinguished principally by the erect process at the tip of the snout. The colour is usually bluish grey or brown, with a continued black dorsal band, resembling that of the viper. This is considered as an extremely poisonous species, and according to Matthioli, proves fatal in the space of three hours. The flesh is used medicinally for the same purposes, as that of the common viper.

LACHESIS. Yellowish-grey, variegated with brown; a black transverse band above the eyes.—*Cobra lachesis*, Laur. Amph. *Serpens ceylonica*, Bitin. *Diâa*, Seba.

Described and figured by Seba, from whom it appears this species is a native of Ceylon, and is known by the name of bitin. Its colour is a rich and somewhat irregular variation of deep and light brown, disposed in streaks and patches, on a yellowish grey ground. The scales, which in many parts are tipped with white, are large, strongly carinated, and fixed only at the base, while the remainder is loose or free. This singular disposition of the scales, affords the animal an opportunity of elevating or depressing them at pleasure, and in moving, is said to occasion a kind of rustling noise.

* This is a poisonous species, being armed with large fangs, and from its general form, appears to be an animal of considerable strength. The head is indistinct, or not distinguished from the rest, by any contraction, or appearance at the neck. The male is deeper coloured than the female, and seems to have the body larger, and the tail more slender. The general length of this snake, seems to be about four or five feet, and the tail short in proportion to the body.

СЛОТНО. Greyish-orange; variegated with numerous waved black bands; keel of the scales on the chin with a white spot; tail very slender.—*Cobra clotbo*, Laur. Amph. *Vipera*, Bitin. *Ceylonica elegantissima*.

Inhabits Ceylon and Cuba, and is supposed to be a poisonous species. This appears to be from the work of Seba to be a large snake, measuring more than six feet in length,

and being thick in proportion; the head large, covered with minute scales, and as in the coluber lachetis, scarce distinguished from the body, by any perceptible contraction at the neck. The colour of the upper parts is greyish orange freckled with black specks, and marked with transverse undulated, or somewhat zig-zag bars of black. The under parts are circereous, variegated with a few black bars, and transverse stripes.

ATROPOS. Hoary, with a quadruple series of large brown ocellar spots, with white margins. *Coluber atropos*, abdominal scuta 131, subcaudal squamæ 22. Linn. *Cobra atropos*, Laur.

The length of this species is about sixteen inches; the head large, marked with four or five dusky spots, and covered with small scales; the body rather bulky; the tail is short, measuring about a ninth part of the whole length. It is a native of America, and is considered as an extremely poisonous animal.

TRISPHONE. Body thick, brown, and without variegations, *Coluber trisphone*. Shaw. Gen. Zool. *Black viper*, Catfby.

This, according to Catfby, is the size of the black American viper, measuring about two feet in length, and being large in proportion; he tells us it is a sluggish reptile, advancing deliberately even to escape danger, but will yet defend itself when attacked with much fierceness, and its bite is said to be very venomous. It is found in Virginia, and Carolina, in the last of which it is called the truceon snake. This species preys on lizards, and other animals.

MEGARA. Brown, varied with yellow: head flat and heart-shaped, and a large orifice between the eyes and nostrils on each side. *La Vipere Fer de lance*, Cæpede.

This is a large species measuring five or six feet in length. It inhabits the island of Martinico, and some of the neighbouring islands, and is considered one of the most formidable of the serpent tribe. A specimen of this snake, preserved in the British Museum, is a rich deep brown, with yellow variegations, the back being marked throughout the whole length, by pretty numerous equidistant, broken, and slightly alternating bars of dull yellow, which, descending and joining at intervals with the neighbouring ones, form obscurely annular and somewhat irregular markings of similar colour along the sides, with still more obscure crossings on the part nearest the scuta, intermixed with smaller patches and spots: the abdomen is dull yellow, clouded and speckled on the sides with pale brown. The head is large, flat, heart-shaped, and covered with very small carinated scales; but the terminal scale of the nose, and those at the sides of the mouth, are very large, and above each eye is also a very large scale. The nostrils are small, and between them and the eyes on each side is a large orifice, which has been regarded as a passage to the organ of hearing; the scales on the whole upper parts of the body are moderately large, ovate, and carinated, the back slightly elevated, the sides rather sloping, and the abdomen flattish.

The fangs of this serpent are of a large size, about three quarters of an inch in length, and curved. The poison is said to resemble that of most serpents, being a clear yellowish fluid, like olive oil. The symptoms are such as follow from that of the viper, but in a much stronger degree. When preparing to bite, it is said to throw itself into a spiral form, and to spring with great rapidity on its prey, but at other times to be rather slow in its motions, and of a torpid nature, concealing itself beneath the herbage, or within the hollows of trees. It frequents sugar plantations, for the sake of the rats, which abound in such situations, and also preys on birds. The female goes six months with young,

and produces the new brood perfectly formed, and amounting to forty, fifty, or even sixty: they are observed to vary in colour when young, some being yellow, others grey, and others intermixed, yellow, grey, and brown.

COBELLA. Brown, kneated with white: head broad with a lead coloured stripe behind each eye. *Coluber cobella*, abdominal scuta 150, subcaudal scales 54. Linn. Amoen. Acad. *Coluber ater, lineolis albis*, Boddaert. *Cerastes cobella*, Laur. Amph.

Grows to the length of two feet nine inches, and varies much in the disposition of its colours, and the number of its abdominal scuta, and subcaudal scales. Gmelin enumerates no less than fourteen variations of this kind. It is a very common snake in America.

COBRA. Entirely brown, compressed: back carinated, scales of the ridge largest; head elongated and rounded. Gmel. Laur. Amph. Allied to the coluber redi.

CORONATUS. Deep black, with white unequal spots and dots. Gmel. *Cerastes coronatus*. Laur. Amph. Inhabits New Spain.

NOVE HISPANIE. Above black, beneath white; back with oblique streaks, posterior parts with oblique bands. Gmel. *Cerastes mexicanus*, Laur. Amph.

Resembles *C. coronatus*, and like that species, inhabits New Spain.

NATRIX. Brown, with a black and yellow patch on each side the neck, and a row of black spots down each side; abdomen dusky. *Coluber natrix*, abdominal scuta 170, subcaudal scales 60. Linn. Fn. Succ. *Natrix vulgaris*, Laur. Amph. *Natrix torquata*, Raj. *Gemine seblange*, Meyer. Thiere. *Common ringed snake*, Penn.

Inhabits moist parts of Europe, where it frequents woods, moist hedges, and shady places. Many varieties of this snake are described by writers, but the colour is in general either a bluish grey, or pale olive above, the sides variegated with black, and the under parts a mixture of black and white. The head is rather small comparatively, and is covered with large scaly plates; the tail is of moderate length, and gradually tapers to the extremity.

This snake preys on frogs, mice, and small birds, insects, and worms, and occasionally frequents the water in search of the first; it is capable of swimming, but not well. It deposits its eggs in any warm and moist situation in the form of a continued chain or necklace of ova, to the number of twelve, fourteen, sixteen, or even twenty, of the size of those of a blackbird, and of a whitish colour, and it appears are hatched in the spring following. During the winter the snake conceals itself and becomes nearly torpid, and re-appears in the spring, at which season it is said to cast its skin; we suspect that it casts its skin twice every year. This is not a poisonous species.

ATROVIRENS. Black green speckled with yellow; abdomen yellow, with a row of black specks down each side. *Anguis asculapii niger*, Aldr. Serp. *La coluvre verte et jaune*, La Cæpede.

A species oftentimes confounded with the preceding: it is described with accuracy by La Cæpede, who informs us it is frequent in some provinces in France. Its haunts are woods, and moist shady places; in size and general appearance it resembles the ringed snake, coluber natrix, but differs in colour, being of an extremely dark or blackish green, appearing at the first view entirely black: the sides are marked with numerous rays of yellow specks, of different forms, some oblong, and some square: the eyes and edges of the mouth are bordered with yellow scales; the abdomen is also yellow, every plate being marked on each side with a black

a black speck. This snake is perfectly harmless. La Cèpede relates from M. Bromare an anecdote relative to a snake, which he supposes to have been of this species, and which had been so completely tamed by a lady as to come to her whenever she called it; follow her in her walks, wreath itself round her arms, and sleep in her bosom. One day, when this lady went in a boat to some distance up a large river, she threw the snake into the water; imagining that it would readily recover the boat by swimming; but the current proving unusually strong at that juncture owing to the advance of the tide, the poor animal in spite of all his efforts to reach the vessel was unfortunately drowned.

GRONOVIANUS. Bluish-ash, beneath blackish; a white arched spot each side the hind head, and one black: back-arched with black. Gmel. Laur. Amph.

Bears a near affinity to the preceding, and is perhaps a variety only of the former, coluber natrix. Number of plates and scales not ascertained.

HUMANUS. Black spotted with white; tail alternately striped with black and white. *Coluber humanus*, Gmel. *Natrix humana*, Laur. Amph.

A snake very commonly domesticated in New Spain; and also said to inhabit Amboyna.

PUNCTULATUS. Fulvous, with very minute spots of white. Gmel. *Natrix punctata*, Laur. Amph. Native country unknown.

TYROLENSIS. Abdominal scuta 178, subcaudal scales 60. Gmel.

Described after Scopoli, who informs us it inhabits the Tyrolean country, and deposits its eggs among stones, these are white and leathery, with a lateral yolk and turbid watery white, and are found sticking together in clusters of about fourteen in number.

BIPES. Abdominal scuta 116, subcaudal scales 58. Gmel. Scop, ann. hist.

Mentioned by Scopoli as an inhabitant of the Tyrolean waters. This kind preys on fish and frogs; and is said to be furnished with two short processes or feet; the eyes are red or tawny, lower jaw whitish, dorsal scales elliptic and margined; sides spotted with white: plates of the belly whitish, with a brown spot in the middle.

AUSTRIACUS. Bluish-grey, with a double dorsal row of rufous spots, and reddish sides and abdomen. *Coronella austriaca*, Laurenti. *La Liffa*, Cèpede.

This bears a general resemblance to the common snake, coluber natrix, and seems to have been first described by Laurenti, who speaks of its being common round Vienna: it occurs also in France, and several other parts of Europe. The principal distinction between this species and the coluber natrix consists in the perfect smoothness of its scales, those of the natrix being somewhat carinated. This animal inhabits moist meadows, hedges, and swampy places, and bites with much eagerness, but is incapable of doing any injury, as nature has not provided it with poisonous fangs. It is said to be easily tamed, in which state it shows a considerable degree of attachment.

ÆSCULAPII. Whitish, with double black transverse zones; abdomen whitish, variegated with black. *Coluber æsculapii*, abdominal scuta 180, subcaudal scales 43. Linn. *Natrix æsculapii*, Laur. *Coluber albus annulis nigris*, Boddaert.

Length from eighteen inches to two feet; the colour pale whitish with a more obscure cast on the back, and is marked throughout with nearly equidistant black bands, each surrounding the body, and divided half way up from the abdomen by a line or narrow stripe of the ground colour; thus giving a banded appearance to the lower part of

each band. The head is covered with large scales, and marked on the fore part by a transverse black bar running across the eyes. This is a native of South America, and is said also to inhabit some parts of Asia.

NAJA. Yellowish brown; on the back of the neck a large spectacle shaped spot. *Coluber naja*, plates of the belly 193; scales of the tail 10. Linn. *Naja luteifens*, Laur. Amph. p. 91. *Serpens Malabarica cobra de capello dicta*. Seb. *Spectacle snake, nagoos*, Russell. Ind. Serp. Shaw Gen. Zool.

The coluber naja is a native of India and the Ternate islands, where it appears to be one of the most common, as well as most noxious, of the serpent tribe; very frequently proving fatal in the space of a few minutes to those who unfortunately experience its bite. The form of this species is very remarkable: its general length seems to be three or four feet, and the diameter of the body about an inch and a quarter. The head is comparatively rather small, and is covered on the fore part with large smooth scales, as in the greater number of innocuous serpents; the scales on the back part and sides of the head, and also on the neck are smaller and ovate: those on the remainder of the animal, on the upper part oblong oval, not ill resembling the general form of a grain of rice. At a small distance beyond the head is a lateral swelling or dilation of the skin, which is continued to the distance of about four inches downwards, where the outline gradually sinks into the cylindrical form of the rest of the body. This part is extensible at the pleasure of the animal; and when viewed from above, while in its most extended state, is of a somewhat cordated form, or wider at the upper than the lower part, and is marked with a singular spectacle-formed spot of black and white, the mark itself being white, and the edges black, and the middle of each of the rounded parts black. This mark is more or less distinct in different individuals, and also varies occasionally in size and form, or in some instances is altogether wanting. The usual colour of the animal is a pale ferruginous brown above; the under parts bluish-white, sometimes slightly tinged with pale brown, or yellow; the tail, which is of a moderate length, tapers gradually and terminates in a slender, sharp pointed extremity. The title of *cobra de capello*, or hooded snake, has been given to this formidable reptile by the Portuguese, from the appearance which it presents when viewed in front in an irritated state, or when preparing to bite, at which time it bends the head rather downwards, and seems hooded, as it were, in some degree by the expanded skin of the neck.

Laurenti enumerates four varieties of this hooded snake, *Naja luteifens*, the common kind; *β Naja fasciata fasciis peritolum corpus ex fusco rubris*, having fulvous red bands over the whole body; *γ Naja flavensis*, ex cinereo grisea, summo dorso rufa. Cinnereous, with the back rufous; and *δ Naja maculata*, ex luteo rufa, squamis singulis alba macula notatis; of a tawny yellow colour, and having every scale marked with a single white spot. But it appears from the work of Dr. Russell "On the Serpents of India," that there are many other varieties of this extraordinary snake. He describes no less than ten different kinds that are found in India alone, and seems to intimate that those are not the whole of the Nagoos tribe which inhabit that part of the world. It is possible, on further investigation, some of those described by Dr. Russell as varieties may prove to be specifically distinct: according to the character laid down by Linnaeus, taken from the number of the abdominal plates and scales on the belly, they are clearly so; but it is not on this criterion, the fallacy of which is too apparent, that we hazard an opinion; we conclude to the different conformation of the spectacle-like mark.

mark on the back of the neck, and still more to the dissimilarity observable in the figure of the scuta; and laminae; the variations in colour are but secondary particulars in consideration. Dr. Russell enumerates the varieties above-mentioned in the following order.

1. *Aege nagoo*. With a pale central spot in the middle of each of the black spots of the spectacle-shaped mark. Abdominal scuta 189, subcaudal scales 60.

2. *Coodum nagoo*. This variety is darker than the other; and the skin is of a yellow cast; but the principal distinction is in the spectacle-mark, which consists of an oblong curved frame without the usual black eyes or centre-spots of the others. Abdominal scuta 187, subcaudal scales 57.

3. *Sunkoo nagoo*. The chief distinction of this is a plain hood, without any mark. This variety is supposed by Seba to be the female of the species; but Dr. Russell informs us that one which he brought home from India, and presented to Mr. John Hunter was a male, and that the usual spectacle-shaped mark is found indifferently both on the males and females. This variety is more rare than the rest. Abdominal scuta 183, subcaudal scales 56.

4. *Mogla nagoo*. The cervical scuta in this variety are spotted here and there with faint greyish spots, and four of the middle ones are entirely of a blueish-grey. Abdominal scuta 192, subcaudal scales 65.

5. *Malle nagoo*. The colour of this variety is of a lighter brown than the rest, and the scuta whiter; and less spotted, but seven of the pectoral ones are completely dark. Abdominal scuta 191, subcaudal scales 62.

6. *Cunkoo nagoo*. In this some deviations were observable in the laminae: all the cervical scuta were dusky, and the trunk had a strong blueish cast. Abdominal scuta 186, subcaudal squamæ 60.

7. *Jenna nagoo*. The skin of the hood in this is tinged with orange colour; the scuta of the neck spotted with grey, and six of the lower ones wholly of a blue grey. Abdominal scuta 189, subcaudal squamæ 57.

8. *Nella tog pam*. With the black on the hood unusually deep, and all the jugular scuta remarkably dusky. Abdominal scuta 186, subcaudal squamæ 62.

9. *Kistna nagoo*. The middle lamina of the three between the eyes remarkably broad, and the posterior part subovate instead of semi-ovate; five of the jugular scuta dusky, and six of the pectoral almost black. Abdominal scuta 186, subcaudal squamæ 63.

10. *Korie nagoo*. The three laminae between the eyes remarkably narrow; the large posterior pair oval; colour of the trunk, and still more of the scuta unusually blueish. Abdominal scuta 184, subcaudal squamæ 57.

The cobra de capello, it is observed, is every where exhibited publicly as a show in India; and is of course more universally known in that country than almost any other race of reptiles. It is carried about in a covered basket, and so managed by its proprietors as to assume, when exhibited, a kind of dancing motion; raising itself upon its lower part, and alternately moving its head and body from side to side for some minutes, to the sound of some musical instrument which is played during the time. The Indian jugglers, who thus exhibit the animal, first deprive it of its fangs, which renders it incapable of inflicting a poisonous wound by means of its bite.

Dr. Russell, in his account of various experiments made in India with this serpent, assures us that as a general standard for a comparison of the effects of its bite with that of other poisonous serpents, he never knew it prove mortal to a dog in less than 27 minutes, and to a chicken in less than half a minute. Thus fatal as it is, its poison seems not so speedy in opera-

tion as that of the rattle-snake, which has been known to kill a dog in the space of two minutes. The following interesting experiments are related by Dr. Russell to confirm the accuracy of this observation.

In the month of June 1787, a dog bitten by a Cobra de capello on the inside of the thigh, howled at first, as if in severe pain; after two or three minutes he lay down, continuing to howl and moan; after twenty minutes he rose, but with much difficulty, being unable to walk, and his whole frame appeared greatly disordered. He soon lay down again, and in a few minutes was seized with convulsions, in which he expired twenty-seven minutes after. This is the only instance mentioned in which the poisonous bite of the Cobra de capello proved fatal to dogs in much less than the space of an hour.—A large and very stout dog was bitten by another Cobra de capello on the inside of the thigh, which in a minute or two was drawn up, the first symptom in general of the poison having taken effect. He continued, however, nearly half an hour longer walking on the three remaining legs, seeming not otherwise disordered; but after this time, he laid himself along in great iniquitude, his head and throat being convulsed in an uncommon degree; he made several vain efforts to rise, his legs became both paralytic, and after continuing in this state for an hour, he expired.—A large dog was bitten by a Cobra de capello which had been captive only two days. He complained a good deal at the instant of the bite, and the leg was soon drawn up. In twenty-five minutes he was seized with convulsions, succeeded by stupor, in which state he lay for ten minutes; the convulsions, however, returned, and he expired in a quarter of an hour, being fifty-six minutes after the bite. This experiment was tried on the 11th of November.

August 9th, a Cobra de capello, which had lost two of his longest fangs, but retained two of the second order, was made to bite a very large stout dog. At first the dog complained loudly, though without drawing up the thigh, or shewing any other symptom of poison; but happening at this time to break loose, he was pursued, and brought back, after a chase of an hour and a half, much fatigued and heated. After resting a quarter of an hour, water was offered to him, which he refused, though he eat some morsels of bread thrown into it. About a quarter of an hour afterwards he became much disturbed, grew entirely outrageous, howling violently, snapping at and gnawing the stake to which he was tied with incredible ferocity. This continued about three hours, when growing faint, his howlings grew weaker, his convulsions increased, and he expired about four hours after the bite.—A pig bitten by a snake of this kind, which had been fed only once in seven days with milk, became greatly disordered in twenty minutes, and expired in less than an hour.—A chicken has been sometimes known to survive two hours after being bitten by a Cobra de capello. Chickens and pigeons bitten by a Cobra de capello, whose fangs had been eradicated, suffered no symptoms of poison; but when poison taken from the same snake was inserted into their bodies, either by incision or puncture, they suffered the usual symptoms, and very often died.

It was endeavoured also to ascertain the effects of the bite of the Cobra de capello upon reptiles of the same species, the result of which appears doubtful. In some instances, the bitten animal experienced no kind of injury, while to others the bite proved fatal. An attempt was made, on the 17th of August 1788, to make a Cobra de capello bite another (of the variety called *Nooni paragnoda*) in the tail, but that part being found too small, the body was bitten, a little above the vent. The bitten snake soon lost its former activity,

activity, and when put under a glass coiled itself up. In this state it was left, and after an hour and a quarter was found dead. On opening the belly, the parts immediately beneath the bite appeared much inflamed, though it could not be discovered whether any fangs had penetrated into the cavity.

A Cobra de capello, received by Dr. Ruffell from Ganjam, under the name of *Saltanus*, was made to bite another remarkably large Cobra brought from the same place, under the name of *Couliab*. The poison was shed on the place, but no marks of fangs could be perceived, and the Couliab remained as well as before: this experiment was repeated with the same result, though a little blood as well as poison was found on the part bitten. Some days after this, a Cobra de capello (of the variety called *Coodam nagoo*) was made to bite the Couliab on the belly; both fangs visibly acted; blood appeared on the wound, but no other consequence followed. A *Tar tuta* snake, bitten immediately after, in the same manner, died within two hours.

RUFUS. Rufous, with distant reddish-fuscous bands; spectacle-spot somewhat heart-shaped, and marked with four black spots. Seba. *Naja brasiliensis*, Laurenti. La Cèpede, &c.

Described by Seba and others after him as a native of Brazil. This is perhaps a variety of the preceding.

BUCEPHALUS. Brown, with transverse whitish bars; head large, cordated, and depressed; body compressed; tail very slender. *Serpens lufitanis cobra de capello diãa*, Seba. *Coluber bucephalus, bull-headed snake*, Shaw Gen. Zool.

According to Seba, this species is a native of Ceylon; he considers it as a kind of Cobra de capello, or hooded snake, in which respect he is mistaken. The length of this snake is between four and five feet; the head is extremely large, depressed, cordated behind, somewhat compressed at the sides of the mouth, and covered above by very large scaly plates. At some distance from the eyes are two remarkable, oblong, brown spots. The neck is thin, and, together with the whole body, extremely compressed on the sides; tail long, round, and tapering to a fine point. From the head, along the back, runs a row of large, broad, hexagonal scales, those on the other parts are ovate; the abdominal plates are very narrow. The general colour of the animal is rufous-brown, with moderately distant, broadish, transverse, pale bands, each of which, at its juncture with the scuta, is marked with a white spot.

RUSSELLI. Brownish-yellow, with acutely-ovate, blackish, dorsal spots, edged with white; lateral spots smaller and ovate. *Ratuka rekula pada*, Ruff. Ind. Serp. *Ruffellian snake*, Shaw Gen. Zool.

The abdominal plates, according to Dr. Ruffell, amount, in this species, to 168, and the scales under the tail to 59. The length of this snake is about four feet. Its colour an elegant pale yellowish-brown, marked throughout the whole length of the back with a continued series of large ovate spots of a deep brown colour, palest in the centre, and surrounded by a narrow line of white. In some parts those spots are nearly confluent; on each side of the body is a row of brown oval spots, smaller than those on the back; and besides these, a few still smaller transverse marks are sparingly scattered on the sides; the under part of the body is white, with a few dusky spots; the head is rather large, the snout obtuse, the mouth wide, the fangs large, and, as in several other poisonous serpents, double, a smaller fang being situated close to the larger one on each side.

Dr. Ruffell informs us, this species is scarce less common in India than the Cobra de capello; but from its not being carried about, like that and some other snakes, as a public

show, is not so universally known either among the natives or Europeans.

Several experiments were made by Dr. Ruffell to determine the effects of its bite, from which it appears to be one of the most poisonous of its tribe. A chicken bitten in the pinion by one of these snakes, which had been caught two or three days before, and seemed in high spirits, was instantly infected, seized with convulsions, and expired in thirty-eight seconds. Immediately after the chicken, a stout dog was bitten in the thigh; within less than five minutes he appeared stupefied; the thigh was drawn up, and he frequently moved as if in pain. He remained, however, standing, and eat some bread that was offered to him. In about ten minutes the thigh became paralytic; in fifteen minutes he entirely lost the use of the wounded thigh, and lay down, howling in a dismal manner, frequently licking the wound, and making, at intervals, ineffectual attempts to rise. In nineteen minutes, after a short cessation, he again began to howl, moaned often, his breathing became laborious, and the jaws were completely shut. The few succeeding minutes were passed alternately in agony and stupor, and in twenty-six minutes after the bite he expired. A second dog, of much smaller size, was next bitten, and expired in the space of six hours. After this, a rabbit was exposed to the bite of the snake, and died in less than an hour; and, lastly, a chicken bitten in the pinion expired in less than six minutes. The whole of the above experiments were made with the same snake in the course of the same morning.

GRAMINEUS. Green, beneath yellowish, with the edges of the abdomen spotted with green. *Boodro pam*, Ruffell Ind. Serp. *Grass-green snake*, Shaw Gen. Zool.

The length of this kind is about thirty inches. The head is rather large in proportion, and obtusely tapering, but not pointed, and is covered entirely with very small scales; the colour is as above described. This is a native of India, and was first described by Dr. Ruffell; it is of the poisonous kinds, and has the fangs remarkably long and slender. From the experiments of the last-mentioned writer it appears, that a chicken died, after having suffered long convulsions, and afterwards stupor, in about eight minutes from the bite; pigs and dogs were seized with a stupor, convulsions, &c. but in a few hours recovered from the effect of the poison.

CROTALINUS. Cinereous, marked above with large alternate blackish spots; beneath yellow, freckled with brown. *Coluber crotalinus*, abdominal scuta 154, subcaudal scales 43. Linn.

A large species, with the habit of the rattle-snake; the head is heart-shaped, the eye-lids protuberant, scales carinated. Native country unknown.

SEVERUS. Cinereous, with oblique linear whitish bands, edged with brown. *Coluber severus*, abdominal scuta 170, subcaudal scales 42. Linn.

Length about seventeen inches; thickness moderate; head broad, obtuse, livid, with cinereous band between the eyes, and behind the nose; eyes large; neck thick; the colour of the upper parts as before described; the abdomen dusky; sides speckled with white; tail short. The figure in Seba, quoted by Linnæus, is of a pale rufous colour, with yellowish bands, somewhat resembling Hebrew characters in form, and edged with brown; the abdomen pale yellow, with a row of blackish spots on each side.

PORPHYRIACUS. Violet-black, with the abdomen and sides crimson, the scuta margined with black. Zool. New Holl. p. 27. pl. 10. Abdominal scuta 188, anal scuta 74, subcaudal squame 45.

First described by Dr. Shaw, who speaks of it as a moderately large and beautiful species; the general proportions nearly

nearly the same with those of *Coluber natix*, the common English snake. The head is rather small, and covered in front with large scales; the colour of the head and whole under parts very fine deep violet; sides and abdomen crimson, deeper on the fore-part, the large scales near the scuta being carmine-coloured, with black tips; the abdomen rose-coloured, with a tinge of yellow, each scutum deeply edged with black, thus forming a beautiful series of transverse black bars down the abdomen. The tail measures about a sixth part of the whole length, and is furnished beneath, exclusive of the divided subcaudal scales, with about seven scuta, or undivided laminae, commencing immediately beyond the v. nt. which is edged with similar smaller squamæ; the colour of the under parts of the tail is a blueish-ash, the rose-colour of the abdomen ceasing at the commencement of the tail. In the *Zoology of New Holland*, Dr. Shaw describes this species as destitute of fangs, and consequently innocuous; an error arising from the mutilated state of the specimen he examined. The snake has been since observed to be furnished with these organs; and, as Dr. Shaw remarks, in his *General Zoology*, to be highly dreaded by the natives of Australia, as a poisonous species.

HÆMACHATES. Red, clouded with white; abdomen yellowish-white. *Serpens asiatica hemachates dicta*, S. b. *Hæmachate*, Cæpede.

Seba describes this snake as a native of the East Indies, having received it from Persia and Japan. Its general length is about two feet or more; its colour red, varying to deeper or paler in different individuals, and sometimes inclining to brown; the variegations white or whitish. The head is moderately large, and covered in front with large scales; tail extremely short and tapering to a point. La Cæpede considers it a poisonous snake.

AQUATICUS. Brown, with the abdomen banded with black and yellow. *Water viper*, Catesby.

We are acquainted with this species only from the account given of it by Catesby. "This serpent (says that writer) is called in Carolina the water rattle-snake; not that it hath a rattle, but is a large snake, and coloured not much unlike the rattle-snake, and the bite said to be as mortal. This snake frequents the water, and is never seen at any great distance from it. The back and head are brown, the belly transversely marked with black and yellow alternately, as are the sides of the neck; the neck is small; the head large, and armed with the like destructive weapons as the rattle-snake; it is very nimble, and particularly dextrous in catching fish. In summer great numbers are seen lying on the branches of trees hanging over rivers, from which, at the approach of a boat, they drop down into the water, and often into the boat on the men's heads. They lie in this manner to surprize either birds or fish, after which last they pounce, and pursue them with great swiftness, and catch some of a large size, which they carry on shore and swallow whole. One of these I surprized swimming ashore with a large catfish in his mouth. The tail is small towards the end, and terminates in a blunt horny point, about half an inch in length, and which, though harmless, is considered as of dreadful efficacy, by the credulous vulgar, who believe that the animal is able, with this weapon, not only to kill men and other animals, but even to destroy a tree by wounding it with it, the tree withering, turning black, and dying."

LACTEUS. Milky-white, the back marked by double black spots; head black, with a longitudinal white line. *Coluber lacteus*, abdominal scuta 203, subcaudal scales 32. Linn.

Length eighteen inches. A native of India and South America, and is reputed poisonous.

NIVEUS. Snowy-white, with variations. *Coluber niveus*, abdominal scuta 209, subcaudal scales 62. Linn. Inhabits Africa.

MELANUS. Deep black; sides clouded with bluish, the eyes brown, with the edge of the pupil silvery. *Coluber melanicus*, abdominal scuta 148, subcaudal scales 27. Gmel. Pallas It.

Observed by Dr. Pallas on the borders of the Volga and Samara rivers in Siberia. It has the general appearance of the viper, but differs in colour, being of a deep black on the back, and of a fleshy lufre beneath, marked with patches of a deeper cast, while the sides are clouded, and spotted at intervals with bluish. The eyes are of a bright white, with perpendicular pupils, and ferruginous irides; tail short, and gradually tapering to the tip.

BUCCATUS. Whitish, with large double brown dorsal spots; head somewhat depressed, cheeks timid. *Coluber buccatus*, abdominal scuta 107, subcaudal scales 72. Linn.

A poisonous species; it inhabits South America and India. Length twelve inches.

ATROX. Grey brown, with transverse linear whitish stripes; abdomen dusky with white transverse variegations. *Coluber atrox*, abdominal scuta 196, subcaudal scales 69. Linn.

Length about eighteen inches: it is a poisonous snake, and is a native of the island of Ceylon.

CORALLINUS. Glaucous, with scales somewhat heart-shaped, and three brown lines down the back. *Coluber corallinus*, abdominal scuta 193, subcaudal scales 82. Linn.

Linnaeus describes this as a poisonous species: it is a native of the eastern regions; it preys on lizards.

LEBERIS. Pale; head white; body marked above with linear black bands. *Coluber leberis*, abdominal scuta 110, subcaudal scales 50. Linn.

Described by Kalm, who informs us that it is a native of Canada, and that the upper parts are traversed by linear black bands; the head white with two rufous spots on the top, and a triangular spot over the nose. Linnaeus mentions it as a poisonous species, a particular considered doubtful by Dr. Gray.

AULICUS. Grey brown, with transverse white bands bifurcating over the sides. *Coluber aulicus*, abdominal scuta 184, subcaudal scales 60. Linn.

The length of this species is six inches; it inhabits America, and is one of the poisonous kind of snakes.

ELEGANTISSIMUS. White; head variegated with black; body marked above by a quintuple series of ocellated red spots. *Coluber elegantissimus*, Gmel. Laur. Amph. *Serpens lemniscata venulissima Americana*, Ssba.

This is a beautiful species, measuring in length about two feet; the colour is white, marked down the upper part with a quintuple series of black spots with red centres; the middle row is composed of very small spots, the next on each side with larger ocellated ones, and the lowest on each side, next the scuta, resembling that on the middle of the back, and consisting of small specks; the head is marked by a cross-shaped spot on the top, and by a few blackish ones across the snout; the tail is short, measuring two inches and a half in length, and tapering to a point.

RHOMBEATUS. Glaucous, with blackish lozenge-shaped spots, blue in the middle. *Coluber rhombeatus*, abdominal scuta 157, subcaudal scales 70. Linn.

Length from two to three feet; colour, in general, grey, sometimes brownish, with three alternating rows of ovate dusky spots, with large blue centres; the abdomen is pale or whitish, and often clouded with bluish grey. This is a native of India and South America.

JAVANICUS. Grey; head striped with blue; body marked with transverse blue stripes edged with golden.

Described by Mr. Wurm in the "Memoirs of the Batavian Society," for the year 1787. This is a large and most beautiful species, and is seen principally in the rice fields, whence it obtains the name of *Oular-Sawa*, or Rice-field Snake. Those which are found in the higher and more wooded situations arrive at a far superior size. The head of this snake is large and flat, and is covered, as in the major part of the coluber genus, with large scaly plates; the mouth is furnished with double rows of sharp teeth, but is destitute of fangs, the animal not being of a poisonous nature; the iris is yellow; upper part of the head grey, mixed with blue; from behind the eyes pass two blue stripes to the upper part of the neck, where they unite into an arch about an inch beyond the head; a third stripe of the same colour proceeds from the snout to the occiput, where it divides into two, and surrounds a yellow spot marked with a few blue specks; the upper part of the body is divided into a kind of lattice-work, formed by stripes of bright blue with gold-coloured edges; the middle parts of the square being of a grey colour, with changeable reflections of yellow, blue, and green; towards the sides the grey colour is of a lighter or paler cast, as well as on the tail, where the squares are smaller than on the back; each side of the body is also marked by a row of white spots, situated at the crossings of the blue stripes. This snake preys on birds, rats, and various other small animals.

BÆIFORMIS. Whitish, with brown variegations; white beneath, with very short scuta. *Pedda pada*, Ruffell Ind. Serp. *Bæiform snake*, Shaw Gen. Zool.

A new species described by Dr. Ruffell. The length of the specimen, examined by that writer, was about two feet and a half; but it is supposed to attain to a much larger size. It was short and thick with moderately large oblong-ovate head, covered with large scales; and the tail short and sharp pointed. The colour of the upper parts very pale or whitish brown, variegated on the back and sides, with large and small irregularly formed, deep-brown patches, and spots, those on the sides being mostly ocellated. The body is covered with very small scales, the three rows next the abdomen being much larger than the rest; abdomen white, the scuta being remarkably narrow or short, and reddish at the margins. The under part of the tail is variegated with black and white.

This is a native of India, and is represented as an animal of great strength, wreathing round the arm, if held for a short time, so closely as to numb the hand; it is not poisonous, its bite producing no other effect than that of temporary pain.

The serpent mentioned by Dr. Ruffell, under the name of *Bæra*, is considered as a variety of coluber bæiformis, and so also is the *Pedda pada*, t. 23, 24. The first is much larger than the serpent above described; the disposition of the scales and colours are the same, but the ground colour is white, and the tail is furnished beneath with several undivided lamellæ towards the tip, or after those immediately succeeding the vent, while the tip itself is again terminated by a few divided scales. This snake is found at Calcutta, where it is pretended the bite is very soon followed by eruptions on different parts of the body, though it does not prove fatal in less than ten or twelve days, but the whole of this is regarded as a mere popular error. The other supposed variety, the *pedda pada*, grows to a very large size, having been seen nine or ten feet in length. In its general appearance it resembles that first described, but the scales are larger in proportion.

VOL. IX.

MELANURUS. Yellowish brown, with black head, and two black spots on the tail. Ruffell. Ind. Serp.

A small species about ten or eleven inches in length, scarcely of the thickness of a goose quill, and nearly of equal diameter from the head to the tip of the tail. The colour is a light yellowish brown, with a dotted black line running from head to tail along the middle of the back, and a few fainter fillets on the sides; the head is small, ovate, black, and covered with large scales; the tail short, scarcely measuring more than an inch in length, and is marked at its origin on the upper part, by a large rhomboidal black spot edged with white; and having a white speck in the middle; the tip of the tail is also marked by a similar black spot; the abdomen is of a pale orange colour, and the under part of the tail white, speckled, and variegated with black. The bite of this species is said to be painful but not poisonous. It is a native of India, and is described among the serpents of that country by Dr. Ruffell.

JARA. Black, with double linear white specks, and yellowish collar and abdomen. *Jara potoo*, Ruffell, Ind. Serp.

This is one of the new species of serpents described by Dr. Ruffell. It inhabits India. The length is fifteen inches; tail very short and tapering suddenly to a point. The abdominal scuta are 175 in number, and the subcaudal scales 56.

ARNENSIS. Yellowish-brown with narrow blackish transverse bands edged with white, and pale abdomen. *Arnee snake*, Ruff. Ind. Serp.

Inhabits the country of Arnee in the East Indies. The length is about eighteen inches; the colour above yellowish, with moderately distant blackish, or very deep brown, transverse bands which are whitish at the margins; the head is small; tail rather short and tapering to a sharp-pointed tip. Abdominal scuta 160, subcaudal scales 50.

SAGITTATUS. Brown, with whitish sagittated dorsal spots edged with black. *Tar tuta*, Ruff. Ind. Serp.

The length of this snake is two feet; the head is rather large in proportion, round, obtuse, and covered with large scales; neck and body slender, the colour on the upper parts yellowish brown variegated, with a chain or series of somewhat triangular, or sagittated spots; the abdomen is yellowish white, and the scuta is marked by a dusky spot on each side. This is a native of India.

STRIATUS. Greenish black, with spotted white bands, and bluish-white abdomen. *Gajoo tatta*, Ruff. Ind. Serp.

This is much smaller than the last, measuring only fourteen inches: the colour above is greenish black, marked with about twenty transverse bands, each composed of a number of longitudinal abrupt white or yellowish white streaks, and along the sides of the body are interrupted rows of similar streaks; the head is obtuse, and covered with large scales, the abdomen bluish-white. Abdominal scuta 174, subcaudal scales 40.

FASCIOLATUS. Cinnereous, with whitish transverse bands and glaucous abdomen. *Nooni paragoodoo*, Ruffell. Ind. Serp.

AGILIS. Banded alternately with white and fuscous, and varied with black dots: head small; tail short.—*Coluber agilis*, abdominal scuta 184, subcaudal scales 50. Linn. *Cerastes Agilis*, Laur.

A native of Ceylon. The head is small, covered with large scales; body slender and smooth, about a span in length, and covered with small scales; tail short, taper, and terminating rather obtusely.

SIMUS. Blackish, with white transverse bands; nose turned up. *Coluber*.

K.

SIMUS.

SMUS. Abdominal scuta 124, subcaudal scales 46. Linn. D. Garden.

Length eighteen inches; head rather large, and roundish, with the nose flat in front, and turned up into a slightly pointed tip: between the eyes is a black curved band, and on the top of the head a white cruciform mark, with a black central spot; abdomen dusky. A native of Carolina, and other parts of North America.

PELIAS. Brownish, with double transverse black bands, beneath green with a yellow lateral band.—*Coluber pelias*, abdominal scuta 187, subcaudal scales 130. Linn.

A native of South America and India. Described by Linnæus from the Museum of Deger.

MUCOSUS. Bluish, beneath pale, with angular head: lips striped transversely with black. *Coluber mucosus*, abdominal scuta 200, subcaudal scales 140. Linn. *Natrix mucosa*. Laur. Amph.

Described by Linnæus from a specimen in the Mus. Ad. Fr. It is a small species, measuring about eighteen inches in length; the native country is South America.

CINEREUS. Cinereous; abdomen white; tail reticulated above with brown, and lined transversely beneath. *Coluber cinereus*, abdominal scuta 200, subcaudal scales 137.

Indies, according to Linnæus South America and India: it resembles the common snake, and is about two feet in length.

DIPSAS. Green with two white stripes. Abdominal scuta 152, subcaudal scales 155. Linn. *Serpens surinamensis carule*, Seba. Inhabits Surinam and other parts of South America.

CASPIS. Body fasciated alternately above with yellow and fuscous, beneath yellow. *Coluber caspius*, Gmel. Lepech. It.

First described by Lepechin as an inhabitant of the shores of the Caspian sea, where it haunts the low grounds and bushy places. It is reported of this species, that when disturbed it first endeavours to escape, but if pursued or irritated, springs forwards on its assailant with great fury, though incapable of doing any injury by its bite. The usual length is about five feet.

PERUVIANUS. Black and white; abdomen rose-coloured. *Serpens Peruviana elegantissima et rara*, Seba.

A native of Peru; described by Seba, who informs us it is rare in European collections. This is an innocuous species. Linnæus does not notice this snake, as the number of its abdominal scuta, and subcaudal plates could not be ascertained.

HYGÆLÆ. White, with somewhat undulated black zones, and head fasciated longitudinally with black. *Serpens siamensis tenuis*, &c. Seba.

A small species of a white colour, barred with numerous irregular black bands, nearly surrounding the body; head small, covered with large scales, and marked by two broad longitudinal streaks uniting at the top of the snout: tail rather short and sharp pointed. Inhabits Siam.

PETHOLA. Lead colour, with testaceous bands. *Coluber pethola*, abdominal scuta 209, subcaudal scales 90. Linn. 207—103. Gronovius. 207—85. Boddart.

This snake inhabits Africa. In the middle of the head, between the eyes is a large shining shield, composed of many plates; the sides of the head and hind-head is covered with imbricated scales each side; and the snout is sharp.

No less than nine varieties of this snake are described by Gmelin after Laurenti. These we shall enumerate in the Gmelinian order, observing only that on further investigation it is not unlikely some at least of those supposed varieties

may prove to be specifically distinct. Those are not noticed by Dr. Shaw, but that writer thinks the *C. Petalarius* of the Museum Adolphi Friderici, can hardly be considered as a species distinct from *Pethola*.

β. *Coronella Africana*, &c. White, with spots on the back; those on the anterior part rounded, and gradually becoming rhomboidal, with the edges reddish. Laur. Amph.

γ. *Coronella ocellata*, &c. Bluish, with a quadruple series of black ocellated spots, which are blue in the middle, and are disposed longitudinally. Laur. Amph.

δ. *Coronella fasciata*, &c. Bluish white with black brown bands, and two longitudinal divided lines. Laur. Amph.

ε. *Coronella latirostrâ*, &c. Brownish, with a few pale bands, snout depress'd. Laur. Amph.

ζ. *Coronella latirostrâ, fasciata*, &c. With yellowish confluent bands near the belly. Laur. Amph.

η. *Coronella ceratoides*, &c. Brownish white, with very pale brown spots; occipital spots two, and longitudinal; dorsal ones elliptic, and disposed in a single stripe. Laur. Amph.

θ. *Coronella teniata*, &c. Middle of the back marked with a brown stripe; belly and sides whitish brown. Laur. Amph.

ι. *Coronella anguiformis*, &c. With entire circular brown bands, beneath obliquely concurrent.

PETULARIUS. Brown, with white bands, beneath pale. Abdominal scuta 212, subcaudal scales 102. Linn. Weigelabb. der. hall. Length from twelve to thirty inches; inhabits South America

LEMNISCATUS. Yellowish white, marked at equal distances with triple dark brown bands. *Coluber lemniscatus*, abdominal scuta 250, subcaudal scales 35. Linn. Amoen. Ac. *Natrix lemniscata*. Laur. *Serpens annulatus*, Seba.

A native of Asia. The length of this snake is about three feet, of a slender form, and white or yellowish marked throughout the whole length, at equal distances, with triple zones of black or deep brown, which entirely surround the body. The head is rather small, covered with large scales, and marked across the snout by a double zone, of which the smallest division passes across the nostrils, and the largest across the eyes. The whole animal is of a smooth and shining surface.

LUVERICUS. Flagelliform; white with equidistant black bands; body glossy. *Coluber luvericus*, Gmel.

Allied to the last species; the body is white, marked with single black bands; the head is marked across the snout by a black band, and at the top by two oblique stripes nearly meeting at an angle in front; the skin is remarkably smooth and glossy. The length of this snake is eighteen inches. According to Gmelin it is a native of Surinam; the snake described by Seba, as *Natrix lubrica, fasciata rubris*, and which is considered as a variety of the same species, is a native of Surinam.

DOLIATUS. Milk-white, marked above by large, approximated, suboval black rings. *Coluber doliatus*, abdominal scuta 164, subcaudal scales 43. Linn.

A small species measuring from eighteen inches to two feet in length; general colour milk white, marked throughout by large oval jet-black rings, the ends of which approaching each other on the top of the back, give the appearance of double bars, corresponding with the description given of this snake by Boddart, *Coluber albidus, annulus nigris per parva digestis*. Inhabits Carolina.

GEMMATUS. Blue, with a black middle-stripe spotted with white, and two lateral white stripes. *Le Chapellei*, La

La Cepede. Abdominal scuta 166, subcaudal scales 103.

The length of this beautiful snake is about fifteen or sixteen inches; the colour on the upper parts blue, with three narrow equidistant stripes from head to tail; the two lateral stripes being white, the middle one black, marked by a row of small white specks alternately oblong and round, resembling a small string of beads and bugles: the head is covered with large scales, and marked on each side with three or four spots, forming a band across the eyes, the top spotted with pale blue marks bordered with black; the abdomen white. The scuta are each marked at the edge with a small black speck, forming two rows down the abdomen. The native country of this kind is unknown, the species was described by La Cepede from a specimen in the royal cabinet.

BILINEATUS. Rufous, with two golden yellow stripes. *La double raie*, La Cepede.

This snake measures twenty-five inches in length, of which the tail exceeds six inches. The general colour is rufous; every scale is bordered with yellow, and down the back from the head to the tail run two bright yellow stripes of a golden hue. The scales on the head are large, those on the body smooth. The native country is unknown.

TRILINEATUS. Rufous, with three black lines. *La trois raie*, La Cepede.

The length is about eighteen inches; the head is covered with large scales; tail about two inches and three quarters long. This is a native of Africa.

TRIFASCIATUS. Body marked with three broad black stripes, the middle one divided by a white line, and three spotted lines down the abdomen. Shaw Gen. Zool.

A small species, measuring a foot in length, and being rather thick in proportion; head rather large, blackish, with the futures pale. Described from a specimen in the collection of Dr. William Hunter.

DIONE. Pale blue, spotted with brown, and three whitish lines. Pallas It.

This species is a native of the salt deserts towards the Caspian sea, and of the hilly regions near the river Irtyz; and was first described by Dr. Pallas. It is of a slender form, about two feet in length; the head small, tetragonal and commonly reticulated with blackish futures. The two intermediate spaces between the three lines on the back are marked with a row of dusky alternate spots; and the tail is about one sixth of the whole length.

MYCETERIZANS. Head angular, with sharp pointed snout, and a yellow line on each side of the abdomen. *Coluber myceterizans*, abdominal scuta 192, subcaudal scales 167. Linn. *Coluber subcaeruleus lateribus lineatis*, Boddaert. *Natrix miederizans*, Laur.

This snake is in general of a grass-green colour, and is distinguished in particular by the yellow line which extends the whole length of the body on each side of the abdomen. It is of a slender form, measuring about three feet and a half in length, and about half an inch in diameter. The head is moderately large, long, and sharp snouted, the upper jaw extending far beyond the lower. Linnæus was erroneously led to consider this as a poisonous species, from thefang-like appearance of the large and long teeth in the upper jaw. It is a native of many parts of North America, where it is principally seen on trees, moving with great velocity in pursuit of insects, on which it feeds.

Gmelin describes the *natrix flagelli formis* of Laurenti, and also the *anguis viridis* of Catesby, as two varieties of the *coluber myceterizans*. The *Bola Passiriki* of Dr. Russell may be perhaps admitted likewise as a variety. This differs in the colour of the under parts, instead of green being of

a cinerous pink colour, elegantly freckled with very numerous minute black and yellowish dots; the margin of the scuta being edged with dull yellow; the skin of the neck also, when the animal is irritated, exhibits by the dilatation of the skin on that part, a beautiful variegation of black and white reticular marks, which do not appear at other times. This creature is represented as of a ferocious nature, hissing violently, and snapping at any thing opposed to it, but producing no other effect by its bite than that of temporary pain in consequence of mere puncture.

COLUBER NASUTUS. *Serpens viridis, ore acuminato ex Java, aspidio species*, Seba.

Whether this be distinct from the former is uncertain; the head is somewhat larger in proportion, and the body less slender: in other respects it very nearly corresponds. The length is about three feet. This snake according to Seba is a native of Java.

LINEATUS. Blue-green, with three or five brown linear stripes, the middle one broadest. *Coluber lineatus*, Linn. *Serpens ceilonica lineis subsuffis*, Seba.

This snake is a native of India, and is commonly about three feet in length. The general colour is pale bluish green above, with a golden gloss, and is marked throughout the whole length by five longitudinal narrow bands, or stripes of dusky brown or greenish. In young specimens there are rarely more than three stripes. The form of this snake is long and slender, with the head small, the abdomen flattish, and the tail long and thin.

JACULATRIX. Whitish, with three blackish stripes, the middle one broadest. *Coluber jaculatrix*, Linn. *Serpens Americana sequipiles diâa*, Seba.

Resembles *lineatus*, but is smaller; the general colour whitish tinged with blue, and marked by three longitudinal stripes of black or deep brown, of which that in the middle is broadest. This appears to vary in colour, that described by Seba being yellowish instead of white. The abdominal scuta are 163 in number, the subcaudal scales 77. This kind inhabits Surinam, and is considered as a harmless animal.

SIBILANS. Bluish, with five dusky lines, and the head spotted. *Coluber sibilans*, abdominal scuta 166, subcaudal scales 100.

This, like the last, resembles *coluber lineatus*, being marked, as in that species, with five dusky stripes, the middle one of which is the broadest, and is nearly black, with a whitish speck on each of the scales. The head is ovate, covered with large scales, and marked with several oblong, blue, subangulated spots, with black edges; and the tail is very long and slender. This animal is of considerable size, sometimes measuring four feet in length; it is a native of Asia, and is esteemed harmless.

SITULA. Grey, with a longitudinal dusky band, bounded on each side by a black line. *Coluber situla*, abdominal scuta 236, subcaudal scales 45. Described by Hasselquist as a native of Egypt.

SAURITA. Brown, with three blue-green stripes. *Coluber saurita*, abdominal scuta 156, subcaudal scales 121.

This is the ribbon snake of Catesby, a species about three feet in length, and very beautiful. The general colour is brown above, with three moderately-broad longitudinal bluish-green stripes; the head is rather small and somewhat pointed, the body slender, and the tail thin. Catesby represents it as an animal extremely swift in its motions; it inhabits Carolina and many other parts of North America, frequents trees, and is perfectly innoxious.

VITTATUS. Whitish, with three black stripes, the middle one very narrow; abdomen white, with the edges of the

C O L U B E R.

feuta brown. *Coluber vittatus*, abdominal feuta 142, subcaudal feales 78. Linn. *Coluber de terrazona*, Seba.

The length of this kind feldom exceeds thirty inches; the colour is whitifh, tinged with blue, and marked along the whole length of the back by three black or dark brown ftripes, the middle one of which is the narroweft; between this and the principal longitudinal ftripe on each fide is a pair of extremely narrow or linear ftripes, which are gradually loft after paffing fome diftance down the back. The head is rather fmall; of an elongated form, covered with large feales, and marked with black variegations; the tail is of moderate length, flender, and gradually tapering to a point. This fnake is a native of South America, and is not of the poifonous tribe of ferpents.

MONILIS. Whitifh, with broad brown bands, and three fpois on the neck. *Coluber monilis*, abdominal feuta 164, fubcaudal feales 82. Linn.

A native of South America. This is a fmall fpecies meafuring about a foot and half in length; the colour whitifh, banded throughout the whole length with very broad tranfverfe brown bars; the head is of moderate fize, whitifh, and bordered with brown.

SCABER. Grey, spotted with brown, and the feales carinated by a rifing point. *Coluber feaber*, abdominal feuta 228, fubcaudal feales 44. Linn. *Raube natarr*, Merrem.

Length about eighteen inches, the form rather flender; head fmall, and marked at the back of the neck with a few tranfverfe ftrreaks; the fpois on the back are fomewhat rhomboidal, of a brown colour, lighteft in the centre, and difpofed in a triple feries. This fnake is a native of India.

MAURUS. Brown, with two black dorsal lines, fides tranfverfly banded with black, and the abdomen black. *Coluber maurus*, abdominal feuta 152, fubcaudal feales 66. Linn. Syst. Nat. A native of Algiers.

JUGULARIS. Black, throat fanguineous. Haffequift. Defcribed as a native of Egypt; the abdominal feuta are 195, and the fubcaudal feales 102.

COCCINEUS. Black, with the back yellow, spotted with red, and the abdomen pale. *Coluber coccineus*, abdominal feuta 175, fubcaudal feales 35. Gmel.

Length about two or three feet, form rather flender, with the head fmall, the ground colour black, with about twenty-three fubovate fpois of bright red, with the fpaces between yellow. This is a native of South America.

CANDIDUS. White, with large ovate brown dorsal fpois. *Coluber candidus*, abdominal feuta 220, fubcaudal feales 50. Linn. *Serpens afculapii brafilienfis*, Seba.

General colour milk white, marked throughout with a row of deep brown ovate patches; the head is brown, and covered with large feales; tail of moderate length, gradually tapering to the extremity. This is a native of South America.

NEBULATUS. Clouded with fufcous and cinereous, beneath varied with white and brown. *Coluber nebulatus*, Linn. Weigel. Abh. Hall. *Cerastes nebulatus*, Latreil.

A native of America. This is of a moderate fize, meafuring about two feet in length; the head is rather large in proportion, and covered with feales of confiderable fize; body rather flender, and the tail tapering rather fuddenly from the body. The colour is yellowifh brown, clouded with irregular deep-brown, or black fh variegations difpofed fomewhat in the form of bands, and nearly furrounding the body.

PADERA. White, with blackifh dorsal fpois, connected by a line and lateral fpois. *Coluber padera*, abdominal feuta 198, fubcaudal feales 56. Linn. A native of India.

AUSTRALASIE. Blackifh brown, fpeckled with yellow;

feuta very narrow, and the abdomen clouded with brown and yellow. *Auftralafian fnake*, Shaw Gen. Zool. White's Journ. New South Wales.

This is a large fnake, meafuring nine or ten feet in length, and being rather flender in proportion; the colour above deep or blackifh brown, variegated with numerous yellow fpecks, arifing from the circumfite of the middle of every feale being marked with an ovate yellow fpoit. On the fides of the body many of the feales are yellow on one half and black on the other, and by degrees appear more tinged with yellow as they approach the abdomen, which is clouded with a mixture of brown and yellow; the head is fmall, and covered in front with moderately large feales; the teeth rather large, and unaccompanied, fo far as can be afcertained from the dried fpecimens hitherto examined, by any poifonous fangs.

SCHOCKARI. Cinereous brown, with a double white longitudinal band each fide; abdomen whitifh; throat yellowifh, and fpeckled with brown. *Coluber fchockari*, abdominal feuta 180, fubcaudal feales 114.

Defcribed by Linnæus after Forfkal, as being about a cubit and a half in length, and the thicknefs of a finger; the colours as above defcribed, except that, as the fnake advances in age, a narrow ftripe, compofed of fmall whit fh fpois, is observable down the middle of the back. The head is ovate, obtufe, and covered with large feales, and the tail about a third of the whole length. A native of the woody parts of Arabia.

HOELLIER. Entirely red. Forfk. Forfkal defcribes this as a native of Arabia. It is about a foot in length; the bite of this fnake is faid to caufe an inflamed tumour, and its breath to excite an itching in the fkin.

REGINE. Violaceous brown; beneath white, with a femi-orbicular brown fpoit on each alternate feuta. *Coluber regine*, abdominal feuta 137, fubcaudal feales 70. Linn. Weigel. Abh. Der. Hall. &c.

Length twelve inches; the tail is of a moderate length, and rather flender, and the feales beneath are plain. A native of India, and confidered, by fome writers, as an inhabitant likewife of America.

CYANEUS. Deep blue, beneath cinereous. *Coluber cyaneus*, abdominal feuta 110, fubcaudal feales 111. Linn. *Anguiculus firinamensis cyaneus*, Seba.

This is a fmall fpecies; the head is of a moderate fize, rather long, and covered with feales of a large fize; tail long, and tapering gradually to a point. Inhabits South America.

EXOLETUS. Blueifh grey; head oblong and flattifh; lips and throat white. *Coluber exoletus*, abdominal feuta 147, fubcaudal feales 132. *Natrix exoletus*, Laur. Amph. p. 78.

Inhabits South America and India. The length is three feet; the feales on the body are obtufe, and arranged in eleven rows; the head oblong and flattifh; tail flender, a foot in length, and pale beneath.

DHARA. Coppery-grey, with the edges of the feales whitifh; beneath white. *Coluber dhara*, abdominal feuta 235, fubcaudal feales 48.

The length of this fnake exceeds a cubit; the thicknefs lefs than a finger. The head is ovate, obtufe, and covered with large feales, of which thofe in the middle between the eyes are larger than the reft. A native of Arabia. Forfk.

TYRIA. Whitifh, with a triple feries of rhomboidal fpois. *Coluber tyria*, Linn. Defcribed by Haffequift as a native of Egypt.

FULVIUS. Fulvous, spotted with brown, the body annulated with black bands, and the tail very fhort. *Coluber fulvius*, abdominal feuta 218, fubcaudal feales 31. Linn.

Length

Length about eighteen inches; the head brown above, and covered with large scales. A native of North America.

CONSTRUCTOR. Shining black, with the body very long and slender. *Coluber constructor*, abdominal feuta 186, subcaudal feales 92. Linn. *Black snake*, Catesby. Carol.

According to Catesby, this is a large and very long snake, some attaining to the length of six feet; they are entirely of a shining black colour, and are very nimble and beneficial in killing rats, which they pursue with wonderful agility to the roofs and all parts of houses and barns, where rats are able to run, and for this service are preferred by most of the inhabitants; they are bold and furious, leaping at and biting those that attack them, though no harm ensues, their bite not being venomous; it is commonly said, in Carolina, they will attack the rattle snakes, and swallow them. "It is certain," says Catesby, "most or all snakes will devour one another, not only of their own but of all other kinds, which I have often seen; one, after a long struggle, swallowing another, but little less than itself."

SIRTALIS. Brown, with three blueish-green bands. *Coluber sirtalis*, abdominal feuta 150, subcaudal feales 114. Linn. Described by Kalm as a Canadian species.

DECORUS. Blueish-green, with a double lateral band of black, and black spots on each side the neck.

A species described by Dr. Shaw, from a specimen in the British Museum. Its habit is slender and flagelliform; length about two feet and a half; the colour pale, blueish, gilded green, with iridescent variegations; beneath paler, or more inclining to white; on each side the body, near the abdomen, a double black stripe; head longish, covered with large scales, immaculate, and marked each side, through the eyes, by a broadish black stripe broken into spots, and which, passing to some little distance along the neck, becomes divided, and forms the double lateral stripe before mentioned. The eyes are large: tail very long and slender.

DOMICELLA. White, with numerous deep black transverse bands meeting beneath, and a blackish abdominal line. *Coluber Domicella*, abdominal feuta 118, subcaudal feales 60. Linn. *Anguis bicolor elegantissimus malabaricus*, Seba.

Length about two feet and a half, diameter half an inch; the head is small, covered with large scales; tail rather short and tapering to a point. This is a native of India; it is said the ladies in India sometimes carry this snake in their bosoms, and hence Linnæus named it domicella.

VIROIDISSIMUS. Bright green; abdomen whitish, with the feuta dilated towards the middle. *Coluber viridissimus*, abdominal feuta 117, subcaudal feales 122.

This beautiful snake is a native of Sericam. The length is about three feet; head slightly obtuse, of moderate size, covered with very large scaly plates; the remainder of the upper parts with ovate scales; the tail is of moderate length and slender. The green on the back inclines more or less to blue or purple in different individuals, and the abdomen in some than in others. It is esteemed a harmless species.

CURSUS. Greenish, with two dorsal stripes of linear white spots, and whitish sides and abdomen.—*La Courresse*, Cepad. Abdominal feuta 185, subcaudal feales 105.

A species described by La Cepadé, from a specimen in the Royal Cabinet at Paris. The length is near three feet; the head is covered with large scales, the tail of moderate length and gradually tapering to the tip. It is said to be a timid animal, and remarkable for the swiftness of its motions. This inhabits the island of Martinico.

HICKANELLA. White, speckled above with blue, and variegated with blue on the abdomen. *Serpens hickanelle Americanus*, Seba.

A native of South America, where it frequents houses, and is very useful in destroying rats, mice, and other vermin. It is about two feet and a half in length, the thickness moderate, head oblong, and covered with large scales, tail rather short, and gradually tapering.

PERLATUS. Pearl-coloured; head and tail sea-green; the former marked by a red spot. *Serpens ex novo Hispanicus*, a Fahro Lynceus.

This snake is about two feet and a half in length, and rather thick, except towards the tail, where it gradually tapers to a slender point; the top of the head is covered with small scales except about the nose and between the eyes. It is a native of New Spain.

PLATURINUS. White, spotted with brown, and annulated with broad brown zones. Shaw Gen. Zool.

Described from a specimen in the museum of Dr. Williams Hunter. It resembles the common snake *C. natrix*, but the tail is rather more slender in proportion; the head is rather large, and covered with large scales of a black brown colour, elegantly marked with intervening spaces of white; the whole animal is about three feet and a half in length.

ARGUS. Chestnut-brow, banded with transverse rows of ocellated red spots; beneath yellow. *Coluber argus*, Linn. *Serpens arabica brassiliensis ibobocata*, and *Boiguacu diâa*; alias *argus*, Seba.

The argus snake is a large and elegant species, measuring, according to Seba, above five feet in length, and being of a moderate thickness in proportion. The head is large, flat-tish, covered in front with small scales, and so very protuberant on each side at the hind part, so as to appear heart-shaped. The ground colour is brown, very beautifully marked from head to tail by numerous transverse rows of round ocellated red spots, surrounded by a white iris, and an exterior red one; the abdomen beneath is pale yellow; tail moderately slender and tapering to a point. It is a native of Arabia, and seems to be considered as a poisonous species.

OCCELLATUS. Chestnut-brown, with ocellated brown spots, and yellow abdomen. *Serpens guineensis rarissima argus diâa*, Seba.

In size resembles the viper; the head is covered with small scales; tail tapers to a moderately slender tip. This, according to Seba, is a native of Guinea, and is a rare species.

CHIAMELLA. Blue, the scales marked with a white spot, body beneath yellow. *Serpens americana chiamella diâa*, Seba.

A beautiful species about four feet and a half in length, found in the West Indian islands.

ZEYLONICUS. Abdominal feuta 180, subcaudal feales 80. Gmel. Gronov. *Coluber maculis majoribus brunneis*, Boddaert. *Serpens maculata ceylonica*, Seba. *Serpens americanus*, Scheuchz.

CATUS. White; the scales disposed in fours, black, and thickly crowded into patches. *Coluber catus*, Gmel. *Coronella catus*, Laur. Amph.

A native of America; it is observed of this snake that it lies in wait, and springs upon mice like the cat, whence its name.

CERVINUS. White, dotted in the middle with black, and branched with black at each end. Gmel. *Coronella virginica*, Laur. Amph. Inhabits America.

TESSELLATUS. Above alternately tessellated with black and brown; beneath black with white unequal spots each side; head long and shielded. Gmel. *Coronella tessellata*, Laur. Amph.

RUBER. Bright red with the spots alternately uniting; beneath white. Gmel. A doubtful species.

MOLUURUS. Abdominal plate 248, subcaudal scales 59. Gmel.

This kind inhabits South America, and resembles the Boa tribe, but is distinguished by the plates, and large scales on the head, as in the coluber genus.

MINERVÆ. Glaucons, with a brown dorsal stripe, and three on the head; abdominal scuta 238, subcaudal scales 90. Linn.

Length about eighteen inches; thickness exceeding that of a swan quill; the colour glaucous, with a broad, longitudinal, brown band down the back, and three longitudinal bands on the heads, two of which pass through the eyes. The head is oblong, ovate, convex, and smooth; the eyes large; tail slender, and measuring about a third of the whole length. Described by Linnaeus from a specimen in the museum Adolphi Friderici brought from the East Indies.

SCUTATUS. Black; scuta extremely broad; tail subtriangular. *Coluber scutatus*, abdominal scuta 190, subcaudal scales 50. Pallas.

Resembles the common snake, *coluber natrix*; the length is about four feet; colour entirely black, except that the abdomen is marked alternately on each side with a row of smallish square yellowish-white spots. The principal character consists in the scuta being remarkably wide, extending on each side in such a manner as to embrace two-thirds of the body. This species was observed by Dr. Pallas about the borders of the river Ural; it is found occasionally both in the water and on land.

HIPPOCREPTIS. Livid, spotted with brown, with a reversed lunulated or horse-shoe mark on the back part of the head. *Coluber hippocrepis*, abdominal scuta 232, subcaudal scales 94. Linn. Mus. Ad. Fr. *Natrix hippocrepis*, Laur.

Length about twelve inches; head of moderate size, marked by a transverse arched brown band between the eyes, and a larger horse-shoe-shaped mark on the back of the head; abdomen pale; tail tapering gradually from the tip. A native of America.

DOMESTICUS. Grey, spotted with brown; a bipartite black spot between the eyes. *Coluber domesticus*, abdominal scuta 245, subcaudal scales 94. Linn.

This is a native of Barbary, where it appears to be in some degree domesticated, being very common in the houses of the inhabitants, where it is kept to destroy the smaller kind of noxious animals. In its general appearance this snake is allied to the last-mentioned species, and like that is perfectly harmless.

DUBIUS. Abdominal scuta 141, subcaudal scales 24. Linn. Gron. Mus. Seb.

EXALBIDUS. Whitish with transverse broad spots mixed with black and white.

COLUBER EXALBIDUS, abdominal scuta 135, subcaudal scales 42. Gmel. *Coluber exalbidus maculis transversis latissimis ex et albo mixtis.*

CAHIRINUS. Grey, with large oval brown spots on the back, and small quadrangular notched spots on the sides; beneath silky white. *Coluber cahirinus*, abdominal scuta 230, subcaudal scales 82. Forst. Fn. Arab.

Inhabits Cahira. Length four feet and a half, and the thickness that of a finger; the head is flattish, subcordated, with two pale oblong scales on the crown,

CALAMARIUS. Livid, with transverse brown bands and linear points; beneath tessellated with brown and white.

Coluber calamarius, abdominal scuta 140, subcaudal scales 22. Linn.

This is a small snake, measuring about a span in length, the thickness that of a goose-quill; colour above livid, sprinkled with linear dusky spots, and marked by several dark narrow transverse bars; the head is very small, convex, and ovate; the tail short and terminating obtusely. This species inhabits America.

CARINATUS. Lead-coloured, with large ovate, porous scales; back carinated; abdomen whitish. *Coluber carinatus*, abdominal scuta 157, subcaudal scales 115. Linn. Mus. Ad. Fr.

A large species, growing to the length of five or six feet, and of a moderate thickness; tail tapering gradually to a point; tail much carinated, rising into a ridge on the top; colour deep bluish brown, or cinereous, inclining to lead-colour, paler or whitish underneath; scales very large and marked with numerous impressed points as if pierced with pin-holes. This is represented as a harmless species; it inhabits North America, and varies in colour.

GETULUS. Bluish-black, with linear yellow lines on the sides and bifid bands on the belly. *Coluber getulus*, abdominal scuta 215, subcaudal scales 44. Linn. D. Garden.

Inhabits Carolina, where it frequents moist woods and shady places, and preys on lizards. Length about three feet. An elegant species.

Plicatilis. Livid, with a stripe of dusky brown confluent spots on each side, the anterior ones ocellated with a white pupil. *Coluber plicatilis*, abdominal scuta 131, subcaudal scales 46. Linn. Amoen. Acad. *Cerastes plicatilis*, Laur. Amph. *Serpens balisalan-boeket*, Seba.

Length from two to three feet; the colour brownish-ellor or livid, with a dusky and lateral stripe of confluent spots immediately above the centre, the anterior ones of which have a white dot in the centre. The abdomen is pale, and marked with three or sometimes four rows of small dusky spots. The head is covered in front with large scales, snout obtuse; tail thick and rather blunt. The specimen described by Linnaeus measured, as above-mentioned, less than three feet, that described by La Cèpede, a specimen in the Museum of the king of France, was more than six feet long, from which it appears this snake is of a large size when full grown.

BATAEN. Spotted with black and white. Forst. Fn. Arab.

Described by Forskal as a native of Arabia; it is a foot in length and two inches in thickness, and is highly poisonous; the body swelling to a great size after being bitten by this snake.

HANNASCH. Entirely black. Gmel. Inhabits Arabia, a cubit in length, and as thick as a finger.

PURPURASCENS. Abdominal scuta 189, subcaudal scales 122. Gmel.

PICTUS. Abdominal scuta 172, subcaudal scales 142. Gmel. Boddaert.

HAFJE. Black, with oblique bands, and scales half white. *Coluber hafje*, abdominal scuta 207, subcaudal scales 109. Linn.

First described by Forskal. This snake inhabits Lower Egypt, is of a very large size, when irritated lifts up, and stretches out its head to bite.

PULLATUS. Bands of the body black with white dots; temples snowy with black spots; beneath white with black spots. *Coluber pullatus*, abdominal scuta 217, subcaudal scales 108. Gmel. A native of Asia.

CABACARAS. Blue, with the scales on the fore-part of the

the body elongated; those behind rhomboidal, and the neck transversely striated with black, *Coluber caracas*, abdominal scuta 190, subcaudal scales 125. Linn. *Serpens caracas brasiliensis singularis*, Seba.

A species of moderate size, length two feet and a half; the head rather large and oblong; snout obtuse; from behind each eye a black streak; colour pale blue, the posterior part of the body tinged with rose colour; the scales on the fore parts of the animal are of a narrow lengthened form, and on the hind parts rhomboid; neck and anterior parts elegantly marked by numerous transverse black lines; tail rather long, and gradually tapering to the tip. This species inhabits Brazil.

STOLATUS. Glaucous, with two whitish stripes, and quadrangular transverse brown spots between. *Coluber stolatus*, abdominal scuta 143, subcaudal scales 76. Linn. Laurenti. Seba.

Described from a specimen in the Museum Adolphi Fridenici as a poisonous snake, but it appears erroneously so. This species inhabits India. It is of the middle size, measuring from a foot and a half to two feet or more in length. The colour is bluish above, with two rather remote white lines down the back, and a continued series of brown, transverse, equidistant zones. The abdomen is pale or white, each scutum being marked on each side by two small specks; the head is covered with large scales, pale or bluish above, and of moderate size; tail rather short and tapering to a point.

AURORA. Orange coloured, with the dorsal band and abdomen yellow. *Coluber aurora*, abdominal scuta 179, subcaudal scales 37. Linn. Mus. Ad. Fr. *Cerastes aurora*, Laur. Amph. *Serpens aconius*, &c. Seba.

Length two feet and a half, and of moderate thickness in proportion; general colour dull orange, with a broad dorsal line of pale yellow; head rather large and covered with very large scales; tail rather short and tapering to an obtuse point. Inhabits South America.

PALLIDUS. Grey, speckled with brown, and marked with a double, interrupted black line on each side. *Coluber pallidus*, abdominal scuta 156, subcaudal scales 96. Linn. Amoen. Acad.

Linnæus describes this as being a foot and a half in length, and the thickness of a swan-quill, with the back slightly angulated each side. The head is roundish, much thicker than the neck and covered with large scales; the ground colour pale variegated with scattered grey spots and points. Inhabits India.

ORIENTALIS. Abdominal scuta 202, subcaudal scales 95. Gmel. Boddart. *Viperæ vera orientalis*, Seba. Inhabits Eastern countries.

OVIVORUS. Abdominal scuta 203, subcaudal scales 73. Gmel. *Guinipujura*, Pfl. Brasil.

We only know of this species that the plates and seals are as above described, and that the species inhabits America.

CENCHOA. Head globose; body whitish, with transverse rhomboidal brown bands. *Coluber cenchoa*, abdominal scuta 210, subcaudal scales 124. Linn. *Anguis de cenchoal americanus*, Seba.

A long and very slender species growing sometimes to the length of three or four feet, and yet scarcely exceeding the thickness of a swan-quill. The head is very large and nearly globular, the neck extremely thin; and the tail remarkably long, measuring nearly a third part of the whole animal, and gradually tapering to the extremity. The colour is white or yellowish, marked throughout the whole upper part from the head to the end of the tail, with nu-

merous transverse rhomboidal bars, or patches of brown, the points of which descend on each side.

FLAGELLUM. Extremely long, slender, and brown; abdomen pale. *Coacab-cobip snake*, Cateby.

This species measures from four to five feet; or even six feet in length, and is remarkably slender. Cateby, who describes this snake, speaks of it as an active nimble creature, running very swiftly and being perfectly harmless, "yet, says he, the Indians report, not without gaining many proselytes to their silly belief, that it will by a jerk of its tail, separate a man in two parts." This snake is a native of Carolina and Virginia.

AHAFTULLA. Bright blue-green and iridescent; abdomen pale, with a black streak across the eyes. *Coluber ahaftulla*, abdominal scuta 163, subcaudal scales 150. Linn. Amoen. Acad. *Natrix ahaetulla*, Laur. Amph. *Serpens ornatiflora amboinensis bouguatrorra*, Seba. *Long green Borneo snake*, Petiver.

The general colour is a bright blue green with a golden gloss, and highly iridescent. The length is from three to four feet, and the diameter about three-fourths of an inch; the head is covered above with large scales, and the snout is slightly elongated, though not pointed; the tail is somewhat angular, and of considerable length. It is an innocuous species, is found in several parts of India, and is esteemed one of the most beautiful of the serpent race.

AESTIVUS. Blue green, slender; snout obtuse; abdomen pale green. *Coluber aestivus*, abdominal scuta 155, subcaudal scales 144. Gmel. *Green snake*, Cateby.

Long and slender, the general length about three feet; the head is obtuse; colour of the upper parts blue green, slightly tinged with purple; tail very long and slender. This kind inhabits many parts of North America, where it frequents trees and preys on flies and other insects. Cateby, to whom we are indebted for the above particulars, adds, that it is easily reclaimed from its natural wildness, becoming tame and familiar, and affirms that some people carry it in their bosoms.

FILIFORMIS. Very slender, black; beneath white. *Coluber filiformis*, abdominal scuta 165, subcaudal scales 158. Linn. Mus. Ad. Fr. *Natrix filiformis*, Laur.

Length about twelve inches, and thickness that of a goose-quill; the colour above black, appearing like a broad dorsal stripe, beneath white; the head is ovate, twice the diameter of the body, above black and beneath white; tail about one-third the whole length, very slender, and sharp-pointed. A native of India.

TORQUATUS. Black above, beneath red, with a white collar round the neck. Shaw Gen. Zool. *Little black and red snake*, Edwards.

A small species, less than an earth-worm; head and upper parts jet black, and glossy; the head rather large, and covered with large scales; eyes flame-coloured. This is a native of Pennsylvania where it inhabits crevices of rocks, old walls, &c. and feeds on insects.

SIPEDON. Entirely black or deep brown. *Coluber sipedon*, abdominal scuta 144, subcaudal scales 73. Linn. A native of North America; described by Kalm.

DABOVA SNAKE, Le daboie, La Cepede.

Described by La Cepede who considers it as the species which in the kingdom of Juda, and some other parts of Africa, is regarded as a deity, and kept in temples consecrated to its worship. This superstition is said by the traveller, De Marchais, to have arisen from the following circumstance; the army of Juda being on the point of yielding to that of Ardra, it happened that a large serpent of this species made its appearance, which the chief priest probably

probably knowing it to be innocuous lifted it up in his arms and displayed as a kind of miracle, or at least as a propitious omen, persuaded the army again to rally, by which means a signal victory was obtained, and the animal was in consequence exalted into a divinity. It is said to arrive at a very considerable size, and is of a whitish colour, ornamented on the upper part throughout the whole length by a triple row of large oval rufous patches bordered with black, the head is rather large, and is covered with oval carinated scales similar to those on the rest of the animal. The individual described by La Cèpede was preserved in the Royal Cabinet, and measured three feet five inches in length.

BRASILIAN SNAKE, *La brasiliens*, La Cèpede.

Length three feet; head and body covered with oval carinated scales, snout terminated by a large and almost perpendicular scale rounded at the top, but emarginate at the bottom for the passage of the tongue; upper parts of the animal marked with large oval rufous patches bordered with black, and in the intervals between the large patches are several much smaller ones of a dusky colour; fangs very large. This is a native of Brasil, and La Cèpede believes may be about six feet in length when it has attained its full size.

TRIANGULAR-HEADED SNAKE, *La tête triangulaire*, La Cèpede.

Refembling the common viper in general appearance. The colour is greenish, with spots of different shapes on the head and body, uniting so as to form a regular band down the back; abdomen dusky, edged with white. The head is of a more triangular shape than usual, and covered with smooth scales, as are likewise the body. Its total length is two feet. This kind inhabits the island of Eulstatia.

PANTHER SNAKE, *La tigrée*, La Cèpede.

Allied to the last; length about eighteen inches; head as in the common viper. Colour of the upper parts whitish, rufous, with dusky spots bordered with black like those on the skin of the panther or leopard. The native country unknown.

The *coluber hydrus*, and *coluber laticaudatus* of Linnæus, are excluded from the above, and will be described under the article HYDRUS, the new genus to which they are referred by Mr. Schneider, and which we think it right to adopt. They are generally distinguished from the colubrine tribe by having the body slender in front, becoming gradually thicker, scaled, and the tail compressed. See HYDRUS.

COLUBRARIA *Insula*, in *Ancient Geography*, an island of the Mediterranean sea, near the Baleares. Pliny says that the soil engendered serpents. It is thought to be the present isle of Formentera, and the same with that which the Greeks called Opdiua, from *ὄπις*, *aphis*, a *Serpent*. It lies S. of Yicca, and was inhabited.

COLUBRINUM *Lignum*. See LIGNUM COLUBRINUM.

COLVEND *Copper-Mine*, in *Mineralogy*, Galway county, in Ireland; the specimens of ore found in this mine are very beautiful and deserving the attention of mineralogists and collectors. See Willmes's Mineral Kingdom.

COLVILLE, CAPE, in *Geography*, a cape on the east coast of New Zealand; lying in S. lat. 36° 26'. E. long. 194° 27'. This cape rises directly from the sea, to a considerable height, and is remarkable for a lofty rock, which may be distinguished at a very great distance. From the S. point of this cape the river Thames runs in a direct line S. by E., and is no where less than three leagues broad for the distance of fourteen leagues above the cape, and there it is contracted into a nar-

row stream, but continues the same course through a flat country, or broad valley, which lies parallel with the sea-coast. On the east side of the broad part of this river the land is tolerably high and hilly; on the west side it is rather low, but the whole is covered with verdure and wood, and has the appearance of great fertility, though there were in Cook's voyage, Nov. 1769, but a few small spots which had been cultivated. Six leagues within cape Colville, under the eastern shore, are several small islands, which, together with the main, seem to form good harbours; and opposite to these, under the western shore, the other islands of which, probably, good harbours may be formed. The river affords good anchorage, and is defended from the sea by a chain of islands, lying across the mouth of it, and on this account called by Cook "Barrier Islands;" these stretch N.W. and S.E. 10 leagues. The S. end of the chain lies N.E. between two and three leagues from cape Colville; and the N. end lies N.E. 4½ leagues from Point Rodney. "Point Rodney" lies W.N.W. nine leagues from cape Colville, in S. lat. 36° 15'. W. long. 84° 33'. The natives, residing near the river, are numerous; but they are a strong, well-made, and active people, and all of them paint their bodies with red ochre and oil from head to foot. Their canoes were large and well built, and adorned with carving.

COLUMB, ST. MAJOR, a market town of England, in Cornwall, in the hundred of Pider; 19 miles N.E. of Truro, and 245 W. of London. This town had for some years a communication with the sea coast by means of the Columb canal, but which is now filled up and disused. The Mewgan canal was also another abortive attempt at conducting a permanent navigation into this elevated neighbourhood for the conveyance of its China stoneware and potters' clay to the place of shipping.

COLUMB, *St. Minor*, a village of Cornwall, in the hundred of Pider: the situation of its church steeple was determined in the Government Trigonometrical Survey in 1798, by observations from St. Agnes's station, distant 58,448 feet, and bearing 44° 7' 57" S.W. from the parallel to the meridian of St. Agnes; and from Henbarrow station distant 53,942 feet; whence is deduced its latitude 50° 25' 21" 0 N. and its longitude 5° 1' 29.3" or 20" 5.9 W. of Greenwich.

COLUMBA, in *Ornithology*, the genus pigeon. Those have the bill straight, and descending towards the tip; the nostrils oblong, and half covered with a soft tumid membrane.

The pigeon tribe is divided into two families, the first having the tail even at the end, and of moderate length; the other cuneated and long.

* *Section*. Tail of moderate length, and even at the end. **OENAS**. Bluish; neck above glossy-green; double band on the wings and tip of the tail blackish. Linn. Fn. Succ. *Oenas*, or *Vinago*, Aldr. Will. *Stock dove*, Arct. Zool. *Holtstaule*, Friesch.

The rock dove inhabits Europe and Siberia, frequenting rocky places and ruins in retired situations.

DOMESTICA. Cincereous; rump white; band on the wings, and tip of the tail blackish. Linn. Fn. Succ. Scopoli. *Columba domestica*, Briff. *Common pigeon*, Ray, Albin, &c. *White rumped pigeon*, Lath.

The common, or domestic pigeon admits of an infinite number of varieties, many of which are remarkable for the beauty and elegance of their plumage; the principal varieties of these birds have been minutely regarded by Buffon and some other writers, and are enumerated in the following order in the Gmelinian *Sytlema Naturæ*.

LIVIA. Stock dove. Wings with a double blackish band, called by Buffon *biset*, and by Albin the *stock dove*.

SAXATILIS. Rock pigeon. Quill-feathers fulvous. *Columba rupicola* of Ray.

HISPANICA. Roman pigeon. Cere whitish and scurfy. *Columba romana* of Brisson. *Columba domesticus major*, Ray. *Pigeon romain*, Buff. *Greater tame pigeon*, Willughby.

DASYPUS. Rough-legged pigeon. Legs rough with feathers. *Rough footed dove*, Willughby. *Rauchsfisge taube*, Frisch.

CRISTATA. Crested pigeon. Head crested; legs hirsute and cinerous. *Pigeon huppé*, Buff.

NORWEGICA. Norway pigeon. Head crested; legs hirsute and snowy. Briff.

BARBARICA. Barbary pigeon. Area of the eyes naked and papillous; a double black spot on each wing. *Pigeon de barbarie*, Buff. *Barbary pigeon*, Ray.

CUCULLATA. Jacobine. Feathers of the hind head erect, reflected. *Columba anglica*, or *ruffica*, Gess. *Pigeon nonain*, Buff. *Jacobine*, Ray. *Zahne selbstaube*, Frisch.

HISPIDA. Laced pigeon. Down small, erect, and dispersed over the back and wings. *Columba crispata*, Aldr. *Pigeon frisé*, Buff.

TURBITA. Turbit pigeon. Feathers on the breast recurvate. *Pigeon à cravate*, Buff. *Turbit*, Ray.

LATICAUDA. Shaker pigeon. Tail erect, many-feathered, and broad. *Pigeon paon*, Buff. *Broad-tailed shaker*, Ray. *Pfaunttaube*, Frisch.

GYRATRIX. Tumbler pigeon. Throws itself over and over in flight. *Pigeon culbutant*, Buff. *Tumbler*, Ray. *Tummeltaube*, Frisch.

GALEATA. Helmet pigeon. Head and quill-feathers of one colour, and different from that of the body. *Pigeon casquée*, Buff. *Helmet pigeon*, Ray.

TURCICA. Turkish pigeon. Cere papillous and red. *Türkische taube*, Frisch. *Turkish or Persian pigeon*, Willughby.

TABELLARIA. Carrier pigeon. Cere broad, carunculated and whitish; eye-lids naked. *Carrier pigeon*, Ray, Willughby.

GUTTUROSA. Cropper pigeon. Breast inflated. *Pigeon grosse gorge*, Buff. *Cropper pigeon*, Ray. *Kropftaube*, Frisch.

EQUES. Light-horseman pigeon. Breast inflated; cere carunculated. *Light horseman pigeon*, Ray.

PERCUSSOR. Smiter pigeon. Strikes its wings violently in flight. *Smiter pigeon*, Ray, Willughby.

JUBATA. Turner pigeon. Crest hanging down from the crown like a mane. *Turner pigeon*, Will.

MACULATA. Spot pigeon. White tail and frontal spot of one colour. *Spot pigeon*, Willughby.

MONTANA. Orbits naked and red; body rufous, beneath yellow. Linn. *Columba rufa cayennensis*, Briff. *Perdix montana*, Ray. *Mountain partridge*, Sloane, Brown, &c. *Partridge pigeon*, Latham.

This bird, is eight inches and a half in length. The bill is red, with a black tip; the irides red, and surrounded with a warty skin of the same colour; the upper parts of the body are rufous, with a purplish hue; the under part of the neck, with the breast flesh colour; belly, sides, and vent, somewhat rufous; under wing-coverts, quills, and tail rufous; legs red, with the claws black. Those birds inhabit Cayenne; they build in trees which have the boughs hanging low, and line their nests with hair and cotton. They feed on the berries of the myrtle. Dr. Latham suspects, that this species is found in St. Helena, as a bird

is mentioned in Mr. Anderfon's catalogue, under the name of *columba perdix*, and which is said to be very common in that island. A kind of pigeon, conceived to be a variety of the above, is described by Edwards; the forehead is of a clay colour; the head and neck, reddish purple; back, wings, and tail, red brown, with a gloss of copper-colour; the fore part of the neck is reddish clay colour; breast, belly, thighs, and under tail-coverts, light clay colour; a white mark on each side under the eye, and another at the side of the throat, and just at the joint of each wing.

TETRAOIDES. Head, and neck black, with white margin. Scop. *Tetraoid pigeon*, Lath.

The only account we have of this bird, is from the work of Scopoli. Ann. 1. p. 125. He informs us it equals the red-legged partridge in size, and that the head and neck are black, and encompassed with a white margin, as in that bird. The description was taken from a bird living in a menagerie.

LEUCOCEPHALA. Bluish; orbits and crown white. *Columba leucocephala*, Linn. *Columba minor, capite albo*, Ray. *Columba saxatilis jamaicensis, le pigeon de roche de la Jamaïque*, Briff. *Bald pate pigeon*, Sloane. *White crowned pigeon*, Arct. Zool.

Breeds in vast numbers among the rocks on the coasts of Jamaica, St. Domingo, and the Bahama islands; and subsists on the berries of the sweet wood. The length is ten inches and a half; the bill red with a white tip; the eyes surrounded with a white skin, the irides yellow; crown of the head white, beneath changeable; neck green and blue, varied with a gloss of copper; the quill, feathers, and tail are brown; the legs red, with grey claws.

LEUCOPTERA. Orbits naked, and blue; tail feather cinerous, with the tips white, the middle ones fulvous, Linn. *Columba indica*, Briff. *Brown Indian dove*, Edwards. *White winged dove*, Brown, Jam.

This bird is the same size as the common turtle, and measures in length eight or nine inches. The bill is dusky black. A fine blue skin furrounds the eyes, and according to the figure in the plates of Edwards, goes on to the base of the upper mandible. The irides are crimson; the forehead, cheeks, and front of the neck and breast, pale rufous brown; hind part of the head and neck dull brown. The upper part of the body is dark brown, with a mixture of blue; greater wing-coverts the same, but the outer margins, and tips are white. The two middle tail feathers, are the same colour as the back, the rest dull ash, with white tips; legs red, with black claws. The white winged dove, inhabits the East Indies, and is observed to stir up its tail at intervals, like the common wagtail.

FUSCA. Fulvous; eyes black; neck and breast white, undulated with black. Jacq. Beyr.

This is the size of the turtle, and inhabits Carthage, in America. Latham considers it as a variety of the last.

MARTINICA. Somewhat violaceous; abdomen reddish; quill feathers-rufous on the inner webs. *Columba martinica*, Linn. *Columba violacea martinica*, Briff. *Pigeon violet de la martinique*, Buff. *Martinico pigeon*, Lath.

About the size of a turtle; the length nine inches and a quarter; the bill is red, and the eyes are surrounded with crimson tubercles; the head, neck, and upper parts of the body, are chestnut glossed with violet; the under parts of the body, more or less rufous; the quills the same as the upper, but on the outer edges only, the inner rufous; the tail feathers, the same on both margins; legs reddish with brownish claws. Inhabits Martinico. *Le pigeon de la Martinique* of Brisson, and which Buffon calls *Le pigeon rouge de Cayenne*, is considered as a variety or rather the female

male of the above mentioned bird; it is of a reddish brown colour, with a collar of golden violet; the wings are spotted with black; lateral tail feather black at the end, with the tip white. Inhabits also Martinico.

JAMAICENSIS. Purplish brown, beneath white; tail feathers blue, terminated by a white line. *Columba jamaicensis*, Linn. *Pigeon de la Jamaïque*, Buff. *Columba minor ventre candido*, Raii. *White bellied pigeon*, Lath. *White bellied dove*, Sloane.

The length of this species is nine inches. The nostrils are much elevated, and form two tubercles at the base; the top of the head, with the under parts of the neck and body are white; hind part of the neck varied with blue and purple; back, rump, and upper tail-coverts, purplish brown, with a light reddish tinge. This bird is found in the savannas of Jamaica, in the month of January. It feeds on berries, frequents trees, and has a mournful note, which is sometimes very loud and disagreeable.

CORONATA. Bluish, above cinereous; orbits black; erect crest; shoulders ferruginous. Gmel. *Columba nungens*, Scop. Ann. *Phasianus cristatus indicus*, Briff. *Faisan couronné des Indes*, Buff. *Gouris de la nouvelle Guinée*, Sonnerat. *Grest crowned Indian pigeon*, Edwards.

The crowned pigeon is nearly the size of a turkey, in which particular, it far exceeds any other species of the same tribe. Brisson has placed it with the pheasants, and his example is followed in the *planches enluminées*, but the bird possesses in every respect, the manners of the pigeon tribe; its note is cooing and plaintive like those birds, only louder in proportion. We are told, the mournful notes of these birds, alarmed the crew of Bougainville very much, when they touched in their voyage at one of the islands they inhabit, as they mistook it at first for the cries of the human species. The crowned pigeon, we are assured by Scopoli, has been known to build its nest and lay eggs in Europe, though the young were not hatched; they made a nest on trees in the menagerie, where they were kept, composed of hay and stalks. The female it is observed never fat, but stood upon the eggs, and it is supposed by Scopoli, that it must be from this cause alone, these eggs proved abortive. In the East Indies, they are occasionally kept in court yards like other domestic poultry.

CRISTATA. Reddish brown, crested; under side, head, and neck, black; back and tail green; front with six very long, erect feathers. *Columba cristata*, Gmel. *Le zontoul de Malacca*, Sonnerat. *Uncannon bird from Malacca*, Phil. Trans. *Lesser crowned pigeon*, Lath.

The bill of this species is conical and rather bent; the colour black, except the under mandible, which is yellow at the base. On the fore part of the head, are six very long black bristly hairs, which stand upright, and may be depressed or elevated by the bird at pleasure; on the back part of the head, is a crest of a gilded red colour, composed of hard and stiff feathers. The space between the two crests is white, forming a band across the head. The eyes are encircled with stiff white feathers. The legs are yellow; the toes are separated at their origin, and the hind claw is delicate of a claw. Size of the common pigeon. A variety of this bird, formerly in the Leverian Museum, measured ten inches in length: the bill was yellowish, with the tip black; the back part of the head, crested as in the former; the forehead white, passing backwards on each side beneath the crest; the eyes were surrounded with feathers of a reddish colour, which passed backwards in a point; and the head and neck were of a dark reddish brown; breast, belly, and vent, violet black; wings blue reddish brown; back, rump, and tail, dull brownish green; tail-coverts long and falling

over the tail; legs reddish yellow, with black claws. The history of this last bird is unknown, but it is considered as a variety, or perhaps a sexual difference.

POMPADORA. Green; wings purplish, quills black; chin and throat yellow. Gmel. *Pompadour pigeon*, Lath. Gen. Syn. Brown. Illustr. *Yellow faced pigeon*, Brown (fem).

The Pompadour pigeon is a native of India, and appears to be most common in the island of Ceylon. It is constantly seen on trees, and for the most part on those known by the name of *Waringia grathebris*, on the berries of which it delights to feed. They are shot by Europeans, who esteem them excellent eating; the natives take them with bird-lime. The size is less than that of the common turtle; the back, breast, and belly, are pale green; the wing-coverts of a fine pompadour colour; tail green; and legs red. The female is paler, and has the wing-coverts the colour of the body. These birds are common in the country about Bangalore, where they are called *coovla*; it is said to have a whistling note, resembling that of the thrush.

ERYTHROPTERA. Black; eye-brows, and front white; neck above, shoulders and wing-coverts garnet colour; tail from the base to the middle cinereous; legs brown.

Length nine inches and a half; tail two inches and a half long and even at the tip; legs brown.

This inhabits the island of Eimeo. Another bird much resembling this, and supposed to be the female, was met with at Oahete; the forehead, throat, front of the neck and breast, were white, the hind part of the neck dusky; over the eye a ferruginous streak, passing a little downwards on each side of the neck; the back dusky black; belly dusky; quills and tail blackish. Another analogous kind, found in the South Sea islands, is of a reddish black colour, with the breast, and eye-brows white, and the legs red.

ALBICAPILLA. Green; crown hoary; sides of the neck chestnut with a golden gloss; greater quill feathers and tail black. *Columba albicapilla*, Gmel. *The pigeon vert à tête grise d'Antique*, Sonnerat. *Grey headed pigeon*, Lath.

A native of the isle of Panay. Its size is equal to that of the common pigeon; the bill dull red with the irides yellow; the lesser quill feathers are green, with a metallic lustre, and on the arm-pits is a semi-circular spot, half grey, and half green; the legs are dull red.

INDICA. Body purple; shoulders green; cap bluish. *Columba indica*, Linn. *Palumbus amboinensis*. *The pigeon ramier d'amboina*, Briff. *Green winged pigeon*, Lath.

Size of the turtle; the bill scarlet and ten inches in length; nostrils bluish; forehead white, with a streak of the same through the eye. The sides of the head, neck, and breast is reddish, the hind part deepest; upper part of the back and wing-coverts green gold, glossed with coppery; ridge of the wing spotted with white; lower part of the back, rump, and upper tail-coverts reddish brown; quills brownish, and rufous next the base; tail three inches long; two middle tail feathers black; the rest cinereous, with the tips black; legs red, with black claws. A native of Amboina. Jacquin describes a variety of this bird, having the quills and tail feathers green; wing-coverts violet; and the rump and vent blue.

PURPURATA. Green; cap scarlet; vent fulvous; head, neck, and collar white. *Columba purpurata*, Gmel. *Purple-crowned pigeon*, Lath.

A general inhabitant of the islands in the Pacific ocean, and subject to considerable variations in the colour of its plumage. The natives of Tongo Taboo call it *kurakuru*, those of Otaheite Oopa, and Oopara. It lives on the banana, and is easily tamed.

JAMBOOS. Green; front red; breast white. *Columba jambu*, Gmel. *Pooni jamboa*, Marsd. *Jambo pigeon*, Lath.

Rather smaller than the common dove; the bill is yellow, the fore part of the head of a deep pink, resembling the colour of the blossoms of the jamboo, whence its name of jamboo pigeon; the back, wings, and tail are green, with the breast and crop white; the eyes are yellow, and from the orbits to the breast extends a white streak, edged on one side with green, and on the other with pink. This is a native of Java, and feeds chiefly on berries.

RUBRICAPILLA. Violet-black; cap and orbits of the eye naked and red; neck, upper part of the back, and breast greyish. *Columba atricapilla*, Gmel. *Le pigeon violet à tête rouge d'Antique*, Sonn. *Red crowned pigeon*, Lath.

Found in the isle of Panay by M. Sonnerat. This bird is the size of the jacobin pigeon. The bill is grey. At the base of the upper mandible is a fleshy membrane of a bright red colour entirely encircling the eye; and legs grey.

PURPUREA. Green; head and neck purplish; breast fulvous; vent scarlet. *Columba purpurea*, Gmel. *Purple pigeon*, Brown, Lath.

Size of the common wood-pigeon. The front is pale green; breast orange; back, scapulars, and belly light green; quills dusky. A native of Java where it is called *janan*.

EIMENSIS. Greenish brown; front, collar, and beneath vinaceous; crown and neck above brown; double band on the breast purple and white. *Columba eimensis*, Gmel. *Purple breasted pigeon*, Lath. Inhabits the island of Eimeo. Length fourteen inches.

VERRANS. Green, beneath yellow, outer margin of the wing pale yellow. *Columba verrans*, Linn. Gmel. *Le pigeon vert de Philippines*, Buff. *Columba madera spatana*, Raii Syn. *Le pigeon vert male de l'isle de Luçon*, Sonnerat. *Parrot pigeon*, Lath.

Inhabits the islands of Manilla and Panay. The female is of a greenish-grey, and greenish yellow beneath. The species is rather larger than the turtle.

AROMATICA. Green-olive; back bay-colour; double bar on the wings yellowish and black; quill feathers black, with yellow edges. *Columba aromatica*, Gmel. *Columba viridis amboinensis*, Briff. *Pigeon vert d'Amboine*, Buff. *Aromatic pigeon*, Lath.

Size of the common turtle; length ten inches and a half. The bill is greenish; crown grey; tail beneath black at the base, and at the tip whitish; legs grey or red. A native of Amboina.

ST. THOMAE. Green; vent yellow; bill curved, blue, and red at the base. *Columba viridis S. Thomae*, Briff. *A wild pigeon from St. Thomas's island*, Will. Ray. *St. Thomas's pigeon*, Lath.

The size of the common pigeon; the eyes are black, surrounded by blue orbits, with the wings and tip of the tail brown. Inhabits the island of St. Thomas.

CURVIOSTRA. Green; beneath yellowish; vent white; back and shoulders bay; wings with two yellow bars; middle tail feathers green; lateral ones cinereous with a black band. *Columba curvirostra*, Gmel. *Hook billed pigeon*, Lath.

Inhabits the isle of Tanna in the South Seas; the bird, supposed to be the female of this species, differs from the male in having the back and shoulders green, and the under tail-coverts, together with the vent white.

TANNENSIS. Green; wing-coverts spotted with white; secondary quill feathers edged with yellow at the tip. Lath.

Described from a drawing in the possession of Sir Joseph

Banks. The bird is eleven inches in length, and inhabits the isle of Tanna. This is, perhaps, only a variety of the last.

CYANOCEPHALA. Vinaceous-brown; head and throat blue, with a white band between the eyes. *Columba cyanocephala*, Linn. *Turtur jamaicensis*, Briff. *Tourterelle de la Jamaïque*, Buff. *Turtle dove from Jamaica*, Albin. *Blue-headed turtle*, Lath.

A native of the island of Jamaica, Cuba, and other warm parts of America. Size of the common pigeon.

PACIFICA. Back greenish brown; head, neck, breast, and abdomen cinereous white; tail blackish. *Columba pacifica*, Gmel. *Ferruginous vented pigeon*, Lath.

The length of this species is thirteen inches and a half; the nostrils are gibbous, the throat whitish; breast vinaceous, and the legs either red or brown. It is a native of the Friendly Islands. A variety of this species has the head, neck, breast, and belly whitish; back, wing-coverts, and tail greenish, and the bill gibbous at the base. This inhabits Otaheite and Tongataboo.

MEXICANA. Fulvous, orbits scarlet; breast and tip of the wings white. *Columba mexicana*, Briff. *Pigeon du Mexique*, Buff. *Cebolot*, Ray. *Mexican pigeon*, Lath.

A native of Mexico; the irides are black; the legs red.

NAEVIA. Above fulvous, spotted with black; beneath pale fulvous; under tail-coverts, and beneath the wings, cinereous. *Columba naevia*, Gmel. *Oenus mexicana*, Briff. *Hoiolot*, Ray. *Black spotted pigeon*, Lath.

Inhabits the same country as the last, and frequents woods; size of the common pigeon.

HOILOT. Rufous purple; lesser wing-coverts white; bill and legs scarlet. *Columba Hoiolot*, Gmel. *Columba mentana Mexicana*, Briff. *Hoiolot*, Ray. *White-shouldered pigeon*, Lath. Inhabits the mountainous parts of Mexico.

CAERULEA. Blue; beneath, bill, legs, and wing-coverts red. *Columba caerulea*, Gmel. *Columba caerulea mexicana*, Briff. *Flacohoiolot*, Ray. *Blue pigeon*, Lath.

Size of the domestic pigeon; and an inhabitant of Mexico.

PALUMBUS. Cinereous; tail feathers black on the posterior part; primary quill feathers whitish on the outer edge; neck on each side white. *Columba palumbus*, Linn. *Le pigeon ramier*, Buff. *Colombo fassaiuolo*, Cetti. *Ringel tauben*, Gunt. *Ring pigeon*, Lath.

Inhabits the woods of Europe and Siberia, and builds its nests on trees.

ENEA. Legs feathered halfway down; beak and legs greenish; body brassy. *Columba enea*, Linn. *Palumbus moluccensis*, Briff. *Pigeon ramier des moluques*, Buff. *Nutmeg pigeon*, Lath.

Inhabits the Molucca islands, and feeds on the nutmeg; its size is equal to that of the ring-pigeon. A variety of this species is described by Sonnerat, under the title of *Pigeon cuivre mangeur de muscade*, and which appears to have been found in New Zealand; another variety has been met with at Amsterdam island, where it is called *Orooba ya*.

ALBA. Body white; primary quill-feathers and tip of the tail black. *Columba alba*, Gmel. *Le pigeon blanc mangeur de muscade*, Sonnerat. Voy. *White nutmeg-pigeon*, Lath.

This bird inhabits New Guinea, and is described by Sonnerat, who mentions its feeding on nutmegs, observing, that it is probably only the outer skin which serves them for nourishment, as the nut itself is voided whole, and so little altered, that, after passing through the organs of digestion, it is not rendered less fit for vegetation; and hence it happens, that those birds flying from one island to another, dis-

perfe, and fow the feeds of thofe valuable plants in every part they frequent. A variety of this fpecies having the tail white inftead of black.

GUINEA. Orbits naked and rufous; wings spotted with triangular fpoats of white; tail-feathers black at the tip. *Columba guinea*, Linn. Gmel. *Pigeon de guinée*, Buff. *Le tourterelle du cap de Lun efpérance*, Sonner. *Triangular spotted pigeon*, Edwards, Lth.

Inhabits the rocky parts of Africa, and is a particular common about the Cape of Good Hope. The fize is that of the wood-pigeon; its bill is brown, irides yellow; head and neck cinereous, upper parts gloffed with violet and purple; rump and belly white.

CARIBÆA. Blueifh; abdomen white; head, lower part of the neck, and breast purplifh; tail falciated tranfverfely with black. *Columba caribæa*, Gmel. *Columba cauda falcata notata*, Ray. *Ring-tail pigeon*, Lath.

A bird the fize of the ring-pigeon, and which is found in all the woods of the Caribbee iflands. It is in great eftem for food, each bird felling for the table at the price of a dollar. In Jamaica it is frequently called the mountain pigeon. An fupposed variety of this bird is defcribed by Jacquin, which has the tail cuneated, the orbits bare of feathers, and yellowifh, and the body blueifh; the tail of the laft-mentioned bird is as long as the body, and is deftitute of the black band fo confpicious in the ring-tail pigeon. We conceive this ought fcarcely to be confidered as a mere variety.

ZEALANDICA. Red; abdomen white; rump blue; tail black. *Columba novæ zelandiæ*, Gmel. *New Zealand pigeon*, Lath.

A native of New Zealand, obferved by the Englifh circumnavigators, in Dufky bay, where the inhabitants call it *Hagarreroo*. The length of this bird is eighteen inches. The bill and irides are red; quill-feathers dufky; vent blueifh.

BRUNNEA. Cap, neck above, back, and wing-coverts brown; breast, neck beneath, and the rump fhining green. Lath. Inhabits New Zealand; the bill and legs are fanguineous.

CHALCOPTERA. Brown-cinereous, edged with rufous; front and chin white; a bright copper-gold band acrofs the wing, and a black one near the tip of the tail. *Columba chalcoptera*, Lath. Ind. Orn. *Bronze-winged pigeon*, Phil. Bol. Bay.

This beautiful bird is a fpecies recently difcovered, and was firft defcribed by governor Phillips, in his account of Botany bay. It is the fize of the common wild pigeon, and appears to be found chiefly in Norfolk ifland. The moft remarkable character of the bird is the rich band of coppery-gold acrofs the wings; a few fpoats of the fame colour occurs alfo on the leffer wing coverts. Its bill and legs are red; quill-feathers brown, beneath rufous; the two middle tail-feathers brown, the reft pale lead colour.

MADAGASCARIENSIS. Legs feathered; tail violaceous; body blue-black. *Columba madagafcarienfis*, Linn. *Le fouinga*, Buff. *Pigeon ramier bleu de madagafcar*, Pl. Enl. *Madagafcar pigeon*, Lath.

The length of this fpecies is ten inches and a half; its fize that of the common pigeon. The bill and legs are red; the eyes placed in a bare reddifh fkin; the feathers on the neck are narrower than the others, and have a mixture of afh.

AUSTRALIS. Green; abdomen, vent, and thighs spotted; fhoulders violet. *Columba australis*, Linn. *Palumbus viridis madagafcarienfis*, Buff. *Pigeon ramier verd de madagafcar*, Buff. *Madagafcar pigeon*, Lath.

A native of Madagafcar. Length twelve inches; bill

lead colour; eyes and legs fanguineous; pofterior part of the abdomen and thighs spotted with black. Perhaps a variety of the laft.

FRANCIÆ. Blue; orbits naked; rump and tail red; feathers of the neck long, narrow, and pointed at the end. *Columba franciæ*, Gmel. *Le pigeon hollandais*, Sonnerat. *Hacked pigeon*, Lath.

This bird confiderably exceeds the ring-pigeon in point of fize. The bill and irides are crimfon; the feathers of the neck, neck, and breast are long, narrow, pointed, of compact texture, and with a highly polifhed furface. It inhabits the ifle of France, and is never eaten, the fefh being reputed poifonous.

MACULATA. Deep green; body above spotted with whitifh; belly blackifh; tail black, with the tip ferruginous. *Columba maculata*, Gmel. *Spotted green pigeon*, Lath.

Defcribed by Dr. Latham from two fpecimens, one in the collection of general Davies, the other in that of fir Jofeph Banks. The length is twelve inches. The bill black, with the tip yellow; the general colour is dark green, with a gloffy furface; the head and neck darker than the reft. The feathers of the neck are long and narrow; every feather of the wings and fcapulars are marked with a pale cinereous-white, and fub-triangular fpot; the quill-feathers are black, with the tip cinereous; the legs are brown, and are covered half way down with downy feathers. The native place of this fpecies is unknown.

NICOBARICA. Tail white; body black; wings blue; back fhining green; feathers of the neck long. *Columba nicobarica*, Linn. Gmel. *Pigeon de nincombar*, Eull. *Nicobar pigeon*, Albin.

This is one of the moft fplendid of the pigeon tribe. Its fize is that of the common pigeon; the bill is dufky; the irides hazel; head, neck, breast, belly, and thighs, and under tail-coverts dark blueifh-purple; the feathers on the neck are long and pointed, and with the upper parts of the wings are of the fineft green colour, gloffed with the moft vivid hues of red, blue, copper, or golden. The tail and upper coverts are white; legs reddifh. The female is diftinguifhed by the plumage being lefs brilliant and gloffy, and in having the pointed feathers of the neck fhorter than in the male. Thofe birds inhabit the ifle of Nicobar.

SPECIOSA. Ferruginous; tail blackifh; neck and breast varied with rufous, white, and purple undulations. *Columba fpeciofa*, Gmel. *Le pigeon ramier de Cayenne*, Buff. *Le ramiret*, Ib. *Scallop-necked pigeon*, Lath.

Rather larger than the common turtle. The bill is red, covered with a white cere; the head ferruginous; neck and breast varied with rufous white and purple, each feather being rufous, with a white mark, and the margin blue, giving the whole plumage in this part a beautiful undulated appearance; the back and wings are ferruginous; quills darker than the reft; tail dufky black, and rounded; the legs red. The female is marked in the fame manner as the male, but is much duller in colour. A native of Cayenne.

TURTUR. Tail-feathers white at the tip; black grey breast fefh-colour; on each fide of the neck a patch of black feathers, white at the tip. *Columba turtur*, Linn. *Turtur auritus*, Ray. *Palumbus turtur*, Klein. *Tourterelle*, Buff. *Tortora*, Zinnar. *Common turtle*, Penn.

The turtle is a general inhabitant of Europe, China, and India, and appears to be moft frequent in Turkey and the fouthern parts of Ruffia, and in the rocky country beyond the lake Baikal. In England thofe birds are not uncommon during the fummer, but it is only in this feafon that they

they are observed with us, for they arrive late in the spring, and depart in autumn. They build on the highest trees in thick and deep forests, and lay two eggs like the other kinds of pigeons.

It is related by baron de Tott, that this bird is highly favoured in the Turkish dominions, where it is extremely plentiful, government allowing a certain rate per cent. on the duty imposed on corn that those birds may be allowed to feed unmoled. A crowd of them constantly alight on the vessels which cross the port of Constantinople, and carry the corn uncovered either to the mills or magazine, and the boat-men never oppose them. This permission to feast on the grain brings them in great numbers, and familiarizes them to such a degree, that they are seen standing on the shoulders of the rowers watching for a vacant place where they might fill their crops in turn. The same custom is mentioned by Sonnini.

"In the Leverian Museum (says Dr. Latham) is a bird shot in Buckinghamshire, which differs from the common turtle in having almost the whole side of the neck black, instead of a patch only, and instead of each feather being tipped with white, there is a round spot of white on each very near the end, giving the sides of the neck a most beautiful appearance." There were three of those elegant birds in the Leverian Museum, including the male, female, and young, all which are now preserved in the London Museum. Those we are persuaded ought rather to be considered as a distinct species than a variety of the turtle. Two others, considered as varieties of this bird, are the Portugal dove of Albin, and *La tourterelle grise de l'isle de luçon* of Sonnerat, the first inhabits Portugal, as its name implies, and is of a brown colour, with the spot on the side of the neck varied with black and white, and the lateral tail feather on the outer side tipped with white; the other is distinguished principally by having the two middle tail-feathers black, and the lateral ones white. This inhabits Manilla. Besides the above Dr. Latham describes *La tourterelle brune de la Chine* of Sonnerat as a further variety of this bird in his "Synopsis," but in the "Index Ornithologicus," it is enumerated as a species under the name of *orientalis*.

ORIENTALIS. Griseous brown; feathers on the sides of the neck black, with pale cinereous tips; band on the wings yellow. *Chinese turtle*, Lath.

A native of China, and of the size of the common turtle; the bill and irides are red; head, neck, breast, and back dirty brownish grey, palest on the breast; wings brown; rump and tail deep cinereous grey; belly and thighs vinous grey; legs red.

ÆGYPTIACA. Testaceous-flesh colour; chin spotted; the feathers black, and two lobed, truncated and ferruginous at the tip. Fork. Fn. Arab.

This bird is described by Forkal, who informs us it frequents houses in Egypt; the bill is black; head violet and flesh-colour; orbits naked and bluish; back cinereous; breast violaceous flesh-colour; belly and thighs whitish; wings brown; the two outermost tail feathers cinereous at the base, black in the middle, and the remainder white; the two next on each side cinereous at the base, black in the middle, cinereous beneath, and whitish at the tips, the fifth on each side brown, in the middle pale black, the two middle ones wholly brown; legs flesh-colour.

SURINAMENSIS. Cinereous, beneath white; chin varied with black and green; bill blue. *Columba surinamensis*, Gmel. *La tourterelle*, Sonnerat. *Surinam turtle*, Lath.

Length ten inches; the bill long and slender, of a fine deep blue without, and red within; and the legs red. The species is thus described by Fermin, who informs us it is a

common bird in Surinam. It lays eggs twice in a year, making its nest in woods on the highest trees; the flesh is juicy and delicious.

RISORIA. Above yellowish, beneath white, with a black crescent on the back of the neck. *Columba risoria*, Linn. *Turtur torquatus*, Briss. *Turtur indicus*, Aldr. *La tourterelle à collier*, Buff. *Indian turtle*, Albin. *Collared turtle*, Lath.

Exceeds ten inches in length; the female differs from the male in having the colours less vivid, and inclining to grey. Inhabits India, and the southern parts of Europe.

La tourterelle grise de la Chine of Sonnerat is considered as a variety of this bird; it is of a brown colour, beneath vinaceous grey; crown grey; black crescent on the neck, above spotted with white; lateral tail-feathers black, spotted with white. This kind inhabits China and Madras.

La tourterelle mule, turtur hybridus of Briss. is also of this species; or, at least, a mixed breed between the common and collared turtles. The head, neck, and breast are vinaceous; the back dull reddish-ash-colour; belly, beneath the wings, and tip of the tail as in the last mentioned bird; the quills are brown; legs sanguineous.

SINICA. Fuscous, fasciated with black; abdomen somewhat sanguineous; wings and bill black. *Columba sinica*, Linn. *Turtur sinensis striatus*, Briss. *Tourterelle rayée de la Chine*, Buff. *Dove* from China, Albin. *Striated turtle*, Lath.

This is a native of China, and is the size of the last. The bill is bluish ash-colour; the irides white; crown of the head ash colour; tail palish brown; legs red, and claws white.

STRIATA. Orbits and lores white; body cinereous, fasciated with black; beneath rufous. *Columba striata*, Linn. *Turtur indicus striatus*, Briss. *Tourterelle rayée des Indes*, Buff. *Barred turtle*, Lath.

Length nine inches and a half; the bill three quarters of an inch long, and of a pale horn colour; the nostrils pale blue; irides blue grey. The eyes are placed in a bare white skin, which passes to the nostrils; forehead, cheeks, and throat pale blue; top of the head and hind head incline to rufous; upper part of the neck, the back, and wing-coverts are brownish ash marked with transverse arcuated black bands; sides of the neck and body bluish, crossed with blue, black, transverse slender lines; fore part of the neck, breast, belly, and thighs tinged with rose-colour; under tail-coverts white; legs pale red; claws brown.

This bird is frequent at Malacca and the island of St. Helena; and is also found, according to Jacquin, in South America.

SURATENSIS. Griseous; neck above black; hind head white; nape banded with rufous; quill-feathers black; back, rump, and tail obscure grey. *Columba suratensis*, Gmel. *La tourterelle de Surate*, Sonner.

About ten inches in length. The bill is black; the irides and legs red. It is a native of Surat in the East Indies.

CAMBAYENSIS. Grey, beneath white; head somewhat vinaceous; collar beneath black, varied with rufous; lateral tail-feathers half black and half grey. *Columba cambayensis*, Gmel. *La tourterelle grise de Surate*, Sonner. *Cambayana turtle*, Lath.

Described after Sonnerat as a native of Surat, and other provinces of Cambaya. Its size is that of the collared turtle.

VRIDIS. Brassy, fore part of the neck purple-violet. *Columba viridis*, Linn. *Turtur viridis amboinensis*, Briss.

Le turvert, Buff. *La tourterelle à gorge pourprée d'amboine*, Pl. Enl. *Green turtle*, Lath.

The length of this bird is seven inches and three quarters. The bill is red; fore part of the head and throat ash-colour; the hind head and back part of the neck, back, rump, upper tail and wing-coverts, breast, belly, sides, and thighs green gold, glossed with copper; the greater wing-coverts have the outer edges of the feathers at the tip sulphur-coloured; under wing-coverts ash, quills blackish; tail blue-green, glossed with copper; the legs are red, and covered half their length with feathers; the claws grey-brown. This bird inhabits Amboina.

MALABARICA. Cinereous, beneath white; middle wing-coverts with oval spots; lateral tail-feather black two-thirds their length from the base, the remaining part white. *Columba malabarica*, Gmel. *Tourterelle de la cote de malabar*, Sonner. *Melbar turtle*, Lath.

A species of the size of the last, and also described by Sonnerat. It inhabits the coast of Malabar. The bill and irides are red; the head, back, and wings are of a pale cinereous-grey; the neck and breast grey, tinged with vinaceous; the two middle tail-feathers grey; the belly white; and legs red.

MELANOCEPHALA. Green; head somewhat cinereous; head blueish-ash; hind head black; chin and throat yellow; vent orange; six middle-tail-feathers green; the outer ones on each side fine crimson. *Columba melanocephala*, Zool. Ind. *Turvert*, Buff. *Tourterelle de Batavia*, Pl. Enl. *Black-capped pigeon*, Ind. Zool.

Found in the island of Java. The length is nine inches and a half; the bill black, short, and yellow at the tip; the tail is of a somewhat embeated form; and the legs are black.

JAVANICA. Green; head and neck vinaceous red; abdomen dusky; primary quill-feathers fuscous. *Columba javanica*, Gmel. *Le turvert*, Buff. *La tourterelle de java*, Buff. Pl. Enl. *Javan turtle*, Lath.

Length nine inches; the bill pale red; covered with a white cere; tail dusky beneath; legs red. Inhabits Java.

CERULEOCEPHALA. Green, beneath red; crown blue; wings and tail black-blue. *Columba ceruleocephala*, Lath. *Columba cyanocephala*, Gmel. *Blue-crowned turtle*, Lath. Syn.

Size of the last; it is an inhabitant of China, where it is called by the natives *Taupam*. Common also in the island of Cuba, where it is caught in traps, and brought to the markets in great numbers as an article of provision.

AFRA. Grisfous brown, beneath whitish; exterior tail-feathers, at the outer base, and the spot at the tip white; wing-coverts with violet-azure spots. *Columba afra*, Linn. Gmel. *La tourterelle du senegal*, Buff.

The length of this bird is eight inches. The bill is reddish; top of the head ash-coloured; hind part of the neck, back, wing-coverts, and rump grey-brown; throat whitish; fore part of the neck and breast pale vinaceous; the belly, sides, thighs, and under tail-coverts dirty white; the upper tail-coverts are grey-brown, with the tips blackish; quills brown, with the inner webs rufous; on the wings are some spots of green gold-colour, glossed with violet; the tail is two inches and three quarters in length; the two middle tail-feathers blackish brown, the rest grey-brown, with the ends blackish; the legs are red, with brown claws. This is a native of Senegal, and is the *Columba senegalensis* of Brisson, but not of Linnæus; the latter writer describes the next species under that name.

SENEGALENSIS. Reddish-brown, beneath white; neck beneath spotted with black; three outer tail-feathers white

on the lower half. *Columba senegalensis*, Linn. *Turtur guttata maculato senegalensis*, Brisson. *Tourterelle à gorge tachée de senegal*, Buff. *Senegal turtle*, Lath.

The length of this species is nearly ten inches; the bill is blackish, the head, neck, and breast vinaceous; upper part of the back brown, lower cinereous; the six middle feathers cinereous brown; the three others on each side dark-ash from the base to the middle, and from thence to the ends white; beneath the colours are half ash, and half black in the six middle feathers, and white in the three outer ones; the legs are red, the claws brown. This bird is found chiefly near the river Senegal.

VINACEA. Grey-brown, beneath white; on the upper part of the neck a black collar; wings fuscous, with the outer margin of the feathers whitish. *Columba vinacea*, Gmel. *Turtur torquatus senegalensis*, Brisson. *Tourterelle à collier du senegal*, Buff. *Collared senegal turtle*, Lath.

Size of the last, and inhabits the same country. The bill is blackish; head, neck, and breast claret-colour; upper part of the back brown, lower cinereous; belly white; six middle tail-feathers ash-coloured-brown; beneath from the base to the middle black, the rest cinereous.

CRUENTA. Grey; neck beneath white; nape violet; three greyish bands across the wings; on the breast a sanguineous spot. *Columba cruenta*, Gmel. *La tourterelle grise ensanglantée*, Sonner. *Red-breasted turtle*, Lath.

First described by Sonnerat; it inhabits Manila. The length of this bird is eight inches; the bill is black; the irides ferruginous; collar on the neck violet; glossed with green; the blood-coloured spot on the breast darkest in the middle; wings with three grey and two black transverse bands; quill-feathers black; tail grey at the base, and black at the end; legs blackish, and somewhat violet.

SANGUINEA. Body entirely white; spot on the breast, the bill and legs sanguineous. *Columba sanguinea*, Gmel. *Tourterelle blanche ensanglantée*, Sonner. *Sanguine turtle*, Lath.

This bird inhabits Manila, and was first described by Sonnerat. It is a species of great singularity, the whole of the plumage being white, except the spot on the breast, which is of a deep sanguineous colour; the bill and legs are red, the irides purplish.

PASERINA. Wings and tail dusky; body purplish; bill and legs yellow. *Columba passerina*, Linn. Gmel. *Turtur parvus americanus*, Brisson. *Columbus minimus*, Klein. *Turtur indicus*, or *Cocotzin*, Ray. *Cocotzin*, Buff. *Les petites tourterelles*, Pl. Enl. *Ground dove*, Cateby.

The ground dove is a native of the warmer parts of America, and the contiguous islands; and is observed as far north as Carolina, but more rarely. Willoughby says it is very common in Mexico, where it inhabits mountainous places. Bancroft observes, that it is the only kind of dove met with at Guiana. In the Caribbee islands it is very abundant, and is commonly eaten, being in much esteem for food; its haunts are flowery places under bushes. It is also common in Jamaica, where, as Sloane mentions, "they feed on the ground like partridges, and spring as they do, rising and flying for a short flight, and then light again on the ground." They subsist chiefly on grain and seeds of vegetables; and are taken in traps baited with the seeds of the *Ricinus*, or will cascada.

This is a small and elegant species, the length about six inches. The bill is pale red, with the tip blackish; the irides orange; upper part of the head and neck ash-colour; back, rump, and upper tail-coverts the same, but deeper; front vinaceous; throat and breast spotted with brown; two middle tail-feathers are deep ash-colour; the others blackish; legs

legs red, the claws blackish. The female differs in the general colour of the plumage being paler.

There are several varieties of this species, one of which, found at Carthagena in South America, is distinguished by having fewer brown spots than usual; another has the body more inclining to reddish, and the eyes chestnut; and a third with the feathers of the neck and breast of many colours.

MINUTA. Brown; wings with from five to seven iridescent spots; outermost tail-feathers white at the tip. *Columba minuta*, Linn. *Turtur parvus fuscus americanus*, Brisf. *Coccyzus alaud niger*, *halapalococuli*, Will. *Passerine turtle*, Lath.

It admits of some doubt whether this pigeon is distinct from the last, *C. passerina*. This kind inhabits America, and is five inches and a half in length. The upper parts of the body are brown, the under more or less rufous-white; wing-coverts rufous; two middle tail-feathers brown, the others ash-coloured at the base, black in the middle, and brown at the tip; the bill and legs are black.

MALACCENSIS. Undulated with black lines; above cinereous-grey; beneath cinereous; sides of the neck white; tail-feathers fuscous, sides near the tips white. *Columba malaccensis*, Gmel. *La petite tourterelle de queda*, Sommer. *Malacca turtle*, Lath.

This is a beautiful species, scarcely exceeding the size of the common house-sparrow; the bill is yellow, and in the middle black; the forehead and throat are light cinereous-grey; breast and belly vinaceous-grey; middle tail-feathers brown for two-thirds of their length, and from thence to the end white; thighs and under tail-coverts white; legs yellow. This species inhabits Malacca, and is esteemed a delicacy for the table.

VERREANS. Green; beneath yellowish; outer edges of the wings pale yellow. *Columba viridis philippinensis*, Brisf. *Pigeon vert des philippines*, Buff. *Columba verrans*, Gmel.

A native of the Philippine islands; the bill and legs are red, the breast azure.

SECTION *. *Tail long and cuneated, or wedge form.*

MIGRATORIA. Orbits naked; and sanguineous; body cinereous; breast rufous. *Columba migratoria*, Linn. *Borowk*. *Aenas Americana*, Brisf. *Palumbus carolinensis*, Klein. *Pigeon de passage*, Buff. *Passenger or migratory pigeon*, Phil. Transf. Kalm, &c.

Those birds inhabit North America, passing the summer in the higher latitudes, and retiring to the more southern provinces at the approach of winter. They build in trees, and lay two eggs. It is said these pigeons are so abundant in America, that at the period of their migration they are seen passing from one place to another in flocks of two or three miles in length, and a quarter of a mile in breadth, and which literally darken the air as they proceed. Frequently at such times we are told they alight on trees, and sometimes in such immense numbers as to break down pretty strong branches. They are esteemed excellent eating, and, during the time of migration, furnish the common people of America with abundance of food. About Philadelphia they sit on these birds from the tops of their houses, or knock them down in the evening from their roosting places. In Louisiana they adopt another mode of capture: a party of five or six go in the evening into the wood; and taking with them several dishes, or other fat vessels, they set fire to one or two of these under such trees as the birds commonly prefer to roost upon, the smoke and vapour of which ascending so rapidly the birds that they drop down from their roosting places, and are picked up and secured in sacks previously provided for that purpose. It is said such parties are often accompanied in those nocturnal rambles by the

ladies; this mode of taking pigeons being esteemed a delightful evening's amusement. The chief food of these birds are acorns, rice, corn, and other grain.

The passenger, or migratory pigeon of America, is about the size of the common domestic pigeon of this country. The bill is black, the space round the eyes crimson; irides orange; head, throat, and hind part of the neck, back, rump, and upper tail-coverts cinereous; wing-coverts the same, marked with dusky or black spots; the sides of the neck are glossy, variable purple; fore part of the neck vinaceous; belly, sides, and thighs, with the under tail-coverts, the same colour; paler, quills black brown, edged with white; the tail rather long, with the two middle feathers blackish brown, the rest hoary; legs red, with black claws.

A variety of this species is described by Gmelin. The colour is brownish above, beneath whitish-rufous; neck on the forepart somewhat vinaceous; lateral tail feathers with a round black spot in the middle on the under surface.

CAROLINENSIS. Body rufous-cinereous, beneath reddish; orbits blue. *Columba carolinensis*, Linn. *Turtur carolinensis*, Brisf. *Picacuroba*, Will. *Tourterelle de la Caroline*, Buff. Pl. Enl. *Carolina pigeon*, Arct. Zool. Lath.

Rather larger than the common turtle. The bill is blackish; irides black; front, throat, and breast rufous, with a green-gold and violet gloss. The hind part of the head and neck are brownish ash; the back, rump, upper tail, and wing-coverts ash-brown; on the wings, near the tip of the greater coverts, are a few black spots; quills blackish ash with whitish edges; tail-feathers unequal, the two middle ones four inches and an half in length; the outer ones very short; the two middle ones entirely ash-coloured brown; the next two on each side ash coloured, marked with black in the middle, the others light ash-colour, whitish at the end, with a black spot between the two colours; the legs are red, the claws black. The female is destitute of the glossy violet colour on the breast. Those birds inhabit Carolina, Brazil, and St. Domingo.

CANADENSIS. Body grey-brown, beneath whitish; primary quill feathers yellowish at the tip; tail feathers white at the apex. *Columba canadensis*, Linn. *Tourterelle de Canada*, Buff. *Canada turtle*, Arct. Zool.

Length thirteen inches; the bill blackish; upper part of the head, neck, back, and wings grey-brown; the lower part of the back, rump, and upper tail coverts ash-coloured; throat and fore part of the neck grey-brown tinged with yellowish; wing-coverts marked with blackish brown spots; tail ash-coloured, the feathers tipped with white, except the two middle ones; legs red; claws black. In the female most of the feathers are tipped with dirty white, which gives the plumage a striated appearance. The native place is Canada.

MARGINATA. Body above fuscous; beneath brown-grey; breast red; tail feathers black at the tip, the edges white. *Columba marginata*, Linn. *Turtur Americanus*, Brisf. *Tourterelle d'Amérique*, Buff. *Long tailed dove*, Edw. *Margined pigeon*, Lath.

Inhabits America. Length ten inches; the bill is hoary; irides rufous; lores white; front and chin reddish brown; hind head bluish ash; under the ears a black spot; upper part of the body brown; shoulders spotted with black; throat rosy; two middle tail feathers blackish, the rest cinereous.

AMBOINENSIS. Body rufous; neck waved with black. *Columba amboinensis*, Linn. *La tourterelle d'Amboine*, Buff. *Amboina turtle*, Lath.

Length fourteen inches; bill black; feathers of the

crown, neck, and breast with a blackish transverse bar near the tip; feathers of the upper part of the back, and wing-coverts brown tipped with rufous; wings brown; tail reddish-brown. A native of Amboina.

CAPENSIS. Body grey-brown, beneath white; primary quill feathers rufous on the inside. *Columba capensis*, Linn. *La tourterelle*, Buff. *Cape pigeon*, Lath.

Inhabits the southern parts of Africa. The length of this bird is nine inches and a half; the bill is red; body grey-brown; belly whitish; spot on the wing steely; secondary quill feathers brown, with the exterior edge grey; tail black beneath; lateral feathers at the base grey-brown, with the tips blackish; legs red, with the claws black. The female differs in having the throat and fore-part of the neck of the same colour as the rest of the head, and the greater wing-coverts not tipped with black. There are several varieties of the cape pigeon.

MACROURA. Body cinnamon colour, beneath whitish; tail whitish at the tip. *Columba macroura*, Gmel. *Le touroco*, Buff. *La tourterelle à large queue*, Pl. Enl. *Great tailed pigeon*, Lath.

The length of this bird is twelve inches, the bill red, with a white cere; tail as long as the body; legs red. A native of Senegal.

BANTAMENSIS. Orbits naked and fleshy coloured; neck, breast, and flanks waved with black and white. *Columba bantamensis*, Mus. Cur. f. 3. t. 67.

Common in the island of Java. The species is small, being about the size of the wry neck; the bill is black; body above hoary ash; beneath whitish; back, wings, and breast with lunate black spots; tail same length as the body, and consisting of fourteen feathers, the six middle of which are black, the rest white towards the tip; legs red.

MELANOPTERA. Body livid or bluish; wings black. Molin. Gmel. Described as a native of Chili. Vide Molin. Hist. Chili.

DOMINICENSIS. Body grey; sides of the head and collar beneath the nape white; spot on the crown; band under the eyes, and collar on the neck black. *Tourterelle de St. Domingue*, Pl. Enl. *Columba dominicensis*, Lath. Ind. Orn.

A native of St. Domingo; the length of this bird is eleven inches; the bill black; wings with a few blackish spots; breast vinaceous; front, chin, and vent white; tail grey; the outermost feathers white; legs red.

COLUMBA, *roenlandica*, a name given by authors, as Ray, Willughby, and Albin, to the black guillemot. See **COLUMBUS grylle**.

COLUMBA is also the name of a military order instituted by John I. of Castile, about the year 1379.

COLUMBA Nocchi, a small constellation in the southern hemisphere, consisting of ten stars. The longitudes, latitudes, &c. of which are given in Sharp's Catalogue.

COLUMBAC denotes that part of the agallochum, which is between the heart, and that part next to the bark.

COLUMBARIA, in *Ancient Geography*, an island of the Mediterranean on the coast of Etruria, according to Pliny. — Also, another island of the Mediterranean, near Drapanum in Sicily, called by the Greeks "Pelias."

COLUMBARIUM, a promontory of the isle of Sardinia, N. of Portu Olbianus, on the E. coast: the same with *Colymbarium*.

COLUMBATE of iron. See **COLUMBIUM**.

COLUMBIA, in *Geography*, a county of America, in New York, bounded N. by Rensselaer, S. by Dutchess, E. by the state of Massachusetts, and W. by Hudson river,

which divides it from the county of Albany. It is 32 miles long and 21 broad, and is divided into 8 towns, viz. of which Hudson, Claverack, and Kinderhook are the chief. It contained, in 1790, 27,732 inhabitants, and in 1796, 3560 electors.

COLUMBIA, a county of America, in the upper district of Georgia, bounded by the Savannah river on the E. and N.E., which separates it from the state of Carolina, and N.W. of Richmond county.

COLUMBIA, a township of Washington countv, in the district of Maine, on Pleasant river, adjoining Machios on the N.E., was incorporated in 1796.

COLUMBIA, a post-town of America, the capital of Kernshaw county, and the seat of government of S. Carolina. It is situated in Camden district, on the E. side of the Congaree river, just below the confluence of Saluda and Broad rivers. The streets are regular, and the town contains upwards of 70 houses. It lies 115 miles N.N.W. of Charlestown, 35 S.W. of Camden, and 678 S.W. of Philadelphia. N. lat. 34° 1'. W. long 81° 5'.

COLUMBIA, a flourishing town of Goodland county in the state of Virginia, on the side of James river, near its junction with the Rivanna, 45 miles from Richmond, and 35 miles from Charlottesville.

COLUMBIA, a town of America, in the county of Lancaster and state of Pennsylvania, seated on the N.E. bank of the Susquehanna river, 10 miles from Lancaster, and 76 W. by N. from Philadelphia.

COLUMBIA, a town of America, in the county of Hamilton and state of Ohio, seated at the confluence of the Little Miami with the Ohio, 6 miles above Cincinnati. The settlement began in 1789. N. lat. 39° 20'.

COLUMBIA College. See **COLLEGE**.

COLUMBIA, territory of. See **WASHINGTON**.

COLUMBIANA, a county of America, in the state of Ohio, bounded N. on the county of Trumbull, S. on Jefferson and Muskingum counties, E. on the state of Pennsylvania, and the Ohio, and W. on Muskingum river, and county.

COLUMBIC ACID, in *Chemistry*. See **COLUMBIUM**.

COLUMBIERS, in *Geography*, a town of France, in the department of the Aveyron, and district of Rhodes; 10 miles W. of it.

COLUMBINA, a name given by Aëturius, and some other medical writers, to the verberna, or common vervain.

COLUMBINA Marga. See **MARLE**.

COLUMBINE, in *Botany*. See **AQUILEGIA**.

COLUMBINE feathered. See **THALICTRUM aquilegifolium**.

COLUMBINE, a kind of violet-colour, called also dove-colour. See **DYEING**.

COLUMBIUM, in *Chemistry*, a new metal discovered by Mr. Hatchett, in the year 1802, in a mineral which he had from the British Museum. The mineral, it appears, had been sent with some specimens of iron ores from Massachusetts in America, to Sir Hans Sloane, in whose catalogue it is described as "a very heavy black stone, with golden streaks." By Mr. Hatchett it is described as of a dark brownish grey externally, and more inclining to an iron grey internally; he found the longitudinal fracture lamellated; and the cross fracture had a fine grain. Its lustre is vitreous, slightly inclining in some parts to metallic, moderately hard, and very brittle. The colour of the powder was dark chocolate brown; but the streaks were yellow mica. The particles were not attracted by the magnet. Its specific gravity, at the temperature of 65°,

was 5,918. A series of very accurate experiments made by Mr. Hatchett proves that this ore consists of iron combined with a new metallic acid: of 200 grains of the ore 42 were found to be the oxyd of iron, and 155 of acid. The mode which Mr. H. adopted to analyse this columbate of iron was this: he took one part of the ore reduced to powder, and mixed it with five times its weight of carbonate of potash, and fused them in a silver crucible. An effluence took place, which being sublimed, the whole was poured into a proper vessel, and suffered to cool. Boiling distilled water was then poured upon it, and the whole was transferred upon a filter. The insoluble residuum was repeatedly washed in distilled water. The filtered fluid was now supersaturated with nitric acid. The result of which was a white flocculent precipitate, which he denominated *columbic acid*. The insoluble residue was again fused with carbonate of potash, and treated as before, but scarcely any effect was produced, the alkali was therefore washed away, and the powder digested with muriatic acid, in order to get rid of the iron. The acid was then decanted, and the residuum washed in distilled water. It was again fused with carbonate of potash, dissolved, and precipitated with nitric acid. The residuum was repeatedly treated in a similar manner, till the whole was completely decomposed. By these means he obtained a precipitate of oxyd of iron which combined with the muriatic acid. The columbic acid is of a pure white colour, but not very heavy, and has scarcely any perceptible taste; it is not soluble in boiling water. When some of the powder is placed upon litmus paper, moistened with distilled water, the paper in a few minutes becomes red. When exposed to the blow-pipe, it is not fusible, but only becomes of a less brilliant white. Having found that this acid possessed properties different from all other acids, and that the base was metallic, Mr. H. gave to the metal the name of *columbium*. In the attempts which he made by heat to reduce it to the metallic state, the oxyd was found only in a state of black powder. From his experiments he found that the metal combines with oxygen in different proportions, and these oxyds are distinguished by different colours. It combines with some of the acids, and forms salts; thus we have the sulphate, muriate, &c. of columbium.

Sulphate of Columbium. Boiling sulphuric acid forms a transparent colourless solution with columbic acid. When water is added to this solution, it becomes turbid, assuming a milky appearance; and a white precipitate is gradually deposited, which cracks as it becomes dry upon the filter, and from white it changes to a lavender blue colour; and when completely dry, to a brownish grey. It is then insoluble in water, is semitransparent, and breaks with a vitreous fracture. This precipitate obtained from the sulphuric solution, by the addition of water, is a sulphate of columbium.

Muriate of Columbium. Columbic acid, when recently separated from potash is soluble in boiling muriatic acid. This solution may be considerably diluted with water, without any change being produced. When evaporated to dryness, it left a pale yellow substance, insoluble in water, and which is dissolved with great difficulty, when it is again digested with muriatic acid.

Phosphate of Columbium. A few drops of phosphoric acid being added to a part of the solution of columbium in concentrated sulphuric acid, at the end of 12 hours converted the whole into a white, opaque, stiff jelly, which was insoluble in water. When a small quantity of phosphoric acid was added to the muriatic solution of columbium, in a few hours a white flocculent precipitate was formed. Philosoph. Trans. 1802, part i.

COLUMBO, in *Geography*, the capital of the island of Ceylon, and the seat of government, is situated towards the S. W. part of the island, in about 7° N. lat. and 80° E. long. from London. It was captured from the Dutch by the British troops under general Stewart in 1766. At the conquest of Trincomator, on account of its situation and its more of greater consequence to the British nation to retain, yet Colombo is in every respect greatly superior. The number of its inhabitants is much greater; its fort and black town are much larger; the country in which it is situated much more fertile; and the rich district depending upon it much wider, being not less than 20 leagues in length and 10 in breadth. Colombo is commonly supposed to have been first fortified by the Portuguese; but captain Percival questions the truth of this statement, as Laurence de Almeyda, after his first treaty with the king of the island, found that the Moors and Malabars had a fortress here, on which some guns were planted, which had been procured from ships wrecked on this coast. That part of the fort, where these ancient works stood, is now strongly fortified, and shewn as the first works of the Portuguese. It is in a manner detached from the main body of the fort, being separated from it by an entrenchment and wall, with a fosse or ditch, now almost choked up. The fort is placed on a peninsula projecting into the sea, and it is thus exposed on all sides to the sea-breezes, by which the air is rendered temperate and healthy, though it lies so very near the equator. This fort is upwards of a mile in circumference; and is indebted for its strength both to nature and art. On the fourth side the surf runs so high, and the shore is so rocky, that it would be dangerous to approach it. On the west side of the bay, where the sea is smoother, and near the wharf or landing place, which at all seasons of the year is safe for boats, the only attempt could be made; but these quarters are so well defended by the batteries which command the harbour, that there is hardly any probability of its succeeding. On the west side of the fort, and facing the sea, are two very fine batteries, *en barbette*, intended for the security of the harbour. These stand on a part that projects a considerable way from the main body of the fort, from which they are separated by a high wall and ditch flanked with bastions, and have gates that communicate with the interior of the fort. Here the wharf or landing place is found; it consists of large piles of timber, extending several yards into the sea, and affords a very commodious station for loading and unloading sloops and large boats, which may be brought close alongside. At this end several store-houses, and barracks for half a regiment are erected. The ramparts of the fort are very strong, having eight principal bastions; and they have also a number of lesser ones, with curtains, banquets, and parapets, communicating with each other all round the fort, and fitted for troops to line and defend with musketry and field-pieces. The whole fort is surrounded by a road and deep oval ditch, over which draw-bridges are thrown at each of the gates. On the outides are some small magazines, with a powder-mill and a saw-mill attached to the fort. Adjoining to the covert-way, and at the foot of the plain, is a lake extending three or four miles into the country, in a N. E. direction. For near a mile on the outside of the fort, the neck of land which connects it with the country, is not above five or six hundred yards broad; and in the middle of this space lies the lake, leaving room on each side only for a narrow causeway. Near the plain an approach might be entirely cut off, by opening the sluices and cutting the road across, where the lake would be connected with the sea, and the garrison completely insulated. In the centre of the lake is an island, communicating with

a Sally-port on the east face, by a narrow causeway and draw-bridges. This is a pleasant spot, abounding with cocoa-nut trees, and was called by the Dutch "Slave Island," as it was the place whither they sent their sick slaves. A battalion of Malays is stationed here. This island is very convenient, as it lies contiguous to the fort, and opens the nearest way to the cinnamon gardens, which are close by it. The fort has three gates, the principal one, where the main-guard is stationed, which is called the Delph-gate, and leads into the "pittah," or black town. It has two draw-bridges to pass over the ditch, which here forms an angle. At each of the gates are guard-houses, with a subaltern's guard placed over them.

The plan of Colombo is regular. It is nearly divided into four equal quarters, by two principal streets, which cross each other, and extend the whole length of the town. To these smaller ones run parallel, with connecting lanes between them. At the foot of the ramparts, on the inside, is a broad street or way, which goes round the whole fort, and communicates with the battions and soldiers' barracks; and also affords, at the different angles, open spaces for their private parading. The grand parade is by no means sufficient for the garrison, as it can hardly contain one complete regiment. On one side of it are ranges of public offices for the civil and military departments, with the town or stadt-house in the centre of them, where the Dutch held their high court of justice. On the arrival of the British troops they found a rack, wheel, and many other implements of torture, which had been used for inflicting punishment on criminals, particularly slaves, but these savage modes of punishment were immediately abolished by the British government. On the other side of the grand parade stand the cinnamon store-houses, or "go-downs," as they are here called. At the upper end of the parade the Dutch had begun to erect a church, which has never been finished. The Dutch usually attended divine service at a spacious and handsome church in the black town, about a mile distant from the fort; and worship is still performed there for the English, either before or after that of the Dutch inhabitants. The government house, which faces the harbour, is a very long and capacious building, but more convenient than elegant: several offices are attached to it, where the business of government is transacted. Behind it is an excellent garden, intended for a "tank" or reservoir, in case of a siege; for though every house has a well plentifully supplied with water through the year, yet it is of a brackish quality, and not fit to drink. The Europeans, therefore, both of the civil and military establishment, are supplied with water from a spring, about a mile from the fort, which is brought by means of bullocks, in leathern bags, called here "puckally bags," a certain number of which is attached to every regiment and garrison in India.

Colombo is built more in the European style than any other garrison in India. The interior of the fort has also more the appearance of a regular town; the Dutch houses are all regularly built, though few are above one story high; and the windows have all glass-panes, after the European manner. Before each house, and connected with it, is a large open space, roofed in and supported on pillars of wood, called a "viranda," affording a shade from the sun, and exposed to the refreshing breeze of the sea. The houses are also agreeably shaded by a double row of thick foreading trees, planted on each side of the several streets. The walls of the houses are plastered over and white-washed with a very fine bright lime, made of burnt shells. This beautifully white colour may contribute to the coolness of the houses, but it throws an insupportable glare on the eyes of

the passengers along the streets. The houses are for the most part uniformly constructed, consisting of the hall in the front, with a chamber at each side, and another room in the back part, equal in length to the other three, and called the "back viranda." Behind these are one or two ranges of small buildings, proportioned to the size of the house and designed for the accommodation of servants, for cellars, and sometimes for sleeping rooms. The hontes are covered with indented tiles, which afford no security against rain. In the centre of the principal street is a very handsome and lofty house, which belonged to the Dutch governor, and has since been occupied by the commander of the British forces on the island. There is a few another very handsome and spacious house for the commandant of the garrison, with suitable offices and gardens. The hospital, designed for soldiers and sailors, is a roomy and convenient building. Three or four battalions are usually stationed as a garrison in the fort of Colombo.

The harbour of Colombo, which lies on the west side, is an open road, affording good and safe anchorage to ships for only four months of the year, from December to April, when the N.W. winds do not prevail to any great degree; but about May, when the monsoon sets in from the Malabar coast, and extends its ravages to the W. coast of Ceylon, the roads of Colombo no longer afford any protection. Hence it is, that Colombo is cut off from any intercourse by sea, with the other parts of the island, for two thirds of the year. For six months of the stormy season, this side of the island is subject to very heavy falls of rain, accompanied with dreadful thunder and lightning, and violent winds blowing in there. During this season the variations of the climate are very great. The heavy rains, predominating most by night, render the air damp and chill; and the excessive heat of the sun by day is almost insupportable. These transitions make the climate more unhealthy at this season than during the hot weather. During the rainy season, the Indians from the continent are very subject to fluxes, dysenteries, and fevers. They are also subject to another very extraordinary disease, called the "Berry berry," occasioned by low diet and hard water, which swells the body and legs of the patient to an enormous size, and generally carries him off in twenty-four hours. The cure is effected by rubbing the diseased person all over with cow-dung, oil, cinamon, lime juice, and other preparations from herbs, and then burying him up to the chin in hot sand. The British soldiers contract the bad effects of the air and water, by drinking plentifully of arrack and smoking tobacco. The "Pittah," or black town, of Colombo deserves particular notice, on account of its extent and superior structure, compared with other such towns attached to the forts of India. It is divided into two parts; that nearest the fort consists of one very large street, beginning at the esplanade near the walls, and running on till stopped by an old mud wall, and a gate called the "Kenman's port." In this division of the Pittah are most excellent houses, where many Dutch gentlemen and merchants reside. Through Kenman's port there is a narrow passage leading into the other division, which consists of a long straggling town, skirted on one side by the lake above described. Besides a principal street, there are several smaller ones running parallel to it, in one of which is a large well-constructed building, called the "Orphan seminary, or school," where the Dutch used to educate the children of their soldiers and the poorer Europeans, as well as those they had by the native women. Here the boys were educated at the public expence, till they were fit for trades; and the females were either settled in some comfortable situation, or married to persons of their own rank. This laudable institution is still maintained by
the

the British government. Close by the esplanade, and adjoining the black town, is the burial ground of the garrison. The shops, bazars, and stalls, placed all along the streets, are replenished with various articles of merchandize, peculiarly in use among the natives of India; and the town, during the whole day, swarms with people of all descriptions. The boats or canoes used in the fisheries of Columbo are of a curious shape and construction. They are about fifteen feet long, and not more than two in breadth. They move with great speed, especially with the addition of a very large square sail; and, to prevent their oversetting, a log of wood is extended five or six feet from the end of the boat, by way of out-rigger; this log is fastened to the boat by two long and bent poles, and seems to serve at once for helm and ballast. A paddle, somewhat in the form of a shovel, is used to guide the boat's head. The body of the canoe is a large tree, hollowed out by fire, or scooped out by the carpenters. Along its sides boards are nailed to the height of about two feet, and in the form of a gun-wale, to prevent the water from getting in. When large burdens are to be carried inland by the canals or rivers, two or three of these canoes are lashed together without the out-riggers. Split canoes, bamboes, or betel tree, are then laid across them, so as to form a kind of raft; which, though ever so much loaded, will draw but very little water. Other flat-bottomed boats of a much greater breadth are also used by the natives. These are thatched with cocoa-tree leaves, like a house, and are large enough to hold couches. Near Columbo may be seen two or three hundred of these boats in regular rows, moored along the banks of the rivers, with entire families on board, who make them their habitations.

Columbo, for its size, is one of the most populous places in India: and its population consists of a great variety of nations. Besides Europeans and Cinglese, the proper natives of the island, you meet, scattered over the town, almost every race of Asiatics; Moors of every class, Malabars, Travancorians, Malays, Hindoos, Gentoos, Chincse, Persians, Arabians, Turks, Maldivians, Javians, and natives of all the Asiatic isles; Perfices, or worshippers of fire, who would rather have their houses burnt, and themselves perish in the flames, than employ any means to extinguish it. Here are also a number of Africans, Caffrees, Biganese, or a mixed race of Africans and Asiatics; besides the half-casts, people of colour, and other races which proceed from a mixture of the original ones. Each of these different classes of people has its own manners, customs and language. The language most generally spoken by both the Europeans and Asiatics, who resort to Columbo is the Portuguese of India, a base, corrupt dialect, altogether different from that spoken in Portugal.

Columbo, though difficult of access, is situated in a rich district, and furnishes a great variety of articles to commerce; and, therefore, it is much frequented both by Europeans and the natives of the different coasts of India. From this district large quantities of cinnamon and pepper, the staple spices of the island, are yearly transported to Europe in vessels that touch here on their voyage from Madras and Bengal. A great quantity of arrack is made in the neighbourhood of Columbo and the other districts along the west coast. A large quantity of Coya rope, or cordage is also manufactured here, for the supply of our ships on the various stations in those seas. The inferior articles, exported by the Moors and Malabars, who reside here for that purpose, are betel-leaf and aracca-nut, jaggory, or a sort of coarse blackish sugar, cocoa-nut, and oil, honey, bees-wax, cardamoms, coral, ivory, fruit, and a variety of other smaller articles. In return they import coarse wool-

len cloths, and calicoes, pieces of printed or painted cloths for women's apparel, coarse muslins, handkerchiefs, palampores, stockings, china-ware, tin, copper, and a variety of toys; also bonivelses, a species of fish peculiar to Bombay, and onions, from the same place, where they are remarkably good. Every year, generally towards February, a Portuguese or Chincse ship arrives from Macao with teas, sugar, candied sweetmeats, hams, silks, velvets, nankeens, umbrellas, straw-hats, all kinds of china-ware and toys; all which articles find a very ready sale, and are paid for in hard cash. The current coin at Columbo, as well as in the other European dominions on the island, consisted, on the arrival of the English, of six-dollars, a nominal coin, like one pound sterling, valued at a certain quantity of copper money. There were besides several small copper coins, called pice or flivers, half-pice, and dudies. Four pice or two dudies made a fanam, and seven fanams were equal to a six-dollar. New regulations have been adopted with regard to the coin since the island has belonged to the English. There is now current a new coinage of double and single pice and half-pice made by our East India Company. A pice is about a halfpenny sterling; four pice are equal to a fanam, and twelve fanams to a six-dollar, or, as it is usually called by our people, a copper rupee. This latter coin passes for about two shillings sterling; and four of these are equivalent to a star pagoda, a Madras gold coin worth eight shillings sterling, the fluctuation in the value of money in Ceylon is very great, and depends upon the plenty and scarcity of gold and silver there. The expence of coining at Columbo is more considerable than on the continent of India. Horses and servants are particularly expensive, vegetables are extremely scarce, and they form a great article of food in those warm climates. Such articles, however, as are the native produce of the island, are found in great abundance, and at a moderate price. Beef, fish, and fowl, in particular, are both cheap and plentiful. Mutton is excessively dear, as no sheep can be reared in the neighbourhood of Columbo, which some attribute to the noxiousness of the climate or pasture of the island, but which may be principally owing to their falling an easy prey to jackals, snakes, and other destructive animals, and also to certain poisonous herbs that occur in many places. Pigs and ducks are plentiful and cheap. Geese are rare, and turkeys are not to be had, except occasionally by importation from other parts of India.

The country round Columbo for several miles is flat and very rich. It is diversified with fields of rice and pasture, as well as a variety of groves, in which the cocoa-tree is conspicuous. The scene is embellished by a number of small rivers, lakes, and canals. The shady roads, which every where intersect the country, afford to the traveller an agreeable shelter; while the numerous country fairs and gardens which skirt them present his eye with a continual change of gratification. The river Mutwal extends itself here into a very broad channel, and by its numerous windings affords a most enchanting prospect from the road, which runs along its banks for many miles. Several temples of the natives are situated along the banks of this river and among the adjoining groves. One of the chief beauties in the vicinity of Columbo is the immense number of cinnamon trees, which produce the nicotia of the island. In the woods they grow wild in abundance, and in the gardens they are now regularly cultivated with the greatest success. Percival's Account of the Island of Ceylon, 1805.

COLUMBO, in the *Materia Medica*. This root was first brought from the town of Columbo, in the island of Ceylon,

in which country it had long been used as a valuable remedy in bilious fevers, and other disorders of the stomach and bowels. Our practitioners in the East Indies adopted the use of this root from them, and it is now deservedly in high reputation in most parts of Europe. The plant that yields it is not commonly known.

Columbo root comes to us in circular pieces about two inches in diameter, covered with a thick wrinkled bark of a dark brown externally, but a light yellow within. On paring off this bark the root is seen to consist of three distinct lamina. The whole is used indiscriminately in medicine.

Columbo root has an aromatic smell; the taste is bitter and nauseous. It gives no essential oil when distilled with water, and contains scarcely any volatile aromatic parts. When boiling water is poured on the powdered root a strong infusion is produced, which possesses all the sensible qualities and virtues of the plant, but it grows mouldy in a day or two. Spirit of wine also extracts the active qualities of this root very readily.

Columbo is employed with nearly equal advantage in substance in spirituous tincture or in watery infusion, and generally with the addition of cinnamon or some grateful aromatic. This root is of singular efficacy in strengthening the fibres of the stomach and bowels, either in chronic cases, or more particularly in cholera morbus, dysentery, and other violent disorders of the alimentary canal, where, after due evacuations, it may be employed with great success in checking the incessant vomiting action of the bowels that bring down the powers of life with such rapidity.

An extract and a tincture of Columbo are kept in the shops, the latter of which is by itself a very useful stomachic taken daily in very small doses.

COLUMBUS, CHRISTOPHER, in *Biography*, a subject of the republic of Genoa, celebrated in history as the discoverer of America. Neither the exact time nor place of his birth can be ascertained with any degree of certainty, but it is generally supposed that he was born in some part of the Genoese dominions about the year 1447. He is said to have descended from an honourable family, reduced by various misfortunes to a state of indigence. In whatever rank of society his parents moved, it is certain that they gave their son an education adapted to the bent of his genius; at school he acquired the elements of the Latin language, and made some proficiency in geometry and the other sciences which he was enabled in the future part of his life, to apply to the practical parts of navigation. At the age of fourteen he went to sea, and though his first voyages were confined to the Mediterranean, yet he very soon ventured out on the northern seas, and visited the coasts of Iceland, to which the English and other nations resorted on account of its fishery. About the year 1467 he entered into the service of a sea captain of his own name and family, and spent some years in a predatory warfare against the Mahometans and Venetians the rivals of his country in trade. In this situation he continued acquiring both wealth and reputation, till at length in an obstinate engagement with some Venetian vessels, off the coast of Portugal, the ship in which he served took fire, and he, with difficulty, preserved his life by throwing himself into the sea, and swimming a distance of two leagues to the shore. As soon as he had recovered strength for the journey he repaired to Lisbon, where his brother Bartholomew had settled, and where he found many of his countrymen, who, like himself, had embarked in the sea service. Here his merit and talents were soon appreciated; and here he married the daughter of Perestrele, one of the captains employed by prince Henry in his early navigations, and who, under his protection, had discovered and planted

the islands of Porto Santo, and Madeira. Columbus got possession of the journals and charts of this experienced navigator, and from them he learned the course which the Portuguese had held in making their discoveries, as well as the various circumstances which guided and encouraged them in their attempts. While he contemplated the labours of his father-in-law, and read the description of the countries which he had seen, his own impatience to visit them became irresistible. To indulge it he made a voyage to Madeira, and for several years traded with that island, with the Canaries, the Azores, the settlements in Guinea, and all other places which the Portuguese had discovered on the continent of Africa. He now began to think of extending the boundaries of nautical knowledge. He was satisfied, not only that there must be lands still further to the west, than those already explored, but that a shorter passage to the East Indies, than the great object of the Portuguese navigators, might be found by steering in that direction, than round the continent of Africa. When he had settled his plan, he was anxious to secure the patronage and support of some European power capable of undertaking so important an enterprise. With this view, he laid his scheme before the senate of Genoa, and, making his country, for which he bore a filial and sincere affection, the first tender of his service, offered to sail under the banners of that republic, in quest of new regions, which he expected would render illustrious his own name, and the nation which should enable him to realize his vast projects. Genoa rejected his offer: and Portugal, to whom he next applied, treated him with so much duplicity, that he went himself to Spain, while at the same time he sent his brother Bartholomew into England to make the like proposals to both courts. By both, his schemes were at first slighted, till by the interposition of some zealous friends at the court of Spain, a change was effected in his favour, and in the spring of 1472 a treaty was signed with Columbus, by which Ferdinand and Isabella, the sovereigns of Spain, appointed him their high admiral in all the seas he should discover, and their viceroy in all the islands and continents. They granted him and his heirs a tenth of all the profits that should accrue from the enterprize, with some other important advantages. As soon as the treaty was signed, Isabella, by her activity and attention, in forwarding the preparations for the voyage, endeavoured to make some reparation to Columbus for the time which he had lost in fruitless solicitation.

On the third of August 1492, Columbus set sail with three small ships and ninety men. The expense of which did not amount to more than 4000*l*. He had already, in the most public manner, implored the guidance and protection of heaven, and on the morning of his departure the shores were crowded with spectators, who sent up their supplications to the Almighty for the prosperous issue of the voyage. Columbus steered directly for the Canaries, where, on account of the ill condition of the ships, he was obliged to rest. Having supplied himself with fresh provisions, he sailed from Gomera, one of the most westerly of the Canary islands, on the sixth day of September. Here the voyage of discovery may be said to begin; for Columbus holding his course due west, left immediately the usual track of navigation, over a vast and unknown ocean, with no other guide, than well-founded hopes and rational conjectures. Scarcely had he lost sight of the Canaries, when several of his men exhibited signs of consternation bordering on despair. He comforted them with the vast wealth which was to be found in those regions whither he was conducting them, and in his own person he set such an example of patience and industry

as could not fail of exciting the admiration of those about him. Scarcely did he allow himself time for necessary refreshments; he regulated every thing; he superintended the execution of every order, and kept the deck with the sounding line or instrument for observation perpetually in his hand, and noting down every unusual appearance with the utmost accuracy and precision. Three weeks had they traversed the ocean, and had proceeded to a distance which Columbus thought it prudent to conceal, when his men became mutinous, and even threatened to throw their admiral overboard should he persist in an undertaking which they supposed must prove fatal to them all. He succeeded for the present in quieting their apprehensions, but in a few days they became more violent, declaring that nothing should induce them to proceed in so mad an enterprise; after trying every means of persuasion in vain, he at length promised to direct his course homewards within three days, should not land be discovered. This proposition did not appear unreasonable to the men, and to the commander it appeared sufficiently safe, for the pretexts of discovering land by the flight of birds, &c. were now so numerous and promising that he deemed them infallible. From a variety of symptoms Columbus was so confident of being near land, that on the evening of the 11th of October, after the usual invocations to heaven for success, he ordered the sails to be furled, and the ships to be to, keeping the strictest watch, lest they should be driven on shore. During this interval of suspense and expectation, no man shut his eyes, all kept upon deck, gazing intently towards that quarter where land was expected to be discovered. At ten o'clock Columbus, standing on the forecalk, observed a light at a distance: he pointed it out to another, and he again to a third person; all three saw it in motion, and at midnight there was heard from the foremost vessel the joyful sound of *land, land*. Having, however, been frequently deceived by false appearances, every man was slow of belief; and waited in all the anguish of uncertainty and impatience for the return of day. When the morning dawned their doubts were dispelled, and an island was seen about two leagues to the north, whose verdant fields, well stored with wood, and watered with many rivulets presented the aspect of a delightful country. Thanksgivings were instantly offered to heaven: never was gratitude more sincere, never were the expressions of joy more ardent, than those which proceeded from every tongue. Their duty to God was followed by an act of justice to their commander. They threw themselves at the feet of Columbus, with feelings of self-condemnation, mingled with reverence entreating pardon for their past conduct; and now they regarded as the favourite of heaven the man whom they lately reviled as a visionary and impostor. No sooner had the sun tinged with its rays the shores of the newly discovered island, than their boats were manned and armed. As they approached the coast with colours, music, and martial grandeur, they saw it covered with a multitude of people, whom the novelty of the spectacle had drawn together, whose attitudes and gestures expressed wonder and astonishment at the strange objects which presented themselves to their view. The land proved to be one of the Bahama islands, named afterwards by Columbus, San Salvador: he was the first European who set foot in the New World which he had discovered, and he took solemn possession of it for the crown of Castile and Leon, with all the formalities which the Portuguese were accustomed to observe in acts of this kind, in their new discoveries. The Spaniards, while thus employed, were surrounded by many innocent and unsuspecting natives, who gazed in silent and awful admiration upon actions which they could not comprehend, and of

which they could not foresee the direful consequences. Towards the evening Columbus returned to his ships accompanied with many of the islanders in their canoes. "Thus," says Dr. Robertson, "in the first interview between the inhabitants of the Old and New Worlds, every thing was conducted amicably, and to their mutual satisfaction. The former, enlightened and ambitious, formed already vast ideas with respect to the advantages which they might derive from the regions that began to open to their view. The latter simple and unfeeling had no forethought of the calamities and desolation which were approaching their country."

From San Salvador, Columbus proceeded on other discoveries; he saw several islands, and touched at three of the largest, on which he bestowed the names of St. Mary of the Conception, Ferdinando, and Isabella. He visited also Cuba and Hispaniola; wherever he went he inquired for gold, and having obtained a certain quantity of the precious metal, and made other arrangements, he took his departure homewards. He encountered a violent tempest, in which he had nearly lost his ships. While all on board were overwhelmed with a sense of personal danger, Columbus was only anxious for the means of preserving a record of his great discoveries. Retiring to his cabin, he wrote an account of what he had seen and done, which he covered with wax, enclosed in a tight case, and committed to the sea with a proper direction, hoping that it might be fortunately landed on some European shore. The storm, however ceased, and in a few days he found himself approaching the Azores. Here he obtained provisions, and renewed his voyage. When he was almost within sight of the Spanish coast, another storm arose, that forced him to take shelter in the Tagus, from whence he proceeded to Lisbon; where, in the presence of the king of Portugal, he narrated every thing that he had done and seen. Columbus remained at Lisbon but five days, and on the fifteenth of March he arrived in the port of Palos, seven months and eleven days from the time when he set out thence. As soon as his ship was discovered, the inhabitants ran eagerly to the shore, to welcome their relations and fellow-citizens, and to learn the tidings of their voyage. Columbus repaired to the court, then at Barcelona, where he was received with all the respect and honour due to his great achievements. Every mark of attention that gratitude or admiration could suggest was conferred upon him. All his stipulated privileges were confirmed, his family was ennobled, and, which was most satisfactory to his active mind, another armament was immediately fitted out for him. This consisted of 17 ships and about 1500 persons; of whom a large number were men of distinction, desirous to settle in the newly discovered countries.

On the 25th day of September 1493, Columbus sailed on his second voyage from Cadiz. He first reached the Caribbee or Leeward islands, which he visited, and then proceeded to Hispaniola, where he had left a small garrison of his own men, but who had been destroyed, probably from misconduct on their own parts, by the natives. Instead of wasting his time in punishing past wrongs, Columbus took precautions for preventing any future injury. With this view he built a small town, which he named Isabella, in honour of his royal patroness. While some were employed in the necessary operations of building, he sent others to explore the interior of the country, in the hope of finding gold. The hardships to which the Spaniards were obliged to submit, rendered them impatient of control, and it was with the utmost difficulty that Columbus could maintain any subordination. Signs of mutiny were every where exhibited; and to the commander was imputed the most unworthy motives, by persons from
 whose

whose rank in society better and more rational conduct might have been expected. Having, however, by prudence and vigour allayed the ferment, he left his brother Diego as governor of the settlement, and proceeded with a squadron in quest of new discoveries. During a tedious voyage of five months, in which he endured every hardship, he discovered only the island of Jamaica. But on his return to Hispaniola, he had the satisfaction of finding there his brother Bartholomew, whom he had not seen for a long period, and who had brought with him a large supply of provisions and men. About this period the native Indians perceiving that the yoke imposed upon them by the invaders would prove intolerable, resolved, if possible, to free themselves from so dreadful an evil. Hostilities were commenced, and much blood was shed on both sides; but in the event the Indians were completely defeated. The consternation with which the Indians were filled by the noise and havoc made by the firearms, by the impetuous force of the cavalry, and the fierce onset of twenty large dogs trained for the purpose, was so great, that they threw down their weapons, and fled, without attempting farther resistance. Many were slain, more were taken prisoners, and reduced to a state of the most humiliating servitude; a rigorous tax was imposed upon them of gold, which was the dearest object of European ambition, and which was now become necessary to plead the cause of Columbus in Spain, where numerous accusations had been laid against his conduct. Willing, however, to meet the charges in person, he invested his brother Bartholomew with full power of government during his absence, and then set sail. He arrived in Spain in 1496, and immediately appeared at court, with the modest but determined confidence of a man, conscious not only of his own integrity, but of having performed many very eminent services for the state, in whose employment he had embarked. The dignity of his conduct silenced his enemies; and, with the assistance of the gold and precious commodities which he had brought with him, he recovered the good opinion of his sovereigns. They resolved to make every exertion to render the new colony a permanent and complete establishment, by sending out such reinforcements as Columbus thought necessary for the purpose.

It was not, however, till late in the spring of 1498, that he was enabled to proceed on his third voyage; during which he discovered Trinidad, at the mouth of the Orinoco. The vast size of this river, though only ranking in the third or fourth magnitude of rivers in the New World, convinced him that it must have its rise in a great continent. He even touched upon various parts of the continent, without suspecting it, conceiving that they belonged to islands which he had not leisure to explore. Columbus arrived at Hispaniola in August, where he found that his brother had removed the colony to St. Domingo, on the opposite side of the island. During his absence, a mutiny had been excited, and some of his people had seceded from the main body. To calm the discontent, he gave them allotments of land, to which were annexed distributions of poor natives, that proved to them an intolerable source of oppression. New complaints were secretly transmitted to court against him and his brothers; and having no opportunity of vindicating his conduct, his powers were at first greatly abridged by a separate commission of discovery having been granted to Alphonso d'Ojeda; who was accompanied in his voyage by Amerigo Vesputci, after whom the whole New World has since been named. Columbus was then recalled, and Francis de Bovadilla appointed in his stead. By his unworthy and insolent successor, Columbus was thrown in chains, and treated with other indignities, which have for ever disgraced

the court that granted to him so much power. The captain of the ship, to whose charge Columbus was given, offered, in the most respectful manner, to liberate him, but he indignantly refused to suffer his irons to be removed, but by the express command of his sovereigns. On his arrival in Spain, he was instantly set at liberty, and treated with that civility and kindness from the king and queen which he had formerly experienced. Bovadilla was disgraced, but Columbus could not forget the injuries which he had sustained; he carried with him, wherever he went, the fetters he had worn, and ordered that they should be buried in the same grave with himself.

In 1502, he obtained permission to make a fourth voyage and on arriving off St. Domingo, he found eighteen ships richly laden ready to depart for Europe. His own experience led him to perceive an approaching storm; he accordingly requested permission to enter the harbour, and at the same time warned the fleet of the dangers to which it would infallibly be exposed by sailing at that juncture. His request and his warning were equally disregarded. The hurricane came on, and though, by proper precautions, he saved his own vessels, it fell upon the fleet with so much violence, that only two or three vessels escaped; and Bovadilla, with several others of his most inveterate enemies, perished with all their ill-gotten wealth. Among the vessels that weathered the storm, was that on which the wreck of Columbus's property was embarked. This, which, by some, was referred to the superintendance of providence, was, by others, imputed to certain magical arts exercised by Columbus himself. In pursuing his voyage, he traced the coast of Darien, in hopes of discovering a strait, which he fondly imagined would open a new tract to the East Indies. Although he was disappointed in his expectations, he was, nevertheless, so much delighted with the fertility of the country, and conceived such an idea of its wealth, from the specimens of gold produced by the natives, that he resolved to leave a small colony upon the river Belem, in the province of Veragua, under the command of his brother, and to return to Spain, to procure the means requisite for rendering the establishment permanent. On his voyage, he was driven back by a violent tempest from the coast of Cuba, his ships fell foul of one another, and were so much shattered by the shock, that with the utmost difficulty they reached Jamaica. Here he endured the greatest calamities, as well from the malicious dispositions of his own men, as from the suspicions of the natives, who refused to supply him with provisions, till, by his skill in astronomy, he predicted the event of an approaching eclipse, a circumstance that gave him an irresistible authority over their minds. From this time the superstitious natives venerated him as a god, and not only furnished him profusely with provisions, but cautiously avoided every thing that could give him offence. Columbus was at length delivered by a fleet sent from Hispaniola; and, after various difficulties, he arrived at St. Lucar in Spain in December 1504. Here, in addition to his other sufferings, he learned that his patroness, Isabella, was dead: from her alone he anticipated the redress of his wrongs, which he little expected from the king. To him, however, as the last resort, he applied, who amused him with promises, but, who, instead of granting his claims, insulted him with the proposal of renouncing them all for a pension. Disgusted with the ingratitude of a monarch whom he had served with fidelity and success; exhausted with the calamities which he had endured; and broken with the infirmities which these brought upon him, Columbus breathed his last at Valladolid, on the 20th of May 1506, in the 59th year of his age. In the closing scene he exhibited a dignity and composure

of mind suitable to the greatness of his character, and to those sentiments of piety which he had ever cherished in all the trials to which his life had been exposed. Ferdinand, who had slighted his well-founded claims when living, bestowed upon him funeral honours, and confirmed to his children their hereditary rights. Columbus was buried in the cathedral at Seville, and on his tomb was engraven an epitaph, in memory of his renowned actions and discovery of a New World, which in justice ought to have been denominated Columbia, in order that the name might for ever excite the remembrance of the hero who, in spite of every obstacle, succeeded in realizing a project, esteemed by his contemporaries as the chimera of a disturbed imagination. Robertson's *Hist. of America*.

Jullianus, in his curious edition of the P. yglot Pfalter, 1516, of which a beautiful copy is preserved in the Crache-rode collection in the British Museum, has introduced, by way of commentary on Pl. xix. 4, "their words are gone forth to the ends of the earth," a very curious sketch of the life of Columbus, an account of his discovery of America, and also a description of the inhabitants, particularly of the female native Americans.

COLUMBUS, *Congregation of St.*, is the name of a congregation of regular canons, formerly of great extent; having under it an hundred abbeys or monasteries, in the British islands. See CONGREGATION and CANON.

COLUMELLA, in *Anatomy*. See UVULA.

COLUMELLA, in *Botany*, is used by Linnæus for the central pillar of a capsule, to which the seeds are usually attached. Gærtner is content with the term receptacle for this part. See RECEPTACLE.

COLUMELLA, LUCIUS JUNIUS MODERATUS, in *Bio-graphy*, was born at Cadiz, and flourished at Rome in the time of the emperor Claudius. He is chiefly celebrated for a work which has come down to our own times, entitled "De Re Rustica," and which contains, in twelve books, rules concerning the culture of various vegetables, and the management of domestic animals. A separate book "De Arboribus," is annexed to these. They have gone through many editions, but the best and most accurate is that in Gelner's collection of the *Rei Rusticæ Scriptores*. Mori.

COLUMELLÆ *musculus teres*, a name given by Morgagni, and some others, to the muscle called by Albinus *axylgus uvulae*.

COLUMELLIA, in *Botany*, Willd. 1525. Jacq. Hort. Schoenb. 3. 28. tab. 301. Class and order, *syngenesia superflua*. Nat. Ord. *Compositæ*, Linn. *Corymbiferae*, Juss. Vent.

Eff. Ch. Receptacle naked, honey-combed. Down with a toothed margin. Common calyx cylindrical, imbricated. Rays of the florets undivided.

Sp. C. *biennis*. Root biennial. Stem cylindrical, pubescent, coriaceous at the top. Leaves an inch and a half long, sessile, linear, obtuse, hairy. Flowers both of the disk and ray yellow, sessile, solitary at the divisions of the branches. A native of the Cape of Good Hope.

COLUMN, in *Architecture*, *columna*, Latin, derived from *coluena*, a support. In a strictly architectural sense a column may be defined as an object consisting of a nearly cylindrical shaft with a capital, and either with or without a base. The column, as forming the principal part of an order of architecture, will be considered under the articles DORIC, IONIC, CORINTHIAN, TUSCAN, and COMPOSITE Orders, and in the present article we shall treat of columns according to their matter, construction, disposition, and use; under the first head may be placed

COLUMN, *moulded*, is that made by impaction of gra-

vel and flints of divers colours, which are bound together with a cement, which grows perfectly hard, and receives a polish like marble.

The secret of making these, it appears, the ancients were masters of, by the columns lately discovered near Algiers; which are, doubtless, the ruins of the ancient Julia Cæsarea; on all these is found the very same inscription in antique characters; the contours, accents, and even faults, being repeated in every shaft; an incontestible proof of their being moulded.

COLUMN, *sifible*. Under this term are comprehended, not only columns of various metals, and other sifible matters, as glass, &c. but also those of stone, said to have been cast; the secret of which some will have us believe to have been known to the ancients.

COLUMN, *transparent*. any column made of transparent matter; as were those of crystal in the theatre of Scæurus, mentioned by Pliny; and those of transparent alabaster, in the church of St. Mark, at Venice.

COLUMN, *water*, is a sort whose shaft is formed of a large jet d'eau; which spouting out water violently from the base drives it within the tambour of the capital, which is made hollow; whence, falling down again, it has the effect of a liquid crystal column. See FOUNTAIN.

An instance of this we have at Quinto d'Aviro, near Lisbon.

COLUMN, *hydraulic*, is that whose shaft appears to be of crystal; being formed by a number of little threads of water, falling from holes made in a girt of metal, at equal distances, by means of a pipe mounting through the middle thereof; as in the gardens at Versailles.

COLUMN, *hydraulic*, also denotes a column from whose top proceeds a jet d'eau, to which the capital serves as a basin; whence the water descends by a little pipe, which turns spirally around the shaft. Such are the Ionic columns of the cascade of the Belvidera at Fiescati; and those of the vineyard Matthei at Rome.

COLUMNS, *with regard to their Construction*.

COLUMN of *bands or tambours*, a column whose shaft is formed of several courses of stone or blocks of marble of less height than the diameter of the column, this is what Ulpian means by *columna struicilis*, or *adpacta*, which is opposite to the *columna solida*, or *integra*, i. e. of one piece. This method is only practised in very large columns, for instance as the Trajan column. Smaller columns are often composed of three or four pieces, and this method the French distinguish by a particular term, *colonne par tronçons*, of which we have no proper translation.

COLUMN of *Masonry*, is built of rough stones or compass bricks, and covered with stucco.

COLUMN, *geminated*, that whose shaft is formed by three similar and equal sides, or ribs of stone, fitted within one another; and fastened at bottom with iron pins, and at the top with cramp-irons. This is to be fluted, that the joints may be the less discernible.

COLUMN, *encrustated*, is made of several ribs, or thin shells of fine marble, or some other rare stone, cemented upon a mould of stone, brick, or the like. This is done with design both to save the precious matter, as oriental jasper, lapis lazuli, agate, &c. or to represent pieces of such stones, of an extraordinary size, by the neatness and closeness of the incrustation, which renders the joints imperceptible.

COLUMN, *banded*; a column whose shaft has several bands or circumsures either plain or ornamented, which project somewhat beyond the general line of the shaft.

Banded columns were first introduced by De Lorme at the Chapel de Villers-Coherets, and at the Thuilleries, who imagined

imagined this method of concealing the joints of the different blocks of stone forming the shafts.

COLUMN, fluted, called also *channeled*, and *fluted column*; that whose shaft is adorned with flutes or channellings; either from top to bottom, or only two thirds of its height.

COLUMN, cabled or rudented, is a fluted column, whose channels are filled in with astragals which generally reach one third of the height of the shaft from the base.

COLUMN, cylindrical, is that which has neither swelling nor diminution.

COLUMN, diminished, is that which has no swelling, but whose shaft is tapered in a straight line from the base to the capital. This is the method observed in, we believe, all the Grecian remains of architecture, and in many of the Roman, as in the portico of the Pantheon. The opposite practice of giving an entasis or swelling in the middle of the shaft is obscurely mentioned by Vitruvius, and has been generally followed by modern architects.

COLUMN, oval. There are a few instances of oval columns in the remains of antiquity. The Massini Palace at Rome, and the frontispiece of the church of the P. P. de la Merce at Paris offer some modern examples.

COLUMN, pastoral, that whose shaft is formed in imitation of the trunk of a tree, with bark and knots.

This kind of column, in the Tuscan proportion, may be used in the gates of parks and gardens; and in the decoration of pastoral scenes, &c.

COLUMN, polygonous; a column of which the horizontal section forms a polygon. There are various examples of this form in Egyptian architecture, it is also observed in the lower part of the columns of a portico on the island of Delos and at the temple of Cora.

COLUMN, twisted, a column whose shaft is twisted round in the manner of a screw with six circumvolutions. Vignola first discovered a method of drawing it by rule. The barbarous and ridiculous practice of twisting columns has been much used by modern architects, especially in the screens and altar-pieces of churches. The most celebrated instance is the Baldaquin of St. Peter's. Columns spirally fluted are seen in the temple of Spoleto, they are also not uncommon on the sarcophagi's and other ornamental works of the lower ages.

COLUMN, Corolitic, that adorned with foliage, or leaves and branches turned spirally around the shaft; or in form of crowns and festoons.

These were used by the ancients for erecting statues on; which hence took the denomination of *corolitic*. They are very suitable in triumphal arches, and decorations of theatres.

COLUMN, hermetic. See HERMA.

COLUMNS, denominated from their disposition.

COLUMN, inserted, or backed, is that let into a wall, a third or fourth part of its diameter.

COLUMN, niched, is that whose shaft enters, with half its diameter, into a wall, which is hollowed for its reception; with its plane parallel to the projection of the tore. Such is that in the portal of St. Peter at Rome.

COLUMN, angular, is an insulated column, placed in the corner of a portico; or inserted into the corner of a building; or even a column that flanks an angle, either acute or obtuse, of a figure of many sides.

COLUMNS, cantoned, are those engaged in the four corners of a square pillar, to support four springs of an arch.

COLUMNS, coupled, are those disposed, by two and two, so as almost to touch each other at their bases, and

capitals, as those in the peristile of the Louvre and at St. Paul's cathedral.

COLUMN, doubled, is an assemblage of two columns, joined in such a manner, as that the two shafts penetrate each other with a third of their diameter. Such are those of the four angles in the court of the Louvre.

COLUMN, flanked, according to M. Blondel, is a column engaged with one half, or at least one-third of its diameter, between two demi-pilasters.

COLUMNS, grouped, are those placed on the same pedestal, or socle; either by three and three, or by four and four.

COLUMN, insulated, is that standing free, and detached on all sides, from any other body.

COLUMNS, median. Vitruvius gives the name *columnæ medianæ* to the two columns in the middle of the porch, which have their intercolumniation larger than the rest: that if these last, for instance, be *pycnostie*, the *medianæ* are *eustyle*.

The term may also be applied to the middle row of columns, in a frontispiece adorned with three orders.

COLUMNS, denominated from their use.

COLUMN, astronomical, is a kind of observatory, in form of a very high tower; built hollow, and with a spiral ascent to an armillary sphere placed at the top, for observing the motions of the heavenly bodies.

Such is that, of the Doric order, erected at the Hotel de Soissons, at Paris, by Catherine De Medicis, for the observations of Orontius Fineus, a celebrated astronomer of that time.

COLUMN, chronological, that which bears some historical inscription, digested according to the order of time; as by lustris, olympiads, fasti, epochas, annals, &c. At Athens there were columns of this kind, whereon were inscribed the whole history of Greece digested into olympiads.

COLUMN, funeral, a column placed over a tomb, and bearing an urn, or some symbol or inscription relating to the deceased. See CIPPUS.

COLUMN, gnomonic, is a cylinder, whereon the hour of the day is represented by the shadow of a style.

Of these there are two kinds: in the one, the style is fixed, and the hour-lines are no more than the projection of a vertical dial on a cylindrical surface.

In the other, the style is moveable; and the hour-lines are drawn to the different heights of the sun, in the different seasons of the year. See DIAL.

COLUMN, indicative, that which serves to shew the tides, &c. along the sea-coasts. Of this kind, is the nilometer at Grand Cairo, whereon the overflowings of the Nile are expressed: by this they form a judgment of the succeeding season: when the water, for instance, ascends to twenty-three feet, it is a sign of great fertility in Egypt.

COLUMN, itinerary, a column with several faces, placed in the cross-ways in large roads; serving to shew the different routs, by the inscriptions thereupon.

COLUMN, lazarary, at Rome, according to Festus, was a column erected in the herb-market, which is now the place Montanara; which had a cavity in its pedestal, wherein young children, abandoned by their parents out of poverty or inhumanity, were exposed, to be brought up at the public expence.

COLUMN, legal. Among the Lacedæmonians there were columns raised in public places, whereon were engraven the fundamental laws of the state.

COLUMN, limitrophous, or boundary, is that which shews the

the limits of a kingdom, or country conquered. Such was that, which Pliny says Alexander the Great erected at the extremities of the Indies.

As to those of Hercules, ordinarily called his columns, or pillars; they are two very steep mountains in the streights of Gades, now Gibraltar.

COLUMN, manubriary, from the Latin *manubie*, *spoils of the enemy*; a column adorned with trophies, built in imitation of trees, whereon the spoils of enemies were anciently hung.

COLUMN, menian, any column which supports a balcony, or meniana. The origin of this kind of column, Suetonius and Afcenius refer to one Menias; who, having sold his house to Cato and Flæcius, consuls, to be converted into a public edifice, referred to himself the right of raising a column without-fee, to bear a balcony; whence he might see the shows.

COLUMN, military, was a column of marble, raised by order of Augustus, in the middle of the Roman Forum; from whence, as a centre, the distances of the several cities, &c. of the empire were reckoned, by other military columns disposed at equal distances, on all the grand roads. This column was of white marble; the same with that which is now seen on the balustrade of the staircase of the capitol at Rome. Its proportion is massive; being a short cylinder, supporting a symbol of the globe of the earth.

It was called *milliarium aureum*, as having been gilt, at least the ball, by order of Augustus. It was restored by the emperors Vespasian and Adrian; as appears by the inscriptions.

COLUMN, military, among the Romans, a column whereon was engraven a list of the forces in the Roman army, ranged by legions, in their proper order; with design to preserve the memory of the number of soldiers, and of the order preserved in any military expedition.

The Romans had another kind of military column, which they called *columna bellica*, standing before the temple of Janus; at the foot whereof the consul declared war, by throwing a javelin towards the enemies countries.

COLUMN, phosporical, a light house; or a hollow column, built on a rock or the tip of a mole, or other eminence, to serve as a lantern to a port.

COLUMN, symbolical, is a column representing some particular country, by the attributes proper thereto; as that of the French order, set with *feurs de lis*, in the front-piece of the Jesuits church at Rouen; or some memorable action; as the *Corvinian column*, on which was a crow; erected to Valerius Maximus, surnamed Corvinus, in memory of his defeat of a giant in the army of the Gauls, by the assistance of a crow.

Under the title of *symbolic columns*, may also be comprehended those that serve for symbols. Such is that on a medal of Nero, which expresses the stability of the Roman empire. See **SYMBOL**.

COLUMNS, historical, memorial, honorary, triumphal. Under this head may be placed various distinguished columns, which rank among the eminent works of art ancient and modern, and form the chief ornaments of the situation in which they are placed. The most celebrated of these is the triumphal column of Trajan at Rome. This monument was built by Apollodorus the most famous Roman architect in the Forum Romanum. The height of the column is 106 feet, with a diameter of nearly 13 feet; it is placed on a pedestal of 10 feet high; upon the capital there is a crowning which formerly supported a statue of the emperor, but, at present, a bronze statue of St. Peter, about 14

feet in height. The base and capital are of the Tuscan order. The column, with the crowning, is composed of 24 tambours or blocks of white marble, and the shaft is adorned, mounting spirally from top to bottom, representing the victories of Trajan over the Dacæ. Four eagles at the corners of the pedestal support, in their beaks, festoons of laurel, and the sides of the pedestal are richly ornamented with a variety of military weapons. The inside of the column contains a staircase, which ascends to the capital, and as each block of stone forms the whole diameter of the shaft, the steps are wrought out of the solid.

The Antonine column, though inferior in design, and the beauty of sculpture to the last mentioned, is one of the most considerable monuments of ancient Rome. It was erected by Marcus Aurelius, and consecrated by him to Antoninus Pius, whose statue was placed upon the summit, on the shaft however are represented the action of Marcus in the Marcoman war. The column is 96½ feet in height, with a diameter of 11½, raised upon a pedestal of 26½ feet. The construction of this column is exactly similar to that of Trajan; its base and capital have Doric profile.

At Alexandria there is a remarkable column, which is commonly called Pompey's pillar. It is a column of the Corinthian order raised upon a short pedestal. The shaft is 67 feet long, and nearly nine feet in diameter, at the bottom of a single piece of granite. The whole height of the column and pedestal is about 94 feet.

At Constantinople there were two triumphal columns similar to those of Trajan and Antoninus; the column of Constantine is entirely destroyed, and of the other erected to Arcadius by Theodosius, only the pedestal and the first course of the shaft remains.

Lastly, may be mentioned the monument of London, which is the largest column in existence, being fifteen feet in diameter, and 202 feet high, including the pedestal and crowning. This column was erected in memorial of the great fire of London; its architect was Sir C. Wren.

COLUMN, rostral, a triumphal column adorned with the beaks or prows of galleys, in memorial of a naval victory. The first rostral column was erected in the capitol, on occasion of the defeat of the Carthaginians by C. Duilius. Augustus constructed four with the prows of the ships taken from Cleopatra.

COLUMN, Scenography of. See **SCENOGRAPHY**.

COLUMNS, in French *Colonne*. Column has been very erroneously defined by many writers on military subjects to be a long deep file of troops or baggage. This definition, confining a column to a file of troops, so far from giving a true idea of it, conveys one totally erroneous. For a column consists both of ranks and files. A column may, therefore, be defined to be a corps or body of men with ranks and files in the form either of a square or rectangle, who march in time, or with one and the same movement, leaving a sufficient interval between every two of the said ranks and files, in order to avoid confusion. A column may be in the form of a square, having its front equal to its depth; or it may be of a rectangular form, having either its front equal to one of the shortest sides of the rectangle, and its depth equal to one of the longest, or its front equal to one of the longest sides of the rectangle, and its depth equal to one of the shortest.

In marching troops in columns, particularly towards the enemy, great care should be taken, that they advance as nearly as possible alike, and not one before another, that they may, if attacked, be able to afford mutual aid and assistance to one another, and that as they approach the field of battle they preserve their distances with so much

accuracy, that when they wheel and form there may be neither too much nor too little ground for each squadron and battalion. This is a nice point, and an operation that is seldom executed correctly.

The most disadvantageous order of march is that which compels an army to move in one column. The more columns it is divid'd into, and the smaller their depth, the more easily and expeditiously are the troops composing them formed in order of battle. And the most advantageous method of marching an army is that which makes it move in order of battle, without dividing it into columns at all. But open level, and unembarras'd ground of sufficient extent for this purpose is rarely to be met with.

COLUMN, *Class.*, a solid compact column, with very little space or interval between the divisions composing it.

COLUMN, *Opera*, a column with intervals between the the divisions equal commonly to their respective fronts.

COLUMN, among *Prætoris*, is half a page, when the page is divided into two parts, from top to bottom. See *PRINTING*.

COLUMNA, *Fabius*, in *Biography*, a learned botanist, was born at Naples in 1567. He attached himself early to the study of natural history, particularly to acquire a knowledge of the properties of plants, in which he became eminent. He excelled also in the knowledge of languages, of music, of mathematics, and in drawing, of which he is said to have made much use, the greater part of the engravings in his works being taken from his own designs. He was led to study the works of Dioscorides, Boerhaave says, in order to find a remedy for eiptic fits, to which he was subject. That he was not successful in his search is probable, as he is said to have received the greatest benefit, having previously tried numerous medicines, by the application of a caustic to one of his thighs. The operation was performed by Severinus in the year 1630. He died in 1651, aged 83 years, and is said to have totally out-lived his faculty's. Haller gives him great credit as a reviver and improver of the study of botany, for the light he threw on many obscure passages in Dioscorides, and for the number of plants he described not before known. The figures of the plants he has given, which he generally assisted in executing, are among the earliest copper-plate engravings in that part of natural history. His first work, which was published when he was only 24 years of age, "Plantarum aliquot historia, in qua describuntur plantæ rarioræ, antiquarum delineationibus respondentes." Neap. anno 1592, 4to. far exceeding what had been before done in that line. The engravings also are more accurate than had been before seen. "In p̄bu (the wild valerian) charactrem exacte expressit." Haller says, it is the plant, the root of which, Dioscorides recommended in his complaint. He took of it for a long time with advantage, he says, but it did not effect a cure. The works were republished in 1744, 4to. by James Plaucus, with observations by the Lyncei, a society of naturalists, to which Fabius had belonged. Annexed is a short history of his life. "Minus cogitarum rariorumque nostris celo orientium sibi, cephalis: quæ non paucæ ab antiquioribus descriptæ disquuntur, et declarantur." Rome, 4to. This was prepared for the press in the year 1606. The dedication was written in the year 1612, but it did not appear until the year 1616. He now delineated the flowers, fruits, and seeds of the plants, and began to arrange them from the similitudes of those parts. A second part of this work soon followed. In 1617, his "Adnotationes, et additiones ad opus Francisci Hernandez, et Nautii Antonii Recchi" appeared. In this he makes further advances in the classification of plants,

from the resemblance of the petals. "Stylum et flamma novit." In his work appear the first dawning of the system, by which Linnæus, more than a century afterwards, became immortalized. He was a member of the illustrious academy of the Lyncei, established at Rome, which rendered great services to the republic of letters as long as it subsisted. Columna invented a musical instrument, which he called "Sambuca Lyncia;" from the name of his academy; it was composed of 500 strings of different lengths, and the tone of each was divided in four parts, according to the method of Aristoxenus, to include all the genera, diatonic, chromatic, and enharmonic. He published his invention in a work likewise entitled "Sambuca Lyncia," printed at Naples in 1618. Some later editions were published under the title, "Dell'istrumento perfetto." We make no reflections on the excellence of this instrument, having never seen it; but conjecture, that from the belly being loaded with so great number of strings, the tone must be very feeble; it must likewise have been difficult to tune for all the three genera, and still more difficult to keep in tune. Haller Bib. Botan. Eloy. Diet. Hist.

COLUMNA nafi, is used by some writers of anatomy, for the fleshy end of the nose, jutting out over the upper lip.

COLUMNA oris, is sometimes used for the uvula.

COLUMNA regia, in *Ancient Geography*, a place of Italy, over-against Sicily, on the bank of the frait, and near Regium Julium. It is mentioned in the Itinerary of Antonine.

COLUMNÆ, a name given by Ephorus, cited by Pliny, to a small island on the route from the Red Sea to the island of Cerne. G. Hardonin thought they were the Mascarenhas isles.

COLUMNÆ albæ, or white columns, called by Herodotus (l. v. c. 118.) λευκὰ στῆλαι, a place of Asia Minor, to the south of the river Mæstias, and very near it.

COLUMNÆ carnæ, in *Anatomy*, called also *lacertæ*, and *coluææ cordis*, are several small muscles in the ventricles of the heart; derived, and, as it were, detached from the parietes of those ventricles, and connected by tendinous extremities to the valves of the heart.

These little columns, or pillars, being fastened to the parietes of the heart on one side, and the tricuspid and mitral valves on the other, do, by the contraction in the systole of the heart, draw out the valves; and by that means not only fill the orifices of the veins, but more exactly close the ventricles in their systole.

COLUMNA herculis, the columns of Hercules, in *Ancient Geography*, the name given to the frait of Gibraltar, called also *Fretum Gaditanum* and *Fretum Herculeum*. These columns of Hercules were properly the two mountains of Calpe in Europe, and of Abyla in Africa. Some have supposed that Hercules called them by his name; but others consider Hercules as an imaginary hero, whose name is formed of the Phœnician "Harokel," signifying a merchant or voyager. Hence, they say, it is not astonishing, that this frait should be called "the Strait of Voyagers;" and that its name should be derived from the Phœnician language, since the Phœnician navigators had made it known, and continually sailed through it.

COLUMNAR Marble. See *BASALTES*.

COLUMNAR strata, a mineralogical term for the strata into which different strata of the earth are sometimes found split or divided, generally in a direction perpendicular to the lamina of the strata or nearly; these most commonly occur in basalt or trap, those of Stople in Saxony, exceed 300 feet in length, without any articulation or division. Dolomien observed columnar basalt in the strata of mount

Etua.

Etna. At Cleton in Derbyshire, Mr. Mawe observed an irregular column in the Toad stone or trap (Mawe's *D. rb.* p. 40 and 51). Porphyry is often found in a columnar form. (See 2 B. *rg. Journ.* 1790, 325, and Haiding, 48. Sandstone in the east and north parts of Bohemia, are often split into columns, resembling basalts, 2 *Berg. Journ.* 1792, 70. Limestone is sometimes found rent into polygonal pillars of 4, 5, &c. sides like balais, as at Rhoms and Ridon in the Vivarais, and in Saxony. Charpentier 49. See **BASALT TRAP** and **PRISMATIC COLUMNARS**.

COLUMNARIS, in *Botany*, a name given by some to the tall, milky bell flower; the *campanula lactescens*, Ger. Emac. Ind. 2.

COLUMNARIUM, in *Roman Antiquity*, a heavy tribute, demanded for every pillar of a house. It was first laid on by Julius Cæsar, in order to put a stop to the extravagant expences laid out on sumptuous buildings.

COLUMNÆA, in *Botany*. (So named by Plumier in honour of Fabius Columna, or Fabio Colonna, of the noble family of Colonna in Italy.) *Linn. Gen.* 792. Schreb. 1064. Willd. 1210. Plum. 33. Juss. 121. Clafs and order, *dichynania angiosperma*. *Nat. Ord. Personate*, *Linn. Scrophulariæ*, Juss.

Gen. Ch. Cal. One-leaved, deeply five-cleft, generally somewhat swelling at the base, permanent; segments erect, equal, lanceolate. *Cor.* monopetalous, much longer than the calyx, labiate; upper lip erect; lower lip two or three-cleft. *Stam.* Filaments four free; anthers joined together. *Pist.* Germ superior, egg-shaped; style filiform, the length of the upper lip; style bifid, obtuse. *Peric.* Capsule globular, one or two-celled. *Seeds* numerous, small, attached to a large receptacle.

Essen. Ch. Calyx five-cleft. Corolla labiate; upper lip erect, emarginate; lower lip three-cleft. Anthers connected. Capsule, one or two-celled. *Seeds* bedded in the receptacle.

Sp. 1. C. Scandens. *Linn. Sp. Pl.* Mart. 1. Lam. 1. Willd. 1. Jacq. Hort. vol. iii. tab. 48. Amer. Picé. 88. tab. 170. Plum. Gen. 28. ic. tab. 89. fig. 1. Lam. Ill. tab. 524. fig. 1. "Leaves egg-shaped, acute, entire or slightly crested, somewhat villous; calyx pubescent; segments entire; corolla pubescent; upper lip undivided." *Root* perennial. *Stem* slender, very long, pale green, slightly villous, either creeping on the ground, or attaching itself to the trunks of trees, by small lateral roots. *Leaves* opposite, petioled, resembling those of *Parietaria*. *Flowers* blood-red, two inches long, axillary, solitary, villous on the outside, on short peduncles, a little curved. *Capsule* globular, white, softish, resembling a berry, but opening, about the size of a nut, one-celled. A native of South America, and the West Indies. There is a femial variety with yellowish flowers. 2. *C. longifolia.* *Linn. Mant.* 90. Mart. 2. Lam. 3. (*Achimenes selsoides*; Vahl. *Symb.* 2. 71. Willd. 1190. Babel. Tibuli. Rheed. Mal. 9. tab. 87. *Selamum javanicum*; Burm. Ind. 133.) "Leaves lanceolate, very long, somewhat ferrated, smooth." *Stem* about two feet high, herbaceous, quadrangular, smooth, branched. *Leaves* three inches long, opposite, nearly sessile. *Flowers* red, opposite; in simple, long, erect, terminal racemes; border of the corolla four-cleft; upper lip large, oblong, entire; lower lip trifid; anthers divided at the base into two diverging lobes, connected, and forming a cross. *Capsule* egg-shaped, two-celled, two-valved. *Seeds* numerous, fixed in a globular receptacle. A native of the East Indies. 3. *C. hirsuta.* Mart. 3. Willd. 2. Hort. Kew. 2. 366. Lam. Ill. tab. 524. fig. 2. Swartz. Prod.

94. Flor. Ind. occ. 2. 1080. (*Achimenes major*; Brown. Jam. 270. tab. 30. fig. 3. *Rapunculus pinnatus*; Sloan. Jam. 58. Hort. 1. tab. 100. fig. 1.) "Leaves egg-shaped; acuminate, ferrated, rough, with hairs on the upper surface, segments of the calyx tooth ferrated, hirsute; corolla hirsute; upper lip bifid." *Root* perennial. Whole plant succulent. *Stem* thick, throwing its branches to the height of four or five feet when supported. *Leaves* opposite, alternately larger. *Flowers* large, beautifully variegated; segments of the calyx almost pinnated like those of the rose. A native of the cooler mountains of Jamaica; introduced in 1780, by the marquis of Rockingham; flowering in November. 4. *C. hispida.* Mart. 4. Willd. 4. Swartz. Prod. 94. Flor. Ind. occ. 2. 1083. "Leaves egg-shaped, obtuse, slightly toothed, hirsute hirsute; segments of the calyx entire, hairy; stem hairy, scabrous." A native of Jamaica. 5. *C. natalans.* Mart. 5. Willd. 3. Swartz. Prod. 94. Flor. Ind. occ. 2. 1083. "Leaves ovate-lanceolate, slightly toothed, rather scabrous, hirsute and coloured underneath; calyx villous; segments lacinated; corollas villous." A native of Jamaica, in shady woods, attached to the trunks of trees. 6. *C. stellata.* Willd. 6. Lour. Cochin. 384. "Leaves sessile; flowers solitary; stem creeping." *Stem* herbaceous, perennial, cylindrical, slender, whitish. *Branches* somewhat erect, four inches long, very tender. *Leaves* egg-shaped, three lines long, serrated, stellate in threes, pale green, odoriferous, petioled. *Flowers* white, striped with red, axillary, hirsute, peduncled; tube of the corolla scarcely gibbous; upper lip arched, trifid; lower bifid; anthers egg-shaped, connected, separated with difficulty. *Capsule* awl-shaped, two-celled. The whole plant, except the capsule, hairy. A native of Cochin-china. It is an aquatic, of a very pleasant appearance and smell, and being emollient and cooling, is used as a wash by the women, for which purpose it is cultivated in pots or tubs filled with water, having earth at the bottom.

COLUMNÆA erecta; Lam. See **CYRILLA pubescella**.

Propagation and Culture. All the species require the heat of a stove. They are propagated by seeds, and should be treated like other tender exotics.

COLUMNELLA, *little columnæa*, denotes the substance that passes through the capsule, and connects the several partitions and seeds.

COLUMNIA POMPEI, in *Ancient Geography*, a place of Thrace, at the entrance of the Thracian Bosphorus, on the coast of the Euxine sea.

COLUMNATED winding stairs. See **STAIRS**.

COLUMNIFERE, in *Botany*, the thirty fourth natural order in the "Philosophia Botanica," of Linnæus, and the thirty-seventh of "Prælectiones." In the "Philosophia Botanica," it contains the following genera; *camellia*, *xylo*, *gossypium*, *ureva*, *hibiscus*, *turnera*, *malope*, *lavatera*, *althæa*, *alcea*, *malva*, *melochia*, *sida*, *nappa*, *waltheria*, *mentzelia*, *hermannia*, *helictes*, and *stewartia*. In the *Prælectiones* all these are connected, except *mentzelia*, which is removed to the *calycanthææ*; and *xylo*, which was suppressed as a distinct genus by Linnæus himself, and its species placed under *bombax*. The following are added by Linnæus, *triumfetta*, *bixa*, *corechora*, *theobroma*, *græwia*, *montingia*, *tilia*, all of which originally formed part of the now suppressed order *columniææ*; and beside these, *mala-chra*? *pentapetes*, *bombax*, *adanfonia*, *heliocarpus*, *antichorus*, *maiernia*, *kleinovia*, *ayenia*, *microcos*, *thea*, *kigg-claria*. *Stewartia* is placed by Linnæus under both the *columniferæ* and the *tricoceæ*. In the "Philosophia Botanica" it had been placed among the latter, and when it was afterwards

wards removed to the former, it was most probably left in its original station, merely through inadvertence. The following have since been added; but Giske acknowledges himself in doubt whether the arrangement would in all cases have been approved by Linnæus. *Symplocos*, Linn., and *terstroemia*, Linn., referred to this order by Swartz.; *palavia*, Cav.; *anoda*, Cav.; *ruizia*, Cav.; *alfonia*, Cav.; *dombera*, Cav.; *ochroma*, Swart.; *paronia*, Cav.; *achania*, Sol. Swart.; (*malvavifens*, Dill. Cav.) *Lagunera*, Cav.; *cinifogofia*, Cav.; *myrodia*, Swart. (*Quararuba*, Aubl. Cav.), *auletia*, Schreb. (*Aceiba*, margr. Aubl. Swart.) *Marila*, Swart.; *hubroma*, Schreb.; *malacodendron*, Mitch. Cav. *eroteum*, Swart.

Linnæus confiders that the essential character of the order is not to be understood from the name, which properly belongs only to some of the more remarkable genera. In all of them the root is fibrous; in none bulbous or tuberous. The stem in most is herbaceous, but some are large trees; it is amongst the latter only, that thorns are to be found; and prickles only in some hibiscif. Scarcely any plant in the whole order is smooth. All have stipules in pairs. The leaves are never opposite, most commonly petioled; the foetation, as far as Linnæus could recollect, always pinnate, and many have glanduliferous pores under the rib. There are no tendrils in any plant of the order. The inflorescence is various. The calyx in many is simple and five-cleft; in some double. The petals in most are five; but since the filaments are united, and in most genera adhere to them, the corolla falls off all together, as if it consisted only of one petal. Their claws, by converging often, constitute the nectary. The pills, or at least the stamens, are equal in number to the parts of the fruit. The fruit is always superior, but various in other respects. None of the foecies are poisonous or fetid; they are generally more or less mucilaginous; and the flowers of most are beautiful.

COLUMNATENSIS, in *Ancient Geography*, an episcopal see in Africa in Mauritania Cæsariensis, according to the conference of Carthage.

COLUPPA, in *Botany*, Rheed. See *ILLECEBRUM f. f. f.*

COLURES, in *Geography* and *Astronomy*, are two great circles, imagined to intersect each other at right angles in the poles of the world.

The word is derived from *κόρος*, *mutilus*, or *truncatus*, and *οψα*, *tail*; q. d. *appearing with the tail cut off*; because never seen entire above the horizon.

The colures pass one of them through the solstitial, and the other through the equinoctial point of the ecliptic; whence the first is denominated the *solstitial*, and the second *equinoctial colure*.

The equinoctial colure determines the equinoxes; and the solstitial, the solstices.

By thus dividing the ecliptic into four equal parts, they also mark the four seasons of the year.

It is disputed over what part of the back of Aries the equinoctial colure passed in the time of Hipparchus. Sir Isaac Newton, in his *Chronology*, takes it to have been over the middle of the constellation. Father Soucier insists on its having passed over the dodæcatemorian of Aries, or midway between the rump and first of the tail. We have some observations in the Philosophical Transactions, N° 466, concerning the position of this colure in the ancient sphere, from a draught of the constellation Aries, in the *Aratæa* published at Leyden and Amsterdam, 1652, which seem to confirm Sir Isaac's opinion; but the antiquity and authority of the original draught may still remain in question. See *CHRONOLOGY*.

COLURI, in *Geography*, an island in the gulf of Egeia, near the coast of Livadia, about seven miles long and two wide; 10 miles W. of Athens. N. lat. 38°. E. long. 23° 36'.

COLUSITANUS, in *Ancient Geography*, an episcopal see in the proconsular Africa, according to the conference of Carthage; supposed to be the same with *Calcutanensis*.

COLUSSA, a Greek town of Paphlagonia.

COLUTEA, in *Botany*, (*Κολούτις*), the name of a plant in Theophrastus. Tourn. Clafs 22. fect. 3. Gen. 2. Linn. G. n. 80. Schreb. 1196. Willd. 1365. Gært. 488. Juss. 359. Vent. 3. 412. Bagnewandier; Encyc. Clafs and order, *diadelphia decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss. Vent.

Gen. Ch. Cal. Perianth one-leaved, bell-shaped, five-cleft, erect, permanent. Cor. Papilionaceous. Standard, wings and keel differing in different species with respect to number and proportion. Stam. Filaments nine united; one separate; anthers simple. Pissl. Germ. superior, oblong, compressed peduncled; style ascending; stigma bearded on the lower side. Peric. Legume very large, membranous, transparent, generally inflated, appearing almost empty, perfectly one-celled. Seeds small, kidney-shaped, attached to the two edges of the upper suture.

Ess. Ch. Calyx five-cleft. Stigma bearded on one side. Legume peduncled, membranous, inflated or compressed, one-celled.

Obs. This species is nearly allied to *atragalus* and *phaca*. The total want of a partition in the legume is its only certain generic distinction. The atragali are completely two-celled. The phacæ have a partial partition, which extends the whole length, but only half the breadth of the legume, making it semi-bilocular.

Sp. 1. *C. arborefens*. Common bladder-fenna. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Gært. tab. 154. fig. 4. Lam. 11. 624. fig. 2. Bot. mag. tab. 81. (C. vesicaria; Bauh. Pin. 206. Tourn. 649. C. hirsuta; Roth. Germ. 1. 305. II. 168.) "Leaflets inversely heart-shaped." Linn. "Leaflets oval-obcordate; standard gibbous, abbreviated." Hort. Kew. A shrub. Stems several, woody, twelve or fourteen feet high; branches numerous, woody. Leaves alternate, winged, terminated by an odd one; leaflets nine or eleven, green and smooth above, glaucous underneath. Flowers yellow, with a reddish curved line at the base of the standard, in a short raceme, consisting of three or four flowers; wings only a little shorter than the keel. Legume closed at the tip. Seeds twenty or more. A native of the warmer parts of Europe; observed by Mr. Ray, in the ascent to the crater of mount Vesuvius, where there are scarcely any other plants. It flowers with us in the early part of June, and sometimes again in the month of August, continuing till October. Both leaves and legumes are purgative, and may be substituted for the officinal fenna, (cassia fenna), but must be taken in larger doses. They have an acid, nauseous taste. The seeds, in the quantity of a dram or two excite vomiting; but notwithstanding these qualities, the plant is said by Haller and Ray to afford a food grateful to cattle. 2. *C. cruenta*. Oriental bladder fenna. Mart. 2. Willd. 2. L'Heretier Stimp. nov. 2. tab. 41. Hort Kew. 3. 55. Lam. 11. tab. 624. fig. 3. (C. orientalis, flore, sanguinei coloris, luteâ maculâ notata. Tourn. Cor. 44. C. fanguinea. Pel. r. off. 1. 88. C. orientalis. Lam. 2. C. humilis. Scop. influr. 2. 23. tab. 12.) "Shrubby; leaflets wedge-shaped, inversely heart-shaped; standard gibbous, obtuse, very small." Stem woody; branches seven or eight feet high. Leaves pinnated; leaflets eleven or thirteen, small, smooth, glaucous, more fleshy than those of the preceding species.

Flowers

Flowers deep red, with two yellow spots on the standard, small; wings considerably shorter than the keel; keel erect, appearing cut off at the end. *Legume* opening beneath the tip into a wide hole. Discovered by Tournfort in the Levant; cultivated by Miller in 1752. 3. *C. poccockii*. Poccock's bladder-fenna. Mart. 3. Willd. 3. Hort. Kew. 3. 55. (*C. procumbens*; L'Heretier Stirp. nov. 2. tab. 42. *C. halepica*; Lam. 3.) "Shrubby; leaflets roundish-elliptical, very obtuse, mucronate; standard gibbous, elongated, ascending." A lower shrub than the preceding. *Branches* slender, spreading. *Leaflets* thirteen or fifteen, very small, entire, of a cinereous-green colour underneath. *Flowers* bright yellow, larger than those of *C. arboreascens*, opening a month earlier, and continuing in succession till late in the autumn; peduncles shorter than the leaves, axillary, solitary, one or two-flowered. The seeds were first brought to England from Turkey, by Dr. Poccocke, and are said by Dr. Ruffell to be very common about Aleppo. 4. *C. frutescens*. Scarlet bladder-fenna. Linn. Sp. Pl. 2. Mart. 4. Lam. 4. Willd. 4. Bot. Mag. tab. 181. "Leaflets oblong, retuse, hoary underneath; branches silky-tomentous." A shrub, from two to four feet high; branches erect. *Leaflets* from twenty-one to twenty-five, green and smooth on their upper surface. *Flowers* bright scarlet large; peduncles axillary, from three to five-flowered; keel considerably longer than the standard; wings very small. *Legumes* very large. A native of the Cape of Good Hope, and other parts of Africa. 5. *C. americana*. Mart. 8. Houft. MSS. "Shrubby; leaflets egg-shaped, emarginate; legumes oblong, compressed, acuminate." *Stem* twelve or fourteen feet high, much branched; leaflets seven, light green. *Flowers* bright yellow, two or three upon each peduncle. *Legumes* near four inches long, compressed, winged, ending in long points. Sent to Miller in 1730, by Dr. Houlton, from Vera Cruz in New Spain. 6. *C. galegifolia*. Bot. Mag. tab. 792. "Shrubby; leaflets oval, emarginate, in about nine pairs, with a terminal one; legumes on longish pedicels." *Stem* low, zig-zag; branches herbaceous, angular. *Stipules* two, egg-shaped, small, embracing the common petiole, but distinct from it. *Flowers* dull red, inclining to orange, in a many-flowered raceme; common peduncles longer than the leaves, axillary; pedicels alternate, short, curved; bracte under each flower, single, small, egg-shaped; calyx-teeth wide at the base, with white villous margins; standard roundish, somewhat reflexed, marked at the base with a greenish yellow spot; wings smaller than the keel; keel one-petailed, when folded nearly orbicular; style hairy on the upper surface of its whole length. *Legume* inflated, membranous, veined, oblong, oval, beaked, on a pedicel four times longer than the calyx. *Seeds* many, shining, kidney-shaped. A native of New South Wales. 7. *C. procumbens*. Mart. 9. "Stems trailing; leaflets oblong, egg-shaped, tomentous; flowers axillary, on very long peduncles." *Stems* several, woody, slender, much branched; branches not much more than a foot long; leaflets twenty-five or twenty-seven, small, narrow. *Flowers* purple, small; peduncles with three or four flowers. *Legumes* little more than half an inch long, but like a sickle, compressed. *Seeds* kidney-shaped. A native of the Cape of Good Hope. Cultivated by Miller in 1753. 8. *C. rigida*. Willd. 5. Thunb. prod. 134. "Shrubby; leaflets lanceolate, smooth; stem erect, smooth. A native of the Cape of Good Hope. 9. *C. obtusata*. Willd. 6. Thunb. prod. 134. "Shrubby; leaflets linear; stem erect; flowers in racemes, reflexed." A native of the Cape of Good Hope. 10. *C. linearis*. Willd. 7. Thunb. prod. 135. "Herbaceous; leaflets linear, acute; stem erect; racemes terminal, incurved." A native of the Cape of Good Hope.

11. *C. herbacea*. Linn. Sp. Pl. 2. Mart. 6. Lam. 5. Willd. 8. Gart. tab. 154. fig. 2. "Leaflets linear, emarginate, smooth; stem herbaceous; racemes axillary." *Stems* annual or triennial. *Stems* near a foot and half high, clothed with very short hairs, branched. *Leaflets* fifteen or seventeen, greenish. *Flowers* dark blood-red, small; standard striated, the length of the wings and keel. *Legumes* imbricated, membranous, somewhat transparent, very thin, compressed, egg shaped, obliquely mucronate, two-valved, pitted. *Seeds* two or four, rather large, kidney-shaped, compressed, of a dull chestnut colour. A native of the Cape of Good Hope; cultivated by Miller in 1731. 12. *C. perennans*. Mart. 5. Willd. 9. Hort. Kew. 3. 56 Jacq. Hort. 3. tab. 3. (*C. fistulosa*; Retz. Obs. 3. 40. Mart. 7.) "Herbaceous; leaflets oblong, pubescent; stem erect; racemes terminal." *Root* perennial. Whole plant slightly pubescent. *Stem* cylindrical, striated, pale green, annual, simple, or with almost barren branchlets. *Leaves* alternate, neat together, spreading; leaflets from thirteen to seventeen, entire, obtuse, on very short petioles. *Flowers* flesh-coloured, small, without scent; standard wide, roundish, emarginate, marked with deep purple streaks; wings shorter than the keel, oblong, obtuse; keel dark purple, ascending at the end, almost as long as the standard; style smooth; stigma obtuse, with white villous hairs, but bearded only at the tip. *Legume* ovate-roundish, acuminate at both ends, compressed, flat, little inflated, smooth, membranous, somewhat pellicid, not opening of itself. *Seeds* few, compressed black. A native of the Cape of Good Hope; introduced by Dr. Jacquin in 1776. 13. *C. prostrata*. Willd. 10. Thunb. prod. 134. "Leaflets lanceolate, villous; stem herbaceous, diffuse; peduncles axillary, with about two flowers." A native of the Cape of Good Hope. We should have supposed this to be *C. procumbens* taken up by professor Martyn from Miller, if Miller had not expressly asserted that his plant has woody stems. 14. *C. excisa*. Willd. 11. Thunb. prod. 134. "Leaflets egg-shaped, cut; stem herbaceous, decumbent; racemes terminal." A native of the Cape of Good Hope. 15. *C. vesicaria*. Willd. 12. Thunb. prod. 134. "Leaflets egg-shaped; stem herbaceous, decumbent villous; legumes orbicular, inflated." A native of the Cape of Good Hope. 16. *C. tomentosa*. Willd. 13. Thunb. prod. 135. "Leaflets egg-shaped, hoary; stem herbaceous, tomentous; flowers in racemes. A native of the Cape of Good Hope. 17. *C. alpina*. Lam. 6. (*Phaca alpina*; Linn. P. leguminibus pendulis femiovatis; Gmel. Sib. 4. 35. tab. 14. *Astragalus*; Hall. Helv. n. 401. *Astragaloides elatior*, erecta, vicie foliis, siliquis pendulis. Amon. Ruth. 148.) "Herbaceous, much branched; leaflets oblong, elliptical, hairy underneath; flowers pale yellow." *Root* perennial. *Stems* near a foot and half long, weak, sometimes quite upright, sometimes half decumbent and diffuse. *Leaflets* nineteen or twenty-one, green and smooth above, diminishing in size towards the top. *Flowers* yellowish, in peduncled spikes, situated in the axils of the upper leaves; calyx beset with a few short blackish hairs. *Legumes* vesicular, perfectly one-celled, pedicelled in their calyx, demi-oval, or a little crescent-shaped, acute, pendulous on the common peduncle. *Seeds* from four to six, small, kidney-shaped. A native of the mountains of Dauphiné, Switzerland, Lapland, and Siberia. 18. *C. australis*. Lam. 7. (*Phaca australis*, Linn.; *astragalus*. Hall, Helv. p. 403. *Astragaloides alpina supina glabra*, Till. Hort. Pin. 19. tab. 14. fig. 1.) "Herbaceous, diffuse; leaflets lanceolate, nearly smooth; peduncles longer than the leaf." *Root* perennial. *Stems* from five to seven inches long, slender, weak, commonly procumbent, almost smooth, branched. *Leaflets* thirteen or fifteen, acute.

acnte. *Stipules* two, embracing the stem, oval-obtusely. *Flowers* yellowish white, with a tint of violet at the extremity of the keel, sessile, in axillary spikes. *Legumes* vesicular, demi-oval, pedicelled in their calyx, terminated by a short bent thread, perfectly one-celled, smooth, not pendulous. *Seeds* five or six, small. A native of the mountains of Provence, Italy, and Switzerland. After some hesitation, we have placed the last two species under this genus, in concurrence with La Marck, although that botanist has not, in this particular, been hitherto followed by any other author. Gartner has even figured the legume of this species alone, to illustrate the genus phaca. As far, however, as the partition is concerned, he completely gives up the point, acknowledging the legume to be absolutely one-celled, without a vestige of a partition. He has accordingly introduced *aur. rarius unicolor*, into his generic character, and has founded the essential distinction between *colutea* and *phaca* on the form of the flowers. To us the entire want of a partition appears decisive. Jacquin, indeed, has attributed to his alpina a half two-celled legume; but he seems to refer to a different plant. There is much confusion in authors with respect to the synonyms of *phaca-alpina*; and that with the kindred species, stands in need of further investigation.

COLUTHUS, in *Biography*, a Greek poet, a native of Lycopolis, lived under the emperor Anastasius in the beginning of the sixth century. His only work that has come down to us is upon the "Rape of Helen," which, though of inferior merit, has been frequently edited, and was translated into French by M. du Molard in 1742. Moreri.

COLVIUS, ANDREW, was born at Dort in Holland, in the year 1574, where he officiated during a considerable part of his life as pastor of the Walloon church. In 1620, he was chaplain to the embassy at Venice, and cultivated an intimate friendship with the celebrated father Paul, whose treatise on the inquisition he translated from the Italian into the Latin language. Colvius was intimately acquainted with many literary characters of his own age, and was himself a philosopher and poet of eminence, but he is chiefly

known as a collector of rarities of every description, of which, in the year 1655, he published a catalogue intitled "Catalogus Musei And. Colvii." He died at Dort in 1671. Moreri.

COLYBA, or **COLYBUS**, a term in the *Greek Liturgy*, signifying an offering of corn and boiled pulse, made in honour of the saints, and for the sake of the dead.

Balfamon, P. Guar, Leo Allatius, and others, have written on the subject of *colyba*: the substance of what they have said, is as follows:

The Greeks boil a quantity of wheat, and lay it in little heaps on a plate; adding beaten peas, nuts cut small, and grape-stones, which they divide into several compartments, separated from each other by leaves of parsley. A little heap of wheat, thus seasoned, they call *colyba*.

They have a particular formula for the benediction of the *colyba*: wherein, praying that the children of Babylon may be fed with pulse, and that they may be in better condition than other people, they desire God to bless those fruits, and those who eat them, because offered to his glory, to the honour of such a saint, and in memory of the faithful deceased. Balfamon refers the institution of this ceremony to St. Athanasius; but the Greek Synaxary to the time of Julian the Apostate.

Many of the Latin divines having spoken injuriously of this ceremony, Gabriel archbishop of Philadelphia, has written a discourse in its vindication: wherein he endeavours to shew that the design of the *colyba* is only to represent the resurrection of the dead, and to confirm the faithful in the belief thereof. The *colyba*, he says, are symbols of a general resurrection; and the several ingredients added to the wheat, signify so many different virtues.

COLYBRASSENSIS, in *Ancient Geography, an episcopal see of Africa, in Pamphylia, according to the acts of the council of Constantinople, held in the year 381.*

COLYMBIS, in *Ornithology*. Bellonius describes the tufted duck *anas fuligula* of modern writers under the name of *colymbis*.

COLYMBUS, a genus of the *anseræ*, having the bill toothless, subulate, straight, and pointed; throat denticulated; nostrils linear, and situated at the base of the bill; legs fettered.

Linnaeus includes in the *colymbus* genus three families of birds; the guillemot, the divers, and the grebes, each of which, in the opinion of most ornithologists, ought to be considered generically distinct. The guillemots live chiefly aloft to the sea, and inhabit rocks; they have a slender tongue the size of the bill, and the bill itself of a compressed form, with the upper mandible a little bent, and the base covered with short feathers: they are principally distinguished by having the feet three-toed. The divers have a strong bill, less pointed, cylindrical, the edges of the mandible turned in, the upper one longest; nostrils divided in the middle by a membrane tongue long, sharp, serrated at the base each side; legs slender; tail-feathers twenty in number; the chief character of these consist in the feet being furnished with four toes, and palmate; they frequent fresh waters. The grebes are without a tail, have a strong bill; lores naked; tongue a little cleft at the tip; body depressed, and thickly covered with soft shining plumage; wings short, and the legs compressed; the principal characteristic of this family are the lobate feet; consisting of four toes each. Those last mentioned birds frequent meres, and other inland water places.

* *Feet three-toed*, Guillemot.

MARMORATUS. Above streaked with chestnut and brown; beneath

beneath waved with dusky and white; legs tawny; bill, tail, wings, and claws black. *Colymbus marmoratus*, Gmel. *Marbled guillemot*, Lath. Syn. *Uria marmorata*, Lath. Ind. Orn.

Inhabits the western parts of America and Kamtschatka. This bird is ten inches in length; the crown is dusky; some of the greater quill-feathers edged with white; chin dusky, with white stripes.

LACTEOLUS. Snowy; bill and legs brownish flesh-colour. *Colymbus lacteus*, Gmel. *Cephus lacteus*, Pallas Spic. *White guillemot*, Lath. Gen. Syn. *Uria lactea*, Lath. Ind. Orn.

Lives on the sea-coasts, and chiefly inhabits the Northern lands. A variety of this bird is described by writers (Sander Naturf. &c.) that has a black spot on each side behind the eyes; interscapulars and area of the wings black; upper mandible black, the lower yellowish.

GRYLLE. Body deep black; wing-coverts white. *Colymbus grylle*, Linn. Gmel. *Colymbus groenlandicus*, Klein. *Uria minor nigra*, Briff. &c. *Greenland dove, sea turtle*, Albin. *Black guillemot*, Lat. Donov. Brit. Birds, &c.

A general inhabitant of Europe and America, frequenting the sea-coast, and preying on fish; it builds its nest on the ground, the eggs are whitish, and spotted with black. This species is liable to some variation in the disposition of its spots, and appearance of plumage. One variety found at Anonahika is of a sooty black colour, with a double white band. Another is streaked above; beneath white, banded with cinereous; upper wing-coverts varied with white and black; this is the *uria balltica* of Brunnich, and inhabits Greenland. A second variety mentioned by the same author has the back, wings, and tail black; head, neck, and body beneath, with the spot on the wings white. Dr. Latham describes a variety from Kamtschatka of a black colour, with the crown clouded; the greater wing-coverts, and under side of the body, varied with white and black; throat entirely white; and lastly, the *uria gryllodes* of Brunnich is considered by some as a variety of this species; the upper part of the plumage of this bird is spotted white and black, the colour beneath white.

TROILE. Body black; breast and abdomen snowy; secondary wing-feathers white at the tip. *Colymbus troile*, Linn. *Lomvia boieri*, Ray. *Le guillemot*, Buff. *Lumme*, Marten Spitz. *Foolish guillemot*, Penn. Donov. Brit. Birds, &c.

This bird inhabits Europe and America, and is found in maritime frictions, as its principal food consists of sea-fish; its usual resorts are the steep and most inaccessible cliffs on the sea-coast, and in such places is seen in vast numbers on our own coasts during the summer, in which season they breed. The places most celebrated as the resort of these birds are the ile of Prielholm, in Beaumaris bay, between Caernarvonshire and the island of Anglesea; on a rock called Godreve, not far from St. Ives, Cornwall; the Farn island, near the coast of Northumberland; and the cliffs about Scarborough, Yorkshire. They are silly birds, and so stupid, that having once attained access to their haunts, they may be knocked down in any numbers with a stick, for though they see their companions killed before them, they never attempt to quit the rocks. In many parts they are killed by the inhabitants both for the sake of their flesh and skin; the former is, however, not remarkable for its delicacy, and has a strong fishy taste. The natives of Greenland and Kamtschatka make garments of their skins. Like the auk, this bird lays but a single egg; the eggs are in more esteem for the table than the flesh. The length of this

bird is seventeen inches. There are several varieties of this species.

We have followed the example of Linnæus and Gmelin in considering the four above-mentioned birds as appertaining to the *colymbus* genus, but it should be at the same time observed, that Brunnich constitutes a distinct genus of them under the title of *uria*, and that this genus is adopted by Dr. Latham, in his "Index Ornithologicus," though he adheres to the Linnæan method in his "General Synopsis."

* * * Feet four-toed, palmated, Diver.

GLACIALIS. Head and neck violaceous black; a white interrupted band on the chin and upper part of the neck. *Colymbus glacialis*, Linn. *Colymbus torquatus*, Brun. *Mergus nevius*, Briff. *Colymbus maximus caudatus*, Ray. *L'Imbrina*, Buff. *Greatish speckled diver or loon*, Albin. *Northern diver*, Penn. Donov. Brit. Birds.

This is a large bird, measuring about three feet in length; the upper part of the body with the bill, legs, and tail are black; the back and upper part of the wings is marked with a number of white spots disposed in rows. Inhabits the Northern seas, and is rare in England. The specimen in the London Museum.

In Iceland and Greenland, where these birds breed, they are very frequent. It is also abundant on the shores of Norway, and along the Arctic coasts as far as the river Obey, in the dominions of Russia. It is seldom seen on land, except in the breeding season, being, for the most part, in the open sea, where it is continually diving for fish, which it does with the greatest address. Among the northern maritime nations, the skins of these birds are prepared by the natives, and manufactured with the feathers on them into caps and other articles of dress. Garments, we are told, made of these skins are warm, and never imbibe the least moisture, and are also more durable in wear than might be imagined. The bird is likewise met with among the lakes of Hudson's bay, where the natives adorn their heads with ciclets of their feathers.

IMMER. Body above blackish, undulated with white; beneath entirely white. *Colymbus immer*, Linn. *Mergus major*, Briff. *Le grand plongeon*, Buff. *Ember goose*, Sibbald. *Imber diver*, Penn. Donov. Brit. Birds.

The length of this bird is two feet; the feathers of the back, wings, and tail are edged with white; in the male bird the front and sides of the head and neck are spotted with brown. This species inhabits the Arctic ocean; it ranks as a British species, but is rarely taken in our country.

STELLATUS. Cinereous-brown or dusky, spotted with white; throat pale ash, beneath white. *Colymbus stellatus*, Brun. Gmel. *Mergus minor*, Briff. *Colymbus caudatus stellatus*, Will. *Le petit plongeon*, Buff. *Speckled diver, or loon*, Lath.

Observed in plenty about the shores of the Baltic, and white sea, and in America. They occasionally migrate in flocks, pursuing the same course as the shoals of herrings and sprats, the latter in particular, and it is for this reason known in many parts by the name of *sprat loon*. These birds are more common in the temperate, or southern parts of Europe, than any other of the diver tribe. The length is twenty-seven inches, the bill horn colour; legs brown. It builds no nest, but lays its eggs, which are two in number, in the grass on the borders of lakes contiguous to the sea-coast; these eggs are dusky, spotted with black.

ARCTICUS. Head hoary; neck beneath violaceous, black, with an interrupted white band. *Colymbus arcticus*, Linn. *Mergus gutturo nigro*, Briss. *Black-throated diver*, Lath.

Length two feet; inhabits the north of Europe, Asia, and America.

SEPTENTRIONALIS. Body above blackish, beneath white; neck beneath with a shield-like spot. *Colymbus septentrionalis*, Linn. *Mergus gutturo rubro*, Briss. *Le plongeon à gorge rouge*, Buff. *Red throated diver*, Lath. *Donov. Brit. Birds*, &c.

Inhabits Europe, Asia, and America, frequenting lakes, and oftentimes the open sea in quest of prey, which consists of fish, marine insects, and crabs. The body is brown above, with minute white spots, beneath white; bill black, head and chin cinereous, spotted with brown; neck above with small white and brown lines; the legs dusky. Length about thirty inches. These birds lay their eggs in June, the young are hatched and ready to fly before the end of August, and undertake their annual migrations with the parent birds in September. They breed chiefly in America.

BOREALIS. Body above blackish, with numerous white stellated spots; beneath white; neck on the fore-part rufous. *Colymbus borealis*, Brun.

This bird was shot near Copenhagen; it resembles in size and appearance *colymbus stellatus*, and is, perhaps, a variety of that bird. Brunnich considers it as a distinct species.

STRIATUS. Blackish, beneath white; head and neck grey, lined with black. *Colymbus striatus*, Gmel. *Striped diver*, Lath.

Inhabits North America, where it frequents lakes; it is represented as a noisy clamorous bird, and one continually in motion or on the wing, flying backwards and forwards. The bill of this species is dusky, or black, and strong; the cheeks white.

SINENSIS. Greenish-brown, with deeper spots; breast and belly reddish-white, spotted with rufous; wings and tail blackish. *Colymbus sinensis*, Gmel. *Chinese diver*, Lath.

This species inhabits China, and is supposed to be one of those kinds of aquatic birds which are trained up, and employed by the Chinese for catching fish. The bill is dusky; and the irides and legs cinereous.

*** *Feet four-toed, and lobed.* Grebe.

CRISTATUS. Fuscous, beneath white; head rufous; collar black; secondary quill-feathers white. *Colymbus cristatus*, Linn. *Colymbus cornutus*, Briss. *Le grebe cornu*, Buff. *Crested grebe*, Lath.

Length of this species twenty-three inches; bill flesh-colour, with the tip brown, beneath white; head tumid, varies in colour by age, and has been described in the first, second, and third years' plumage, as three distinct species.

Like the rest of the grebe tribe, these birds form a floating nest, composed of grass and flags, interwoven with the roots and stalks of other aquatic plants. The female lays four eggs, which are of a white colour, and sits in the nest half immersed in water till the eggs are hatched. It preys on eels and fish, which it procures with great facility, by diving into the water. The flesh is rank, but the skins, which are prepared with the beautiful silken and silvery white plumage on them are in high request for muffs and tippets. Many of the grebes are taken on the lakes of

Geneva for that purpose. In England, those birds frequent the meres of Shropshire and Cheshire, and the great fens of Lincolnshire, in all which places they are known to breed. The tippet grebe is said to be the young of this species.

CAYANUS. Blackish brown, beneath white; under side of the neck rufous. *Colymbus cayennensis*, Gmel. *Le grande grebe*, Buff. *Grebe de Cayenne*, Pl. Enl. *Cayenne grebe*, Lath.

A native of Cayenne. This bird is nineteen inches and a half in length; the bill and legs are dusky; and the lower mandible yellow at the base.

AURITUS. Blackish-fuscous, beneath white; neck beneath rufous. *Colymbus auritus*, Linn. *Le petit grebe*, Buff. *Dusky grebe*, Penn. *Donov. Brit. Birds*.

Inhabits sunny places in Europe and America. Length eleven inches. The bill is black, and red at the sides; irides and lores purple; upper edge of the wings white; legs flesh-colour, inclining to purple.

CORNUTUS. Head glossy-green, and tumid; neck beneath, and breast fulvous; through the eyes a yellow tufted band. *Colymbus cornutus*, Gmel. *Horned grebe*, Arct. Zool.

An inhabitant of Hudson's bay; length twelve inches. Dr. Latham describes the little horned grebe, *le petit grebe cornu* of Buffon as a variety of this species.

RUBRICOLLIS. Somewhat crested; chin, checks, and regions of the ears ash-coloured; neck beneath, and breast rusty red; belly and secondary quill feathers white. *Colymbus rubricollis*, Gmel. *Colymbus subcristatus*, Jacq. *Le grebe à joues grises jongris*, Buff. *Red necked grebe*, Lath. *Donov. Brit. Birds*.

The length of this bird is eighteen inches; the bill is dusky, and at the sides at the base tawny; the legs dusky. This is a British species; the male is very rare, the female scarcely known; both sexes are preferred in the London Museum.

CASPIUS. Head smooth; body above dark brown, beneath silvery; bill lead colour; chin and cheeks white; wing-coverts brown. S. G. Gmel. Inhabits near the Caspian sea.

THOMENSIS. Fuscous; beneath white, spotted with grey; quill-feathers pale rufous; breast with a black spot. *Colymbus thomensis*, Gmel. *Le grebe du laart*, Buff. *Black-breasted grebe*, Lath.

Less than the common hen; the bill is black, with the tip pale; irides and spot between the bill and eyes white; legs dusky. Inhabits St. Thomas's island in America.

MINOR. Fulvous brown; beneath, spot on the quill-feathers, and lower part of the rump; silvery white; neck beneath tawny grey. *Colymbus minor*, Gmel. *Podiceps minor*, Ray. *Little grebe*, Lath. *Donov. Brit. Birds*.

This bird inhabits Europe and America, is ten inches in length, and feeds on worms, small fish, and aquatic insects. Buffon describes a variety of it under the title of "Le Castagneux des Philippines;" it is larger than the former, the plumage above purple brown; and the cheeks and sides of the neck reddish. Found in the Philippine isles.

DOMINICUS. Head smooth; body beneath thickly spotted. *Colymbus dominicus*, Linn. *Le castagneux de St. Domingue*, Buff. *White winged grebe*, Lath.

Inhabits the Antilles and Surinam. Its length is eight inches; the bill is black; body dusky, beneath silvery grey; quill-feathers cinereous white; legs brown.

HEBRIDICUS. Head smooth; body blackish; chin black;

black; throat sub-ferruginous; belly cinereous, mixed with filvery. *Colymbus hybridicus*, Gmel. *Black-chin grebe*, Lath.

A small and rare species, found chiefly in Three, one of the islands of the Hebrides.

PODICERS. Body fuscous; bill olive, dusky at the base, with a transverse black band in the middle. *Colymbus podiceps*, Linn. *Le colagnens à bec circlé*, Buff. *Pied bill grebe*, Lath.

A native of North America; length fourteen inches; irides white; chin black, surrounded with white; body beneath silvery; breast waved with cinereous; secondary quill-feathers black at the tip. The female has no black mark on the bill.

LUDOVICIANUS. Fuscous; sides of the neck and body ferruginous; beneath white, with transverse blackish spots. *Colymbus ludovicianus*, Gmel. *Le grebe de la Louisiane*, Buff. *Louisiane grebe*.

Inhabits Louisiana. The head is smooth; legs dusky; middle of the belly silvery white.

COLYTON, or CULLTON, in Geography, is a small but ancient market town in Devonshire, England. It is called by Rifeon, a "borough of reputation;" the housekeepers of a small district, called the borough, annually chose a portreeve at the lord's court. At the Norman conquest, Colyton was the king's demefne; and king John granted the inhabitants a fair, to continue eight days. The houses are in general built with flints and mostly thatched. The parish church is a spacious stone fabric, with a tower rising above the chancel, the upper part of which is octagonal. On the fourth side of the chancel is an inclosed burial-place, belonging to the De la Pole family, containing various effigies, and other monumental decorations: and in a small aisle adjoining, is the figure of a girl, apparently about five years of age, under a canopy of flaxe; she is said to have been the grand-daughter of Edward IV., and to have been choked by a fish-bone; over her are the royal and Courtenay arms. Colyton arms is situated 153 miles S.W. from London: the number of houses is 289; of inhabitants 1641.

COLYTTUS, or COLYTUS, in Ancient Geography, the name of a quarter of the city of Athens, belonging to the Egeide tribe, and adjoining to that called Melitos.

COM, or KOM, in Geography, one of the oldest, and formerly of the largest towns of Persia in the province of Irak Aghem. It has suffered greatly by the civil wars with which the Persian empire has been so often distracted, but is still a very populous place; 60 miles S. of Calbin, and 150 N. of Ispahan. It is celebrated for its silk manufactures, chiefly velvet. N. lat. 34°. E. long. 50°.

COMA. See **COMO.**

COMA, in Medicine, a preternatural propensity to sleep, though the patient frequently does not sleep, or if he does, awakes without relief. If sleep ensues, the disease is called *coma somnolentum*; in this case the patient continues in a profound sleep, and when awaked, immediately relapses, without being able to keep open his eyes. If he does not sleep, but is continually awakened with frightful dreams, it is called *coma vigil*: in this case he appears to sleep, having his eyes constantly shut. Coma is produced by debility, by the want of food, exercise, &c. See **APoplexy**.

COMA, in Botany, from *κῆρυξ*, a head of hair, is applied to a leafy crown, whether of the proper leaves of the plant, or of bractes, rising above the frutification. In the pineapple and crown imperial it is of the former kind; in *Salvia herbimona*, or purple topped clary, of the latter, being moreover elegantly coloured with pink or purple. See **COMOSER**.

VOL. IX.

COMA foliis multifidis glaucis, Burm. See **ATHANASIA parvisifolia**.

COMA Berenices, Berenice's Hair, in Astronomy, a modern constellation of the northern hemisphere; composed of unformed stars between the Lion's tail and Boetes.

This constellation is said to have been formed by CONON, an astronomer, in order to console the queen of Ptolemy Evergetes, for the loss of a lock of her hair, which was stolen out of the temple of Venus, where she had dedicated it on account of a victory obtained by her husband. Ricciol. Alm. lib. vi. cap. 4.

The stars in the constellation Coma Berenices, in Tycho's Catalogue, are 14; in Hevelius's, 21; and in the Britannic Catalogue, 42.

COMACENUS LACUS, in Ancient Geography, the lake of *Como*, which see.

COMACHIO, in Geography, a small town of Italy, the see of a bishop, in the Ferrarese, surrounded by salt marshes, which render the air insalubrious, and inhabited chiefly by fishermen; 33 miles S. E. of Ferrara. N. lat. 44° 32'. E. long. 12° 6'.

COMACLUM, in Ancient Geography, a town of Venetia.

COMAGENA. See **COMMAGENE**.

COMAGENE, a place of NORICA, distant, according to Antonine's Itinerary, 24 miles from mount Cetus.

COMANA, a town of Pontus, seated on the river Iris, towards the mountain of Paryadræ, on the south. It was famous for a temple of Bellona. The town and territory depended on a pontiff, who, on solemn days, wore a diadem, and possessed a kind of sovereignty. Venus also was worshipped in this city; her feast was celebrated with great magnificence, and she had many courtizans.

COMANA, a town of Asia, in the greater Cappadocia, seated on the river Sarus, in Cataonia. It was also called *Chryse*, and bore the appellation of Cappadocian.

COMANA, or BOCANA, a town of the island of Taprobana, according to Ptolemy.

COMANA, or Commacus, a town of Asia, in Pisidia.—Also, another town in Phrygia. Ptolemy.

COMANA, in Geography, a town of South America, in the northern division of Terra Firma. It lies on the north-eastermost part of the sea-coast.

COMANCHES, or HIETANS, a tribe of Indians in Louisiana in America, who have no fixed place of residence, and who have neither towns nor villages. They are divided into so many hordes, that they have scarcely any knowledge of one another. They never continue in the same place for more than a few days, but follow the buffalo, the flesh of which is their principal food. Some of them purchase of the Panis or Towaches, another tribe, corn, beans, and pumpkins; but their number is so great, that these articles furnish a small quantity of their food. Their tents are made

of skins neatly dressed, and fashioned in the form of a con-
affording room for a family of 10 or 12 persons; those of
the chiefs are capable of accommodating 50 or 60 persons.
When they pitch their tents, they form regular streets and
squares, exhibiting a sort of town suddenly raised, as it were
by enchantment, and at a signal for march, they are as sud-
denly struck: to every tent are allotted two horses or mules,
one for carrying the tent, and another for removing the
poles or sticks, which are neatly made of red cedar; they all
travel on horseback. Their horses are tied for grazing with
a long halter, and they are so numerous as to require fre-
quent change of place. Their horses are so managed, as to
be remarkably docile and gentle. It is their practice to
hunt the buffalo on horseback; and they kill this
animal with the bow, or a sharp stick like a spear,
which they carry in their hands. They are generally at war
with the Spaniards, committing frequent depredation upon
the inhabitants of Santa Fé and St. Antoine; but they have
been always friendly and civil to any French or Americans
who have been amongst them. With regard to their per-
sons, they are strong and athletic, and, in advanced life, cor-
pulent. As savages, they are uncommonly clean: the dresses
of their women is a long loose robe, reaching from the chin
to the ground, tied round with a fancy sash or girdle, all
neatly made of dressed leather, on which they paint figures
of different colours and significations; the dresses of the men
consist of close leather pantaloons, and a hunting shirt, or
froek of the same. Their continuance in the same place does
not admit of their making any plantation; but the small
Cayenne pepper grows spontaneously in the country, and
with this, together with some wild herbs and fruits, particu-
larly a bean that grows plentifully on a small tree, resembling
a willow, called Masketo, the women cook their buffalo beef
in a manner that renders it grateful food. They alternately
occupy the immense space of country from the Trinity and
Braces, crossing the Red river, to the heads of Arkansas and
Missouri, to river Grand, and beyond it, about Santa Fé,
and over the dividing ridge on the waters of the Western
Ocean, where, as they say, they have seen vessels, which
they describe as ships, with sails and rigging. Their native
language differs from that of any other nation; but they
have a mode of making themselves understood to all the In-
dians by signs. Among them are many Spanish men and
women, who are slaves, and who were made prisoners by
them in their youth.

COMANI, in *Ancient Geography*, a people of Asia, prob-
ably of Scythia, who inhabited the country Comania, men-
tioned by Ptolemy. They were probably the same with the
Comi of Ptolemy, and the Comari and Coamani, placed by
Pomponius Mela in the vicinity of the Paropamisians.

COMANIA, a country of Asia, according to Xenophon.
See COMANI.

COMANIA, also called *Daghestan*, a country in the north-
ern part of Turkey in Asia, south from Little Tartary, and
north from Georgia bounded on the east by the Caspian sea,
W. by the Caucasus, N. by Circassia, and S. by Skirvan.
Its inhabitants are known by the name of Comoucks. See
DAGHESTAN.

COMANNA, an inland country of Africa, on the
Slave coast, bounded on the east by Infoko, on the south
by Lobadde and Ningo, two provinces of Aquimboe; its
northern limit is unknown. Little is known of the country,
except that its natives bring great quantities of gold to the
markets of Akkaradi, a kingdom touching it on the west,
who afterwards carry it to Aboni, and thence to the negroes
of the sea-coast. Beyond Comanna, in regular succession
from E. to W. but with unascertained boundaries to S. and

N., are the kingdoms of Iatabi, Equca, Bonu, situated
far north; Tasiu, Quaka, Aboni, Sarkuz, Aqua, and
Achem, all supposed to be rich in gold; but more espe-
cially Quak.

COMARCHIOS, in *Antiquity*, the name of a particu-
lar air, or tune, designed to be sung at entertainments.

COMARGO, in *Geography*, a town of North Amer-
ica, in New Leon, situate on the south side of Rio
Bravo, which empties itself into the gulf of Mexico on the
west side.

COMARIA PROMONTORIUM, in *Ancient Geography*, a
maritime place of India, at the extremity of the peninsula,
on this side of the Ganges. Ptol. See CAPE COMORIN.

COMARIS, in *Lithology*, a name given by the Greek
writers to the *selenites*, or *apophelene*.

COMAROIDES, in *Botany*, *alpina argentum*; See
See POTENTILLA nitida.

COMARTCH, in *Geography*, a river of South Wales,
in the county of Brecknock, which runs into the Yrwon,
eight miles W. of Buith.

COMARUM, in *Botany*, (*Κομαρρις*, a name given by
Theophrastus to an evergreen tree, supposed to be an arbutus.)
Linn. Gen. 638. Schreb. 869. Willd. 1004. Gart.
451. Vent. 3. 347. (Pentaphylloides; Tourn.) Clafs and
order, *jocandrius polygynia*. Nat. Ord. *Senticofa*, Linn.
Rofacea, Juss. Vent.

Gen. Ch. Cal. Perianth one-leaved, ten cleft, very
large, spreading, coloured, permanent; alternate segments
smaller, inferior. Cor. Petals five, oblong, acuminate, in-
serted on the calyx, much smaller. Stam. Filaments about
twenty, awl-shaped, inserted into the calyx, length of the
corolla, permanent; anthers crescent-shaped, deciduous.
Pist. Germs numerous, roundish, very small, collected into a
head; styles simple, short, from the inside of the germ;
stigmas simple. Peric. none. Seeds naked, even-surfaced;
attached to a large, egg-shaped, spongy, villous, persisting
receptacle.

Eff. Ch. Calyx ten-cleft, inferior. Petals five, less than
the calyx. Receptacle egg shaped, spongy, villous, per-
sisting. Seeds even-surfaced.

Sp. C. *palustre*. Marth cinquefoil. Linn. Sp. Pl. Mart.
Willd. Flor. Dan. tab. 636. Lam. Ill. tab. 444. Eng.
Bot. tab. 172. (Quinquiflorum rubrum; Bauh. Pin. 3. 6.
Pentaphyllum palustre; Cord. Hist. 96. 1. Fragaria,
Hall. Helv. n. 1128. Potentilla; Scop. Carn. n. 617.)
Root creeping. Stems decumbent at the base, cylindrical,
leafy, smooth. Leaves on long petioles, quinate-pinnate;
leaflets on short petioles, oblong, serrated, hoary under-
neath; stipules embracing the stem. Flowers dark purple,
somewhat panicle; peduncles one-flowered, bracts two,
lanceolate; stamens, anthers, style, and receptacle, nearly
black. A native of England, and most other parts of Eu-
rope in boggy ground, and by the sides of ponds. There
is a variety with thicker and more villous leaves, but Miller
assures us that after one year's growth in a garden it is not
to be distinguished from the common fort.

COMARUS PORTUS, in *Ancient Geography*, a name
given by Dion Cassius to a port of Epirus, which he places
in the gulf of Ambracia. Strabo calls it Comarus Sinus,
and maketh it a small gulf of Epirus.

COMAYUAGUA, or VALLADOLID, in *Geography*, a
large town of the province of Honduras, in Old Mexico,
or New Spain, in North America, on a river which falls
into the gulf of Honduras. It is the see of a bishop, and
has rich silver mines in its neighbourhood; 90 miles S.E. of
Truxillo. E. long. 88° 4'. N. lat. 14° 30'.

COMB,

COMB, an instrument made of horn, ivory, tortoise-shell, box, or holly-wood, &c. and useful for separating and adjusting the hair, &c.

Comb making. Combs are not only made for the purpose of cleaning the hair, but for ornament: they are sometimes set with brilliant stones, pearls, and even diamonds; some again are studded with cut steel; these are of different shapes, and are used to fasten up the hair when ladies dress without caps. Combs may of course be had of all prices, from the value of a few pence to almost any sum. They are generally made of the horns of bullocks or of elephants, and sea-horke's teeth, and some are made of tortoise-shell and ivory, others of box or holly-wood. The horns of bullocks are thus prepared for this manufactory: the tips are first sawn off; they are then held in the flame of a wood fire, this is called roasting, by which they become nearly as soft as leather. While in that state they are fit open on one side, and pressed in a machine between two iron plates; they are then plunged into a trough of water, from which they come out hard and flat; they are then sawn into lengths, according to the size wanted. To cut the teeth, each piece is fixed into a tool called a claw. The maker sits on a triangular sort of a stool to his work, and under him is placed the claw that holds the horn, ivory, &c. that is to be formed into a comb. The teeth are cut with a fine saw, or rather a pair of saws, and they are finished with a file. A coarser file, called a rasp, is used to reduce the horn, &c. to a proper thickness; and when they are completely made they are polished with charcoal and water, and receive their last finish with powder of rotten stone. The process used for making ivory combs is nearly the same as that already described, except that the ivory is first sawed into thin slices. The best ivory comes from the island of Ceylon and Achen in the East Indies, as it possesses the property of never turning yellow; it is consequently much dearer than any other kind.

Tortoise-shell combs are much esteemed; and there are methods of staining horn, so as to imitate it, of which the following is one: the horn to be dyed is first to be pressed into a flat form, and then done over with a paste, made of two parts of quick-lime and one of litharge, brought into a proper consistence with soap-lye. This paste must be put over all the parts of the horn, except such as are proper to be left transparent, to give it a nearer resemblance to tortoise-shell. The horn must remain in this state till the paste be quite dry, when it is to be brushed off. It requires taste and judgment to dispose the paste, as to form a variety of transparent parts, of different magnitudes and figures, to look like nature. Some parts should also be semi-transparent, which may be effected by mixing whitening with a part of the paste. By this means spots of a reddish brown will be produced, so as greatly to increase the beauty of the work. Horn thus dyed is manufactured into combs, and these are frequently sold for real tortoise-shell. The wages of journeymen in this business are from 21s. to 31s. per week.

In *Plate XV. of Mechanics* is represented a machine for cutting combs, for which Mr. Wilham Bundy, of Pratt Place Camden Town, took out a patent in the year 1756, and the same is described in the *Repository of Arts*. The frame A A. *fig. 3* of the machine, is like a common lathe, containing a spindle, with a crank and fly-wheel, D, upon it, turned by the alternate motion of the treadle, B, which is moved by the workman's foot; E is a wheel fixed on the crank spindle, carrying a line in its groove, crossing between the cheeks of the lathe, and passing over the pulley, F, which turns on a centre fixed in the puppet, G; it has two holes in it to receive the horned catch, *h*, *fig. 2*, screwed on the end of an arbor, *b*, about seven inches in length, and half an

inch in diameter; this arbor is mounted between two circular brass plates, H, I, *fig. 1*, connected by three pillars, it carries as many circular steel cutters, or saws, K, *fig. 4*, as the comb to be cut is to have teeth. M, *fig. 5*, represents another arbor, which is fixed in the frame-plates, *fig. 1*, by its ends; it is triangular, and has a piece of steel, L, *fig. 4* (called a guide), fitted on it between each saw, on the arbor, *b*. These parts are put together by first putting the end of the arbor, *b*, *fig. 2*, through the hole in the centre of the frame-plate, I, and screwing on the catch, *a*; the end of the arbor *fig. 5*, is put into a square hole made in the plate, I, to receive it, and is fixed by a screw: a guide, L, *fig. 4*, is then put on the arbor, M, close against the shoulder, *d*; next a cutter, K, is put on the arbor, *b*, touching its shoulder, *e*; a piece of steel plate, N, called a guide-washer, is then put on the arbor, M, and another guide, L, close to it; the guide-washer is a little thicker than the cutter opposite it, so that the cutters each turn between two guides without touching them. These being in their places, a small washer, O, *fig. 4*, is put on the arbor, *b*, and a cutter, then a guide-washer and guide, on the arbor, M, and so on alternately, till the right number of cutters are put on; the sliding shoulder, *f*, *fig. 2*, is then taken, and with the octagonal nut, *g*, screwed fast up against the last cutter, put on the arbor, *b*, this will pinch all the cutters and washers between the shoulders, *e* and *f*, and hold them fast. The same is done to the arbor of the guides, *l*, and, lastly, the frame-plate, H, is put on the ends of the pillars, and screwed fast; the whole forming the resemblance shewn in *fig. 1*. The frame plates with the arbors, as in *fig. 1*, are now to be put in their place in the machine, *fig. 3*, the horns of the catch, *a*, going into two holes in the pulley, F, and the other end of the arbor, *b*, into a centre that goes up with a screw in the puppet, Q; the screws, *h*, *h*, are designed to steady the frame-plate (which hold the arbor of the guides) against the dove-tail, P P, supported by brackets projecting from the front of the cheeks, sufficiently to let the block, *i*, which slides in the dove-tail, and holds the comb, be drawn forwards to give room for the hand to put in or take out the combs clear of the cutter. To the base of the dove-tail is screwed a plate, holding one of the centres for a worm-wheel, *k*, whose axis is made of steel, and has its end cut with a deep thread-screw; the screw-end of this axis works in a centre, fixed to the base of the dove-tail, and the block, *i*, is cut away to pass clear over it and the threads of the screws, without touching them. The worm-wheel, *k*, is turned by an endless screw, on the arbor of the wheel, *r*, which receives its motion from the pulley, *z*, by an endless line. The block, *i*, which holds the comb, moves in the dove-tail, and is to carry the comb towards the cutters while cutting. As the screw on the axis of the wheel, K, is to carry the block up in lieu of a nut; a knife-edge, fastened to a small lever, *l*, moveable on a centre in the face of the block, is applied to it, and kept down (so that the knife-edge may take into the threads of the screw) by a catch similar to the latch of a door, which is released by pushing in a thumb-stud, and allows the spring, *o*, to throw up the lever, *l*, and disengage the screw, so that the block may be brought forwards in the dove-tail. The piece of ivory intended to be cut into a comb, is put under a plate, *p*, and held down by two screws to the face of the block, which is in the same plane with the arbor of the cutters; the workman then puts down the knife-edge, and the catch keeps it so; he then turns the machine by his foot, and pushes the block towards the cutters (the comb being close on the guides) till the knife-edge take the first thread of the screw, which turns round as before described, and pushes the block and comb up to the cutters, as far as

the screw extends, and the cutters saw the teeth in the comb; the thumb-end is then pushed in, and the spring, *s*, throws the knife-edge up, so that the block can be brought back by hand, and the comb taken out. The distance which the comb projects from the face of the block towards the cutters, and consequently the length of the teeth, is regulated by a straight edge of metal on the top of the block, *i*, under the plate, *p*, against which the back of the comb rests; it can be moved parallel to itself across the top of the block by two screws, (which are seen at the upper corners of the face of the blocks), for combs of longer or shorter teeth. The spindle of the crank has a wheel, *R*, on it, turning an arbor, *S*, by a line, which carries a set of cutters for pointing the comb. The arbor is shewn separately in *fig. 6*, and a cutter in *fig. 7*; it is made up in the same manner as the former one, and fastened by a screw, *T*; the ends of the teeth of the comb are applied to this cutter by hand, first on one side, and then on the other, till the points are made. This is performed to one comb, while the teeth are cutting in another.

COMB, or *Coomb*, in *Husbandry*, a measure of corn, consisting of 2 long strikes = 4 Winchester bushels = 16 pecks = 32 dry gallons = 128 dry quarts = 256 dry pints = 8601.6 cubic inches = 4.57 cubic feet = 1.843621 cubic yards = 17.32142 cubic links: in some places the bush l contains eight gallons and a quart.

COMB, *Coomb*, or *Carnook*, of wheat, according to the 6th and 5th Henry III. 12th Henry VII., &c., was 256lb. troy = 210.6614lb. avoirdupoise = 2 strikes = 16 pecks = 32 gallons = 256 pints or pounds.

COMB, in *Ornithology*, the crest, or red fleshy tuft growing on the head of a cock.

COMB, in a *ship*, a little piece of timber, set under the lower part of the beak-head near the middle: it has two holes in it, and supplies to the fore-tacks, what the chest-trees do to the main-tacks; that is to bring the main-tacks aboard.

COMB, in the *Manufacture of Tapestry*. See **TAPESTRY**.

COMB-MARTIN, in *Geography*, a town of England, on the north coast of Devonshire, in the Brillol channel, with a small creek for boats; near it are silver-mines, which formerly yielded a considerable quantity of ore; 59 miles W. of Bridgewater, and 176 W. of London.

COMBA, in *Ancient Geography*, a town of Asia Minor, in the interior of Lycia, and in the vicinity of mount Cragus. Ptolemy.—Also, a marsh of Greece, in Macedonia, near mount Athos, mentioned by Athenæus.

COMBAHEE, in *Geography*, a considerable river of South Carolina, which enters St. Helena Sound, between Coosa and Ahepoo rivers. The ferry of the same name on this river is distant 17 miles from Jackson's borough; 15 from Pocotaligo, and 52 from Charleston.

COMBAM, or **COMBAMA**, a town of Hindoostan, in the country of Cuddapah; 65 miles N. of Cuddapah. Combam is reckoned 25 colles from Inaconda, and 32 from Onzole, or about 51 geographical miles from the latter. Tavernier calls it Kaman.

COMBAMET, a town of Hindoostan, in the country of Golconda; 68 miles E. of Hydrabad.

COMBANA, or **NOMMANA**, in *Ancient Geography*, a town of Asia, in Carmania, situated near the sea.

CAMBARONES, in *Antiquity*, the fellow-barons or commonly of the Cique-Pais.

COMBAT, in a general sense, denotes an engagement; or a difference decided by means of arms.

Authors sometimes distinguish in an army, between a combat and a battle; the latter expressing the general ac-

tion of the whole army; the former only a particular skirmish, or engagement of a single part; so that the combat is properly a part of a battle.

COMBAT, in *Law*, or *single combat*, denotes a formal trial, between two champions, of some doubtful cause or quarrel, by the sword or batons.

This form of proceeding was anciently very frequent, particularly among the barbarous nations in their original settlements; and obtained, not only in criminal, but also in civil causes; being built on a presumption, that God would never grant the victory but to him who had the best right. It was originally permitted, in order to determine points respecting the reputation of individuals, but afterwards became much more extensive. See **DUEL**. The form and ceremony of the combat are described in the grand Coutumier of Normandy. The accuser, first, swore to the truth of his accusation; the accused gave him the lie: upon which, each threw down a gage, or pledge of battle; and the parties were committed prisoners to the day of combat. See **CHAMPION**.

Historians tell us, that Alphonfus, king of Castile, in the eleventh century, desiring to abolish the Mosarabic liturgy, and to introduce the Roman office; the people opposing it, it was agreed to terminate the difference by combat, and leave the cause to the decision of Heaven. One of the earliest restrictions of this practice that occurs in the history of Europe, is that of Henry I. of England; which was afterwards followed by an edict of Louis VII. of France to the same effect. Robertson's Hist. of Charles V. vol. i. p. 61, &c. and 350, &c. 8vo.

COMBAT is also used for the solemn games of the ancient Greeks and Romans, performed in honour of their gods; as the Olympic games, Pythian, Isthmian, and Nemean games; the Iudi Aetiaci, Circenses, &c. which see in their places, **OLYMPIC**, **ISTHMIAN**, &c.

The combats here celebrated, were *running, wrestling, boxing, equestrian*, &c. The combatants, who were called *athletes*, prepared themselves for it from their youth, by constant exercise, and a very rigid regimen: they only eat certain things, and at certain hours; drank no wine; had no commerce with women; and both their labour and their rest were regulated.

COMBATANT, in *Heraldry*, termed by the French *heralds confronté*, when two animals are borne in coat armour in a fighting posture, erect on their hind feet, and facing each other.

COMBATANT, in *Ornithology*, the name given by French writers to the Linnæan *tringa pugnax*, the bird known in this country by the name of *Ruffs* and *Reeves*, the male being called the Ruff, the female Reeve. See **TRINGA PUGNAX**.

COMBEAUFONTAINE, a small town of France, in the department of Upper Saone, chief place of a canton, in the district of Vesoul. It contains 583 and the canton 7596 inhabitants. The territory includes 190 kilometres and 17 communes.

COMBESIS, FRANCIS, in *Biography*, a learned French monk, was born at Guienne, in the year 1605. He pursued his studies first under the Jesuits at Bourdeaux and afterwards at Paris. He devoted himself principally to the pursuit of Greek literature, and was employed in editing new editions of the Greek fathers, for which he received a very handsome remuneration. He likewise published a collection of the lives of different fathers, popes, and martyrs; some additions to the "Bibliotheca Græcorum Patrum," in Greek and Latin, in three volumes folio; "Hætoræ Byzantius Scriptores, post Theophaum," undertaken by command

command of the celebrated Colbert. He died in 1679 of the stone, a disease to which studious and sedentary men are peculiarly liable. *Nouv. Dict. Hist.*

COMBANY, in *Geography*, a river of South Wales, in Carmarthenshire, which discharges itself into the Loughor, 5 miles N.E. of L'analhy.

COMBER, THOMAS, in *Biography*, was born at Westerham in Kent, in the year 1645, where he received the rudiments of a learned education; from thence he was admitted in Sydney college Cambridge. He was remarkable for diligence in his studies, and took his degrees of bachelor of arts in 1662, and of master of arts in 1666. Some years afterwards he was created doctor of divinity, probably by a diploma from Lambeth. After this he attained to considerable rank in the church, and was preferred to the precentorship of York, the deanery of Durham, to be chaplain to their majesties, and other posts of emolument and honour. Dr. Comber maintained a correspondence with Tillotson, Burnet, and other most eminent divines of the age in which he flourished. The excellence of his character, and his zeal for the church of which he was a member, were the causes that led him to that distinction to which he attained, and which was a true earnest and pledge of still greater preferment if he had lived, but he died in November 1699, in the 55th year of his age, and was buried at Stonegrave in Yorkshire, of which he was rector. He was author of many learned works relating principally to the Common Prayer, and to the offices of the Church of England.

There was also another Dr. Thomas Comber, born in Suffex, Jan. 1575, who was educated in Trinity college Cambridge, and afterwards made dean of Carlisle. In 1642 he was imprisoned, plundered, and deprived of all his preferments, and died at Cambridge in 1653. He is known as the author of "An Historical Vindication of the Divine Right of Tythes," &c. written in answer to "Selden's History of Tythes." *Biog. Brit.*

COMBER, in *Ichthyology*, a species of wrasse or old-wife fish, found sometimes on the coast of Cornwall, and which is described under this name in Ray's Synopsis, No. 163. See **LABRUS Comber**.

COMBER-MERE, in *Geography*, a lake of England in the county of Chester, on the borders of Shropshire; five miles S. of Nantwich.

COMBINATION, is properly understood of an assemblage of several things by two and two; but is more particularly used in *Mathematics*, to denote the variation, or alternation of any number of quantities, letters, sounds, or the like, in all the different manners possible.

P. Merenne gives us the combination of all the notes and sounds in music, as far as sixty-four; the sum whereof amounts to ninety figures, or places.

The number of possible combinations of the twenty-four letters of the alphabet, taken first two by two, then three by three, &c. according to Mr. Pretet's calculation, amounts to 139172428887252999425128493402200.

The words in the following verse may be combined a thousand and twenty-two several ways.

Tot tili sunt dotes, virgo, quot sidera celo.

F. Truchet, in the Memoirs of the French Academy, shews, that two square pieces, each divided diagonally into two colours, may be arranged and combined sixty-four different ways, so as to form so many different kinds of chequer work, which appears surprising enough, when one considers that two letters, or figures, can only be combined twice. This note may be of use to masons, paviours, &c. See **PAYEMENT**, and **CHANGES**.

COMBINATION, doctrine of.—Any number of quantities being given, together with the number in each combination; to find the number of combinations.

One quantity, we observe, admits of no combination; two, *a* and *b*, of one, viz. *ab*; of three, *a, b, c*, there are three combinations, viz. *ab, ac, bc*; of four, six, *ab, ac, bc, ad, bd, cd*; of five, ten, *ab, ac, bc, ad, bd, cd, ac, bc, ce, ce, de*.

Whence it appears, that the number of combinations proceed as, 1, 3, 6, 10, &c. which are triangular numbers, whose side differs by unity from the number of given quantities, or which are produced by the continual addition of the ordinal series, 0, 1, 2, 3, 4, 5, &c. Hence if the number of things to be combined be *q*, the side of the number of combinations will be *q-1*; and therefore the number of combinations $\frac{q-1 \times q-0}{1 \times 2}$. See **TRIANGULAR number**.

If three quantities are to be combined, and the number in each combination be three, there will be only one combination, *abc*, if a fourth be added, the combinations will be found *abc, abd, bcd, acd*; if a fifth, ten, *abc, abd, bcd, acd, ade, bde, bec, ace, ade, cde*; if a sixth, twenty, &c. The numbers of combinations, therefore, proceed, as 1, 4, 10, 20; i. e. they are the first pyramidal triangular numbers, whose sides differ by two units fr the number of given quantities. See **PYRAMIDAL number**.

Hence, if the number of given quantities be *q*, the side will be *q-2*; and therefore, the number of combinations $\frac{q-2 \times q-1 \times q-0}{1 \times 2 \times 3}$.

Hence is easily deduced a general rule for determining the number of combinations in any case; for, suppose the number of quantities to be combined, *q*, the exponent of the combination *n*, the number of combinations will be $\frac{q-n+1 \times q-n+2 \times q-n+3 \times q-n+4 \times q-n+5}{1 \times 2 \times 3 \times 4 \times 5}$ &c. till the number to be added be equal to *n*.

Suppose, v. gr. the number of quantities to be combined = 6; the exponent of the combination 4; the number of combinations will be $\frac{6-4+1 \times 6-4+2 \times 6-4+3 \times 6-4+4}{1 \times 2 \times 3 \times 4} = \frac{6-4+4}{1} \times \frac{6-2}{2} \times \frac{6-1}{2} \times \frac{6-0}{4} = \frac{2}{1} \times \frac{2}{2} \times \frac{5}{2} \times \frac{6}{4} = 15$.

Coroll. If it be desired to have all the possible combinations of the given quantities beginning with the combinations of the several twos, proceeding to threes, &c. there must be added $\frac{q-1 \times q-0}{1 \times 2}, \frac{q-2 \times q-1 \times q-0}{1 \times 2 \times 3}, \frac{q-3 \times q-2 \times q-1 \times q-0}{1 \times 2 \times 3 \times 4},$ &c.

Whence the number of combinations possible will be $\frac{q \times q-1}{1 \times 2} + \frac{q \times q-1 \times q-2}{1 \times 2 \times 3} + \frac{q \times q-1 \times q-2 \times q-3}{1 \times 2 \times 3 \times 4} + \frac{q \times q-1 \times q-2 \times q-3 \times q-4}{1 \times 2 \times 3 \times 4 \times 5},$ &c. which is the sum of the unciæ of the binomial, raised to the power *q*, and abridged of the exponent of the power increased by unity, *q+1*. Wherefore, if 1 + 1 = 2 represent the binomial to which these unciæ belong, 2^q - *q* - 1 is the number of all the possible combinations. V. gr. If the number of quantities be 5, the number of possible combinations will be 2⁵ - 6 = 32 - 6 = 26.

2. Any number of quantities being given, to find the number of changes and alterations, which these quantities, combined in all the manners possible, can undergo.

Suppose two quantities, a and b , their variations will be 2; consequently, as each of those may be combined, even with itself, to these there must be added two variations. The whole number, therefore, will be $2 + 2 = 4$. If there were three quantities, and the exponent of the variations were 2, the combination will be 3, and the changes 3; to which if the three combinations of each quantity with itself aa, bb, cc , be added, we shall have the number of changes, $3 + 3 + 3 = 9$.

In like manner it is evident, if the given quantities were 4, and the exponent 2, the number of changes would be 10; if 5, 25, &c. in general, if n, n^n .

Suppose the quantities 3, and the exponent of variation 3; the number of changes is found $27 = 3^3$; viz. $aaa, aab, aba, baa, abb, aac, aca, caa, abc, bac, bca, acb, cab, cba, acc, cac, cca, bba, bab, bbb, bbc, cbb, bcb, cbc, ccb, ccc$.

After the same manner, it will appear, if the quantities were 4, and the exponent 3; the number of changes would be $64 = 4^3$; and, in general, if the number of quantities be n , and the exponent 3, the number of changes will be n^3 . By thus proceeding, it will be found that if the number of quantities be n , and the exponent n , the number of changes will be n^n ; wherefore, if all the antecedents be added, where the exponent is less, the number of possible changes will be found $n^n + n^{n-1} + n^{n-2} + n^{n-3} + n^{n-4} + n^{n-5} + n^{n-6}$, &c. Till at length, the number subtracted from n leaves 1; because the beginning is from single quantities taken once.

Since then the number of possible changes is in a geometrical progression, whose first or smallest term is n^1 , the greatest n^n , and the ratio n ; it will be $= \frac{n^{n+1} - n}{n - 1}$.

Suppose, v. gr. $n = 4$, the number of possible changes $\frac{4^{4+1} - 4}{4 - 1} = \frac{1020}{3} = 340$. Suppose, again, $n = 24$, the

number of possible changes will be $\frac{24^{25} - 24}{24 - 1} = \frac{24^{25} - 24}{23} = 3200975864440681898677795534827600$. In so many various manners, therefore, may the twenty-four letters of the alphabet be varied and combined among themselves.

COMBINATION, in *Chemistry*, denotes the union of two bodies of different natures, from which a new compound body results. An acid united with an alkali furnishes an instance of combination. See AFFINITY.

COMBINATIONS, in *Law* Combinations to do unlawful acts, are punishable before the unlawful acts are executed; this is to prevent the consequences of combination and conspiracies, &c. 9 Rep. 57.

COMBINATION, in *Military Science*. One ought to regard combination as forming a part of military science. A general, who has an enterprise in contemplation, should, before he risks the execution of it, combine well in his mind all the ideas, that can lead to its success; and he ought not always to rely on his own solution of the case. But when his ideas on the subject are pretty well fixed, he should lay them before the general officers, who are under his orders or command, for their opinion and concurrence.

COMBINATORY *distillation*. See DISTILLATION.

COMBINATORY *music*, *Musica combinatoria*, that part of music which teaches the manner of combining sounds va-

riously; that is, of changing their place and figure in different manners. See MUSIC.

COMBING of *wool*, in *Commerce*, the drawing of wool across the teeth of a kind of card, calculated to dispose it for spinning. See CARDING and SCRIBBLING.

COMBLEAN. *Cologne*, which serves for changing and discharging the pieces of artillery, for mounting them on their carriages, and for raising other great weights by means of a crane.

COMPLEMENT des *Fossés*, the filling of the ditches. When the besiegers have advanced so far as to be masters of the covert-way, they exert themselves by every possible means to fill up the ditches by cutting off the galleries to put their workmen under cover, in order to be able to conduct the miner with security to his operations, and to retrench themselves there at the same time, to secure themselves against the sallies and assaults of the besieged.

COMBLES, in *Geography*, a town of France, in the department of the Somme, chief place of a canton, in the district of Péronne. It contains 1579, and the canton 12196 inhabitants. The territorial extent is of 155 kilometres, and it includes 23 communes.

COMBOURG, a small town of France, in the department of Ille and Vilaine, chief place of a canton, in the district of St. Malo, 18 miles S. of St. Malo. The place contains 4170, and the canton 12,151 inhabitants; the territory includes 217½ kilometres and 10 communes.

COMBRAILLE, formerly a subdivision of the bishopric of Limoges, in France, now a department of Creute. It was a barony belonging to the ducal house of Orleans.

COMBREA, in *Ancient Geography*, a town of Greece, situated to the north of Pallene, on the Theraic gulf. Herodotus calls the country in which it lay *Croffia*, between Lipaxos and Lisie.

COMBRETE in *Geography*, a town of France, in the department of the Mayne and Loire, and chief place of a canton in the district of Saillé; 7 miles W. of Saillé.

COMBRET, a town of France, in the department of the Aveyron: 8 leagues E. of Alby.

COMBRETUM, in *Botany*, (the name of a plant in Plin.) Linn. Gen. 475. Schreb. 641. Gert. 212. Juss. 320. (Chigomier, Lam. Encyc.) Class and order, *ombrovia monocotyled.* Nat. Ord. *Calycanthem.* Linn. *Onagra*, Juss.

Gen. Ch. Cal. Perianth superior, one-leaved, bell-shaped, four or five-toothed, caducous. Cor. Petals four or five, egg shaped, about the length of the calyx, and placed between its teeth. Stam. Filaments eight or ten, generally very long, inserted into the calyx; anthers egg-shaped or oblong. Pist. Germ inferior, linear; style bristle-shaped, about the length of the stamens; stigma acute. Peric. none. Seed single, with four or five thin membranous wings. (Capsule with four or five wings. Seed linear, small, with four or five angles, Lam.)

Eff. Ch. Calyx four or five-toothed, bell-shaped, superior, corolla four or five-petaled, inserted into the calyx. Stamens generally very long. Seed single, with four or five membranous angles.

Sp. 1. *C. laxum*. Linn. Sp. Pl. 1. Mart. 7. Lam. 7. Willd. 1. Jacq. Amer. 104. Gert. tab. 136? Aubl. Guian. 1. 350. tab. 137? Lam. II. nst. tab. 282, fig. 1? L'eph. It. 308. Swartz. Obs. 143. (Guara fruticosa, Less. It. 248?) "Flowers octandrous; spikes lax, quite simple." Lam. "Leaves opposite; racemes lax, without bracts; calyx villous within." Willd. A shrub. Branches cylindrical, climbing, younger ones bracteate. Leaves three inches long or more, petioled, acuminate, sometimes obtuse, entire,

entire, smooth. *Flowers* yellowish or whitish; in simple, axillary, and terminal spikes, or rather racemes; filaments more than an inch long. A native of Guiana and the West Indies. 2. *C. secundum*. Linn. Sp. Pl. 2. Mart. 2. Lam 2. Willd. 2. Jacq. Amer. 103. tab. 176. fig. 30. Swartz. Obs. 144. "Flowers octandrous; spikes compound, panicle-pinnate." Lam. "Leaves opposite; racemes unilateral, without bractes; calyces smooth." Willd. A shrub, or small tree, ten or twelve feet high. *Branches* cylindrical, very long, supporting themselves by the neighbouring trees and shrubs. *Leaves* three or four inches long, on short petioles, ovate-oblong, acuminate, entire, smooth, veined underneath. *Flowers* very numerous, whitish or yellowish, in several spikes or racemes, which form a kind of panicle at the summit of the branches; anthers red. The flowers, and not the racemes, are often unilateral. Lam. A native of South America, in Guiana, and about the neighbourhood of Carthagen. The synonyms of these two species are very confused and uncertain. Jacquin supposes Aniblets and Leoffing's plants to be the same, and to constitute a third species. 3. *C. purpureum*. Mart. 3. Willd. 3. Vahl. Symb. iii. 51. (*C. coccineum*, Lam 3. Ill. tab. 283. fig. 2. *Cristaria coccinea*, Sinnerat. It. ii. 247. tab. 140.) "Flowers decandrous; spikes lax, panicle-1." Lam. "Leaves opposite, egg-shaped, acute; racemes unilateral, bracteate; bractes shorter than the peduncle; flowers decandrous." Willd. A very smooth furmentous shrub, with cylindrical brachiote branches. *Leaves* three inches long, petioled, quite entire, somewhat coriaceous. *Flowers* bright red, in terminal panicle racemes; bractes solitary, at the base of each pedicel bristle-shaped. A native of the island of Madagascar. 4. *C. decandrum*. Willd. 4. Roxb. Coroman. i. 45. tab. 59. "Leaves opposite, oblong, acuminate; racemes lax, bractes longer than the flower; flowers decandrous, in two rows." *Flowers* white, in panicle racemes; bractes lanceolate; filaments alternately shorter, a little longer than the corolla. A native of woody mountains in the East Indies. 5. *C. alternifolium*. Willd. 5. Jacq. Amer. 104. Plst. 53. tab. 262. fig. 27. (*C. decandrum*, Mart. 4.) "Leaves alternate; flowers decandrous." A weak climbing shrub, twenty feet high; older branches prickly. *Leaves* two or three inches long, oval-oblong, ending in a blunt, channelled, cartilaginous, quite entire, shining, petioled. *Spikes* lax, half a foot long, about ten on one common peduncle, near the end of the little branches, which are often continued weak and leafless, six feet beyond the flowers. *Flowers* small, usually coming out before the leaves on very short pedicels. A native of South America, about Carthazena.

COMBRONDES, in *Geography*, a town of France, in the department of Puy de Dôme, chief place of a canton, in the district of Riom, containing 1568 inhabitants. The territorial extent is of 125 kilometres, with a population of 7580 individuals distributed in 12 communes.

COMBS OF Bees. See *Honey-comb*.

COMBURENDO HERETICO. See *HERETICO*.

COMBUST, in *Astronomy*. When a planet is in conjunction with the sun, or not distant from it above half their disk; it is said to be combust, or in combustion.

According to Argol, a planet is combust or in combustion, when not above eight degrees and thirty minutes distant from the sun, either before or after him.

COMBUSTA, in *Ancient Geography*, a town of Gallia Narbonensis, marked in the Itinerary of Antonine, on the route that leads from Narbonne to the passage of the Pyrenées.

COMBUSTIO pecunie, the ancient way of trying mixed and corrupt money, by melting it down, upon payments into the Exchequer. In the time of king Henry II. a constitution was made, called the trial by combustion; the practice of which differed little or nothing from the present method of assaying silver. But whether this examination of money by combustion was to reduce an equation of money only of sterling, viz. a due proportion of alloy with copper, or to reduce it to pure fine silver, does not appear. On making the constitution of trial it was considered that though the money did answer *numero et pondere*, it might be deficient in value; because mixed with copper or brass, &c. Vide Lowndes's Essay upon Coin, p. 5.

COMBUSTION, a fire, a burning, denotes the decomposition of certain substances, which are thereby called combustibles; accompanied with heat and light. The process of combustion, the various phenomena it exhibits, its astonishing effects, its infinite uses, and its devastations, have at all times rendered it the principal object of human attention in all the various stages of life. The whole extent of civil economy, the preparation of food, as well as of almost all the articles of necessity and of luxury, most of the arts of more essential use to mankind, such as the manufactures of metals, of glass, of pharmacy, &c. depend almost entirely upon combustion. The inclemencies of the weather, and the dismal darkness of night, are removed by means of combustion. The most active instruments of destruction depend upon combustion. The greatest scenes of wonder, admiration, and terror, like the conflagration of towns, and the eruptions of volcanos, are those in which combustion is the sole actor.

Whilst the wants and the economy of the multitude, have at all times called forth their industry in devising easy methods of lighting and warming their apartments, of cooking their victuals, &c.; the calm contemplations of philosophers have endeavoured to investigate the cause or causes, the commencement, the progress, the various intensity, and the products of combustion. It is natural to suppose that their first ideas must have been extremely fanciful and incoherent; since the present theory, which rests upon the foundation of innumerable experiments and strict reasoning, is vastly different from any sort of hypothesis, which even the wisest philosopher would have been led to form, without the light of those experiments.

The first plausible theory of combustion was formed by Stahl, an eminent chemist. The striking difference between bodies combustible and incombustible; that is, between bodies that are, and those that are not susceptible of combustion, induced him to suppose that the combustibles were endowed with a peculiar principle of inflammability, which the incombustibles had not, and to this supposed principle he gave the name of *phlogiston*. According to this supposition, when combustibles were heated to a certain degree, they began to part with this phlogiston, and continued to burn as long as they had phlogiston to lose; after which, they remained in a state of incombustibility; hence, in the former state, those bodies were said to be phlogisticated, and in the latter they were said to be dephlogisticated. With certain bodies the combustion was attended with a separation of other components, so that afterwards they could not be brought back to their former state by the mere addition of phlogiston; but with other bodies, as for instance, with the metals, the processes of dephlogistication and phlogistication might be repeated without end. Thus, a piece of zinc in the metallic state was supposed to be loaded with phlogiston, therefore, when exposed to a sufficient degree of heat, it would burn, viz. it would part with its phlogiston, and would thereby be reduced into the
state

state of a calx, destitute of phlogiston, and of the metallic appearance; but by placing this calx in contact with bodies which contained abundance of phlogiston, in a proper situation, the calx would thereby be enabled to recover its phlogiston, and with it its metallic state and combustibility. It might then be burnt again, and so forth. This plausible theory was no sooner made known, than it was eagerly adopted by philosophers and chemists; so that for a long period it remained the most prevailing theory of combustion. But though the theory was universally adopted, the existence of the principle upon which it was established could not be proved. There was no exhibiting the phlogiston by itself; and it was merely a supposition that a body acquired or lost its inflammability, according as it was combined with, or deprived of, its phlogiston. A supposition which, on a closer examination of facts, was found inadequate to the explanation of the concomitant phenomena. For instance, when a piece of zinc (and such was also the case with other combustibles as far as they might be subjected to experiments) of a determinate weight, was burnt and reduced to a calx, the weight of the calx was found to exceed the original weight of the zinc. It was, therefore, evident that it had acquired something ponderable, and this was utterly repugnant to the phlogistic theory, for by the loss of phlogiston it ought rather to have lost part of its original weight. In answer to this, a strange idea was suggested, namely, that the phlogiston was a principle of lightness; so that bodies became lighter by the addition of phlogiston and *vice versa*. But this supposition, so singular and so repugnant to the general laws of gravitation, was soon abandoned by philosophers when a variety of decisive experiments, the concurrence of recent discoveries in other branches of philosophy, and a strict mode of reasoning, introduced a new theory of combustion, which is both supported by accurate experiments, and sufficient to account for the phenomena. One of the principal labours in the experimental investigation, and the full establishment of this new and rational theory, was the unfortunate Lavoisier, to whose genius, and to whose persevering industry, the scientific world must ever think itself indebted.

In order to render this theory more easily understood by the reader, we shall prefix the following experiment. Take a glass vessel of a cylindrical shape, having a stopple capable of excluding the entrance or exit of any air, and let the outside of this vessel be graduated, so as to divide its capacity into pretty small portions. Put into this vessel, first of common air, a piece of dry phosphorus of a determinate weight; close the vessel tight, and heat gradually that part of it in which the piece of phosphorus stands, by means of the flame of a candle. As soon as the phosphorus has been heated to a certain degree, it takes fire of itself, burning with a flame and thick white smoke; but it soon ceases to burn. Suffer the vessel to cool, and the smoke will fall in the form of flakes, if the vessel and the air contained in it were quite dry, otherwise these flakes will melt in the moisture. If, in this experiment, the vessel be weighed before and after the combustion, it will be found precisely of the same weight. When the vessel is cooled to the actual temperature of the atmosphere plunge the aperture of it under water, and in that situation remove the stopple. You will find that the water rises in it, which shews that a portion of the air has been destroyed or absorbed; and that it has disappeared. By measuring the height of the water risen within the vessel, which is indicated by the graduation on the outside of it; in general, it will be found that about one quarter of the original quantity of air has

disappeared; and the remaining air will be found unfit for the combustion of phosphorus or of any other combustible; and is likewise unfit for the respiration of animals, so that if a bird, a mouse, or any other animal be confined in it, death will soon ensue. If the water which has rushed into the vessel be examined, it will be found to have contracted a sour taste indicating that an acid has been generated. If the vessel, instead of being opened in water be inverted and opened in quicksilver, then the flakes which in the preceding experiment were dissolved by the water, will now remain on the surface of the quicksilver. This is the acid of phosphorus, and if it be carefully gathered and weighed, it will be found together with the remaining phosphorus (if part of it remains unburned), equal to the weight of the original quantity of phosphorus together with the weight of the air that has disappeared. Therefore it is evident that the whole process of combustion consists in a decomposition of the purest part of respirable or atmospherical air; the pure part of it, which is about a quarter of the whole, is decomposed, its base is absorbed by the combustible, and generally communicates to it acid properties, in consequence of which that portion of the atmospherical fluid has been called oxygen gas, from the Greek; meaning the acidifying principle. Therefore, in combustion, the decomposition of the oxygen gas is effected by the burning body, when this body has been heated to a certain degree, which degree varies with the nature of the body. The base of the oxygen gas is also bad and fixed by the burning body, which has thereby its weight increased, and its nature changed; whilst the caloric being disengaged, passes off in the state of sensible heat, and sometimes with such a portion of light as gives the appearance of red or white heat. Acids in general are formed from the absorption of oxygen during combustion. See OXYGEN GAS.

When the combustion is accompanied with red heat, but not with flame, it is called *ignition*. But ignition may also be applied to inconcombustible substances, for these may be rendered red or white hot, without suffering any decomposition. When a vapour arising from the heated body burns over it, it is then called *inflammation*; and when the inflammation is rapid and attended with noise, it is called *detonation*. Having now compendiously stated the new theory of combustion, it is necessary to add several necessary remarks respecting every part of it, which could not be intermixed with the theory without rendering it confused and less intelligible.

In the first place, since the process of combustion consists in a decomposition of oxygen gas, the generalizing spirit of modern philosophy includes every process, in which oxygen gas is decomposed, under the general name of combustion; thus, animal respiration, in which this gas is decomposed, its base absorbed, and heat evolved, may be reckoned amongst the processes of slow combustion. See RESPIRATION. The gradual absorption of oxygen by metallic bodies may also be reckoned amongst these processes.

Since combustion consists in a decomposition of oxygen gas, it naturally follows that without oxygen no combustion can take place. The oxygen, however, may be contained in other substances, in consequence of which those substances become capable of assisting combustion. Now there are seven of those substances, which, from their containing oxygen, are called *supporters* of combustion; and these are oxygen gas, atmospheric air, nitrous oxyd, nitric oxyd (which is prepared by digesting copper and mercury in diluted nitrous acid, and collecting the gas which is extricated), nitric acid, oxygenized muriatic

riatic acid, and hyperoxygenized muriatic acid. See the nature of those substances under the article GAS. It also follows that with a given combustible, the quickness of the decomposition is proportionate to the supply of oxygen, which shews the reason why a fire is increased by blowing common air, and much more by blowing oxygen gas upon it. But cæteris paribus with different combustibles, the fire is strongest when the combustible has the strongest attraction for oxygen. The flame of hydrogen gas urged by oxygen gas is reckoned to produce the most intense heat.

A combustible body, though exposed to oxygen, generally requires to be heated to a certain degree before the combustion commences. That degree varies with the nature of the body, and the purity of the oxygen; so much so that some of them, though not many, take fire immediately on being exposed to some of the above-mentioned supporters of combustion in the common temperature of the atmosphere, whilst others must be heated to a red and even to a white heat, before the decomposition takes place.

When the combustion has once commenced, the heat or caloric, in the form of sensible heat, which is extricated from the oxygen gas, raises the temperature of the adjacent parts of the combustible to that degree which is necessary for its combustion, and the heat evolved by the burning of this part heats the next and so on. But this is not the case with all sorts of combustibles; for some there are which must be kept up at a given high temperature in order to effect their combustion, and a diamond is of this sort. However the nature of combustibles in this respect varies according to the purity and quantity of oxygen. For instance, if a slender steel wire be exposed to the flame of a candle in common air, that part of it only will burn, which is acted upon immediately by the flame: but if the same wire be lighted by means of a bit of tinder, and then be plunged in a vessel full of oxygen gas, it will burn successively to the very end, like a slip of paper; exhibiting a remarkable bright light, and very considerable heat.

Of the simple bodies of nature, the chemists reckon three combustible ones, and two that are incombustible. The former are sulphur, phosphorus, and hydrogen; and the latter are azote and muriatic acid; but amongst the compound bodies, the combustibles are much more numerous. Such are oils, acids, and a vast variety of others which being of a fluctuating nature need not be particularly specified.

A variety of experiments, which may be found under the article GAS, prove that gasses owe their elastic nature to a considerable quantity of caloric, which must necessarily combine with their base, in order to assume the aerial form. Therefore, when, in consequence of the superior affinity of the combustible for oxygen, the oxygen gas is decomposed, and its base condensed, the caloric, which was necessary to its aerial form, being set at liberty, appears in the form of sensible heat; hence the heat which accompanies combustion is naturally supposed to proceed from the oxygen gas; and the quantity of it varies according to the rapidity of the process, so much so that in certain processes like the decomposition of oxygen effected by metallic substances in common air, it is not attended with any sensible degree of heat; for the heat evolved, being very slight, is instantly dissipated among the surrounding bodies.

With certain combustible bodies a peculiar process takes place. It is a remarkable slow process of spontaneous combustion. The body, by attracting oxygen from the atmosphere, becomes thereby gently heated, in consequence of which its affinity to oxygen is increased, a greater decomposition of the latter ensues, more heat is evolved, and thus the process is gradually accelerated until flame and

visible combustion take place. Such is sometimes the case with hay, the saw-dust of certain woods, and various other substances. The well known mixture of iron filings and sulphur moistened with a little water, is an instance of this sort; for if this mixture be buried a little below the surface of the ground, it will of itself, after the lapse of several hours, burst forth in a state of ignition. This experiment has been generally called the *artificial volcano*.

Though heat in combustion is derived from the oxygen gas, the derivation of light is not so evident. It has been for a long time supposed that this element also was one of the components of oxygen gas; but the observations made respecting the light yielded by several bodies when they are slightly heated, or even spontaneously, and that some of them yield much more light than others, seem to prove, that light forms a component principle of most bodies, and that it is evolved from the combustible. It is likely, however, that part of it may be derived from the oxygen also.

The following list of bodies subject to spontaneous inflammation is given by professor Bartholdi; meaning the inflammation occasioned by different bodies acting upon each other, without the aid of another body previously in a state of combustion.

1. Friction. Thus pieces of wood rubbed against each other are thereby inflamed. The best for this purpose are box-wood rubbed against mulberry, or Laurel against poplar, or against ivy, &c. It is in consequence of friction that the wheels and axletrees of carriages sometimes take fire, when they are not sufficiently greased. In turning aloft, pieces of wood sometimes take fire.

2. The action of the sun's rays concentrated by lenses, or concave reflectors, or even by plane reflectors, provided their reflections be thrown upon the same spot. See BURNING-GLASS, and REFLECTORS.

3. The sudden flacking of quicklime has sometimes been known to produce the combustion of adjacent bodies.

4. The fermentation of animal and vegetable substances. Thus great accumulations of hay, turf, or flax, and hemp, heaps of linen rags in paper mills, &c. take fire, provided they are not quite dry; for without moisture, fermentation and the consequent evolution of heat cannot take place.

5. The accumulation of animal and vegetable substances covered with an oil, especially when the oil is of a drying quality. Thus lamp-black mixed with linseed oil is apt to take fire, and an earth of a brown colour, called the *black sand of Derbyshire*, sprinkled over with a little linseed oil, takes fire and appears red-hot like burning small coal, in about an hour's time.

6. There are several substances, which have the property of inflaming spontaneously, increased by torrefaction. Coffee, French beans, lentils, &c. are of this nature.

7. Sulphurated and phosphorated hydrogen gas. The cause of subterraneous fires and volcanoes in general, is attributed to the decomposition of pyrites, or metallic sulphurets, buried in the interior of the earth. These pyritous masses are decomposed by the contact and concurrence of water and air, and the decomposition is always accompanied with a great extrication of caloric, and a disengagement of a very inflammable gas, called *sulphurated hydrogen gas*. This gas inflames at an elevated temperature, and communicates the inflammation to the sulphur of the pyrites, to the coal and other bituminous matters, which generally accompany it.

8. Sulphuret and phosphuret of lime and of potash, formed in the combustion of several vegetables.

9. Phosphorus sometimes contained in charcoal.

The last particulars which we need take notice of, concerning the theory of combustion, are its products. But these must not be mistaken for those bodies which existed in certain combustible, and have been left by themselves when the other components of the combustible have been separated, such as earthy particles, &c. The real products of combustion are those which did not exist before, and these, upon a strict examination, will be found to be either water, or an oxide, or an acid. Water consists of oxygen and hydrogen. See WATER. An oxide is a compound of the combustible with oxygen, but not such as to possess decided acid properties, (and the process is called *oxidation*), or an acid, which consists of the acidifiable part of the combustible, combined with oxygen sufficiently to give it decided acid properties. Thus, the combination of carbon and oxygen forms the carbonic acid gas, and this is produced in almost every combustion, also in respiration, &c.

COMCHE, in *Geography*, a town of Persia, where the caravans rest in their way from Ispahan to Ormus.

COME, in *Biography*. See CESSAR.

COME. The hull, fibres or tails of malt, upon its first shooting forth, are thus called.

COMES IN. Soldiers are said to come in as recruits, volunteers, &c. when they come to join any particular corps or standard.

COME-OVER. When men desert from one army and join another opposed to it, they are said to come over to the one, which they join or go over to.

To come in *to*, to join, to bring aid or assistance.

To come up *with*, to overtake. To come up *with* an enemy, is a military phrase much made use of.

COME *sopra*, in the *Italian Music*, literally signifies as above, and is used when any foregoing part is to be repeated.

COMEA, in *Ancient Geography*, a place of European Myfia, which was an episcopal see, called by the council of Nice *Comensis*.

COMEDÆ, a people of Scythia, comprised by Ptolemy under the general name of Saces.

COMEDONES, a name given to a species of worm, with which the children of Misina, and some other countries, are terribly afflicted; and of which Hoffman, in his "Treatise of Endemial Diseases," gives this account; children in the country are frequently tormented with a sort of tabs, which so destroys their flesh, that they appear merely like shadows. The common people generally suppose these children to be under the influence of witchcraft; but such as have inquired more narrowly into the distemper, have found that it is owing to certain worms, resembling black hairs or cords, lodged under the skin. When the skin is rubbed with honey, in a bath, or any warm place, they will appear and come out; but when it is contracted by cold, they keep concealed within. See AFFECTIO *bovina*, and DRACUNCULI.

COMEDY, in its proper sense, signifies an allegorical representation of some characteristic transaction in private life. The drama, under its various forms, has in all ages and countries been cultivated, not only as a rational and polite amusement, but as a serious art, affecting the moral conduct of men, and influencing the condition of society. According to the field it occupies, whether the lighter train of incidental character, or the important events of life, it assumes the form of tragedy or comedy. The first commands awe; the last excites more pleasurable and exhilarating sensations. The first exhibits the fall of a hero; the last conducts the fortunes of lovers to the goal of marriage, and sets down the eccentricities of every character it meets with on the way. If therefore tragedy is more exalted, comedy

comes closer to the heart, and appeals more powerfully to the experience of man. The stronger passions, the virtues, the crimes, the sufferings of mankind are the theme of the one; our humours, our follies, the effervescence of youth, or the severity of years the topics of the other. Terror and pity are the instruments of pleasure in the first case, but ridicule in the last.

It is therefore very easy to discriminate the general spirit and strain of comedy from that of tragedy. Neither is it less moral or less useful, when considered as a satirical exhibition of human life, with all its improprieties and absurdities. There is nothing in the nature of these compositions, in either kind, which militates against good morals; though a French author endeavoured to affix the imputation of a profane and antichristian spirit on the great Corneille. The improvement of manners, the regulation of social intercourse, the subjection of vicious conduct to the lash of infamy, are among the benefits resulting from this species of poetry. Ridicule often succeeds where argument fails. Yet is it a dangerous weapon, when unskillfully wielded. For it is by no means the test of truth. It may be applied to mislead and seduce, instead of reforming; and the blended colour of ridicule are sometimes more difficult to separate, than the strong lights and shades of truth and error. Cicero quotes some lines of a comedy, where love is represented as the greatest of the deities. On the strength of this sentiment, he exclaims loudly against comic poetry as a corrector of morals; contending at the same time, that the art could not exist, if it had not vanity or villainy to feed upon. Besides this, it happens too frequently, that the ridicule falls where it is least deserved. This however is the fault of the writer, and not to be imputed to the nature of his subject. It depends on the combatant, whether the sword shall be drawn in a good cause, or in a bad one. The success of tragic representations gave rise to the ancient comedy at Athens. In the latter, as well as in the former, the unity of action and subject is absolutely requisite, and those of time and place should be as nearly as possible preserved. By this is meant, that the time of action should be reduced to moderate limits, and the pace never changed but with the termination of the act. The scenes of conversation must be united in a natural succession, and the stage should be perpetually occupied during the continuance of the act. The audience should likewise be made to perceive the necessity of the various personages appearing and disappearing just as they do. By these means, the imitation is allied to probability, and pleases in proportion. Probability is indeed more indispensably necessary in comedy, which descends to ordinary life, than in tragedy. Nature, whether in the management of the incidents, or the delineation of character and sentiment, is the only solid foundation for this species of writing. The scene and subject of comedy should be laid in the country and time, where and when it is to be represented. The little proprieties or indecorums of character and behaviour vary with the moment, and become uninteresting or unintelligible, except where they are seen and known in real life.

The various personages in a well managed comedy ought to be distinctly marked, without the assistance of contrasting them by pairs. Ordinary writers may seem to acquire a strong light and shadow by quaint artifices like these; but a matter looks no further than real life, and represents it as it is. The diction should be easy, natural, and polished, on a level with the conversation of gentlemen in the higher walks, but above the grossness of the vulgar in the lower. Perhaps there is nothing in the art so difficult, as to support a spirit of and happy dialogue. The parade of misplaced wit has spoiled almost as many comedies as actual dulness.

The feast of Bacchus, Sufarion on his stage, and Thephis in his cart, are the humble origin usually ascribed to the drama. Sufarion represented his first pieces towards the year 580 B. C. Thephis made his first attempts in tragedy, and acted his *Alecltis* in 536 B. C. The former attacked the vices and absurdities of his time; and the latter treated more noble subjects, which he took from history. See **DRAMA** and **THEATRE**. Comedy had three flags among the Greeks. The ancients indulged in the licence, not only of dramatising actual and well-known occurrences, but of identifying them with living persons. The name even of Socrates was not withheld from theatrical ridicule; and the philosopher was among the number of the audience. This licence in process of time was interdicted by the authority of the magistrates. The players no longer at liberty to sport with real names, contrived masks to resemble the features of those whom they meant to attack: this was the middle comedy. This latter abuse was scarcely less offensive than the former; and was at length prohibited. Deprived of masks as well as of names, the new comedy confined itself within those modest and moral bounds, which Menander set to its irregularities in the time of Alexander the Great. On this model, Plautus and Terence formed their style, without taking the trouble of transcribing the scene to their own country. This species of entertainment was then scarcely naturalized among the Romans; and their performances were rather translations than originals. In the course of time, Rome distinguished its comedy, founded on native manners, by the name of *Comædia Togata*, and that which was borrowed from the Greeks, was distinguished as the *Comædia Palliata*.

Before the introduction of modern comedy, a species of dramatic representation was in vogue, taken from the stories in the Old and New Testament, the Martyrdoms of the Saints, and other religious subjects. They were called *mysteries*: as the *mystery* or *Play* of the Passion, the *mystery* of the Acts of the Apostles, the *mystery* of the Apocalypse, &c. These entertainments were at first given in the churches, and made a part of the ecclesiastical ceremonies. Afterwards the *mysteries* were played on a public stage. On the entrance of Charles VII. into Paris in the year 1437, scaffolds were erected all along the great street, St. Denis's, on which were acted, with splendid and appropriate decorations, the Annunciation of the Blessed Virgin, the Nativity, our Lord's Passion, his Resurrection, the day of Pentecost, and the last Judgment. In the year 1486, the chapter of the cathedral at Lyons voted sixty livres to the performers in the *mystery* of Jesus Christ's passion. About 1549, the same city exhibited on Sundays and holidays, for the space of three or four years, the greater part of the historical facts in the Old and New Testament, succeeded by a farce, in the same manners in our theatres. The popular name of the play-house was *Paradise*. These sacred comedies were much in fashion in France under Francis I. who patronized them, and attended their representation. One of those, which attracted his approbation, was entitled the *mystery* of the passion of our Lord and Saviour Jesus Christ. It is said in the title page to have been performed "triumphantly at Angiers;" and indeed for it must have been; for there were one hundred and forty-one characters in the dramatic personæ. The date of it is 1541. But the abuses to which these religious performances gave rise occasioned at length a very severe law throughout the kingdom, against the exhibition of "Our Lord's Passion," and other similar subjects. Many of these pieces are still extant in print.

One of the first objects in modern comedy, is the Spanish theatre, fertile as it has been in dramatic productions. Lopez de Vega, Gullin, and Calderon, are the principal comic writers of Spain. The best of these, and the most celebrated, is said to have written above a thousand plays. But our surprise at their number is lessened when we become acquainted with their nature. Neither the numbers, nor any other rules of dramatic writing are in any degree observed. One piece often contains the life of a man, nor is the scene limited to one quarter of the globe. They are for the most part tragicomedies, taken from Spanish history; where war and heroism are coarsely mixed up with ridicule and buffonery. Allegorical and psychological characters, the Pætheon and the sacred *mysteries*, contribute their joint stock to these extravagant and unique performances. Yet are they not without strong traits of genius, and much splendour of imagination. The characters are sometimes well drawn, and the situations happy. To this writer, more than any other, are the public indebted for that taste for the surprising, which so strongly pervades the modern drama. It is plain from his own apologies, that Lopez de Vega complied with the whimsical fancies of his countrymen; and that had he been at liberty to have led the taste of his times, instead of following it, his efforts would have been more natural, his intrigues more skillfully entangled and unavailed, and his characters more consistently preserved.

The French comic theatre is in general an excellent school of manners; correct, chaste, and decent. It may well boast of such writers as Regnard, Dufresny, Dancourt, and Marivaux; but Moliere is the glory of their stage. No writer in any department rose to a higher reputation, in the brilliant age of Louis XIV. It may indeed be questioned, whether any comic writer has ever appeared with so many excellencies and so few defects. Vice and folly are the only objects of his satire. Though his characters are often peculiar to his own country and times, the ridicule is applied so justly as scarcely to have lost its force with foreigners or with posterity. His mirth is not indulged at the expense of good morals. The "*Misanthrope*," and "*Tartuffe*," are in verse; they therefore rise into greater dignity, and assume the style of elegant satire. In his prose comedies he is more ludicrous. His excellence consists more in the strength of his characters, than in the conduct of his plots. He is occasionally too farcical in his prose, and too prolix in his verse. "*Tartuffe*," in the grave comedy, and his "*Avare*," in the lighter, are usually considered as his master-pieces.

English comedy abounds more in original characters, than the comedy of any other modern nation. Humour is a leading feature in the character of the people. The freedom of our government and manners affords a wider scope to the comic muse, than she is allowed in the despotic courts of the continent. This boldness has, however, too often degenerated into a licence almost bordering on the immorality of the ancient Greek comedy. But this error has, however, been corrected in later times, and the stage has conformed to the more decent manners of an age which is rapidly discarding the grossness of vice from public view.

It now only remains to give a character of some of our most eminent comic writers.

Shakspeare decidedly takes the lead in each department of the drama; but his excellencies are so universally felt and understood that it would be superfluous to enter into a criticism of his productions. Of Jonson it will only be necessary to notice a few leading pieces. "Every Man in his Humour" is a play which places this writer scarcely lower

than the highest, whether we advert to the variety of its characters or the energy of its composition. It is to the credit of the present taste, that it regained possession of the stage, in defiance of its obsolete allusions, and antiquated garb. "Every Man out of his Humour" has much less to recommend it than the preceding comedy, though strongly marked in point of character. It has undergone the usual fate of personal satire, to die with the individuals at whom it glances.

"Cynthia's Revels" and the "Poetaster" are chiefly to be remembered, as having been acted by the children of queen Elizabeth's chapel; a relic of theatrical entertainment after the mode of its ancient institution, when the sacred mysteries were represented by the choir of the church or manatory.

Volpone is perhaps the best of this author's comedies. The language and character are wrought up to the highest finish, and the poet exhibits an originality of plot, conception, and execution, which proves that he could throw aside the trammels of the student, and lay claim to the honours of an undebated thinker, as well as those of a successful imitator. The pictures of Volpone and Mosca are finely imagined, and their circumstances most happily delineated. His "Epicure" is exceeded by few comedies in the English language. If to these two we add the "Alchymist," the merits of which are universally allowed, though the object of its satire has given place to other errors and other follies, we shall form such a constellation of comic genius, as will outline all competition but that of his illustrious contemporaries. His later pieces, consisting of his "Bartholomew Fair," "Staple of News," "New Inn," "Magical Lady," and "Tale of a Tub," rather detract from his reputation than augment it; and prove, what many other dramatic writers would have done well to consider, that faculties devoted to the entertainment of the public will at length be exhausted, without some sources of replenishment from change of scene or circumstances.

The triumvirate, such as was never equalled, before or since, in the republic of letters, was completed by John Fletcher, whose merits are closely blended with those of his associate Beaumont. His genius rather assimilates with Shakspeare than with Jonson, to whom he is confessedly inferior in propriety and precision, while he surpasses him in creative powers and poetical fecundity.

The next writer that obtained a large portion of the public favour and attention was Davenant, whose propensity to poetry is said to have appeared sufficiently early in life to attract the favourable notice of Shakspeare, though the great bard died when this young rhymer was only ten years old. What is commonly considered as Davenant's first play was produced in 1629, though he had attempted dramatic composition two or three years before. It is not worth while to enumerate the order or titles of his plays and masques; which were in general well received, and procured his promotion to the laurel, vacant by the death of Jonson, as a reward for the assiduity with which he directed the diversions of the court, as long as the troubles of the times permitted it to have any. It was to his address, that the people were indebted for the gradual restoration of the muses, after an interregnum of severity and gloom. At first he prevailed on men of taste and learning to countenance a healthy species of dramatic melange, which was allowed because it was bad, by the ignorant bigots who held the reins of empire, while rational and regular plays were absolutely prohibited. But he imperceptibly enlarged his sphere of composition, and after the restoration

obtained the patent of the theatre in Lincoln's Inn Fields. The stage is not perhaps more deeply indebted to any man than to Davenant, for the convenience and aptitude of its arrangements in the manager's department. Besides many less material improvements, it owes to him the introduction of female performers, and painted scenery; and from his revival of "Macbeth" and the "Tempest" may be dated that devotion to embellishment, which has ever since inundated the English stage, and, in the judgment of severer critics, overwhelmed the sense and discernment of the audience. His irregular entertainments, resorted to in the first instance only as substitutes for better things, may indeed be considered as the root of all that theatrical evil, we so gravely condemn, but at the same time so freely encourage. Yet he had the praise of bringing forward to the public eye scenery, women, and Betterton.

Mallinger was also among the sterling supports of the English drama; of which he may justly be reputed one of the fathers. His style was rough, manly, and vigorous; he pressed upon his subject with a severe but matterly hand; his wit was caustic, and his serious dialogue, according to its subject, stern and impressive, or natural, easy, and interesting.

Dryden did not commence his career as a writer for the theatre, till the thirty-second year of his age; but from that period he kept possession of it, and produced eight and twenty dramas, not indeed without competition or censure, but with a large share of predominant reputation. His first production was the "Wild Gallant;" a comedy, which met with so indifferent a reception, that had Dryden been a man of fortune, the stage had never again been benefited by his assistance. He was associated with Davenant, in the alteration of the "Tempest;" but he acknowledges the invention and writing of the new characters chiefly to belong to his colleague. We cannot, however, help contemplating the perfections of Shakspeare with astonishment, when we find that two such powerful minds could produce little or no addition to the effect.

On the character of his comedies, it will not be difficult to decide. He has, himself, acknowledged his inaptitude to that species of composition; and certainly his plays in general have much less merit than his other writings. Yet, after all, he has established a reputation that will never fade, even in this branch of poetry; and his drama of the "Spanish Friar" may be selected, as an instance of happy coincidence and real ingenuity, in the combination of serious and risible materials. Indeed the unfitness of his comic performances for modern representation arises more from their extreme licentiousness and immorality than from any defect of power.

The comedies of Otway are deservedly excluded from the reading desk as well as from the stage, on account of their undignified obscenity.

Congreve, at the age of twenty-one, produced the "Old Bachelor," at the theatre in Drury Lane, to amuse himself in a slow recovery from a fit of sickness. It received some requisite touches from the maturer judgment of his friends, and Dryden declared that he had never seen such a first play. The "Double Dealer," and "Love for Love" succeeded it, at an interval of a year each. Five years afterwards his comedy, called the "Way of the World," closed his dramatic labours at a time of life, when writers in general are but beginning their career. The indifferent success of his masterpiece excited his disgust at the caprices of the public. He never resumed his pen in the service of the theatre, except to write a masque, called the "Judgment of Paris." and

and an opera, called "Semele," which was never represented; but as his fame rests on his five regular pieces, we may consider him as lost to the stage, after the unkind reception of a play, which has since vindicated its station among the most brilliant ornaments of the drama.

It is on his comedies principally, that Congreve's reputation subsists. Here, all is luminous, all genuine, pointed, and original. His men of fashion are gentlemen, and even his fops are wits. Congreve is considered as having less humour and less of real life, than his illustrious rivals of the sock. But, surely "Forefight!" abounds with the richest humour, and that of a description, which, though now antiquated, was living and current at the time. Indeed it is an undoubted testimony to the happy drawing of this character, that though it is only recognized by the modern spectator as a picture of the days that are gone by, it never fails to excite ribbidity on the stage in a very powerful degree. The leading feature of Congreve's genius is wit. Dr. Johnson says, that he formed a peculiar idea of comic excellence, which he supposed to consist in gay remarks and unexpected answers. Now, certainly, in adopting such a theory of composition, he too much narrowed his own sphere. Still, however, no more is to be required of a writer, than what he himself undertakes; and Congreve performed what he undertook with a brilliancy of success, which, with the exception of Mr. Sheridan, has neither been rivalled nor approached in the revolution of the century that has elapsed. It has been objected, that "his personages are a kind of intellectual gladiators; every sentence is to ward or strike; the contest of smartness is never intermitted." This remark is undoubtedly true; yet, when we find Congreve thus formidably censured for the exuberance of his wit, it is impossible not to feel as the king of Prussia did, when he wished a certain mad commander to bite some of his generals.

Could the licentiousness of Congreve's topics be as easily justified as the overflowings of his gaiety, his fame would continue to blaze without danger of eclipse. But in truth, the offence his muse occasions to the purer ears of a more moral age, has an unhappy tendency to shorten his theatrical existence. The observation applies equally, if not in a greater degree, to all his witty, but graceless contemporaries; and it may be remarked on such freedoms in general, that they create disgust and alienation, at least in some minds, in a place and on an occasion, where it should be as much an author's study never to offend any, as occasionally to please all; consequently though they may increase the number of temporary plaudits, they infect the vitals of a reputation, that otherwise might have been immortal, with a principle of early decay.

To particularize the merits either of Congreve's rivals, Wycherly, Farquhar, Vanburgh, &c. or the numerous class of writers in the succeeding ages, who have cultivated the *comédie larmoyante*, would exceed the limits of this article. The latter is indeed almost as obsolete as the coarse but sterling wit of king Charles's days. It has given place to the distorted portraits and philosophy-run mad of the German school; a taste from which it is most devoutly to be wished that the drama may be speedily rescued.

COMENII, in *Ancient Geography*, a people of Illyria, according to Ptolemy, adjoining to the Dauriani and Vardzani.

COMENITZA, in *Geography*, a town of European Turkey, in the province of Epire, 52 miles S.W. of Delfino.

COMENIUS, JOHN AMOS, in *Biography*, a celebrated grammarian and divine, was born in the year 1592, in Moravia. He studied at Herborn, and returned to his own

country in 1614, and was appointed rector of a college there. In 1618 he became pastor of the church at Fulnee, and was appointed master of the school which had been lately erected. Here he conceived the idea of an improved method of teaching the languages, but his writings on this subject were destroyed in 1621, when the town was taken and plundered by the Spaniards. In 1624 he retired from the persecutions inflicted upon the Protestants in Germany, to Lesna, a city of Poland, where he devoted himself to the instruction of young persons in the Latin language: here he published in 1631 his "*Janua Linguarum reферата*," a work which obtained for him great reputation, and which was speedily translated into 12 European languages, and also into the Arabic, Turkish, Persian and Mogul languages. He was now invited into Sweden to take the charge of the public schools in that kingdom, which he declined; and having published the "*Panophiz Prodomus*," or "*Forerunner of Universal Science*," he was solicited by the parliament of England to undertake the reformation of the schools there. He arrived in London Sept. 1641, but owing to the civil wars his proposals were neglected, and he went to Sweden, and from thence to Elbing in Prussia, where he employed six years in perfecting his new method of instruction, but did not meet with sufficient encouragement to induce him to publish his thoughts on the subject. In 1648 Comenius was invited to the court of Sigismund Ragotzki, prince of Transylvania, where he lived four years, and proposed regulations for the college of Patak, upon the plan of his Panophia, from whence he returned to Lesna, and continued there till 1656, when the town was burnt in the war between the Swedes and the Poles. On this occasion he lost all his manuscripts excepting what he had composed on his Panophia, and the Apocalypse. He fled into Silesia, thence to Brandenburg, afterwards to Hamburg, and lastly to Amsterdum, where he continued till his death, which happened in 1671. At Amsterdum he published his "*New Method of Teaching*," which added nothing to his reputation, and which the learned Bayle has declared of no worth whatever in the art of instruction. In this opinion he is sanctioned by the concurrent voice of the learned in every succeeding age to the present time.

Comenius was not only intent upon the reformation of scholastic learning, but he embraced the notions of a speedily approaching millennium, and pointed out as characters who were to be eminently distinguished in fulfilling the prophecies, Gultavus Adolphus, Cromwell, and others, who had little claim to the honours of a divine mission. Succeeding events contributed to dissipate, in some measure, the enthusiastic notions which he had embraced and cherished. By some of his contemporaries he was charged with having possessed more knavery than credulity, but of this there seems to be no satisfactory evidence. He published "*Commentaries on the Apocalypse*," some treatises on the Socinian controversy, and "*Historia Fratrum Bohemorum*," in 4to. Nonv. Hist. Dict. Bayle.

COMENOLITARI, in *Geography*, a country of modern Greece, which comprises the ancient kingdom of Macedonia and Thessalia.

COMENSES, in *Ancient Geography*, a people of Asia Minor, towards Galatia, according to Pliny. Hardouin calls them Chomenes, deriving their name from Choma, a town situated in the interior of Lycia.

COMERCHIN, in *Geography*, a town of European Turkey, in the province of Romania; 62 miles E. of Emboli.

COMES *Nervi Phrenici*, in *Anatomy*, is a small branch of the internal mammary artery. See ARTERIES.

COMES,

COMETS, in *Antiquity*. See *COURT*.

COMES, NAPALIS, in *Biography*, was born at Milan in the sixteenth century, and is greatly distinguished for his classical learning. He translated from Greek into Latin the "Diipnosophistæ of Athenæus," the "Rhetoric of Hermogenes," and he published poems of his own in both these languages. In 1581 he published a history of his own times from 1545 to 1573, but his principal work is a system of mythology entitled, "Mythologia, sive Explicationis Fabularum, lib. x." It was dedicated to Charles IX. of France. He died in 1589, and on account of his love of allegory and mythicism he was denominated by Joseph Scaiger "Homo futilissimus." *Moreri*.

COMES *Domeficorum Equitum et Peditum*: Colonels of the archers of the body-guard of the Roman emperors. These archers were all of them chosen men of Armenia; and their number amounted to seven thousand five hundred.

COMESSAZZA, in *Geography*, a river of Italy, which runs into the Oglio; 9 miles N.E. of Sabinetta.

COMESSAZZO, a town of Italy, in the duchy of Mantua, $3\frac{1}{2}$ miles N. of Sabinetta.

COMESUS, a lake of America, in the state of New York; 27 miles S. of the lake of Ontario.

COMET, in *Astronomy*, a heavenly body, in the planetary region, appearing suddenly, and again disappearing; and during the time of its appearance moving in a proper, though very eccentric orbit, like a planet. Comets, like the planets, move in different planes, but the motion of some of them is direct, and that of others retrograde.

Comets, popularly called *blazing stars*, have this to distinguish them from the other stars, that they are usually attended with a long train of light, always opposite to the sun, and which is of a fainter lustre, the farther it is from the body. Hence arises a popular division of comets into three kinds, viz. *bearded*, *tailed*, and *hairy comets*; though in effect this division rather relates to the several circumstances of the same comet, than to the phenomena of several.

Thus, when the comet is eastward of the sun, and moves from it, it is said to be *bearded*, because the light precedes it in manner of a beard. When the comet is westward of the sun, and sets after it, it is said to be *tailed*, because the train follows it in manner of a tail. Lastly, when the comet and the sun are diametrically opposite, (the earth being between them), the train is hid behind the body of the comet, excepting a little that appears around it in form of a border of hair, or *coma*, whence it is called *hairy*, and whence the name of comet is derived.

COMETS, *nature of*.—As to the nature of comets, the infrequency of their appearance, together with the seeming irrelevance of their phenomena, have left philosophers of ancient, and even more modern times, much in the dark. Those who lived before Aristotle, accounted for them by supposing the heavenly spaces full of an infinite number of stars; and many of them too remote, or too small, to have ever come under the notice of astronomers; these invisible stars they farther supposed to move by their own proper motion every way; finishing their courses in very unequal times. Now, a comet, according to them, was a vast heap or assemblage of these little stars, meeting together, by reason of the inequality of their motions, and uniting into a visible mass; which must again disappear, as those stars separated, and each proceeding in its course. But how these stars should thus meet, coalesce, and form a body, which in all positions of the sun should resemble a tail, and again separate, is a mystery.

This opinion, therefore, Aristotle easily overturned; substituting another in its stead. According to Aristotle, comets were only a kind of transient fires or meteors, consisting of exhalations raised to the upper region of the air, and there lit on fire; far below the moon's course. But whether is this hypothesis more just than the other; for on this principle, the light of the comet, being independent of the sun, would be dispersed every way alike, without any appearance of a train; or tail, which is contrary to the phenomena. Moreover, they are observed at the same time in places on the earth very remote from each other. Besides, the modern astronomers who have measured the distance between the comets and the earth, find that the comets have no sensible diurnal parallax; which could not be, were they not much more remote than the moon, whose parallax is sensible; and yet as they have a sensible annual parallax, they are not so remote as the fixed stars. Indeed, there were some, Pliny tells us, among the ancients, who had juster notions; who took these stars to be perpetual, and believed they moved in their proper orbs; but were never seen, unless when left by the sun." Aristotle, in his first book of Meteors, mentions this doctrine of the ancient philosophers; and observes, that some of the Italians, called Pythagoreans, said, that a comet is one of the planets, but that they do not appear unless after a long time, and are seen but for a short time, which happens also to Mercury. Apollonius Myndius declared, that he took comets for regular stars; affirming also, that the comets were reckoned by the Chaldeans among the planets, and to have their periods like them. He also ventured to foresee, that one day the periods and laws of their motion would be discovered. And more fully Seneca, *Quæst. Nat. lib. vii.* He had himself seen at least two comets, one in the reign of Claudius, the other in that of Nero; besides that which he saw in his youth, a little before the death of Augustus, which in one place he calls a comet, and in another a prodigy. He intimates that he thought them above the moon, and argues strongly against those who imagined that they were meteors elevated into the air by winds, or who held some other absurd opinions concerning them. "I am not of the common opinion," says he, "nor do I take a comet to be a sudden fire, but esteem it among the eternal works of nature." *Quid autem miramur cometas, tam rarum mundi spectaculum, nonnum tenuis legibus certis, nec initia illorum sineque innotescere, quorum ex ingentibus nec intervallis recursum est? Veniet tempus quo ista que nunc latent, in lucem dies extrahat, & longioris ævi diligentia. Veniet tempus quo pelleri nostri tam aperta nos n. sisse mirentur. Erit qui demonstret aliquando, in quibus comete partibus errent; cur tam se ducti a cæteris errent quanti qualeque sint.*

This prediction we have seen accomplished in our days by the great sir Isaac Newton; whose doctrine concerning them will appear in the sequel of this article. Seneca recommended it to astronomers to keep a catalogue of the comets, in order to be able to determine whether they returned at certain periods. The authority of Aristotle, however, long prevailed; and comets were generally considered as meteors, existing in our atmosphere, till the time of Tycho Brahe. This excellent astronomer was the first among the moderns, who, after diligently observing the comet of 1577, and finding that it had no sensible diurnal parallax, assigned it its true place in the planetary regions. (See his book *De Cometa*, anni 1577.)

Although few comets have approached so near the earth as to have a diurnal parallax, they afford sufficient indications of an annual parallax; that is, the revolution of the earth in her orbit causes their apparent motion to be very different

from

from what it would be, if they were viewed from the sun, or any fixed place. See the first of the phenomena recited in the sequel. This shews that they are not so distant as the fixed stars, which have no annual parallax; and, as Hevelius observes, affords a proof of the earth's revolution round the sun; for, without supposing that, these motions of comets are inexplicable. Tycho was preceded by Kepler, who, in his book "De Cometis," concluded from observations of the comets which appeared in 1607 and 1618, that comets move freely through the planetary orbs, with a motion not much different from a rectilinear one; but of what kind he could not precisely determine. He was followed by Hevelius, an accurate observer of the heavenly bodies, who found, by his own observations of two comets that appeared in his time, that they were not subject to diurnal parallax; that calculations of their places, made upon a supposition that they moved in straight lines, did not agree with their true places; but that their orbits were concave towards the sun; and concluded, that they moved in parabolic trajectories.

Hevelius, from a great number of observations, supposes it as his opinion, that the comets, like the solar macula or spots, are formed and condensed out of the grosser exhalations of his body: or that they are generally in the atmosphere of a planet, and discharged from it, partly by the rotation of the planet, and then revolved about the sun in a parabola by the force of projection and its tendency towards the sun, in the same manner as a projectile upon the earth's surface describes a parabola. In which notion he agrees nearly with Kepler, who maintains, that comets are generated in the ether in vast numbers, like fishes in the ocean; though they do not all become visible; either because of their smallness, or because they lie a long time under the horizon.

But sir Isaac Newton has shewn the fallacy of this hypothesis; by proving that the comet of 1682, in its passage through the neighbourhood of the sun, would have been dissipated, had it consisted of exhalations of the sun and planets: for the heat of the sun, it is allowed, is as the density of his rays, i. e. reciprocally as the squares of the distances of places from the sun. Wherefore, since the distance of that comet in its perihelion, December the 5th, was observed to be to the distance of the earth from the sun, nearly as 6 to 1000; the sun's heat in the comet at that time, was to his heat with us at midsummer, as 100000 to 36, or 28000 to 1.

And again, finding by experiment, that the heat of boiling water is little more than three times the heat of our dry earth, when exposed to the midsummer's sun; and assuming the heat of red-hot iron to be about three or four times as great as that of boiling water; he thence concludes, that the heat of the dried earth, or body of the comet in its perihelion, must be near 2000 times as great as that of red-hot iron.

Such an immense heat once acquired in its perihelion, the comet must be a long time in cooling again. The same author computes, that a globe of red-hot iron, of the dimensions of our earth, would scarce be cool in 50000 years. If then the comet be supposed to cool 100 times as fast as red-hot iron; yet since its heat was 2000 times greater, supposing it of the bigness of the earth, it would not be cool in a million of years.

James Bernoulli, in his "Systema Cometarum," supposes some primary planet revolving round the sun in the space of four years and one hundred and fifty-seven days; and at the distance, from his body, of 2583 semidiameters of the magnus orbis; this planet, he concludes, either from

its vast distance, or smallness, to be invisible to us: but, however, to have, at various distances from him, several satellites moving round him, and sometimes descending as low as the orbit of Saturn; and that these becoming visible to us, when in their perigæum, are what we call comets.

Des Cartes advances another opinion: he conjectures that comets are only stars, formerly fixed like the rest, in the heavens; but which becoming by degrees covered with maculae, or spots, and at length wholly robbed of their light, cannot keep their place, but are carried off by the vortices of the circumjacent stars; and, in proportion to their magnitude and solidity, moved in such manner as to be brought nearer the orb of Saturn; and thus coming within reach of the sun's light, rendered visible.

But the vanity of all these hypotheses abundantly appears from the phenomena of comets; the chief of which we shall enumerate; as being the tell by which all theories are to be tried.

First, then, those comets which move according to the order of the signs, do all, a little before they disappear, either advance slower than usual, or else go retrograde, if the earth be between them and the sun; and more swiftly, if the earth be situate in a contrary part. On the other hand, those which proceed contrary to the order of the signs, proceed more swiftly than usual, if the earth be between them and the sun; and more slowly, or go retrograde, when the earth is in a contrary part.

2. So long as their velocity is increased, they move, nearly, in great circles; but towards the end of their course, they deviate from those circles; and as often as the earth proceeds one way, they go the contrary way.

3. They move in ellipses, having one of their foci in the centre of the sun; and by radii drawn to the sun, describe areas proportionate to the times.

4. The light of their bodies, or nuclei, increases in their recess from the earth toward the sun; and on the contrary, decreases in their recess from the sun.

5. Their tails appear the largest and brightest, immediately after their transit through the region of the sun, or after their perihelion.

6. The tails always decline from a just opposition to the sun towards those parts which the bodies, or nuclei, pass over, in their progress through their orbits.

7. This declination, *ceteris paribus*, is the smallest, when the heads, or nuclei, approach nearest the sun: and is less, still, nearer the nucleus of the comet, than towards the extremity of the tail.

8. The tails are somewhat brighter, and more distinctly defined in their convex than in their concave part.

9. The tails always appear broader at their upper extreme than near the centre of the comet.

10. The tails are always transparent, and the smallest stars appear through them.

These are the chief phenomena of comets; which it is evident, cannot easily be reconciled with the wild notions of the ancients, and the weak conjectures of many of the moderns.

"The comets," says sir Isaac Newton, "are compact, solid, fixed, and durable bodies: in one word, a kind of planets; which move in very oblique orbits, every way with the greatest freedom; persevering in their motions, even against the course and direction of the planets; and their tail is a very thin slender vapour, emitted by the head or nucleus of the comet, ignited or heated by the sun."

This at once solves all the foregoing phenomena: for, 1. It is evident, that those which proceed according to the order of the signs, a little before they disappear, must move more slowly, or appear retrograde, if the earth be between them and the sun; and swifter if the earth be in a contrary part. On the contrary, those proceeding against the order of the signs," &c. For since this course is not among the fixed stars, but among the planets; as the motion of the earth either conspires with them, or goes against them; their appearance, with regard to the earth, must be changed; and, like the planets, they must sometimes appear swifter, sometimes slower, and sometimes retrograde.

2. "When the comets move the swiftest, they must proceed in straight lines; but in the end of their course, decline," &c. Because, in the end of their course, when they recede almost directly from the sun, that part of the apparent motion which arises from the parallax, must bear a greater proportion to the whole apparent motion.

3. "The comets must move in ellipses, having one of their foci in the centre of the sun." Because they do not wander precariously from one scintillating vortex to another; but, making a part of a solar system, return perpetually, and run a constant round.

Hence, their elliptic orbits being very long and eccentric they become invisible, when in that part most remote from the sun.

From considering the curvity of the paths of comets, Sir Isaac concludes, that when they disappear, they are much beyond the orb of Jupiter; and that in their perihelion they frequently descend below the orbit of Mars, and the inferior planets.

4. "The light of their nuclei must increase in their recess from the sun, and *vice versa*." Because as they are in the regions of the planets, their access toward the sun bears a considerable proportion to their whole distance.

From observations of the comet of 1680, Sir Isaac Newton found, that the vapour in the extremity of the tail. January 25th, began to ascend from the head before December 11th; and had therefore spent more than forty-five days in its ascent; but that all the tail which appeared December 10th, ascended in the space of those two days, then just past since its perihelion. The vapour, therefore, at the beginning, when the comet was near the sun, ascended with a prodigious swiftness; and afterwards continued to ascend with a motion retarded by the gravity of its particles; and by that ascent increased the length of the tail; but the tail, notwithstanding its length, consisted almost wholly of vapours, which had ascended from the time of its perihelion; and the vapour which ascended first, and composed the extreme of the tail, did not vanish till it was too far from the sun to be illuminated by him, and from us to be visible. Hence also, the tails of comets that are shorter, do not ascend with a quick and continual motion from the head, and then presently disappear; but are permanent columns of vapours and exhalations, gathered from the head, by a very gentle motion, and a great space of time; which yet, by participating of that motion of their heads they had at the beginning, continue easily to move along with their heads through the celestial regions: whence also the vacuity of those regions is argued. See VACUUM.

5. "Their tails must appear the largest and brightest immediately after their transit through the region of the sun." Because, then, their heads being the most heated, will emit the most vapours.

From the light of the nucleus, or apparent star, we infer

their vicinity to the earth, and that they are by no means in the region of the fixed stars, as some have imagined; since, in that case, their heads would be no more illuminated by the sun, than the planets are by the fixed stars.

6. "The tails must still decline from a distinct opposition to the sun, towards the parts which the heads pass over, in their progress through their orbits." Because all smoke, or vapour, emitted from a body in motion, tends upwards obliquely, still receding from that part, towards which the smoking body proceeds.

7. "That declination will be still the least near the nucleus of the comet; and when the comet is nearest the sun." Because the vapour ascends more swiftly near the head of the comet, than in the higher extremity of its tail; and when the comet is at a less distance from the sun than when at a greater.

8. "The tail is brighter, and better defined in its convex part than in its concave." Because the vapour in the convex part, which goes first, being somewhat nearer and denser, reflects the light more copiously.

9. "The tail must appear broader towards the higher extremity of the comet than towards the head." Because the vapour in a free space is perpetually rarified and dilated.

10. "The tails must be transparent." Because consisting of infinitely thin vapour, &c.

Thus accurately does the hypothesis tally to the phenomena.

COMETS, *phases of*.—The nuclei, which we also occasionally call the *heads* and *bodies* of comets, viewed through a telescope, shew a very different face from those of the fixed stars, or planets. They are liable to apparent changes, which Sir Isaac Newton ascribes to changes in the atmosphere of comets; and this opinion was confirmed by observations of the comet in 1744. Hist. Acad. Scienc. 1744. Sturmius tells us, that, observing the comet of 1680, with a telescope, it appeared like a coal dimly glowing, or a rude mass of matter illumined with a dusky smoky light, less sensible at the extremes than in the middle: rather than as a star, which appears with a round disk, and a vivid light.

Hevelius observed of the comet of 1661, that its body was of a yellowish colour, very bright, and conspicuous, but without any glittering light: in the middle was a dense ruddy nucleus, almost equal to Jupiter, encompassed with a much fainter, thinner matter. February 5th, its head was somewhat bigger and brighter, of a gold colour; but its light more dusky than the rest of the stars: here, the nucleus appeared divided into several parts. February 6th, the disk was lessened; the nuclei still existed, though less than before: one of them, on the lower part of the disk, on the left, much denser and brighter than the rest, its body round, and representing a very lucid little star: the nuclei still encompassed with another kind of matter. February 10th, the head somewhat more obscure, and the nuclei more confused, but brighter at top than bottom. February 13, the head diminished much, both in magnitude and brightness. March 2d, its roundness a little impaired, its edges lacerated, &c. March 28th, very pale and exceeding thin; its matter much dispersed; and no distinct nucleus at all appearing.

Weigelius, who saw the comet of 1664. the moon and a little cloud illumined by the sun at the same time, observed, that the moon, through a telescope, appeared of a continued luminous surface; but the comet very different; being perfectly like a little cloud in the horizon illumined by the sun.

fun. From these observations it was, that Hevelius concluded comets to be like maculæ, or spots formed out of the solar exhalations.

COMETS, *magnitude of.* The estimates that have been given by Tycho, Hevelius, and some others, of the magnitude of comets, are not sufficiently accurate to be depended upon; for it does not appear, that they distinguished between the nucleus and the surrounding atmosphere. Thus Tycho computes that the true diameter of the comet in 1577, was in proportion to the diameter of the earth as 3 is to 14. Hevelius made the diameter of the nucleus of the comet of 1661 and also that of 1665 at the commencement of their appearances to be less than a 10th part of the diameter of the earth, and from the parallax and apparent magnitude of the head of the comet of 1652 on the 10th of December, he computed its diameter to be that of the earth, as 52 to 100. By the same method he found the true diameter of the head of the comet of 1664 to be at one time 12 semi-diameters of the earth, at another time not much above 5 semi-diameters. The diameter of the atmosphere is often ten or fifteen times as great as that of the nucleus; the former, in the comet of 1682, was measured by Flamsteed, and found to be 2', but the diameter of the nucleus only 11 or 12". Some comets, from the apparent magnitude and distance compared, have been judged to be much larger than the moon, and even equal to some of the primary planets. The diameter of that of 1744, when at the distance of the sun from us, measured about 1', and therefore its diameter must be about three times the diameter of the earth: at another time the diameter of its nucleus was nearly equal to that of Jupiter.

Hence it has been conjectured that some of the solar eclipses, recorded in history, that cannot be verified by calculation from tables of the sun and moon, have been occasioned by the interposition of comets between the sun and the earth. The eclipses of the sun mentioned by Herodotus (l. vii. c. 37, and l. ix. c. 10.) have been thus accounted for, and also the eclipse that happened a few days before the death of Augustus, mentioned by Dion: and it is observable, that Seneca saw a comet the same year. History records four comets that have appeared as large as the sun, (vid. Seneca, N. Q. l. 7. c. 15); and, therefore, if such a comet near its perigee were to come between the sun and our earth, it would eclipse him for a time. Some have thought that the darkness which occurred at our Lord's crucifixion might have been occasioned by a comet then passing between the earth and the sun. (Hevel. Cometogr. p. 542. Freret, réflexions sur un ancien phénomène céleste au temps d'Osyges, Mem. de Littérature, vol. xix. p. 357).

Dr. Herschel observed several comets which seemed to him to have no nucleus. The six comets discovered by his filter were of this kind, and appeared to be mere collections of vapours condensed about a centre. Five more were observed by himself, which were nearly of the same nature. This circumstance, he says, "throws a mystery over their destination, which seems to place them in the allegorical view of tools, probably designed for some salutary purposes to be wrought by them; and, whether the restoration of what is lost to the sun by the emission of light may not be one of these purposes, I shall not presume to determine. The motion of the comet discovered by M. Messier, June, 1770, plainly indicated how much its orbit was liable to be changed by the perturbation of the planets, from which, and the little agreement that can be found between the elements of the orbits of all the comets that have been observed, it appears clearly that they may be directed to carry their salutary influence to any part of the heavens."

VOL. IX.

COMETS, *Formation of the tails of.* Sir Isaac Newton shews, that the atmosphere of comets will furnish vapour sufficient to form their tails: this he argues from that wonderful rarefaction observed in our air, at a distance from the earth: a cubic inch of common air, at the distance of half the earth's diameter, or four thousand miles, would necessarily expand itself so far as to fill a space larger than the whole region of the planets. Since then the coma or atmosphere of a comet, is ten times higher than the surface of the nucleus, counting from the centre thereof; the tail, ascending much higher, must necessarily be immensely rare: so that it is no wonder the stars should be visible through it.

Now, the ascent of vapours into the tail of the comet, he supposes occasioned by the rarefaction of the matter of the atmosphere at the time of the perihelion. Smoke, it is observed, ascends the chimney by the impulse of the air wherein it floats; and air, rarified by heat, ascends by diminution of its specific gravity, taking up the smoke along with it: why then should not the tail of a comet be supposed to be raised after the same manner by the sun? for the sun beams do not act on the mediums they pass through any otherwise than by reflexion and rarefaction.

The reflecting particles, then, being warmed by the action, will again warm the æther wherewith they are compounded; and this, rarified by the heat, will have its specific gravity, whereby it before tended to descend, diminished by the rarefaction, so as to ascend, and carry along with it those reflecting particles, whereof the tail of the comet is composed.

This ascent of the vapours will be promoted by their circular motion round the sun; by means whereof, they will endeavour to recede from the sun, while the sun's atmosphere, and the other matters in the celestial spaces, are either at rest, or nearly so; having no motion but what they receive from the sun's circumrotation.

Thus are the vapours raised into the tails of comets in the neighbourhood of the sun, where the orbits are most curve; and where the comets, being within the denser atmosphere of the sun, have their tails of the greatest length.

The tails thus produced, by preserving that motion, and at the same time gravitating towards the sun, will move round his body in ellipses, in like manner as their heads; and, by this means, will ever accompany, and freely adhere to their heads. In effect, the gravitation of the vapours towards the sun will no more occasion the tails of the comets to forsake their heads, and fall down towards the sun, than the gravitation of their heads will occasion them to fall off from their tails: but by their common gravitation, they will either fall down together to the sun, or be together suspended, or retarded. This gravitation, therefore, does not at all hinder, but that the heads and tails of comets may receive and retain any position towards each other, which either the above mentioned causes, or any other, may occasion. The tails, therefore, thus produced in the perihelion of comets, will go off along with their heads into remote regions; and either return thence, together with the comets, after a long series of years; or rather, be there lost, and vanish by little and little, and the comets be left bare; till at their return, descending towards the sun, some little short tails are gradually and slowly produced from the heads; which afterwards, in the perihelion, descending down into the sun's atmosphere, will be immensely increased.

The vapours, when they are thus dilated, rarified and
Q
diffused

diffused through all the celestial regions, the same author observes, may probably, by little and little, by means of their own gravity, be attracted down to the planets, and become intermingled with their atmospheres.

He adds, that for the conservation of the water, and moisture of the planets, comets seem absolutely requisite; from whose condensed vapours and exhalations, all that moisture which is spent in vegetations and putrefactions, and turned into dry earth, &c. may be replenished and recruited. For all vegetables grow and increase wholly from fluids; and, again, as to their greatest part, turn, by putrefaction, into earth again; and earthly slime being perpetually precipitated to the bottom of putrifying liquors. Hence, the quantity of dry earth must continually increase, and the moisture of the globe decrease, and at last be quite evaporated, if it has not a continual supply from some part or other of the universe. And I suspect, adds our great author, that the spirit, which makes the finest, subtlest, and the best part of our air, and which is absolutely requisite for the life and being of all things, comes principally from the comets. So far are they from portending any hurt or mischief to us which the natural fears of men are apt to suggest from the appearance of any thing that is uncommon and astonishing.

On this principle, there seems to be some foundation for the popular opinion of presages from comets; since the tail of a comet thus intermingled with our atmosphere, may produce changes very sensible in animal and vegetable bodies.

But the transmutation of water into earth is now justly exploded: Woodward, Boerhaave, and others, having observed that water is only an agent in conveying the nutritious matter to vegetable bodies, and not that matter itself.

Another use which Sir Isaac Newton conjectures comets may be designed to serve, is that of reuniting the sun with fresh fuel, and repairing the consumption of his light by the flames continually sent forth in every direction from that luminary. In support of this conjecture he observes, that comets in their perihelion may suffer a diminution of their projectile force, by the resistance of the solar atmosphere; so that by degrees their gravitation towards the sun may be so far increased, as to precipitate their fall into his body. Thus also, fixed stars which have been gradually waded, may be supplied with fresh fuel, acquire new splendour, and be taken for new stars: of this kind are those fixed stars, which appear on a sudden, or shine with a surprising brightness at first, and afterwards vanish by degrees.

There have been various conjectures also, touching the generation of the tails of comets. Apian, Cardan, Tycho Brahe, and some others, apprehended that they were produced by the sun's rays transmitted through the nucleus of the comet, which they supposed to be transparent, and there refracted as in a lens of glass, so as to form a beam of light behind the comet. But this cannot be the case, because the figure of a comet's tail does not correspond to such a refraction, and also because such refracted light would not be seen by an eye placed sideways to it, unless it fell upon some reflecting substance denser than the circumambient air. Kepler supposed, that the rays of the sun carry away some of the gross parts of the comet which reflect the sun's rays, and give the appearance of a tail. Hevlhus thought, that the thinnest parts of the atmosphere of a comet are raised by the force of the heat, and driven from the fore-part and each side of the comet towards the parts turned from the sun. Des Cartes accounted for the phenomenon of the tail by the refraction of light from the head of the comet to the eye of the spectator. If this were the case, the planets and principal

fixed stars must have tails also; for their rays pass through the same medium before they reach our eyes, as light from the comets does. Mairan supposes that the tails are formed out of the luminous matter that composes the sun's atmosphere, which is supposed to extend as far as the orbit of the earth, and to furnish matter for those northern lights called the *Aurora borealis*, which see. M. De la Lande combines this hypothesis with that of Newton above recited. He thinks that part of the vapour which forms them arises out of the atmosphere rarified by heat, and is pushed forward by the force of the light streaming from the sun; and also that a comet passing through the sun's atmosphere is drenched therein, and carries away some of it. Mr. Rowning, who is not satisfied with Sir Isaac's opinion, accounts for the tails of comets in the following manner. It is well known, says he, that when the light of the sun passes through the atmosphere of any body, as the earth, that which passes on one side, is by the refraction thereof made to converge toward that which passes on the opposite one; and the convergency is not wholly effected either at the entrance of the light into the atmosphere, or at its going out; but beginning at its entrance, it increases in every point of its progress. It is also agreed that the atmospheres of the comets are very large and dense. He therefore supposes that by such time as the light of the sun has passed through a considerable part of the atmosphere of a comet, the rays thereof are so far refracted toward each other, that they then begin sensibly to illuminate it, or rather the vapours floating therein; and so tender that part they have yet to pass through visible to us: and that this portion of the atmosphere of a comet, thus illuminated, appears to us in form of a beam of the sun's light, and passes under the denomination of a comet's tail. Rowning's *Natural Philosophy*, part iv. chap. 11.

We have an inquiry into the cause of the tails of comets, by Mr. Euler, in the *Mem. de l'Acad. de Berlin*, tom. ii. p. 117, seq. He thinks there is a great affinity between these tails, the zodiacal light, and the *Aurora borealis*; and that the common cause of them all, is the action of the sun's light on the atmosphere of the comets, of the sun, and of the earth. He supposes that the impulse of the rays of light on the atmosphere of comets, may drive some of the finer particles of that atmosphere far beyond its limits; and that this force of impulse combined with that of gravity towards the comet, would produce a tail, which would always be in opposition to the sun, if the comet did not move. But the motion of the comet in its orbit, and about an axis, must vary the position and figure of the tail, giving it a curvature, and deviation from a line drawn from the centre of the sun to that of the comet; and that this deviation will be greater, as the orbit of the comet has the greater curvature, and that the motion of the comet is more rapid. It may even happen, that the velocity of the comet, in its perihelion, may be so great, that the force of the sun's rays may produce a new tail, before the old one can follow; in which case the comet might have two or more tails. The possibility of this is confirmed by the comet of 1744, which was observed to have several tails while it was in its perihelion. See *AURORA borealis*, and *ZODIACAL light*.

Dr. Hamilton urges several objections against the Newtonian hypothesis; observing, that we have no proof of the existence of a solar atmosphere: and if we had, that when the comet is moving in its perihelion, in a direction at right angles to the direction of its tail, the vapours which then arise partaking of the great velocity of the comet, and being also specifically lighter than the medium in which they move,

mult

must suffer a much greater resistance than the dense body of the comet does, and therefore ought to be left behind, and would not appear opposite to the sun; and afterwards they ought to appear towards the sun. Besides, if the splendour of the tails be owing to the reflexion and refraction of the sun's rays, it ought to diminish the lustre of the stars seen through it; which would have their light reflected and refracted in like manner; and consequently their brightness would be diminished. He concludes that the tail of a comet is formed of matter which has not the power of refracting or reflecting the rays of light; but that it is a lucid or self-luminous substance; and from its similarity to the *Aurora borealis*, produced by the same cause, and a proper electrical phenomenon. Dr. Hamilton supports his opinion by the following arguments. A spectator, at a distance from the earth, would see the *Aurora borealis* in the form of a tail opposite to the sun, as the tail of a comet lies. The *Aurora borealis* has no effect upon the stars seen through it, nor has the tail of a comet. The atmosphere is known to abound with electric matter, and the appearance of the electric matter in vacuo resembles exactly that of the *Aurora borealis*, which, from its great altitude, may be considered to be in as perfect a vacuum as we can make. The electric matter in vacuo suffers the rays of light to pass through, without being affected by them. The tail of a comet does not expand itself sideways, nor does the electric matter. Hence, he supposes the tails of comets, the *Aurora borealis*, and the electric fluid to be the same kind of matter. As a further confirmation of this opinion it may be added, that the comet in 1607 appeared to shoot out the end of its tail. Le P. Cyat remarked the undulations of the tail of the comet in 1618. Hevelius observed the same in the tails of the comets in 1652 and 1661. M. Pingré noticed the same appearance in the comet of 1769; and these are circumstances similar to the *Aurora borealis*. Dr. Hamilton conjectures, that the use of the comets may be to bring the electric matter, which continually escapes from the planets, back into the planetary regions. These arguments very much corroborate this hypothesis; and if it be true, we may further add, that the tails are hollow; for if the electric fluid only proceed in its first direction and do not diverge sideways, the parts directly behind the comet will not be filled with it; and this thinness of the tails will account for the appearance of the stars through them. Dr. Halley seemed inclined to this hypothesis, when he said, that the streams of light in an *Aurora borealis* so much resembled the long tails of comets, that at first sight they might well be taken for such: and that this light seems to have a great affinity to that which the effluvia of electric bodies emit in the dark. Phil. Transf. N^o 347. Hamilton's Philosophical Essays, p. 91, &c.

Hevelius particularly informs us, that he observed the comet of 1665 to cast a shadow upon the tail, for in the middle of its length there appeared a dark line. Cassini also observed in the tail of the comet of 1680 a darkness in the middle of the tail; and the same appearance was taken notice of by a curious observer in the tail of the comet of 1744. The lengths of the tails of comets are various, and depend on a variety of circumstances. Longomontanus mentions a comet that in 1618, December the 10th, had a tail which appeared under an angle of 104° : that of 1680 appeared under an angle of 70° , according to sir I. Newton, and very brilliant: the comet of 1744 had a tail, which at one time appeared to extend 16° from its body; and which, allowing the sun's parallax to be $10''$, must have been above 23 millions of miles in length. The diameter of its nucleus was nearly equal to that of Jupiter. The tail of the comet of 1759 appeared, according to M. Pingré, under an angle of 90° ; but the

light was very faint. The length of a comet's tail may be thus found. Let S (Plate IV. *Astronomy*, fig. 23.) be the sun, E the earth, C the comet, CL the tail when directed from the sun; then, knowing the place of the comet, we know the angle FCL. EC, and the angle CEL, the angle under which the tail appears; hence we find CL the length of the tail. If the tail deviate by any angle LCM, found from observation, we shall then know the angle ECM, with CE, and the angle CEM, to find CM.

M. Fatou has suggested that some of the comets have their nodes so very near the annual orbit of the earth; that if the earth should happen to be found in that part next the node, at the time of a comet's passing by; as the apparent motion of the comet will be incredibly swift, so its parallax will become very sensible; and the proportion thereof to that of the sun will be given: whence such transits of comets will afford the best means of determining the distance of the earth and sun.

The comet of 1472, *v. gr.* had a parallax above twenty times greater than the sun's: and if that of 1618 had come down in the beginning of March to its descending node, it would have been much nearer the earth, and its parallax much more notable. But, hitherto, none has threatened the earth with a nearer approach than that of 1680: for, by calculation, Dr. Halley finds that November 11th, 1 h. 6 min. P. M. that comet was not above one semidiameter of the earth, to the northward of the way of the earth; at which time had the earth been in that part of its orbit, the comet would have had a parallax equal to that of the moon: what might have been the consequence of so near an approach, a contact, or, lastly, a shock of the celestial bodies?

If the earth had been at this time in that part of her orbit nearest to that node of the comet, through which it passed, their mutual gravitation must have caused a change in the plane of the orbit of the earth, and in the length of our year. Dr. Halley adds, that if so large a body, with so rapid a motion as that of this comet near its perihelion, were to strike against our earth, a thing by no means impossible, the shock might reduce this beautiful frame to its original chaos. Whiston, who, from Flamsteed's measure of the apparent diameter of this comet, concluded its nucleus to be about ten times as big as the moon, or equal to a fourth part of our earth, attributes the universal deluge, in the time of Noah, to its near approach. His opinion was, that the earth passing through the atmosphere of the comet, attracted from it a considerable part of the waters of the flood; that the proximity of the comet raised a great tide in the subterranean waters, so that the outward crust of the earth was changed from spherical to oval; that this could not be done without making fissures and cracks in it; that through these fissures the subterranean waters were forced, in consequence of the change of the hollow of the earth into a less capacious form;—that, along with the water thus squeezed up upon the surface of the earth, much slime or mud would rise; which, together with the grosser parts of the comet's atmosphere, would, after the subsiding of the water partly into the fissures and partly into the lower parts of the earth to form the sea, cover all over to a considerable depth the antediluvian earth:—and thus he accounts for trees and bones of animals being found at very great depths in the earth. He also supposed, that before the fall the earth revolved round the sun in the plane of the ecliptic, keeping always the same points of its surface towards the same fixed stars; by this means, as every meridian would come to the sun but once in a whole revolution, a day and a year were then the same: but that a comet striking obliquely upon the

earth gave it the diurnal rotation. Moreover, he apprehended, that the antediluvian year consisted of 360 days; but that the additional matter deposited upon the earth from the atmosphere of the comet at the time of the deluge, so retarded its revolution round the sun, that it is not now performed in less than 365 days and about a quarter.

The same comet, he imagined, would probably, by coming near the earth after being heated to an immense degree in its perihelion, be the instrumental cause of that great catastrophe, the general conflagration, foretold in the Sacred Writings, and from ancient tradition, mentioned by heathen writers. See CONFLAGRATION, DELUGE, and *Theory of the Earth*.

COMETS, distance of. The analogy between the periodical time of the planets, and their distances from the sun, discovered by Kepler, takes place also in the comets. Hence, the mean distance of a comet from the sun may be found by comparing its period with the time of the earth's revolution round the sun: thus, the period of the comet that appeared in 1531, 1607, 1682, and 1759, being about 76 years, its mean distance is found by this proportion; as 1 the square of one year, the earth's periodical time, is to 5776 the square of 76, the comet's periodical time, so is 1000000 the cube of 100, the earth's mean distance from the sun, to 5776000000 the cube of the comet's mean distance; the cube root of which is 1794, the mean distance itself, in such parts as the mean distance of the earth contains 100. If the perihelion distance of this comet 58 be taken from 3588 double the mean distance, we shall have the aphelion distance 3530 of such parts as the distance of the earth contains 100; and this is a little more than 35 times the distance of the earth from the sun. By a like method the aphelion distance of the comet of 1680 comes out 138 times the mean distance of the earth from the sun, supposing its period to be 575 years; so that this comet in its aphelion goes to more than 14 times the distance from the sun that Saturn does.

The limit of a comet's distance may be very easily ascertained from its tail, it being supposed to be directed from the sun. Let S (*fig. 24.*) be the sun, E the earth, ET the line in which the head of the comet appears, EW the line in which the extremity of the tail is observed, and draw ST parallel to EW; then the comet is within the distance ET; for if the comet were at T, the tail would be directed in a line parallel to EW, and therefore it could never appear in that line. TEW is known by observation, and consequently its equal ETS, together with TES, the angular distance of the comet from the sun, and ES, to find ST the limit. E. G. On December 21, 1680, the distance of the comet from the sun was $32^{\circ} 24'$, and length of the tail 70° ; hence ST : SE :: $\text{fin. } 32^{\circ} 24' : \text{fin. } 70^{\circ} :: 4 : 7$ nearly; consequently the comet's distance from the sun was less than $\frac{4}{7}$ of the earth's distance from the sun. Hence Sir Isaac Newton deduced this conclusion, that all comets, whilst they are visible, are not further distant from the sun than three times the earth's distance from the sun. This must, however, depend upon the goodness of the telescope, and magnitude of the comet. *Vince's Altr.* vol. i. p. 446.

COMETS, motion of. If the paths of comets be supposed directly parabolic, as some have imagined, it would follow, that being impelled toward the sun by a centripetal force, they descend as from spaces infinitely distant; and by their falls acquire such a velocity, as that they may again run off into the remotest regions; and moving upwards, with such a perpetual tendency as never to return. But the

frequency of their appearance, and their degree of velocity, which does not exceed what they might acquire by their gravity towards the sun, seem to put it past doubt that they move, planet-like, in elliptic orbits, though exceedingly eccentric; and so return again, though after very long periods.

The apparent velocity of the comet of 1472, as observed by Regiomontanus, was such as to carry it through 40° of a great circle in 24 hours; and that of 1770 was observed to move through more than 45° in the last 25 hours.

G. S. Doërfell, minister at Plaven in Upper Saxony, made observations upon the comet of 1680, and found that its motion might very well be represented by a parabola, having the sun in its focus; but not understanding the laws by which the motion of a body in a parabola is regulated, he erred considerably in his parabola, making the perihelion distance about 12 times greater than it was. This was published five years before the "Principia" of Newton, in which this illustrious author proved that Kepler's law, by which the planetary motions are regulated, was a necessary result of his theory of gravity; whence it immediately followed, that comets were governed by the same law; and the observations upon them agreed so accurately with his theory, as to leave no doubt of its truth.

Newton, Flamsteed, Halley, and the English astronomers, &c. seem satisfied of the return of the comets. Cassini, and others of the French, thought it highly probable; but De la Hire, and others, opposed it.

Those on the affirmative side suppose the comets to describe orbits prodigiously eccentric, inasmuch that we can only see them in a very small part of their revolution: out of this, they are lost in the immense spaces; hid not only from our eyes, but from our telescopes. That little part of their orbit near us, M. Cassini, &c. has found to pass between the orbits of Venus and Mars.

For the reasons of the return of comets, M. Cassini gives these which follow. 1. In considering the course of the comets, with regard to the fixed stars, they are found to keep a considerable time in the arc of a great circle, *i. e.* a circle whose plane passes through the centre of the earth: indeed, they deviate a little from it, chiefly towards the end of their appearance; but this deviation is common to them with the planets.

2. Comets, as well as planets, appear to move so much the faster as they are nearer the earth; and when they are at equal distances from their perigee, their velocities are nearly the same.

By subtracting from their motion the apparent inequality of velocity occasioned by their different distances from the earth, their equal motion might be found: but we should not be certain this motion were their true one; because they might have considerable inequalities, not distinguishable in that small part of their orbit visible to us. It is, indeed, probable, their real motion, as well as that of the planets, is unequal in itself: and hence we have a reason why the observations made, during the appearance of a comet, cannot give the just period of their revolution.

3. There are not two different planets whose orbits cut the ecliptic in the same angle, whose nodes are in the same points of the ecliptic, and whose apparent velocity in their perigee is the same; consequently, two comets seen at different times, yet agreeing with all those three circumstances, can only be one and the same comet. And this were the comets of 1577 and 1680 observed to do; and those of 1652 and 1698; not that this exact agree-

agreement, in these circumstances, is absolutely necessary to determine them the same comet. M. Cassini finds the moon herself irregular in them all; accordingly, he is of opinion, there are several which disagree herein, and yet may be accounted the same.

The great objection against the return of comets, is, the rarity of their appearance, with regard to the number of revolutions assigned to them.

In 1702, there was a comet, or rather the tail of one, seen at Rome, which M. Cassini takes to be the same with that observed by Aristotle, and that since seen in 1668, which would imply its period to be thirty-four years. Now, it may seem strange, that a star which has so short a revolution, and of consequence such frequent returns, should be so seldom seen.—Again, in April, of the same year, 1702, a comet was observed by Mess. Bianchini, and Maraldi, supposed by the latter to be the same with that of 1664, both by reason of its motion, velocity, and direction. M. de la Hire took it to have some relation to another he had observed in 1698, which M. Cassini refers to that of 1652. On this supposition, its period appears to be forty-three months; and the number of revolutions between 1652 and 1698, fourteen; but it is hard to suppose, that in this age, wherein the heavens are so narrowly watched, a star should make fourteen appearances unperceived; especially such a star as this which might appear above a month together: and of consequence be frequently disengaged from the repensula.

For this reason M. Cassini was very reserved in maintaining the hypothesis of the return of comets, and only proposed those for planets, where the motions are easy and simple, and are resolved without straining, or allowing many irregularities.

M. de la Hire proposes one general difficulty against the whole system of the return of comets, which would seem to hinder any comet from being a planet: and it is this; that by the disposition necessarily given to their courses, they ought to appear as large at first as at last; and always increase, till they arrive at their greatest proximity to the earth: or, if they should chance not to be observed, as soon as they become visible, for want of attention thereto; at least it is impossible but they must frequently shew themselves before they have arrived at their full magnitude and brightness. But he adds, that none were ever yet observed till they had arrived at it.

But the appearance of a comet in the month of October 1723, while at a great distance, so as to be too small and dim to be viewed without a telescope, may serve to remove this obstacle, and set the comets, still, on the same footing with the planets.

Sir Isaac Newton supposes, that as those planets which are nearest the sun, and revolve in the least orbits, are the smallest; so among the comets, such as in their perihelion come nearest the sun, are the smallest, and revolve in lesser orbits.

In order to prove that comets describe ellipses, and not parabolas or hyperbolas, Dr. Halley, in his "Synopsis of the Astronomy of Comets," advances the following reasons. "Hitherto I have considered the orbits of comets as exactly parabolic; upon which supposition it would follow, that comets being impelled towards the sun, by a centripetal force, would descend as from spaces infinitely distant; and, by their so falling acquire such a velocity, as that they may again fly off into the remotest parts of the universe, moving upwards with a perpetual tendency, so as never to return again to the sun. But since they appear frequently enough, and since none of them can be

found to move with an hyperbolic motion, or a motion swifter than what a comet might acquire by its gravity to the sun, it is highly probable they rather move in very eccentric elliptic orbits, and make their returns after long periods of time; for so their number will be determinate, and perhaps not so very great. Besides, the space between the sun and the fixed stars is so immense, that there is room enough for a comet to revolve, though the period of its revolution be vastly long. Now the *latus rectum* of an ellipse is to the *latus rectum* of a parabola, which has the same distance in its perihelion, as the distance in the aphelion, in the ellipse, is to the whole axis of the ellipse. And the velocities are in a subduplicate ratio of the same; wherefore, in very eccentric orbits, the ratio comes very near to a ratio of equality; and the very small difference which happens, on account of the greater velocity in the parabola, is easily compensated in determining the situation of the orbit. The principal use therefore of the table of the elements of their motions, and that indeed which induced me to construct it, is, that whenever a new comet shall appear, we may be able to know, by comparing together the elements, whether it be any of those which has appeared before, and consequently to determine its period, and the axis of its orbit, and to foretell its return. And, indeed, there are many things which make me believe, that the comet which Apian observed in the year 1531, was the same with that which Kepler and Longomontanus more accurately described in the year 1607; and which I myself have seen return, and observed in the year 1682. All the elements agree, and nothing seems to contradict this my opinion, besides the inequality of the periodic revolutions; which inequality is not so great neither, as that it may not be owing to physical causes. For the motion of Saturn is so disturbed by the rest of the planets, especially Jupiter, that the periodic time of the planet is uncertain, for some whole days together. How much more therefore will a comet be subject to such like errors, which rises almost four times higher than Saturn, and whose velocity, though increased but a very little, would be sufficient to change its orbit, from an elliptical to a parabolical one. And I am the more confirmed in my opinion of its being the same; for, in the year 1456, in the summer-time, a comet was seen passing retrograde between the earth and the sun, much after the same manner; which, although nobody made observations upon it, yet, from its period, and the manner of its transit, I cannot think different from those I have just now mentioned. And since looking over the histories of comets, I find, at an equal interval of time, a comet to have been seen about Easter, in the year 1305, which is another double period of 151 years before the former. Hence, I think, I may venture to foretell that it will return again in the year 1758." Dr. Halley computed, *lavi calamo*, as he himself informs us, the effect of Jupiter upon this comet in 1682, and found that it would increase its periodic time above a year, in consequence of which he predicted its return at the end of the year 1758, or the beginning of 1759. M. Clairaut computed the effects both of Saturn and Jupiter, and found that the former would retard its return in the last period 100 days, and the latter 511 days; and he determined the time when the comet would come to its perihelion to be in April 15, 1759, observing that he might err a month, from neglecting small quantities in the computation. It passed the perihelion on March 13, within 53 days of the time computed. Now if we suppose the time stated by Dr. Halley, to mean the time of its passing the perihelion, then if we add to that 100 days, arising from the action of Saturn

which

which he did not confid^r, it will bring it very near to the time in which it did pass the perihelion, and prove his computation of the effect of Jupiter to have been very accurate. If he mean the time when it would first appear, his prediction was very accurate, for it was first seen on December the 14th, 1758. and his computation of the effects of Jupiter will then be more accurate than could have been expected, considering that he made his calculations only by an indirect method, and in a manner professedly not very accurate. Dr Halley, therefore, had the glory, first to foretel the return of a comet, and the event answerd remarkably to his prediction. He further observed, that the action of Jupiter, in the descent of the comet towards its perihelion in 1682. would tend to increase the inclination of its orbit; and accordingly the inclination in 1682 was found to be 22' greater than in 1657. From the observations of M. Messier upon a comet in 1770, M. Edric Propperin, member of the Royal Academies of Stockholm and Upsal, shewed, that a parabolic orbit would not answer to its motions, and he recommended it to astronomers to seek for the elliptic orbit. This laborious task was undertaken by M. Lexell, who has shewn that an ellipse, in which the periodic time is about 5 years and 7 months, agrees very well with the observations. (See Phil. Transf. for 1779.) As the ellipses which the comets describe are all very eccentric, astronomers, for the ease of calculation, suppose them to move in parabolic orbits for that part which lies within the reach of observation, by which they can very accurately find the place of the perihelion of a comet, its distance from the sun, the inclination of the plane of its orbit to the elliptic, and the place of the node. But before we can determine the orbit of a comet, from observation, it will be necessary to premise such particulars respecting the motion of a body in a parabola, as may be requisite for such an investigation.

Accordingly let $\triangle P M$ (fig. 25.) be a parabola, S it's focus, A the vertex, P the place of the body, draw P Q perpendicular to A S, and P D perpendicular to the tangent P T, also S M perpendicular to A D. Now, by the property of the parabola, Q D is equal to half the latus rectum; hence if A S = 1, then Q D = 2; also the angle P S A = 2 P D A; therefore if Q D be radius, P Q will be the tangent of P D A, or $\frac{1}{2}$ P S A; hence to the radius A S, P Q will be twice the tangent of $\frac{1}{2}$ P S A; therefore if 2t = P Q, t will be the tangent of ($\frac{z$) half the true anomaly P S A, to the radius A S = 1. Also, by the property of the parabola, A Q \times 4 A S = P Q², hence A Q = t²; also the area A Q P = $\frac{2}{3}$ t³; and as Q S = 1 - t, the area Q P S = 1 - t²; hence the area A S P = $\frac{1}{3}$ t³ + t; also the area A S M = $\frac{2}{3}$. Now let a and b be the times in which the comet moves from A to M, and from A to P; then, as the areas described about S are proportional to the times, a : b :: $\frac{2}{3}$: $\frac{1}{3}$ t³ + t, therefore a t³ + 3 a t = 4 b.

Hence if a, and the true anomaly be given, we have the time b = $\frac{1}{3}$ a t³ + $\frac{2}{3}$ a t. Also, because a : b :: $\frac{2}{3}$: $\frac{1}{3}$ t³ + t, therefore if the true anomaly, and consequently t, be given in different parabolas, the times of describing those true anomalies from the perihelions will be in proportion to the times of describing 90° from the perihelions.

If the times a and b be given, the true anomaly may be found from resolving the cubic equation t³ + 3t = $\frac{b}{a}$, which may be done thus. In the right-angled triangle C A B, (fig. 26.) let A B = 1, A C = $\frac{b}{a}$, and compute B C; then find two mean proportionals between B C + A C and B C - A C, and their difference is the value of t.

Take the fluxion of t³ + 3t = $\frac{4b}{a}$, and we have $\dot{t} = \frac{4}{3a} \times \frac{b}{1+t^2}$; but $\dot{t} = \frac{1}{1+t^2} \times \dot{z}$; hence we get 2 z $\dot{z} = \frac{8}{3a} \times \frac{b}{1+t^2}$; $\frac{\dot{z}}{1+t^2} = \frac{8}{3a} \times \frac{b}{1+t^2}$ \times col. $\frac{z}{1+t^2}$ \times \dot{b} the variation of the true anomaly corresponding to any small variation \dot{b} of time expressed in decimals of a day, a being expressed in days.

Let S A (fig. 25.) be the mean distance of the earth from the sun; then the area of the circle, described with that radius, will be 3.14159; also the area A M S = $\frac{1}{2}$. Now the velocity in the parabola : velocity in the circle :: $\sqrt{2} : 1$; for let P p (fig. 27.) be an indefinitely small arc described by the body, S the place of the sun, S N a line drawn from the focus S, perpendicular to a tangent to the parabola A P D at the point P; then, 1st, The velocity u in any point P of the parabola, is as the square root of the parameter to the axis, divided by S N: for, the velocity is as the arc P p or u = p P: now, p M being perpendicular to P S, in the similar right-angled triangles p P M, P S N: S P :: p M : p P = $\frac{p M \times S P}{S N}$. But the parameter is as

the square of the described sector; therefore R (the parameter) = p M² \times S P², and $\sqrt{R} = p M \times S P$; and by substitution, p P or u = $\frac{\sqrt{R}}{S N}$ or u = $\frac{\sqrt{4 A S}}{S N}$, from the

nature of the parabola. 2dly, The velocity u in any point P of the parabola, is to the velocity V of a body running through the circumference of a circle with a central force tending to its centre, the radius being equal to S P, as $\sqrt{2} : 1$. For, since u = $\frac{\sqrt{4 A S}}{S N}$, u² = $\frac{4 A S}{S N^2}$; or, because S N² = S P \times

S A (by the property of the Parabola), u² = $\frac{4 A S}{S P \times A S}$ = $\frac{4}{S P}$. But the circle whose radius is S P, being taken as an ellipsis, its parameter is = 2 S P; and the velocity V being uniform, it is every-where as $\frac{\sqrt{2} S P}{S P}$; therefore V V = $\frac{2 S P}{S P^2} = \frac{2}{S P}$; consequently u² : V² :: $\frac{4}{S P} : \frac{2}{S P}$:: 2 : 1; and therefore u : V :: $\sqrt{2} : \sqrt{1}$:: $\sqrt{2} : 1$.

The areas described in the same time will be in the same ratio as the velocities, because at A the motion in each orbit being perpendicular to S A, the areas described will be as the velocities, and it being so in one case, it must be always so, because in each orbit respectively equal areas are described in equal times. But the times of describing any two areas are as the areas directly, and the areas described in the same time inversely; therefore

$\frac{3.14159}{2} : \frac{4}{3\sqrt{2}} \left(\frac{\sqrt{S}}{3} \right)$:: the time of the revolution in the circle = 365d. 6h. 9' : the time of describing A M = 109d. 14h. 46'. 20". Now as the time of describing A M is in a given ratio to the time in the circle, which

varies as A S, therefore if r = the perihelion distance in any other parabola, we have 1³ : r³ :: 109d. 14h. 46'. 20" : the time of describing 90° in that parabola from the perihelion. Hence, knowing the time corresponding to any true anomaly in that parabola whose perihelion distance = 1, we know the time corresponding to the same true anomaly in any other parabola, because the times

times of describing 90° are as the times corresponding to the same true anomaly; therefore if n be the number of days corresponding to any given anomaly in that parabola

whose perihelion distance is unity, then $n r^{\frac{2}{3}}$ will be the time t corresponding to the same anomaly in that whose perihelion distance is r ; this may be readily found thus. Multiply the log. r by 3 and divide by 2, and to the quotient add the log. n , and the sum will be the log. of the time required.

Hence also $n = \frac{t}{r^{\frac{2}{3}}}$; therefore if from the log. t we subtract $\frac{2}{3} \log. r$, it gives the log. n of the number of days corresponding to the same anomaly in the parabola, whose perihelion distance = 1; hence the anomaly will be found from a table which exhibits the times corresponding to the true anomaly for 200000 days from the perihelion, in that parabola whose perihelion distance is unity. This table may be constructed by the preceding problem, by taking $a = 109, 6154$, and assuming $b = 1, 2, 3, 4, \&c.$ and finding the corresponding values of t . Dr. Halley first constructed a table of this kind. M. de la Caille changed it into a more convenient form, by putting the areas for the times; Mr. Vince has given that which was computed by M. de Lambré. (See Vince's Astron. vol. i. p. 454, &c.)

Draw SY perpendicular to the tangent; then SP : SY :: SY : SA, therefore $\sqrt{SP} : \sqrt{SA} :: SP : SY :: \text{rad.} : \text{cof. PSY}$, or $\frac{1}{2}$ PSA the true anomaly; or SP : SA :: $\text{rad.}^2 : \text{cof.}^2 \text{ true anom.}^2$. Hence, if SA = 1, and $a + x = \frac{1}{2}$ PSA, $a - x = \frac{1}{2}$ PSA, then $1 : \sqrt{SP} :: \text{cof. } a + x : \text{rad.}$ and $\sqrt{SP} : 1 :: \text{rad.} : \text{cof. } a - x$; hence $\sqrt{SP} : \sqrt{SP} :: \text{cof. } a + x : \text{cof. } a - x$.

Hence $SP = \frac{SA}{\text{cof. } \frac{1}{2} \text{ true anom.}}$, radius being unity; therefore from log. SA subtract twice the log. cof. $\frac{1}{2}$ true anomaly, and the remainder is the log. of the distance of the comet from the sun.

Erect BD (fig. 2S.) perpendicular to AB, take BC = AB, produce AC to E, and draw EDF perpendicular to AE, meeting AF parallel to BD in F, join AD, and draw DG, CH parallel to AB. Then, as EAF = 45° , EA = EF; also FG = GD = AB; hence AF = BD + BA, and GH = BD - BA; a fo, by similar triangles, AF or BD + BA : CD = GH or BD - BA : EF or EA : ED :: $\text{rad.} : \tan. DAE$; but AB : BD :: $\text{rad.} : \tan. BAD$. from which (subtract 45° and we have $BD + BA : BD - BA :: \text{rad.} : \tan.$ of that difference. If $BD = \sqrt{SP}$, and $BA = \sqrt{SP}$, then

$$\sqrt{SP} : \sqrt{SP} :: \text{rad.} : \tan. BAD = \sqrt{\frac{SP}{SP}}; \text{ hence,}$$

to get that angle, take half the difference of the logarithms of SP and SP , and add 10 to the index (because in the log. tangents, the index of log. tan. of 45° , or log. of rad. = 1, is 10, instead of 0), and it gives the log. tangent of the angle; from which take 45° , and we have $\sqrt{SP} + \sqrt{SP} : \sqrt{SP} - \sqrt{SP} :: \text{rad.} : \text{tang. of that difference.}$

Hence if we know two radii SP, Sp (fig. 25.) and the angle PSp between, we can find the two anomalies. For let a be $\frac{1}{2}$ of ASP + ASp, and x be $\frac{1}{2}$ of ASP - ASp, then $\frac{1}{2}$ ASP = $a + x$, and $\frac{1}{2}$ ASp = $a - x$; hence $\sqrt{SP} : \sqrt{SP} :: \text{cof. } a + x : \text{cof. } a - x ::$ (by plane Trig.) $\text{cof. } a \times \text{cof. } x - \text{fin. } a \times \text{fin. } x : \text{cof. } a \times \text{cof. } x + \text{fin. } a \times \text{fin. } x$, therefore $\sqrt{SP} + \sqrt{SP} : \sqrt{SP} - \sqrt{SP} :: \text{cof. } a \times \text{cof. } x - \text{fin. } a \times \text{fin. } x : \text{cof. } a \times \text{cof. } x + \text{fin. } a \times \text{fin. } x$. Now the ratio of the two first terms is found from the last article, and as the angle PSp is given, the value of x will be given, hence we find a , and consequently we know the sum and difference of ASP, ASp, therefore we know the angles themselves. If β lie on the other side of A, then we know a , to find x .

$-\sqrt{SP} :: \text{cof. } a \times \text{cof. } x : \text{fin. } a \times \text{fin. } x :: \frac{\text{cof. } a}{\text{fin. } a}$
 $\frac{\text{fin. } x}{\text{cof. } x} :: \text{cot. } a : \tan. x$. Now the ratio of the two first terms is found from the last article, and as the angle PSp is given, the value of x will be given, hence we find a , and consequently we know the sum and difference of ASP, ASp, therefore we know the angles themselves. If β lie on the other side of A, then we know a , to find x .

Given two distances SP, Sp from the f cus to the curve of a parabola, and the angle between them, to find the parabola (fig. 29.) With the centres P and p, and radii PS, pS, describe two circular arcs $rw t, m \sigma n$, to which draw the tangent $a \sigma \sigma b$; draw ST perpendicular to ab , and bisect it in A, and it will be the vertex of the parabola; hence we may describe the parabola.

Having the Elements of the Orbit of a Comet, to compute its place at any time.

The elements of the orbit of a comet are, 1. The time when the comet passes the perihelion.—2. The place of the perihelion.—3. The distance of the perihelion from the sun.—4. The place of the ascending node.—5. The inclination of the orbit to the ecliptic. From these elements, the place at any time may be computed; and, for example, we shall take that given by M. de la Caille in his Astronomy. The comet in 1759, which was retrograde, passed its perihelion on June 17, at 10h. 6' 52" mean time; the place of the perihelion was in $3^\circ 12' 38'' 40''$; the perihelion distance was 0.67358, the mean distance of the earth from the sun being unity; the ascending node was in $0^\circ 27' 25'' 14''$, and the inclination of the orbit $55^\circ 42' 44''$; to compute the place seen from the earth on August 17, at $14^\circ 20'$ mean time.

Let WAW (fig. 3.) be the parabolic orbit of the comet, N the ascending node, P the place of the comet, T the corresponding place of the earth, and draw Pw perpendicular to the ecliptic; produce SN, Sw, SP, ST to n, u, p and t the sphere of the fixed stars, and describe the great circles $nps, nu \sigma t$ and pu .

I. The interval of time from the perihelion to the given time is 61d. 4h. 10' 30" = 61.174, whose log. is 1.786567; also the log. of .67358 is 9.828388, $\frac{1}{2}$ of which log. (from the nature of logarithms) is 9.424282, which subtracted from 1.786567 leaves 2.042985, the log. of 110.6547 days, which, by the table, answers to $3^\circ 0' 21' 38''$ the true anomaly PSA at the given time.

II. Subtract $3^\circ 0' 21' 38''$ from $3^\circ 12' 38'' 40''$ the place of the perihelion, because the comet was retrograde, and had passed the perihelion, and it leaves $12^\circ 17' 1''$ for the heliocentric place β of the comet in its orbit.

III. The longitude of n is $27^\circ 27' 14''$, also $\beta n = 27^\circ 14'' - 12^\circ 17' 1'' = 15^\circ 8' 13''$; hence $\text{rad.} : \text{cof. } \beta n u = 55^\circ 42' 44'' :: \tan. \beta n = 15^\circ 8' 13'' : \tan. nu = 8^\circ 30' 53''$ the distance of the comet from the ascending node, measured upon the ecliptic.

IV. Subtract this value of nu from the place of the node, and there remains $18^\circ 45' 21'' = \sigma n$ the true heliocentric place of the comet reduced to the ecliptic.

V. As $\text{rad.} : \text{fin. } \beta n = 15^\circ 8' 13'' :: \text{fin. } \beta n u = 55^\circ 42' 44'' : \text{fin. } \rho = 12^\circ 27' 34''$ the latitude seen from the sun, which is fourth.

VI. The true place T of the earth at the same time is $10^\circ 24' 34' 36''$; hence TS $\sigma = 35^\circ 25' 24''$; therefore TS $\sigma + \sigma n = TS u = 1^\circ 24' 10' 45''$. Also TS = 1.0115.

VII. In the preceding article, $\cot. 45^\circ 10' 49'' : \text{rad.}^2 :: 67.358 : S P = 1.3557$.

VIII. As $\text{rad.} : \cot. P S \nu = 12^\circ 27' 34'' :: S P = 1.3557 : S \nu = 1.3277$.

IX. In the triangle $T S \nu$, we know $T S$, $S \nu$ and the included angle $T S \nu$; hence, by plain trigonometry, we find the angle $S T \nu = 77^\circ 33' 38'' \frac{1}{2}$, which subtracted from $4^\circ 24' 34'' 36'$, the place of the sun, leaves $2^\circ 7' 0' 57'' \frac{1}{2}$ for the comet's true geocentric longitude.

X. Moreover, as $\sin. 54^\circ 10' 4'' : \sin. 77^\circ 33' 38'' \frac{1}{2} :: \tan. P S \nu = 12^\circ 27' 34'' : \tan. P T \nu = 14^\circ 54' 4''$ the comet's true geocentric latitude.

To determine the Orbit of a Comet from Observation.

Sir I. Newton first resolved this problem, which he called *Problema longe difficillimum*. The orbit of a comet may be computed from three observations; but although these data be sufficient, the direct solution of the problem is impracticable. Astronomers therefore have solved this problem by indirect methods, first finding an orbit very near to the truth by mechanical and graphical operations, and then, by computation, correcting it, until such a parabola was found as would satisfy the observations. Mr. Vince therefore begins, by shewing the methods by which the orbit may be nearly determined; and then explains the manner in which it may be corrected by calculation.

M. de la Lande proposes the following mechanical method of finding the orbit nearly. Divide the distance of the earth from the sun into ten equal parts, and describe ten parabolas whose perihelion distances are, 1, 2, 3, &c. of these parts, and divide these parabolas into days from the perihelion, answering to the motion of a body in each. Let S (*fig. 31.*) be the sun, a, b, c , the places of the earth at the times of three observations of the comet. Then take three geocentric latitudes and longitudes of the comet, and set off the elongations $S a \alpha$, $S b \beta$, $S c \gamma$, in longitude. From a, b, c , extend three fine threads am, bn, ep , vertical to aa, bb, cc , making angles with them equal to the geocentric latitudes respectively. Then take any one of the parabolas, and placing its focus in S apply the edge to the threads, and observe whether you can make it touch them all, and whether the intervals of time cut off by the threads upon the parabola be equal to the respective intervals of the observations, or very nearly so; and if these circumstances take place, you have then gotten the true parabola, or very nearly the true one. But if the parabola do not agree, try others, till you find one which does agree, or very nearly so, and you will then have got very nearly the true parabola, whose inclination, place of the node, and perihelion, are to be determined as accurately as possible from mensuration; also the projection upon the ecliptic. If none of these parabolas should nearly answer, it shows, that the perihelion distance must be greater than the distance of the earth from the sun, in which case, other parabolas must be constructed; but this does not very often happen. This method will determine the elements very nearly; but it would be extremely troublesome to construct and divide so many parabolas, if we only wanted to compute the elements of one comet; for those who purpose to make many computations of this kind, it might be worth while to have a set of parabolas thus divided. To avoid this trouble therefore, Mr. Vince proposes to do it in the following manner, by means of one parabola, without dividing it.

Take a firm board perfectly plane, and fix on paper for the projection; let a groove be cut near the edge, and five perpendiculars be moveable in it, so that they may be fixed at any distances. Let S (*fig. 32.*) represent the sun, and

describe any number of circles about it. Compute five geocentric latitudes and longitudes of the comet, from which you will have the five elongations of the comet at the times of the respective observations. Draw $S A, S B, S C, S D, S E$, making the angles $A S B, B S C, C S D, D S E$, equal to the sun's motion in the intervals of the observations; and on any one of the circles, make the angles $S a \alpha, S b \beta, S c \gamma, S d \delta, S e \epsilon$, equal to the respective elongations in longitude, and fix the five perpendiculars, so that the edge of each may coincide with $a, b, \gamma, \delta, \epsilon$. From the points a, b, c, d, e , extend threads to the respective perpendiculars, making angles with the plane equal to the geocentric latitudes of the comet; then fix the focus of the parabola in S , and apply its edge to the threads, and if it can be made to touch them all, it will be the parabola required, corresponding to the mean distance $S a$ of the earth, which we here suppose to revolve in a circle, as it will be sufficiently accurate for our purpose. If the parabola cannot be made to touch all the threads, change the points a, b, c, d, e , to such of the other circles as you may judge, from your present trial, will be most likely to succeed, and try again; and by a few repetitions you will get such a distance for the earth, that the parabola shall touch all the threads, in which position, find the inclination, observe the place of the node, and measure the perihelion distance, compared with the earth's distance, and you will get very nearly the elements of the orbit.

The next method of approximating to the orbit of a comet, which we shall explain, is that given by Bolcovich. Let S (*fig. 33.*) be the sun, $X Z$ the orbit of the earth, supposed to be a circle; T the place of the earth at the first observation, and t at the third; draw $T C, t c$ to represent the observed longitudes of the comet; and let L, l, λ be the longitudes at the first, second, and third observations; m and n the geocentric latitudes of the comet at the first and third observations; and t, T , the intervals of time between the first and second, second and third observations. Assume C for the place of the comet, at the first observation, reduced to the ecliptic; then to determine the point at the third observation, say $T \times \sin. \lambda - T : t \times \sin. T - T :: T C : t c$, and c will be nearly the place required; (See B *scov.* "Opuscula," vol. iii. or Sir H. Englefield's valuable work upon comets, p. 27.) join $C c$, and it will represent the path of the comet on the ecliptic, upon this assumption. Perpendicular to the ecliptic draw $C K, c k$, taking $C K : T C :: \tan. m$; radius, and $c k : t c :: \tan. n$; radius; join $K k$, and it will represent the orbit of the comet, if the first assumption be true. Bisect $C c$ in x , and draw $x y$ parallel to $C K$, and y will bisect $K k$; join $y S$. Let $S X = r$; then if v be the mean velocity of the earth in its orbit, the velocity of the comet

at $y = \frac{\sqrt{2} \times v}{\sqrt{S y}}$; taking therefore $v = T t$, compute

$\frac{\sqrt{2} \times v}{\sqrt{S y}}$, and if this be equal to $K k$, measured by the

scale, the assumed point C was the true point. But if these quantities be not equal, assume a new point for C , in doing which, the error of the first assumption will direct you which way, from the first assumed point, it must be taken, and about how far from it; if, for instance, the computed value of $K k$ be greater than the true value, and the lines $C K, c k$, are diverging from each other, and receding from the sun, the point C must be taken further from T , and how much further we must conjecture from the value of the error, and also from hence, that the velocity of the comet diminishes as it recedes from the sun. These considerations

derations will lead us to make a second assumption near to the truth. Having thus determined the true points C, c, very nearly, produce cC, cK to meet at N, join NS, and it will be the line of the nodes. Draw Cr, cz perpendicular to SN, and the angles KCr, Kzc will measure the inclination of the orbit. From the two distances SC, Sz, and the angle between, the parabola may be constructed, and applied as in the last method, from which the time of passing the perihelion may be found.

Another method by which we may readily get the orbit very nearly, is this. Let S (fig. 34.) be the sun, T, t, τ three places of the earth at the times of the three observations; extend three threads Tβ, tβ, τβ, in the directions of the comet, as before directed. Assume a point y for the place of the comet at the second observation, and measure Sy; then if ST = 1, and the velocity of the earth

be v, the velocity of the comet at y will be $\frac{\sqrt{2} \times v}{\sqrt{S y}}$; let

v be represented by Tt, tτ; and upon any straight edge PQ, set off ce = $\frac{\sqrt{2} \times T t}{\sqrt{S y}}$, and ed = $\frac{\sqrt{2} \times t \tau}{\sqrt{S y}}$; then

apply the point e to y, and, by turning about the edge, try whether you can make the point c fall in Tβ, and the point d in τβ; if you find this can not be done, the error will direct you to assume another distance; and by a very few trials you will find the point y where the points c and d will fall in Tβ, τβ. This method is very easy in practice, and sufficiently accurate to obtain a distance Sy, from which you may begin to compute, in order to find the orbit more correctly, when the comet is not too near to the sun, as, says Mr. Vince, I have found by experience.

Having determined the parabola nearly, we first assume some one quantity as known at the first and second observations, and thence compute the place of the comet at those times, and also the time between; and if that time agree with the observed interval, you have got a parabola which agrees with the two first observations; if the times do not agree, alter one of the assumed quantities, and see how it then agrees; and then, by the rule of false, you may correct the supposition which was altered, and get a parabola which will agree with the two first observations. In like manner, by altering the other assumed quantity, you get another parabola agreeing with the two first observations. Then see how they agree with the third observation, and if they do not, a correction must be made by proportion, and the three observations will be answered.

For further particulars we must refer to Vince's Astronomy, vol. i. p. 428, &c. See also "An account of the discoveries concerning comets, with the way to find their orbits, and some improvements in constructing and calculating their places, to which are added new tables, fitted for these purposes," by Thomas Barker, Gent. Lond. 1757.

As the comets do not move in parabolas, but in very eccentric ellipses, it is impossible to find a parabola agreeing accurately to all the data; it will be sufficient, therefore, when it agrees very nearly. When great accuracy is required, we must take into consideration the effect of aberration and parallax; the former may be computed in the manner stated under the article ABERRATION, and the latter by taking the horizontal parallax to that of the sun = 8".75 as the distance of the sun is to the distance of the comet; and then finding the parallax in latitude and longitude.

To ascertain the periodical time of a Comet, and the axes of its Orbit.

If comets, after having receded from the lower regions

of the solar system to vast distances beyond the orbits of the most distant planets return again to the neighbourhood of the sun, the paths they describe must be nearly elliptical; and then, if observations have been made sufficiently exact to be a basis of the operations, the requisites of the problem may be determined in the following manner: Let A K B I (fig. 35.) be the trajectory of a comet, A B its major axis, I K the minor, S, F, the two foci, the former of which being the place of the sun, C the place of the comet, C S its distance from the sun, C c the space it passes over in a very small portion of time, D C E a tangent to the curve in the point C, S D, F E, perpendiculars demitted thereon from the foci: draw S G parallel to the tangent, and join F C. Also, let A L B be a circle, described on the major axis A B; A P T B a rectangle about the ellipse A I B, and A Q R B a square about the circle A L B. Lastly, let A N O be the elliptic orbit of any planet, S, f, its foci; put S C = a, S D = b, C c = z, the time in which it is described by the major axis of the cometary orbit A B = x, of the planetary orbit A O = q, the circumference of the circle A V O described on the same axis = p, the periodical time of the comet = t, and that of the planet = v.

The space C c described, the distance S C, and the angle S C D, being all determinable by observation, are given quantities. The mean distance of the comet is A H = S K = $\frac{1}{2} x$, and of the planet is A g = S N = $\frac{1}{2} q$; and, because the squares of the periodical times are as the cubes of the mean distances, we have $\frac{1}{2} q^3 = \frac{1}{2} x^3 :: n^2 = t^2$; therefore $t^2 = \frac{1}{2} \frac{x^3 n^2}{q^3}$, and $t = \frac{n x}{q} \sqrt{\frac{x}{q}}$.

But it is necessary to find another expression for the periodical time t, which may be done thus: because C c is a very minute portion of the orbit, it may be esteemed a right line, and the sector C S c as a rectilineal triangle, whose area $\frac{1}{2} S D \times C c = \frac{1}{2} b c$ is given: then, as the area $\frac{1}{2} b c$, is to the whole area of the ellipse A K B I = A; so $\frac{1}{2} b c$ is to the whole periodical time t; wherefore $t = \frac{f}{\frac{1}{2} b c} \times A$.

Now, in order to determine the area A, we must find the semiconjugate H K; and here, because A B = S C + F C, we have F C = x - a; and by the similar triangles S D C, F E C, we have S C : S D :: F C : F E, that is, a : b :: x - a : $\frac{b x - a b}{a}$ = F E; consequently F G = F E -

G E = $\frac{b x - 2 a b}{a}$. Again, S C : C D :: F C : C E;

or a : $\sqrt{a^2 - b^2} :: x - a : \frac{x - a}{a} \sqrt{a^2 - b^2}$: hence D E or

S G = C E + C D = $\frac{x - a}{a} \sqrt{a^2 - b^2} + \sqrt{a^2 - b^2} = \frac{x}{a} \sqrt{a^2 - b^2}$. But F G = $\frac{b x - 2 a b}{a}$; therefore F S =

$\sqrt{F G^2 + S G^2} = \sqrt{\frac{b^2 x^2 - 4 a b^2 x + 4 a^2 b^2 + a^2 x^2 - 4 a^2 x \sqrt{a^2 - b^2} + 4 a^2 (a^2 - b^2)}{a^2}}$; and, of course, S H =

$\frac{1}{2} F S = \sqrt{\frac{a^2 x^2 - 4 a b^2 x + 4 a^2 b^2}{4 a^2}}$.

Moreover, since S K = A H = $\frac{1}{2} x$, H K = $\frac{1}{2} \sqrt{4 x^2 - a^2 x^2 - 4 a b^2 x + 4 a^2 b^2}$

$\sqrt{S K^2 - S H^2} = \sqrt{\frac{4 x^2 - a^2 x^2 - 4 a b^2 x + 4 a^2 b^2}{4 a^2}}$
 = $\frac{b}{a} \sqrt{a x - a^2}$; therefore I K = 2 H K = $\frac{2 b}{a}$

$\sqrt{ax - a^2}$, and $\frac{x}{a} \sqrt{ax - a^2}$ = area of the rectangle
 APTB. Let P be the periphery of the circle AIB, whose diameter is x , then its area will be $\frac{1}{2} L.H \times P = \frac{1}{2} x P$, and we shall have $x^2 : \frac{1}{2} x P : \frac{1}{2} x P : \frac{1}{2} x P :: AQRB : AIB :: APTB : AIB :: \frac{1}{2} q p : \frac{1}{2} q p$; that is $q p : \frac{1}{2} q p :: \frac{x}{a} \sqrt{ax - a^2} : \frac{b p}{4 a q} \sqrt{ax - a^2} = AIB$. But

$2 AIB = AIKB = A = \frac{b p x}{2 a q} \sqrt{ax - a^2}$; therefore, substituting this value of A , in the preceding expression, we have $t = \frac{f p x}{a e q} \sqrt{ax - a^2}$. Equate this value

of t , with that already given, then $\frac{n x}{q} \sqrt{\frac{x}{q}}$
 $= \frac{f p x}{a e q} \sqrt{ax - a^2}$; which equation reduced, gives $x = \frac{a^2 e^2 p^3 q}{f^2 p^2 q - a^2 n^2} = A B$, the major axis of the comet's elliptical trajectory.

If we substitute this value of x , in the above equation, for t , we shall have $t = \frac{p^3 f^2 n^2 a^{\frac{3}{2}}}{q^{\frac{3}{2}} p^2 - a^2 e^2 n^2} \cdot \frac{1}{2}$ = the periodical time. Also, because the conjugate $IK = \frac{2 b}{a} \sqrt{ax - a^2} = c$, we have $x = \frac{c^2 a^2 + 4 b^2 a^2}{4 b^2 a} = \frac{a f^2 p^2 q}{f^2 p^2 q - a^2 e^2 n^2}$, whence

by reduction, we find $c = 2 b e n \sqrt{\frac{a}{f^2 p^2 q - a^2 e^2 n^2}}$, the minor axis of the orbit.

From these equations, it obviously appears, that when the velocity of the comet is such that $f^2 p^2 q = a^2 e^2 n^2$, the axis x will be infinite, and consequently the trajectory will be a parabola; if $a^2 e^2 n^2$ be greater than $f^2 p^2 q$, the direction of the axis will be on the other side of the curve, which will be an hyperbola; in either of which cases, the comet can never return: but in every instance where $f^2 p^2 q$ is greater than $a^2 e^2 n^2$, the comet will describe an ellipsis; among these we may comprise the circle, where $x = 2 a = \frac{a f^2 p^2 q}{f^2 p^2 q - a^2 e^2 n^2}$ and $f^2 p^2 q = 2 a^2 e^2 n^2$, whence $e = C c = \frac{f p}{a} \sqrt{\frac{q}{2 a}}$, the

arc of the circle described in one day, or one hour, according as the value of n is given in days, or hours.

Let the earth be the planet which we supposed to describe the ellipsis ANO; then its mean distance $\frac{1}{2} q = 100000$, or $q = 200000$, and $p = 628318$; also the periodical time $n =$ one year: then if Cc be the portion of the comet's orbit described in one day, we have $f = \frac{t}{365.2505} = 0.0027378$. The other expressions will become as follow: for the principal axis, $x = \frac{5918 \cdot 6599235 \times a}{5918 \cdot 6599235 - a^2 e^2}$, and for the periodical time $t = \frac{4750560000 \times a^{\frac{3}{2}}}{591820599235 - a^2 e^2 \cdot \frac{3}{2}}$.

It is extremely difficult to determine, from computation, the elliptic orbit of a comet, to any degree of accuracy; for when the orbit is very eccentric, a very small error in the observation will change the computed orbit into a parabola, or hyperbola. Now, from the thinness and in-quality of the atmosphere with which the comet is surrounded, it is impossible to determine, with any great precision, when either

the limb or centre of the comet pass the wire at the time of observation. And this uncertainty in the observations will subject the computed orbit to a great error. Hence it happened, that M. Bouguer determined the orbit of the comet in 1729 to be an hyperbola. M. Euler first determined the time for the comet in 1744; but having received more accurate observations, he found it to be an ellipse. The period of the comet in 1680 appears, from observation, to be 57.5 years, which M. Euler, by his computation, determined to be 166 $\frac{1}{2}$ years. The only fair way to get the period of comets, is to compare the elements of all those which have been computed, and where you find they agree very well, you may conclude that they are elements of the same comet, it being so extremely improbable that the orbits of two different comets should have the same inclination, the same perihelion distance, and the places of the perihelion and node the same. Thus, knowing the periodic time, we get the major axis of the ellipse; and the perihelion distance being known, the minor axis will be known. When the elements of the orbits agree, the comets may be the same, although the periodic times should vary a little; as that may arise from the attraction of the bodies in our system, and which may also alter all the other elements a little. We have already observed, that the comet which appeared in 1759, had its periodic time increased considerably by the attraction of Jupiter and Saturn. This comet was seen in 1682, 1607, and 1531, all the elements agreeing, except a little variation of the periodic time. Dr. Halley suspected the comet in 1680, to have been the same which appeared in 1106, 531, and 44 years before Christ, when Julius Cæsar was murdered; and that its period was five hundred and seventy-five years. Mr. Dunthorne, however, in the Phil. Trans. vol. xliii., has endeavoured to shew from a MS. in Pembroke-hall library, that the comet in 1106 could not be the same with that of 1680. But M. de la Lande adopts the opinion of Dr. Halley. He also conjectured, in the first edition of his Synopsis, without repeating it in the second edition, that the comet observed by Apian in 1532, was the same as that observed by Hevelius in 1661; if so, it ought to have returned in 1789, or 1790, but it has never been observed. The interval between the passages of the comet by the perihelion in 1532 and 1661 is 128 years, 80 days, 1 hour, 29 minutes, (32 of the years being bissextile) which, added to the time of the perihelion in 1661, together with 11 days to reduce it from the Julian to the Gregorian stile, which we now use, brings out the time of the next perihelion, to be April 27th, 1st 20', in the year 1789. But M. Mechain having collected all the observations in 1532, and calculated the orbit again, found it to be sensibly different from that determined by Dr. Halley, which renders it very doubtful whether this was the comet which appeared in 1661; and this doubt is increased, by its not appearing in 1790. The comet in 1770, whose periodic time M. Lexell computed to be five years and seven months, has not been observed since. There can be no doubt but that the path of this comet, for the time it was observed, belonged to an orbit whose periodic time was that found by M. Lexell, as the computations for such an orbit agreed so very well with the observations. But the revolution was probably longer before 1770: for as the comet passed very near to Jupiter in 1767, its periodic time might be sensibly increased by the action of that planet; and as it has not been observed since, we may conjecture, with M. Lexell, that having passed in 1772 again into the sphere of sensible attraction of Jupiter, a new disturbing force might probably take place: as to destroy the effect of the other. According to the above elements, the comet would be in conjunction with Jupiter on

August 23, 1779, and its distance from Jupiter would be only $\frac{1}{337}$ of its distance from the sun, consequently the sun's action would be only $\frac{1}{337}$ times that of Jupiter. What a change must this make in the orbit! If the comet returned to its perihelion in March 1776, it would then not be visible. See M. Lexell's account in the Phil. Transf. 1779. The elements of the orbits of the comets in 1264 and 1556 were so nearly the same, that it is very probable it was the same comet; if so, it ought to appear again about the year 1848.

Mr. Cole, in his "Theory of Comets," advances an hypothesis, which, in some cases, may perhaps, be accurate. He supposes that the orbit of a comet is not an ellipse; but that, when it passes its perihelion, it has acquired so great a velocity, that its centripetal force is overcome by its centrifugal, and that consequently the comet continues to fly off in a parabola or hyperbola, till it come within the attraction of some fixed star; that this attraction may give it a new direction, and increase its velocity till it come to an apsis below that star, when it may again fly off either in a parabola or hyperbola, and proceed till it fall within the attraction of another star; and thus visit many different systems.

Dr. Halley has given us a table of the astronomical elements of twenty-four comets, on the supposition that they moved in parabolas; though he thought it extremely probable that they really moved in very eccentric ellipses, and consequently returned after long periods of time. This table commences with the year 1337, and closes with 1698. By means of this table, and others similar to it, it may be determined whenever a new comet shall appear, by comparing it therewith, whether it be one of those which have already appeared, and consequently its period and the axis of its orbit be ascertained, and its return foretold. See his Synopsis of the Astronomy of Comets, annexed to Gregory's Astronomy. This was first published in the Philosophical Transactions in 1705, and republished with his Astronomical Tables in 1749. M. de la Caille changed this table into another of a more convenient form, by putting the areas for the times.

Another table has since been computed, from the observations contained in the Philosophical Transactions, De la Caille's Astronomy, and De la Lande's Histoire de la Comete de 1759, and Connoissance des Mouvemens Celestes 1763 & 1764. In this table are seen the elements of twenty-five other comets, from the year 1264 to 1762. The most extensive table for calculating the motions of comets, was computed by M. de Lambert; it is inserted, as we have already mentioned, in Mr. Vince's Astronomy, vol. i. Another table on an extensive scale, computed by Mr. Lee, an ingenious friend of the editor, an excellent astronomer, and an attentive observer of the heavens, is annexed to this article.

The number of comets that are stated in the most accurate accounts to have appeared, since the commencement of our æra, is about 500; and before that æra, about 100

others are recorded to have been seen, though it is probable that not more than half of them were comets.

The elements of the comet of 1770, and the trajectory of its path, may be found in the Transactions of the American Philosophical Society, vol. i.

In Whiston's Solar System, the orbits of several comets are delineated, and the periods of as many of them as were then known, expressed.

COMET, *To determine the place and course of a.* For this purpose, it will be advisable to take the apparent diameter very frequently; as a judgment may thus be formed of its relative distance at different times; its degree of motion, its brightness, &c. must also be regarded; for when it moves with the greatest velocity, or appears most bright, we may infer that it is near its perihelion. If the place of the comet can be observed when it has no latitude, the place and time of its being in one of its nodes will then be exactly known; but as this can seldom be actually observed, these elements are generally obtained by approximation from other observations. In order to obtain the proper course of a comet, observe its distance from two fixed stars, whose longitudes and latitudes are known; or, find its altitude when in the same azimuth with any two known fixed stars; from the distance or altitude thus found, calculate the place of the comet by trigonometry, after the manner delivered under PLANET, or in the preceding article. By repeating the observations and operations for several days successively, the course of the comet will be had.

COMET, *to determine the course of a, mechanically, and without any apparatus of instruments.* The following ingenious method, by a thread, we owe to Longomontanus: Observe four stars round the comet, such, as that the comet may be in the intersection of the right lines that join the two opposite stars; which is easily found by means of a thread placed before the eye, and extended over-against the stars and comet.

Suppose, v.g. the comet's place in the heavens A (*Pl. IV. Astronomy, fig. 36.*) between the four stars, B, C, D, E; where the line joining the stars B and D, passes through the body of the comet; and the like does the line passing through C and E.

On a globe, whereon these four stars are found, extend a thread through B and D, and another through C and E; the point of intersection will give the place of the comet. This practice being repeated for several days, the comet's course will be had on the globe; which course will be found to be a great circle: if this great circle, drawn through three distant places, and shewing its path among the stars, be continued till it intersect the ecliptic, it will shew nearly the place of the node, and the inclination of the orbit to the ecliptic. The plane of the node and inclination of the orbit being thus found from several triplets of places independent of each other, a medium of the results may be considered as tolerably accurate.

COMET, *to determine the parallax of a.* See PARALLAX.

COMET, *trajectory of a.* See TRAJECTORY.

COMETARIUM.

On the subject of *Comets*, see Newton's *Principia*, lib. iii. Halley's *Synopsis of Comets*; Sejmou Elfaï for les Cometes, 1775; M. Pingre's *Cometographie*, 2 vols. 4to. 1781, Sir H. Englefield's work "On the determination of the Orbits of Comets," M. Bode's *General Considerations on the situations of the Orbits of all the Planets and Comets* which have hitherto been calculated, inserted in the *Memoirs of the Academy of Sciences of Berlin*; Dr. Gregory's *Astronomy*; O. Gregory's *Treatise on Astronomy*, 1803; De la Lande, *Théorie des Cometes*, 1759; and *Astronomie*, vol. iii.; An Account of the Discoveries concerning Comets, with the way to find their Orbits, &c. by Thomas Barker, 1757; Vince's *Astronomy*, &c. &c.

COMETARIUM, or COMETARIAN, in *Mechanics*, is the name of a machine, contrived by Dr. Desaguliers, for the purpose of exhibiting and explaining the eccentric motion of a comet, agreeably to that law, of planetary motion, by which equal areas are described by the radius vector in equal times. Ben. Martin has given an account of this machine, in his "Young Gentleman and Lady's Philology," and Mr. Ferguson has described it still more particularly in his "Astronomy," but as those authors have not given a perspective view of the parts of action, we have thought it necessary to give a new drawing, such as we conceive will render the mechanism clearly intelligible to every reader. In *Plate I. of Planetary Machines*, *fig. 1.* represents the cover of the cometarium, taken from the box which contains the wheel-work, and *fig. 2.* shews the box and its contents, with the exception of the cover, and one side, the latter of which is supposed to be removed, in order to disclose more fully the disposition of all the contained parts. A B in *fig. 2.* is the bottom of the box, which supports the lower pivots of the three vertical arbors; C D is a longitudinal bar inserted into the ends of the box, and bearing the upper pivots of the said arbors, as may be clearly seen in the figure; E is the handle put on the end of the horizontal arbor E F, which arbor is pivoted into the front and back sides of the box; on this horizontal arbor, under the letter C, is an endless screw actuating the wheel G, with teeth not rounded but cut a little obliquely; the number of which teeth may be assumed at option, to correspond to an aliquot part of a circle, suppose $\frac{7}{2}$, in which case one tooth, or revolution of the handle, will correspond to 5° ; at the inferior end of the arbor of wheel G, is fixed another wheel H, of the same number of teeth, that actuates a similar wheel I, on the second vertical arbor; so that these two wheels, H and I, also revolve each in $\frac{1}{2}$ d part of a circle, or 5° , at each revolution of the handle. Mr. Ferguson has placed the endless screw as in *fig. 2.* of *Plate II.*, between the wheels H and I in such a way, as to impel them both in contrary directions at the same time, which construction is still more simple, as it dispenses altogether with the wheel G, and requires no rounding of the teeth; to the arbor of wheel I a solid plate K, in the form of an ellipse, is fixed fast at a point out of the centre, and has a groove round its edge to admit a cord to pass round it; and a second elliptic plate L, every way similar to plate K, is attached, at a point equally distant from the centre, to the third vertical arbor, but in such a way, that, when an endless cord is made to embrace the grooves of both, after crossing between them, the long radius of one is always directed towards the short radius of the other reciprocally, so that as the radius of plate K continues to lengthen in revolving half round, the radius of L continues to shorten, and *vice versa* during the other half of the revolution; this alteration of gradual lengthening and shortening of the radii, of the equally moving elliptic plate K, produces an

alternate acceleration and retardation of motion in the plate L, such as corresponds with the equated motion of a heavenly body, describing equal areas in equal times; and the quantity of eccentricity given to the elliptic plates determines the quantum of the greatest equation in the orbit to be represented. Above the cross-bar CD is fixed an elliptic plate M, by two ferrets, seen in both the figures, round which the comet O is confined to move in its motion round N, the sun, which is a ball attached to the superior end of the arbor of the plate L of unequal motion; to the ball N, the arm or radius vector N O is attached, which therefore also moves with alternate accelerations and retardations of motion along with plate L; and as the comet O has liberty to slide along the radius vector, while a fluid under it penetrates the black elliptic groove, made in the cover round the plate M, the variation of distances is thereby effected as the comet is carried round: the point of the greatest distance, where the motion is slowest, is called the *aphelion*, from *απο*, *from*, and *ήλιος*, the *sun*, and the point of nearest distance, where the motion is quickest, is called the *perihelion*, from *περι*, *round*, and *ήλιος*, the *sun*. The two circles of signs, and also the graduated ellipse, are marked on the cover of the machine, and the arm G, in *fig. 1.* is placed on the equally moving arbor of wheel G, in *fig. 2.* so that when the arm G moves through the signs in the small circle, by equal arcs in equal times, the arm N O moveable round the point N, passes through corresponding unequal arcs in the larger circle of signs, while the difference between the places of the two said arms shews the quantity of prosthaphæresis, or equation in any situation in the large graduated circle, which is assumed to be parallel to the comet's orbit. In order that the nature of the comet's motion may be the more apparent to the eye of a spectator, when referred to its own orbit, the small ellipse, beyond the darkened aperture that regulates the distances, is also divided into signs, but in such a way, that the angles subtended by each sign, when referred to the point N, or centre of motion, are unequal among themselves throughout each six successive signs, and if lines were drawn from each point where the comet is found at the end of each day or week, to the point N, they would include equal areas, or plane surfaces taken geometrically; in some of the machines indeed, those lines are actually drawn, and the separate triangular areas corresponding to each equidistant period are painted alternately black and white, to render the doctrine of the celebrated Kepler still more evident to the senses. The principal objections to the construction of the machine before us is, that the comet O is apt to move by jerks in certain parts of the orbit, particularly when the eccentricity is great; and also the cord is liable to slide in some situations, without producing the corresponding motion in the elliptic plates K and L; the latter of which objections has been attempted to be obviated, by attaching forked pieces of metal to the plane of one of the elliptic plates near its end, and pins to the other, as in *fig. 2. Plate II.* to form a kind of teeth; but a better plan, and which has been adopted sometimes in practice, where the eccentricity is not very great, is to cut the elliptic plates themselves into toothed wheels, and to substitute them for the wheels H and I, in which case the cord may be dispensed with altogether, and the arm N O, we presume, will thus be less liable to jerks.—After all, however, this machine does not profess to represent the period of a revolution of any of the comets or planetary bodies, but is intended merely to explain the law of their motion, which it will do in a very satisfactory manner, when well made; and it is easy to see, that, as the plate M may be fixed more or less out of the centre, such a change of distances

distances may be produced, as shall correspond to the changes of angular velocity; which is the chief difficulty to be overcome in the mechanical representation of the orbit.

New Cometarium by Mr. Jones.

Subsequently to our writing the preceding account of the cometarium, Mr. W. Jones, optician in Holborn, has favoured us with a drawing and description of a new construction of the cometarium, which he says is free from the jerks that we have stated as an objection to the plan of Dr. Desaguliers, and which, therefore, we lay before the public as nearly in the author's own words as our arrangement and observations on it will admit.

Fig. 1. of *Plate II.* of *Planetary Machines* is a representation of the external part of the machine, which is not confined to any particular dimensions, but has generally been made as follows; *viz.* A B C D is a mahogany box, about 12 inches long, 9 wide, and $4\frac{1}{2}$ deep, containing the wheelwork that gives motion to the comet *x*; the dark elliptical space is a groove representing the orbit of the comet, which is carried round in the direction of the alphabetical order of the letters. The point *a* is the perihelion, and the point *g* the aphelion; and the triangular spaces or areas, *a S b*, *b S c*, &c. are all respectively equal to each other: in one turn of the handle N, the comet *x* is moved over one of these areas; consequently, in the same time that it moves from *f* to *g*, or from *g* to *b*, it moves from *m* to *a*, or from *a* to *b*, and in like manner through each succeeding area, the quicker motion being at *a*, and the slowest at *g*; thus showing that the velocity of a comet in its orbit continually and gradually decreases from the perihelion *a* to the aphelion *g*, and increases in the same proportion from the aphelion to the perihelion. The elliptical orbit is divided into twelve signs with their respective degrees, and in a similar manner is the circle *n o p s t*, which represents a great circle in the heavens, and to which the motion of the comet is referred by the extremity of the wire W, moveable at S, and actuated by the stem of the comet, which slides against it, in and out alternately, in its progress in the orbit. During the comet's motion in its orbit from *f* to *g*, its apparent motion is only about five degrees in this circle, as pointed out by the end of the wire; but in the same time as the comet moves from *m* to *a*, or from *a* to *b*, it appears to describe the large angular space *1 m*, or *n o* in the heavens, each of which arcs contains about 120° , or four signs; and if the eccentricity of the orbit were still greater, the greater would be the difference between the two extreme velocities. The figures 1, 2, 3, 4, &c. to 12, represent a small comparative circular orbit, for shewing the equable motion of a body, supposed to move concentrically round the sun S, and to describe equal arcs, as well as equal areas, 1 S 2, 2 S 3, &c. in equal times with those of the comet *x* in its elliptical orbit before mentioned. Suppose now the bodies *x* and *o* to commence their motions at the same instant from the points *a* and *1*, and to arrive at the same respective points again, after a revolution of each, at the same instant, it will be observed, during their progress, that the body *x* will be more forward than the body *o* in the first six signs from *a* to *g*, but more backward in the next signs from *g* to *a*, and the difference between the places of the two bodies, in any part of the small or equable orbit, will be the *equation of the centre* in that particular part. At the points *a*, 1, and *g*, 7, the bodies are together, and consequently the equation vanishes, and from thence begins to take an opposite character, changing from plus to minus, and *vice versa* at the respective points; also, the distance from the aphelion point, in the small orbit, is called the *mean anomaly*, reckoned in

signs and degrees; and the distance from *a*, in the large circle, reckoned in a similar manner, is called the *true or equated anomaly*. Thus the reason appears evident, why, in astronomical calculations taken from the tables of Dr. Halley, or la Lande, the grand equation of a body moving in an elliptic orbit is *additive* in the first six signs, and *subtractive* in the second six, with respect to the place ascertained by an assumption of mean motion; and the same application of the grand equation, after some modification of its varying quantity, is used from the apogee to the perigee, and back again from the perigee to the apogee of the lunar orbit.

The mechanism, by means of which these motions are produced in the original cometarium, has been already explained above, from which that of Mr. Jones is very different, and is thus explained by him.

From the circumstance of its being considered as impracticable to obtain an easy and uniformly steady motion of a comet, by Dr. Desaguliers's mechanism, Mr. Jones has adopted the plan of using only one great wheel revolving on an arbor placed out of the centre, agreeably to the drawing exhibited in *fig. 3.* of *Plate II.* near the point H, and under the cock attached to the plane of the wheel, by three visible screws. The different parts and action of the mechanism are these; A B represents the inside bottom of the box, seen in *fig. 1.* of the same plate; C D is an oblong piece of mahogany, fitted so as to slide easily but steadily in the grooves of two parallel side-pieces of the same wood, made fast to the bottom, and denoted by the letters E and F; G is the large brass wheel, about five inches diameter, which we have said revolves on an eccentric arbor, near the point H; over this point is placed the cock, or bent arm, H I, with an oblong slit through it, to receive the sliding piece *a*, which piece supports the low end of the stem that carries the comet X in *fig. 1.* K and L are two wheels pivoted above into a bridge P, shaped like a cross, and have equal numbers of teeth, the latter of which wheels is actuated by the contrary wheel M, inserted on the axis B, of the handle N; on the same arbor with K, and close under the bridge P, is a small wheel (seen in the figure) that impels the large wheel G, round its eccentric arbor; it will not perhaps appear evident to an ordinary mechanic, how the action of the small and large eccentric wheel is rendered continual, and the pitching of the teeth made good all round the great wheel, notwithstanding the constant variation of the distances from the eccentric point, which is the centre of its motion, and the successive points of its circumference; to effect this apparently difficult purpose, considerable ingenuity was necessary; by examining the crosses and rim of the large wheel, it will be seen, that the thickness of the crosses, and of the teeth, is less than of the rim, so that the rim may be said to have a circular edge-bar on its plane projecting upwards; this edge-bar is embraced by two rollers, the larger one moving round on the arbor of wheel K, above the small wheel, and the smaller one carried by a cock O, fast to the crossed bridge P; so that, as the great wheel is urged round by the small one, these two rollers give motion to the sliding piece of wood C D, alternately in and out, and consequently bring the teeth of the wheel borne by this sliding piece, into a proper depth to act with its small impelling wheel, in every part of the revolution of the former, which therefore acts as well, when the teeth are directed towards the centre of motion, as if the arbor had been in the centre of the wheel, and placed on a stationary bar. The wheel, however, has many more teeth coming successively into action during one half of its revolution, round the eccentric point of its motion, than it has during the other; and on this circumstance depends the variable velocity of the comet attached

to its arm I, as it regards the said centre of motion. We shall have occasion to shew, in another place, that the equation, produced by this cause only, would be just one half of the proper equation of the centre, or very nearly so, provided the sun were placed exactly over the centre of motion, or eccentric point of the wheel: it is also not difficult to shew, that if the wheel had no eccentric motion, but had the sun placed at a similar distance out of its centre of motion, one half of the due equation would also, in that case, be effected, supposing the circle of figures, pointed to by the wire, to be eccentric with regard to the wheel, and supposing the sun to be in its centre; now, in the instrument before us, these two causes operate together to produce the total equation due to the orbit, where the eccentricity of the wheel is to its radius, and also the eccentricity of the sun's position, at the opposite side of the wheel's centre, to the same, as the eccentricity of the comet is to the radius of its orbit. It must, however, be acknowledged, that the joint agency of the two said causes of the equation, supposes the sliding bar CD to be stationary, in which case the action of the wheels would soon be impeded; consequently, that part of the equation which depends on the sun's eccentric position, as it regards the wheel's arbor, is variable, and in some measure must derange the scale of equations, as it would have been, if the wheel's arbor had been stationary; the remedy for this small deviation from perfect accuracy in the scale of equations thus produced by the joint agency of three causes, is best effected by making the straight lines, that form the triangular areas, to correspond, not to a geometrical measurement, but to the actual turns of the handle, one of which will correspond to each triangular area, when the contrate wheel M, and also the small wheel over K, have each one twelfth part of the number of teeth that the great wheel has, which wheel, in that case, may have any optional number that is divisible by twelve. When the centre of the large wheel lies exactly in a line joining the centre of motion H, and the arbor of K, the sliding board CD is the most pushed out, and the comet is at the aphelion *g*, *fig. 1.* moving slowly; but when the centre of the wheel's motion lies between the central point of it and of wheel K, then the comet is at the perihelion *a*, moving quickly. The cock *y*, in *fig. 1.*, holds the elliptic plate, with the triangular areas marked on it, and bearing on it the sun, in such a situation, that the groove round its edge, in which the stem of the comet moves, limits the distance at all times of this body, as it respects the sun, which is done by making the sliding piece in *fig. 3.* move in or out in the slit of the arm I, already described. Thus the jerks of the old cometarium are avoided, and all its apparent properties are preserved, except that a portion of the large graduated celestial circle is unavoidably concealed by the superior elliptic plate of triangular areas.

COMETES, in *Botany*, (*comætes*, *crinitus*, so called on account of the remarkably hispid involucre,) Linn. Mant. 39. Schreb. 211. Willd. 211. Lam. II. 203. Juff. 437. Class and order, *tetrandria monogynia*. Nat. Ord. *Tricoccoe*.

Gen. Ch. *Calyx* common. Involucre four-leaved, inclosing three fessile flowers, oblong, equal, ciliate-hispid. *Calyx* proper. Perianth four-leaved; leaflets oblong, equal the length of the involucre. *Cor.* none. *Stam.* Filaments four, capillary, the length of the involucre; anthers roundish. *Pist.* Germ superior, roundish; style filiform; stigma triû. *Peric.* Capsule tricoccos. *Seeds* solitary.

Eff. Ch. Involucre four-leaved, three-flowered. *Calyx* proper, four-leaved. *Corolla* none. *Capsule* tricoccos.

Sp. C. *alternifolia*. Linn. Syst. Nat. Mart. Willd. Burm. Ind. 39. tab. 15. fig. 5. (*Clinopodium parvum finicum*; Puk. Alm. 61. tab. 380. fig. 4.) *Root* annual. *Stem* a foot high, herbaceous. *Leaves* opposite, narrowing into a petiole; inversely egg-shaped, acuminate, quite entire. *Peduncles* in pairs, terminal and axillary. A native of Surat.

COMETITES, in *Natural History*, a name given by some writers to a kind of afroites, which has flars much larger than those of the common kind, and therefore called *comets*.

COMEUS, in *Mythology*, a surname of Apollo, under which title he was worshipped at Seleucia, whence his statue was carried to Rome, and placed in the temple of Apollo Palatine.

COMFETS, **STONY**, in *Natural History*, drop-stones or confets. These are stalactites, broken into short pieces, somewhat resembling comets, and certain kinds of sugar-plums, and which in Italy and other places are sometimes put up in boxes and labelled, so as to deceive strangers at first sight, in supposing them to be real comets.

COMFLOENTA, in *Ancient Geography*, a town of Spain, in the Tarragonensian territory, placed by Ptolemy in the country of the *Arevaci*.

COMFORT POINT, in *Geography*, is the fourth easternmost part of Elizabeth-city county, in Virginia, formed by James river, at its mouth in Chesapeake bay; 19 miles W. by N. of Cape Henry.

COMFREY, or **COMPHRY**, in *Botany*. See *SYM- PHYTUM*.

COMHOLA, in *Geography*, a river of Ireland, which runs into Bantry bay; 3 miles N. of Bantry.

COMI, in *Ancient Geography*, a people of Asia, in Bactriana, said by Ptolemy to have dwelled in the vicinity of the *Chomari*.

COMILDAVA, a town of Dacia, according to Ptolemy.

COMILLAH, in *Geography*, a town of Hindoostan, in the province of Bengal; 160 miles E. N. E. of Calcutta, and 176 E. S. E. of Moorshedabad. N. lat. 23° 25'. E. long. 91° 15'.

COMIN and **COMINOT**, two small islands in the Mediterranean, lying between Malta and Gofa or Gozo; the former supposed to be the Hephestia, or isle of Vulcan of the ancients. They were formerly uninhabited; but by the care of Vingnacourt, a fort having been built upon each of them for their safety, they have been since partly inhabited, and that of Comin, which is about 4 or 5 miles in circuit, breeds a large quantity of cattle. See *MALTA*.

COMINES, a town of Flanders, situated on the *Lis*, which divides it into two parts; formerly a considerable place, but reduced by war and various accidents; 25 miles S. of Bruzes, and 7 N. of Lille.

COMINGE, in *Military Language*, a shell of uncommon magnitude, which takes its name from the person who invented it.

COMING-TO, in *Sea Language*, denotes the approach of a ship's head to the direction of the wind.

COMINIUM, in *Ancient Geography*, a town of Italy in Samnium, which did not subsist in the time of Pliny.

COMIOLA, in *Botany*, a name given by some of the old Roman authors, to the plant commonly called *LUTEOLA*, or dyers' weed.

COMITATU commissio, in *Law*, a writ or commission, by which a sheriff is authorized to take upon him the charge of the county.

COMITATU et castra commissio, a writ by which the charge of a county, together with the keeping of a castle, is committed to the sheriff.

COMITATUS, in *Law*, a county. Ingulphus tells us, that England was first divided into counties by king Alfred; and the counties into hundreds, and these again into tythings; and Fortescue writes, that *regnum Anglie per comitatus, ut regnum Francie per balivatus, distinguitur*. Sometimes it is taken for a territory or jurisdiction of a particular place; as in Mat. Paris, anno 1234. See COUNTY.

COMITATUS *posse*. See POSSE.

COMITIA, an assembly of the Roman people, either in the Comitium, or Campus Martius, i. e. *Field of Mars*; meeting for the election of magistrates, or for consulting on the important affairs of the republic.

The word comes from the verb *coco*, or *comco*, to go together.

There were certain days fixed for these assemblies, called *dies comitiales*; marked with a C in the calendar of Julius Cæsar. Comitial assemblies, held for the election of consuls, were called *consular comitia*: in like manner, the other comitia took names from the officer to be created; whether a tribune, a pontiff, ædile, or the like.

There were three kinds of these comitia, viz. *curiata, centuriata, and tributa*; so distinguished from the manner wherein the people voted, and gave their suffrages, viz. by curiæ or parishes, tribes, or centuries.

The power of calling these assemblies pertained to all of the chief magistrates, and sometimes to the sovereign pontiff.

Authors make the difference between *comitia* and *concilia*, to consist in this; that in the former the whole people were called together, in the latter only a part.

COMITIA *curiata*. Romulus instituted the *comitia curiata*, or the public assemblies of the people, called to vote in their several curiæ: and it is agreed by all that the matters subjected to their decision, were the choice of all the magistrates, and the right of making laws, war, and peace: an ample jurisdiction, comprehending the most important articles of government, yet not wholly absolute, according to Dionysius, unless the senate concurred with them. This method of transacting all the greater affairs by the people, assembled in their curiæ, after it had subsisted through five successive reigns, was found to be inconvenient.

Servius Tullius, the sixth king of Rome, in order to correct the inconvenience of the *comitia curiata*, instituted a new division of the people into six classes, according to a census, or valuation of their estates; whence proceed the *comitia centuriata*: then he subdivided these classes into one hundred and ninety-three centuries, and contrived to throw a majority of these centuries, that is, ninety-eight of them, into the first class of the richest citizens. By which regulation, though every man voted now in his century, as before, in his curiæ; yet, as all matters were decided by a majority of the centuries, the balance of power was wholly transferred into the hands of the rich; and the poorer sort deprived of their former weight and influence in the affairs of state: which wise institution was ever after observed, through all succeeding ages, in the elections of the principal magistrates, and the determination of all the principal transactions of the republic.

COMITIAL *days*. Paulus Manutius is of opinion, that there were certain days on which the Roman senate might regularly be assembled; and others on which it could not: and that these last were called comitial days, and marked under that name in the calendars, as days wholly defined, and set apart by law, for the assemblies of the people. But Sigonius contends, that the senate might meet on any of those days, unless when the people were actually assembled, and transacting business on them; and consequently that

the title of comitial denoted such days only, on which the people might be legally assembled, not such on which they were of course to be assembled. Middlet. of Rom. Senat. p. 138, 139.

The truth of the matter seems to be this, that though the days called comitial were regularly destined to the assemblies of the people, yet the senate also might not only be convened on the same, after the popular assemblies were dissolved; but had the power likewise, whenever they found it expedient, to supersede and postpone the assemblies of the people to another day; and, by a particular decree, to authorize their own meetings upon them, for the dispatch of some important affair therein specified.

COMITIALIS *morbus*, in *Medicine*, an ancient term for the *epilepsy*, or falling sickness; so called, because if any person was seized with it in the Roman comitia, the assembly was immediately dissolved; this being esteemed an unlucky omen; or, rather, because those liable to it were chiefly seized in the comitia, or great assemblies. See EPILEPSY.

COMITIUM, the place where the comitia were ordinarily held, which was a large hall in the Roman Forum: it was a long time open at top; on which account the assemblies were often interrupted by bad weather: it was first covered over in the time of the second Punic war. See FORUM.

Rosinus observes, that the consuls and tribunes were not created in the *comitium*, but in the Campus Martius.

It was in this place that the rostra were placed. See COMITIA.

COMITLAN, in *Geography*, a town of North America, in Mexico, and province of Chiapa.

COMITOLO, PAUL, in *Biography*, one of the ablest of the society of Jesuits, acquired great reputation by his instructions in morality and theology at the commencement of the seventeenth century. He died in 1626, at the age of eighty years. His publications are "Catena illustrium authorum in Librum Job," translated from the Greek into the Latin language;—"Concilia seu responsa moralia;"—"Doctrina de contractu universo." Nouv. Dict. Hist.

COMMA, in *Grammar*, a point, or character, formed thus [,]; serving to mark a short stop, or pause; and to divide the members of a period.

The word is formed of *comisus*, *scio*, I cut.

It is very difficult to fix the precise use of the comma; different authors define and use it differently: the ordinary doctrine is, that the comma serves to distinguish nouns, verbs, adverbs, and the several parts of a period that are not necessarily joined together. But this conveys no clear, precise idea; for what is it to distinguish the parts of a period not necessarily joined together? F. Buffler has carried the doctrine of the comma farther: according to him, the comma serves to distinguish those members of a period, in each whereof is a verb, and the nominative case of the verb. Thus, "That so many people are pleased with trifles is owing to a weakness of mind, which makes them love things easy to be comprehended."

Besides this, the comma is used to distinguish, in the same member of a period, several nouns substantives, or nouns adjectives, or verbs, not united by a conjunction. Thus, "Virtue, wit, knowledge, are the chief advantages of a man:" or, "A man never becomes learned without studying constantly, methodically, with a just application, &c."

If those words be united in the same phrase by a conjunction, the comma is omitted: thus, "The imagination and the judgment do not always agree." The comma may also be omitted between the phrases that are very short, especially

if they depend upon the same regimen, and are united by a conjunction: thus, "Alexander conquered Asia and established the monarchy of the Greeks."

The ingenious author of the tract "De Ratione Interpungendi," printed with Vossius's Element. Rector. Lond. 1724, lays down the use of a comma to be, to distinguish the simple members of a period, or sentence; i. e. such as only consist of one subject, and one definite verb. Thus Cicero, "Veni in hac ad voluptates agrorum, quibus ego incredibiliter delector. quæ nec ulla impediuntur lenitate, & mihi ad lapentis vitam proxime accedere videntur." See SENTENCE.

But this rule does not go throughout; the same author inducing many particular cases, not included herein, where yet the comma is advisable.

Sometimes, *e. gr.* a proposition includes another, which may be called *paritibus*, as being only a part of the entire phrase; in which case, the two are to be divided from each other by commas. Thus, "He always says, as he tells us, the finest things in the world."

The points, or pauses in discourse, if is observed, are in a kind of musical proportion: the comma stops the reader's voice while he may privately tell one; the semi-colon, two; the colon, three; and the period, or full-stop, four. Others make the stop at the colon four; and the period six. Professor Ward observes, that the suspension of the voice should be twice as long for a comma, as between words separated by no mark of distinction; thrice for the semi-colon; and so in the same proportion. Bishop Lowth assigns to the period a pause in duration double to the colon; to the colon, double of the semi-colon; and to the semi-colon, double of the comma: so that they are in the same proportion to one another as the semibreve, the minim, the crotchet, and the quaver in music. But whatever be the duration of the several pauses, the proportion between them would be ever invariable, if the doctrine of punctuation were exact. Introd. to English Grammar, ed. 1772. p. 167.

The ancients only made use of two kinds of points, or pauses, in a period; the larger they call *members*, the Greeks *cola*, marked thus [:]; the smaller *incisæ*, the Greeks *commata*, thus [,].

The moderns, refining on their predecessors, have subdivided the first into a colon, and semi-colon; some say, without any good foundation in nature; though others maintain the usefulness of the division.

As the member, or colon, divides the period into two parts, each containing a sense, though that imperfect; thus, "Antequam de republica, patres conscripti, dicam ea quæ dicenda lege tempore arbitror;" where the sense does not rest, nor is the period or sentence perfect, without the addition of "exponam vobis brevier & protectionis & reversionis meæ;" the comma subdivides each member into intermediate divisions, which, of themselves, have no precise meaning at all: *e. gr.* "Nihil est, mihi crede, virtute formosius, nihil pulchrius, nihil amabilius."

Frequent commas, as on other occasions they promote perspicuity and distinctness, and ease the reader, both in the rehearsal and comprehension of his author; so, in oratory, are of especial use and effect; particularly where an adversary is to be closely and pointedly attacked, upbraided, reprehended, wounded, &c. Witnesses that of Cicero against Verres: "Non enim nos color iste fervilis, non pilosa genæ, non dentis putridi deceperunt: oculi, supercilium, frons, vultus denique totus, qui sermo quidam tacitus mentis est, hic in fraudem, homines impulit: hic, eos, quibus erat ignotus, decepit, sefellit, in fraudem induxit: pauci tua ista

Intulenta vitæ novimus; pauci tarditatem ingenii, suporem, debilitatamque linguam;" &c. On the use of commas, see Murray's English Grammar, ed. 8. p. 224, &c.

COMMA, in Music. By this term, theoretic writers on music have denominated several different small intervals in the musical scale, which makes it necessary that we should here enter rather minutely into the subject. We shall begin with that very essential interval in almost all musical calculations which is for the most part implied by the word comma without further addition, otherwise the

COMMA Major, Greater Syntonic or Elementary of various writers, being also the *Schisma* or *Schisma* of Des Cartes, Holder, and others. This interval seems first to have been noticed by the Greek writers, as the quantity by which the major tone T ($\frac{9}{8}$) exceeds the minor tone t ($\frac{8}{9}$); its ratio is $\frac{81}{80}$ and its value in the common or Briggs's logarithms is .0946049,6811, or when reckoned downwards .0053950,3189; and in the logarithms of Euler .017970; this last being, in fact, its decimal value, compared with the octave = 1. This comma is usually marked C, and is equal to 11.0078631 times the *Schisma* (Σ) = to 73.55198 times the lesser fraction (*f*) = to 1400.0913 times the minute (*m*), and = to $\frac{1}{375}$ of the octave nearly.

It is equal to the sum of 11 *Schismas* and a minute, ($11\Sigma + m$), or of a minor comma and a *Schisma*; it also results as the difference or remainder, after subtracting the following intervals from each other, *viz.* a *Schisma* from a *Diasthisma*, a minor comma from an *Euharmonic Disis*, a *Semitone minor* from a *Semitone medius*, a *Semitone medius* from an *Apotome*, (here observing that $\frac{21}{16}$ is the *Apotome* and not $\frac{21}{32}$, erroneously printed in our article), an *Euharmonic Disis* from a *Semitone minimum*, a *Limma* from a *Semitone major*, a *Semitone major* from a *Semitone maximum*, a *Semitone subminimum* from a *Semitone minor*, &c. The comma major is equal to the following additions of intervals, in triples, *viz.* two *Schismas*, a *Medius Residual* and a *Major Residual*; three *Schismas*, a *Minor Residual* and a *Major Residual*; five *Schismas*, a *Lesser Fraction* and a *Major Residual*; ten *Schismas*, a *Lesser Fraction* and a *Greater Fraction*; ten *Schismas*, three *Lesser Fractions* and a *Medius Fraction*, &c. See these several articles.

The curious, and those concerned in these kinds of calculations, will find a great variety of other relations, in which the comma major stands, to the musical intervals, both great and small, in the elaborate manuscript treatise on music by the late Marmaduke Overend, organist of Isleworth, and by the late Dr. Boyce, which Dr. Callcott lately presented to the library of the Royal Institution in Albemarle-street, after kindly permitting the writer of this article to peruse and extract from them for the use of this work. The ratio of the major comma may be resolved into the component primes $\frac{3}{2} \cdot \frac{3}{2} \cdot \frac{3}{2} \cdot \frac{3}{2}$, and then, according to the method of Mr. Farey in the Philoſophical Magazine, vol. xxvii. p. 103, (see our articles MUSICAL PRIMES, and TUNEABLE INTERVALS) can be resolved into factors $\frac{3}{2} \cdot \frac{3}{2} \cdot \frac{3}{2} \cdot \frac{3}{2}$ or two fifths (V) reversed, a fourth (IV) and a major sixth (VI); whence it appears, that the interval of a major comma can be tuned on an instrument, having a sufficient number of strings or pipes, by tuning two fifths downwards in succession, and thence upwards a major sixth, and a minor fourth in succession, or VI + 4 - 2 V; where it is observable, that two Vths might have been tuned upwards, and a V and 4th downwards, which would also produce the interval of a major comma. but *above* the first or *key* note, instead of *below* it, as in the first case, where VI + 4 - 2 V is a negative quantity, as well as all the following. The fraction $\frac{3}{2} \cdot \frac{3}{2} \cdot \frac{3}{2} \cdot \frac{3}{2}$, does not at first appear capable of division into any other tuneable ratios, than

than the above; but, if we multiply the same by $\frac{3}{2}$, it will then be resolvable into the factors $\frac{3}{2}, \frac{3}{2}, \frac{3}{2}, \frac{3}{2}$, and may be tuned thus, $2 VI - III - 2 V$; or multiplying by $\frac{3}{2}$, we can obtain $2 fourths - V - 3$; or if by $\frac{3}{2}$, we can get $2 fourths + III - 2 V$; and if by $\frac{3}{2} \times \frac{3}{2} \times \frac{3}{2}$, we may get $3 fourths - 6 - V$; and if by $\frac{3}{2} \times \frac{3}{2} \times \frac{3}{2} \times \frac{3}{2}$, we shall have $2 fourths - III - 2 thirds$: and thus, we have six methods of exactly tuning a major comma, either above or below any given note, by help of perfect intervals only.

The method above explained, of analysing musical ratios or intervals, and expressing them in different ways, by the use of tuneable intervals only, is calculated to instruct the musical student, in the curious and important relations which the several concordant intervals bear to each other: hence we see, for instance, that if in any chant, or passage in a melody, to be performed by voices, by violins, or other perfect instruments, any one of the above six successions of notes were to occur, and the intervals were all to be performed perfect, or without temperament in the melody, the conclusion would not be in the key-note, or that set out from, but a comma different in pitch, which property of the musical scale is called *divergency of tune*; see that article.

It is observable, that all of the above six expressions or passages in melody, which diverge a comma, contain two *fifths* or two *fourths*, each moving the same way, and to which the divergency seems attributable, when the same is not counteracted by a proper succession of other intervals. Mr. Maxwell in his "Reformed or Complete Diatonic Scales for the Organ and Violin," &c. in his "Essay on Tune," (and so does Overend in his manuscripts) proposes to mark the rise of a comma by the acute accent ($'$), and the fall of the same by the grave accent ($`$), and that when either of these are required to be taken off, this mark ($^{\circ}$) is to be used, in the writing of music, in the same way as the musical mark \natural is used, to take off or destroy the effect of a \sharp or \flat , which has gone before, either accidentally, or in the signature of the staff. Mr. Maxwell shews, how a violin performer may practically tune a *comma* upon his instrument, in a variety of ways.

Modern writers on the temperament of the musical scale, usually refer their temperaments, or small corrections, to be applied to the concords, to this major *comma* as a unit or standard, on which account we shall present our readers with some further particulars relating to this small interval of the scale. Dr. Robert Smith, in his "Harmonics," Lemma to the 9th proposition, cor. 4, has demonstrated, that if any part or parts of a comma c , denoted by $\frac{q}{p}c$, be the interval of imperfect unisons (or temperament), the ratios of the times of their single vibrations will be $161 \frac{p}{p} - q$ to $161 \frac{p}{p} + q$, extremely near: for example, if we want a finite or approximate ratio for a $\frac{1}{3}$ of a comma, we have $q = 1$, $p = 4$, and $\frac{161 \times 4 - 1}{161 \times 4 + 1} =$

$\frac{643}{645}$ is the ratio, the complement arithmetical of its logarithm being 13487, which is true to the last of 7 places of figures: in like manner, $\frac{161 \times 3 - 1}{161 \times 3 + 1} = \frac{483}{484}$ or $\frac{241}{242}$ is the ratio answering to $\frac{2}{3}c$, or $\sqrt[3]{\frac{80}{81}}$, which is also true to the last of 7 places in the logarithm, and is sufficiently

accurate for all purposes: but it must be noticed that these are not composed of musical primes.

It may be of use here to enquire, what proportion the major *comma*, or ratio of $\frac{80}{81}$, bears, to the hemitone or ratio of $\frac{15}{16}$; for which purpose we have the logarithm of the latter divided by the logarithm of the former, or $\frac{280287}{539501}$

$= 5.195282$, the number of major commas in one hemitone (or H) very nearly: and as it may be useful on many occasions for the student to know, how many major commas make up any interval, we have subjoined a short table, shewing very exactly how many major commas make up the different concords within the octave, and also some of the smaller discords.

Intervals.	Ratios.	N ^o . of Commas.
VIII	$\frac{1}{2}$	55.797636
VI	$\frac{2}{3}$	41.120938
6th.	$\frac{3}{4}$	37.834808
V	$\frac{4}{5}$	32.639526
4th.	$\frac{5}{6}$	23.158110
III	$\frac{6}{7}$	17.962828
3rd.	$\frac{7}{8}$	14.676696
II	$\frac{8}{9}$	9.481414
I ^o	$\frac{9}{10}$	8.481414
2nd.	$\frac{10}{11}$	5.195282
comma	$\frac{80}{81}$	1.000000
Key.	$\frac{1}{1}$	0.000000

From the above table it appears, that the octave, whose ratio is $\frac{1}{2}$, contains something more than $55\frac{3}{4}$ major commas, the VI, a little more than 41 commas, &c. We shall next consider the

COMMA *Minor*, or *Lesser*, of Rameau, Overend, &c., being also the *apotome* minor of Salomon de Caus, Boetius, &c. the *diatichisma* of Euler, and the major *diefs* of Maxwell. This interval seems first to have been noticed by the Greek writers, as the quantity by which two *semitones* major $2S$ ($\frac{15}{16} \times \frac{15}{16}$) exceeded the *tone* major T ($\frac{8}{9}$). Its

ratio is $\frac{2025}{2048}$, and its value in Briggs's logarithms .99509597525, which reckoned downwards, by its arithmetical complement, is .00490492475; and its value in Euler's logarithms is .016295, being that decimal part of an octave. The minor comma is marked by Overend, Dr. Boyce, Dr. Callcott, and others, with a dashed c , (c'), similar to the mark for scruple in apothecaries weight, but reversed. (See Philosophical Magazine, vol. xxviii.) It is equal to 10.007863 times the *schisma* (Σ) = to .909170 times, or nearly $\frac{15}{16}$ ths of the major comma. It is equal to the sum of ten *schismas* and one minute ($10 \Sigma + m$). And it results as the difference when a *schisma* is taken from a major comma, a *diatichisma* from two major commas, two major commas from a *semitone* minimum, a major comma from an *enharmonic diefs*, a *semitone* minor from a *limma*, an *apotome* from a *semitone* maximum, a *semitone* minimum from two *enharmonic diefs*, a *semitone* medius from a *semitone* major, a *lesser fraction* from a *prima*, two *schismas*

fichimas from a diachisma, a hyperoche from a semitone sub-minimum, two semitones medii from a tone major, &c. The comma minor is equal to the following additions of intervals in triples, v. z. a schisma, a major residual and a medius residual; two schimas, a major residual and a minor residual; four schimas, a major residual and a lesser fraction; six schimas, a greater fraction and a medius residual; nine schimas, a greater fraction and a lesser fraction; nine schimas, a medius fraction and two lesser fractions, &c. (See Overend's MS. before quoted.)

The ratio of this interval is composed of these primes, $\frac{3^2 5^2}{2^7}$, which resolved as shewn above, give 3^4 ths - V - 2^4 ths, and 3^4 ths - 2^4 ths - 3, as different methods of practically tuning the minor comma upon an organ, piano-forte, &c.

COMMA *Maximum*, of Pythagoras, Boetius, &c. or ancient comma; this interval, whose ratio is $\frac{524,288}{531,441} = 12 \Sigma + m$, is now called the DIASCHISMA; see that article.

COMMA, *Greater*, has erroneously been applied by some to the ratio $\frac{125}{138} = 21 \Sigma + 2 m$, which is the *Enharmonic DIESIS*; see that article.

COMMA *Minimum*, according to some former writers, expresses the ratio $\frac{32768}{32805} = \Sigma$, which is now called the SCHISMA; see that article.

COMMA, *Ancient*, according to Galileo, had a ratio of $\frac{625}{648} = 32 \Sigma + 3 m$, which is now called the SEMITONE *Minimum*, which see.

COMMA of *Philolaus*, is the ratio of $\frac{229}{230}$, intended as an approximation for $\frac{1}{2}$ th part of a tone major, but which it exceeds considerably; besides, the fraction $\frac{229}{230}$ is not composed of the small or musical primes 2, 3, and 5, and cannot therefore be admitted into musical computations.

COMMA of *Boetius*, according to Giareanus, also of D. Nicola was $\frac{1}{3}$ th part of the tone major, or $11 \frac{5}{9} \Sigma + \frac{2}{9} f + m$, whereof 5 made their semitone major or apotome, and 4 made their semitone minus or limma; this interval was anciently supposed by some to be the same with the modern diachisma ($12 \Sigma + m$), but from which it differs, $\frac{4}{9} \Sigma - \frac{2}{9} f = .477702 \times \Sigma$, or nearly half a schisma.

The ancients mention another comma, $\frac{1}{4}$ of the tone minor, or $11 \frac{5}{8} \Sigma + \frac{1}{4} f + m$. (See Dr. Callcott's "Musical Grammar," pages 119 and 49.)

COMMA, *Artificial*, of Nicholas Mercator, is the $\frac{3}{5}$ part of the octave, or $11 \frac{29}{53} \Sigma + \frac{12}{53} f + m$. (See Mercator's "Temperament of the Musical Scale".)

COMMA of *Mersennus*. According to Holder's "Treatise on Harmony," page 104, Mersennus divided the octave into about 58 $\frac{1}{2}$ parts, and called one of these a comma.

COMMA of *Galileo*. The interval $\frac{524441}{524288}$, called a

comma in the writings of this author, was intended to have been the diachisma or $\frac{524288}{531441}$, as Mr. Overend has shewn, vol. i. p. 140, of his MS. before referred to; the error originated in an erroneous multiplication, in the second figure of Galileo's numerator, by which it was rendered unfit for the musical scale. (See Sir John Hawkins Hist. Mus. vol. i. p. 321.)

COMMA and half of *Galileo*, has a ratio of $\frac{625}{648} = 32 \Sigma + 3 m$, which is the SEMITONE *minimum*; see that article.

COMMA and half of *Rameau*. This interval results from the addition of a major comma and a major residual, and is also the difference between a semitone subminimum and a hyperoche; its ratio is $\frac{1953125}{1990625}$, its common logarithm is $-.9917338,2179$ and Euler's log. $0.027456 = 17 \Sigma - f + 2 m$. The component primes of this ratio are $\frac{5^9}{2^{12} 3^3}$, whence it appears, from the procefs before explained, that $3^3 - 4$ ths, or five minor thirds upwards, and four major thirds downwards, furnish a practical method of tuning this interval above any note, and the reverse of this procefs or 4 ths - 3^3 would tune the same below any given note.

COMMA, *Semi*. See SEMI-COMMA.

COMMA *Redundant*, or *superfluous*, or *deficient*, or *diminished*; these terms are applied to such intervals, whether concords or discords, as exceed or fall short of the true ratio of that interval by a major comma, as a comma redundant fifth, a comma deficient third, &c. Sometimes the term comma is omitted in naming these intervals, as a redundant fifth, a deficient third, &c. See FIFTH, THIRD, &c.

COMMAGENE, or COMAGENE, *Kamagb*, in *Ancient Geography*, a country of Syria, bounded on the west by mount Amanus, on the north by part of mount Taurus, on the east washed by the Euphrates; and with regard to its southern boundaries, it is uncertain whether it is contiguous to Seleucia, Cyrrhestica, or both. It is near the north corner of Syria. This country is mentioned by Strabo, Ptolemy, Pliny, and Ammianus Marcellinus, but they assign to it different extents. Its chief cities were Samofata upon the Euphrates, its capital, Antiochia ad Taurum, Germanicia, Singa, Chaonia, and several other cities, once of great note, but long since utterly destroyed. In the time of Antiochus the Great, Commagene was subject to the Syrians, and left to him by the treaty of peace which he concluded with Rome, after the famous battle of Magnesia; and hence it is probable, that it was seized by some of the princes of the Seleucian family, during their intestine wars, as no mention of the kings of Commagene occurs till the time of Pompey, and the names of those, who afterwards reigned there, are altogether Syrian. The first that is mentioned is Antiochus, who joined with Darius king of Media, in opposing the entrance of Pompey into Syria, after the defeat of Tigraues; but, being overcome in battle, he submitted to the conqueror, and was not only confirmed in his kingdom, but rewarded with part of Melopotamia. In the civil war between Cæsar and Pompey, he sent large supplies to the latter. Antiochus having been put to death by order of Augustus, for the assassination of the Roman ambassador, was succeeded by Mithridates, on whom Augustus bestowed the kingdom of Commagene, in recompence of his services during the war with Antony and Cleopatra. Upon the death of Mithridates, Antiochus II., the son of Antiochus I., was permitted by Augustus to take posses-

tion

gor of the kingdom. This prince died in the reign of Tiberius; and Commagene became a Roman province, and at the request of the nobles, it was governed by a prætor. But Caligula restored the kingdom to Antiochus III., the son of Antiochus II., adding to it the maritime parts of Cilicia. He was succeeded by his son Antiochus IV., surnamed Epiphanes, who distinguished himself under Vespasian in his war with the Jews, and particularly at the siege of Jerusalem. Vespasian, however, having reduced Commagene to the form of a Roman province, would not allow any of the sons of Antiochus to succeed him. This country was afterwards made part of the province called Augustopatensis, or as Ammianus has it, Euphratensis, and was commonly known by the name of Euphratensis.

COMMAND, in French *Commandement*, in *Military Language*; the act or action of him who commands; a thing commanded; the right of commanding and making one's self obeyed. The movements of a battalion at exercise, are performed by the words which the major or commanding officer pronounces. Hence, the *word of command* is a phrase in common use among military people.

COMMAND denotes also authority. Every command falls to the eldest officer in the same circumstances, whether he belong to the horse dragoons, artillery, engineers, foot, or marines. In our service when the commissions of two officers are of the same date, a retrospection of former commissions takes place, or length of service is examined into, and the dispute, if any arises, is determined according to precedents, and the rules of war.

COMMAND, in the *Royal Navy*, implies the rank or power of an officer, who has the management of a ship of war of any kind under twenty guns. He ranks with a major in the army.

COMMANDANT, or **COMMANDER**, the person who commands an army, a brigade, a garrison, a fort, castle, regiment, company, &c.

COMMANDE, a rope made use of for boats and pontoons.

COMMANDER, is a name given to a large wooden mallet used in a ship.

COMMANDERY. See **COMMANDRY**.

COMMAND in *front*, in *Fortification*, a height, or an eminence, which is directly opposite to, or faces the work, that it commands.

COMMAND in *rear*, an eminence or a height, which is directly behind the work that it commands.

COMMAND in *flank*, or *by enfilade*, a height or an eminence on the flank, or prolongation of any part of a work, which it sees and looks along.

COMMANDEMENT, *Fr.* A commanding ground, an eminence or elevation, which overlooks a post or strong place. There are three sorts of *commandemens*; namely the *commandement in front*, which faces a work, and batters or fires on it in front; the *commandement en revers*, or *in reverse*, which is behind a work or place, and fires on its rear either directly or obliquely; and the *commandement de courtoine* or *en enfilade*, which is on the flank of a work, and fires along the whole extent of a rectilinear part of it. Nine feet in perpendicular height, constitute a simple command or *commandement*; 18 feet a double one; 27 feet a triple one; and so on.

COMMANDEMENT, *Order of*, among the officers of *infantry and cavalry*. In France it was customary in a place of war, and every inclosed city, for the officers of infantry to have the command over those of the cavalry, and on the other hand to be commanded by them in the open field.

COMMANDEUR, *Fr.* The commander of an order

of knights. In some orders of chivalry it is the title, which a professed knight takes the moment he pronounces the vows, that subjected him to celibacy without his ceasing on that account to be military. There are, however, in Spain orders of chivalry, that do not require celibacy on the part of the commanders.

COMMANDEUR, in *Ornithology*, the French name of *Oriolus Phœnicæus*, which see.

COMMANDINUS, **FREDERICK**, in *Biography*, was born at Urbino, in Italy, 1509. He was descended from a noble family, and celebrated for his great classical learning, and for his extensive acquaintance with the mathematical sciences. He was patronized by Francis Maria, duke of Urbino, and by his liberality enabled to publish translations of various parts of the works of Archimedes: the Conics of Apollonius; the Elements of Euclid, and many other works of high reputation. He was also author of a book entitled, "De Centro Gravitatis Solidorum." Bologn. 1565; and of another entitled, "Horologiorum Descriptio." Romæ, 1562. He died in 1575; a funeral oration was delivered in his praise, by Antonio Toronco. Gen. Biog.

COMMANDMENT, in a *Legal Sense*, has various uses: as, *Commandment of the king*, when on his own mere motion, and from his own mouth, he calls a man into prison.

Commandment of the justices, is either *absolute* or *ordinary*; *absolute*, as when, on their own authority, and their own discretion, they commit a man for contempt, &c. to prison, as a punishment. *Ordinary*, as when they commit him rather for safe custody, than punishment.—A man committed by an ordinary commandment is releivable. Persons committed to prison by the special command of the king were not formerly bailable by the court of king's bench; but at this day, the law is otherwise. 2. Hawk. P. C. c. 15. § 36.

COMMANDMENT, is also used for the offence of him who directs or wills another to transgress the law; as by murder, theft, and the like. See **ACCESSORY**.

He that commandeth any one to do an unlawful act, is accessory to it and all the consequences, if it be executed in the same manner as commanded: but if the commander revoke the command; or if the execution varies from it, or in the nature of the offence; in such case he will not be accessory. 3 Inst. 51, 57. 2 Inst. 182.

In another sense of this word, magistrates may command others to assist them in the execution of their offices, for the doing of justice; and so may a justice of peace, to suppress riots, apprehend felons; or any officer to keep the king's peace, &c. Bro. 3.

A master may command his servant to drive another man's cattle out of his ground, to enter into lands, to seize goods, to distrain for rent, or to do other things; if the thing be not a trespass to others. The commandment of a thing is good; where he that commands hath power to do it; and a verbal command is in most cases sufficient; unless it be, where it is given by a corporation, or when a sheriff's warrant is to a bailiff to arrest, &c. Bro. 288. Dyer, 202.

In trespass, &c. the master shall be accountable for the act of the servant done by his command; but servants shall not be excused for committing any crime, when they act by command of their master, who have no authority to give such commands. The commands of infants and feme covert are void; but in forcible entries, &c. an infant or feme covert may be guilty in respect of actual violence done by them in person.

COMMANDMENTS, *Ten*. See **DECALOGUE**.

COMMANDRY, or **COMMANDERY**, a kind of benefice.

or fixed revenue belonging to a military order, and conferred on ancient knights, who had done considerable service to the order.

There are *strict*, or regular commandries, obtained in order, and by merit: there are others of *grace* or *favour*, conferred at the pleasure of the grand master.

There are also commandries for the religious in the orders of St. Bernard and St. Antony.—The kings of France have converted several of the hospitals for lepers into commandries of the order of St. Lazarus.

The commandries of Malta are of different kinds; for as the order consists of knights, chaplains, and brother servants, there are peculiar commandries, or revenues, attached to each.

The knight to whom one of these benefices or commandries is given, is called commander: which agrees pretty nearly with the *propofitus* fed over the monks in places at a distance from the monastery, whose administration was called *obediencia*: because depending entirely on the abbot who gave him his commission. Thus it is with the simple commanders of Malta, who are rather farmers of the order than beneficiaries: paying a certain tribute, or rent, called *responfo*, to the common treasure of the order.

The commandries belonging to the priory of St. John of Jerusalem in England, consisting of manors, lands, &c. such was that of New Eagle in Lincolnshire, Selbach in Pembrokehire, and Shengay in Cambridgehire, were given to Henry VIII. by statute 32 Hen. VIII. c. 20.; so that the name of commandries only remains, the power being long since extinct.

COMMANI, in *Geography*. See COMMENDO.

COMMANIPULARIS, in *Ancient Military Language*, a Roman soldier, who could not sleep but with his own company, nor fight but under its standard.

COMMANOËS, in *Geography*, one of the small Virgin isles in the West Indies, situated to the N.N.E. of Tortola. N. lat. 13° 25'. W. long. 63°.

COMMANTAWANA, a bay on the north coast of the island of St. Vincent, about one mile east of Tarray Point.

COMMARCHIO, in *Antiquity*, the confines of the land; whence probably is derived the word *marches*. "Imprimis de nostris landemais, commarckionibus" Du-Cange.

COMMARODES, in *Ancient Geography*, a piece of Thrace, in the vicinity of Constantinople.

COMMEATUS, in *Military Language*, a passport or permission granted to a Roman soldier to absent himself from the army for a fixed or limited time. The same name was also given to soldiers' provisions and their escorts.

COMMELIN, JOHN, a distinguished botanist, was born at Amsterdam, July 23, 1629. He succeeded his father as one of the magistrates of the city, and while holding this office, was very active in forming a new botanical garden; the ground occupied by the old gardenhaving been taken into the city. The second and third volumes of the "Hortus Indicus Malabaricus," owe much of their value to his judicious notes and observations. He published "Catalogus Plantarum indigenarum Hollandiæ," 1683, 12mo. It contains a list of 776 plants; and, in 1789, "Catalogus Plantarum Horti Medici Amstelodami, pars prior." These have been frequently reprinted. While preparing to complete this work, he died at Amsterdam in 1692.

COMMELIN, GASPARD, nephew to John Commelin. After taking his degree of doctor in medicine, he was appointed professor in botany, and director of the garden at Amsterdam, offices which he filled with distinguished ability and

attention. He completed the work begun by his uncle, which he published in 1701. His next production was "Flora Malabarica, seu Horti Malabarici Catalogus," serving as an index to the Hortus Malabaricus. This was followed by "Præluia Anatomica," 4to. 1703; and the same year, "Præluia Botanica," with figures for the benefit of students in those arts. In 1715, he published, "Icones Plantarum, præsertim ex Indis Collectarum," 4to.; and, in 1718, "Botanographia Malabarica, a Nominum Barbarissimis restituta," Lugduni Bat. folio. All useful to students in botany, but serving rather to shew the great industry, than the genius of the writer. Haller. Bib. Botan. Eloy. Dict. Hist.

COMMELINA, in *Botany*, (so named by Plumier from the two brothers, John and Gaspar Commelin, celebrated Dutch botanists.) Plum. 38. Linn. Gen. 62. Schreb. 86. Willd. 104. Lam. Ill. 83. Gart. 56. Juss. 15. Vent. 2. 152. Class and order, *triandria monogynia*. Nat. Ord. *Enfatæ*. Linn. *Junci*, Juss. *Juncaceæ*, Vent.

Gen. Ch. *Cal. common*. Spathe heart-shaped, converging, compressed, very large, permanent. *Cal. proper*. Perianth, three leaved; leaves egg-shaped, concave. *Cor.* Petals three, unguiculated, larger than the calyx, alternating with its leaves; one sometimes smaller. *Stam.* Filaments two, three, or six, awl-shaped, reclined; anthers oblong, versatile. *Nect.* three, often cruciform, fixed to the top of their proper filaments, rising above the stamens. *Pysl.* Germ superior, roundish; style awl-shaped, revolute, stigma simple. *Peric.* Capsule, somewhat globular, two or three-celled; two or three-valved. *Seeds* few.

Ess. Ch. Calyx proper, three-leaved. Petals three, unguiculated. Nectaries three, on their proper filaments.

Observ. Linnæus considers the spathe as the only calyx, and attributes fix petals to the flower; three exterior, small, resembling a perianth, and three interior, very large, coloured.

* Two petals larger; one small.

Sp. 1. *C. communis*. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Encyc. 598. Ill. Willd. 1. Dill. Elth. tab. 78. fig. 89. Gart. tab. 15. fig. 1. Lam. Ill. tab. 35. fig. 1. Koefkii. Kempf. fig. 888. tab. 889. *β. C. polygama*; Roth. Catal. Bot. 1. p. 1. "Leaves ovate-lanceolate, acute, stem creeping, smooth." *Root* annual. *Stems* several, two feet long, jointed, branched, leafy. *Leaves* alternate, nerved, supported by a membranous sheath with short hairs at its edge. *Flowers* axillary, two or three together, on short peduncles; two of the petals blue, the third whitish green. *Capsule* egg-shaped, slightly compressed on each side, somewhat two-celled, two-valved; valves thin, membranous, with the longitudinal partition on their inner side. *Seeds* two in each cell, affixed to the valves near the insertion of the partition, two adhering to each valve, gibbous and pitted on one side, flat and furrowed, with a longitudinal line on the other, truncate at the end where they are opposite to each other, umbilicated. A native of North America, Africa, and Japan. *β.* differs only in having polygamous diandrous flowers. In all other respects it exactly corresponds with *C. communis*, of which it appears to be only a variety. Willd. 2. *C. africana*. Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Ill. 599. Willd. 2. Gart. tab. 15. fig. 3. Lam. Ill. tab. 35. fig. 3. "Leaves lanceolate, smooth; stem decumbent." *Root* per annual. *Stems* about a foot long, branched, smooth. *Leaves* narrower, with ciliated or bearded sheaths, and a smaller one within the other. *Flowers* with two petals; yellow, unguiculated and roundish, or kidney shaped; the third small, oval, sessile, and

and of a pale colour. *Capsule* egg-shaped, two-valved, three-celled. *Seeds* in the upper cells, two, three, or four, roundish, smooth, umbilicated; but always barren and destitute of albumen; in the lower cell solitary, fertile, adnate to the valve on its whole length. A native of Africa. 3. *C. mollis*. Willd. 7. Lam. III. 600. Jacq. Collect. 3. 253. ic. rar. 293. "Leaves egg-shaped, petioled, villous; stem creeping." A native of South America. 4. *C. bengalensis*. Linn. Sp. Pl. 3. Mart. 3. Lam. 3. Ill. 601. Willd. 3. (Ephemeron bengalense repens; Pluk. Alm. 135. tab. 27. fig. 3.) "Leaves egg-shaped, obtuse; stem creeping." *Root* annual. *Stems* numerous, slightly villous, slender, branched. *Leaves* from an inch to an inch and half long, edged with very short hairs, petioled above the sheath; sheath ciliated, marked with lines, spotted with purple. *Spathes* terminal, cowed, somewhat triangular, marked with lines. *Peduncles* within the spathe, two; one slender, longer, with a single flower; the other thicker, channelled, bearing from two to four flowers, on jointed inflexed pedicels. *Petals* blue; smaller one paler. *Nectaries* yellow. A native of Bengal and Cochin-china. 5. *C. erecta*. Linn. Sp. Pl. 4. Mart. 4. Lam. 4. Ill. 602. Willd. 4. Dill. Elth. 91. tab. 77. fig. 88. "Leaves ovate-lanceolate; stem erect, scabrous, quite simple." *Root* perennial, fibrous. *Stems* a foot and half high, leafy. *Leaves* a little lufure, but not hairy, except at the sheath. *Flowers* pale blue; smaller petal very narrow, whitish and pellicid. *Capsules* roundish, obtusely triangular, with three feeds. A native of Virginia.

* * *Petals* nearly equal.

6. *C. virginica*. Linn. Sp. Pl. 5. Mart. 5. Lam. 5. Ill. 603. Willd. 5. (Ephemeron phalangoides; Pluk. Alm. 135. tab. 174 fig. 4.) "Leaves lanceolate, in short petioles; bearded at the edge; stems erect." Nearly allied to the preceding, and perhaps, only a variety. *Root* perennial. *Stems* two feet high, simple, slightly villous. *Leaves* scabrous on the upper surface when rubbed from the base, pubescent underneath, narrowed near the sheath. *Sheaths* nerved, somewhat pubescent, ciliated at the edge with reddish hairs. *Flowers* blue; the lower one on a short pedicel; petals heart-shaped, quite entire. A native of Virginia. 7. *C. longicaulis*. Willd. 6. Jacq. ic. rar. 2. tab. 294. Collect. 3. p. 234. "Leaves linear-lanceolate, sessile; sheaths ciliated; stem decumbent." *Root* perennial. *Leaves* smoothish. *Pedicels* in pairs, filiform, jointed. A native of Caracae. 8. *C. hexandra*. Lam. 6. Ill. 604. Aubl. Guian. tab. 12. "Flowers hexandrous, in racemes." *Root* perennial. *Stems* three feet high or more, farmentous, climbing, bent at the joints. *Leaves* egg-shaped, acute, narrowed and petioled near the sheath; sheaths half an inch long, ciliated. *Flowers* blue; filaments short and not villous, as in Tradescantia. 9. *C. tuberosa*. Linn. Sp. 6. Mart. 6. Lam. 7. Ill. 605. Willd. 8. Dill. Elth. 94. tab. 79. fig. 90. Gært. tab. 15. fig. 2. Lam. tab. 35. fig. 2. "Leaves sessile, ovate lanceolate, somewhat ciliated." *Root* perennial, consisting of several tubers somewhat like those of ranunculus, or of common orpine (sedum telephium), joining together at the top and forming a head, diminishing gradually downwards. *Stems* a foot high, weak, ascending, branched at their base. *Leaves* villous underneath, smooth above; sheath smooth, striated, reddish, simply ciliated at the edge. *Flowers* blue, growing several together on slender peduncles. *Capsule* ovate-acuminate, somewhat depressed, two-valved, three-celled; upper valve, divided longitudinally into two cells; lower valve one-celled, a little concave above, convex below, closely adnate to the feed. *Seeds* in each of the upper cells two, tubercle wrinkled,

ferruginous; in the lower cell, one, elliptical, smooth, lenticularly compressed, of a bay colour. Gært. A native of Mexico. 10. *C. barbata*. Lam. III. 606. "Leaves egg-shaped, sessile; sheaths bearded; stem creeping." A native of the island of Mauritius. 11. *C. longifolia*. Lam. III. 607. "Leaves lanceolate-linear; peduncles very long." A native of the island of Java. 12. *C. zanonica*. Linn. Sp. Pl. 7. Mart. 7. Lam. 8. Gært. tab. 15. fig. 4. Lam. Ill. tab. 35. fig. 4. (Zanonica; Plum. Gen. 38. Tradescantia zanonica; Willd. Swartz.) "Peduncles thickened; leaves lanceolate; sheaths hairy at the edge; bractes in pairs." *Root* perennial. *Stem* about two feet high, cylindrical, jointed, smooth, branched towards the top. *Leaves* four or five inches long, about two broad, green and smooth above, slightly pubescent underneath when young, with purple-brown, or violet edges; sheaths whitish-green, large. *Flowers* white; Lam. Sky-blue; Miller. *Fruit* berryed, in an egg-shaped terminal raceme; berries false, dark-purple, formed of the corolla changed into a fleshy succulent three-lobed substance which completely encloses the capsule; capsule cylindrical-egg-shaped, crustaceous, dotted in rows, testaceous, three-celled, opening at the tip into three parts. *Seeds* two, or one in each cell; in the cells which have two, angular, a little wrinkled, cinereous, with a small pap on the side covering the embryo; in the cell which has only one, elliptical plano-convex, a little wrinkled about the edge, bearing the embryo on the middle of the back. Gært. A native of Cayenne, in South America. 13. *C. vaginata*. Linn. Mant. 177. Mart. 8. Lam. 9. Ill. 609. Willd. 9. "Leaves linear; flowers d'androus, sheathed with an involucre." *Root* annual. *Stems* ascending, numerous, somewhat scabrous. *Leaves* sessile, acute. *Peduncles* terminal and axillary, elongated, ending in a striated, lanceolate involucre, which is so convolute as to be almost cylindrical; calyx-leaves lanceolate, acute, coloured at the tip; petals oval, the length of the calyx; filaments of the nectary four, half the length of the filaments; nectaries linear; filaments of the stamens two, bearded, somewhat recurved, the length of the corolla; anthers yellow, marked with a black spot; style awl-shaped, somewhat recurved. Found by Koenig in the East Indies. 14. *C. nudiflora*. Linn. Mant. 177. Mart. 9. Lam. 10. Ill. 609. Willd. 10. "Peduncles capillary; leaves linear, without an involucre; flowers diandrous." *Root* annual. *Stem* about seven inches high, slender, nearly erect, decumbent at the base, somewhat scabrous. *Leaves* sessile, acute; sheath short, edged with a few lax hairs. *Peduncles* for the most part terminal, from two to four together, accompanied by a very short bractee. *Flowers* from four to six on each peduncle, naked, pedicelled; calyx-leaves ovate-lanceolate, acute, less than the corolla; petals three, egg-shaped, unequally distributed; the two lower ones most distant; filaments of the nectary three, half the length of the stamens, naked; nectaries deltoid; filaments of the stamens two, bearded, declining at the opening of the corolla; style declining. Found by Koenig in dry pastures of the East Indies. 15. *C. cucullata*. Linn. Mant. 176. Mart. 7. Lam. 11. Ill. 611. Willd. 11. (C. nervosa; Burm. ind. 18. tab. 7. fig. 3.) "Leaves egg-shaped; involucre cowed, turbinate." *Root* annual. *Stems* seven inches high, creeping at the base, and sending out sixform roots. *Leaves* nerved, petioled; sheaths wider than the stem; ciliated at the edge with distant, spreading, bristle-shaped hairs; involucre terminal, truncated, many-flowered, entirely coalescent by the side. *Flowers* peduncled, minute. A native of the East Indies. 16. *C. japonica*. Thunb. in Linn. Transf. 2. 332. Mart. 12. Willd. 12. "Leaves ovate-lanceolate, undulated; stem erect, angular,

hairy; flowers panicled." *Stem* a foot high, furrowed, panicled at the top. *Leaves* alternate, sheathing, acute, firmish; lower ones three inches long; upper ones about 2½ inch. A native of Japan. 17. (*C. spirata*. Linn. Mant. II. 176 Hort. Kew. 77. (*C. bracteolata*; Lam.?) "Leaves lanceolate; flowers panicled." Linn. "Leaves lanceolate-linear, undulated, somewhat curled; peduncles panicled, furnished with small bractes, half-embracing the stem." Lam. *Root* annual. *Stem* creeping, ascending, somewhat scabrous; Linn. *Stem* six or seven inches long, very slender, bent at the joints, almost smooth, leafy, branched; Lam. *Leaves* lanceolate, sheathing, very minutely serrated; upper leaf cordate-lanceolate; sheaths ciliated at the edge. Linn. *Leaves* narrow; sheaths short, ciliated; Lam. *Flowers* small, blueish; Lam. *Panicle* terminal, divaricated, with small sheathing bractes; Linn. Lam. *Peduncles* capillary, compound; Lam. *Calyx* three-leaved; leaves ovate-lanceolate, concave; Lam. *Petals* three, equal, orbicular-egg-shaped; Linn. *Petals* three, egg shaped, a little longer than the calyx. Lam. *Filaments* of the *stamens* three, bearded, naked above the middle. Linn. Almost entirely naked. Lam. *Filaments* of the *nectary* three, somewhat ciliated at the sides. Corpuscles cruciform, globular at the tips, whitish; Linn. corpuscles yellow; Lam. *Style* and *stigma* spirally convolved, and evolved variously; Linn. *Style* permanent, a little spirally twisted when the flower is past; Lam. Found by Koenig in moist ground, by the side of rivulets in the East Indies; communicated to La Marek from the East Indies by Sonnerat. La Marek seems to have no good reason to doubt the identity of his plant with that of Linnæus.

Obs. It is evident from the above descriptions, that this genus, as it now stands, is a very anomalous one. *C. hexandra*, if it had bearded filaments, would unquestionably be a *tradesantia*. *C. virginata*, *undiflora*, and *spirata*, approach that genus, by their partially bearded filaments, but differ in the number of stamens; the first two have the additional anomaly of being diandrous, without a corresponding diminution in the number of the other parts. Linnæus, when he took up these three species, in his second Mantissa, seems to have forgotten, or to have discarded, his original idea with respect to the flower; for he there attributes to it, not a six petalled corolla, but a three-petalled one, with a proper three-leaved calyx. Gærtner is of opinion that *commelina* and *tradesantia* are one truly natural genus.

COMMELINA axillaris et cristata. Linn. See TRADESANTIA.

Propagation and Culture. All the species are propagated by seed. If the seeds of *C. communis*, which is an annual, be sown upon a warm border of light earth in the autumn, they will come up early in the spring and ripen their fruit. The roots of *C. africana* send out offsets, by which the plant is easily propagated; but they will seldom live through the winter in the open air. The other species are tender, and must be sown in a moderate hot bed in the spring; transplanted to a fresh hot-bed, when they are two inches high; and in June, again transplanted into a warm border of light earth. *C. tuberosa* may be preserved, if planted in pots, and placed in the bark-stove in autumn; or its roots may be taken out of the ground in the autumn, kept in a warm place during the winter, and planted again in the spring; they will be more forward and stronger if placed on a hot-bed.

COMMEMORATION, the remembrance of any one; or something done in honour of a person's memory.

Among the Romanists, it is a practice for dying persons

to leave a legacy to the church, for the rehearsing so many masses in commemoration of them.

The eucharist is a commemoration of the sufferings of Jesus Christ.

COMMEMORATION is also the name of two religious feasts, otherwise called *all-joints* and *all-souls*. The occasion of their institution is variously related. See the articles.

COMMEMORATION of *Handel*, in *Music*. In order to record an event so honourable to a liberal art, we shall draw our information from the history of that art, and from the account itself of the commemoration written expressly at the time, and published in 4to. by the same author, an attentive auditor of all the performances, whose sensations and memory were more fresh then than at the distance of 22 years.

In the "History of Music," vol. iv. p. 518. it is laid, that "The year 1784 was rendered a memorable æra in the annals of music, by the splendid and magnificent manner in which the birth, genius, and abilities of Handel, were celebrated in Westminster Abbey and the Pantheon, by five performances of pieces selected from his own works, and executed by a band of more than 500 voices and instruments in the presence and under the immediate auspices of their majesties and the first personages in the kingdom. This event so honourable to the art of music and an illustrious artist, and so worthy of a place here, having been minutely recorded already in a distinct work, *viz.* "Account of their usual performances in commemoration of Handel," by the author of this history, written and published for the benefit of the musical fund; an establishment which his majesty having since deigned to honour with his patronage, the members and guardians have been permitted to incorporate themselves under the title of Royal Society of Musicians: We shall only add, that this celebration has been since established into an annual musical festival for the benefit of the fund, in which the number of performers, and perfection of the performances, as well as favour of the public, have continued to increase. In 1785, the vocal and instrumental band amounted to six hundred and sixteen. In 1786, to seven hundred and forty-one; and in 1787, to eight hundred and six vocal and instrumental performers."

And in the same "History of Music," at the end of the same vol. the author tells us, that "The commemoration of Handel, in 1784. having been crowned with a success equally honourable to that great artist and to the nation, since its performance has since been annually repeated, to still more numerous audiences, for charitable purposes, in Westminster-Abbey, under the title of a "Grand Musical Festival." In 1787, the band of vocal and instrumental performers amounted to eight hundred and six musicians, exclusive of the principal singers, consisting of twenty-two, with Madame Mara, Rubinelli, Harrison, and Morelli at their head. And such is the state of practical music in this country, that the increase of performers, instead of producing confusion, as might have been expected, has constantly been attended with superior excellence of execution; as experience, the best of a teachers, has so guided the zeal of the directors, and the science of the conductor and leader of this great enterprise, that a certain road to full perfection in every department seems to have been attained.

Though this celebration happened so recently, and is so well known as scarcely to need being mentioned here for the information of the present race, among musical articles; yet as our plan extends to history and biography, as well as definitions and scientific explanations, a record of a musical event of such magnitude seems necessary for the information of distant times, if we may dare hope to reach them. The origin and progress of the plan, as related in

the introduction to the printed narrative, dedicated by permission to the king, is the following.

“ It was in the year 1783, that the idea of this great enterprise was conceived in a conversation between lord viscount Fitzwilliam, the late sir Watkin Williams, and Joah Bates, late commissioner of the victualling office, on observing how much more London abounded with great musicians, vocal and instrumental, foreigners and natives, than any other city in Europe: but so dissipated and dispersed at the operas, oratorios, theatres, and public and private concerts, that they can never be heard in the aggregate, nor can the effects which may be produced by such a united band as our capital could furnish, ever be known, unless some plan was formed of a public periodical occasion for collecting and consolidating them into one band; by which means a performance might be exhibited on so grand and magnificent a scale as no other part of the world could equal. The birth and death of Handel naturally occurred to three such enthusiastic admirers of that great master, and it was immediately recollected, that the next (now the present) year, would be a proper time for the introduction of such a custom: as it formed a complete century since his birth, and an exact quarter of a century since his decease.

The plan was soon after communicated to the governors of the Musical Fund, who approved it, and promised their assistance. It was next submitted to the directors of the concert of Ancient Music, who, with an alacrity which does honour to their zeal for the memory of the great artist Handel, voluntarily undertook the trouble of managing and directing the celebrity. At length, the design coming to the knowledge of the king, it was honoured with his majesty's sanction and patronage. Westminster Abbey, where the bones of the great musician were deposited, was thought the properest place for the performance: and application having been made to the bishop of Rochester for the use of it, his lordship, finding that the scheme was honoured with the patronage of his majesty, readily consented; only requesting, as the performance would interfere with the annual benefit for the Westminster Infirmary, that part of the profits might be appropriated to that charity as an indemnification for the loss it would sustain. To this the projectors of the plan acceded; and it was afterwards settled, that the profits of the first day's performance should be equally divided between the musical fund and the Westminster Infirmary; and those of the subsequent days be solely applied to the use of that fund which Handel himself so long helped to sustain, and to which he not only bequeathed a 1000*l.*, but which almost every musician in the capital annually contributes his money, his performance, or both, to support.

Impressed with a reverence for the memory of Handel, no sooner was the project known, but most of the practical musicians in the kingdom eagerly manifested their zeal for the enterprise; and many of the most eminent professors, waving all claims to precedence in the band, offered to perform in any subordinate station, in which their talents could be most useful.”

“ By the latter end of February, the plan and necessary arrangement were so far digested and advanced, that the directors ventured to insert in all the newspapers, the following advertisement.

Under the Patronage of His Majesty,
In Commemoration of Handel, who was buried in
Westminster Abbey, on the 21st of April, 1759.

On Wednesday the 21st of April next, will be performed in Westminster Abbey, under the management of the

Earl of Exeter	Lord Paget
Earl of Sandwich	Right Hon. H. Morrice
Vicount Dudley Ward	Sir W. Williams Wynn, Bart.
Vicount Fitzwilliam	Sir Richard Jebb, Bart.

Directors of the concert of Ancient Music;

Some of the most approved pieces of sacred music, of that great composer.

The doors will be opened at 9 o'clock, and the performance will begin precisely at twelve.

And on the evening of the same day, will be performed, at the Pantheon, a grand miscellaneous concert of vocal and instrumental music; consisting entirely of pieces selected from the works of Handel.

The doors will be opened at 6 o'clock, and the concert will begin exactly at eight.

And on Saturday morning, April 24th, will be performed, in Westminster Abbey, the sacred oratorio of the Messiah.

Such is the reverence for this illustrious master, that most of the performers in London, and a great many from different parts of the kingdom, have generously offered their assistance; and the orchestra will consist of at least 400 performers, a more numerous band than was ever known to be collected in any country, or on any occasion whatever. The profits arising from the performances, will be applied to charitable purposes.

In order to render the band as powerful and complete as possible, the trombone, fagot, or double curtle, and double kettle drums, were sought and their use revived.

In preparing Westminster Abbey for the reception of their majesties and the royal family, as well as the archbishops and bishops, judges, great officers of state, and principal nobility and gentry in the kingdom, to the amount of three or four thousand, Mr. James Wyatt, the admirable architect of the ill-fated Pantheon, furnished the elegant drawings for the orchestra, throne, and galleries.

As this commemoration is not only the first instance of a band of such magnitude being assembled together, but of any band, at all numerous, performing in a similar situation, without the assistance of a conductor, to regulate the measure, the performances in Westminster Abbey may be safely pronounced, no less remarkable for the multiplicity of voices and instruments employed, than for accuracy and precision. When all the wheels of that huge machine, the orchestra, were in motion, the effect resembled clock-work in every thing, but want of feeling and expression.

And, as the power of gravity and attraction in bodies are proportioned to their mass and density, so it seems as if the magnitude of this band had commanded and impelled adhesion and obedience, beyond that of any other of inferior force. The pulsations in every limb, and ramifications of veins and arteries in an animal, could not be more reciprocal, isochronous, and under the regulation of the heart, than the members of this body of musicians under that of the conductor and leader. The totality of sound seemed to proceed from one voice, and one instrument; and its powers produced, not only new and exquisite sensations in judges, and lovers of the art, but were felt by those who never received pleasure from music before.

This celebration was at first designed to be extended to no more than two performances on the same day: one at noon in Westminster Abbey, for sacred music; and the other in the evening of the same day at the Pantheon, for secular compositions, selected from the operas and miscellaneous works of the hero whose apotheosis was the efficient cause of this extraordinary undertaking. But being countenanced by his majesty, the directors of the concert of ancient music,

the governors of the musical fund, and eagerly patronized by the public in general, while the plan was digesting, it determined the projectors, at the instigation of his majesty, to have three performances. The first and third in the morning, at Westminster Abbey, and the second at the Pantheon.

These performances having given such entire satisfaction to all that were present, and becoming, of course, the general subject of discussion and praise, excited a great desire in all lovers of music, and even of splendid spectacles, who were absent, to be enabled to judge and speak of transactions so memorable, from the conviction of their own senses. But even these were not more eager in wishing there might be a repetition of the performances, than those who had already attended them. Luckily for all parties, the wishes of their majesties coincided with those of their subjects; and as the scaffolding was still standing, and the band not yet dispersed, two more opportunities were given for the display of Handel's wonderful powers, and the gratification of public curiosity.

The fourth day was supplied with a well chosen selection of Handel's most grand and captivating compositions, from his oratorios and anthems; and on the fifth, that sublime production, the Messiah, was repeated; and though it had been performed in the Abbey but a week before, in so perfect and magnificent a manner, that no rehearsal, previous to its repetition, was necessary to the band; yet, to gratify the wishes of many timid and infirm lovers of music, who dreaded the crowd that was likely to be assembled at a public performance, as well as to raise money for charitable purposes, another rehearsal would certainly have been announced, if it had not been prevented from taking place by the celebration of his majesty's birth day, on which occasion there was a certainty that the chief part of the performers and company would be engaged.

Those who attended this day's commemoration at the Abbey were, seemingly, of a higher class than had yet appeared there; so that though the crowd was somewhat less than at the preceding performance of the same oratorio, the exhibition was more splendid. Indeed, as a spectacle, it was so magnificent to the sight, and, as a musical performance, so mellifluous and grateful to the ear, that it will be difficult for the *mind's eye* of those who were absent, to form an adequate idea of the show, or the *mental ear* of the found, from description. Every one present must have found full employment for the two senses which afford us the most refined pleasure; as it is from the eye and the ear that intellect is fed, and the mind furnished with its best intelligence.

At the first performance of the Messiah, his majesty expressed a desire to the earl of Sandwich of hearing the most truly sublime of all choruses, "Allelujah! for the Lord God omnipotent reigneth," a second time; and this gracious wish was conveyed to the orchestra, by the waving of his lordship's wand. At this second performance of that matchless oratorio, his majesty was pleased to make the signal himself, with a gentle motion of his right hand, in which was the printed book of the words, not only for the repetition of this, but of the final chorus, in the last part, to the great gratification of all his happy subjects present; and, perhaps, the subjects of no sovereign prince on the globe were ever before so delighted with the effects of a royal mandate.

Thus ended the fifth and last of the performances for this memorable celebration; and so great and perfect was the pleasure which the audience had received, that those who

had attended all the five exhibitions seemed most to regret this final close.

The whole receipts at the five performances of this most splendid and magnificent celebration amounted to 12,73*l.* 12*s.* 10*d.* Of which, after all disbursements for building, band, and other incidental expences, to the amount of 57,36*l.* 12*s.* 10*d.*, 6000*l.* remained for the fund of the society of decayed musicians, and 1000*l.* for the Westminster hospital.

At the end of the printed account of the first year's Commemoration of Handel, is added in the Appendix, a "History of the Rise and Progress of the Fund for the Support of decayed Musicians and their Families, established in 1738," which has been since laudably imitated by other professions, and in other countries; and it appeared in 1784, after these performances, that by the great accession to the fund from the commemoration, its capital became a serious and weighty concern, amounting to upwards of 22,000*l.*, in South-sea annuities and three per cents.; which realizes and ascertains an income of 678*l.* a year, exclusive of benefits or subscription.

The path therefore which the governors and court of assistants have now to pursue, is perfectly plain and pleasant; the power of alleviating distress and misery, of feeding the hungry, clothing the naked, and administering comfort to age and infirmities, is placed in their hands, without the trouble of providing the means.

COMMENASA, in *Ancient Geography*, a river of Asia, according to Arrian, who says that it ran into the Indus.

COMMENDAM, in the *Canon Law*, expresses the charge, trust, and administration of the revenues of a benefice, given to a layman to enjoy, by way of depositum, for the space of six months, in order to its being repaired, &c. or to another bishop, or ecclesiastic, to perform the pastoral offices thereof, till such time as the benefice is provided of a regular incumbent. See BENEFICE.

Anciently, the administration of vacant bishoprics belonged to the nearest neighbouring bishop; which continued to be practised between the archbishopric of Lyons, and the bishopric of Autun: on this account they were called *commendatory bishops*.

This custom appears to be very ancient: St. Athanasius says of himself, according to Nicephorus, that there had been given him in *commendam*, i. e. in administration, another church besides that of Alexandria, whereof he was styled bishop.

The care of churches, it seems, which had no pastor, was committed to a bishop, till they were provided with an ordinary: the register of pope Gregory I. is full of these commendations, or commendams, granted during the absence or sickness of a bishop, or the vacancy of a see. Some say, that pope Leo IV. first set the modern commendams on foot, in favour of ecclesiastics who had been expelled their benefices by the Saracens; to whom the administration of the vacant churches was committed for a time, in expectation of their being restored: though St. Gregory is said also to have used the same, while the Lombards desolated Italy.

In a little time, the practice of commendams became exceedingly abused: and the revenues of monasteries were given to laymen for their subsistence. The bishops also procured several benefices, or even bishoprics, in commendam, which served for a pretext for holding them all without directly violating the canons. Part of the abuse has been retrenched; but the use of commendams is still retained, as an expedient to take off the incompatibility of the persons, by the nature of the benefice.

When a parson is made bishop, his parsonage becomes vacant; but if the king by special dispensation give him power to retain his benefice, notwithstanding his promotion, he shall continue parson, and is said to hold it in *commendam*; but this must be done before consecration, for afterwards it comes too late, because the benefice is then absolutely void. There are several sorts of commendams founded on the stat. 25 Hen. VIII. cap. 21. as a *commendam fensivis*, which is for the benefit of the church, without any regard to the commendatary, being only a provisional act of the ordinary, for supplying the vacation of 6 months, in which time the patron is to present his clerk, and only implies a sequestration of the cure and fruits till the clerk is presented: *commendam retinere*, by means of which a bishop retains benefices on his preferment, which has operated for a certain number of years, or even as long as the *commendatary* lived, and continued bishop; and these commendams are granted on the king's mandate to the archbishop, expressing his consent, which continues the incumbency, so that there is no occasion for institution: a *commendam recipere*, which is to take a benefice *de novo*, in the bishop's own gift, or of some other patron, whose consent is obtained; and for life, when it is equal to a presentation, without institution, or induction. But all dispensations beyond 6 months were only permissive at first, and granted to persons of merit; the *commendam retinere* is for one or two years, &c. and sometimes for three or six years, and doth not alter the censure which the incumbent had before; and this, as long as the commendatary should live and continue bishop, hath been thought good. Vaugh. 18. The *commendam recipere* must be for life, as other parsons and vicars enjoy their benefices; and as a patron cannot present to a full church, so neither can a *commendam recipere* be made to a church that is then full. Show. 414.

A benefice cannot be *commended* by parts, any more than it may be presented unto by parts; so that one shall have the glebe, another the tythes, &c. Nor can a commendatary have a *juris utrum*, or take to him and his successors, sue or be sued, in a writ of annuity, &c. But a *commendam perpetua* may be admitted to do it. 11 Hen. IV. Compl. Incomb. 360. (See Nels. Abr. 454.)

These commendams are now in fact seldom or never granted to any but bishops; and in that case the bishop is made commendatary of the benefice while he continues bishop of such a diocese, as the object is to make an addition to a small bishopric; and it would be unreasonable to grant it to a bishop for life, who might afterwards be translated to one of the vacant sees.

COMMENDAM, in popish countries, is a real title of a regular benefice; as an abbey, or priory given by the pope to a secular clerk, or even to a layman, with power to dispose of the fruits thereof during his life.

No benefice that has a cure of souls, i. e. no parsonage, or bishopric, can be given in *commendam*. This practice being entirely contrary to the canons, none but the pope, who has a power of dispensing with the canons, can confer it.

When the commendam becomes vacant by the death of the *commendatary*, it is not esteemed vacant by his death; but as it was before the commendam was granted: that making no alteration in the thing; yet the pope gives the same benefice in *commendam* again, by a privilege which he still continues.

By the pope's bulls, a *commendatary* abbot has the full authority of the regular abbot to whom he is substituted. For this reason, the bulls expressly require, that he be a priest; or, that if he have not yet attained the age of priest-

hood, he shall take orders as soon as he has. But this is a mere formality, or matter of style, the thing is never executed.

Indeed, the spiritual direction of the abbey, while it is in *commendam*, is lodged wholly in the claustral priors.

The commendatary abbots have not any authority over the religious in *spiritualibus*: they even cannot either appoint or set aside the claustral priors, who are nominated in the bulls the administrators of the spiritualities; in which, however, this restriction is added, viz. till the abbot arrive at the age of twenty-five years, to assume the priesthood.

The popes grant benefices in *commendam*, not only to clerks, by dispensing with their age, and other qualifications required; but they also dispense with the clericate even in children yet in the cradle, till they become of age to take the tonsure: it being sufficient to obtain a bull, that it be represented at Rome, that the child is declined for the ecclesiastical state. In this case there is an *oeconomus*, or steward, appointed to take care of the temporal concerns.

COMMENDATARY, a person who holds a church living or preferment in *commendam*.

COMMENDATARY Letters, are such as are written by one bishop to another in behalf of any of the clergy, or others of his diocese traveling thither; that they may be received among the faithful; or that the clerk may be promoted; or necessaries may be administered to others, &c. Several forms of these letters may be seen in our historians; as in Bede, lib. ii. cap. 18.

COMMENDATUS, one that lives under the protection of a great man.

Commendati homines were persons who, by a voluntary homage, put themselves under the protection of any superior lord; for ancient homage was either predial, due for some tenure, or personal, which was by compulsion, as a sign of necessary subjection; or voluntary, with a desire of protection. And those who by voluntary homage put themselves under the protection of any men of power, were sometimes called *homines ejus commendati*, sometimes only *commendati*, as often occurs in Domesday. *Commendati dimidii* were those who depended on two several lords, and paid one half of their homage to each; and *sub-commendati*, were like under-tenants, under the command of persons who were dependants themselves on a superior lord. There were also *dimidii sub-commendati*, who bore a double relation to such depending lords. Domesday. This phrase seems to be still in use, in the usual compliment, *commend me to such a friend*, &c. which is to let him know I am his humble servant. Spelm. of Feuds, cap. 20.

COMMENDO, called also *Commani*, *Kommani*, *Aguello*, and *Guaffo*, in *Geography*, a kingdom of Africa, on the Gold coast, bordered on the west by the countries of Jabani Jaben, on the north-west by Adomi, by Ambramo on the north; on the east, by a little republic lying between Commendo and Fetu, called Addena, or Elmna; and by the ocean on the south. The dimensions are about five miles along the sea-coast, and about as many up the country. In the centre, on the strand, stands Little Commendo, or *Commani*, called by the negroes Ekki Tekki, having cape Aldea das Terras on the west, and Ampani on the east, with some small hamlets in the intermediate spaces. Commendo had formerly been a part of Saba and Fetu, but of late years it has been erected into a separate monarchy. The chief city, or residence of the king, is called "Guaffo," which is large and well inhabited, containing no less than 400 houses, and situated on high ground, at the distance of four miles from Little

Little Commendo; the Dutch distinguish both by the name of Great and Little Commendo. This kingdom produces but little rice; nevertheless, the valleys are no less fertile than agreeable, and the hills covered with wood, which affords a very delightful prospect. Behind Little Commendo, the land rises by a gentle ascent into little hills, beautifully sheltered with woods of a perpetual verdure; and at the bottom are meadows and plains disposed in the most agreeable manner, and abounding with various kinds of fruit-trees. The natives are warlike, and so numerous, that in this little kingdom, the sovereign is able to raise an army of 20,000 men. His ordinary body-guard is composed of 500 stout fellows, well armed, resolute, and loyal. It has been said that Commendo abounds in gold mines, but that the king, for fear of exciting the avarice of the Europeans, prohibits the working of them. This country is divided into two distinct provinces. We shall content ourselves with describing Little Commendo. This province is called by the Portuguese Aldea das Terras, and by the natives Ekki Tekki. The town is said to contain at least 100 houses. It is situated on the banks of a fine rivulet, that empties itself into the sea on the southward, which forms a kind of canal, or little oblong harbour for canoes. The N.E. side of the town, where the French had formerly a settlement, is bordered by little hills, at the foot of which lie fine rich meadows and pasture, as well as fertile fields, every where interspersed with groves of fruit-trees. Little Commendo, which was once a place of great note, and one of the finest towns in Guinea, has since exhibited only the remains of a town destroyed by fire, and the well peopled ruins of a once flourishing and great city. The natives of Little Commendo are in general turbulent, cunning, and deceitful; much addicted to lying and stealing. Their employment consists either in fishing or in commerce, and their neighbours employ them as brokers and factors, particularly the people of Akamen, who carry on a considerable trade. Every morning 70 or 80 large canoes may be seen upon the coast fishing, or trading with the European shipping in the road. About the middle of the day they put to shore when the south-west winds begin to blow, both for facility of unloading, and for securing a market for their cargoes, either at Great or Little Commendo, where the inland negroes assemble with the commodities of their principal countries. No markets on earth are better supplied with all sorts of grain, roots, fruits, pulse, and fish, than these, nor at a more reasonable price. Here the English and Dutch have forts. Next to Cape Coast, the English fort is said to be the principal which they possess in Guinea, at least on the Gold Coast. The Dutch fort of Wodenborough, lies at the distance of a musket shot, and was built in the year 1688. N. lat. $4^{\circ} 54'$. E. long. $0^{\circ} 34'$.

The principal commodities for which there is a demand by the negroes of Commendo, are galls beads, brass bells, and buttons, long linen cloths and woollen stuffs. They are very dextrous in the adulteration of gold, and the practice is very common. When the people of Commendo are at war, they have usually a slave-market at Little Commendo, for the more quick dispatch of their business. Here also they keep quantities of gold in the hands of certain agents employed to carry on trade, while the rest are fighting the enemy in the field. The gold trade, however, is not very considerable.

COMMENDONE, GIANFRANCESCO, in *Biography*, an eminent prelate in the church of Rome, was born at Venice in 1524, and began, at the early age of ten years, to compose verses. He pursued his studies at Padua, and in the year 1550, he was introduced to pope Julius III., by whom he

was made chamberlain, and afterwards employed on public business. In 1553, he accompanied the legate cardinal Baddino to Flanders, and from thence he was dispatched secretly to England, to enquire into the state of religion under queen Mary. Paul IV. made him bishop of Zart, and commissioned him to excite the different states of Italy to unite with him in a common league. By Pius IV. he was raised to the office of cardinal in 1565, while he was nuncio in Poland. He was employed in various other missions to foreign states, and in all these he acted with zeal for his church, and executed whatever was committed to his charge with the utmost dispatch and fidelity. Under Gregory XIII. he was promoted by the imperial faction for having too great a partiality towards France; his own party was, however, so strong, that he was not only acquitted, but upon a dangerous illness of the pope, it was projected to raise him to the papal crown. The pope, by recovering his health, disappointed his expectations, and Commendone himself died at Padua, in December, 1584. He is not celebrated as an author, having left behind him only some Latin poems, among those of the Academy of Occulti, of which he was the zealous patron, and some letters inserted in the notes to those of Julio Poggiano. Commendone was reckoned one of the ablest politicians of his own time, a man of great learning, and a friend to literature. He cultivated an intimate friendship with many of the most eminent scholars in Italy, and to him were addressed some letters of Annibal Caro. Gen. Biog.

COMMENSURABLE *Quantities*, in *Geometry*, are such as have some common aliquot part, or which may be measured or divided without leaving a remainder, by some measure or divisor, called their common measure. Thus, a foot and a yard are commensurable; there being a third quantity which will measure each, viz. an inch; which taken 12 times makes a foot, and 36 times a yard.

Commensurables are to each other as one rational whole number to another. In incommensurables it is otherwise. The ratio of commensurables, therefore, is rational; that of incommensurables irrational: hence, also, the exponent of the ratio of commensurables is a rational number.

COMMENSURABLE *Numbers*, in *Arithmetic*, whether integers or fractions, are such as have some other number which will measure or divide them without any remainder. Thus, 6 and 8, both divided by 2, are respectively commensurable numbers: $\frac{2}{3}$ and $\frac{4}{3}$, or $\frac{1}{3}$ and $\frac{2}{3}$, are commensurable fractions, because the fraction $\frac{1}{6}$ or $\frac{1}{12}$ will measure them both; and in this sense all fractions may be said to be commensurable.

COMMENSURABLE in *Power*. Right lines are said to be commensurable in power, when their squares are measured by one and the same space, or superficies.

COMMENSURABLE *Surds*, are such surds as, being reduced to their least terms, become true figurative quantities of their kind; and are therefore as a rational quantity to a rational: such are $3\sqrt{2}$ and $2\sqrt{2}$ being one to the other as 3 to 2. See *Surd*.

COMMENTACULA, among the Romans, the rods which the flamens carried in their hands when going to sacrifice.

COMMENTARIENSIS, in *Ancient Military Language*, the person who was gaoler of the soldiers' prison among the Romans, and kept its registers. He was subject to the "triumviri capitales."

COMMENTARY, or COMMENT, a gloss, or interpretation, affixed to some ancient, obscure, or difficult author, to render him more intelligible, or to supply what he has left undone. The biblical student may find some judicious and useful remarks on commentators, or those who have written commentaries on the Sacred Scripture, in Mr. Locke's Preface

face to his Paraphrase and Notes on the Epistles of St. Paul.

COMMENTARY is also used for a sort of history, written by a person who had a chief hand in the transactions related.

Such are the commentaries of Cæsar, of Sleidan, Montluc, &c.

The word is also used for certain books written on some particular subject: Kepler has an excellent book of commentaries on Mars, containing observations on the motion of that planet.

COMMEQUIERS, in *Geography*, a town of France, in the department of the Vendée, 15 miles N. of Sables d'Olonne.

COMMERAGH, or CUMMERAGH, the name of a high ridge of mountains which lie between Dungarvan and Clonmel, in the county of Waterford, Ireland. On the sides of this chain, says Dr. Smith, are many horrid precipices and steep declivities, and the vallies are full of large fragments intermixed with sand and gravel. On the tops of most of them are also large heaps of stones. Smith's Waterford.

COMMERCE, the interchange of commodities, or the disposal of produce of any kind for other articles, or for some representative of value for which other articles can be procured, with the view of making a profit by the transaction. The term is usually restricted to the mercantile intercourse between different countries; the internal dealings between individuals of the same country, either for the supply of immediate consumption, or for carrying on manufactures, being more commonly denominated *trade*.

The mutual convenience of an exchange of commodities, must have been evident almost as soon as any part of mankind had acquired an idea of distinct property; the difficulty of communication between different countries must, however, have long rendered commercial intercourse very limited and uncertain. The dangers attending long journeys induced those who engaged in trading to distant parts, to associate together for mutual assistance and defence; and these companies of merchants, or caravans, were well adapted for the improvement of commerce, from the information which the individuals composing them would communicate to each other, and the connections they might occasionally form. In the book of Genesis, mention is made of the companies or caravans of Ishmaelite merchants trading in spices from Gilead into Egypt; to one of whom Joseph was sold, about 620 years after the flood. But this mode of communication between different countries was insufficient for the enterprising spirit of commercial adventurers; remote countries cannot convey their commodities by land to those places where, on account of their rarity, they are most desired, and consequently become most valuable. It was not till some progress had been made in the art of navigation, that the power was acquired of transporting with facility the superfluous stock of one part of the earth to supply the wants of another part, and that the active spirit of commerce could extend its multifarious concerns to all the known parts of the globe.

The Egyptians, soon after the establishment of their monarchy, are said to have opened a trade between the Arabian Gulph or Red Sea, and the western coast of the great Indian continent. The commodities which they imported from the east, were carried by land from the Arabian Gulph to the banks of the Nile, and conveyed down that river to the Mediterranean: but the maxims and manners of Egypt were inimical to commerce, and this profitable traffick soon declined.

The situation and circumstances of the Phenicians naturally led them to look to commerce as the only source from which they could derive opulence or power; and accordingly, the foreign trade carried on by them, particularly from Sidon and Tyre, became more extensive and important than that of any state in the ancient world. Their ships not only frequented all the ports in the Mediterranean, but they were the first who ventured beyond the ancient boundaries of navigation, and passing the straits of Gibraltar, visited the western coasts of Spain and Africa. They revived a commercial intercourse with Arabia and the continent of India, on the one hand, and with the eastern coast of Africa on the other; the cargoes which they purchased in Arabia, Ethiopia, and India, being landed at Elath, the safest harbour in the Red Sea towards the north: thence they were carried by land to Rhinocolura, the distance not being very considerable, and being re-shipped in that port, were transported to Tyre, and distributed over the world.

The wealth which the Phenicians acquired by monopolizing the commerce of the Red Sea, incited their neighbours, the Jews, under the prosperous reigns of David and Solomon, to aim at being admitted to some share of it. Solomon fitted out fleets, which, navigated by Phenician pilots and mariners, sailed from the Red Sea to Tarshish and Ophir, from whence they brought such valuable cargoes as suddenly diffused wealth and splendour through the kingdom of Israel. But the institutions of the Jews were by no means favourable to commerce, which was never carried to any great extent by them while they inhabited Judea.

The Carthaginians applied themselves to commerce and navigation with ardour, ingenuity, and success; but as the Phenicians had engrossed the commerce of India, their adventures were chiefly made to the west and north. Following the course which the Phenicians had opened, they extended their voyages beyond the shores of the Mediterranean, visiting not only all the coasts of Spain, but those of Gaul, and penetrating at last to Britain. They made voyages of discovery in different directions, and thus established a commercial intercourse with places which before were wholly unknown; but whatever knowledge of this kind they acquired, it was concealed from the inhabitants of other states with the utmost care.

The Greeks, although their country was almost encompassed by the sea, which formed many spacious bays and commodious harbours, and though it was surrounded by a number of fertile islands, were, notwithstanding such a favourable situation, a long time before they attained any degree of perfection in navigation. They scarcely carried on any commerce beyond the limits of the Mediterranean. Their chief intercourse was with the colonies of their countrymen planted in the lesser Asia, in Italy, and in Sicily. They sometimes visited the ports of Egypt, of the southern provinces of Gaul, and of Thrace, or passing through the Hellespont, they traded with the countries situated around the Euxine sea. The expedition of Alexander into the east considerably enlarged the geographical knowledge of the Greeks. He had observed the resources which commerce creates, in the exertions of the republic of Tyre, and therefore it became part of his plan to render the empire which he proposed to establish, the centre of commerce as well as the seat of dominion. With this view, he founded Alexandria near one of the mouths of the Nile, that by the Mediterranean sea, and the neighbourhood of the Arabian gulph, it might command the trade both of the east and west. This situation was so judiciously chosen, that Alexandria soon became the chief commercial city in the world. Not only during the subsistence of the Grecian empire in Egypt and

in the east, but amidst all the succeeding revolutions of those countries, commerce, particularly that of the East Indies, continued to flow in the channel which the sagacity and foresight of Alexander had marked out for it, till the discovery of the navigation by the Cape of Good Hope opened a more expeditious and independent channel to all the maritime states of Europe.

In the early periods of the Roman history, commerce appears to have been much neglected and undervalued; it seems to have been thought a degrading employ by this military people, and to have been left almost entirely in the hands of the natives of the countries they conquered. The extent, however, of the Roman power, which included the greatest part of the known world, the vigilant inspection of the Roman magistrates, and the spirit of the Roman government, no less intelligent than active, gave such additional security to commerce, as animated it with new vigour; and, as soon as the Romans acquired a taste for the productions of other countries, commerce, particularly the trade with India through Egypt, was pushed with new vigour, and carried on to a greater extent. The pilots who sailed from Egypt to India first ventured to quit sight of the shore, and depending wholly on the trade winds, boldly sailed from Ocellis at the mouth of the Arabian gulph, across the ocean, to the coast of Malabar, returning with the eastern monsoon, and thus procuring the spices and other rich commodities of the continent and islands of the farther India, which were brought to the port of Muziris by the Indians themselves. The commerce thus carried on will appear considerable even in the present age, as the trade with India is said to have drained the Roman empire every year of more than four hundred thousand pounds, and that one hundred and twenty ships sailed annually from the Arabian gulph to that country. The reign of Augustus was very favourable to commerce, as the peace which then prevailed over the civilized parts of the world, enabled the merchants to pursue it unmolested. Under Tiberius we find the Romans extending their protection to the north, and the town of Havern, the most ancient in Friesland, founded. Under Nero, the capital of England is first mentioned as a considerable place. Tacitus, who lived for some time at London, says it was famous for its many merchants, and plenty of its merchandize. Rome, however, as the seat of wealth and luxury, continued to be the metropolis of the commercial world, until the fourth century, when Constantine removed the seat of empire to Constantinople, and made it the emporium of commerce. This city was undoubtedly well adapted for that honour; it was favoured by nature with a fine climate, and in a most advantageous situation for carrying on an extensive correspondence with every part of the world then known.

The invasion by the northern nations in the fifth century, not merely arrested the progress of commerce, but effectually dissolved all commercial connections, and deprived the merchants of any market for their commodities. Europe became parcelled out into many small and independent states, differing from each other in language and customs; no intercourse subsisted between the members of these divided and hostile communities; their mode of life was simple, they had few wants to supply, and few superfluities to dispose of. Cities, in which alone an extensive commerce can be carried on, were few, inconsiderable, and destitute of those immunities which produce security or excite enterprise. It became disagreeable and dangerous to visit any foreign country, and thus the knowledge of remote regions was lost; their situation, their commodities, and almost their names, were unknown. The preservation of Constantinople from

the general destruction, however, prevented commercial intercourse with distant nations from ceasing altogether. In that city the knowledge of ancient arts and discoveries was preserved; a taste for splendour and elegance subsisted; the productions of foreign countries were in request; and commerce continued to flourish there when it was almost extinct in every other part of Europe. The merchants of Constantinople did not confine their trade to the islands of the Archipelago, or to the adjacent coasts of Asia; they took a wider range, and following the course which the ancients had marked out, imported the commodities of the East Indies from Alexandria. When Egypt was torn from the Roman empire by the Arabians, the industry of the Greeks discovered a new channel, by which the productions of India might be conveyed to Constantinople. They were carried up the Indus, as far as that great river is navigable; thence they were transported by land to the banks of the river Oxus, and proceeded down its stream to the Caspian sea. There they entered the Volga, and sailing up it, were carried by land to the Tanais, which conducted them into the Euxine sea, where vessels from Constantinople waited their arrival. This extraordinary and tedious mode of conveyance, Dr. Robertson observes, is a proof not only of the violent passion which the inhabitants of Constantinople had conceived for the luxuries of the east, and of the ardour and ingenuity with which they carried on commerce, but it demonstrates, that during the ignorance which reigned in the rest of Europe, a knowledge of remote countries was still preserved in the capital of the Greek empire. Robertson's Hist. Amer. vol. i.

The devastations of the Huns in Italy induced many of the richest inhabitants of the country near the bottom of the Adriatic, to fly with their best effects into the numerous small sandy isles lying amongst the shallow waters near the shores of the continent; on which isles, about seventy-two in number, they built such habitations as their circumstances would admit; and here by degrees arose the celebrated commercial city of Venice. Necessity first obliged them to devote themselves to commerce, the earliest branch of which was naturally the fisheries. Their next commercial object was the manufacture and exportation of salt. Thus by the application of its inhabitants, and the security of its situation, Venice gradually became the general magazine for the merchandize of the neighbouring continent, to which the many rivers that fall into the Adriatic sea greatly contributed; and as the Venetians in time became the carriers of this merchandize into distant countries, they were enabled to bring back raw materials for various manufactures which greatly enlarged their commercial dealings.

In this manner, Venice first, and Genoa, Florence, and Pisa afterward, from inconsiderable places became populous and wealthy cities, and laid the foundation for the revival of commerce throughout the Mediterranean, which, in process of time, was extended to the countries of Europe without the freights of Gibraltar. The free cities of Italy, were, for several centuries, the only places in Europe, west of the Eastern or Greek empire, which had any considerable commerce, or any valuable manufactures for the supply of other nations. Their merchants frequented Aleppo, Tripoli, Alexandria, and other ports of Syria and Egypt, where they procured the produce of India; and visiting the maritime towns of Spain, France, the Low Countries, and England, by distributing their commodities over Europe, communicated to its various nations some taste for the valuable productions of the east, as well as some ideas of manufactures and arts, which were then unknown beyond the precincts of Italy.

The first mention of the city of Antwerp, afterwards so famous for its trade, is in the year 517, when Theodorick expelled the Danes from it. Some towns in England, as Clichelster and Abingdon, are said to have been founded about this time, which shews that trade and manufactures were gaining ground in this country.

The unsettled state of Europe, arising from the fierce and restless disposition of the barbarous tribes who had taken possession of the western empire, caused for several centuries a great stagnation of commercial intercourse. Venice however continued to improve its commerce, and London became "a mart town of many nations, which repaired thither by sea and land." Some of the Italian cities began to assume a degree of independence, and several towns were founded in Germany and Flanders, which afterwards became of much commercial importance. The commerce of Europe revived a little under the government of Charlemagne, who, among other endeavours to promote it, is said to have formed a project for uniting the two great rivers of the Rhine and the Danube, and thus forming a communication between the German ocean and the Black sea, without failing up the Mediterranean. But his engineers had not sufficient skill to overcome the difficulties they met with, and the undertaking was soon relinquished. In a letter from this prince to Ossa, king of Mercia, he grants leave for such English as went in pilgrimage to Rome, to pass through his dominions free; but such as travelled for the purposes of trade were to pay the customary tolls; and promises that the merchants should have legal patronage and redress of grievances. These merchants were probably persons who carried their whole stock with them, which of course could not be of any very great amount.

The establishment of Christianity in Germany produced a much more intimate and regular correspondence between the north of Europe, and the earlier Christianized countries of Italy, France, Spain, and Britain; so that their superfluities and produce were mutually communicated to each other, while Germany received by degrees, from its intercourse with those countries, considerable improvements with respect to agriculture, mining, vine-dressing, manufactures, and the arts, more immediately conducive to the comforts of civilized life. It considerably increased the cities and towns, where cathedral churches and houses for the bishops and clergy were erected. Thus the propagation of Christianity greatly favoured the advancement of commerce in the north of Europe; while Charlemagne by his conquest of Italy, and by rebuilding and restoring many of the decayed cities of that country, inspired those cities with the spirit of commerce, manufacture, and navigation, for which they became in after times so justly famous. This period may be considered as the first dawn of the revival of commerce in Europe; for although subsequent to this time the Saracens or Moors, and the Normans, by their ravages and conquests in various parts, greatly obstructed and retarded its progress, yet in spite of all opposition, the free cities in both the extreme parts of Europe in consequence of the increase of their wealth and population from the encouragement of commerce, gradually arose to very considerable importance.

In the tenth century, the commercial intercourse which the Germans had previously cultivated with the neighbouring states was much increased by the discovery of valuable silver mines at Goslar in Saxony, which occasioned other parts of Germany to be explored for mines with considerable success. The woollen manufacture of Flanders began to acquire some degree of importance, being much encouraged by Baldwin, third earl of Flanders, who invited into

the country all manner of handicraftsmen for making all sorts of manufactures, to whom he granted great privileges. He also established annual fairs, and fixed markets on stated days of the week at Bruges, Courtray, Tournout, Mont-Cassel, and other places, where merchants could exchange their goods for others; for "by reason of the scarcity of money at that time, the Flemings dealt mostly by permutation, or barter of one kind of merchandize for another; which we read was also the practice of almost all the Germans and Sarmatians."

The republic of Venice had now acquired so much wealth and strength by the great extension of her commerce, as to have become a formidable political state, and having annexed to their dominions many cities and towns on the east coast of the Adriatic sea, the doge of Venice assumed the title of duke of Dalmatia. They established a regular commercial intercourse with the Saracens of Egypt and Syria, "countries ever famous for the production of rice, sugar, dates, senna, cassia, flax, linen, balm, perfumes, galls, wrought silk, soap, &c. besides the rich spices and precious stones of India, brought to those two countries; with all this rich merchandize, the Venetians now traded all over the western parts of Europe, to their immense profit." They obtained from the Greek emperors a freedom from all customs and taxes in their empire; and in the year 996 the emperor Otho III. likewise granted them various privileges, with a right to set up fairs in several parts of Germany, where they carried on a vast commerce.

The crusades contributed materially to the extension of commerce during the 11th and 12th centuries. The Genoese, the Pisans, and the Venetians, furnished the transports necessary to carry the vast armies that embarked on these wild enterprises; they also supplied them with provisions and military stores. Besides the immense sums which they received on this account, they obtained commercial privileges and establishments of great consequence, in the settlements which the crusaders made in Palestine, and in other provinces of Asia. From these sources they acquired great wealth, and a proportionate increase of power. By the expeditions into Asia, the inhabitants of all the states of Europe had an opportunity of observing the manners, the arts, and the accommodations of people more polished than themselves. The adventurers who returned from Asia communicated to their countrymen the ideas which they had acquired, and the habits of life they had contracted by visiting more refined nations. The Europeans began to be sensible of wants with which they were formerly unacquainted; and such a taste for the commodities and arts of other countries gradually spread among them, that they not only encouraged the resort of foreigners to their harbours, but began to perceive the advantage and necessity of applying to commerce themselves.

The great commercial progress of the city of Lubeck soon caused other towns to be founded in the neighbourhood of the Baltic; which, suffering much from the occasional attacks of neighbouring powers, and the depredations of pirates, were induced to enter into an association for their mutual safety, and the protection of their navigation. This was gradually formed the famous Hanseatic confederacy, which made so great a figure in the commercial history of several succeeding centuries, and of which Lubeck was from the first considered as the director or head. Werdenhagen fixes on the year 1169 for the first of this confederacy, which consisted of the twelve following towns on the Baltic shore: viz. Lubeck, Wismar, Rostock, Straelsund, Grypswald, Anclam, Stetin, Colberg, Stolpe, Dantzick, Elbing,

and Königsberg; though probably not all of them at the first; as some of them do not appear to have been founded till a later period. Lambecius, librarian to the emperor Leopold, is of opinion, that the Han-league did not properly commence till after the league between Lubeck and Hamburgh in 1241, at which time the towns comprehended in this association were in possession of all the commerce of the fourth shores of the Baltic, from Denmark to the bottom of the gulph of Finland, besides an extensive commerce to more distant parts. About this time the commerce of Norway began to acquire some degree of importance, and in a treaty between the monarch of that country and Henry III. of England, in 1217, it was agreed that their respective states should be free for merchants and others on both sides.

At the beginning of the 13th century, the German merchants of the Steel-yard engrossed all the foreign commerce which then existed in England, which at that time had very few merchants, and fewer ships of her own. About 1250, however, a society of English merchants was formed, who are said to have had privileges granted to them in the Netherlands, by John duke of Brabant; whither they had begun to resort with English wool, lead, and tin, bringing in return fine woollen cloths, linen, and other articles. From this society, the company styled "Merchants of the Staple of England" took its rise. In 1274, a treaty was concluded with the earl of Flanders for the settlement of some commercial disputes which existed between the two countries.

France at this period possessed very little foreign commerce, but in the cities of Italy it had increased greatly. The republic of Genoa was in its meridian glory, being the greatest maritime power then existing. Even Venice, great as it was now become, was eclipsed by Genoa, which, towards the conclusion of this century, had reduced the republic of Pisa, till then also powerful at sea, to the lowest ebb of fortune, never again to rise to greatness, and soon to lose her independence.

A new era was now about to commence in commercial history. The discovery of that valuable, but now familiar instrument, the mariner's compass, Dr. Robertson observes, may be said to have opened to man the dominion of the sea, and to have put him in full possession of the earth, by enabling him to visit every part of it. But the effects of this discovery were not so sudden or extensive as might be expected. The use of the compass enabled the Italians to perform the short voyages to which they were accustomed, with greater security and expedition, but near half a century elapsed, before navigators ventured into any seas which they had not been accustomed to frequent. One of the first fruits of such adventures, was the discovery of the Canary islands by the Spaniards.

Many of the princes of Europe were now becoming more sensible of the importance of commerce, which led them to enter into treaties for its regulation and defence. Edward I. in 1302 published his famous charter styled Charta Mercatoria, by which "The merchants of Almaine, France, Spain, Portugal, Navarre, Lombardy, Florence, Provence, Catalonia, Aquitaine, Thouloufe, Flanders, Brabant, and of all other foreign parts, who shall come to traffic in England, shall and may safely come with their merchandize into his cities, towns, and ports, and sell the same, by wholesale only, as well to natives as to foreigners." Some particular articles they were allowed to sell by retail; and they were to export any goods they might want from England on paying the usual customs, except wine, which could not be exported without a special licence. The countries here mentioned shew the

parts to which the commerce of England was at that time chiefly confined; and a very good idea of its extent may be gained from the following account of the exports and imports, in the 28th year of Edward III. from a record in the Exchequer.

<i>Exports.</i>	<i>£.</i>	<i>s.</i>	<i>d.</i>
31,651½ sacks of wool, at six pounds per sack, and 3036 hundred weight and 65 fells, each hundred weight being 6 score, at forty shillings per hundred weight, with the customs, &c. thereon, amounted to	277,605	2	9
Leather, with its custom	95	2	6
477½ coarse cloths, at 40 shillings each, and 8061½ pieces of worsted, at 16s. 8d. per piece	16,266	13	4
Customs thereon	-15	13	7
Total Exports, with the duties thereon	294,184	17	2

<i>Imports.</i>	<i>£.</i>	<i>s.</i>	<i>d.</i>
1831 fine cloths, at 6l. per cloth, which, with the customs, comes to	11,033	12	0
397¾ hundred weight of wax, at 40 shillings per hundred weight, which, with the customs, comes to	815	7	5
1829½ tons of wine, at 40 shillings per ton, which, with the customs, comes to	3,841	19	0
Linen cloth, mercery, grocery, and all other wares whatever	22,943	6	10
On which the custom was	-285	18	3
Total Imports, with the duties thereon	38,970	3	6

Thus, as sir William Temple observes, "when England had but a very small foreign commerce, we were rich in proportion to our neighbours, by selling so much more than we bought." It is not very probable, however, that the excess of the exports was generally so great as is here stated.

The materials of commerce were now increasing by the improvement of manufactures in various parts of Europe; while the discoveries of the Portuguese on the coast of Africa, and in the adjacent seas, excited a more enterprising spirit of mercantile adventure, and at length, in 1487, led to the discovery of the Cape of Good Hope, which they doubled about ten years after, and thus accomplished the first regular voyage to the East Indies. About the same time also was accomplished the great discovery of the western continent. These events, which filled the world with astonishment, and gave rise to an infinity of new speculations, have since supplied it with a prodigious increase of wealth, and with many new and excellent materials for the immense additional commerce which has thus accrued to all the states of Europe.

The whole of the vast regions discovered in the East and West, was by the papal authority divided between the Spaniards and Portuguese. The former first made herself mistress of the islands, and next of the principal part of the continent of America; in consequence of which the cities of Seville and Cadiz became the store-houses for the riches of the newly-discovered western world. Portugal pursued her commerce and rapid conquests in the East Indies, so that

Lisbon

Lisbon soon became (what the now declining city of Venice had been for many centuries past) the great magazine for all the rich productions of the East. They had also discovered Brazil in South America, which soon became an almost inexhaustible fund of wealth to Portugal, which may be said to have been then at the height of its commercial greatness.

In the course of the 16th century many circumstances occurred which contributed greatly to the extension of commerce. The English in the pursuit of a north-west passage to India had discovered the whole coast of North America, where, after some years, they began to attempt settlements. They engaged in the Newfoundland fishery, and also in the whale fishery at Spitzbergen or Greenland. The continual jealousies and disputes between the English merchants and the German Hanseatic merchants of the Steel-yard in London, were at length terminated by the abolition of the peculiar privileges of the latter. The discovery of a passage to Russia round the north Cape of Lapland, opened a field for other new discoveries, and new branches of commerce; in consequence of which a company for trading to Russia was immediately formed and incorporated. The commerce with Turkey was encouraged by the incorporation of a company; and the intercourse with Guinea and other places on the coast of Africa, was also thought of sufficient importance to have a company established for carrying it on.

While the importance of the Italian cities was declining, and the commerce of the towns on the Baltic experiencing some diminution, the cities of Hamburg and Antwerp had risen into considerable importance. The latter in particular, from the convenience of its situation, might for some time be considered as the centre of the commerce of Europe, as well for the merchandize of both the Indies, as for the naval stores and other bulky commodities of the northern states. It was however soon to find a rival among its industrious neighbours in the United Provinces, who, from the time of their independence, applied themselves to manufactures and commerce with the utmost assiduity. France was at this time beginning to encourage the cultivation of the vine, and the improvement of her broad silk manufacture; while Spain, by expelling the protestants from the Netherlands, supplied England, Holland, and the Hanse-towns with great numbers of wealthy and industrious manufacturers and artificers, as well as with an accession of many ingenious and beneficial new manufactures.

The 17th century was the period in which the principles were adopted, and most of the establishments formed, which have contributed to advance the commerce of Europe to its present astonishing height. The interests of nations became better understood than in any former age; the utility of commerce had become evident to every one, from the wealth and power it had conferred on the states which had encouraged it; and commercial treaties became frequent between the different nations. Navigation was improved; new settlements were formed, and many of those before made were rising into importance; manufactures were advancing in many parts of Europe; shipping was increasing, and the intercourse between distant places, from the accumulation of knowledge and experience, becoming more expeditious and secure.

The lucrative commerce of the East became one of the leading objects of mercantile pursuit. An English East India company was formed in 1600; and the Dutch companies, which were united in 1602, became one of the most celebrated commercial establishments ever formed. The French visited the East Indies in 1601, but did not establish a regular company for carrying on the trade till 1664. The

Danes established an East India company in 1617, and in 1627 the king of Sweden issued letters patent for forming an East India company, but it was not carried into execution till some years after. The Spaniards and Portuguese, however, at this period, possessed by far the greatest share of the commerce of India, which had now become very considerable. The following account published by Mr. Munn, in 1621, of the quantity of Indian merchandize consumed annually in Europe, gives a very good idea of the proportion of the different articles of this branch of commerce: the prices affixed are the prime cost in India, including all charges till actually shipped for Europe.

	s.	d.
6,000,000 lb. pepper, at	0	2½ per lb.
450,000 lb. cloves, at	0	9 per lb.
150,000 lb. mace, at	0	8 per lb.
400,000 lb. nutmegs, at	0	4 per lb.
350,000 lb. indigo, at	1	2 per lb.
1,000,000 lb. raw silk, at	8	0 per lb.

This statement was probably meant to include only the principal articles; at least it is certain that about 1631 several other kinds of merchandize were usually imported from India, as taffaties, painted calicoes, druzs of various sorts, and China ware. Tea, the great object of commercial intercourse with China, was either not yet an object of commerce, or was imported in such small quantities, that in England at least, in 1660, it was not thought of sufficient consequence to be subjected to a duty.

Dr. Davenant, who published his "Discourses on Trade" in 1698, was of opinion, that from about the year 1556 to 1688, England had every year gradually increased in riches; and that about the last mentioned year, the increase or addition to the wealth, and general stock of the nation, arising from foreign trade and home manufactures, was at least two millions per annum. In this estimate the different branches of trade are stated as follows:

The plantation trade may bring in	-	£ 600,000
The East India trade may bring in	-	500,000
The European, African, and Levant trade, by our own product may bring in	-	600,000
Ditto, by re-exports of plantation goods	-	120,000
Ditto, by re-exports of East India goods	-	180,000
Total	-	2,000,000

This account is probably somewhat beyond the truth, with respect to the period to which it refers; but that there had been a considerable influx of wealth, is shewn by the observations of the same author, that from the year 1600 to 1688, the general rental of England was nearly trebled, and the purchase of land half doubled; that the stock of the kingdom was multiplied above five fold, and the money in circulation above four fold. This rapid advance in wealth, can be ascribed to no other cause than the improvement of commerce, which was now becoming of the utmost importance to all the European states, particularly to such as were desirous of maintaining any degree of naval power.

The increase of wealth arising from the extension of commerce, gave rise to the establishment of banks, by which its operations have of late years been so much facilitated. The commercial cities of Venice and Genoa had long experienced the utility of such institutions, which were now adopted in other states. The banks of Amsterdam, of

COMMERCE.

Hamburgh, and of Rotterdam were established; and in 1694, the bank of England, and the bank of Scotland. The business of private bankers likewise took its rise, and had become considerable, when it received a severe check from the unjustifiable conduct of Charles II. in seizing the money which the bankers had advanced on credit of the tax. This branch of mercantile intercourse has however been since carried to an extent which in former times would have been deemed wholly incredible.

This, with its principles generally understood; with most of the establishments formed which are necessary to facilitate its operations; with laws and treaties in force for its encouragement and protection; markets established for the purchase or sale of commodities in almost every part of the globe; navigation brought to a high degree of perfection, vast improvements in arts and manufactures; and a great increase of artificial wants from the progress of luxury and refinement; the commerce of the world, and particularly of Europe, has, during the 18th century, expanded in an astonishing degree, and become intimately connected with the political existence of almost every state.

COMMERCE of Great Britain. The most authentic materials from which an idea can be formed of the progress and extent of the commerce of Great Britain, are the accounts kept in the office of the inspector-general of exports and imports, at the custom-house of London. These accounts do not shew the current value of the commodities exported or imported, but are formed from their quantities, according to certain rates of value, affixed to the several articles of foreign trade in 1696, by which they have been rated ever since. It is evident, therefore, that, as the price of all kinds of merchandize is subject to great fluctuation, and in general has much increased in this country within the last hundred years, these accounts are far from shewing the actual values in the later years; they are, however, from this very circumstance of being uniformly made up at the same rates, the better adapted to a comparative view, and shew a progressive increase which has arrived to an amount never before known in the commerce of any nation. According to these estimates the total amount of the exports and imports of Great Britain have been as follows:

Years.	Imports.	Exports.
1700	£ 5,970,175	£ 7,302,716
1701	5,869,606	7,621,053
1702	4,159,304	5,235,874
1703	4,526,596	6,644,103
1704	5,383,200	6,552,019
1705	4,031,649	5,501,077
1706	4,113,933	6,512,086
1707	4,274,055	6,707,178
1708	4,638,663	6,069,089
1709	4,510,593	6,027,045
1710	4,011,341	6,090,828
1711	4,685,785	6,447,170
1712	4,454,682	7,468,857

At the conclusion of the war, by the peace of Utrecht, a commercial treaty with France was likewise negotiated; but when the particulars of it came to be discussed, two of the articles, by which the produce and manufactures of France were to be admitted into this country on the same terms as those of the most favoured nation, excited such general disapprobation, that the bill for carrying it into effect was rejected by the house of commons. The strongest objections to the principle of the treaty, was that it might ruin the trade then carried on with Portugal, which was

considered as the most valuable branch of our European commerce.

It is evident, that from the year 1705, notwithstanding the disadvantages it always labours under in time of war, commerce had been gradually increasing; but when peace enabled it to return to its usual channels, and restored some branches which had been considerably interrupted, its general advancement became more obvious, and although from the mode then usually adopted, of judging of the profits of commerce merely by the excess of the value of the exports, the balance appeared less than it had been in former years, the wealth which flowed into the country from foreign trade, being no longer absorbed in public loans, soon enabled the government to make a permanent reduction in the legal rate of interest. The war with Spain in 1718, did not cause much interruption of commercial intercourse, except in the direct trade with that country.

Years.	Imports.	Exports.
1713	£ 5,811,077	£ 7,352,055
1714	5,929,227	8,361,638
1715	5,640,943	7,379,409
1716	5,800,258	7,614,025
1717	6,346,778	9,147,700
1718	6,609,390	8,555,202
1719	5,507,499	7,295,528
1720	6,090,083	7,936,728
1721	5,768,510	8,681,200

At this period the judicious principle of promoting the exportation of British manufactures, which had hitherto been applied only to woollen goods, was extended to British manufactures and produce in general; which were allowed to be exported duty free, except a few articles chiefly materials for manufactures, the exportation of which it would not have been proper to encourage; while drugs and other materials used for dyeing, were, upon being first duly entered, to be imported duty free, but upon re-exportation were to pay specific duties. For this highly beneficial regulation, so simple in its principle, and so comprehensive in its extent, the country was indebted to the enlightened wisdom of Mr. Walpole: the experiment excited much doubt and solicitation as to its success, but it soon appeared that the loss of revenue in the duties thus given up, was a mere trifle in comparison with the stimulus it gave to manufactures and the consequent extension of commerce.

Years.	Imports.	Exports.
1722	£ 6,378,098	£ 9,650,789
1723	6,505,676	9,489,811
1724	7,394,405	9,143,356
1725	7,094,708	11,352,480
1726	6,677,805	9,406,731
1727	6,798,908	9,553,043
1728	7,569,299	11,631,383
1729	7,540,620	11,475,771
1730	7,780,019	11,974,135
1731	6,991,500	11,167,380
1732	7,087,914	11,786,658
1733	8,016,814	11,773,206
1734	7,095,861	11,000,645
1735	8,160,184	13,544,144
1736	7,307,966	11,616,356
1737	7,073,638	11,842,320
1738	7,438,960	12,289,495

The above period was almost wholly a time of peace, during which the commerce of Great Britain was gradually advancing,

advancing, both from the improvement of several of the existing branches, and the acquisition of new ones. The South-Sea company undertook the Greenland whale fishery, which had been entirely relinquished by this country for some years past; and encouragement was given to fisheries on the coast of America. Attempts were made to obtain a share of the fur trade of north America, which was almost entirely in the hands of the French. The Ostend East India company, which had been found prejudicial to the English trade in those parts, was suspended; while our trade with China increased considerably, particularly in the article of tea. The trade of the Levant company was very flourishing; as was likewise that of the Hudson's bay company, though the latter was but of small extent. The produce of several valuable commodities was at the same time augmenting, from an increased cultivation of rice in the American colonies, and of coffee in the West India islands, while great quantities of corn were annually exported from Great Britain to France, Portugal, Spain, and Italy.

The war which began in 1739, was occasioned chiefly by disputes respecting our commerce in the West Indies, which had been much interrupted by the Spaniards. It ceased, at first, some decline of foreign trade, which however soon regained the extent to which it had been carried during the preceding peace.

Years.	Imports.	Exports.
1739	£ 7,829,373	£ 9,495,366
1740	6,703,778	8,809,939
1741	7,936,084	11,469,872
1742	6,866,864	11,584,427
1743	7,802,353	14,623,653
1744	6,362,971	11,429,628
1745	7,847,123	10,497,329
1746	6,205,687	11,360,792
1747	7,116,757	11,442,049
1748	8,136,408	12,351,433

At this time, a much greater proportion of the exports consisted of unmanufactured produce than it has since; as it appears there had been exported from England in five years, from 1744 to 1748, no less than 3,768,444 quarters of corn, which at medium prices was worth 8,007,048 l.

That a considerable increase of commerce had taken place, is evident from the quantity of shipping employed. The total tonnage of vessels that cleared outwards on an average of three years preceding the war, had been 503,568 tons; the average of the three years, ending with 1751, was 661,184 tons. The encouragement of the fisheries, and the regulation of the Guinea or African trade, which had been in the hands of an exclusive company, but was now in a great measure laid open; caused some extension of foreign trade, although the Levant, or Turkey trade, which had been considered as one of the most valuable branches, was beginning to decline rapidly, from the French improving the natural advantages they possess for a trade with those parts.

Years.	Imports.	Exports.
1749	£ 7,917,804	£ 14,099,366
1750	7,772,039	15,132,004
1751	7,943,436	13,967,811
1752	7,889,379	13,221,116
1753	8,625,029	14,264,614
1754	8,093,472	13,396,853
1755	8,772,865	12,182,255
1756	7,961,603	12,517,640
1757	9,253,227	13,438,285
1758	8,415,025	15,034,994

Years.	Imports.	Exports.
1759	8,622,576	14,606,892
1760	9,832,802	15,579,073
1761	9,543,601	16,365,933
1762	8,870,234	14,134,093

It is evident that commerce had not been very materially affected by the war. The years 1755 and 1756 marked the lowest point of its depression; whence it gradually rose, till it had gained a superiority over the unexampled traffic of 1750, a year of establishment peace and security.

By the peace of 1763, although many islands which had been taken in the West Indies were restored, Great Britain retained a number of newly acquired islands, perhaps more than could be immediately brought into cultivation with advantage. The arrangements respecting Asia were very favourable to the East India company, and in Africa an exclusive trade was secured in the article of gum Senegal, a material indispensably necessary to the perfection of many of our manufactures. The immediate consequence, however, of the acquisition of additional territories, was, that a wide field was opened for speculation and commercial enterprise, which caused much productive capital to be withdrawn from the trade and manufactures of Great Britain; yet our merchants were not only able to maintain their own credit, but also to assist their correspondents during the commercial embarrassments in Holland and other parts of the continent.

In 1765, the principles and measures were adopted which soon involved the country in disputes with its American colonies. Impolitic restrictions were laid on a beneficial intercourse which had long subsisted between the British colonies and the Spanish West India settlements; which being soon followed by other causes of discontent, drove the Americans into public resolutions to make no further importations from Great Britain, but such as were unavoidably necessary, and to encourage, to the utmost of their power, every kind of manufacture that was practicable among themselves. This step soon produced serious effects in Great Britain; the merchants connected with America found themselves unable to fulfil their engagements by the stoppage of large sums due to them from that country; the whole system of their business was deranged, and general distress spread through the circle of their connections; the manufacturers suffered by the want of regular payments from the merchants, while their materials, and made up goods, to an alarming amount, were becoming a dead stock upon their hands; in consequence of which, great numbers of workmen were thrown out of employ. Petitions were presented to parliament from all the trading and manufacturing towns, which probably had some effect in procuring a temporary adjustment of the dispute.

The non-importation agreement in America, was renewed in 1766 and 1770; yet the commerce of Great Britain, notwithstanding these interruptions of an important branch of it, continued to increase; and previous to the war which followed, had attained to a greater extent than in any former years.

1791	19,669,783	22,731,993
1792	19,659,353	24,965,200

The prohibition of all trade and intercourse with the American colonies excited serious alarms, not only on account of the loss of a valuable branch of trade, but from the supposed encouragement which the acquisition of it would give to the trade of those powers who afflicted the colonies. These apprehensions, however, in a few years appeared to be in a great measure groundless, many British manufactures found their way to America, though not imported directly from hence; and Mr. Chalmers observes, that "there was an evident tendency in our traffic to rise in 1779, till the Spanish war imposed an additional burthen. There was a similar tendency in 1780, till the Dutch war added, in 1781, no inconsiderable weight. And the year 1781, accordingly, marks the lowest degree of depression, both of our navigation and our commerce, during the war of our colonies. But with the same vigorous spirit, they both equally rose, in 1782, as they had risen in former wars, to a superiority over our navigation and commerce, during the year wherein hostilities with France began."

The total number of vessels which belonged to the several ports of the British empire on the 30th September 1792, was 16,079; the amount of their tonnage 1,540,145 tons; and the number of men and boys usually employed in navigating them 118,285. The number of vessels that entered inwards at the several ports of Great Britain (including their repeated voyages) was as follows:

	Ships.	Tons.
British - - -	12,030	1,587,645
Foreign - - -	2,477	304,074
Total	14,507	1,891,719

At this period, the commerce of Great Britain, was generally admitted to be in a very flourishing state. The application and improvement of machinery in almost every branch of manufacture, had reduced the charges of workmanship so far, as to enable our manufacturers to supply foreign markets on better terms than any other country could offer; while the increase of capital, arising from the accumulation of the profits of successful commerce during a period of peace, gave our merchants the means of allowing longer credit than could be obtained elsewhere. The high price of the public funds, led many persons to employ their money in discounting private securities, which greatly facilitated the extension of commercial credit, but probably tempted some to trade much beyond the amount which their capital justified, or to speculate largely without any real property of their own; so that when the apprehension of war produced a greater degree of caution, and began to affect particular branches of trade, many were involved in embarrassments; and on the commencement of the war in 1793, commercial concerns, in general, experienced a serious shock. The assistance afforded by government to such houses as appeared to be really solvent, by lending them exchequer bills for a certain time, operated very successfully, and averted the consequences that were apprehended; credit revived, and as the war in its progress almost annihilated the foreign trade of some of the powers engaged in it, the commerce of Great Britain received a considerable augmentation; and, protected by its naval superiority, continued to increase, notwithstanding all the measures which political animosity could devise to obstruct or destroy it.

Years.	Imports.	Exports.
1775	£ 14,816,955	£ 16,946,523
1776	12,449,189	15,685,107
1777	12,643,834	24,152,243
1778	10,975,533	12,375,712
1779	11,435,263	13,597,771
1780	11,714,067	13,689,073
1781	12,723,613	11,470,388
1782	10,341,628	13,224,637

The opportunity of renewing the commercial connections between this country and America, from the conclusion of peace, was eagerly embraced; but subsequent experience proved, that a greater degree of caution had now become necessary to render it a beneficial trade. The arrangements relative to the commerce of Ireland, had a very beneficial effect in that country, which had hitherto been excluded from almost every species of commerce, and refrained from sending the produce of her own soil to foreign markets. The convention with Spain settled more accurately the limits within which British subjects were allowed to cut logwood on the Musquito coast, and consequently gave greater certainty and security to the trade with those parts. The commercial treaty with France, by discontinuing many of the prohibitions and prohibitory duties which had existed for almost a century between the two nations, opened a wide field for speculation and adventure. The consolidation of the customs by the abolition of all the confused and complex duties which then existed, and the substitution of a single duty on each article in their stead, was a measure of great convenience to all persons engaged in mercantile transactions. Under all these circumstances, supported by the improvements which had taken place in several of the principal manufactures, the foreign trade of Great Britain increased greatly during the peace, and in the year 1792, had attained to an unparalleled height, both in point of value, and with respect to quantity of shipping employed in it.

Years.	Imports.	Exports.
1793	£ 19,256,717	£ 20,399,180

1795	22,736,889	27,312,338
1796	23,187,319	30,424,184
1797	21,013,956	28,917,010
1798	27,857,889	33,591,777
1799	26,837,432	35,991,329

C O M M E R C E.

Years.	Imports.	Exports.
1800	30,570,605	43,152,019
1801	32,795,557	42,317,011

In 1803	£ 40,100,870
1804	40,349,642
1805	41,063,942
1806	43,242,176

The increase during the above period, though really very great, was not however equal to what it would appear from the above accounts to have been. This irregularity in the comparative view which the account of imports and exports generally furnishes with sufficient accuracy, of the commerce of Great Britain, arises from the article of coffee, the import of which was formerly little more than sufficient to supply its small consumption in this country. But the interruption of the trade of France, the conquest of their West India islands, and the greatly increased cultivation of coffee in Jamaica, caused nearly the whole supply of the continent with this commodity to depend during the war on Great Britain. In the inspector-general's book of rates, coffee is valued on importation at 7*l.*, and on exportation, at no less than 14*l.* 10*s.* per cwt.; while, during the above period, the real average value was about 5*l.* per cwt. when imported, and 5*l.* 10*s.* when exported. The official account, therefore, from 1794, when coffee suddenly became a very considerable article of exportation, requires some correction; and if the over-estimated value of this article is deducted, the exports of the year 1800 will appear to have been 38,120,120*l.*, and of 1801, 37,786,856*l.*

The short interval of peace in 1802, produced an immediate extension of foreign trade; and Mr. Addington thought himself justified "in pronouncing the commerce of the country to be in a state of unrivalled and unexampled prosperity." The value of British manufactures exported, considerably exceeded the preceding year, and the total amount of the exports, according to the official values, was 46,120,962*l.* But in this and the succeeding years, it will be proper to adopt the correction just mentioned, which will give the amount of the imports and exports as follows:

Years.	Imports.	Exports.
1802	£ 31,442,318	£ 41,411,966
1803	27,992,464	31,578,495
1804	29,201,490	34,451,307
1805	30,344,028	34,954,845
1806	31,094,089	36,528,132

The account of imports for the last year is not quite correct; the imports from the East Indies for that year being incomplete.

Almost every article being greatly under-valued in these accounts (except in one or two instances) the total must give a very inadequate idea of the real extent of the commerce of Great Britain. Some idea may be formed of the undervaluation of the imports by those of the East India company, taking the account of their sales as the importation; the medium value of which, on an average of three years, was 6,100,000*l.*; whereas, the medium value by the accounts of the inspector-general, for the same three years, was 4,572,000*l.* Of the actual value of British produce and manufactures exported, which usually constitutes about two-thirds of the total export, we have more correct information. By an act passed in 1798, and revived in 1802, called the convoy act, the exporters were required to declare the real value of British manufactures exported, in order to ascertain the amount of duty chargeable thereon; and from these declarations, the actual value of British produce and manufactures exported has been ascertained as follows:

The extent of shipping employed in commercial intercourse at this period, will be seen in the following account of the number of vessels which belonged to the several ports of the British empire, on the 30th September 1805.

	Ships.	Tons.	Men & Boys.
England - - -	14,790	1,799,210	117,668

The commerce of Great Britain with Ireland, has increased with the improvement of that country, particularly since the year 1780, when a more liberal system of policy was adopted with respect to the foreign trade of Ireland. The imports from thence consist chiefly of butter, beef, pork, bacon, lard, tallow, cattle, hides, feathers, starch, rape-seed, linens, linen-yarn, wool-en-yarn, pearl-shells, copper-ore, and a few other articles of less importance. The exports are coals, ironmongery and hardware, hoops for barrels, beer, cyder, dried cod, herrings, chiefly from Scotland, earthenware, bottles and window-glasses, refined sugar, hops, lead, tin-plates, sail-cloth, cabinet-ware, wearing apparel, apothecaries-ware, books and stationery, painters' colours, hats, haberdashery, woollen, cotton, and silk manufactures of all kinds; with rum, brandy, geneva, wines, groceries, drugs, dye-stuffs, flax and hemp, raw and thrown silks, and other foreign produce.

Years.	Imports.	Exports.
1798	£ 2,735,686	£ 2,974,353
1799	2,770,731	4,086,986
1800	2,312,824	3,714,499

Considerable endeavours have been made to improve the manufactures of Ireland, but with little success, except in the linen manufacture, which probably proceeds from the want of sufficient capital, and from the facility with which British manufactures can be procured at a very small additional expence; the latter will, therefore, for a long time, continue to constitute a large proportion of the imports of Ireland.

Value of British manufactures exported from Great Britain to Ireland.

In 1791	£ 1,470,972	In 1796	£ 1,781,789
1792	1,511,844	1797	1,310,996
1793	1,055,276	1798	1,657,954
1794	1,281,316	1799	2,405,999
1795	1,612,270	1800	1,787,966

The trade between Great Britain and Russia has been considered highly beneficial to both countries; to Russia in point of profit, and to Great Britain, as supplying articles essential to the support of its navy. The capital employed must be much greater than formerly, from the increased value of the principal articles; and the balance of trade, which is considerably

ably in favour of Russia, is paid by means of the commercial transactions between Great Britain and other countries. The articles imported are iron, hemp, flax, tallow, pot-ashes, deals, and lath-wood, coarse linens, hog's bristles, &c. The exports are principally broad-cloths and woollen stuffs, refined sugar, cotton, lead, tin, iron and steel wares, earthen ware and glass, coals, alum, salt, horses, London porter, with articles of less importance.

Years.	Imports.	Exports.
1800	£ 2,332,098	£ 1,025,335
1801	2,246,877	919,843
1802	2,182,432	1,379,399

The total number of vessels that entered inwards from Russia, and that cleared out for that country from Great Britain in three years, ending with 1806, was as follows:

Years.	Inwards.		Outwards.	
	British.	Foreign.	British.	Foreign.
1804	830	29	558	53
1805	966	14	927	52
1806	1101	21	677	32

The trade to Denmark and Norway, though of ancient date, is not of very great extent; the imports consist chiefly of timber and corn; and the exports, of West India produce and other foreign merchandize; the quantity of British manufactured goods which those countries take being of small amount.

Years.	Imports.	Exports.
1800	£ 241,563	£ 540,698
1801	208,794	416,475
1802	155,672	537,517

The total number of vessels which entered inwards from Denmark and Norway, in the year 1806, was 1607, of which 529 were British ships: the total number which cleared outwards was 1690, of which 790 were British.

The trade with Sweden, which is carried on chiefly in ships of that country, has not varied materially in its extent during the last twenty years. The imports consist chiefly of iron of a superior quality, pitch, tar, deal boards, and sail-cloth. The exports are principally colonial produce.

Years.	Imports.	Exports.
1800	£ 309,280	£ 78,840
1801	295,645	111,254
1802	327,350	108,266
1803	288,651	98,245

The total number of vessels which entered inwards from Sweden, in the year 1806, was 353, of which 187 were British ships: the total number which cleared outwards was 362, of which 142 were British.

The imports from Prussia, consist of all kinds of grain, hemp, flax, madder, lintseed, goose-quills, bristles, pearls, affes, mill-stones, and timber of various descriptions. The exports are chiefly alum, coppers, coals, beer, salt, wrought brass and iron, lead, tin plates, earthen-ware, glass, woollen and cotton goods, some cotton yarn, India goods, raw and refined sugar, drugs, dye-stuffs, pepper and other spices, coffee, rum, tobacco, &c.

Years.	Imports.	Exports.
1800	£ 1,340,904	£ 794,452
1801	1,357,140	660,739
1802	1,057,602	1,071,896
1803	831,225	1,916,502

The total number of vessels which entered inwards from

Prussia in the year 1805 was 1946, of which 937 were British ships: the total number which cleared outwards was 1627, of which only 482 were British. In 1806 the total numbers were much less, in consequence of Prussia being involved in the war.

The trade with Germany had not experienced any considerable variation with respect to its extent, from the commencement of the last century, till on the extension of the war with France in 1794, it suddenly became the channel through which the principal part of the continent received the goods they had before obtained direct from Great Britain. The following account of exports to Germany shows the rapid increase of trade with that country during the war.

Years.	British Manufactures.	Foreign Merchandize.
1793	£ 718,474	£ 1,764,221
1794	1,634,530	4,308,695
1795	1,763,133	6,311,876
1796	1,591,810	6,582,179
1797	1,964,967	6,419,587
1798	2,042,774	8,646,691
1799	2,032,567	6,640,729
1800	4,364,120	8,300,470
1801	4,928,617	6,186,687

The total number of vessels which entered inwards in the several ports of Great Britain from Germany (including Hamburgh) and which cleared outwards for that country, was as follows:

Years.	Inwards.		Outwards.	
	British.	Foreign.	British.	Foreign.
1793	217	54	292	77
1794	258	108	443	152
1795	259	222	257	406
1796	347	342	333	415
1797	237	257	314	371
1798	408	113	647	187
1799	409	126	426	181
1800	435	459	574	458

The total number of vessels which entered inwards from Germany (including Hamburgh) in the year 1806 was 604; the total number which cleared outwards for that country 956.

The imports from Holland are butter and cheese in large quantities, geneva, juniper berries, flax, hemp, oak barks, rags, flower-roots and seeds, books, maps and prints. The exports are raw and refined sugars, train oil, coppers, a few cotton goods, some woollen goods, coffee, rice, and foreign merchandize of various kinds: their amount, as follows:

Years.	Imports.	Exports.
1800	£ 972,600	£ 3,208,613
1801	1,025,958	3,496,744
1802	974,537	4,957,997
1803	630,403	1,565,355

The total number of vessels which entered inwards from Holland in the year 1804 was 790, and the number which cleared outwards 521. The number which entered inwards in 1805, was 709; outwards 323; which, from the two countries being at war, were of course nearly all neutral vessels.

France possesses such natural advantages in the produce of its soil, and the convenience of its situation for procuring the commodities of all other countries, that while its manufac-

COMMERCE.

tures were encouraged, and it retained possessions in the East and West Indies, little inducement remained for commercial intercourse with Great Britain, and even this limited traffic was much impeded by the high duties and prohibitions which mutual jealousy had imposed. In 1786 a more liberal system was adopted by a treaty of commerce, in consequence of which the trade between the two countries increased considerably. In the year 1792, the exports to France amounted to 1,228,166*l.* 3*s.* 9*d.* of which 743,280*l.* 12*s.* 1*d.* was British manufactures, and 484,885*l.* 11*s.* 8*d.* foreign merchandize. In the following year, the trade with France was suspended by war, on the termination of which, in 1802, commissioners were appointed for adjusting the conditions of a new commercial treaty, but its completion was prevented by the renewal of hostilities.

The trade with *Portugal* was formerly a very beneficial branch of our commerce, but has declined very much. The imports consist chiefly of wine, cotton-wool, and indigo, with considerable sums in cash and bullion. The exports are almost wholly British produce and manufactures.

Years.	Imports.	Exports.
1798	£ 700,383	£ 750,918
1799	1,047,054	1,073,411
1800	916,848	1,011,593

The total number of vessels which entered inwards from *Portugal* in the year 1800 was 340, of which 270 were British vessels. The number which entered inwards in the year 1806 was 468; outwards 332.

The extent of the trade with *Spain*, previous to the war in 1796, will appear from the statement of imports and exports.

Years.	Imports.	Exports.
1792	£ 897,840	£ 794,101
1793	485,872	476,726
1794	748,546	634,554
1795	992,853	437,830
1796	809,881	546,126

The year 1806 being a year of war, the trade with *Spain* was of course confined to neutral vessels: the number which entered inwards was 222, and the number which cleared outwards 126.

The *Mediterranean trade* was subject to much interruption during the war which began in 1793, in consequence of which many of the goods usually imported from *Venice* and *Italy* were brought over-land through *Switzerland* and *Germany* to *Hamburg* and *Tonningen* to be shipped for *England*. The *Turkey and Levant trade* was formerly one of the principal branches of *English commerce*, but it is now of much less importance. The chief articles imported, are cotton-wool, mohair, goats' hair, opium, fenna, and other drugs, galls, madder, vullonea, and other dye-stuffs, currants, figs, raisins, goat skins, and box-wood; raw silk was formerly a principal article, but very little is now brought from *Turkey*, that of *Italy* being much superior. The exports consist of lead, tin-plates, wrought and cast iron, hardware, a considerable number of watches, some cotton goods, and a few woollen goods, India piece goods, coffee, sugar, cinnamon, cloves, pimento and other spices. The extent of the different branches of the *Mediterranean trade* will appear from the following statements.

Vol. IX.

Years.	GIBRALTAR and the STREIGHTS.		Ships	
	Imports.	Exports.	inward.	outward.
1799	£ 62,992	£ 358,784	47	56

1803	175,427	155,369	27	9
1804	148,277	81,625	16	1
1805	103,590	135,411	22	8

In the year 1806, the number of vessels which entered inwards was 23, outwards 3.

The articles imported from the coast of *Africa* into *Great Britain* are gum arabic, gum fandarach, and fenegal, camwood, red-wood, ebony, ivory, a few ostrich feathers, and some skins; their amount in the year 1800 was 82,280*l.* 5*s.* 8*d.* The exports have hitherto been of far greater value.

X

being

C O M M E R C E.

bring principally intended for the purchase of slaves for the West Indies. They consist of bugles, cowries, spiritous liquors, a great number of guns and cutlasses, gunpowder, wrought brass, copper and iron, glass, earthen ware, rice, gr. cereals, apothecaries' ware, woollee, cotton, and linen goods, and large quantities of India piece goods. The total official value in the year 1800 was 1,017,365*l.* 11*s.* 5*d.* of which 514,922*l.* 19*s.* 11*d.* was British merchandise. The abolition of the infamous traffick in human beings, must cause a great revolution in the trade to this part of the world, as it appeared in the year 1789 that about 38,000 of the inhabitants of Africa were annually carried away in British ships for supplying the colonies with slaves, which of course employed a considerable number of vessels. The number of ships that cleared out from Great Britain for Africa, in the year 1804, was 176.

The *East India* trade furnishes a remarkable instance of an extensive branch of commerce carried on successfully in the hands of an exclusive company, while most other commercial monopolies have made very small profits, and generally soon expired. The trade to India, however, since the immense territorial acquisitions of the English in that part, can no longer be considered as a mere commercial adventure, as it is now in a great measure a business of agency, for transmitting to Europe the fortunes acquired by British individuals in the East. The quantity of merchandize brought from thence, consequently greatly exceeds the value of the exports to India. The latter consists chiefly of woollens, metals, and naval and military stores, the remaining articles being of trifling amount in comparison, and almost wholly for the use of Europeans, as the natives are peculiarly attached to the use of their own produce and manufactures. The exports to China include a considerable amount in bullion, the other articles are woollen cloths and camblets, lead, and tin; the articles exported in private trade are, skins and furs, glass of various descriptions, jewellery, toys, and watches, cuttings of cloth, a very few woollens, some cutlery and hard ware, and silver. The amount of the company's exports to India and China, will appear from the following statements.

INDIA.

Season.	Merchandize, or Manufacture.	Metals.	Stores.	Bullion.
1781	£ 200,808	£ 157,614	£ 163,878

1785	2,703,940	1797	3,942,384
1786	3,156,687	1798	7,616,930
1787	3,430,868	1799	4,384,505
1788	3,453,897	1800	4,542,775
1789	3,164,545	1801	5,424,441
1790	3,149,870	1802	5,794,006
1791	3,698,713	1803	6,348,887
1792	2,701,547	1804	5,214,621

But a more accurate idea of the real value of the imports from the East Indies, may be formed from the annual amount of the company's sales, which was

In 1801	£ 7,595,181	In 1803	£ 6,042,526
1802	6,626,347	1804	5,866,073

The *West India* trade is, in some respects, the most important branch of the commerce of Great Britain; as on the colonial produce which it supplies, much of the trade with different parts of Europe chiefly depends. The value of the British West India produce from the old islands, imported into Great Britain, on a medium of four years, preceding the 5th of January 1796, according to the current prices during that period, was estimated, exclusive of the duties, at about 6,800,000*l.* per annum. This sum is not wholly a return for goods exported, a part of it must be considered as remittances of the property of persons who possess estates in the West Indies; but who are wholly or occasionally resident in England; and of persons who have lent money on mortgage or otherwise in the West Indies, and receive their interest from the sale of the produce.

Official Value of Imports from the West Indies.

Years.	British West Indies.	Conquered Islands.	Total.
1801	£ 6,759,617	£ 4,105,839	£ 10,865,456
1802	7,293,316	2,699,504	9,992,820
1803	5,786,432	3,020,014	6,148,436

The value of the British West India islands, in a commercial view, will be very conspicuous from the following statement of the total quantities of sugar, rum, coffee, and cotton-wool, exported from them.

Years.

Years.	Sugar. Cwt.	Rum. Gall.	Coffee. Cwt.	Cotton Wool. lbs.
1793	2,129,750	4,997,051	92,016	9,173,583
1794	2,141,921	5,597,520	141,007	8,473,175
1795	1,743,939	4,173,734	144,800	11,675,495
1796	1,816,584	5,567,754	94,086	8,854,413
1797	1,636,631	4,279,164	114,947	6,918,153
1798	2,015,602	6,224,076	165,075	7,609,832
1799	2,628,470	6,270,449	132,259	7,529,881
1800	2,413,997	6,231,225	180,374	12,611,340
1801	2,959,958	8,148,571	199,359	11,261,014
1802	3,463,566	8,676,381	230,148	8,759,891
1803	2,886,479	8,781,496	173,883	5,650,615

The total number of vessels which entered inwards from the West Indies, in the year 1804, was 721, containing 204,411 tons, and navigated by 13,119 seamen. The number of vessels which cleared outwards was 790. The value of British produce and manufactures exported to the British plantations in the West Indies, exclusive of the Conquered islands, was 3,468,232*l*.

The trade with the United States of America, has rapidly advanced to very considerable importance; and Great Britain now supplies them with commodities to a far greater amount, than in the most favourable years previous to their independence, although the number of British ships employed is considerably less. In the year 1789 the number of British vessels which entered inwards in this trade was 53, the number outwards 358; in the year 1799, the number which entered inwards was only 42, the number outwards 57.

Years.	Imports.	Exports.
1798	£ 1,782,720	£ 5,580,370
1799	1,818,941	7,056,558
1800	2,357,922	6,885,597

The total number of vessels which entered inwards from the United States, in the year 1806, was 561, of which 53 were British; the total number which cleared outwards was 575, of which only 39 were British.

The remaining possessions of Britain in North America, being countries not very fertile or fully inhabited, the trade with them is not of very great extent. The following statement of the exports to those parts in the year 1800, will, however, shew that the trade is well worth preserving, independent of the consideration that it is the means of procuring articles of much importance in other branches of commerce.

To Hudsons bay	- -	£ 38,061	0	9
Newfoundland	- -	219,458	5	11
Canada	- - -	460,155	13	3
New Brunswick	- -	81,230	15	4
Nova Scotia	- - -	177,083	17	10
Total		£ 975,989	13	1

With respect to the general balance of trade, or the ultimate profit which Great Britain derives from its commerce with all other countries, Mr. Irving, the inspector-general of imports and exports, to whom the public have, for many years, been indebted for the judicious arrangement and explanation of the official documents relating to foreign trade, has justly remarked, that there are perhaps few questions to which the human attention can be directed more difficult to form an opinion upon, from the variety of considerations, and the vast statements with which it is

connected, and also from the materials on which conclusions are to be formed, being in some instances defective; he has, however, stated it as his opinion, that the balance of trade in favour of Great Britain, according to the true value of the goods exported and imported, amounted on a medium of the four years preceding 1796, to upwards of 6,500,000*l*. per annum, exclusive of the profits derived from the East and West India trades, which he estimated at upwards of 400,000*l*. per annum; and exclusive of the profits derived from the fisheries.

An accurate view of the progress and extent of commerce in all the European states, would furnish much information; but with respect to several, no authentic particulars of this kind have been made public, and the foreign trade of others has been so entirely turned out of its usual channels since the commencement of the war of the French revolution, that any account of its present state would be very incomplete and unsatisfactory.

With respect to domestic commerce, we may observe, that the king is the arbiter of it; as it pertains to his prerogative to establish public marts, as markets and fairs, to regulate weights and measures, and to give money, which is the universal medium of commerce, authority and currency.

A great part of the foreign commerce of England is now carried on by collective companies; some incorporated by the king's charters, with an exclusive privilege, as the East India company; others only private associations, as the Turkish and Hamburg companies. See COMPANY.

COMMERCE, *Chambers of*. See CHAMBER.

COMMERCE, *Characters in*. See CHARACTER.

COMMERCE, in *Geography*, a handsome town of France, and chief place of a district in the department of Meule, on the western shore of that river. E. long. 5° 24'. N. lat. 48° 20'. It has a sub prefect, and counts 3418 inhabitants. The district contains 181 communes, with a population of 73,103 individuals. There are several iron forges, paper mills, glue, violin, and linen manufactures.

COMMERSONA, in *Botany*. Sonnerat. See BARRINGTONIA.

COMMERSONIA, (so named by Forster, in memory of M. Commerçon, the celebrated French naturalist and traveller.) Forst. Gen. 22. Linn. jun. Suppl. 26. Schreb. 535. Willd. 596. Lam. Ill. 550. Gart. 586. Juss. 428. Vent. 4. 17. Clafs and order, *pentandria pentagynia*. Nat. Ord. Undetermined; Juss. Vent.

Gen. Ch. *Cal.* one-leaved, five-cleft, bearing the petals between the segments; segments egg-shaped, acute, longer and broader than the petals. *Cor.* Petals five, dilated at the base on each side, with an inflexed lobe, spreading. *Stam.* Filaments very short, situated at the base of the petals; anthers roundish, didymous. *Nectary* a five-cleft ring, between the petals and the germ, with five filiform villous small bodies between the divisions; divisions lanceolate, erect, shorter than the petals. *Pist.* Germ superior, globular, villous, with five projections; styles five, filiform, approximating, short. *Per.* Capsule roundish, hard, echinate with long soft brittle-shaped hairs, five-celled; two seeds in each cell. *Seeds* egg-shaped.

Eff. Ch. Calyx one-leaved, bearing the corolla. Petals five. Nectary five-cleft. Capsule five-celled, echinate.

Sp. C. *cebinata*. Linn. jun. Suppl. 26. Mart. Lam. Willd. Gart. tab. 94. Lam. Ill. tab. 218. (Rettbana; Rumph. Amb. 3. tab. 119.) A middle-sized tree. *Trunk* rarely the bulk of a man, with a diffuse head and smooth bark, easily separable from the wood; young branches woolly. *Leaves* alternate, petioled, obliquely egg-shaped, acuminate, serrated, a little wrinkled, shining, dark green

above, hoary underneath. *Flowers* very small, white, in axillary panicles. *Capsule* somewhat globular, with a coriaceous echinate rind, five-cocccous, five-valved; cocci inversely egg-shaped, narrowing downwards, femibilocular from the back, two-valved; valves of the contiguous cocci united and forming the proper partitions of the capsule. *Seeds* two in each cell, attached to the central angle of the cells, ovate-oblong, a little thicker upwards, slightly compressed, of a red-ferruginous colour, blackish at the top, incompletely arilled; aril membranous, very thin, whitish, lacerated, fixed to the umbilicus of the seed, covering its whole ventral, but not its dorsal part. *Germt.* A native of Otabeite, the Friendly Isles, and the Moluccas.

COMMIA, *Bofch. Nouv. Dict.* Clafs and order, *diacna monandra*.

Gen. Ch. *Male catkins.* Scales obtuse, each concealing a single filament. *Female catkins.* Calyx proper three-leaved; leaves acute, permanent. *Cor.* none. *Pist.* Germ superior; styles three, short; stigma thick. *Peric.* Capsule three-lobed, three-celled. *Seeds* one in each cell.

A tree. *Leaves* alternate, lanceolate, quite entire, smooth, recurved. *Flowers* in axillary and terminal catkins. A native of Cochinchina. A white gum exudes abundantly from its bark, which is sometimes used as a medicine in dropsies and obstructions, but is too violent in its effects to be taken without great caution.

COMMINATORY, a clause inserted in a law, edict, patent, &c. importing a punishment wherewith delinquents are menaced; which, however, is not to be executed in its rigour.

Thus, in France, when an exile is enjoined not to return on pain of death, it is deemed a *comminatory* penalty; since, if he do return, it is not strictly executed; but a second injunction is then laid on him, which is more than comminatory, and from the day of the date thereof, imports death without remedy.

COMMINES, PHILIP DE, in *Biography*, a celebrated historian, was born of a noble family in Flanders in 1445. He spent the early part of his life in the court of Charles the Bold, duke of Burgundy; but in 1472 he went over to the service of Louis XI. king of France, who adopted him as a favourite, and employed him in various important negotiations. He married an heiress of the house of Anjou, by whom he acquired considerable landed property. He accompanied his sovereign in many of his journeys and in some expeditions of a more serious nature; and he attended upon his successor Charles VIII. to the conquest of Naples. Under this prince he was accused of having espoused the cause of the duke of Orleans, for which he was arrested, and imprisoned in an iron cage for eight months. He was afterwards transferred to a prison at Paris, where he was eighteen months without being able to obtain a trial. Commines was at length honourably acquitted, but it does not appear that, either in the remainder of this reign, or in that of the duke of Orleans who succeeded, and for whom he had suffered, he was afterwards publicly employed. He died, at his seat of Argenton, in Poitou, of which he had been denominated the lord. Commines possessed various qualities well adapted to render him eminent as a statesman. He had a fine person, and an excellent understanding: he was a complete master of many modern languages, and had so great a command of his own powers that he could dictate to four secretaries at once. As a literary character he is chiefly known for his "Memoirs," which contain an account of the principal events of the reigns of Louis XI. and Charles VIII. during a period of thirty-four years. This work is highly esteemed on account of the personal knowledge and observation of the

author, who united a sincere and candid disposition, with simple and unaffected style. By the learned Lippius, Commines is regarded as equal to the historians of antiquity; his "Memoirs" he recommends as the vade mecum of princes. They have gone through many editions, which have been illustrated with notes by different learned men; but the most esteemed impression is that of the abbé Lenglet du Fresnoy, 1747, in 4 vols. 4to. printed at Paris, with London in the title page. *Nouv. Dict. Hist. Du Fresnoy.*

COMMINGES, in *Geography*, (in Latin *Comvengis*), was before the French revolution of 1789, a county in the province of Gascony, and forms now part of the department of Haute-Garonne in France.

COMMUNITION, the act of grinding, or breaking any matter into smaller particles.—The effect of chewing, or masticating our food is the communication thereof.

COMMIRE, JOHN in *Biography*, a Jesuit, was born in 1625 at Amboise, where his father kept a tennis-court. He received a good education, and applied himself chiefly to classical literature. He acquired great reputation as a poet, by a collection of pieces in Latin which appeared in 1678, but he was, at the same time, diligent in his profusion, as a teacher and director in theology. His poems consist of paraphrases on various parts of the scriptures, od 8. fables, epigrams, &c. of which the general character is facility, copiousness, and amenity. He is thought to have succeeded best in his odes, but his fables are in high repute. He died at Paris in 1702, leaving behind him the character of an open and upright disposition. An edition of his poems was published in 2 vols. 12mo. in the year 1754. *Nouv. Dict. Hist.*

COMMIS, Fr. A clerk, deputy, or subordinate person, who is employed in any of the war-departments of the French.

Commis general du parc des vivres, commis-general of the provision-park. This officer exercises his functions under the orders of the director-general of provisions. His employment requires a good deal of capacity and zeal, as well as of probity. His duties and relations are multifarious and extensive. He should always encamp in the centre of the baggage, to be able to have an eye to the whole, and to be less interrupted.

Commis General des travaux du parc des vivres, commis-general of labour and work in the provision-park. The duties of this employment are troublesome, and require much attention. It should never be bestowed on a man that does not possess experience, prudence, and firmness, without being too rigorous or severe, as he has authority over every thing connected with the different kinds of work in the park.

Commis des entrepreneurs pour la fourniture des lits, clerks of undertakers for the furnishing of beds. They have a right to visit and examine the beds and every thing connected with them, and to refuse or reject whatever is insufficient or defective.

Commis du tresorier de l'extraordinaire des guerres, clerks of the treasurer of the wars, or of the paymaster general of the army. They deliver the certificates to the troops who leave lodgings or quarters. They were under the jurisdiction of the high council.

COMMISERATION, in *Pathology* and *Ethics*, is frequently used as synonymous with *compassion*, which fee; but, in its general use, it is somewhat different. It is always preferred, when we wish to express our sympathy for misfortunes, which it is not in our power to remove, or for which there is no apparent remedy. Commiseration, ruminating upon the state and suffering of others, induces a permanent concern. In such cases it may be said, that we commiserate
the

the unfortunate sufferer, rather than that we have compassion upon him. But although this is a more helpless, it is not an useless affection. It soothes the mind of the afflicted, and greatly alleviates their sorrows, when every other consolation fails. *Condolence* is the expression of our commiseration. Cogan on the Passions, p. 124.

COMMISSAIRE, Fr. Commissary. This word or term was used in the old French service, to express a variety of occupations, and was annexed to a good many different appellations, of which the following are the principal.

COMMISSAIRE General des Guerres ou commissaire General des Armées, commissary general of the wars. This charge, office, or appointment, was created for *Besangon*, in 1637, and did not long exist, being suppressed in his person, because it gave too much authority, and too many privileges, to the person invested with it.

COMMISSAIRE Général de la Cavalerie légère. Fr. He was the third general officer of all the regiments of cavalry, and he had a regiment of his own under the name of the regiment of the *commissaire général*, or commissary general.

COMMISSAIRE Ordonnateur des Guerres. This appointment was superior to that of an ordinary or provincial commissary of war. It was commonly a sort of recompence and advancement granted in consideration of services rendered by the one or the other commissaries of war, whether of the armies or in the interior of the state. The *commissaire ordonnateur* is charged with objects of the first importance, and with a greater variety of them than the other commissaries are.

COMMISSAIRES des Guerres, commissaries of the wars, or multer-masters general. They enjoyed peculiar privileges, but were subordinate to the governors and commandants of towns and garrisons, without whose permission they could not multer any regiment.

COMMISSAIRES Ordinaires des Guerres, ordinary commissaries of the wars, or deputy-multer-masters. Officers subordinate to the immediately preceding, who ought to assist at reviews, who are charged with the conduct, police, and discipline of troops, and with making the men observe the military decrees. With the army, they have the detail of the hospitals, bread, victuals, &c. &c. They make inventories of provisions, and are charged with the management of convoys. Their creation is very ancient: for there is mention made of them under the reign of king Jean I. in 1355. They were called at first *conducateurs des gens de guerre*, (conductors of the people of war, or of military people) a title or appellation which they enjoyed for a long time under Louis XIII., and they are still called so in their commissions. Those who were not gentlemen, had the right of taking the rank of squire, or equire; of enjoying all the privileges of the noblesse, and of acquiring noble siefs.

COMMISSAIRE Provincial des Guerres, provincial commissary of the wars. There were no *commissaires provinciaux des guerres* before the year 1635. They were afterwards suppressed, and were re-established in 1704, under Louis XIV., with the same privileges, rights, attributions, and authorities for the service of cities of war, that the ordinary commissaries of the wars enjoyed for the service of marches, and of the armies.

COMMISSAIRE General des Vivres, commissary general of provisions. This officer has under him several other commissaries, who ought to know the number of men, which each of them will have to subsist, in order to make choice of a proper place for causing the provisions to be brought to, as also to form magazines for the

duration of the campaign, and of course to procure a sufficient number of bakers and workmen.

COMMISSAIRE d'Artilerie, commissary of artillery. There is one such officer in each department of the ordnance, who keeps one of the three keys that belong to the artillery-magazine. It is at his requisition that the governor or commandant of a place sends soldiers to remove, when necessary, the pieces of artillery and stores of war. He has the superintendance and direction of every thing connected with the cleanliness and general management of the magazines.

COMMISSAIRES provinciaux d'Artilerie, provincial commissaries of artillery. These were of two sorts or descriptions. The one had the names or titles of the provinces; the other had merely the title of provincial. But on service, they both received the same pay.

COMMISSAIRES ordinaires d'Artilerie, ordinary commissaries of artillery. These were subordinate to the provincial commissaries, and were distributed among the forts, garrisoned towns, navy, and dockyards.

COMMISSAIRES extraordinaires d'Artilerie, extraordinary commissaries of artillery. Under the monarchy of France, these formed the third of ordnance-commissaries, and they were in like manner distributed on duty in garrisoned places, and on board ships of war.

COMMISSAIRE provincial en l'Arsenal de Paris, ou departement de l'Isle de France, provincial commissary in the arsenal of Paris, in the department of the isle of France. This officer received his commission from the grand master, in whose gift it was, and possessed the exclusive privilege of being made privy to every alteration or movement that took place in the arsenal.

COMMISSAIRE General des Poudres et Salpêtres, commissary general of gun-powder and saltpetre. This appointment was created in 1634, with that of superintendent general of gun-powder and saltpetre. It was at last suppressed, and the grand master of the ordnance appointed a person to exercise its functions.

COMMISSAIRE General des Fontes, commissary general of the founderies. This appointment was the gift of the master of the ordnance, and was invariably bestowed on those who had given convincing proofs of their abilities and skill in the casting of cannon, &c.

COMMISSAIRES des Guerres entretenus dans l'Hotel des Invalides, commissaries of war kept in the hotel des invalides. It was a principal part of their duty to keep a regular roll or list of all the names of the different officers, non-commissioned officers, and soldiers, that might be detached on garrison duty, &c. from which they made a monthly return to the secretary at war. Each commissary, at every review or inspection of the corps of invalids, had particular directions to mark and point out those men who appeared to be capable of serving, of whom a regular return was made to the secretary at war.

COMMISSAIRE General des Fortifications, commissary general of fortifications. This was an office of great importance, as it was his duty to give the plans for places and new works; to approve or condemn those that had been ordered by others; to visit the fortified places of the kingdom; to order the reparation of works that had been damaged; to regulate the conduct of the engineers, and to give them orders for the good of the service.

At a siege, he directed the tracing out of the lines of circumvallation and countervallation, and the securing of the posts; he decided on attacks which were made according to his plan; he directed the making of lodgments, saps, mines, the traverse of the ditch, the attack of the breach, and

and after the place was taken, caused it to be repaired. In defending a place, he had the same or equal power. His appointments amounted to about 30,000 livres per annum.

COMMISSARY, in *Military Language* of Britain, has various denominations, though he is generally a civil officer appointed to inspect the musters, stores, and provisions for the army. The number of such officers is not limited in time of war.

Commissaries *general*, and commissaries *of accounts*, in our service, are appointed by warrant under the king's sign manual, directing them to obey all instructions given to them for the execution of their duty by the lords commissioners of the treasury. These instructions are generally prepared by the comptrollers of the army-accounts, under the orders of the treasury, and subject to its subsequent inspection.

COMMISSARY General of the Musters, or *Master-muster general*. This officer takes an account of the strength of every regiment as often as he pleases; reviews them; sees that the horse are well mounted, and that all the men are well armed and clothed. He receives and inspects the muster-rolls, and thereby knows exactly the strength of the army. A new officer has been appointed under the appellation of *Inspector-general of Cavalry*, who performs the duties in that respect, which used to be performed by the muster-master general.

COMMISSARY General of Stores. A civil officer who has charge of ordnance stores, for which he is accountable to the office of ordnance. He has other commissaries under him, as well as clerks and conductors, particularly in time of war.

COMMISSARY of the Train-horses. A civil officer of the ordnance, who has the inspection of all horses belonging to the train of artillery, the hospital, and the bakery. He has a number of conductors, drivers, &c. under him.

COMMISSARY of Accounts. A person of responsibility, who, with a proper establishment, attends each army, sufficiently large and numerous to render it necessary for the purpose of taking, examining, and controlling accounts on the spot. All such commissaries make returns of their examinations, on which, as documents, the comptrollers of the army-accounts ground their inquiries into that branch of the public expenditure.

COMMISSARY General of Provisions. An officer who is charged with furnishing the army in the field and on service, with all sorts of provisions; forage, &c. generally by contract, and sometimes otherwise. He has a variety of commissaries, store-keepers, clerks, &c. under him.

COMMISSARY, in the *Ecclesiastical Law*, an officer of the bishop, who exercises ecclesiastical jurisdiction in those parts of the diocese, which are so remote from the see, that the chancellor cannot call the subjects thereof to the bishop's principal consistory, without their too great molestation.

This officer, called by the canonists *commissarius*, or *officialis foraneus*, is appointed to supply the bishop's office in the out-parts of the diocese, and in such parts as are peculiar to the bishop, and exempted from the jurisdiction of the archdeacon: for where the archdeacons have jurisdiction, as in most places they have, either by prescription or composition, the commissary is superfluous, and frequently vexatious, and ought not to be: yet in such cases, a commissary is sometimes appointed by the bishop, and takes prebendation of the archdeacon yearly *pro exteriori jurisdictione*, as it is ordinarily called. But this is held to be a wrong to archdeacons and the poorer sort of people. Cowel's *Interp.* 4 Inst. 378.

COMMISSARY Court, in *Scots Jurisprudence*. At the reformation, all episcopal jurisdiction exercised under the au-

thority of the bishop of Rome was abolished; and the course of justice in consistorial causes was thus stopped. Hence queen Mary, besides naming a commissary for every diocese, did, by a special grant, establish a new *commissary court* at Edinburgh, consisting of four judges or commissaries. This court is vested with a double jurisdiction; one diocesan, which is exercised in the special territory contained in the grant, *viz.* the counties of Edinburgh, Haddington, Linlithgow, Peebles, and a great part of Stirlingshire; and another universal, by which the judges confirm the testaments of all who die in foreign parts, and may reduce the decrees of all inferior commissaries, provided the reduction be pursued within a year after the decree. Bishops, upon their re-establishment in the reign of James VI., were restored to the right of naming their several commissaries. The commissaries retain to this day an exclusive power of judging in declarations of marriage, and of the nullity of marriage; in actions of divorce and of non-adherence, of adultery, bastardy, and confirmation of testaments; because all these matters are still considered to be properly consistorial. Inferior commissaries are not competent to questions of divorce, under which are comprehended questions of bastardy and adherence, when they have a connection with the lawfulness of marriage, or with adultery. Commissaries have now no power to pronounce decrees in absence for any sum above 40*l.* Scots, except in causes purely consistorial; but they may authenticate tutorial and curatorial inventories; and all bonds, contracts, &c. which contain a clause for registration in the books of any judge competent, and protests on bills, may be registered in their books.

COMMISSION in *Common Law*, is the same with *delegatio* among the civilians; and is taken for the warrant, or letters-patent, which all persons exercising jurisdiction, either ordinary or extraordinary, have to authorize them to hear or determine any cause or action: such as the commission of judges, &c.

The term, however, is sometimes extended farther than to matters of judgment; as in the commission of purveyors, which seems to be null by the statute for taking away purveyance, 12 Car. II. and the high commission court, which was founded by the statute 1 Eliz. and is also abolished by act of parliament 16 Car. I. The persons charged with a commission are hence called *commissioyers*; sometimes *commisses*.

Commissions of inquiry shall be made to the justices of one bench or the other, &c., and to do lawful things are grantable in many cases. Most of the great officers, judicial and ministerial, of the realm, are made by commission. And by such commissions, treasons, felonies, and other offences, may be heard and determined: by this method, likewise, oaths, cognizances of fines, and answers, are taken, witnesses examined, offices found, &c. Bro Ab. 12. R.p. 39. See stat. 42 E. III. c. 4. Most of these commissions are appointed by the king under the great seal of England; but a commission under the grand seal may be determined by a privy seal; and by granting another new commission to do the same thing, the former commission determines; and on the death or demise of the king, the commissions of judges and officers generally cease. Bro. *Commiss.* 2 Dver 289.

COMMISSION of Anticipation, was anciently a commission given under the great seal, to collect a tax or subsidy before the day. 15 Hen. VIII.

COMMISSION of Array. See *MILITIA*.

COMMISSION of Association, is a commission under the great seal to associate two, or more learned persons, with the several justices, in the several circuits and counties in Wales.

COMMISSION of Bankruptcy, a commission under the great seal,

feal, directed to five or more commissioners, to enquire into the particulars of a man's circumstances, who hath failed, or broke; and to act according to certain statutes made in that behalf. See *BANKRUPT*, and *PETITION of Bankruptcy*.

COMMISSIONS of Charitable Uses go out of the chancery to the bishop and others, where any lands given to charitable uses are misemploy'd, or there are any fraud or disputes concerning them, to enquire of and redress the abuse, &c. 43 Eliz. cap. 4.

COMMISSION of Delegates, a commission under the great seal to certain persons, usually two or three temporal lords, as many bishops, and two judges of the law, to sit upon an appeal to the king in the court of chancery, where any sentence is given in any ecclesiastical cause by the archbishop. Stat. 25 Hen. VIII. c. 19. Now generally three of the common law judges and two civilians sit as judges. See *COURT and DELEGATES*.

COMMISSION to enquire of faults against the law, an ancient commission set forth on extraordinary occasions and corruptions.

COMMISSION of Lunacy, a commission out of chancery to enquire whether a person represented to be lunatic, be so or not; that, if lunatic, the king may have the care of his estate, &c. 17 Edw. II. c. 10.

COMMISSION of Peace See *JUSTICE of Peace*.

COMMISSION of Rebellion, or *Writ of Rebellion*, is issued out when a man, after proclamation made by the sheriff upon a process out of the chancery, to present himself, under pain of his allegiance, to the court by a certain day, does not appear. See *REBELLION*.

This commission is directed by way of command to certain persons; three, two, or one of them; to apprehend, or cause to be apprehended, the party as a rebel; and to bring him to the court on a day assigned.

This writ or commission goes forth after an attachment returned, *non est inventus*, &c.

COMMISSION of Sewers, is directed to certain persons to see drains and ditches well kept, and maintained, in the marshy and fenny parts of England, for the better conveyance of water into the sea, and preserving the grass upon the land. Stat. 23 Hen. VIII. c. 5. 13 Eliz. c. 9. The stat. 3 Jac. I. c. 14. ordains, that all ditches, water-courses, &c. within two miles of London, falling into the Thames, shall be subject to the commission of sewers; and the lord-mayor, &c. is to appoint persons who have this power. 7 Ann. c. 10.

COMMISSION to examine witnesses, is sometimes appointed by the court of equity in cases that require it, as when the cause arises in a foreign country, and the witnesses are at home, or when the witnesses are abroad, or soon to leave the kingdom; or again, when they are aged and infirm. This commission is empowered to exercise the same jurisdiction as would have been exercised if the witnesses had attended. See *SUIT*.

COMMISSION of Treaty with Foreign Princes, is where leagues and treaties are made and transacted, between states and kingdoms, by their ambassadors and ministers, for the mutual advantage of the kingdoms in alliance.

COMMISSION to take up Men for War, was a commission to press or force men into the king's service. This power of impressing has been heretofore doubted; but the legality of it is now fully established. Folt. Rep. 154. Blackf. Com. v. 419. Comp. 517. See *IMPRESSING*.

COMMISSION, Militaire. A brevet, or power, granted in writing by the minister of war in the name of the sove-

reign, and sealed with the great seal, by which he, to whom it is given, exercises the military charge entrusted to him, and takes his rank from the day of the date thereof. Commission in a military sense, in our forces, denotes any situation or place, which an individual may hold in the regular army, militia, or volunteers. All commissions in the line, guards, or volunteer-corps, must have the royal sign manual. Commissions however in the militia do not bear the royal sign manual, except that of the adjutant, who is commonly called a king's officer. The lieutenants or deputy-lieutenants of counties affix their seals and signatures to militia-commissions after they have been laid before the king for his approbation. Fourteen days constitute the time allotted for the royal approbation or disapprobation. And if his majesty does not within that time *disapprove* of the person so recommended, a notification of his pleasure and acquiescence is sent by one of the principal secretaries of state to the ord. lieutenant or to those acting by commission in his absence.

COMMISSION Militaire is also a momentary or temporary tribunal appointed or ordered to sit for the trial of military crimes and offences. When judgment is pronounced and the duty is performed, for which it was appointed, its authority, as well as its existence, ceases.

COMMISSIONS of Array. Commissions issued to experienced officers to draw out and array the fittest men in each county for service, and to march them to the sea coasts, or to such other parts of the county as were thought to be most in danger. There were hundreds of such commissions between the 5th of Henry III., and the reign of Edward IV. The form of one is to be seen in "Rushworth's Historical Collection," published in 1640. Such commissions were attempted to be revived by Charles I.; but they were voted illegal and unconstitutional by the parliament.

Non commissioned is a term commonly employed to denote a class of men, who stand between the rank and file of a battalion, and the commissioned and warrant officers, as serjeants-major, serjeants for instance.

COMMISSION-OFFICERS. See *OFFICER*.

COMMISSIONS, Book of. See *BOOK*.

COMMISSION, in Commerce. See *FACTORAGE*.

COMMISSIONER, he who has a commission, *c. pr.* a patent, or other legal warrant, to execute any public office. See *WARRANT*, &c.

Such are, *commissioners of hawkers and pedlars, commissioners of alienation, commissioners of the stamps*, &c.

COMMISSIONERS of Public Accounts. See *ACCOUNTS*.

COMMISSIONERS of the Customs. See *CUSTOM-house*.

COMMISSIONERS of the Dock-yards. See *DOCK-yARDS*.

COMMISSIONERS of Excise. See *EXCISE*.

COMMISSIONERS of the Navy. See *NAVY*.

COMMISSIONERS, Lords, of the Treasury. See *TREASURY*, and *EXCHEQUER*.

COMMISSIONERS of Trade, &c. See *BOARD*.

COMMISSUM Fidei. See *FIDEI*.

COMMISSURE, *COMMISSURA*, a term used by some authors for the junctures, or for the small interstices of bodies; or the little clefts between the particles; especially when those particles are broadish or flat, and lie contiguous to one another, like thin plates, or lamellæ.

The word literally signifies a *joining*, or connecting of one thing to another.

COMMISSURE, in *Architecture*, &c. denotes the joint of two stones; or the application of the surface of the one to that of the other.

COMMISSURÆ *Cerebri*, in *Anatomy*, are parts of the brain, which join together the right and left sides of the viscus.

There are three of these commissures: an anterior one which is directly under the anterior crura of the fornix; a posterior, which is behind the optic thalami, and in front of the tubercula quadrigemina; and a middle one, which joins together the opposed convexities of the thalami nervorum optico-rum. For a further description of these parts, see **BRAIN**.

COMMITMENT, in *Law*, the sending of a person to prison by warrant or order, who hath been guilty of any offence not bailable, or for which bail is refused. It may be by the king and privy council, or secretary of state, by the judges of the law, justices of peace, and other magistrates, who have authority by the laws and statutes of the realm to do it, which must be exactly pursued.

As to the manner of commitment, it is enacted by 2 & 3 P. & M. c. 10., that justices of peace shall examine persons brought before them for felony, &c. or suspicion thereof, before they commit them to prison, and shall bind their accusers to give evidence against them. A justice of the peace may detain a prisoner for examination, and it is said that three days are a reasonable time for this purpose. 2 Hawk. P. C. c. 16. § 11, 12. Dalt. c. 125. 2 Inst. 52, 591.

Every commitment must be in writing, under the hand and seal, and shew the authority, of him that made it, and the time and place, and must be directed to the keeper of the prison. It may be either in the king's name, and only tested by the justice, or in the name of the justice. It may command the gaoler to keep the party in safe and close custody, which he is bound by law to do. 2 Hawk. P. C. c. 16. § 13, 14, 15. It ought to set forth the crime with convenient certainty, whether the commitment be by the privy council, or by any other authority; otherwise the officer is not punishable by reason of such mittimus, for suffering the party to escape; and the court before which he is removed by Habeas-corpus, ought to discharge or bail him; and this holds not only where no cause at all is expressed in the commitment, but also where it is so loosely set forth, that the court cannot judge whether it were a reasonable ground for commitment or not. 2 Hawk. P. C. c. 16. § 17. See **ARREST** and **BAIL**. A commitment for high treason or felony in general, without expressing the particular species, has been held good. (2 Hawk. P. C. c. 16. § 16.) But now, since the Habeas-corpus act, it seems that such general commitment is not good. Moreover, it is safe to set forth that the party is charged upon oath; but this is not necessary, for it hath been resolved, that a commitment for treason, or for suspicion of it, without setting forth any particular accusation or ground of the suspicion, is good. 2 Hawk. P. C. c. 16. § 17. Every such mittimus ought to have a lawful conclusion, *viz.* that the party be kept till he be delivered by law, or by order of law, or by due course of law; or that he be kept till further order (which shall be intended of the order of law) or to the like effect; and if the party be committed only for want of bail, it seems to be a good conclusion of the commitment, that he be kept till he can find bail; but a commitment till the person who makes it shall take further order, seems not to be good; and it seems that the party committed by such or any other irregular mittimus, may be bailed. 2 Hawk. P. C. c. 16. § 18.

A commitment grounded on an act of parliament ought to be conformable to the method prescribed by such

statute. Where a man is committed as a criminal, the conclusion must be, "until he be delivered by due course of law;" if he be committed for contumacy, it should be "until he comply."

All commitments must be to some prison within the realm of England; for by the Habeas-corpus act (stat. 31 Car. II. cap. 2.) it is enacted "that no subject of this realm, being an inhabitant or resident of this kingdom of England, dominion of Wales, or town of Berwick-upon-Tweed, shall or may be sent prisoner into Scotland, Ireland, Jersey, Guernsey, Tangier, or into any ports, garrisons, islands or paces, beyond the seas, which then were, or at any time after should be, within or without the dominions of his majesty." By stat. 14 Ed. III. c. 10, sheriffs shall have the custody of the gaol as before that time they were wont to have, and they shall put in such under keepers for whom they will answer. This is confirmed by stat. 19 Hen. VII. c. 10. It hath also been held, that regularly no one can justify the delivering of a prisoner in custody out of the common gaol, unless there be some particular reason for so doing, as sickness endangering life, or evident danger of a recess from rebels, &c.: nevertheless constant practice seems to authorize a commitment to a messenger; and it is said, that it shall be intended to have been made in order to the carrying of the party to gaol. 2 Hawk. P. C. c. 16. § 8, 9. And it is said, that if a constable bring a felon to gaol, and the gaoler refuse to receive him, the town where he is constable ought to keep him till the next gaol delivery. H. P. C. 114. 2 Hawk. P. C. c. 16. § 9. A prisoner in the custody of the king's messenger, on a warrant from the secretary of state, who is brought into K. B. by Habeas-corpus to be bailed, but has not his bail ready, cannot be committed to the same custody, under which he came; but must be committed to the custody of the marshal, which will prevent the necessity of suing out a new Habeas corpus; as he may be brought up from the prison of the court, by a rule of court, whenever he shall be prepared to give bail. 1 Burr. 466. If a person arrested in one county for a crime done in it, fly into another county, and be retaken there, he may be committed by a justice of the first county to the gaol of such county. (H. P. C. 92.) But by the better opinion, if he had, before any arrest, fled into such county, he must be committed to the gaol thereof by a justice of such county. 2 Hawk. P. C. c. 16. § 8. Dalt. c. 118. It seems also to be laid down as a rule by some books, that any offender may be committed to the gaol next to the place where he was taken, whether it be in the same county or not. 2 Hawk. P. C. c. 16. § 8. By stat. 6 Geo. I. c. 19, vagrants and other criminals, and persons charged with small offences, may, for such offences, or for want of surties, be committed either to the common gaol or house of correction, as the justices shall think proper. By stat. 24 Geo. II. c. 55, if a person is apprehended, upon a warrant indorsed, in another county, for an offence not bailable, or if he shall not there find bail, he shall be carried back into the first county, and be committed, or if bailable, bail'd by the justices in such first county.

With respect to the charges of commitment, it is enacted by stat. 3 Jac. I. c. 10, that offenders committed are to bear their own charges, and the charges of those who are appointed to guard them; and if they refuse to pay, the charges may be levied by sale of their goods. And by stat. 27 Geo. II. c. 3, if they have no goods, &c. within the county where they are apprehended, the justices are to grant a warrant on the treasurer of the county for payment of their charges. But in Mid-

differs the same shall be paid by the overseers of the poor of the parish where the person was apprehended. By stat. 3 Hen. VII. c. 3. the sheriff shall certify the names of all prisoners in his custody to the justices of gaol delivery.

Prisoners, committed at night to the proper prison, ought not to be removed thence, except in some special cases; and in peculiar circumstances, specified by 31 Car. II. c. 2. A person, legally committed for a crime, which certainly appears to have been done by some one or other, cannot be lawfully discharged by any other but the king, till he be acquitted on his trial, or have an *ignoramus* found by the grand jury, or none to prosecute him on a proclamation for that purpose, by the justices of gaol-delivery. But if a person be committed on a bare suspicion, without any appeal or indictment, for a supposed crime, when afterwards it appears there was none; as for the murder of a person thought to be dead, but afterwards found to be alive, it hath been held that he may be safely dismissed without any farther proceeding. 2 Hawk. P. C. c. 16. § 22. But the safest way for the gaoler is to have the authority of some court, or magistrate, for discharging the prisoner. If the words of a statute are not pursued in a commitment, the party shall be discharged by Habeas-corpus. Jacob's Law Dict. by Tomlin. See ARREST, BAIL, IMPRISONMENT, MITTITUS, &c.

COMMITTEE, in *Law*, one or more persons, to whom the consideration of any matter is referred, either by a court, or by consent of the parties concerned.

COMMITTEE of *Parliament*, is a board consisting of a certain number of members, appointed by the whole house for the examining of a bill, or making report of an inquiry, or process of the house, &c.

Sometimes the whole house is resolved into a *committee*; on which occasion each person has a right to speak, and reply as much, and as often as he pleases; and an expedient they usually have recourse to in extraordinary cases, and where any thing is to be thoroughly canvassed. When the house is not in a *committee*, each gives his opinion regularly, and is only allowed to speak once, unless to explain himself.

The standing *committees*, appointed by every new parliament, are those of *privileges and elections*, of *religion*, of *grievances*; of *courts of justice*, and of *trade*, though only the former act. See PARLIAMENT.

COMMITTEE of *the king*, is used for a widow of one of the king's tenants; thus called, as being by the ancient law of the realm committed to the king's care and protection. See WIDOW.

COMMITTEE of a *Lunatic*, *Idiot*, &c. denotes the person to whom the care and custody of such lunatic, &c. is committed by the court of chancery. See LUNATIC.

COMMITTEES of *Corporations*, &c. are select members who perform the general routine of business. See CORPORATIONS.

COMMEDIATE, COMMODATUM, in the *Civil Jurisprudence*, the loan or free concession of any thing moveable or immovable, for a certain time on condition of restoring again the same individual after a certain term.

The commode is a kind of loan; there is this difference, however, between a loan and a commode, that the latter is gratis, and does not transfer the property: the thing must be returned in essence, and without impairment: so that things which consume by use, or time, cannot be objects of a commode, but of a loan; in regard they may be returned in kind, though not in identity.

COMMODAVIENSIS, an appellation given by some authors to a species of *lapis calaminaris* found in Bohemia.

But as it yields no zinc, Mr. Margraff denies it to be true calamine.

COMMODITIES, *Staple*. See STAPLE.

COMMODORE, in the *British Marine*, a general officer invested with the command of a detachment of ships of war designed on any particular enterprise; during which time he bears the rank of a brigadier-general in the army, and his ship is distinguished by a broad red pendant tapering towards the outer end, and sometimes focked.

COMMODORE is also a name given to a select ship in a fleet of merchantmen, which leads the van in time of war, bearing a light in her top to conduct the rest.

COMMODUS, LUCIUS AURELIUS ANTONINUS, in *Biography*, was the only son of the emperor Marcus Antoninus and Faustina, and born A. D. 161. He was educated with the utmost attention, and he enjoyed every superior advantage from the precepts and instructions of tutors appointed to prelude over his infantile studies and pursuits; but from the first openings of his mind, he displayed an untoward disposition, and a strong propensity for low and unworthy gratifications. He discovered an aversion from whatever was rational and liberal, and a fond attachment to the sports of the circus, amphitheatre, the combats of gladiators, and the hunting and destroying of wild beasts. To wean him from these pursuits, and with a view of engaging his mind in useful and manly occupations, his father made him a partaker of the sovereign power in his fifteenth year. This instance of parental affection did not produce the desired effect; it only furnished him with better opportunities of indulging every sensual gratification. Upon the death of Marcus, in the year 180; he succeeded to the quiet and undisputed possession of the throne; he saw about him neither competitor to remove nor enemies to punish, and during the first three years of his reign, the influence of his father's virtuous counsellors restrained him from any acts of tyranny towards his subjects. During this period, however, he indulged in every species of licentiousness, and revelled in all the licence of sovereign and unrestrained power, but his hands were unstained with blood, and occasionally he displayed a generosity of sentiment worthy of a great mind; he had in one instance refused to see the proofs of a conspiracy formed against him, and it was hoped he might have followed the track of his illustrious father. A fatal incident decided his fluctuating character. An assassin was employed to destroy him; in making the attempt he exclaimed "the senate sends you this." The deed was prevented, and Commodus from that hour encouraged a deep-rooted hatred for the whole body of senators. Spies and informers increased his suspicions and excited his jealousy of power in any other hands than his own. Accusation was regarded as proof, and the mockery of a pretended trial led only to certain condemnation. The execution of any considerable senator was ever attended with the death of all those who should attempt to revenge, or publicly dare to lament his fate, and when Commodus had tasted of human blood, he became incapable of pity or remorse. His ministers were one after another the victims of his fears or of his cruelty. Perennis was condemned to die for a charge of aspiring to the empire, and after his death the conduct of Commodus assumed the appearance of virtue. He repealed the most odious of his minister's acts, loaded his memory with public execrations, and ascribed to his pernicious counsels, all the errors of inexperienced youth. But his seeming repentance lasted only a short month, and then every sentiment of humanity appeared to be obliterated from his breast. He abandoned the reins of government to the most unworthy, and he valued nothing in sovereign power,

except the unbounded licence of indulging his sensual appetites. His hours were spent in a seraglio of beautiful women and boys, selected from all ranks of the people, and from every province of the empire. The intervals of lust were filled up with the basest amusements. The ferule crowd, whose fortune depended on their monarch's vices, applauded these vile pursuits. Having by long practice attained great skill in the use of the bow, he exhibited his talents before the people, and animals of the rarest species were collected from the remotest part of his dominions in order to serve as marks for the leoparded archer. The peridious voice of flattery reminded him that by exploits of the same nature, the Grecian Hercules had acquired a place among the gods, and an immortal memory among men. He accordingly assumed the title and insignia of Hercules; in this character he assembled all the helpless and distressed of the city, and causing them to be wrapped up in fantastical habits, like dragons and monsters, and armed with sponges instead of stones, he rushed upon them with his club and laid them all dead at his feet. He exhibited himself more than 700 times in the character of a gladiator, and in all his combats he was victorious, but his amusements in this way were frequently fatal to his antagonists. It would take more of our work than can be allotted to this article to describe all the cruelties and acts of savage barbarity which disgraced the reign of Commodus. At length his detestable career came to its merited end. Opposition to his bloody designs was given by some of his bosom counsellors, among whom was Marcia, his favourite concubine. He resolved to put them to death, and entered their names in a long list destined to the same fate. Marcia discovered his intentions, and apprized her friends of their common danger. They resolved to anticipate the blow, and Marcia mixing some poison in wine, presented it to him as he came from the bath. He soon fell asleep, but the dose not being sufficiently strong, he awoke; while, however, he was labouring under the effects of the poison, a robust youth, by profession a wrestler, entered his chamber, and strangled him without resistance. The body was secretly conveyed out of the palace, before a suspicion was entertained either in the city or the court of the emperor's death. Such was the fate of Commodus, and "so easy," says the historian, "was it to destroy a tyrant, who, by the artificial powers of government, had oppressed, during thirteen years, to many millions of subjects, each of whom was equal to their master in personal strength and personal abilities." Gibbon.

COMMOUNGNE, in *Law*, a word signifying a fellow-mosk, that lives in the same convent. 3 Inst. 15.

COMMON, in *Agriculture*, an open piece of ground, made use of equally by different persons who occupy lands in the parish to which it belongs or in which it lies.

It is remarked by Mr. Marshall in his "Treatise on Landed Property," in regard to the origin of commonable lands, "that, a very few centuries ago, nearly the whole of the lands of England lay in an open, and more or less in a commonable state. Each parish, or township, (at least in the more central and northern districts) comprised different descriptions of lands; having been subjected, during successive ages, to specified modes of occupancy, under ancient and strict regulations, which time has converted into law. These parochial arrangements, however, varied somewhat in different districts; but, in the more central and greater part of the kingdom, not widely. Under this ingenious mode of organization, each parish or township was, he says, considered as one common farm, though the tenantry were numerous. Round the village in which the tenants resided lay a

few small inclosures or *grass yards* for rearing calves, and as baiting and usury grounds for other farm-stock. This was the common farmlet or *homestead*, which was generally placed as near the centre of the more culturable lands of the parish or township as water and shelter would permit." And that "round the homestead lay a suit of *arable fields*, including the deepest and fondest of the lower grounds, situated out of waters' way, for raising corn and pulse: as well as to produce fodder and litter for cattle and horses in the winter season." While in the lowest situation, as in the water-formed base of a rivered valley, or in swampy dips, shooting up among the arable lands, lay an extent of *meadow grounds* or *ings*, to afford a supply of hay for cows and working flock, in the winter and spring months.

That on the out-skirts of the arable lands, where the soil is adapted to the pasturage of cattle, or on the springy slope of hills, less adapted to cultivation, or in the fenny leases of valleys, which were tunnel or gravelly water-formed lands, which were too dry to produce an annual supply of hay with sufficient certainty, one or more *stinted pastures*, or hams, were laid out, for milking cows, working cattle, or other stock which requires superior pasturage, in summer.

While the best and worst-soiled, and most distant lands of the township were left in their native wild state, for *timber and fuel*, and for a *common pasture*, or suit of pastures, for the more ordinary flock of the township, whether horses, rearing cattle, sheep or swine, without any other stint, or restriction, than what the arable and meadow lands indirectly gave; every joint tenant, or occupier of the township, having the nominal privilege of keeping as much live stock on these commons, in summer, as the appropriated lands he occupied would maintain, in winter.

Further, that the appropriated lands of each township were laid out with equal good sense and propriety. That each occupier might have his proportionate share of lands of different qualities, and lying in different situations, the arable lands more particularly were divided into numerous parcels, of sizes, doubtless, according to the size of the given township, and the number and rank of the occupiers.

And that the whole might be subjected to the same plan of management, and be conducted as one common farm, the arable lands were moreover divided into compartments, or "fields," of nearly equal size, and generally three in number, to receive, in constant rotation, the triennial succession of fallow, wheat (or rye), and spring crops, (as barley, oats, beans, and peas), thus adopting and promoting a system of husbandry, which, howsoever improper it is become in these more enlightened days, was well adapted to the state of ignorance and vassalage of feudal times, when each parish or township had its sole proprietor; the occupiers being at once his tenants and his soldiers, or meane vassals. The lands were in course liable to be more or less deserted by their occupiers, and left to the feebleness of the young, the aged, and the weaker sex. But the whole township being, in this manner, thrown into one system, the care and management of the live stock at least would be easier and better than they would have been under any other arrangement. And at all times, the manager of the estate was better enabled to detect bad husbandry, and enforce that which was profitable to the tenants and the estate, by having the whole spread under the eye at once, than he would have been had the lands been distributed in detached inclosed farmlets, besides avoiding the expence of inclosure. And another advantage, he thinks, arose from this more social arrangement: in barbarous times the tenants, by being concentrated in villages, were not only best situated to defend each other from predatory at-

tacks,

tacks, but were called out by their lord with greater readiness in cases of emergency.

But it is remarkable, that beside the organized townships which were inhabited and cultivated in the manner described, there were, and are to the present day, in different parts of England, extensive tracts of lands, some of them of a valuable quality, which lie nearly in a state of wild nature!—These uninhabited tracts are styled *forstles*, and heretofore many or most of them have been attached to the crown; and some of them are still under royal patronage. Whether they were originally set out for amusement merely, or whether the timber which stood on them was of peculiar value, or whether, at the time of laying out townships, those tracts were impenetrable woods inhabited by wild beasts, and when these were destroyed, or sufficiently overcome to render them objects of diversion, were taken under the protection of the crown, is not perhaps well ascertained. But let the original intention have been either of these, it no longer exists. The timber in most cases has fallen a sacrifice to age and neglect, and the game is no longer an object of regal pastime. But whether or not the forests (now so called) originated in wild woodlands, occupied by ferocious animals at the time of laying out townships, there were doubtless tracts of that description in different parts of the kingdom, and which now bear no marks of the common field system; but which appear evidently to have been inclosed from a state of woodland or common pasture; though it is possible they may have been nominally attached to neighbouring parishes. Of this description principally are the woods of Kent and Sussex, and many other old inclosed lands in different parts of the kingdom, whose fields or inclosures are of irregular shapes, and their fences crooked. And it is observable, that these woodland districts, as the forest lands, are divided into manors, which have not an intimate connection, or correspondence with parishes or townships; a further evidence that they were in a wild state, when the feudal organization took place.

It is stated by the author of "Modern Agriculture," that "on all the open field parishes, where the same arrangement continues as was at first established, there is a considerable extent of common field allotted for the pasturage of the live stock belonging to the inhabitants. These generally consist of such lands as are left fit for the plough, or more distant from the town or village. The parish commons are for the most part divided into three fields; one for the pasturage of the horses, another for the neat cattle, and the third for the sheep. These horses are generally tended by one of the farmer's servants. The whole of the sheep belonging to the parish are put under the charge of a common shepherd, who is hired at the general expence; and the cows and young cattle are taken care of nearly in a similar manner. Where the inhabitants of several adjoining parishes possess rights of common pasturage on an extensive common, as is frequently the case, particularly in the counties of Middlesex, Surry, Northampton, and other districts in the middle and southern parts of the kingdom, all the horses, cattle, sheep, hogs, &c. which are sent to the commons, are committed to the care of one or more persons appointed for the purpose. In some cases the right is limited; or, as it is called, *flinted*. When that is the case, such a number of cattle only, as the straw and hay growing on the farms will maintain in winter, is permitted to pasture these commons in summer. And therefore each farmer is, by particular laws, prevented from sending above a certain number, which is regulated, partly by the extent of his farm, and in some cases by the title on which he claims a right of commonage in the particular instance.

But where the common is unlimited; or in other words, where the farmers possess right of pasturing any number and species of live stock which they choose to send, and without restraint of any kind, the value of such right is considered by many farmers to be inconsiderable as not to be worthy of their attention. Such farms as possess improved breeds of horses, cattle, and sheep, seldom, indeed, if ever, send any of them to be pastured on the commons, whether flinted or unlimited. They generally dispense of their right, for a trifle, to some neighbouring farmers or dealers, who have no objection, in the view of profit, of running the risk of their cattle meeting with accidents, or being infected with disease, as most naturally be expected to happen on these extensive commons, where so many cattle are promiscuously collected together.

It has been remarked by a late able writer, that "the commons in Middlesex, as in most other places, are three fourths of them covered with heath and furze, from which a little of the worst sort of firing is obtained by the poor. The trifling quantity of food which cattle consume from these shrubs, does not, and indeed cannot, improve them, as it is barely sufficient to keep them from starving. Much of the remainder is occupied by roads, gravel pits, and ponds, yielding nothing. After the most mature consideration, I am inclined to think, that about 5,500 acres of the commons in the above county are employed in the production of grass for the feeding of cattle, affording indeed but a miserable pasture, as the greater part is under water during winter; and, from being poached and trodden down by cattle while wet, is rendered hard, lumpy, full of holes, and partakes of the sterility of moor during summer. The grasses are mostly of the dwarf kind, and of scanty produce, with a large proportion of the carnation and other grasses which are known to be rather more dangerous than nourishing; so much so, as to induce some of the most observing farmers in various parts of the kingdom, possessing extensive common rights, after a fair trial to refrain altogether from turning their cattle on such commons.

On such authority it may well, he says, be questioned, whether commons are of any more use to the community than they would be were they confined to the bottom of the deep. But without attempting the solution of such a question at present, he may be allowed to observe, that the value of commons, considered solely as to their power of increasing animal food, and as totally unconnected with the adjoining inclosures, is extremely small indeed. But when considered as affording an opportunity to the neighbouring farmer to turn his stock out, at certain seasons of the year, they become an object of some importance. For in the spring quarter of the year, by receiving the stock during these months, the growth of hay is encouraged, they answer the purpose of pasture, and the farmer is thereby enabled to mow all his grass land; which must sensibly increase the quantity of hay to be sent to market; as at Finchley and Harrowweald in this county; or being applied during the winter months to the support of a greater quantity of live stock in places more distant from a good hay-market; and in others, for the purpose of folding on the arable land."

It is further stated, that "on estimating the value of the commons in the same county, including every advantage that can be derived from them in pasturage, locality of situation, and the barbarous custom of turbarry, it appears, he says, that they do not produce to the community, in their present state, more than four shillings per acre! On the other hand, they are, in many instances, of real injury to the public, by holding out a lure to the poor man for procuring the means of materials

wherewith to build his cottage, and ground to erect it upon; together with fising, and the run of his poultry and pigs for nothing. This is of course temptation sufficient to induce a great number of poor persons to settle upon the borders of such commons. But the mischief does not, he says, end here: for having gained these trifling advantages, through the neglect or connivance of the lord of the manor, it unfortunately gives their minds an improper bias, and inculcates a desire to live from that time forward without labour, or at least with as little as possible. The animals kept by this description of persons, it is soon discovered by their owners, are not likely to afford them much revenue, without better feed than the scanty herbage of a common. Hence they are tempted to pilfer corn, &c. towards their support: and, as they are still dependent on such a deceptive supply, to answer the demands of their consumption, they are in some measure constrained to resort to various dishonest means, so as to make up the deficiency.

And there is another very serious evil which the public suffers from these commons, the same writer observes, which is, "that they are the constant rendezvous of gipsies, strollers, and other loose persons, living under tents, which they carry with them from place to place according to their convenience. Most of these persons have asses, many of them horses, nay, some of them have even covered carts, which answer the double purpose of a caravan for concealing and carrying off the property they have stolen, and also of a house for sleeping in at night. They usually stay a week or two at a place; and the cattle which they keep serve to transport their few articles of furniture from one common to another. These, during the stay of their owners, are turned adrift to procure what food they can find in the neighbourhood of their tents, and the deficiency is made up from the adjacent hay-stacks, barns, and granaries. They are known, he says, never to buy any hay or corn, and yet their cattle are supplied with these articles of good quality. The women and children beg and pilfer, and the men commit greater acts of dishonesty. In short, says he, the commons of this county are well known to be the constant resort of footpads and highwaymen, and are literally and proverbially a public nuisance. And that they are so in the more distant counties is evident, from the Gloucester and Hereford reports of the state of agriculture. There are also many additional injuries which commons render to society, of other kinds to those which have been noticed above. But that the commons of Middlesex, says he, are capable of being improved, so as to produce large crops of all the vegetables usually cultivated, and to rear and support a very highly improved breed of cattle, there can be no sort of doubt. Indeed it is truly lamentable to see, in every part of these kingdoms, such extensive tracts of land lying waste or uncultivated; producing no revenue to the owners of such property, and extremely doubtful if of any, the smallest benefit to the community. But it is particularly disgraceful to this, the first and principal county, which, so far from raising a sufficient supply of bread for its inhabitants, is under the necessity of importing corn from every quarter of the world (Europe, Asia, Africa, and America) while, at the same time, it has so many acres of good land lying waste, and locked up from the operation of the plough. By the single means of inclosure an abundant quantity of corn might be produced, and 150,000*l.* a year added to the wealth of the county, which is now absolutely lost to society, with as careless an indifference as if the proprietors of the soil were afraid of becoming too rich; or, as if like the dog in the manger they would not permit the community to share in a blessing of which they themselves are not inclined to partake.

The benefits and advantages that would be derived from a general inclosure of commons, are, he thinks, so numerous, as far to exceed his powers of description or computation. The opportunity it would afford of separating dry ground from wet, of well draining the latter, and liming the rotten parts, is of infinite consequence: as such an arrangement would, with the aid of intelligent breeders, be the means of raising a breed of sheep and neat cattle far superior to the present race of wretched half-starved animals now seen in such situations. It would have the effect of supporting a more numerous flock upon the same quantity of food by restraining the cattle and sheep within due bounds. Their restlessness and rambling disposition not only treads the grass off the ground, but also takes the flesh off their bones. This renders the attendance of a shepherd necessary, and requires likewise that they may be driven to and from the fold. Further, the live-stock would by this means be rendered many hundreds per cent. more valuable to individuals and the community than it has hitherto been, or can possibly be, without inclosure; and, what is of the last, the greatest importance, it would tend to preserve such improved breeds from that destructive maul, (the rot) which makes such terrible havoc among our flocks. Add to this, that the markets would be more plentifully supplied with beef and mutton, and the price of these articles considerably reduced.

It does not, he says, appear necessary to state with precision (nor indeed is it capable of being so stated) what would be the increase or value of the commons of this country on their being inclosed and well and properly cultivated. It may, however, with safety be stated at upwards of 15 times their present value to the proprietors, and 40 times their present value to the public. But increasing the rental of such land to 15, or perhaps 20 times, its present amount, is by no means the greatest advantage that may be expected to result from an inclosure of commons. The general salubrity and healthiness of the country would necessarily be improved, while industry would be largely increased among the most useful classes of society, beggary and robbery much lessened, and the general stock of corn and cattle almost inconceivably augmented. And wherever inclosures are made with due attention to the interest of the poor (as they ought always to be), they will be found to ameliorate their condition, as much as they increase the property and the comforts of the rich."

It is further observed, that "the commons of this kingdom being, with very few exceptions, without ridges, furrows, or drains, have not the means of discharging that superfluous water from the surface of them, which is well known to be of great detriment to vegetation in general.

Many commons in low situations, and where the soil happens to be of a retentive quality, hold water like a sponge, which being always stagnant, as well as excessive in quality, renders the soil of such commons much too wet for the pasturage of sheep, and is, no doubt, the cause of many of the disorders which that animal is subject to, particularly that fatal malady, the rot. From the same causes, also, the neighbourhood of most commons must be particularly unfriendly to the health and longevity of man. Only let us, says he, reverse the scene, and for a moment suppose these commons to be inclosed, the necessary ditches and drains sunk, and the land brought into tillage, and we shall see all the superabundant moisture got rid of; and the water, being kept in constant motion, by trickling down the sides of the ridges into the furrows, and from thence into the ditches and rivulets, will be found to fertilize the very soil which in its present stagnant state it serves to injure;

injure; while, by leaving the land dry, it will be rendered more healthy both for men and cattle. The effects of such a measure would soon shew themselves in many districts of this island, which, at present, are very unpropitious to the health of man, in the much greater longevity of the inhabitants. It may also be further noticed, he says, that commons are entirely defective in the great article of labour; but no sooner does an inclosure take place, than the scene is agreeably changed from a dreary waste, to the more pleasing one of the same spot, appearing all animation, activity, and bustle. Every man, capable of performing such operations, is furnished with plenty of employment, in sinking ditches and drains, in making banks and hedges, and in planting quicks and trees. Nor are the wheelwright, carpenter, smith, and other rural artificers, under the necessity of being idle spectators of the scene, since abundance of work will be found for them, in the creation of farm houses, and the necessary appendages thereto; and in the forming and making of roads, bridges, gates, stiles, implements of husbandry, &c. Even after a few years, when this kind of temporary exertion is over, by the whole being brought into a regular system of husbandry, it will still continue to provide both food and employment for a very increased population.

“It is highly probable, he thinks, that if the legislature should pass an act for the general inclosure of waste land, it would increase the quantity of rural labour so much as to advance its price considerably, and thereby have the good effect of drawing a vast number of hands out of the unwholesome confinement of manufactories; where, in addition to the life-shortening effects of such confinement, the morals of the people are exposed to certain contamination.”

With respect to the effect produced by inclosures on the population of the country, it may be observed, that the inclosing of 1000 acres in any one parish would probably require 100 different labourers, many of whom would undoubtedly be drawn from such of the adjoining parishes as had less work than workmen. Thus it must follow, that the neighbouring towns and villages would diminish, just as much as the parish in which the inclosure is going forward, would increase its numbers; yet the amount of the community will evidently be the same. But although the inclosing of waste land certainly does not immediately either increase or lessen population, as some writers seem to have supposed, yet, that inclosures ultimately affect population, (and that as to its increase,) inasmuch as the district is thereby made more conducive to health, is, he says, sufficiently evident. Every thing that has a tendency to make a nation more healthy and productive, must, of necessity, operate as a stimulus to population. The certainty of a man's being able, with ease and comfort, to provide for himself and family, by the increase of rural labour, is at once an inducement to marriage, and a consequent increase of population.

The inhabitants wholly supported by agriculture in England and Wales, appear, the same writer says, to be nearly, or perhaps quite, six millions, (while it supplies provisions for near two millions more,) or one to every six acres and a half of cultivated soil. The estimation is made in this manner.

ESTIMATE.

Cultivators of farms, six persons to every	
100 acres, is	2,340,000
Ditto of gardens, hop-grounds, nurseries, &c.	300,000

Smiths, wheel-wrights, bricklayers, masons,	Brought over
carpenters, painters, plumbers, glaziers,	2,640,000
various manufacturers of furniture, woollen	
cloth, and making it up, linen, and making	
it up, leather, and making it into shoes,	
boots, &c. horse, harness, and saddlery; as	
many of each of this description of persons,	
as are wholly employed by the cultivators	
of the soil; men, women, and children,	
about seven persons to each farm, of 100	
acres, is	2,800,000
The like of millers, bakers, maltsters, brewers,	
distillers, starch-makers, dealers in corn, and	
persons employed in the commerce of corn	500,000
The landlords of farms	40,000
Persons supported by taxes on the produce of	
land	120,000
	<hr/>
	6,100,000

Not but that the extremes vary much, as there are some few grazing farms, with only one soul to fifty, and arable farms that are peopled in the proportion of one person to three acres of land. In point of produce, the commons, in their present state, apparently, though, he thinks, not really afford entire support to human beings, in the proportion of one to an hundred acres. But by being inclosed, and brought into the present ordinary cultivation of the country, every six acres and a half might do the same.

Should agriculture experience a rapid advance towards perfection, as there is reason to imagine it will, both from the exertions of the board, and of intelligent individuals, every three or four acres, would, in a few years, be capable of supporting its inhabitant; and, as from its nature, it might certainly be carried on from one degree of perfection to another; it may even arrive at such a pitch of excellence, as that every acre of land shall support its man.”

It has long since been well observed by Dr. Anderson, that while land is in the condition of common, man is debarred from ever being able to ameliorate the soil, and thus to augment its product to the state; but that he is not prevented so effectually from deteriorating it. While, in the state of a common, the surface of the ground may be broken by him in such a way, as not to recover for ages a swart equal to that which was originally upon it. It may be cast up and sunk into pits; it may be converted into wet and rotten marshes, by casual obstructions being thrown in the way of the water, which no one finds it his interest to remove; it may, in short, while a common, be abused in a thousand ways, by reason of the obliquity, indolence, or caprice of individuals, but it never can be benefited by the industry of man; and not only may this be done, but these things actually are done, in innumerable instances; so that to a person who contemplates the loss that the nation must sustain by these deplorable abuses, nothing can afford a more melancholy train of reflections, than that which the frequent recurrence of those disgusting commons suggests to his mind, as he travels over the otherwise delightful country of England. When he stops to inquire more minutely into the effects of this kind of property upon the morals and domestic economy of the individuals who claim a right to these commons, he only finds additional causes, he says, of regret. He frequently discovers that the quiet and industrious cultivator, having a right upon a common, is obliged to aban-

don that right, because of the harrassments to which he is subjected from turbulent and assuming neighbours, who have obtained a small footing there, with a predetermined resolution, to baps, to encroach much farther than their right would authorize; because they know that towards the restraining of these excesses, no obvious and easy means occur. Thus does the peaceable man often find it better to relinquish his right almost entirely, than be subjected to the perpetual contention that would occur in defending it. Such an inquirer frequently finds, that in consequence of this, the small flocks of the poor cottager, who cannot afford to look after them continually himself, are so tormented by being chased from place to place by these marauders, that instead of a relief to the poor cottager, these flocks prove only a torment to him; his family becomes, in consequence of this, a burthen on the parish, which is obliged to support them; he finds, that among those who are bred up in these situations, there are many young men who delight more in active plunder, than in sober industry; and who, tempted by the high prices that luxurious inhabitants of towns offer for game, become poachers, and from such powerful confederations of determined profligates for their mutual protection, that no one, less determined than themselves, will dare to interfere with them; which enables them to carry on their depredations with impunity. He further observes, that the money these young men thus acquire, is usually squandered in drinking and riotous excesses; the young women are contaminated by their conversation, corrupted by their excesses, and debauched; the last evil attending which courses, is a great number of illegitimate children, and an extravagant poor rate. But who, says he, can estimate the detriment that a nation sustains, when the morals of the country inhabitants of it become corrupted? It is like, says he, tainting the springs of water with poison, which, instead of promoting health and vigour, as they naturally ought to have done, produce one universal cause of infectious disease. It is common, he adds, to read in the History of Britain, that the rot became at times so prevalent in England, as to carry off many millions of sheep at once; and these diseases were regarded, like the pestilence among the human species, as a terrible visitation of heaven for the sins of a guilty land. There is great reason to believe that these frequent mortalities among the flocks were entirely occasioned by the numerous commons, which were in those times much more extensive than at present; for it is still known, that in neglected spots, where water is allowed to stagnate and congregate marshes, as is often the case with commons when the season proves wet, the sheep pastured upon them are, to this day, so much subjected to the rot, as to induce many persons, as has been observed, rather to give up their right, than to allow their flocks to enter upon these unhealthy pastures. Considered under every possible point of view, then, says he, it appears to be undeniable, that the prevalence of commons is a great national grievance, which ought, if possible, to be removed; and that the Board of Agriculture cannot be more beneficially employed, than by granting all the aid that their wisdom can devise, for removing these bars that at present tend to prevent the equitable division of this kind of property.

It is evident from every one of the agricultural surveys which have been yet made, he says, that in every county in England and Wales, there are extensive tracts of land of this description (for commons and wastes may be considered as nearly synonymous terms, although it be a truth that many of these commons consist of land naturally as good as any in the kingdom). Of the extent of these lands, were it necessary, a tolerably accurate knowledge, he thinks,

might be obtained; but as to the amount of improvement, it is impossible for any person to form at present an idea of it, should the prosperity of this country be permitted to go forward for a considerable length of time in that accelerating ratio into which it would naturally fall, if the general tranquillity of the nation were preserved, and the obstructions which have hitherto repressed exertions in agriculture removed. It is enough here to say, he thinks, that it would be an object of immense magnitude. He has had occasion to observe, that in some favourable situations, it is well known that land, in the course of a very few years, has been made a thousand times at least more productive than in its original state. Many commons are at present lying waste in situations equally favourable as these; and many other situations may become equally favourable by an extension of those modes of facilitating intercourse, which are now in contemplation, and are only prevented from being carried into effect by barriers that judicious laws may easily remove. See WASTE LAND.

In regard to the appropriation of commonable lands, it has been observed by Mr. Marshall, that the species of unappropriated lands in this country are, at present,

1st. "Forest lands, and other extensive wastes, on which several manors, or adjacent townships, have a right of common pasturage.

2d. "Commonable lands of distinct townships, or manors, whose appropriated lands are wholly inclosed, and in a state of mixed cultivation.

3d. "Commonable lands of townships, whose arable fields, &c. are partially inclosed;" and

4th. "Commonable lands of townships, whose arable fields remain wholly open."

And in respect to the principles on which the appropriation of such lands requires to be conducted, it may be observed, that as, by an established principle of the general law or constitution of the country, immemorial custom establishes right, neither the original rights and regulations, respecting such lands, nor the changes which may have taken place during a succession of centuries, from the origin of forests and townships, to the latest periods of time, are objects of investigation or inquiry; but many acquired rights which exist in any certain case at the time of appropriation, and which would continue to exist were it not to take place. "The possessor of a cottage," says the same writer, "which has enjoyed, time immemorial and without interruption, the liberty of pasturage, though such cottage were originally an encroachment of a *freedbooter* or an *outlaw*, has indisputably as legal a claim to a proportionate share of the commonable lands, as the possessor of the demesne lands of the manor has (merely as such), although they may have descended from father to son from the time of their feofforality. For it is evidently on the estimated values of the respective rights which exist, and which can be rightfully exercised in time to come, and on these alone, that a just and equitable distribution can be effected."

It is, however, stated, that before the distribution of commonable lands among the owners of common pasturage can take place, the more *abstract rights* which belong to commons require to be estimated, and the just claims of their possessors to be satisfied. These are, he says, principally manorial rights, and the rights of tithes.

The manorial claims are to be regulated by the particular advantages which the lord of a given manor enjoys, and which he will continue to enjoy, while the commons remain open and unappropriated; whether they arise from mines, quarries, water, timber, alien tenants, fuel, estover, pannage, or game? And that "his claim, as guardian of the soil, as productive

productive of *pasturage only*, is in most cases only honorary; he cannot as such (unless through ancient custom) profit by the *herbage* or the *browse* that the soil produces." But that "the claim of the lord of the manor, in right of the soil on which *thriving timber* is standing, is substantial. For out of this, he has, in effect, a real yearly income, equal to the annually increasing value of the timber: a species of advantage which, if the commons remain open and unappropriated, he will in course continue to enjoy, so long as the timber continues to increase in its value. His claim, therefore, in this respect, depends on the quantity of timber, and its rate of growth taken jointly. Young thriving timber *in situ* only affords an annual increase of value at present, but will continue its benefits for many years to come, if it be suffered to remain undisturbed on the soil which supports it, during the estimated period of its future increase; whereas, dotards, and stunted trees which afford no increase of value, do not entitle their owner to any share of the soil they stand upon. The trees themselves, or their intrinsic value, are all the lord of the manor can have a right to claim."

And further, in like manner, the claims of the crown, or of hereditary rangers (if any), on the forest lands, ought, he conceives, to be satisfied.

But the claims of *tithe owners*, aggregately considered, are more complex and obscure. In a case where the great and small tithes are united, where the tithe of wool and lamb, and that of grain, roots, and herbage, belong to the same owner, and where no modus exists, it may seem to be reasonable that he should have the option of receiving land of equal value to the existing value of the whole of the tithes, or of taking the chance of their value, in the state of cultivation. But seeing the evil tendency of corn tithes, and the impropriety of laying on so harmful a burthen, as they are now become, upon lands that have never borne it, there can be little risk in saying that it would be at least politic in parliament to prevent it. Beside, it stands part of the statute law, he believes, that the lands which have never been under tillage, shall not pay tithes during the first seven years of their cultivation; during which time, the incumbent's income might, by leaving the tithe to take its course, be materially abridged, and his circumstances thereby be rendered distressing.

It is therefore concluded, that, on the whole, it appears to be proper in this case, that the law should instruct commissioners to set out lands equal to the existing value of the tithes at the time of appropriation; and, where much corn land (land fit for corn) shall be appropriated, to set out a farther quantity, equal to the reversion of the extra value of the tithes to arise from such corn lands, seven years after the appropriation shall have taken place, above the value of the tithes that exist, provided any such extra value shall appear by the estimates.

And further "in cases in which the tithe of lamb and wool, and the tithe of corn, &c. belong to separate owners, the line of rectitude and strict justice to all parties, appears, he says, to be still more difficult to draw. The former is clearly entitled to land, or a money payment equal to his loss of tithe; but the right of the other is less obvious. To cut him off entirely from any share of the lands, and likewise from any share of tithes to arise from them after they shall be appropriated, may seem unjust; he may be a lay rector, and may have lately purchased the tithes, or a clerical rector who has recently bought the advowson under the expectation of an *inclosure*. On the other hand, it appears to be hard that the proprietors of the parish should first give up land for the tithe of wool and lamb which will no longer exist, and then be liable to a corn tithe on the

same lands, after they shall have bestowed on them great expense in clearing and cultivation. Indeed the injustice of such a measure is evident. A middle way, therefore, he thinks, requires to be sought; and it will be difficult, perhaps, to find one which has more justice in it than that which is proposed for the first case."

It may, however, says he, be urged that, admitting the foregoing regulation to be the true ground on which a remuneration in lieu of tithes of commonable lands ought to be eliminated, the difficulties of cultivation would in some cases be great, and might be the cause of dispute and delay in the general work of appropriation; and a more practical method, though less reconcileable to theory, presents itself. Thus, let a certain proportion in value, of the lands to be appropriated as one, be assigned in lieu of the whole of the tithes of the township or manor, supposing the whole be payable in kind; and if there are more than one tithe owner in the manor or township, let the commissioners divide, such aggregate allotment among the several owners and claimants, as the rector, the vicar, &c.; and the owners of land, &c. who pay tithes by ancient modus not in kind: such owners being entitled to a share of the same as the tithe owners, in proportion to the advantage they receive, by such ancient privilege.

And if any other abstract claim on the lands to be appropriated be fairly made out, or any alien right, as that of a non-parishioner, or extra manorial occupier who has acquired by ancient grant, or by prescription, the privilege of depasturing them, be fully proved, its value requires to be accurately estimated, and land to be assigned in lieu of it."

When this has been done, the remainder of the *unlimited commons* of a given township or manor belongs to the owners of its common right lands and houses; but in what proportion may be difficult to determine with mathematical precision. Nevertheless, by adhering strictly to the general principle, on which alone he conceives an equitable appropriation can be conducted, *viz.* that of determining each man's share by the benefit which he has a right to receive at the time of appropriation, and which he might continue to receive, were it not to take place, truth and justice may be sufficiently near approached.

He considers that one of the first steps towards an equitable distribution of unlimited commons, is to ascertain the common right houses, and to distinguish them from those which have no right of commonage, and which therefore can have no claim to any share of the lands of the unlimited commons, further than the right of the lands they stand upon.

By ancient, and, he believes, pretty generally received, though somewhat vague idea, respecting the rights of commonage, the occupier of every common right house has the privilege of depasturing as many cattle, sheep, or other live stock, on the common in summer (provided, it must be understood, that it is large enough to permit every occupier to exercise this right), as the grounds he occupies within the township or manor can properly maintain in winter; and no one can exceed that proportion, for the surplus of the pasturage (if any) belongs to the lord of the soil, according to Fitzherbert and Blackstone.

Under this regulation, the appropriated lands of a common field township, which are not occupied jointly with a common right house, may be said to be deprived, during the time they are so occupied, of their right of commonage. And in some of the private bills of inclosure, which have been suffered to pass through parliament, the lands which happened to be in this state of occupancy at the time of passing

passing the bills, were deprived of their interest in the common lands, for ever: Notwithstanding, perhaps, they had a few years preceding this accidental circumstance, an undoubted right to their portion of them; a right which, a few weeks or a few days afterward, might have reverted to them, without the smallest hint, by the temporary alienation. If any of the appropriated lands of a township or manor have been estranged from its commons, during time immemorial, have never been occupied jointly with a common right house, or in any way enjoyed of right the common pasturage, within memory, they may, with some reason, be said to have lost their right, and be excluded from a participation.

It is stated, that by this ancient, and in a degree essential, usage, common right houses have a clear right to the land of the commons, superior to the ground they stand upon; especially if they rightfully enjoy a privilege of partaking of the fuel and pannage they afford; for these properly belong to the houses, not to the lands; and still especially if they are not conveniently situated for enjoying the several benefits which the commons afford in their wild state. And whatever a common right house is worth, merely as such, that is to say, whatever it will let or sell for, over and above a non-common right house of the same intrinsic value, it certainly ought to participate, in the distribution, according to such extra value.

“The true proportionate shares of the common right lands are to be ascertained on the same principle. For although the ancient regulation respecting common right may continue in force while the commons remain open and unappropriated, it would be found troublesome, or unmanageable, as a rule to their just appropriation. There are few, if any, commons (of common-field townships at least) that now afford pasturage in summer for all the stock which the appropriated lands are capable of maintaining in winter; so that their several proportions only could be used: and these proportions may be calculated with much greater certainty and dispatch, on the respective rental values of the lands, than on the more vague and troublesome estimation of the quantities of stock they would winter, which indeed would be best calculated by the rental value of the land. Consequently, in adopting this as the basis of calculation, the ancient rule is in effect complied with.

But still there is another circumstance, he says, of some importance, which requires attention, before an equitable distribution can be made. For although each common right occupier may have a right to stock in proportion to the productiveness or rental value of his appropriated lands, every one could not do this with equal profit, and of course could not receive equal benefit. Lands situated on the side of a common, are much more beneficial in this respect, than lands which lie a mile or two from it, with bad roads between them. And it is the real advantage which an occupier can freely receive that is the true guide in the partition; which consequent y ought to be conducted, not on the rental value of the land, abstractly considered, but on this and its situation with respect to the commonable lands, jointly. In other words, it is the rental values of the common right lands while the commons remain open, not what they will become after the commons are inclosed, which he conceives to be the proper ground-work of appropriation. And that in cases where commonable lands are wholly attached to manors, and not common to the parish or township in which they are situated, as in forests and woodland districts, the self-same principle of distribution is applicable. The remainder of the commons (after the owners of abstract rights have been satisfied) belong to the common right lands and

houses, no matter whether such lands and houses belong to copyhold tenants exclusively, or to copyholders and freeholders jointly, provided the immemorial custom of the manor make no distinction in their respective rights; the well established customs of manors being in all cases rules of conduct and unerring guides to commissioners.”

With these, he supposes, end the great difficulties as to the principles of appropriation; the rest he considers as merely technical; the works of admeasurement, estimation, and calculation; operations that are familiar to professional men in every district, and which require nothing but application and integrity to render them sufficiently accurate. It is however a matter of vast importance to have persons fully conversant with the subject as commissioners in all such cases.

Through the uncertainty and expence attending private acts, a great portion of these uninclosed common lands remain nearly as nature left them;—appearing in the present state of civilization and science, as blotches on the face of the country, especially when seen under the threatening clouds of famine, which have now repeatedly overspread it.

COMMON-FIELD Land, signifies a description of land of a somewhat similar kind to that of commons, only lying in extensive fields. There is a large portion of this sort of land in almost every county of the kingdom. It has been observed by Mr. Malleson, that the common arable fields in the county of Middlesex are about 20,000 acres; and in that, as well as in most other counties, are divided into too small properties to be advantageously cultivated. He says he has known thirty landlords on a field of 200 acres; and the property of each so divided as to lie in ten or twenty places, containing from an acre or two downwards to fifteen perches; and in a field of 300 acres he has met with patches of arable land, containing eight perches each. In this instance the average size of all the pieces in the field was under an acre. In all cases, he observes, they lie in long, narrow, winding, or worm-like slips. Land so distributed occasions great loss of time to the farmer, in removing his teams and labourers; and what is of equal importance, he can neither cross-plough nor harrow and clean such land in a workmanlike manner. And another great inconvenience attending common-field land is, the farmer cannot crop with that which best suits his soil, but is confined to sow such grain as must be cut with his neighbour's. An act to inclose common-field land would be advantageous to the farmer, and make the estates compact, and of more value to the owners. Neither can he sow any green or meliorating crops, vary the usual improving succession, or even destroy the vermin. In short, the cultivator of these lands finds his expences double, and his crops only half of what they might be, if the land were laid together and well fenced.”

By inclosing the common-fields, says he, which consist of a turnip and barley soil, both the landlord and the farmer are freed from the shackles of an exhausting and obsolete rotation of crops, and placed at liberty to distribute for cultivation the soil in the most improved manner, keeping it clean, in better heart, raising such roots and green crops as are in the greatest demand at market, and only growing a crop of corn for the sake of renewing the course of green and root crops. In this manner intelligent men, after inclosure, can double the produce of their land.

It is added that the invariable rotation of crops in all the common-fields is, first year a fallow, second year wheat, third year pease or oats, then begin again with a fallow. This, he says, is the destructive system of arable management that mostly prevails in this kind of land, and by which

some

some of the best land in the kingdom is condemned to be unemployed every third year; and the farmer who occupies it is compelled to pay three years rent in taxes, for two years use of it, and of course to maintain his family, servants, cattle, and implements of husbandry, every third year, without having any return from the land. It is, therefore, impossible that lands of this sort can ever be cultivated to the greatest advantage, while they remain in their present state. See INCLOSING.

It is observed by Mr. Marshall that "absurd as the common field system is, in almost every particular, at this day, it was admirably suited to the circumstances of the times in which it originated, the plan having been conceived in wisdom and executed with accuracy as appears in numberless instances, even at this distance of time."

It is remarked that in the western extreme of the island the common field system has never, perhaps, been adopted; has certainly never been prevalent, as in the more central parts of England. There, a very different usage would seem to have been early established, and to have continued to the present time; when lords of manors have the privilege of letting off the lands of common pastures, to be broken up for corn, the tenant being restricted to two crops; after which the land is thrown open again to pasturage. And it is at least probable, that the lands of that country have been cleared from wood and brought into a state of cultivation through similar means. At present they are judiciously laid out, in farms of different sizes, with square straight-lined inclosures, and with detached farmsteads situated within their areas; the villages being generally small and mean; and the more residence of labourers. These are circumstances which strongly evince that the common field system never took place in this part of the island, as it did in the more central parts.

But during the two last centuries, more particularly within the last, the feudal organization, having lost its original basis, has itself been mouldering away. A great majority of the appropriated common field lands and commons have been partially or wholly inclosed, either by piecemeal, each proprietor inclosing his own slip (a very inconvenient mode of inclosure); or by *general consent*: the whole of the proprietors agreeing to commit their lands to the care and judgment of arbiters or commissioners; who, restoring the fields to their original intirety, reparcelled them out, in a manner more convenient to the several proprietors, and laid each man's portion, which had consisted of numberless narrow slips, in one or more well-shaped grounds, or by *acts of parliament*, whereby not only common fields, common meadows, and stinted pastures, but unstinted commons also, have been appropriated, by commissioners named in, or chosen in pursuance of, each respective act, who, throwing back the entire township to its original state, laid it out afresh, according to the directions of the act and their own judgment.

COMMON Field Husbandry, that sort of cultivation which is practised in common fields. See HUSBANDRY. It has been observed in the "Agricultural Report of Wiltshire," that the introduction of the common field husbandry seems to have been very slow and progressive; and that the dispersed situation and smallness of the pieces, of the common field lands now in cultivation, evidently shew that the occupiers began with tilling a single acre, as one day's work for a plough, or perhaps only half an acre each; and that, as a want of corn increased, this cultivation was augmented until they had cultivated all that was most proper for that purpose, still leaving those parts which were less fit for the plough, or more distant from home, in a constant state of

commonage, but by mutual agreement keeping the cattle out of the cultivated parts till after harvest. This was, probably, the origin of common fields. It does not seem probable, that any improved methods of cultivation can be adopted on common field lands, until the system of common field husbandry is abolished. See COMMON and COMMON Field Lands.

COMMON Meadows and Pastures, are such meadows and pastures as are held in a state of commonage. It is remarked, by the author of the "Agricultural Survey of Wiltshire," that, by the same kind of mutual agreement, as is stated in speaking of common field lands, those who have rights shut up, and in some cases inclosed, such parts of their common pastures as were most proper to mow for hay, dividing them into certain specific quantities, either by land-marks, or by lot, for mowing, and suffering the common herd of cattle to feed there again as soon as the hay was carried off, till it was time to lay them up for a new crop; and that this was the origin of common meadows. And that the mutual agreements, originally founded in necessity, became, when approved by the lords, and observed for a length of time by the tenants, what are called "custom of manors," constituting the very essence of the court baron, or manorial court, by which both lord and tenants were and are still bound; and of which, though the lord or his steward is the judge, the tenants are the jury, the custom of the manor equally binding both.

COMMON, Communis, in a general sense, something that belongs to all alike; is owned or allowed by all; and is not confined to this more than that.

In which sense, *common* stands opposed to *proper, peculiar, &c.* Thus, the earth is said to be our *common* mother; in the first, or golden age, all things were in *common*, as well as the sun and elements; the name animal is common to man and beast; that of substance to body and spirit. Philosophers dispute whether there be any such thing as *common* notions, innate, or impressed on the mind by nature herself; or whether our ideas are all adventitious. See IDEA.

COMMON, Communia; (i. e. *quod ad omnes pertinet*) in *Law*, signifies that soil, the use whereof is *common* to a particular town or lordship; or it is a profit that a man hath in the land of another person, usually in common with others; or a right or privilege, which one or more persons claim to take or use, in some part or portion of that which another man's lands, waters, woods, &c. do naturally produce; without having an absolute property in such land, waters, wood, &c. It is called an "incorporeal right," which lies in "grant," as if originally commencing on some agreement between lords and tenants, for some valuable purposes; which by age being formed into a prescription, continues, although there be no deed or instrument in writing which proves the original contract or agreement. 4 Co. 37. 2 Inlt. 65. 1 Vent. 387. And there is not only common of PASTURE, which the word "common," in its most usual acceptation, signifies; but also common of PISCARY, common of ESTOVERS, common of TURBARY, &c. And in all cases of *common*, the law doth much respect the custom of the place: for there the rule is, *consuetudo loci est observanda.* 7 Rep. 5.

COMMON of pasture, is a right of feeding one's beasts on another's land; for in those waste grounds, usually called commons, the property of the soil is generally in the lord of the manor; as in "common fields," it is in the particular tenants. This kind of common is divided into *commons in gross, common appendant, common appurtenant, and common per cause de vicinage.*

COMMON in gross, is a liberty to have *common* alone, that

is without any land or tenement in another man's land, granted either to a person for life or to him and his heirs. This is commonly passed by deed, or specialty, and claimed by prescriptive right.

COMMON appendant, and *COMMON appurtenant*, are usually confounded; both being defined to be a liberty of *common* appertaining to, or depending on, such or such a freehold; which *common* must be taken with beasts *commouable*: as horses, oxen, &c. being accounted fittell for the plowman; and not with goats, geese, and hogs. Others distinguish between the two, thus; *common appurtenant* may be severed from the land whereto it appertains; and is where the owner of land has a right to put in other beasts not *commouable*; as hogs, goats, &c. which neither plough nor manure the land. Whereas *common appendant*, according to lord Coke, had its original in the following manner:

"When a lord enfeoffed another in arable lands to hold of him in socage; the feeſee, to maintain the service of his plough, had at first, by courtesy of his landlord, *common* in his wailes, for necessary beasts to eat and compost his lands; and that for two causes; 1^o. Because it was tacitly implied in the feoffment; by reason the feeſee could not till, or compost his pasture: by consequence, therefore, the feeſee had, as a thing necessary, or incident, *common* in the wailes, or lands of the lord. 2^o. For the maintenance and advancement of tillage."

Common appendant belongs only to ancient arable land, and not to a house, meadow, pasture, &c.; and it is of common right. But it is not common appendant, unless it hath been appendant time out of mind. 1 Danv. 746. It may be upon condition; for all the year, or for a certain time, or for a certain number of beasts, &c. by usage; though it ought to be for such cattle as plough and compost the land to which it is appendant. 1 Danv. 797. *Common appendant* may be to common in a field after the corn is severed, till the ground is sown, and it may be to have common in a meadow after the hay is carried off, till Candlemas, &c. Yelv. 185. This common, which in its nature is not restricted by number, may be limited by custom as to the beasts; whereas *common appurtenant* ought always to be for those levant and couchant, and may be *sans* number. Plowd. 161. A man may prescribe to have common appurtenant for all manner of cattle, at every season in the year. 25 Aff. 8. He who hath common appendant or appurtenant can keep but a number of cattle proportionable to his land; for he can common with no more than the lands to which his common belongs is able to maintain. 3 Saik. 93.

COMMON pur cause de vicinage, i. e. by reason of neighbourhood, is the liberty that the tenants of one lord in one town, have to *common* with the tenants of another lord in another town.

But it is to be observed, that those who claim this kind of *common*, (which is usually called *intercommoning*) may not put their cattle into the *common* of the other lord, for then they are distrainable; but, turning them into their own fields, if they stray into their neighbour's *common*, they must be suffered.

The inhabitants of one town or lordship may not put in as many beasts as they will, but with regard to the freehold of the inhabitants of the other; for otherwise it were no good neighbourhood, upon which all this depends. Terms de Ley. If one lord encloses the common, the other town cannot then common; but though the common of vicinage is gone, common appendant remains. 4 Rep. 38. 7 Rep. 5. Every common *pur cause de vicinage* is a common appendant. 1 Danv. Abr. 799. This is indeed only a permissive right,

intended to excuse what in strictness is a trespass in both, and to prevent a multiplicity of suits. And therefore either township may enclose and bar out the other, though they have intercommoned time out of mind. Blackst. Com. ii. 34.

The property of the soil in the "*common*" is entirely in the lord; and the use of it jointly in him and the commoners. Lords of manors may depasture in commons where their tenants put in cattle: and a prescription to exclude the lord is against law. 1 Inst. 122. The lord may agut the cattle of a stranger in the common by prescription; and he may license a stranger to put in his cattle, if he leaves sufficient room for the commoners. 1 Danv. 755. 2 Mod. 6. The lord may also furcharge, &c. an overplus of the common; and if, where there is not an overplus, the lord furcharge the common, the commoners are not to distrust his beasts; but must commence an action against the lord. F. N. B. 125. The lord may distrust when the common is furcharged, and bring action of trespass for any trespass done in the common. 9 Rep. 113. A lord may make a pond on the common, though he cannot dig pits for gravel or coal; the statutes of improvement extending only to inclosure. 3 Inst. 204. 9 Rep. 112. 1 Sid. 106. If the lord makes a warren on the common, the commoners may not kill the conies; but are to bring their action, for they may not be their own judges. 1 Rol. 90. 495. By statute of Merton (20 H. III. c. 4.) lords may "approve" against their tenants, *viz.* inclose part of the waste, &c. and thereby discharge it from being common, leaving common sufficient; and neighbours as well as tenants, claiming common of pasture, shall be bound by it. If the lord incloses on the common, and leaves not common sufficient, the commoners may not only break down the inclosures, but may put in their cattle, although the lord ploughs and sows the land. 2 Inst. 88. 1 Rol. Abr. 406. By stat. 29 Geo. II. c. 36. Owners of commons, with the consent of the majority, in number and value, of the commoners; the majority of the commoners, with consent of the owners, or any persons, with the consent of both, may inclose any part of a common for the growth of wood. If the wood be destroyed, the offender may be punished according to stat. 1 Geo. I. c. 48.; if not convicted in six months, the owner shall have satisfaction from the adjoining parishes, &c. as for fences overthrown by stat. Weilm. 2. Persons cutting wood on commons shall incur the same penalty. And by stat. 31 Geo. 2. c. 41, the recompence is to be paid to persons interested, in proportion to their interest. A commoner hath only a special and limited interest in the soil, but yet he shall have such remedies as are commensurate to his right; and therefore he may distrust beasts damage-fasant, bring an action on the case, &c.; but not being absolute owner of the soil, he cannot bring a general action of trespass for a trespass done upon the common. A commoner cannot do any thing on the soil which tends to the melioration or improvement of the common, as cutting down of bushes, fern, &c. 1 Sid. 251. 2 Hen. VIII. 2. 13 Hen. VIII. 15. Therefore, if a common every year in a flood is surrounded with water, the commoner cannot make a trench in the soil to avoid the water, because he has nothing to do with the soil, but only to take the grass with the mouth of the cattle. 1 Rol. Abr. 405. 2 Bull. 116. Every commoner may break the common if it be inclosed; and although he does not put his cattle in at the time, yet his right of commonage shall excuse him from being a trespasser. Lit. Rep. 38. 1 Rol. Abr. 406. If a tenant of the freehold ploughs it, and sows it with corn, the commoner may put in his cattle, and with them, eat the corn growing upon the land: so if he lets his corn

corn lie in the field, beyond the usual time, the other commoners may, notwithstanding, put in their beasts. 2 Leon. 202, 203. The commoner cannot use common except with his own proper cattle; but if he hath not cattle to manure the land, he may common other cattle to manure it, and use the common with them; for, by the loan, they are in a manner made his own cattle. 1 Danv. 798. A commoner may diltrain beasts put into the common by a stranger, or every commoner may bring action of the case, where damage is received. 9 Rep. 11. But one commoner cannot diltrain the cattle of another commoner, though he may those of a stranger, who hath no right to the common. 2 Lutw. 1238. See SURCHARGE of Common, and DISTURBANCE of Common.

Upon agreement between two commoners to inclose a common, a party having interest, not privy to the agreement, will not be bound; but one or two wilful persons shall not hinder the public good. Chan. Rep. 48. Commons must be driven yearly at Michaelmas, or within 15 days after; infected heifers and stone-horses under five, &c. are not to be put into commons. Under forfeiture, by Stat. 32 Hen. VIII. c. 13. New erected cottages, though they have four acres of ground laid to them, ought not to have common in the waste. 2 Inst. 740. In law-proceedings, where there are two distinct commons, the two titles must be shewn: cattle are to be alleged commonable; and common ought to be in lands commonable; and the place is to be set forth where the messuage and lands lie, &c. to which the common belongs. 1 Nels. 462, 463. By Stat. 13 Geo. III. c. 81. in every parish where there are "common field-lands," all the arable lands lying in such fields shall be cultivated by the occupiers, under such rules as three-fourths of them in number and value (with the consent of the land and tithe-owners) shall appoint, by writing under their hands; the expense to be borne proportionably, under the management of a field-master, or field-reeve, to be appointed annually in

May. For other particulars, see Jacob's Law Dict. by Tomlins.

COMMON, in *Geometry*, is applied to an angle, line or the like, which belongs equally to two figures, or makes a necessary part of both.

COMMON, in *Grammar*, denotes the gender of nouns which is equally applicable to both sexes, male and female.

Such is that of *patrens*, parent; which is either masculine, or feminine, as it is used to signify either father, or mother.

The Latin grammarians, besides this, which they call the common of two, also make a common of three; which extends to masculine, feminine, and neuter.

COMMON, *Communis*, in *Ancient Music*, was an appellation given to the seventh species of the diapason. See DIAPASON.

COMMON Bail. See BAIL.

COMMON Barretor. See BARATRY.

COMMON Bench. The court of Common Pleas was anciently called *Common Bench*, because the pleas of controversies between common persons were there tried and determined.

In law books and references, the court of Common Pleas is written C. B. from *communi banco*, or C. P.: and the justices of that court are styled *justiciarii de banco*. See COURT and Common PLEAS.

COMMON Centre of Gravity, in *Mechanics*. See CENTRE of Gravity.

COMMON Chord, in *Music*, is sometimes used to denote the third, fifth, and octave of any note, considered as a bass. It will afford some light into the composition of chords, to exhibit all the possible variations in the order or arrangement of the concord, major *third* (111), minor *third* (3d), and minor *fourth* (4th), constituting the common chord in the following manner, *viz.*

1		the common chord.
2		the common chord minor.
3		the chord of sixth, or 3 rd .
4		the chord of b ⁶ _b or b ⁶ _{b3} .
5		the chord of 6 th .
6		the chord of 4 th . b ₆

By a comparison of the several chords in the first arrangement above, it will appear, that when the four notes, C, E, G, and C, constituting the common chord, are sounded together, all of the seven concords, *viz.* 3^d, III, 4th, V,

V, 6th, VI and VIII are in reality heard between the different notes, except the VI: and this circumstance, combined with the III being above the bass or lowest note, seem essential to a full or common chord. In the second arrangement, or C, b E, G and C, it will be perceived, that all the concords are heard except the 6th; and this, combined with the third above the bass note, constitutes the common chord of the minor mode. In the third arrangement, it will be seen, that there is no V produced, while a III occupies the place immediately above the bass note, being the chord of sixth. The fourth arrangement will also be found without a V, but with the 3d next the bass, constituting the chord $b\overset{6}{b}$. The fifth arrangement will be found without a 6th, and with no third (but a 4th), next to the bass, and this constitutes the chord $\overset{6}{4}$. And lastly, the sixth arrangement will be found without a VI, or a third above the bass, which constitutes the chord $b\overset{6}{4}$.

In performances by voices and perfect instruments, as violins, violincellos, &c. these several chords will be all heard *perfectly*; and in each of the six cases, a union or blending of the six concords, almost similar to a single sound, will be perceived, but much more delightful to the ear; the characteristic differences of which constitute the character of the common chord and its five inversions, as above. But upon the common keyed instruments, such as organs, pianofortes, harpsichords, &c. which contain but twelve sounds within the octave, it is impossible that these single or compound chords can all be heard perfect, but the greater part of the whole of them must be tempered or slightly altered from the true chord (see TEMPERAMENT). If, for instance, the III C E above, were sharpened seven semisimas, or 7σ , which is very nearly the case in *Equal Temperament* (which see), the 3d E G flattened 5σ , and the 4th G C sharpened 2σ ; the common chord, or first arrangement upon such an instrument, would produce the following tempered concords, viz. 3d— 8σ , III+ 7σ , 4+ 2σ , V— 5σ , and 6th— 7σ . combined with VIII; which chords, combined and blended, impress upon the ear the peculiar sensation of the common chord in this temperament. In the second arrangement, or common chord minor, the effect produced will depend upon the union of the following tempered chords, viz. 3d— 8σ , III+ 7σ , 4th+ 2σ , V— 5σ , VI+ 8σ and VIII. A common chord C E G C, upon an instrument tuned according to earl Stanhope's temperament, (see Phil.osophical Magazine, vol. xxviii. p.141) will be found to consist of the following perfect chords, viz. 3d, III, 4th, V, 6th, and VIII; whence his lordship denominates his key of C major to be perfect (see STANHOPE TEMPERAMENT); but if we consider the second arrangement, or common chord of C minor, upon one of his lordship's instruments, we shall find 3d— $10\frac{1}{2}\sigma$, III+ $10\frac{1}{2}\sigma$, 4th, V, VI+ $10\frac{1}{2}\sigma$, and VIII to constitute this chord, nearly, the very small interval *minute* (*m*) only, being in any case omitted. Thus it will be easy to compare the effect of any inversions of the common chord, in this, or any other temperament of the scale which may be proposed.

COMMON Clerk. See TOWN Clerk.

COMMON Crier. See CRIER.

COMMON Council. See Mayor's COURTS.

COMMON Day. i. plea of land, signifies an ordinary day in court, as *actibus Hilarii, quindena Pasche*, &c. It is mentioned in 13 Rich. II. stat. 1. cap. 17. and in the statute

51 Hen III. concerning general days in bank. *Blount and Coxe*.

COMMON, *Disturbance of*. See DISTURBANCE of Common.

COMMON Duct, in Anatomy. See DUCTUS Communis.

COMMON, *Estate in*. See ESTATE.

COMMON of Flowers. See BEETWEERS.

COMMON Field-land. See COMMON *supra*.

COMMON Fine, in Law, a certain sum of money, which the tenants within the liberty of some leets pay to the lord thereof; called in some places, *head-silver*; in others, *certmoney*, or *certum leze*, and *head-pence*.

It was first granted to the lord towards the charge of his purchase of the court-leet; whereby the tenants have now the convenience of doing their suit within their own manors, without being compelled to go to the sheriff's turn.

COMMON in Grofs. See COMMON *supra*.

COMMON Hunt, the chief huntsman belonging to the lord mayor and aldermen of London.

COMMON Informer. See INFORMER.

COMMON Intendment, in Law, the common understanding, meaning, or construction of any thing: without straining it to any foreign, remote, or particular sense: and *Bar to Common Intendment*, is an ordinary, or general bar, which is commonly an answer to the declaration of the plaintiff. See BAR and INTENDMENT.

COMMON Jury. See JURY.

COMMON Law, that body of rules generally received, and held as law in this nation, in contradistinction to the statute, or written law, and including not only general customs, or the common law properly so called; but also the particular customs of certain parts of the kingdom, and likewise those particular laws, that are by custom observed only in certain courts and jurisdictions.

The common law is grounded upon the general customs of the realm, and comprehends the law of nature, the law of God, and the principles and maxims of the law: it is founded upon reason, and it is said to be the perfection of reason, acquired by long study, observation, and experience, and refined by learned men in all ages. It is justly regarded as the common birth-right, which the subject has for the self-guard and defence, not only of his goods, lands, and revenues, but of his wife and children, body, fame, and even life. Co. Litt. 97. 142. *Treatise of Laws*, p. 2. According to Hale, the common law of England is the common rule for administering justice within this kingdom, and asserts the king's royal prerogatives, and likewise the rights and liberties of the subject. It is, in general, that law by which the determinations in the king's "Ordinary courts" are guided; and this directs the course of descents of lands; the nature, extent, and qualifications of estates, together with the manner and ceremonies of conveying them from one to another; the forms, solemnities, and obligations of contracts; the rules and directions for the exposition of deeds, and acts of parliament; the process, proceedings, judgments, and executions of our courts of justice; also the limits and bounds of courts, and jurisdictions; the several kinds of temporal offices and punishments, and their application, &c. *Hale's Hist. of the Common Law*, p. 24—44, 45.

As to the origin of the common law, which, adopting the expression of lord chief-justice Hale, is as undiscoverable as the head of the Nile; our ancient lawyers, and particularly Fortescue, warmly insist, that the customs, which constitute our common law, are as old as the primitive Britons, and that they have been continued down, through

the several mutations of government and inhabitants, to the present time, unchanged and unadulterated. This, says judge Blackstone, may be the case as to some; but, in general, as Mr. Selden observes, this assertion must be understood with many grains of allowance; and ought only to signify, as the truth seems to be, that there never was any formal exchange of one system of laws for another; though, doubtless, by the intermixture of adventitious nations, the Romans, the Picts, the Saxons, the Danes, and the Normans, they must have insensibly introduced and incorporated many of their own customs with those that were before established; thereby in all probability improving the texture and wisdom of the whole, by the accumulated wisdom of divers particular countries. Accordingly, lord Bacon observes, that our laws are as mixed as our language; and, as our language is so much the richer, the laws are the more complete. And, indeed, our antiquaries and early historians do all positively assure us, that our body of laws is of this compounded nature.

After the decay of the Roman empire, it has been said, Britain became invaded by three kinds of German people, *viz.* the Saxons, Angles, and Jutes. From the Jutes descended the men of Kent, and those of the Isle of Wight; from the Saxons came the people called the East, South, and West Saxons; and from the Angles came the East Angles, Mercians, and Northumbrians.

Now, as each people had its peculiar customs, so each inclined to different laws; whereof, those of the West Saxons and Mercians, who inhabited the midland counties, were, upon the dissolution of the heptarchy, and establishment of a monarchy, preferred to the rest, and acquired the common appellation of *Jus Anglorum*. Their particular names were *West Saxon-lage*, and *Mercen-lage*.

The first Saxon laws published in England were those of king Ethelbert, in the sixth century. Three hundred years after, king Alfred, whom our historians call *magnus juris Anglicani conditor*, having united the heptarchy, and rendered himself master of the whole nation, made a collection from among the numerous laws and customs of the several provinces of his domains, which were grown so various; and commanded them to be observed throughout his kingdom. This collection was denominated *folk-right*, and soon after the *common law*; as being *common* to the whole nation.

This was written in Alfred's *dome-book*, or *liber judicialis*, which was designed for the general use of the whole kingdom.

This book is said to have been extant in the reign of king Edward IV.; but has since been unfortunately lost. It contained, as we may reasonably imagine, the principal maxims of the common law, the penalties for misdemeanors, and the forms of judicial proceedings.

By these laws the nation was governed for a considerable time, till, being at length subdued by the Danes, the customs of those people were introduced, and incorporated with the rest. Hence the code of Alfred in many provinces fell into disuse, or, at least, was mixed and debased with other laws of a coarser alloy: and thus a new form of *common law* arose, called *Dane-lage*.

The three systems of law above recited, *viz.* the *Dane-lage*, principally maintained in several of the midland counties and also on the eastern coast; the *West Saxon-lage*, which was much the same with the code compiled by Alfred, and which obtained in the counties to the south and west of the island, from Kent to Devonshire, being the municipal law

of the far most considerable part of Alfred's dominions, and particularly of Berkshire, the seat of his peculiar residence; and the *Mercen-lage*, observed in many of the midland counties, and those bordering on the principality of Wales, the retreat of the ancient Britons, and therefore probably intermixed with the British or Druidical customs; were in use about the beginning of the eleventh century. The northern provinces were at this time under a distinct government. In process of time king Edgar began what his grandson Edward the Confessor, on this account called *legum Anglicanarum restitutor*, completed; *viz.* to form one digest or body of laws to be observed throughout the whole kingdom. This seems to have been only a new edition, or fresh promulgation of Alfred's *dome-book*, with such additions and improvements as the experience of a century and a half had suggested.

The Danes being afterwards, in their turn, overcome by the Normans; the Conqueror, on a review of the several laws and customs that then obtained, abrogated some, and abolished others; adding some of his own country laws.

His son, William Rufus, broke through the ancient laws and customs which his father had established; but his next son, Henry I. excluded the civil customs which his brother had introduced, and restored the laws of Edward the Confessor, with those amendments made by his father, under the advice of his barons. These were afterwards confirmed in succeeding reigns.

Hence is derived that system of maxims and unwritten customs, now known by the name of the *common law*, which is of Saxon parentage; though the customs and maxims themselves are of higher antiquity than memory or history reach; many of them being as old as the primitive Britons. The name of common law was given to it, either in contradistinction to other laws, as the *statute-law*, the *civil law*, the *law merchant*, and the like; or, more probably, as a law common to all the realm, the *jus commune* or *folk-right* mentioned by king Edward the Elder, after the abolition of several provincial customs and particular laws.

The *common law* of England is, properly, the common customs of this kingdom; which, by length of time, have obtained the force of laws.

The goodness of a custom depends upon its having been used time out of mind; or, in the solemnity of our legal phrase, time whereof the memory of man runneth not to the contrary. This gives it its weight and authority; and of this nature are the maxims and customs which compose the common law, or *lex non scripta*, of this kingdom. This unwritten, or common law, is properly distinguished into three kinds; 1. General customs, which are the universal rule of the whole kingdom, and form the common law, in its stricter and more usual signification. 2. Particular customs, which for the most part affect only the inhabitants of particular districts. 3. Certain particular laws; which by custom are adopted and used, by some particular courts, of pretty general and extensive jurisdiction. See *CUSTOM*.

Some have divided the common law into two principal grounds or foundations; *viz.* 1. Established customs; such as that, where there are three brothers, the eldest brother shall be heir to the second, in exclusion of the youngest; and, 2. Established rules and maxims; as, that the king can do no wrong; that no man shall be bound to accuse himself; and the like. But judge Blackstone observes, that these are one and the same thing. For the authority of these maxims rests entirely upon general reception and usage; and the only method of proving,

proving, that this or that maxim is a rule of the common law, is by shewing that it hath been always the custom to observe it. See CUSTOM.

It is called *lex non scripta*, the *unwritten law*: not but that we have most of it written in the old Norman dialect, and the monuments and evidences of our legal customs are contained in the records of the several courts of justice, in books of reports and judicial decisions, and in the treatises of learned sages of the profession, preserved and transmitted from times of the highest antiquity; but because it does not appear to be made by charter, or parliament; for those are always matters of record. Its original institution and authority are not set down in writing, but it receives its binding power and the force of law, by long and immemorial usage, and by universal reception through the kingdom. See AUTHORITIES and REPORTS.

Beside the *common law* of England in general, there are in divers parts of the nation particular customs, and common usages, which have the force of *common law* among those people, who have retained them: such as the Borough-English, Gavel-kind, &c.—Where the *common law* is silent, there the STATUTE-law speaks. See STATUTE.

All trials at *common law* are by a jury of twelve men.

Among the ancient and most eminent writers on common law we may select and enumerate the following. Britton wrote his learned book of the common law of this realm by the king's command, and it runs in his name, corresponding to the institutions of the civil law, which Justinian assumes to himself, though composed by others under his direction. This Britton is mentioned by Gwin to have been bishop of Hereford. Bracton, a great lawyer in the time of Henry III., wrote a very learned treatise of the common law of England, held in great estimation; and he was said to be lord chief-justice of the kingdom. The famous and learned Glanvil, lord chief-justice in the reign of Henry II., wrote a book of the common law, which is said to be the most ancient composition extant on that subject. Besides these, in the time of Edward IV. the renowned lawyer Littleton wrote his excellent book of "English Tenures." In the reign of king James I., the great oracle of the law, sir Edward Coke published his learned and laborious "Institutes" of our law, and commentary on Littleton. About the same time likewise Dr. Cowell, a civilian, wrote a short institute of our laws. In the reign of king George I., Dr. The Wood, a civilian and common lawyer, and at last a divine, wrote an institute of the laws of England, somewhat after the manner of the Institutes of the civil law. And to mention no others, the late learned judge Blackstone, in the reign of George III., published his "Commentaries" on the laws of England, the best analytic and most methodical system of our laws, which was ever published; and equally adapted for the use of students, and of those gentlemen who wish to acquire that knowledge of our laws, which is, in fact, essentially necessary for every one. See biographical articles BRITTON. BRACTON, &c. &c.

Common measure divisor, in *Arithmetic*, a number that exactly measures two other numbers, without a remainder. And the greatest number that can measure any two other numbers, is called their greatest common measure; thus 4 is the greatest common measure of 8 and 12.

To find the greatest common measure of two numbers; divide the greater by the less, and if there be no remainder, the less number is the measure required. If there be a remainder, divide the last divisor by it, and thus proceed, till there be no remainder left, and the last divisor is the greatest common measure.

E. G. To find the greatest common measure of 816 and 1488.

$$\begin{array}{r}
 816)1488(1 \\
 \underline{816} \\
 672)816(1 \\
 \underline{672} \\
 144)672(4 \\
 \underline{576} \\
 96)144(1 \\
 \underline{96} \\
 \text{Common measure} = 96
 \end{array}$$

For algebraic quantities, the remainders are to be divided by their simple divisors, and the quotients will be the quantities required.

E. G. Let the quantities be $a^2 + 2ab + b^2$ and $a^2 + 2a^2b + 2b^3$.

Divide the latter of these by the former in the following manner:

$$\frac{a^2 + 2a^2b + 2b^3}{a^2 + 2ab + b^2}$$

The remainder is $-ab^2 + b^3$, which being divided by b^2 , its greatest simple divisor, given $a + b$; and by this divide $a^2 + 2ab + b^2$, and the quotient will be $a + b$, exactly, which is the common measure required. And if fractions are divided by their greatest common measure, they will thus be reduced to their lowest terms.

E. G. Let the fraction be $\frac{816}{1488}$: then divide the numerator and denominator by 48, the greatest common measure, and the fraction will be reduced to $\frac{17}{31}$, its lowest terms.

Let the algebraic fraction be $\frac{a^2 + 2a^2b + 2b^3}{a^2 + 2ab + b^2}$; then, dividing the numerator and denominator by $a + b$ the greatest common measure; and it will be reduced to $\frac{a + b}{a^2 + ab + b^2}$, its lowest terms.

These operations are founded on this principle, *viz.* that whatever quantity measures the whole and one part of another, must also measure the remaining part. For that quantity (whatever it is) which measures both the divisor and dividend, must evidently measure $a^2 + 2ab + b^2$, being a multiple of the former; whence, by the above-cited principle, the same quantity, as it increases the whole dividend, must also measure the remaining part of it, $a^2b + b^3$: but the divisor, which we are seeking, being a compound one, we may call off the simple divisor b^2 , as not answering our purpose; whence $a + b$ appears to be the only compound divisor which the case admits of; and this must be the common measure required, if the proposed example admits of any such.

COMMON OF PISCARY. See PISCARY.

COMMON PLACE BOOK, *Adversaria*, among the learned, denotes a register, or orderly collection of things which occur worthy to be noted, and retained in the course of a man's

man's reading, or study; so disposed, as that among a multiplicity of subjects, any one may be easily found.

Common place-books are of great service: they are a kind of promptuaries or storehouses, wherein to reposit the most valuable parts of authors, to be ready at hand when wanted. Several persons have their several methods of ordering them: but that which comes best recommended, is the method of that great master of order Mr. Locke. He has thought fit to publish it in a letter to M. Toifnard; determined thereto, by the great conveniency and advantage he had found from it in twenty years experience; as well as by the recommendations and intreaties of many of his friends, who had likewise proved it.

The substance of this method we shall here give the reader; whereby he will be easily enabled to execute it himself.

The first page of the book you intend to take down the common places in, is to serve as a kind of index to the whole; and to contain references to every place, or matter there-

in: in the commodious contrivance of which index, so that it may admit of a sufficient copia, or variety of materials, without any confusion, the whole secret of the method consists.

In order to this the first page, as already mentioned, or for more room, the two first pages that front each other, are to be divided by parallel lines, into twenty-five equal parts; whereof every fifth line is to be distinguished, by its colour, or some other circumstance. These lines are to be cut perpendicularly by others, drawn from top to bottom; and in the several spaces thereof the several letters of the alphabet, both capital and minuscule, are to be duly written. The form of the lines and divisions, both horizontal and perpendicular, with the manner of writing the letters therein, will be conceived from the following specimen; wherein what is to be done in the book for all the letters of the alphabet, is here shewn in the first four, A, B, C, and D.

A	a	C	c
	e		e
	i		i
	o		o
	u		u
B	b	D	d
	e		e
	i		i
	o		o
	u		u

The index of the common-place book being thus formed, matters are ready for the insertion of any thing in it. In order to this, consider to what head, the thing you would enter is most naturally referred; in this head, or word, regard is had to the initial letter, and the first vowel that follows it; which are the characteristic letters on which the whole use of the index depends.

Suppose, *e. gr.* I would enter down a passage that refers to the head *beauty*; B, I consider, is the initial letter, and *e* the first vowel; then looking upon the index for the partition B, and therein the line *e* (which is the place for all words whose first letter is B, and first vowel *e*; as *Beauty, Beneficence, Bread, Bleeding, Blemishes, &c.*), and finding no numbers down already direct me to any page of the book where words of this characteristic have been entered, I turn forward to the first blank page I find, which in a fresh book, as this is supposed to be, will be page 2, and here I now write what I have occasion for on the head *beauty*; beginning the head in the margin, and indenting all the other subservient lines, that the head may stand out, and shew itself; this done, I enter the page where it is written. *viz.* 2, in the index, in the space B *e*, from which time, the class B *e* becomes wholly in the possession of the 2d and 3d pages, which are consigned to letters of this characteristic.

Had I found any page or number already entered in the space B *e*, I must have turned to the page, and have written my matter in what room was left therein: so, if after entering the passage on beauty, I should have occasion for *benevolence*, or the like, finding the number 2 already possessed of the space of this characteristic, I begin the passage on benevolence in the remainder of the page; which not containing the whole, I carry it on to page 3, which is also for B *e*, and add the number 3 in the index. When

the two pages destined for one class are full, look forward for the next backside that is blank; if it be that which immediately follows, write at the bottom of the margin of the page filed, the letter *v* for *verte*, turn over; and the same at the top of the next page: and continue from this new page as before. If the pages immediately following be already filled with other classes, then write at the bottom of the page last filled, the letter *v*, with the number of the next blank page; and at the top of that page, the number of the page last filled; then entering that head in this new page, proceed as before. By these two numbers of reference, the one at the top, and the other at the bottom of the page, the discontinued matters are again connected. It may not be amiss, every time you put a number at the bottom of a page, to put it likewise in the index. Now, if the head be a monosyllable beginning with a vowel, the vowel is at the same time both the initial letter, and the characteristic vowel: thus the word *art* is to be wrote in A *a*. Mr. Locke omits three letters of the alphabet in his index, *viz.* K, Y, and W; which are supplied by C, I, U, equivalent to them: and as for Q, since it is always followed by an *u*, he puts it in the fifth place of Z; and so has no Z *u*, which is a characteristic that very rarely occurs. By thus making Q the last in the index, its regularity is preserved, without diminishing its extent. Others choose to retain the class Z *u*, and assign a place for Q *u* below the index.

If any imagine, that those hundred classes are not sufficient to comprehend all kinds of subjects without confusion, he may follow the same method, and yet augment the number to five hundred, by taking in one more characteristic to them.

But the inventor assures us, that in all his collections, for a long series of years, he never found any deficiency in the index

index as above laid down. Other contrivances for commonplace books have been proposed; but they are such as will naturally occur to persons conversant with the subject, and accustomed to orderly arrangement: and it is, therefore, needless to extend this article.

COMMON PLEAS, in Rhetoric. See ARGUMENTS and TOPICS.

COMMON PLEAS. See COURT of Common Pleas.

COMMON PRAYER, is the liturgy of the church of England. Clergymen are obliged to use this liturgy in the service of the church; and refusing to do so, or using any other public prayers, is punishable by 1 Eliz. cap. 2. and every incumbent residing on his living and keeping a curate, is obliged, once every month at least, to read the common prayer in his parish church, in his own person, under a forfeiture of 5*l.* for every failure, by the act of uniformity, 13 and 14 Car. II. cap. 4.; and by the same stat. every church is to be provided with a book of common prayer, under the penalty of 3*l.* a month, and the common prayer is to be read before every lecture. Every minister who speaks any thing in derogation of this book shall, if not beneficed, be imprisoned one year for the first offence, and for life for the second; and, if he be beneficed, he is liable to six months imprisonment, and the forfeiture of a year's value of his benefice; for the second offence to deprivation and one year's imprisonment; and for the third offence to deprivation and imprisonment for life: and any person convicted of reviling it in plays, songs, or other open words, or of forcibly preventing its being read, or of causing any other service to be read in its stead, shall forfeit for the first offence an hundred marks; four hundred for the second; and for the third offence all his goods and chattels, and suffer imprisonment for life. Stat. 1 Eliz. cap. 2. See LITURGY.

COMMON Weal denotes "bonum publicum," or the public good, and is much favoured in our laws; and therefore many things are legally tolerated, with a view to the public good, which otherwise might not be done. Hence it is that monopolies are void in law, and that bonds and covenants to restrain free trade, tillage, and the like, are adjudged void. 11 Co. Rep. 50. Plowd. 25. Shep. Epit. 270.

COMMON Year. See YEAR.

COMMONABLE LANDS, in Agriculture, are such lands as are generally in some measure arable, and which belong, in property, to individuals who are known, and the limits of whose property are ascertained: but which, in regard to their culture and mode of cropping, are subject to certain regulations, which custom, for time immemorial, has established, so as gradually to have acquired the force of law, to which rules every individual occupying such property must adhere, until these old customs shall be abrogated, either by the unanimous consent of all the individuals having a right to such commonable lands, or by an express statute, obtained with their consent, for the purpose of annulling them.

In some countries, Dr. Anderson says, it appears that not much less than one half of the whole arable lands are in this state; although it is evident, by the concurring testimony of all the agricultural reports, that taking all these lands at an average, they do not afford half the produce the same lands would do, if they were put under the ordinary management that appropriated farmers are subjected to in their respective districts: and not perhaps one tenth part of what they might easily be made to afford, within a very short period of time, should all other obstructions to improvement be removed. It would be tiresome, he says, to enumerate all the facts that occur in the different agricultural surveys, tending to point out the pernicious tendency of this mode of tenure: but a few of them may be mentioned. In one place it is stated, that a few inclosures had been made, seemingly with the concurrence of all the parties concerned; but when the hedges had advanced nearly to become a fence, one of the commonable tenants went deliberately and pulled them up by the roots, and eradicated them entirely. In another case the parishioners having come to an agreement to sow clover, after that practice had been universally acquiesced in for the space of eighteen years, one of the farmers, occupying sixteen acres of land, bought a large flock of lean sheep in the month of May, and turned them on the clover crops, which were nearly in bloom, and no one could hinder him. In another case, where custom had established the practice of having one corn crop, and one fallow, alternately, the occupiers of the district came to an agreement to have two crops and a fallow alternately; but before the expiration of ten years, one of the farmers broke through the agreement, and turned his cattle upon the crops of beans, oats, and barley: in which plan he was followed by the rest of his neighbours; and the crops were, in consequence, totally destroyed on that part of the field, which, agreeable to the ancient custom, should have been that year in fallow. These notices, while they tend to illustrate the nature of this particular kind of tenure, at the same time, he says, clearly demonstrate its pernicious tendency to the public. No one, who has considered the subject for a moment, but will readily admit, that it were much for the interest of Britain that no such practice existed in it: and that, of course, no time should be lost in endeavouring to eradicate it; for, were this effectually done, it must appear evident from the facts stated, that the total produce of the kingdom would be greatly augmented and improved. See COMMON.

COMMONALTY, comprehends one distinction of the civil state; the nobility being the other; and like the nobility, includes several degrees of rank and condition. In Art. super Chartas, 28 Ed. 1. c. 1, the words "Tout le commune de l'Engleterre," signify all the people of England. 2 Inst. 539. But the term is generally used for the middle rank of the king's subjects, such of the commons as are raised above the ordinary sort, and having the management of offices, are by that means one degree below burgesses, who are superior to them in order and authority:—and companies incorporated are said to consist of masters, wardens, and commonalty, the first two being the chief, and the others such as are usually called the livery. The ordinary people, and freeholders, or at best knights and gentlemen, under the degree of baron, have been, of late years, called "communitas regni;" or "tota terræ communitas;" yet anciently, if we credit Brady, the barons and tenants in capite, or military men, were the community of the kingdom, and those only were reputed as such in our most ancient histories and records. Brady's Gloss. to his Introd. to Eng. Hist.

COMMONE, in Ancient Geography, the name of an island

in the Mediterranean, placed by Pliny on the coast of Ionia.

COMMONER, is used for a student in some universities, entered in a particular rank.

The word is also applied to a member of the house of commons, in contradistinction to a peer.

COMMONI, in *Ancient Geography*, a denomination given by Ptolemy to a people of Galia Narbonensis, who inhabited the country, including the town of Taurocentium, the promontory of Citharistes, the town of Olbia, that of Forum Julii, &c.

COMMONS, in a general sense, consist of all such men of property in the kingdom, as have not seats in the house of lords; every one of whom has a voice in parliament, either personally, or by his representatives. In a free state, says judge Blackstone, every man, who is supposed a free agent, ought to be in some measure his own governor; and, therefore, a branch at least of the legislative power should reside in the whole body of the people. And this power, when the territories of the state are small, and its citizens easily known, should be exercised by the people in their aggregate or collective capacity; as was wisely ordained in the petty republics of Greece, and the first rudiments of the Roman state. But this will be highly inconvenient, when the public territory is extended to any considerable degree, and the number of citizens is increased. Thus when, after the Social war, all the burghers of Italy were admitted free citizens of Rome, and each had a vote in the public assemblies, it became impossible to distinguish the spurious from the real voter, and from that time all elections and popular deliberations grew tumultuous and disorderly; which paved the way for Marius and Sylla, Pompey and Cæsar, to trample on the liberties of their country, and at last to dissolve the commonwealth. In so large a state as ours, it is therefore wisely contrived, that the people should do that by their representatives, which it is impracticable to perform in person; representatives chosen by a number of minute and separate districts, wherein all the voters are, or easily may be, distinguished.

COMMONS, in parliament, are the lower house, consisting of knights elected by the counties, and of citizens and burghesses by the cities and borough-towns. See BOROUGH, BURGESS, and KNIGHT.

In these elections, anciently, all the people had votes; but in the 8th and 10th of king Henry VI. for avoiding tumults, laws were enacted, that none should vote for knights but such as were freeholders, did reside in the county, and had forty shillings yearly revenue; equivalent to near 20*l.* a year of our present money: the persons elected for counties to be *militæ notabiles*, at least esquires, or gentlemen fit for knighthood; native Englishmen, at least naturalized; and twenty-one years of age: no judge, sheriff, or ecclesiastical person, to sit in the house for county, city, or borough.

The *house of commons*, in Fortescue's time, who wrote during the reign of Henry VI. consisted of upwards of 300 members: in Sir Edward Coke's time their number amounted to 493. At the time of the union with Scotland, in 1707, there were 513 members for England and Wales, to which 45 representatives for Scotland were added; so that the whole number of members amounted to 558.

In consequence of the union with Ireland, in 1801, 100 members were added for that country; and the whole house of commons now consists of 658 members; viz. 80 knights for 40 counties in England; 50 citizens for 25 cities (Ely sending none, and London four); 334 burghesses for 167 boroughs, and 5 burghesses for 5 boroughs, viz. Abingdon, Banbury, Bewdley, Higham Ferrers, and Monmouth; 4

VOL. IX.

burghesses for the two universities of Oxford and Cambridge; 16 barons for the 8 cinque-ports, viz. Hastings, Dover, Sandwich, Romney, Hythe, and their three branches, Rye, Winchelsea, and Seaford; 12 knights for 12 counties in Wales; 12 burghesses for 12 boroughs in that country; 30 knights for the shires of Scotland, and 15 burghesses for its boroughs; 64 knights and 36 burghesses for Ireland. For an account of the privileges of members of the house of commons, and other particulars, see PARLIAMENT.

COMMONS is also used in opposition to *nobles* or *peers*, viz. for all sorts of persons under the degree of a baron; including the orders of knights, esquires, gentlemen, the sons of the nobility, and yeomen. See each under its proper article, ESQUIRE, GENTLEMAN, YEOMAN, &c.

COMMONS, *Doctors*. See COLLEGE of *Civilians*.

COMMONS, *Proctor of the*. See PROCTOR.

COMMONS is also used for the stated and ordinary diet or eating, of a college, inn of court, or other society. See INN, &c.

COMMONWEALTH. See REPUBLIC.

COMMONWEALTH of *England*, in *History*, a form of government introduced after the dissolution of the monarchy by the death of Charles I., in 1649. The change of government seems to have been suggested in the preceding year by a council of officers, who took into consideration a scheme called "The Agreement of the People;" being the plan of a republic to be substituted in the place of that government which they were demolishing; but the commonwealth was not established till after the tragical event of the king's death. Soon after this event, the house of commons published an act to forbid the proclamation of Charles Stewart, eldest son of the late king, or any other person, on pain of high treason. On the same day the lords desired a conference with the commons about settling the government and the administration of justice, the commissions of the judges having been determined by the king's death. The commons, without answering the message, voted the house of lords to be useless and dangerous, and therefore to be abolished. They only left the lords the privilege of being elected members of parliament, in common with other subjects. Thus, the parliament, which at first was composed of the king, 120 lords, and 513 commons, was reduced to a house of commons, consisting of about 80 members, few of whom at the beginning had 500*l.* yearly income. Nevertheless, these few and inconsiderable members assumed the name of a parliament, and acted as if their body had been invested with the authority, which had before resided in the king, lords, and commons. But they were previously disposed and prepared for the business which they undertook to execute, and they were aided and supported by an army of near 50,000 men, formidable from its discipline and courage, as well as its number, and actuated by a spirit that rendered it dangerous to the assembly, which had assumed the command over it. It must be confessed, however, that in this parliament there were some men of distinguished capacity and integrity, and that if they adopted erroneous principles, or pursued those that were just and reasonable to an unwarrantable extent, they were destitute neither of talents nor of influence to defend and support them. The sovereign authority, as they maintained, resided originally in the people, by whom a part of it was committed to the kings, chosen to govern them according to law; and they alleged, that the king's abuse of this trust had broken the original contract between king and people, and that, in consequence of this violation, the contract subsisted no longer, but the sovereign power reverted to the people, as to its original source. Considering themselves as the representatives of the people, they conceived that they

A a

had

had a right to change the form of the government, without any regard to the original contract annulled by the king in his violation of the laws. Upon these principles, the commons, assuming the name of parliament, voted, and afterwards enacted, that the kingly office should be abolished as unnecessary, burdensome, and dangerous, and that the state should be governed by the representatives of the people in a house of commons without king or lords, and under the form of a commonwealth. The former oaths of allegiance and supremacy were abolished, and a new oath was prepared, called "The Engagement," by which every man swore, that he would be true and faithful to the government established, without king or peers. Justice was no longer to be administered in the king's name, but the name, style, and title of the writs were to be, "custodes libertatis Angliæ, autoritate parliamenti;" a new great seal was to be made; new money to be coined; and, in a word, every thing was to be let aside and abolished, that bore any marks of royalty. A great seal was therefore made, on one side of which was seen the parliament sitting, with this inscription: "the great seal of the parliament of the commonwealth of England;" and on the other side, the arms of England and Ireland, with these words, "the first year of freedom by God's blessing restored." This seal was committed to a certain number of persons, who were styled "keepers of the liberties of England." And it was ordained, that, for the future, all public orders should be dispatched in the name of these keepers, under the direction of the parliament. The parliament also made choice of 39 persons to form a council of state for the administration of public affairs under the parliament; to this council all addresses were made; they gave orders to all generals and admirals, executed the laws, and digested all business before it was brought into parliament. They professed to employ themselves entirely in adjusting the laws, forms, and plan of a new representation; and as soon as they should have settled the nation, they avowed their intention of restoring the power to the people, from whom, they acknowledged, they had wholly derived it. The parliament also erected a high court of justice, consisting of 60 members, to try some persons of distinction, who were in their power. The commonwealth, thus formed and established, found England composed into a seeming tranquillity by the terror of its arms. Foreign powers, occupied in wars among themselves, had no leisure nor inclination to interpose in the domestic dissensions of this island. The young king, poor and neglected, living sometimes in Holland, sometimes in France, sometimes in Jersey, indulged the hope, among his present distresses, of better fortune at some future period. The situation alone of Scotland and Ireland occasioned any immediate inquietude to the new republic. As to the Scots, they were allowed for the present to take their own measures in settling their government; but Ireland demanded more immediately their efforts for subduing it. Cromwell, having obtained the appointment of lieutenant in that country by his interest in the council of state, lost no time in passing thither; and he proceeded with such uninterrupted success, that in the space of nine months he had almost entirely subdued it. Afterwards, leaving the command of Ireland to Ireton, who governed that kingdom in the character of deputy, he hastened home, and was declared captain-general of all the forces in England. Having received this honourable appointment, he immediately marched his forces and entered Scotland; where Charles, who had been invited thither, was making considerable progress, with an army of 16,000 men. Cromwell having gained a decisive victory over the Scots in the battle of Dunbar, and having taken possession of Edin-

burgh and Leith, followed the young prince in his march into England, and falling in with an army of about 30,000 men in the city of Worcester, he either killed or took prisoners the whole Scottish army, and obliged the king to fly; and at length to make his escape from Shoreham in Sussex, to Fescamp in Normandy. The ruling members of the commonwealth were destitute of those comprehensive views which might qualify them for acting the part of legislators. They made slow progress in the work to which they professed themselves devoted, that of settling a new model of representation and fixing a plan of government. The nation therefore began to apprehend, that they intended to establish themselves as a perpetual legislature, and to confine the whole power to 60 or 70 persons, who called themselves the parliament of the commonwealth of England. However, the republicans, by the turn of their disposition, and by the nature of the instruments which they employed, shewed themselves better qualified for acts of force and vigour than for the slow and deliberate work of legislation. Notwithstanding the distressed state of the kingdom, occasioned by contending factions and by the devastation of civil wars, the power of England had never, in any period, appeared so formidable to the neighbouring kingdoms as it did at this time, in the hands of the commonwealth. A numerous army served equally to retain every one in implicit subjection to established authority, and to strike a terror into foreign nations. The power of peace and war was lodged in the same hands with that of imposing taxes. The military genius of the people had, by the civil contest, been roused from its former lethargy, and excellent officers were formed in every branch of service. The confusion into which all things had been thrown, had given opportunity to men of low stations to work through their obscurity, and to raise themselves by their courage to commands which they were well qualified to exercise, but to which their birth could never have entitled them. And while so great a power was lodged in such active hands, it is no wonder that the republic was successful in all its enterprizes.

Notwithstanding all the successes that attended the military operations of the commonwealth, both by sea and land, some circumstances occurred which widened the breach that had subsisted for a considerable time between the parliament and the army. Cromwell also saw that the zealous republicans in the government entertained a jealousy of his power and ambition, and were resolved to bring him to a subordination under their authority. He, therefore, without scruple or delay, determined to prevent them. Accordingly he called a council of officers, under the pretence of expediting the establishment of that free and equal government which parliament had so long promised to the people. In this council Cromwell had many friends, and also some opponents. The measure which he proposed was debated by the officers; and during the debate, Cromwell received information, that the parliament was still sitting, and had come to a resolution not to dissolve themselves, but to fill up the house by new elections; and that at this very time it was engaged in deliberations with regard to this expedient. Cromwell in a rage, hastened to the house, taking with him a body of 300 soldiers, whom he arranged about the house. After waiting for some time in seeming suspense, and professing his reluctance in adopting the measure which he had previously determined to execute, that of dissolving the parliament, he carried it into effect in the most rude and violent manner; and, without the least opposition or murmur, though he loaded the parliament with the vilest reproaches, for their tyranny, ambition, oppression, and robbery of the public, he annihilated that famous assembly,

which

which had filled all Europe with the renown of its actions, and with astonishment at its crimes, and the commencement of which was not more ardently desired by the people than its final dissolution. Parliament having been thus dissolved, Cromwell might have assumed the administration of the government by an authority similar to that with which he had dissolved the parliament. But he chose to proceed in his assumption of the sovereign power by more cautious steps, and with some appearance of respect for the popular opinion. Accordingly, by the advice of his council of officers, he sent summonses to 128 persons of different towns and counties of England, to five of Scotland, and six of Ireland; and he pretended by his sole act and deed to devolve upon these the whole authority of the state. This legislative power they were to exercise during 15 months; and they were afterwards to choose the same number of persons, who might succeed them in that high and important office. They immediately voted themselves a parliament, called by way of derision from Barebone, a leather-seller, one of their number, "Barebone's parliament;" and having their own consent, as well as that of Oliver Cromwell, for their legislative authority, they now proceeded very gravely to the exercise of it. The members of this legislative assembly, of which Cromwell himself was ashamed, though he had introduced into it several members entirely devoted to his own interest, found themselves unequal to the burden imposed upon them; and having met, by consent, at an early hour, they agreed to dissolve themselves and to resign the sovereign authority into the hands from which they had received it. They hastened, therefore, to Cromwell, along with Rouse, their speaker; and by a formal deed of assignment restored to him the supreme authority. The council of officers now proposed to adopt another scheme of government, and to temper the liberty of a commonwealth by the authority of a single person, who should be known by the appellation of protector. Without delay, Lambert, who made this proposition, prepared what was called "the instrument of government," containing the plan of this new legislature; and as it was supposed to be agreeable to the general, it was immediately voted by the council of officers. Cromwell was declared "Protector," and with great solemnity installed in that high office. The chief articles of the forementioned instrument are these: a council was appointed, the number of which was not to exceed 21, nor to be less than 13 persons. These were to enjoy their office during life or good behaviour; and in case of a vacancy, the remaining members named three, of whom the protector chose one. The protector was appointed supreme magistrate of the commonwealth; in his name all justice was to be administered; from him were all magistracy and honours derived; he had the power of pardoning all crimes, excepting murder and treason; to him the benefit of all forfeitures devolved. The right of peace, war, and alliance rested in him, with the advice and assistance of his council. The power of the sword was vested in the protector jointly with the parliament, while it was sitting, or with the council of state in the intervals. He was obliged to summon a parliament every three years, and allow them to sit five months without adjournment, prorogation, or dissolution. The bills which they passed, were to be presented to the protector for his assent; but if it were not obtained within twenty days, they were to become laws by the sole authority of parliament. A standing army for Great Britain and Ireland was established, of 20,000 foot and 10,000 horse; and funds were assigned for their support. These were not to be diminished without the consent of the protector; and in this article alone he assumed a negative.

During the intervals of parliament, the protector and council had the power of enacting laws, which were to be valid till the next meeting of parliament. The chancellor, treasurer, admiral, chief governors of Ireland and Scotland, and the chief justices of both the benches, must be chosen with the approbation of parliament; and in the intervals, with the approbation of the council, to be afterwards ratified by parliament. The protector was to enjoy his office during life; and on his death, the place was to be immediately supplied by the council. Such was the instrument of government enacted by the council of officers, and solemnly sworn to by Oliver Cromwell. The council of state, named by the instrument, consisted of 15 persons; men entirely devoted to the protector, and by reason of the opposition among themselves in party and principles, not likely ever to combine against him. The military force of the country was exerted under this government with vigour, conduct, and unanimity; and never did the kingdom appear more formidable to all foreign nations. In September, 1654, a new parliament was summoned. Of 400 members, which represented England, 270 were chosen by the counties; the rest were elected by London, and the more considerable corporations; all the small boroughs having been deprived of their right of election, because they were the most exposed to influence and corruption. The lower populace, so easily guided or deceived, were also excluded from the elections; an estate of 200*l.* value was necessary to entitle any one to a vote. The elections of this parliament, says Mr. Hume, were conducted with perfect freedom; and excepting, that part of the royalists which had borne arms against the parliament and all their sons were excluded, a more fair representation of the people could not be desired or expected. Thirty members were returned from Scotland, and as many from Ireland. This parliament, having heard the protector's speech of three hours length, and having chosen Lenthall for their speaker, immediately entered into a discussion of the instrument of government, and of that authority, which Cromwell, by the title of protector, had assumed over the nation. The greatest liberty was used in arraigning this new dignity; and even the personal character and conduct of Cromwell escaped not without censure. The protector, surprised and enraged at the refractory spirit of the parliament, sent for them to the painted chamber, and authoritatively inveighed against their conduct. He obliged the members to sign a recognition of his authority, and an engagement not to propose or consent to any alteration in the government, as it was settled in a single person and a parliament; and he placed guards at the door of the house, who allowed none but subscribers to enter. Most of the members, after some hesitation, submitted to this condition; but retained the same refractory spirit which they had manifested in their first debate. Cromwell hastened to the dissolution of this dangerous assembly, and having ordered their attendance, he delivered to them a tedious, confused, angry harangue, and dismissed them.

In 1656, Cromwell, having gained by his administration so much lustre and success abroad, and so much order and tranquillity at home, ventured to summon a parliament, having taken previous measures for filling the house with his own creatures and partisans. The fear, however, that the majority would not be favourable to him. He, therefore, set guards on the door, who permitted none to enter but such as produced a warrant from his council; and the council rejected about a hundred, who either refused a recognition of the protector's government, or were on other accounts obnoxious to him. These protested against a violence which was subversive of all liberty; but every applica-

tion for redress was neglected both by the council and parliament. In this parliament a motion was made to bestow the crown on Cromwell; and no surprize or reluctance was discovered on the occasion. A formal motion was afterwards made to the same purpose; but it produced great disorder, and divided the house into parties. The bill was however voted by a considerable majority; and a committee was appointed to reason with the protector, and to overcome those scruples which he pretended against accepting so liberal an offer. Cromwell's chief difficulty arose from the opposition of the soldiers; and he justly dreaded a mutiny in the army. At length he determined to decline the acceptance of that crown, which the representatives of the nation, in the most solemn manner, had tendered to him. The parliament, when Cromwell had rejected the royal dignity, found themselves obliged to retain the name of a commonwealth and protector; and as the government had hitherto been a manifest usurpation, it was thought proper to sanction it by a seeming choice of the people and their representatives. Accordingly, instead of "the instrument of government," which was the work of the general officers alone, an "humble petition and advice" was framed, and offered to the protector by the parliament. This was represented as the great basis of the republican establishment, regulating and limiting the powers of each member of the constitution, and securing the liberty of the people to the most remote posterity. By this deed, the authority of protector was in some particulars enlarged; in others, it was considerably diminished. He had the power of nominating his successor; he had a perpetual revenue assigned him, of a million a year for the pay of the fleet and army, and 300,000*l.* for the support of civil government; and he had authority to name another house, the members of which should enjoy their seats during life, and exercise some functions of the former house of peers. But he abandoned the power assumed in the intervals of parliament, of framing laws with the consent of his council; and he agreed, that no members of either house should be excluded but by consent of that house, of which they were members. The other articles were much the same with those contained in the instrument of government. This model of government, the humble petition and advice, was accepted for the voluntary deed of the whole people in the three united nations; and Cromwell, as if his power had just commenced from this popular consent, was anew inaugurated in Westminster Hall, after the most solemn and pompous manner.

In 1658 the parliament was again assembled; consisting, as in the times of monarchy, of two houses, the commons and the other house: Cromwell, during the interval having sent writs to his house of peers, which consisted of 60 members. Upon the death of Cromwell in 1658 (see CROMWELL) the council recognized the succession of his son Richard. A parliament was called; and in hopes of obtaining greater influence in elections, the ancient right was restored to all the small boroughs; and the counties were allowed no more than their usual members. The house of peers, or the other house, consisted of the same persons that had been appointed by Oliver. All the commons, at first, signed an engagement, without hesitation, not to alter the present government; they next proceeded to examine "the humble petition and advice," and after much debate it was confirmed. But though parliament acquiesced, cabals were formed against the new protector by the army. Richard, who possessed neither penetration nor resolution, was prevailed on to give an unguarded consent for calling a general council of officers; but as soon as they were assembled, they voted a remonstrance; and they proposed that the

whole military power should be entrusted to some person, in whom they might all confide. The protector, who was in his disposition gentle, humane, and generous, was justly alarmed at the movements of the officers; nor was the parliament less alarmed at the military cabals. They voted that there should be no meeting or general council of officers, except with the protector's consent, or by his orders. This enraged the officers, who bateden and demanded of him a dissolution of the parliament. The parliament was dissolved; and by the same act, the protector was, by every one, considered as dethroned. Soon after he signed his dissolution in form; and withdrawing into retirement, extended his peaceful life to an extreme old age. The council of officers, now possessed of supreme authority, deliberated what form of government they should establish. It was agreed at last to revive the long parliament, which had been expelled by Cromwell. The members of this parliament did not exceed 70; but they resolved, since they enjoyed the title of the supreme authority, and observed that some appearance of a parliament was requisite for the purposes of the army; not to act a subordinate part to those who acknowledged themselves as their servants. They chose a council consisting of 7 persons, who should nominate to such commands as became vacant; and they voted, that all commissions should be received from the speaker, and be assigned by him in the name of the house. The general officers were disgusted by those precautions; but the state of the country prevented their manifesting their disgust. As soon as an interval occurred, they renewed their hostility, and expelled the parliament. The officers, again possessed of supreme authority, elected a committee of 23 persons, of whom 7 were officers, whom they pretended to invest with sovereign authority; and they called them "the committee of safety." On the approach of danger, Lenthall the speaker was invited by the officers to summon the parliament, which had twice before been expelled, with so much reproach and ignominy. But general Monk was advancing with his army, and having sent a message to the parliament from St. Alban's, desiring them to remove from London those regiments, which had so lately offered violence to their assembly; he marched towards London and took quarters at Westminster. He afterwards required parliament, in the name of the citizens, soldiers, and whole commonwealth, to issue writs for the filling of their house, and to fix the time for their own dissolution, and the assembling of a new parliament. The parliament attempted to conciliate the general, and dispatched a committee to him for this purpose; but he refused to hear them, except in the presence of some of the secluded members. These members, upon the general's invitation, were restored; and the long parliament, after having passed some resolutions for the composition of the kingdom, dissolved itself, and issued writs for the immediate assembling of a new parliament. When the parliament met, measures were taken for the restoration of Charles II.; he was proclaimed in the presence of the two houses, on the 8th of May, and on the 29th, which was his birth-day, the king entered London. Rapin's Hist. vol. xi. Hume's Hist. vol. vii.

COMMORANCY, in *Law*, an abiding or dwelling in any place; as an inhabitant of an house in a vill, &c. Commorancy for a certain time may make a settlement in a parish. Commorancy consists in usually lying in a certain place. Dalt. Blacklt. Com. iv. 273.

COMMORTH, from the Brit. *Cymmerth*, q. d. subfidium, a contribution which was gathered at marriages, and when young priests said or sung the first masses, &c. See stat. 4 Hen. IV. c. 27. But stat. 26 Hen. VIII. c. 6. prohibits levying any such in Wales, or the marches, &c. *Cowel*.

COMMOTAU, or **CHOMSTON**, in *Geography*, a town of Bohemia, in the circle of Saatz. Large quantities of alum are prepared here. It is distant 10 miles N. W. of Saatz. 38 S. of Dresden, and 42 N. W. of Prague.

COMMOTE, an ancient term in Wales, denoting half a cantred, or hundred; containing fifty villages. Stat. Wallie, 12 Ed. I.

Wales was anciently divided into three provinces; each of these subdivided into cantreds; and every cantred into two *commotes*, or half hundreds.

Silvester Girald, however, tells us, in his Itinerary, that a *commote* is but a quarter of a hundred. *Commote* also signifies a great signory or lordship, and may include one, or divers manors. Co. Litt. 5.

COMMOTION, an intestine motion, or luctation in the parts of any thing.

In medicine, the term is chiefly used for a blow, or shake of the brain. A convulsion is a commotion of the fine medullary fibres of the brain. A fall occasions a commotion, whence frequently arises a counterstroke on the opposite part; which occasions sometimes a contraction, and at other times a rupture of the vessels, and an imposthume, by shaking the whole mass of the brain.

COMMUNAM, *Appropriare*. See **APPROPRIARE**, &c. **COMMUNANCE**, a name formerly given to the commoners, or tenants and inhabitants, who had the right of common or commoning in an open field, &c. Cowley.

COMMUNE, in the present organization of France, denotes the subdivision of a canton, including sometimes a single town, and sometimes an union of several villages, possessing a mayor, and a communal municipality. All the considerable cities are divided into several communes.

COMMUNE Concilium Regni Angliæ, denotes the common council of the king and people assembled in parliament.

COMMUNE Rectum. See **RECTUM**.

COMMUNEM Legem, *Writ of Entry ad*. See **LEGEM**.

COMMUNIA Placita non tenenda in scaccario, an ancient writ directed to the treasurer and barons of the Exchequer, forbidding them to hold plea between "common persons," (*i. e.* not debtors, to the king, who alone originally sued and were sued there) in that court, where neither of the parties belong to the same. Reg. Orig. 187. But little obedience would be now paid to such a writ, if any officers were to dare to issue it; for the court of Exchequer seems, by prescription, to have attained a concurrent jurisdiction in civil suits with the other courts in Westminster-hall.

COMMUNIBUS Locis, a Latin term, in frequent use among philosophical, &c. writers; implying some medium, or mean relation between several places.

Dr. Keil supposes the ocean to be one quarter of a mile deep, *communibus locis*, *q. d.* at a medium, or taking one place with another.

COMMUNIBUS Annis, has the same import with regard to years, that *communibus locis* has with regard to places.

Mr. Derham observes, that the depth of rain, *communibus annis*, *i. e.* one year with another, were it to stagnate on the earth, would amount to, at Townly in Lancashire, 42½ inches; at Upminster, in Essex, 19½; at Zurich, 32½; at Pisa, 43½; and at Paris, to 19 inches.

COMMUNICANS Arteria Cerebri, in *Anatomy*, is a branch of the internal carotid artery, which joins with a branch of the profunda cerebri, to form the circle of Willis. See **ARTERIES**.

COMMUNICATING, in *Theology*, the act of receiving the sacrament of the EUCCHARIST.

Those of the reformed, and of the Greek church commu-

nicate under both kinds; those of the Romish only under one.

The oriental communicants receive the species of wine by a spoon; and anciently they sucked it through a pipe, as has been observed by Beat. Rlicanus on Tertullian.

COMMUNICATION, the act of imparting a thing to another, or making him a sharer with us therein.

The use of speech is for the communicating of our ideas and sentiments to each other.

COMMUNICATION is also used for the connection of one thing with another; or the passage from one place to another. Anciently, it was frequent to have subterraneous communications between one place and another.

COMMUNICATION, *Bridge of*. See **BRIDGE**.

COMMUNICATION, in *Military Language*. Communications are all sorts of ways or passages, above or below ground, which lead from different parts of the works to mines, or from one work to another. Those are best, which cannot be annoyed by the enemy, but are secure against his fire. A place cannot be long or obliquately defended without good communications; whereas, on the other hand, if these be good, it may hold out, if well garrisoned, and sufficiently furnished with every thing necessary for defensive operations, for a length of time. When its ditches are filled with water, or a river runs through it, floating bridges, boats, &c. serve as communications.

COMMUNICATIONS in and with a Camp. In every camp there should be communications between the different parts; and each of the principal, or more necessary ones, ought to be wide enough for forty or fifty men to walk abreast. As to communications with a camp, see the article **CAMP**.

COMMUNICATIONS in the Attack of a Place. Besiegers ought to, and generally do, take care to join their works with one or several communications. All those which they construct in the parallels, on the glacis, and on the counter-scarp, communicate one with another. And as it generally happens, that the besiegers' quarters in their camp are separated by rivers, great or small, or by marshes, it is not only necessary, but of the first importance, to make causeways across the marshes and bridges of communication, across the rivers, either on wooden frames, or on batteaux. It is better, however, to make them on frames or piles, if possible, as they are generally safer and stronger when so constructed, especially if the place be in a situation to open a large sluice of water capable of breaking those placed on batteaux, as actually happened at the siege of Valenciennes, which the besiegers were obliged to raise with loss. That place was besieged in 1656 by the French, under the command of the marshals de Turenne and de la Ferté-Senneterre. But the Spaniards, commanded by Don Juan of Austria, and the prince of Condé, made them raise the siege. And their quarters being separated by the breaking of their bridges of communication, one half of their army was entirely routed, and the marshal de la Ferté was made prisoner. In like manner, when the French were besieging Turin with 72,000 men, prince Eugene, observing that one of their quarters was separated from the rest by rivers, and that their bridges were bad and neglected, attacked them in that place with 24,000 only, defeated them, and raised the siege.

The bridges should be made very strong and secure; and on every communication of difficulty or importance, there should be at the least four, at the distance of forty or fifty fathoms from one another. The avenues to them ought to be rendered as easy and practicable as possible. Guards should be placed near them for their security, and to prevent their receiving any injury. And they should always

always be made within the line of circumvallation, for the safety of those who press and repulse.

COMMUNICATION of *idoms*, in *Theology*, the act of imparting the attributes of one of the natures in Jesus Christ to the other.

The communication of *idoms* is founded on the supposed union of two natures in the person of Christ: by this communication of *idoms* it is, that some divines say, God suffered, died, &c. which is strictly understood of the human nature; and signifies that God suffered in his humanity, that he died as to his human nature, &c.

The Lutherans carry the communication of *idoms* so far, as to say, that Jesus Christ is not only in his divine nature, and by reason of his divine person, but also really and properly in his humanity, immortal, immune, &c.

COMMUNICATION of *motion*, that act of a moving body, whereby another body at rest is put by it in motion, or a body already in motion is accelerated.

F. Malebranche looks on the *communication of motion* as something metaphysical; *i. e.* as not necessarily arising from any physical principles, or any properties of bodies, but flowing from the immediate agency of God: there being, according to him, no more connection, or dependence, between the motion or rest of one body, and that of another, than between the form, colour, magnitude, &c. of one body, and those of another. The motion of one body, therefore, on his principle, is not any physical cause of that of another. See **CAUSE**.

The communication of motion results from, and is an evidence of the impenetrability and inertia of matter as such: unless we admit the hypothesis of penetrable matter, advanced by M. Boscovich and Mr. Michell, and ascribe to the powers of repulsion those effects which have been usually ascribed to its solidity and actual resistance. See **MATTER**.

Action, and re-action, sir Isaac Newton demonstrates, are equal and opposite; so that one body striking against another, and thereby occasioning a change in its motion, does itself undergo the very same change in its own motion, the contrary way. See **MOTION**.

Hence, a moving body striking directly against another at rest, the one loses just as much of its motion as it communicates to the other; and they will proceed with the same velocity as if united into one mass. For the laws and quantity of motion so communicated, either in elastic or non elastic bodies; see **COLLISION**.

COMMUNICATION, *communicatio*, in *Rhetoric*. See **ANACONOSIS**.

COMMUNI CUSTODIA, in *Law*, a writ which anciently lay for the lord, whose tenant holding by knight's service died, and left his eldest son under age, against a stranger that entered the land, and obtained the ward of the body. F. N. B. 89. Reg. Orig. 161. Since the stat. 12. Car. II. c. 24., hath taken away wardships, this writ is of no use.

COMMUNION, in *Theology*, an uniform belief in several persons; whereby they are united under one head, in one church. See **UNITY**, **UNIFORMITY**, &c.

In this sense, the Lutherans, Calvinists, &c. are said to have been cut off from the Romish *communion*.

This is the primitive use of the word *communion*, as appears from the canons of the council of Elvira.

Though the term has been more extensively applied to denote a general agreement in matters of doctrine, discipline, and worship. And unless the term be understood in this large sense, so various are the opinions of men, there could be no *communion* among the members of any one church on earth.

COMMUNION is also used for the act of *communicating* in, or participating of, the sacrament of the **EUCCHARIST**. The

fourth council of Lateran decrees, that every believer shall receive the communion, at least, at Easter; which seems to import a tacit desire, that they should do it oftener; as, in effect they did it much oftener in the primitive days. Gratian, and the master of the sentences, prescribe it as rule for the laity to communicate three times a year, at Easter, Whitsuntide, and Christmas. But in the thirteenth century, the practice was got on foot, never to approach the eucharist except at Easter; and the council thought fit to enjoin it then by a law, lest their coldness and remissness should go farther still.

And the council of Trent renewed the same injunction, and recommended frequent communion without enforcing it by an express decree.

In the ninth century, the communion was still received by the laity in both kinds; or, rather the species of bread was dipped in the wine, as is owned by the Romanists themselves. Acta SS. Benedicti Sac. III. M. de Marca observes, that they received it at first in their hands. Hist. de Bern, and believes the communion under one kind alone to have had its rise in the West under pope Urban II. in 1096, at the time of the conquest of the Holy Land. And it was more solemnly enjoined by the council of Constance in 1414. The twenty-eighth canon of the council of Clermont en-joins the communion to be received under both kinds, distinctly; adding, however, two exceptions; the one of necessity, the other of caution, *nisi per necessitatem, & cautelam*; the first in favour of the sick, the second of the abstemious, or those who had an aversion from wine.

It was formerly a kind of canonical punishment, for clerks guilty of any crime, to be reduced to *lay communion*, *i. e.* only to receive as the laity did, *viz.* under one kind.

They had another punishment of the same nature, though under a different name, called *foreign communion*; to which the canons frequently condemned their bishops, and other clerks. This punishment was not any excommunication, or deposition; but a kind of suspension from the function of the order; and a degradation from the rank they held in the church. It had its name because the communion was only granted to the criminal on the foot of a foreign clerk, *i. e.* being reduced to the lowest of his order, he took place after all those of his rank, as all clerks, &c. did in the churches to which they did not belong. The second council of Agda orders every clerk that absents himself from the church, to be reduced to foreign communion.

COMMUNION, *Infant*. Some instances occur in the early ages of the church, of the practice of administering the eucharist to infants; and some few have imitated this practice in more modern times. Mr. Pierce pleads the use of it even to this day among the Greeks, and in the Bohemian churches till near the time of the Reformation; and he refers to the usage of the ancient churches, recorded by Photius, Angustin, and Cyprian. He urges from Scripture the right which children have to all the privileges of which they are capable, as well as the Jewish children under the law, who were allowed to eat of the passover, and other sacrifices. To which it has been answered, that the sacrifices, of which they were allowed to partake, were chiefly peace offerings, which became the common food of the family, and were not considered as acts of devotion in such a degree as our eucharist. He replies to the objection founded on the incapacity of infants to examine themselves and discern the Lord's body, by observing that the precept extends only to those who were capable of understanding and complying with it; on the same ground that faith is required previous to baptism. Bishop Bedell suggests the following inquiry relative to this subject; what necessity of baptizing infants,

infants, if their baptism produces no effect till they come to years of discretion? To which he replies, though the most principal effect be not attained presently, the less principal are not to be refused: so children were circumcised, who could not understand the reason of it, and the same also did eat the passover: and so did children baptized, in the primitive church, communicate in the Lord's supper: which I know not (says he) why it should not be so still; *de quo olim*. It has been alleged, that the foundation of this practice was a mistaken apprehension of the absolute necessity of this ordinance in order to salvation, resulting from an erroneous interpretation of John vi. 53. See Bishop Bedell's Letter to Dr. Ward, in p. 442 of Archbishop Usher's Life by Parr. Pierce's Essay on the Eucharist. Wall's Hist. of Infant Baptism, part ii. chap. 9. § 15 and 16. Waterland's Review of the Doctrine of the Eucharist, and preface to his two volumes of Posthumous Sermons, p. 32, &c. and Inquiry concerning Infant Communion, vol. ii. p. 75, &c.

COMMUNION SERVICE, denotes that part of the liturgy of the church of England which relates to the administration of the sacrament. See LITURGY.

COMMUNION-TABLE. See ALTAR.

COMMUNIS CAPSULA. See CAPSULA.

COMMUNIS ductus choledochus. See DUCTUS.

COMMUNIS digitorum manus extensor. See EXTENSOR.

COMMUNIS labiorum depressor. See DEPRESSOR.

COMMUNIS labiorum elevator. See ELEVATOR.

COMMUNIS misericordia. See MISERICORDIA.

COMMUNITY, a society or body of men united together under certain common laws, agreed on among themselves, or imposed by a superior.

The Romans, who seem to have given the first hint of communities to the several nations into which their empire was divided, doubtless borrowed it from some rules of their neighbours: they call them *colleges*; which term, among them, had nearly the same signification with community among us. For an account of the introduction and establishment of communities in Europe, see *Charters of COMMUNITY and CITY*. See also CORPORATION and CROISSAGE.

Communities now are of two kinds, *ecclesiastic* and *laic*; the first are either *secular*, as chapters of cathedral and collegiate churches; or *regular*, as convents, monasteries, &c.

Lay communities are of various kinds; some contracted by a fixed abode of a year and a day in the same place; others formed by the discharge of the same office, the profession of the same art, or attending the same place of worship, as those of parishes, fraternities, &c.

Accordingly, the word is commonly understood of pious foundations for the support of several persons, either in a secular or regular life; as *colleges*, *abbies*, *convents*, *priories*, *seminaries*, *hospitals*, *inns*, &c.

Community is more particularly used in the French law, for the joint property in goods between the husband and the wife: the result of which is, that during marriage they are equally intitled to all effects, and liable to all debts, contracted either before or under marriage.

Community is a species of succession, and the acceptance of community resembles an *additio hereditatis*.

Community was set on foot in favour of the wives, to enter them as sharers in their husband's effects.

In countries where the civil law obtains, this community has no place, nor even in several customary countries, as being reputed a burden on the man.

Anciently, the woman's share in the community was only one-third; and this appears (till the sense of the law among us, the widow, at the decease of her husband, being only intitled to one-third part of the moveables.

COMMUNITY, continued, in the *French Law*, is that which subsists between the survivor of two persons joined in marriage, and the minor children of that marriage, when the survivor has not made an inventory of the effects in possession during marriage. The widow may either renounce community with her children, or continue it.

COMMUNITY, *tacit*, is a community contracted between a man and woman, by the mere mingling of their effects, provided they have lived together the space of a year and a day: this community, being odious, is now abolished.

COMMUNITY, *Charters of*. See CHARTERS of Community.

COMMUNITY of Goods, as it has been sometimes denominated, signifies a practice which was adopted for a short time in the primitive church, and which consisted principally in a common use, derived from an unbounded liberality, that induced the opulent to share their riches with their indigent brethren. The rich supplied the wants of their necessitous brethren with such liberality and promptitude, that, as St. Luke tells us (Acts ii. 4. iv. 32.) among the primitive disciples of Christ, all things were in common. This expression, however, has been greatly abused, says Mosheim (E. H. v. i. p. 60), and has been made to signify a "community of rights, goods, and possessions," than which interpretation nothing is more groundless, nothing more false. From a multitude of reasons, as well as from the express words of St. Peter (Acts v. iv.) it evidently appears, that the community which is implied in mutual use, and mutual liberality, is the only thing intended in this passage. This is very clearly and satisfactorily proved by Mosheim, in a dissertation concerning the true nature of the community of goods, which is said to have taken place in the church of Jerusalem. This learned discourse is to be found in the second volume of his excellent work entitled, "Dissertationes ad Historiam ecclesiasticam pertinentes." Mr. Gibbon (see Hist. Decl. and Fall of Rom. Emp. vol. ii. p. 341) has given a very uncandid and unjust statement of this ancient Christian practice, and instead of considering it as honourable to the liberality and mutual benevolence of the first disciples, he seems to attach reproach and censure to it; when he suggests that the community of women, and that of temporal goods, may be considered as inseparable parts of the same system. He also observes that it was of the same kind with that which had so agreeably amused the imagination of Plato, and which subsisted in some degree among the austere sect of the Essenians; although it was undoubtedly of a very different nature. This author further adds, that the progress of the Christian religion relaxed, and gradually abolished this generous institution, which, in hands less pure than those of the apostles, would too soon have been corrupted and abused by the returning selfishness of human nature; and the converts who embraced the new religion were permitted to retain the possession of their patrimony, to receive legacies and inheritances, and to increase their separate property by all the lawful means of trade and industry. Bishop Watson (see his "Apology for Christianity,") has justly observed, that the expression "permitted to retain," in ordinary acceptation, implies an antecedent obligation to part with; but, as he adds, we have no account in scripture of any such obligation being imposed upon the converts to Christianity, either by Christ himself, or by his apostles, or by any other authority: nay, in the very place where

where this community of goods is treated of, there is an express proof to the contrary. When Peter was about to inflict an exemplary punishment upon Ananias (not for keeping back a part of the price, as some men are fond of representing it, but) for his lying and hypocrisy, in offering a part of the price of his land as the whole of it; he said to him, "Whilst it remained (unfold) was it not thine own? and after it was sold, was it not in thine own power?" From this account it is evident, that Ananias was under no obligation to part with his patrimony; and after he had parted with it, the price was in his own power; the apostle would have "permitted him to retain" the whole of it, if he had thought fit; though he would not permit his prevarication to go unpunished.

Pythagoras not only taught his disciples to be contented with a little, but even deprived them of all command over their own property, by casting the possessions of each individual into a common stock, to be distributed by proper officers, as occasion should require. From the time of this sequestration of their goods, as long as they continued members of this society, they lived upon the footing of perfect equality, and sat down together daily at a common table. If any one, however, repented of the connection, he was at liberty to depart, and might reclaim, from the general fund, his whole contribution.

COMMUNITY of the kingdom. See COMMONALTY.

COMMUTATION, in Astronomy. Angle of COMMUTATION, is the distance between the sun's true place seen from the earth, and the place of a planet reduced to the ecliptic. See PLACE.

Thus the angle ESR (Plate V. Astronomy, fig. 11.) subtended between the sun's true place, E, viewed from the earth at S, and that of a planet reduced to the ecliptic, R, is the angle of commutation.

The angle of commutation, therefore, is found by subtracting the sun's longitude from the heliocentric longitude of the planet R; or contrarily.

COMMUTATION, in Law, a change of a penalty, or punishment, viz. of a greater for a less, &c. as when death is commuted for, by banishment or perpetual imprisonment, &c. Suits are, and always were, allowable in the spiritual court, for money agreed to be given as a commutation for penance. Art. Cler. 9 Edw. II. c. 4. F. N. B. 53.

Some doubt whether the word be properly applied to any change but that of punishment: others will have it indifferently serve for the exchanging, or trucking of any thing.

COMMUTATION ACT, an act passed during the session of parliament in 1784, as part of a system for the prevention of smuggling; so called because, whilst it gave up the existing duties and excise on teas, it proposed an additional tax on windows, not as a new tax, but as a commutation for the portion of the duties on tea which it surrendered. The plan of the framers of this bill was to take off all the excise duty on tea, and impose a custom duty of 12 l. 10 s. on Bohea tea, which, it was apprehended, would ruin the smuggling trade in that article. On the finer kinds of tea, a higher duty would be laid; 15 l. per cent. on fouchong, &c.; 20 l. on single and hyson; and 30 l. on congo. The total annual importation of teas into Europe amounted to about 19,000,000 lbs., above two-thirds of which quantity were consumed in Great Britain and Ireland, though the legal importation was not quite 6,000,000; consequently the quantity annually smuggled must have been above 7,000,000 lbs. According to this calculation, the people of England were considerably under-rated at the number of 6,000,000. Of these it was said that

2,000,000 would be relieved from the payment of the present duty on tea, without being obliged to contribute a farthing towards the tax which would be proposed as a substitution; the other 4,000,000, it was calculated, would, one with another, consume 3 lbs. of tea each in the year, for each pound of which, they, at this time, paid on an average 2 s. 7 d. duty; this duty, or the principal part of it being taken off, they could, of course, afford to pay a substituted tax, which was proposed to be raised in the following manner:

On every house with seven windows, which house was also rated to the house tax, it was intended to lay an additional tax of 3 s. and so on, charging 8 s. for every house of eight windows; 9 s. for those of nine windows; 10 s. 6 d. for those of ten windows, and so on, adding 2 s. 6 d. for each window up to 24, and still rising up to 180 windows, for which 20 l. per annum should be paid, over and above the duty at present paid on windows and houses. This regulation was calculated to produce above 700,000 l.; so that with the new duty on tea, the produce would be near 900,000 l. It was suggested that, according to this plan, the public revenue would be a considerable gainer, and the people at the same time have no reason to complain of additional burdens. In England, Scotland, and Wales, it was calculated that there were about 699,958 houses, which might be divided into the following classes; 286,293 houses under seven windows; 211,483 houses having from 8 to 10 windows; 38,324 of 11 windows; 24,919 from 12 to 13; 67,652, from 14 to 19; 52,652, of 20 windows and upwards; and 17,732 houses in Scotland. Of these about 200,000 as being exempted from the house-tax would pay nothing to this new tax, and the inhabitants being of the poorer sort, would be wholly delivered from the duty on tea. This regulation, it was supposed, would check, or rather absolutely ruin, the smuggling trade; besides being productive of other benefits to the fair trader, and particularly to the East India Company. Against this bill, which, however, passed into a law, many objections have been urged. To the East India Company, it has been argued, this afforded certain advantage; but those which the public were to derive from it are less obvious and certain. It has been said that those householders who were to be charged with the new rate for windows were precisely the persons who should have received the reciprocal benefit of the commutation; but that the reverse of this is undoubtedly the case; they who do not pay the new window-tax, or indeed any window-tax at all, being the only persons who share among them any little advantages that have accrued from the agreement. The facts are these: Of the five different sorts of teas consumed by the public, there are three which are chiefly used by those who pay the new window tax, viz. congo, fouchong, and hyson. The price of the two former of these (which are the most used of the three) has been so inconsiderably reduced, as to afford nothing like a pecuniary compensation for the additional window-tax, and the price of the third sort, hyson, which is the dearest and the least used, though rather more reduced, is still wholly disproportionate to the promised commutation. The only two sorts of tea, therefore, where the reduction of price is at all considerable, are bohea and single; and those are in general consumed by the lower orders of people only. From these facts it has been inferred, that they who pay the new tax consume those sorts of tea, from which not one-sixth of the proposed saving arises; while they who do not pay any tax at all, or at most a small portion of it, consume those species of tea upon which almost the whole of the saving, or at least upwards of five-sixths of it arises. The act has been deemed, by those

who strenuously opposed it, unjust in its principle, and oppressive in its operation.

COMNENA, ANNA, in *Biography*, daughter of the emperor Alexius Comnenus, flourished about the year 1118, and wrote fifteen books upon the life and actions of her father, which she called the "Alexiad." She has been accused of a too great partiality in favour of her hero, for which, considering her near relationship, she may claim an indulgence. This work was published with a Latin translation in 1661, and again in 1670; to this last edition are added notes historical and philological by the learned Du Fresnoy.

COMNENO, in *Geography*, a town of European Turkey, in the province of Albania; 35 miles S. E. of Albanopolis.

COMO, DA, FRA. EMANUELLO, in *Biography*, so called from the place of his nativity, a considerable town in the state of Milan, was an historical painter, whose taste for the art was first called forth upon his seeing some painters at work in the cathedral of Como. Without the direction of any master, he afterwards attained some degree of eminence. His works, however, are of very unequal merit; he painted in the refectory of a convent at Como a "Last Supper," by which but an indifferent idea of his talents could be formed, were not his character retrieved by an excellent picture in the church representing a Pieta with Saino. He died aged 75, in the year 1701. Orlandi. Lanzi. Storia Pittorica.

Como, in *Geography*, a strong, populous, and commercial town of Italy, and capital of a district in the Milanese, built by the Gauls, under the conduct of Brennus, situated at the fourth end of a lake to which it gives name, in a plain, almost surrounded with mountains. The town is encompassed by a wall, guarded with picturesque towers, and backed by a conical eminence, on which stand the ruins of an ancient wall. The houses are almost wholly built of stone; and the cathedral is a handsome edifice of white marble, hewn from the neighbouring quarries. The inhabitants have established several manufactures of cotton and silk, and carry on some trade with the Grisons. This town being distinguished as the birth-place of Pliny the younger, his statue is placed in a niche on the outside of the church, and has a Latin inscription bearing the date of 1499. It is distant 20 miles N. of Milan, in N. lat. 45° 44'. E. long. 8° 57'.

Como, *Lake of*, a lake of Italy in the Milanese, on the confines of Switzerland, about 32 miles long and 88 in circumference. At first it is scarcely a quarter of a mile broad, but it widens near a neck of land upon which is situated the small village of Turino. Towards the south it is divided into two branches, at the end of one of which stands Como, and at the end of the other Lecco. The river Adda passes through it, and several country houses and villages are situated on its banks, which are adorned with vines, chestnuts, and almond-trees. The neighbourhood of Turino, and the districts bordering the lake of Como, supply, for the most part, these Italian emigrants, who wander through Europe vending barometers and thermometers, of whom numbers annually resort to England.

COMOCLADIA, in *Botany* (from Κομος, comatus sum; and Κλαδός, ramus; so called because the branches have a tuft of leaves at the end, bearing a fancied resemblance to a head of hair.) Linn. Gen. 49. Schreb. 66. Lam. Ill. 65. Willd. 82. Juss. 370. Vent. 3. 444. Class and order, *triandria monogynia*. Nat. Ord. *Terebinthaceae*; Juss. Vent.

Vol. IX.

Gen. Ch. *Calyx* one-leaved, three or four cleft, spreading, coloured; segments roundish. *Cor.* Petals three or four, roundish-egg-shaped, acute, flat, widely spreading, a little larger than the calyx. *Stam.* Filaments three or four, awl-shaped, shorter than the corolla; anthers roundish, incumbent. *Pistl.* Germ superior, egg-shaped; style none; stigma obtuse, simple. *Peric.* Drupe oblong, somewhat curved, marked at the top with three dots; nut membranous, the form of the drupe. *Seed* single.

Ess. Ch. *Calyx* three, rarely four-cleft. Petals three or four. Drupe oblong; with one seed.

Sp. 1. *C. integrifolia*. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Ill. 423. Willd. 1. Jacq. Amer. 12. Brown. Jam. 124.

Lam. Ill. tab. 27. fig. 1. (*Prunus racemosa*; Sloan. Jam. 2. 137. tab. 222. fig. 1.) "Leaflets entire, smooth on both sides." A tree, seldom more than twenty feet high.

Trunk erect, of a moderate thickness; branches few, leafy at the end in open tufts. *Leaves* unequally winged, two feet long, leaflets not more than seventeen, four inches long, ovate-lanceolate, acuminate, slightly wrinkled by the transverse veins, a little revolute at the edges. *Flowers* very numerous, small, sessile, without scent, of a deep red colour, in panicled racemes; racemes about twenty-four, a foot and a half long, branched, pendulous, always with a few quadrifid tetrandrous flowers intermixed with the others. A native of Jamaica, and St. Domingo. It abounds in a watery, slightly glutinous juice, which grows black when exposed to the air, and stains the hands so as scarcely to be washed off. The wood is hard, of a fine grain, and reddish colour.

2. *C. dentata*. Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Ill. 425. Willd. 2. Jacq. Amer. 13. tab. 173. fig. 4. Pæd. 12. tab. 259. fig. 2. "Leaflets egg-shaped, acute, toothed, somewhat prickly, veined and villous underneath." A tree much like the preceding. *Trunk* upright with few branches.

Leaves a foot and half long, in tufts at the ends of the branches; leaflets from thirteen to twenty-one, oblong, acuminate, shining above, edged with prickly teeth. A native of Cuba. Its juice is milky, glutinous, turning very black in the air, durably staining woollen and linen cloth, corroding the skin and rendering it scaly, smelling like liver of sulphur, or the human excrement. The natives have an idea that to sleep under it is dangerous.

3. *C. ilicifolia*. Swartz Prod. 17. Mart. 13. Lam. Ill. 424. Ill. tab. 27. fig. 2. (*C. tricuspidata*; Nonv. Act. Acad. Paris, 1784, p. 347. *Ilex dodonæa*; Linn. Dodonæa; Plum. Gen. 20. tab. 118. fig. 1.) "Leaves roundish angular-spinous, smooth on both sides." Leaflets sessile, rigid, in crowded pairs terminated by an odd one. *Flowers* comparatively few; panicle very slender; racemes generally simple. A native of the West Indies. La Mark's figure was taken from a dried specimen. Willdenow has both an *ilicifolia* and an *angulosa*, quoting for the latter La Mark's figure in opposition to La Mark himself. His error seems to have been occasioned by mistaking the synonym from Plumier, given by Linnaeus, as a spineless variety of his *illex dodonæa*, which Willdenow read *D. aquifolii folio anguloso et aculeato*, instead of *non aculeato*, as it stands in the species plantarum.

Propagation and Culture.—The first two species have been propagated in England, by seeds obtained from their native climate. They require the same treatment as other tropical plants.

COMODI, ANDREA, in *Biography*, an historical painter, who was born at Florence in 1560. He became at once the disciple and companion of Ludovico Cigoli, and was ranked amongst the best Florentine artists of his time, but the ex-

Bb

trunc

treme difficulty which he found in satisfying himself with his own productions, has occasioned their number to be very small, considering the great age to which he lived. After having gone through the regular routine of academic study, he went to Rome, where he spent many years, and painted several frescoes, particularly one in the tribuna of the church of St. Vitale, a composition of many figures, representing Christ bearing his cross, and on each side stories of martyrdoms. One of his most esteemed easel pictures was a "Magdalen in the Desert," for which the cardinal Barbarini presented him with five hundred crowns, a very large price in those times. His pictures of "Madonas" are very highly esteemed for the beauty of their colouring and the delicacy with which they are finished, and above all for an elegance and lightness of form, joined to an expression of virgin modesty peculiarly their own. His numerous copies of the pictures of Coreggio, and other great masters are much esteemed. He died in the year 1638. Baldinucci. Lanza, Storia Pittorica.

COMOMBO, in *Geography*, or *the bill of Ombo*, anciently *Onobos*, a town of Egypt, situated to the south of Thebes and on the same side of the river, where are still seen considerable ruins of an ancient temple. The inhabitants of this place were famous for the worship of the crocodile, which they fed in their ponds (according to Ælian), where they became so tame, as to obey when they were called.

COMONAVA, a town of European Turkey, in the province of Macedonia; 60 miles N.N.E. of Akrida.

COMOPOLIS, in *Ancient Geography*, a town of Asia, in Assyria, according to Ptolemy.—Allo, a town of Asia Minor, furnished *Madrena*.—Allo, a town of Asia Minor, in Phrygia Salutaris, furnished *Meros*, the fame with *Myré*.

COMORA ISLES, in *Geography*, are African islands in the Indian ocean, between the north-end of the island of Madagascar and the coast of Zanguebar, generally reckoned five in number, Johanna, Mayotta, Mohilla, Angazi, Comora, though some enumerate three, others four, and others eight, between the 41st and 46th degree of E. long. and the 10th and 14th of S. lat., at an equal distance from Madagascar and the continent of Africa. The largest is Johanna, which see. As the Comora isles abound in horned cattle, sheep, hogs, a variety of fruits and rice, they serve to refresh the European shipping to and from India. The inhabitants are negroes of the Mahomedan religion; but they entertain the European seamen with great humanity.

COMORA, one of the fore-mentioned islands, which gives name to the whole cluster, about 6 leagues long, and three wide, but little known. S. lat. 11° 50'. E. long. 43°.

COMORIN, CAPE, the southernmost part of the southern Hindoostan, N.W. of the island of Ceylon. Though not above nine miles in extent, this promontory unites the two opposite seasons of the year, owing to a ridge of mountains called the *Chauts*, on the south side of which trees are seen loaded with blossom and fruit, whilst on the north side, the fame sort of trees are stripped of all their leaves. N. lat. 8°. E. long. 77° 32' 30".

COMORN, COMORRA, Lat. a town of Hungary, and capital of a district, to which it gives name. It is so well defended by a fortress that the Turks could never take it. Its chief inhabitants were Hungarians, or Rascians, who belong to the Greek church. In 1783 it was almost wholly destroyed by an earthquake: 36 miles S.E. of Presburg, and 34 S.E. of Vienna.

COMORTH. See COMMORTH.

COMOSE, in *Botany*, the thirty-sixth natural order in the *Philosophia Botanica* of Linnæus, which he afterwards

abolished. It contained only *spiræa*, *filipendula*, and *aruncus*. These are now all united in *spiræa*, and the genus referred to the order pomaceæ.

COMOSANDALOS, in *Antiquity*, a crown of flowers worn in the festival CHTHONIA.

COMOUCKS, in *Geography*, the Tartar inhabitants of Comania or Daghestan in Asia, under the protection of Persia. They are ferocious robbers. Every town has a chief named *Myrfa*; and the head of those chiefs chosen from among themselves is called *Schmkal*.

COMPACH, a river of Carinthia, which runs into the Moil, near Vellach.

COMPACT, in *Physics*, is a relative term, denoting a body to be close, dense, and heavy; having few pores, and those small ones. The heaviest metals, as gold and silver, are the most compact. See GRAVITY.

COMPACT, in a *Legal Sense*, signifies an agreement, or a contract, stipulated between several parties. A compact carries with it an obligation equal in point of conscience to that of a law; but the original of the obligation is different. In compacts, we ourselves determine and promise what shall be done, before we are obliged to do it; whereas in laws, we are obliged to all without ourselves determining or promising at all. See CONTRACT.

COMPACT is also the name of a celebrated bull, confirmed by pope Paul IV. relating to the cardinals.

In virtue of the bull of compacts, cardinals can only confer benefices in their natural state; i.e. regular benefices on regulars.

COMPAGES *circularis montium*, a term devised by Kircher to express what he in other places calls the annularity, or annular disposition of MOUNTAINS, which he says run in continued chains, forming belts or ridges in the manner of spines, all round the globe of the earth, from north to south, and so on from that point to north again, and in the same manner from east to west, and from west to east again.

COMPAGNE, Fr. The cabin of the commander or chief of a galley.

COMPAGNIES *aux Gardes*. These were the companies of infantry that composed the regiment of French guards, making part of the household troops of the king for the exterior guard. And it was usual to say *Capitaine aux Gardes*, *Lieutenant aux Gardes*, &c.

COMPAGNIE *Ecolaise*. See GENDARMERIE or *Gardes du Corps*.

COMPAGNIES *d'Ordonnance*. These were companies that never formed corps or regiments, like the *gendarmes*, the light horse, the musketeers, &c.

COMPAGNIES *des Gardes*. The four companies of horse-guards made part of the troops of the household of the kings of France for the interior guard. Thus, in speaking of that corps, it was usual to say, a captain of the guards, a lieutenant of the guards, &c. It was customary to speak in the same manner of Swiss guards.

COMPAGNIES *Franches*, Fr. These free companies were not regimented, but in time of war were put on a certain establishment. Each of them had a chief, who commanded it. They were generally composed of dragoons, hussars, and foot soldiers. A1 those who served in these corps or companies were called *partisans*. They were employed in making incursions into the enemy's country, and laying it waste as much as they could. An officer, who had served some campaigns as a partisan, could not easily afterwards serve with regular troops. They are a sort of voluntary pirates, who know no kind of subordination but that which is peculiar to themselves. When these troops have chiefs that

that are hardy, brave, and intelligent, they render important services to armies.

COMPAGNIE du Guet a pied. See the article *MARÉ-CHAUSSEE*.

COMPAGNIE du Lieutenant criminel de Robecourte. See also the article *MARÉCHAUSSEE*.

COMPAGNIE d'Ordonnance a cheval. See the same article.

Independent company is one that is not incorporated into a regiment. Two such companies generally belong to each regiment in England, for the purpose of supplying the regiments with recruits.

COMPAGUS, in *Antiquity*, a kind of summer-shoe worn by the Roman senators, consisting only of a sole at the bottom; it was fastened with leathern straps, crossing one another many times about the leg.

Rubenius makes the *compagi* to have been a sort of caligæ worn by the roman generals as well as senators. Under the later emperors, in the middle age, we read of the same worn by popes, bishops, and abbots.

COMPANION of the Garter, an appellation distinguishing one of the knights of that most noble order, at the head of which is the king, as sovereign. Stat. 24 Hen. VIII. c. 13. See *GARTER*.

COMPANY, a collective term, understood of several persons assembled together in the same place, or with the same design. See *SOCIETY*.

The word is formed of the French *compagnie*, and that of *compaino* or *companies*, which, Chifflet observes, are found in the Saliæ law, tit. 66. and are properly military words, understood of soldiers, who, according to the modern phrase, are comrades, or mess-mates, i. e. lodge together, eat together, &c. of the Latin *cum, with, and panis, bread*. It may be added, that in some Greek authors under the Western empire, the word *κρηταιων* occurs in the sense of *society*.

COMPANY, in *Commerce*, is an association of several merchants, or others, who unite in one common interest, and contribute by their stock, their counsel, and study, to the setting on foot, or supporting, of some lucrative establishment.

Though *company* and *society*, or *fellowship*, be in effect, the same thing, yet custom has made a difference between them; *society*, or *partnership*, being understood of two, or three dealers, or not many more; and *company* usually of a greater number. See *SOCIETY*.

A second difference between *companies* and *societies* is, that the first, especially when they have exclusive privileges, cannot be established without the concession of the prince; and need letters patent, charters, &c. Whereas, for the latter, the consent of the members, fixed and certified by acts and contracts, and authorized by bye-laws, is sufficient.

The several professions and trades exercised in the city of London, being incorporated into distinct fraternities, governed by their particular laws, a tabular view of them may not be unacceptable.

The abstract of their incorporations, and particular privileges, is taken from the records of the Tower, &c. and from the *Firma-Burgi* of Madox, the king's historiographer; the account of their charities from those eminent historians Stow and Strype; and the lines of the liverymen on admission, are taken from the returns to the clerk of the parliament, and the scrutiny-books made after the several polls for the magistrates and representatives of the city.

The companies are here placed according to their precedence, beginning with the twelve principal ones, of one or other of which the lord mayors have generally made themselves free at their election, if they were not so before; for they are not only the oldest, but the richest, many of them having had the honour of kings and princes to be their members, and the apartments of their halls being fit to entertain a monarch.

16 Pewterers †	Lime-street	Edward IV.	1474 20 0 0 † By act of Parl. 25 Hen. VIII. their wardens had the inspection of pewter through- out England.	
17 Barber-furgeons †	Monkwell-street	Edward IV.	1461 10 0 0 † In the reign of Hen. VIII. the furgeons of this company, then but 19, were created by parliament from ward and parish offices, and from military service. They were incorporated separately by 18 Geo. II. cap. 15. and the company of furgeons had an elegant hall in the Old Bailey, with a theatre for the dissection of human bodies. They now form a royal college, and their house is in Lincoln's Inn fields.	
18 Cutlers	Cloak-lane	Henry V.	1417 10 0 0	
19 Bakers	Harp-lane	Edward II.	1327 10 0 0

C O M P A N Y.

Companies.	Halls.	Incorporated by	A. D.	Livery fines.	Charitable Gifts, paid yearly, and Privileges, &c.
51 Turners	College-hill	James I.	1604	l. s. d. 8 0 0	
52 Basket-makers	No hall	No charter			No livery; yet a company by prescription, governed by 2 wardens and 48 assistants, with this motto to its arms, <i>Let us love one another.</i>
53 Glaziers	No hall	Charles I.	1637	3 0 0	The glass painters are incorporated with them.
54 Horners	No hall	Charles I.	1638		No livery; yet they have a master, 2 wardens, and 9 assistants, with a warehouse in Spitalfields; where they divide in lots, among themselves, such horns as are brought up by their members in Leadenhall and other markets: And in 1465, they obtained an act of parliament that none should be exported, but such as they refused.
55 Farriers	No hall	Charles II.	1673	5 0 0	
56 Pavours	No hall	No charter			No livery; yet it is a fellowship by prescription, with 3 wardens, and 25 assistants.
57 Loriners	London-wall	Q. Anne	1712	10 0 0	
58 Apothecaries	Blackfryars	James I.	1617	16 0 0	They are exempt from ward and parish-offices, and have a spacious physic-garden at Chelsea; which in 1721 was granted to the company for ever by Sir Hans Sloane, bart. the lord of the manor, on condition of their paying a quit-rent of 5 <i>l.</i> and continuing it always as a physic-garden, and of presenting every year to the Royal Society fifty samples of different sorts of plants, there grown, till they amount to two thousand.—The latter of these conditions hath been long since more than completed. This is what may be called a trading company.
59 Shipwrights	No hall	James I.	1605		No livery; yet they have a master, 2 wardens, and 16 assistants.
60 Spectacle-makers	No hall	Charles I.			No livery; yet have a master, 2 wardens, and 15 assistants.
61 Clock-makers	No hall	Charles I.	1632	10 0 0	
62 Glovers	No hall	Charles I.	1638	5 17 4	
63 Comb-makers	No hall	Charles I.	1636		No livery; yet they have a master, 2 wardens, and 13 assistants.
64 Felt-makers	No hall	James I.	1604	5 0 0	
65 Framework-knitters	Red cross-street	Charles II.	1663	10 0 0	
66 Silk-throwers	No hall	Charles I.	1630		No livery; yet have a master, 2 wardens, and 20 assistants.
67 Silkmen	No hall	Charles I.	1631		No livery; yet have a governor, and 20 assistants.
68 Carmen, have no hall, nor charter, nor livery; but are a fellowship by act of common council, with the title of Free Carmen of the city of London, and have a master, 2 wardens, and 41 assistants, under the direction of the lord mayor and aldermen. The carts that belong to this fellowship, which are betwixt 4 and 500, are, by an act of common council, subjected to the rule of the president and governors of Christ's Hospital; to whom the owner of every cart pays 17 <i>s. 4 d.</i> a year for a licence to work it, and every cart is brought to the hospital to have a number in bras put upon it.					
69 Pin-makers	No hall	Charles I.	1636		No livery; yet have a master, 2 wardens, and 18 assistants.
70 Needle-makers	No hall	O. Cromwell	1656	5 5 0	
71 Gardeners	No hall	James I.	1616		No livery; yet have a master, 2 wardens, and 18 assistants.
72 Soap makers	No hall	Charles I.	1630		No livery; yet have a master, 2 wardens, and 18 assistants.
73 Tin-plate-workers	No hall	Charles II.	1670	10 0 0	
74 Wheelwrights	No hall	Charles II.	1670	15 15 0	
75 D fillers	No hall	Charles I.	1638	13 6 8	
76 Hatband-makers	No hall	Charles I.	1638		Incorporated with the company of needle-makers.
77 Patten-makers	No hall	Charles II.	1670	6 0 0	
78 Glass-fellers and looking-glass-makers	No hall	Charles II.	1664	5 0 0	
79 Tobacco-pipe-makers	No hall	Charles II.	1663		No livery; yet have a master, 2 wardens, and 18 assistants.
80 Coach and harness-makers	Noble-street	Charles II.	1677	10 0 0	
81 Gunsmiths	No hall	Charles I.	1638	10 0 0	
82 Gold and silver wire-drawers	No hall	James I.	1623		No livery; yet have a master, 2 wardens, and 18 assistants.
83 Long-bow-string-makers	No hall	No charter			No livery; yet a company by prescription, and have 2 wardens, and 19 assistants.

COMPANY.

Companies.	Halls.	Incorporated by	A. D.	Livery fins.	Charitable Gifts paid yearly, and Privileges, &c.
84 Card-makers	No hall	Charles L.	1629	No livery; yet have a master, 2 wardens, and 18 assistants.	
85 Fan-makers	No hall	Q. Anne	1709	No livery; yet have a master, 2 wardens, and 20 assistants.	
86 Woodmongers	were a company incorporated with the carmen by K. James I. 1605. but surrendered their charter in 1668; by an act of common council in 1694, they obtained a privilege of keeping 120 carts, exclusive of the number kept by the carmen, <i>extinct</i> .				
87 Starch-makers, <i>extinct</i>	No hall	James I.	1622		
88 Fishermen, <i>extinct</i>	No hall	James II.	1787		
89 Parish-clerks	Wood-street	Henry III.	1233	By a decree of the Star chamber court in 1625, they obtained a privilege to keep a press in their hall, for printing the weekly bills of mortality, by a person appointed by the archbishop of Canterbury. They are, by their charter, to make a report of all the weekly christenings and burials in their several parishes every Tuesday, and they have a master, 2 wardens, and 17 assistants.	
90 Porters,	are another fellowship, without hall, or livery; consisting of tackle and ticket-porters. They were constituted a fraternity by act of common council in 1646, with a power of annually choosing among themselves twelve rulers, being six of each denomination. However, the court of lord mayor and aldermen have referred to themselves a power of appointing one of their own body, as the chief judge in all controversies. One very laudable custom of the master tackle-porters is, that such of their brethren as happen to be disabled from working, receive their share of all profits, as if actually in business, during life.				
91 The watermen, wherymen, and lightermen	of this city and neighbouring places, were by act of K. William III. constituted a society, or company, under the direction of the lord mayor and aldermen. They are to furnish 1000 men for the navy, upon demand by the admiralty. They have a hall at Coal Harbour, near the Thames; and pay to their poor about 800 <i>l.</i> a year; chiefly raised by ferries over the Thames on Sunday.				
N. B.	The company of Surgeons, Parish-clerks, Porters and Watermen, have not the privilege of making their members freemen of the city of London.				

From the foregoing list, it appears on the whole, that there are ninety-one companies, forty-eight halls, and that the number of livermen, according to the most exact account that could be procured, in 1779, was 8954, but this number is variable. The sums of money yearly distributed in charity by only twenty-three of the companies, amounts to more than 23,655*l.*; and if but forty-pounds each be annually given by the remaining sixty-eight companies, the whole will much exceed 26,375*l.* per annum.

COMPANY seems more peculiarly appropriated to those grand associations, set on foot for the commerce of the remote parts of the world; as the English and Dutch East India company, South Sea company, Mississippi company, &c.; the rise and establishment of which, we shall here set before the reader.

However injurious companies with joint-stock, and incorporated with exclusive privileges, may, at this time, be reckoned to the nation in general; it is yet certain that they were the general parent of all our foreign commerce; private traders being discouraged from hazarding their fortunes in foreign commerce, until the method of traffic had been first settled by joint-stock companies. From this principle it is, that we find several nations that are now endeavouring to improve their trade, and to establish or increase marine power, by the means of joint-stock companies.

But since the trade of this kingdom, and the number of traders have increased, and the methods of assurance of shipping and merchandise, and the navigation to all parts of the known world have become familiar to us; these companies, in the opinions of most men, have been looked upon in the light of monopolies: their privileges have therefore been lessened from time to time, in order to favour a free and general trade; and experience has shewn, that the trade of the nation has advanced, in proportion as monopolies have been discouraged. When companies do not trade upon a joint-stock, but are obliged to admit any person properly qualified, upon paying a certain fine, and

agreeing to submit to the regulations of the company, each member trading upon his own stock, and at his own risk, they are called *regulated companies*. When they trade upon a joint-stock, each member sharing in the common profit or loss in proportion to his share in this stock, they are called *joint-stock companies*. Such companies, whether regulated or joint-stock, sometimes have, and sometimes have not, exclusive privileges. Regulated companies resemble, in every respect, the corporations of trades, so common in the cities and towns of all the different countries of Europe; and are a sort of enlarged monopolies of the same kind. As no inhabitant of a town can exercise an incorporated trade, without first obtaining his freedom in the corporation; so in most cases no subject of the state can lawfully carry on any branch of foreign trade, for which a regulated company is established, without first becoming a member of that company. Of companies of this kind we have had, or still have, in Great Britain, the Hamburg company, the Russia company, the Eastland company, the Turkey company, and the African company. Regulated companies, as sir Joshua Child has observed, though they had frequently supported public ministers, had never maintained any forts or garrisons in the countries to which they traded; whereas joint-stock companies frequently had. And in reality, says Dr. Smith, (Wealth of Nations, vol. iii. p. 116.) the former seem to be much more unfit for this sort of service than the latter; partly, because the directors of a regulated company have no particular interest in the prosperity of the general trade of the country, for the sake of which such forts and garrisons are maintained; whereas the private interest of the directors of a joint-stock company, is connected with the prosperity of the general trade of the company, and with the maintenance of the forts and garrisons which are necessary for its defence; and partly, because the directors of the latter company have always the management of a large capital, the joint-stock of the company, a part of which they may frequently employ, with propriety, in building, repairing, and maintaining such necessary forts and garrisons; whilst

the directors of a regulated company, having the management of no common capital, have no other fund to employ in this way, but the casual revenue arising from the admission fines, and from the corporation duties imposed upon the trade of the company.

Joint-stock companies, established either by royal charter or by act of parliament, differ, in several respects, not only from regulated companies, but from private copartneries. 1st. In a private copartnership, no partner, without the consent of the company, can transfer his share to another person, or introduce a new member into the company. Each member, however, may, upon proper warning, withdraw from the copartnership, and demand payment of his share of the common stock. In a joint-stock company, on the contrary, no member can demand payment of his share from the company; but each member can, without their consent, transfer his share to another person, and thereby introduce a new member. 2dly. In a private copartnership, each partner is bound for the debts contracted by the company to the whole extent of his fortune; whereas, in a joint-stock company, each partner is bound only to the extent of his share. The trade of a joint-stock company is always managed by a court of directors, which is frequently subject, in a variety of respects, to the controul of a general court of proprietors; but these proprietors, being for the most part totally exempted from trouble and from risk, beyond a limited sum, receive contentedly such half-yearly or yearly dividends, as the directors think proper to assign; and many persons are encouraged to become adventurers in joint-stock companies, who would, upon no account, hazard their fortunes in any private copartnership. The directors of such companies being the managers rather of other people's money than of their own, it cannot well be expected, that they should watch over it with the same anxious vigilance with which the partners in a private copartnership frequently watch over their own. Negligence and profusion must always prevail, more or less, in the management of the affairs of such a company. It is upon this account that joint-stock companies for foreign trade have seldom been able to maintain the competition against private adventurers. They have, accordingly, very seldom succeeded without an exclusive privilege, and frequently have not succeeded with one. Without an exclusive privilege, they have commonly mismanaged the trade; with an exclusive privilege, they have both mismanaged and confined it. For other appropriate and just observations on this subject, in its reference to the African company, the Hudson's bay company, the South Sea company, and the East India company, see Smith's *Wealth of Nations*, vol. iii. chap. 1.

When a company of merchants undertake, at their own risk and expence, to establish a new trade with some remote and barbarous nation, it may not be unreasonable to incorporate them into a joint-stock company, and to grant them, in case of their success, a monopoly of the trade for a certain number of years. It is the ancient and most natural way in which the state can recompense them for hazarding a dangerous and expensive experiment, of which the public is afterwards to reap the benefit. A temporary monopoly of this kind may be vindicated upon the same principles upon which a like monopoly of a new machine is granted to its inventor, and that of a new book to its author. But upon the expiration of this term, the monopoly ought certainly to terminate; the forts and garrisons, if it was found necessary to establish any, to be taken into the hands of government, their value to be paid to the company, and the trade to be laid open to all the subjects of the state. Without a monopoly, however, a joint-stock company, as expe-

rience has shewn, cannot carry on any branch of foreign trade. An eminent French author, of great knowledge in matters of political economy, the abbé Morellet, gives a list of 55 joint-stock companies for foreign trade; which have been established in different parts of Europe since the year 1600, and which, according to him, have all failed from mismanagement, notwithstanding they had exclusive privileges. Although he has been misinformed with regard to the history of two or three of them, which were not joint-stock companies, and which have not failed; yet there have been several joint-stock companies, which have failed, and which he has omitted.

The only trades which it seems possible for a joint-stock company to carry on successfully without an exclusive privilege, are those, of which all the operations are capable of being reduced to what is called a routine, or to such a uniformity of method as admits of little or no variation. Of this kind is, first, the banking trade; secondly, the trade of insurance from fire, and from sea-risk and capture in time of war; thirdly, the trade of making and maintaining a navigable cut or canal; and fourthly, the similar trade of bringing water for the supply of a great city. To render the establishment of a joint-stock company perfectly reasonable, with the circumstance of being reducible to strict rule and method, two other circumstances ought to concur. First, it ought to appear with the clearest evidence, that the undertaking is of greater and more general utility than the greater part of common trades; and, secondly, that it requires a greater capital than can easily be collected into a private copartnership. In the four trades above-mentioned both these circumstances concur.

The joint-stock companies, says this judicious writer, which are established for the public spirited purpose of promoting some particular manufacture, over and above managing their own affairs ill, to the diminution of the general stock of the society, can, in other respects, scarce ever fail to do more harm than good. Notwithstanding the most upright intentions, the unavoidable partiality of their directors to particular branches of the manufacture, of which the undertakers mislead and impose upon them, is a real discouragement to the rest, and necessarily breaks, more or less, that natural proportion which would otherwise establish itself between judicious industry and profit, and which, to the general industry of the country, is of all encouragements, the greatest and the most effectual.

COMPANY, *African*; sometimes called "Royal African Company," the name of the original institution. The first commercial voyage from England to the coast of Guinea was in 1536, but nothing like a company was formed till the year 1583, when queen Elizabeth granted a patent for ten years to come, to some merchants of Exeter, and other persons for an exclusive trade to the rivers Senegal and Gambia. In 1618, king James I. granted a charter for establishing a joint-stock company; but separate traders continuing to resort to the coast, the company was soon dissolved. Another company was erected by charter in 1631, which met with little success; and in 1651, the parliament granted a charter for five years to the East India company, for trading to the Gold coast in their way to India. The demand for negroes in the West India and American plantations increasing considerably, another exclusive African or Guinea company was incorporated in 1662, at the head of which was the duke of York, joined with many persons of rank and distinction. This company, like those that had preceded it, was unsuccessful, and its charter was soon after revoked by consent of the parties associated in the enterprise, in consequence of which another exclusive company

was incorporated by letters patent in 1672. They raised a capital of 171,000*l.* and improved the trade considerably; but at the revolution the West India planters joined the separate traders in asserting that they were always best served with slaves when the trade was free to all persons; and exclusive companies, whose privileges had not been sanctioned by parliament, being considered inconsistent with the declaration of rights, the trade became open again; but all private traders were to pay 10 per cent. to the company, towards maintaining the forts and factories on the coast. This contribution was however found insufficient, and in 1750 parliament granted 10,000*l.* for the purpose, which was continued annually till 1744, when, in consequence of the war, 20,000*l.* was granted, and in almost every year since, a sum has been appropriated by parliament to this purpose.

As all the joint-stock companies which had been established for this trade had appeared incompetent to carry it on with advantage, it was in 1750 (23 Geo. II. c. 31.) transferred to a regulated company, the members of which are deemed a body corporate and politic, under the title of *The Company of Merchants trading to Africa*, but are prohibited from trading in their corporate capacity, from having any joint or transferable stock, and from borrowing money under their common seal. Any person intending to trade to Africa, may become free of this company on payment of forty shillings; and out of the monies thus received, a sum not exceeding 800*l.* is allowed for the salaries of clerks and agents at London, Bristol, and Liverpool, the house-rent of their office at London, and all other expences of management, commission, and agency in England. What remains of this sum, after defraying these different expences, they may divide among themselves, as compensation for their trouble, in what manner they think proper. The forts, factories, &c. possessed by the old company on the coast of Africa, are vested in the present company, who continue to receive an annual sum from parliament (generally about 13,000*l.*) for the support of these establishments: the sum granted in the year 1806 was 18,000*l.* For the proper application of this sum, the committee is obliged to account annually to the auditor baron of the exchequer, which account is afterwards to be laid before parliament.

The company is under the management of a committee of nine persons, three being chosen for London, three for Bristol, and three for Liverpool, annually. The committee are enjoined to lay an annual account of the application of the money granted to them before parliament.

Although by the 4th of Geo. III. c. 20. the fort of Senegal, with all its dependencies, had been vested in this company, yet in the year following (by the 5th of Geo. III. c. 44.) not only Senegal and its dependencies, but the whole coast from the port of Salee, in South Barbary, to cape Rouge, was exempted from the jurisdiction of that company, and vested in the crown; the trade to it being declared free to all his majesty's subjects.

Before the establishment of the Royal African company, there had been three other joint-stock companies successively erected one after another, for the African trade. They were all equally unsuccessful. They all, however, had exclusive charters, which, though not confirmed by act of parliament, were in those days supposed to convey a real exclusive privilege.

COMPANIES, English. The *East India Company* was established by charter dated Dec. 31, 1600, by which the earl of Cumberland and 215 other persons were authorized to carry on an exclusive trade to all parts of the East Indies, for 15 years; under the title of "The Governor and Company of Merchants of London trading to the East Indies." They

raised 72,000*l.* in shares of 50*l.* each, and fitted out five ships, which accomplished their first voyage very successfully, in two years and seven months.

Having carried on the trade for about ten years, with different degrees of success, they obtained another charter dated May 31, 1610, by which the company was made perpetual. They had not yet adopted the mode of trading under one joint stock, but carried it on in several partnerships and lesser stocks. In 1613 the proprietors of the several separate stocks, united them into one general joint-capital; and notwithstanding some opposition to their trade, both at home, and abroad, they preserved and extended it, having at this time established factories at about twenty different places in India. In a vindication of the East India Company before the privy council, at a subsequent period, among other remarks for shewing the great difficulties attending an East India trade, it was asserted, that although they had a stock of 1,500,000*l.* yet in fifteen years time $\frac{1}{2}$ of it from 1617 to 1632, their whole profit was no more than 12 and one-half per cent.

In 1637, Charles I. established a new company to trade to China and Japan, but it was soon ruined. The old company likewise from its differences with the Dutch East India company, the encroachments of private adventurers, and other causes, fell into decay, and in 1655 it was dissolved by Cromwell, and the trade laid open. The mischiefs which followed obliged him to re-establish the company about three years after; their joint-stock was now 739,782*l.* of which only one half, or 369,891*l.* was paid in, and was properly their capital. The total exports of the company in three years, ending with 1660, was 227,820*l.* in bullion, and 23,763*l.* in merchandize. After the restoration, they obtained a new charter from Charles II. dated April 3, 1661. By this charter it appears that the company had not then one sole transferable joint-stock; but that every one, who was free of this company paid a certain sum of money to the company on the fitting out of their fleet, for which he had credit in the company's books, and received his proportionate dividend on the profits of the respective voyage. The whole investments were made by the company in their corporate capacity; but they were not established as an irrevocable corporation, as they might be dissolved on three years notice.

In 1664, the company's stock sold at only 70 per cent., but in consequence of an inquiry into the state of their affairs, the result of which was very favourable, the stock soon got up considerably. New charters were granted in 1669 and 1676, confirming all their privileges. In the latter year, the company having made a considerable profit by their trade, agreed, instead of making a dividend thereof, to add it to their capital stock, so as just to double the same, by which their capital became 739,782*l.* 10*s.* In consequence of the extension and success of their trade, which enabled them to make large dividends, their stock in 1680 sold from 280 to 300 per cent; but these great profits, and the doubtful authority on which they held their exclusive privileges, (not having the sanction of parliament) being a great temptation to individual adventurers, interlopers, who had often given them much trouble, became again very numerous, and attempts were made to get the trade laid open, or to have it vested in a regulated company similar to those by which the trade with Turkey and with some other countries was then carried on. The company, however, in 1683 found means to obtain a new charter, by which all their former privileges were confirmed, and they were empowered to seize the ships and merchandize of all interlopers, to raise and maintain military forces, to exercise martial law, and

and to establish a court of judicature for determining all mercantile causes, within their limits. In 1686 they obtained another charter granting them still greater powers and privileges.

Soon after the revolution much popular clamour was raised against the East India company; and in 1691 the house of commons addressed the king to dissolve the company and incorporate a new one; an opportunity for which soon occurred, as in 1693, the charter of the company became void, from their not paying the duty which had been imposed on their stock within the time limited by the act; but a new charter was granted them, on condition of submitting to such regulations as should be obtained before the 29th of September 1694 and which were contained in two charters soon afterwards executed.

In 1698 the complaints of the weavers of London against the importation of India wrought silks, and the company having been prevented by losses from making any dividends for several years, brought it into much disrepute, and the house of commons thought it necessary to take the state of their affairs into consideration. The company thought it prudent to offer to advance 700,000*l.* for the public service at 4 per cent. interest, provided the exclusive trade was legally settled on them; but a number of merchants, countenanced by the chancellor of the exchequer, proposed to advance 2,000,000*l.* at 8 per cent. interest, for similar privileges. The latter proposal was approved, and an act passed by which a new company was established; many difficulties however appeared, with respect to their engaging in the trade, till the expiration of the three years notice for determining the old company. During this unsettled state of the East India trade, the old company's stock had in about nine or ten years fluctuated from 300 per cent. to only 37 per cent.

The great contentions which ensued between the old and new companies, soon rendered it obvious that little benefit would be derived from the trade, unless a coalition between the two rival corporations was effected. This was accomplished in 1702, by an agreement that the old company should purchase an equal proportion of stock in the new company, and that the separate traders, who had subscribed to the new company, but not to their joint-stock, should be included in the union. The old company was to keep their stock in the new company, in their corporate capacity for seven years, then to transfer it to their respective members, and resign their charter to the crown, from which time the new company comprehending the proprietors of both, assumed their present title of "The united Company of Merchants of England trading to the East Indies." In 1708 the term of their exclusive trade to India, which was determinable upon three years notice after 1711, and repayment of the sum they had advanced, was prolonged to three years notice after Lady-day 1726; for which they advanced to government 1,200,000 without any additional interest. In 1712 they obtained an act for continuing the trade and corporate capacity of the company, although the sums they had advanced to government should be repaid; which repayment or redemption of their annual fund, was not to be made till the expiration of three years notice after Lady-day 1733.

The act of parliament being liable to a different construction from what was probably intended, and the term granted being near its expiration, a very powerful opposition to its renewal, was raised in 1730, and specious proposals were made to parliament for redeeming the fund of the company, and transferring the trade to a regulated

company, with similar privileges. After a very full discussion of the subject, a new agreement was entered into with the company, who agreed to pay 200,000*l.* towards the service of the current year, and to have the interest payable to them by government reduced from 5 to 4 per cent.; in consideration of which all their exclusive privileges were continued till the expiration of three years notice, to be given after Lady-day 1746, when upon re-payment of their entire capital of 3,200,000*l.* their exclusive privileges were to cease, but the company to continue a corporation for ever, to enjoy the East India trade in common with all other subjects. In consequence of this reduction of the interest received from government, they thought proper to reduce the dividend payable to their proprietors from 8 to 7 per cent. and soon after to 6 per cent.

In 1743 the company proposed to advance 1,000,000*l.* for the service of the year 1744, at 3 per cent. interest, on having the term of their exclusive trade enlarged for fourteen years, and being permitted to borrow a million on bonds. This proposal being accepted, the debt from the public to the company became 4,200,000*l.*, and the exclusive trade was now extended to three years notice, to be given by parliament after Lady-day 1780, with the former provision, that, after such determination, the company should continue to have a common right with other subjects in the trade to India.

The company not subscribing to the reduction of interest proposed in 1749, the speaker of the house of commons was ordered to give them notice that the sum due from government would be paid off, unless they subscribed before May 30, 1750: with this it was deemed prudent to comply, but a condition was made, that in order to enable the company to reduce their bond debt, they should be empowered to raise money by the sale of 3 per cent. annuities, to the amount of the debt of government to the company. The annuities thus sold were known by the title of 3 per cent. India annuities, and were for many years payable at the India house, but are now consolidated with the 3 per cent. reduced bank annuities.

Hitherto the company had not aspired beyond their original character of merchants, and merely possessed factories at the principal ports to which they traded; these factories were, for the safety of their merchandize and the protection of their servants, converted into forts, which rendered it necessary to maintain a military establishment. Thus possessed of the means of offence as well as defence, they made considerable exertions to oppose the progress of the French in those parts; and as the two companies each endeavoured to procure the assistance of the neighbouring native princes, the field of interest and ambition became much enlarged. In 1751, the company sent a considerable military force into the province of Arcot to support the nabob against his rival, who was powerfully assisted by the French; in which contest they were engaged with little intermission for several years. In Bengal, the company had carried on their commercial intercourse without any connexion with territorial authority, till the death of the subah Ali-Verdi-Khan, in 1756. This prince had viewed their increasing opulence and power with great jealousy, and a short time before his death gave a remarkable charge to his successor, in which he cautioned him to keep in view the power of the European nations in his country, and to free himself from their influence as soon as possible. "The power of the English is great; reduce them first; the others will then give you little trouble. Suffer them not to have forts or soldiers; if you do, the country is theirs." In attempting to put

this advice into execution, Son-Rajah-Dowla was completely defeated by the company's forces, and the new subah of their appointment, besides paying to the company a very large sum for their losses and expences, ceded to them a considerable territory in the vicinity of Calcutta. On the coast of Coromandel, hostilities were carried on against the French settlements with unequal success, but ultimately to the advantage of the English, upon which the subah of the Deccan concluded a treaty with the company, and ceded to them the entire circar of Masulipatam. In 1760, the company's forces completely defeated those of France, and in the following year captured Pondicherry, the chief of the French settlements in India; since which events the power of France in India has been very insignificant.

Such was the commencement of the company's acquisitions of territory, which they have seized every subsequent opportunity of extending, till the sovereigns of India, whose protection they formerly courted, have sunk into the situation of their dependents, and hold their precarious dignities at the will and pleasure of a society of foreign traders.

The annual sales of the imports of the company for sixteen years preceding 1757, amounted on an average to about 2,055,000*l.*; and for the same period, the exported goods and stores amounted annually, at their prime cost, to 238,000*l.*; the bullion exported to 690,000*l.* per annum, and they paid in discharge of bills of exchange 190,000*l.* per annum.

Early in 1764, on the receipt of some unpleasant news from Bengal, India stock fell 14 per cent. The general administration of the company's affairs, both at home and abroad, became soon after the subject of much discussion; and on 29th August 1766, the court of directors received a notice from the secretaries of state, that an investigation would

take place in the next session of parliament. The administration laid claim to the territories which the company had acquired in India, with the revenue arising from them, as of right belonging to the crown; but as the company were very unwilling to have this new source of wealth taken out of their hands, a temporary agreement was made for two years, by which the company, in compensation for this claim, agreed to pay to government 400,000*l.* a year. In 1769, the agreement was renewed for five years, and the territorial acquisitions and revenues in India figured to the company for that term, with a stipulation that the company should be allowed to increase their dividend to 12½ per cent., but not to increase it more than one per cent. in one year.

They now became involved in a war with the famous Hyder Ally, in consequence of which, and of the misconduct of their servants in India, the concerns of the company, from the most flourishing situation, were brought into the greatest embarrassments. Select and secret committees of the house of commons were appointed to investigate the state of their affairs; and in 1773, it appeared, not only that they were unable to make the stipulated annual payment to government, but that it was necessary to assist them with a loan of 1,400,000*l.* Till this sum should be repaid, the dividend to their proprietors was not to exceed 6 per cent., and afterward not to exceed 7 per cent. till their bond debt was reduced to 1,500,000*l.* From these circumstances, the price of the company's stock fell considerably from the latter part of 1772 till February 1774, when their affairs began to wear a brighter aspect. In 1776, the loan from government had been repaid, and their situation being otherwise improved, the dividend on their stock was raised to 8 per cent.

Statement of the Company's Revenues, at their different Settlements in India, in the Year ending April 1777.

To expences in Bengal, civil, military, and fortifications	£ 1,350,000
To ditto at Fort St. George	560,000
To ditto at Bombay	360,000

	2,270,000
Nett balance of the year's revenues	1,770,000

	£ 4,040,000

By nett revenues in Bengal	£ 2,500,000
Benares tribute	250,000
Oude subsidy	370,000
By revenues of Fort St. George and the Circars	560,000
Tanjore subsidy	160,000
By revenues of Bombay, &c.	160,000

	£ 4,040,000

On an average of ten years, ending with 1777, the company's exports in goods were about 490,000*l.*; in bullion, 110,000*l.*; and the sum paid in discharge of bills of exchange, 458,000*l.* per annum. By the aid afforded from the revenues, their investments were increased, so as to produce about 3,300,000*l.* per annum.

In 1779, an act was passed for continuing the territories and revenues in India in the possession of the company for one year, which in 1780 was continued for another year. In June 1781, it was agreed to offer to pay into the exchequer 400,000*l.*, in full discharge of all claims of the public upon the company up to the 1st of March; and as, in the preceding year, they had received notice that the 4,200,000*l.* due to them from government would be paid off on the 10th of April, 1783, it became necessary to enter into a new agreement, the conditions of which were, that the company should continue to enjoy their exclusive privileges to the 1st of March, 1794, then to cease and determine, upon the former conditions of three years previous

notice, and the repayment of all sums due to them. The surplus of their nett profits, after paying their dividends, were appropriated, three fourths for the service of government, and one fourth to be retained by the company; and they were restricted not to increase the dividend of 8 per cent. more than 1 per cent. in any year. This restriction was, however, soon found unnecessary; for the nett profits of the company for the year ending 1st of March, 1782, did not amount to so much as a dividend of 8 per cent. on their stock by 22,023*l.*; in consequence of which, it became necessary for government to allow a farther time for the payment of 396,466*l.* 2*s.* 6*d.*, which was due from the company for customs, besides a part of the sum which they had agreed to pay in 1781; and they were at the same time empowered, notwithstanding the above deficiency, to continue their dividends at 8 per cent. In the following year, the war in India, and other circumstances, increased the embarrassment of the company's affairs; and, by a statement of their accounts to the 1st of March, 1783, it appeared that

the nett profits of that year did not amount to a dividend of 8 per cent. by 255,813*l.*, which dividend they were nevertheless authorized by parliament to continue; and, to enable them to do, government issued exchequer bills to the amount of 300,000*l.*, which the bank undertook to lend money upon to the company.

The long and expensive war in which the company had been engaged in India, terminated in March 1784, by the ratification of peace with the Mysorean government; but the consequence of this war, in addition to the war in Europe, was the general derangement of the company's affairs both at home and abroad. In December 1783, February and May 1784, the directors laid before parliament such accounts as they then possessed, respecting the general state of their finances. But the impossibility of drawing any satisfactory information from statements made up in such a situation of their affairs, with the apprehensions which the measures then in agitation, relative to the future government of India, had excited in the public mind, reduced the credit of the company to the lowest ebb. Their stock sold as low as 118½; their bonds at home, bearing 5 per cent. interest, were negotiated from 2½ to 4 per cent. discount; their bonds and certificates, at Bengal and Madras, bore from 18 to 40 per cent. discount; at Bombay 50 per cent.; and orders on the treasury there sold at 65, and upwards, per cent. discount.

It now became a general conviction, that the company was incompetent to the political government of the extensive territories which they had acquired. A Board of Control was therefore established, composed of a certain number of commissioners to be appointed by the king, and removable at his pleasure. This board was authorized to check, superintend, and control, the civil and military government and revenues of the company. The dispatches transmitted by the directors to the different presidencies were to be previously subjected to the inspection of the Board. The appointment of governor-general, president, or counsellor in the different presidencies, was made subject to the approbation and recall of his majesty; and such other regulations adopted, as in a great measure deprived the company of that political and civil authority which they had hitherto been so grossly abused.

In 1786 some further regulations were made respecting the government of India; and, as the company's trade was increasing, particularly in the article of tea, their import of which had been greatly augmented by the arrangement of the commutation act, they were said to require a greater capital, and were authorized to create 800,000*l.* new stock, on which they raised 1,240,000*l.* at the rate of 155 per cent. In 1789 they obtained another act, enabling them to add 1,000,000*l.* to their capital, which thus became 5,000,000*l.*

In the beginning of 1793, the term of the company's exclusive privileges being nearly expired, the subject of laying open the trade to India was again discussed, and though it was not thought proper to risk the loss and confusion which must unavoidably attend any attempt to take such an immense concern out of the hands in which it has so long continued, a stipulation was made in the agreement for the renewal of the charter, that such regulations should be adopted as to admit of a free exportation by private persons on their own account, of any goods of the growth, produce, or manufacture of Great Britain or Ireland; and of a free importation of such sorts of the raw materials of the East Indies as are used in the manufactures of Great Britain or Ireland; that the company should be obliged to provide shipping for the carriage of the private trade, at as low a

freight as it could be furnished by private merchants; and that they should license a proper number of agents to reside at the company's settlements, under their protection, for the management of the private trade. On these conditions the company's term in the exclusive trade was enlarged for 20 years, or to the 1st of March, 1814, with the former proviso, that if, after the expiration of that term, their right to the sole trade shall cease, in consequence of three years previous notice being given by parliament, and the repayment of such sums as may be then due from the public, they shall continue a corporation, with power to carry on a free trade in common with other persons.

On this occasion, the total income of the company, arising both from their territorial revenues and their commercial concerns, was stated as follows:

The nett annual income in rents and profits of trade, taken in the most unfavourable light to the company, and supposed to be considerably under the mark, was rated at	£ 2,329,164
Subject to the following payments, viz.	
Interest of 3,200,000 <i>l.</i> on bond, at 4 per cent.	£ 128,000
Ditto of 6,669,082 <i>l.</i> debt in India, at various rates of interest, on a medium about 8½ per cent.	561,923
Dividend of 8 per cent. on their capital of 5,000,000 <i>l.</i>	400,000
	1,089,923
Leaving a nett annual surplus of	£ 1,239,241

Of this surplus it was proposed to appropriate 500,000*l.* per ann. to the reduction of the debt in India, to pay 500,000*l.* per annum to government in half-yearly payments; and to pay an increased dividend of 10 per cent. to their proprietors at 6,000,000*l.* to which sum their capital was now raised.

This annual surplus, if it really existed at the time to which the above account refers, was of very short duration. In 1795 the company found themselves unable to continue the proposed contribution to government; and the intrigues of Tippoo Sab with the French, and with some of the native powers, which obliged the company to keep up a large military establishment, and soon after to engage in another expensive war, not only reduced the surplus of their revenues, but occasioned a considerable increase of debt in India, which has since been further augmented in consequence of hostilities with Dowlut Rao Scindia and Jeswunt Rao Holkar.

In order to furnish some idea of the extent of the company's commercial and financial concerns, the following accounts are subjoined.

The amount of all goods sold at the East India Company's sales, from the 1st of March 1805 to the 1st of March 1806,

The vast concerns of this company are under the management of twenty-four directors, who are formed into different committees; each committee having the superintendance of a particular department of the company's business. At the general courts of proprietors, persons possessing 1000l. stock have one vote; 3000l. two votes; 6000l. three votes; and 10,000l. four votes. The number of proprietors entitled to vote, on the 8th of April 1800, was 2163, and the number of votes 2832.

COMPANY, *Hamburg*, is the oldest trading establishment in the kingdom; though not always known by that name, nor restrained to those narrow bounds under which it was afterwards confined. It was first called, the Company of Merchants trading to Calais, Holland, Zealand, Brabant, and Flanders: then it acquired the general title of Merchant-adventurers of England; as being composed of all the English merchants who traded to the Low Countries, the Baltic, and the German ocean. Lastly, it was called the Company of Merchant-adventurers of England trading to Hamburg.

This company was not a society of dealers, each furnishing a part of the sum to constitute the capital stock of the company; but a mere association, or body of merchants, who had nothing in common, but the grant and privilege of trading to Hamburg, and some other cities of Germany; each managing his own commerce, and trading on his own foundation; only observing a certain discipline, and some regulations, which none but the company could establish or change.

This company was first incorporated by Ed. I. in 1206; and established again, by charter, in 1406, under the reign of Henry IV. It was afterwards confirmed and augmented with divers privileges, by many of his successors; among the rest, by Henry V. in 1413; Henry VI. in 1422; Henry VII. in 1493, 1505; and 1506; Henry VIII. in 1509, 1517, and 1536; Edward VI. in 1547; queen Mary, in 1553; Elizabeth, in 1564, and 1586; James I. in 1603; and Charles II. in 1661. But of all these charters, none but those of Henry IV. Henry VII. Elizabeth, James, and Charles, were of any importance, or gave the company any thing new; the rest being only confirmations. Before the charter of Henry IV. all the English merchants, who trafficked out of the realm, were left to their own discretion, and managed their affairs with foreigners as might be most for their respective interests; without any regard to the general commerce of the nation.

Henry observing this disorder, endeavoured to remedy it, by uniting all the merchants in his dominions into one body; wherein, without losing the liberty of trading each for himself, they might be governed by a company; and be subject to regulations, which should secure the general interest of the national commerce, without prejudice to the interest of particulars. With this view, he granted all the merchants, of his states, particularly those of Calais, then in his hands, a power of associating themselves into a body politic, with directors;

directors and governors, both in England and abroad; to hold assemblies both for the direction of business and the deciding of controversies among merchants; make laws, punish delinquents; and impose moderate duties and taxes on merchandizes and merchants to be employed in the service of the corporation.

These few articles of the charter of Henry IV. were afterwards much augmented by Henry VII. who first gave them the title of Merchant-adventurers to Calais, Holland, &c. gave them a power of proclaiming and continuing free fairs at Calais; and ordered, that to be reputed a member of the society, each person should pay twenty marks sterling; and that the several members should attend the general meetings, or courts, appointed by the directors, whether at London, Calais; or elsewhere.

The inexecution of this last article and contempt of some of the rest, occasioning great inconveniences to the company's affairs, another charter was procured, whereby the pain of imprisonment was menaced, for those who should absent themselves from the meetings without lawful cause, or should disobey the laws. A petition being made to queen Elizabeth, in 1564, for an explanation of certain articles in the charter of Henry VII. and a confirmation of the rest granted by other kings; that prince, by a charter of the same year, declares, that to end all disputes, they should be incorporated anew under the title of the "Company of Merchant-adventurers of England;" that all who are members of the former company should, if they desire it, be admitted members of this; that they should have a common seal; that they should admit into their society what other persons, and on what terms, they please; and expel them again on misbehaviour; that the city of Hamburg, and neighbouring cities, should be reputed within their grant, together with those of the Low Countries, &c. in that of the former company; that no member should marry out of the kingdom, nor purchase lands, &c. in any city beyond sea; and that those who do, shall be *ipso facto* excluded for ever.

Twenty-two years after this first charter, queen Elizabeth granted them a second; confirming the former, and further granting them a privilege of exclusion, with a power of erecting in each city within their grant, a standing council.

The woollen manufacture being the principal object of their application, they met with great opposition; first, from the Hanse, who forced them frequently to change their mart, or staple; and afterwards under king James I. who having erected a corporation in 1616, in favour of some private persons, who offered to set up a manufacture for dyeing and pressing cloths, &c. under pretence thereof the company of merchant-adventurers were prohibited dealing therein. But that project not succeeding, and the charter being revoked two years afterwards, the merchant-adventurers, whose company had been dissolved two years before, were restored in 1617, to their ancient privileges, and a new charter was given them, confirming their exclusive rights; and allowing them to have officers in the several custom-houses, to have an eye that they were not prejudiced in their woollens, under pretence of the like merchandizes, which others were allowed to send to other parts. This charter of king James, is the last of those confirmed by Charles II. in the grand charter of 1661.

The revolutions which had happened in the Low Countries towards the end of the sixteenth century, and which laid the foundation of the republic of Holland, having hindered the company from continuing their commerce with their ancient freedom; it was obliged to turn it almost wholly to the side of Hamburg, and the cities on the

German ocean; from which change some people took occasion to change its name to that of the Hamburgh company, though the ancient title of Merchant-adventurers is still retained in all their writings.

This society was greatly reduced, when its trade was laid open by William III. and the company is now extinct.

COMPANY of *Merchants of the Staple* was incorporated by Edward III. Their factory was at Middleburgh, in Zealand; but the staple being removed, in 1389, to Calais, it was soon after, *viz.* in 1399, removed from thence to England.

COMPANY, *Russia*. This was first projected towards the end of the reign of king Edward VI. executed in the first and second years of Philip and Mary; but had not its perfection, till its charter was confirmed by act of parliament, under queen Elizabeth, in 1566. It had its rise from certain adventurers, who were sent in three vessels on the discovery of new countries; and to find out a north-east passage to China; these, falling into the White sea, and making up to the port of Archangel, were exceedingly well received by the Muscovites; and at their return, solicited letters patent to secure to themselves the commerce of Russia, for which they had formed an association.

The charter was promised them by Edward VI. but he dying, was first dispatched by queen Mary, in 1555. By this charter, the association was declared a body politic, under the name of the "Company of Merchant-adventurers of England, for the discovery of lands, territories, islands, &c. unknown or unfrequented." Their privileges were, to have a governor, four consuls, and twenty-four assistants, for their commerce; for their policy, to make laws, inflict penalties, send out ships to make discoveries, take possession of them in the king's name, set up the banner royal of England, plant them; and lastly, the exclusive privilege of trading to Archangel, and other ports of Muscovy, not yet frequented by the English.

This charter, not being sufficiently guarded, was confirmed by parliament in the eighth year of queen Elizabeth; wherein it was enacted, that in regard the former name was too long, they should now be called "Company of English Merchants for discovering new trades;" under which name, they should be capable of acquiring and holding all kinds of lands, manors, rents, &c. not exceeding a hundred marks per ann. and not held of her majesty; that no part of the continent, island, harbour, &c. not known nor frequented before the first enterprise of the merchants of their company, situate to the north, or north-west, or north-east of London; nor any part of the continents, islands, &c. under the obedience of the emperor of Russia, or in the countries of Armenia, Media, Hyrcania, Persia, or the Caspian sea, should be visited by any subjects of England, to exercise any commerce without the consent of the said company, on pain of confiscation. The said company shall use no ships in her new commerce, but those of the nation; nor transport any cloths, ferges, or other woollen stuffs, till they have been dyed and pressed. That in case the company discontinue of itself to unload commodities in the roid of the abbey of St. Nicolas, in Russia, or some other port, on the north coasts of Russia, for the space of three years, the other subjects of England shall be allowed to traffic to Narva, while the said company discontinues its commerce into Russia, only using English vessels.

This company subsided with reputation almost a whole century, till the time of the civil wars. It is said, the czar then reigning hearing of the murder of king Charles I. ordered all the English in his states to be expelled; which the Dutch taking the advantage of, settled in their room

After,

After the restoration, the remains of the company re-established part of their commerce at Archangel, but never with the same success as before; the Russians being now well accustomed to the Dutch merchants, and merchandize.

This company fulfils Bill, nearly on the foot of that of Hamburg, and the northern and Turkey companies; i. e. each member thereof trafficks for himself, and on his own foundation; only paying an acknowledgement as fine for admission, which was reduced by 10 and 11 W. III. c. 6, to five pounds; besides some other dues imposed, from time to time, for the occasions of the company, and the commerce in general. It is under the direction of a governor, four consuls, and assistants.

COMPANY, *English*, is established on similar ground with that of Hamburg; from whence it appears to have been dismembered.

Its charter is dated in the year 1579. By the first article the company is erected into a body politic, under the title of the "Company of Merchants of the East;" to consist of Englishmen, all real merchants, who have exercised the business thereof, and trafficked through the Sound, before the year 1568, into Norway, Sweden, Poland, Livonia, Prussia, Pomerania, &c. as also Revel, Koningberg, Dantzick, Copenhagen, &c. excepting Narva, Muiucovy, and its dependencies. Most of the following articles grant them the usual prerogatives, of such companies; as a seal, governor, courts, laws, &c.

The privileges peculiar to this company are, that none shall be admitted a member who is already a member of any other company; nor any retail dealer at all. That no merchant qualified, be admitted without paying 6*l.* 13*s.* 6*d.* By 29 C. II. c. 7, the fee of admission into this company was reduced to 2*l.* That a member of another company, desiring to renounce the privileges thereof, and to be received into that of the East, shall be admitted *gratis*; provided he procures the same favour for a merchant of the East, willing to fill his place. That the merchant adventurers who never dealt in the East, in the places expressed in the charters, may be received as members of the company on paying forty marks; that, notwithstanding this union of the adventurers of England with the company of the East, each shall retain its rights and privileges. That they shall export no cloths but what are dyed and pressed, except a hundred pieces per annum, which are allowed them *gratis*.

This charter was confirmed by Charles I. in 1629, with this addition; that no person of what quality soever, living in London, should be admitted a member, unless he were free of the city.

This company was complained of as a monopoly, and first curtailed by legal authority in 1672; and since the declaration of rights in 1689, exists only in name; but they still continue to elect their annual officers, who are a governor, deputy, and twenty-four assistants.

COMPANY, *Turkey, or Levant*. This once flourishing body had its rise under queen Elizabeth, who, in 1581, incorporated a small number of merchants, with the privilege of an exclusive trade to Turkey for seven years. James I. in 1605, confirmed their charter, with the addition of some new privileges. During the civil wars some innovations were made in the government of the company; many persons having been admitted members, not qualified according to the charter, or who did not conform to the regulations prescribed, in consequence of which Charles II., upon his restoration, endeavoured to place it upon its ancient basis, for which purpose he gave them a new charter, containing a confirmation of the old one with some additional

articles. By this charter the company was declared to be a body politic, capable of making laws, &c. under the title of "The Company of Merchants of England trading to the Seas of the Levant." The number of members was not limited, but no person residing within twenty miles of London, excepting noblemen and gentlemen of quality, was to be admitted into the company, unless first made free of the city of London: those under 26 years of age were to pay 25*l.* for their admission, and those above that age 50*l.* These fines were reduced by an act passed in 1753. (26 G. O. II. c. 18) by which it is directed that every subject of Great Britain desiring admission into the Turkey company, shall be admitted within thirty days after such request, and shall enjoy all the liberties and privileges of the company, on paying for such admission the sum of 20*l.*

All persons free of the company may, separately or jointly, export any goods or merchandize (not prohibited) from any place in Great Britain, to any place within the limits of the company's charter, in British or plantation built ships, navigated according to law, at any time, and to any persons whomsoever, being free of the company, or to the sons or apprentices of freemen so long as they shall remain under, and submit to, the direction of the British ambassador and consuls for the time being; and may also import, in like manner, any commodities purchased within the company's limits, on payment of the government duties, and such impositions as shall be assessed upon all merchandize so exported or imported, or upon ships laden therewith, for defraying the necessary expences of the company.

The company is under the management of a governor, a deputy governor, and fifteen directors; they have also a deputy governor in every city and port where there are any members of the company. They present the ambassador which the king is to keep at the Porte, and elect two consuls for Smyrna and Constantinople; allowing a fixed salary or pension to the ambassador and consul, and even to their chief officers, as secretary, chaplain, interpreters, and janizaries, that they may not have any pretence for raising any sum whatever on the merchants or merchandize. For defraying these charges the company have power to levy duties on the merchandize imported or exported by their members; but of late years they have frequently found it necessary to apply to parliament for pecuniary assistance.

The commerce of this company was formerly very considerable, having been estimated nearly equal to that of the East India company in extent, and much more advantageous to Great Britain; but the convenient situation of the French ports in the Mediterranean for the Levant trade, gives that country such a decided advantage, that the commerce of Great Britain with Turkey has long been on the decline. In 1797, in order to avoid the hazard to which British vessels in the Levant trade were exposed in consequence of the war, an act was passed giving permission to the members of the Turkey company to import the goods usually brought from Turkey, Egypt, or other parts of the Turkish dominions in the Levant seas, from any port whatsoever, either in British vessels or vessels belonging to any friendly nation, on paying, if in British vessels, the same duties which would have been payable if the goods had been imported directly from the place of their growth, and, if in foreign vessels, the duties to which they were before liable; but no entry of such goods was to be made at the custom house till the importer produced a certificate of his being a member of the Turkey company, and that he had paid the company's duties, and in all respects conformed to the company's regulations.

COMPANY, *South Sea*, originated in a project for relieving the government from the embarrassment of a large amount of unfunded debts, and considerable deficiencies in the funds appropriated for the payment of others; the proprietors of these debts being incorporated for the ostensible purpose of establishing a trade to the south seas and the N.W. coast of America. The capital of the company was 9,177,967*l.* 15*s.* 4*d.*; but this being subscribed wholly in government securities, they issued bonds in 1712, for raising 200,000*l.* in cash in order to fit out their first mercantile adventure. In the following year, they obtained the *Assiento* contract, by which they agreed to import into the Spanish West Indies 144,000 negroes, within the term of 30 years, at the rate of 4800 in each year, and were allowed to send a ship of 500 tons yearly to trade with the Spanish settlements, on condition that the king of Spain should have a fourth part of the gain by such ship, and receive five per cent. on the net gain of the other three parts. See *ASSIENTO*.

The first voyage of their annual ship was in 1717, and the company were again empowered to borrow money under their common seal, for carrying on their trade, or to enable them to fulfil an engagement with government to advance two millions towards carrying into execution a proposed reduction of interest on the public debts. On the war breaking out in the following year, a stop was put to their trade with the Spanish West Indies, by the seizure of their effects, by which they sustained a very considerable loss.

Soon after this interruption of their commercial concerns, they engaged in a scheme for converting some of the government terminable annuities into redeemable debts. They had, in 1715, for the accommodation of government, agreed to increase their capital to 10,000,000*l.*, which, by the annuities now purchased, and an advance to government, became 11,746,844*l.* 8*s.* 10*d.*; and although the scheme did not completely succeed, it prepared the way for the much more extensive project of taking in all the public debts, and thus reducing all the public funds which then existed into one.

The mere rumour of this mercantile project raised the price of the company's stock to 126 per cent.; and, in the beginning of 1720, while the bill for carrying it into execution was depending in parliament, their stock got up from 177 to 319 per cent. As the transaction consisted merely in taking the public debts at a fixed price, and giving the proprietors, in exchange, a certain quantity of the company's capital stock, at prices agreed upon between the company and the subscribers, it is evident that the great gain which the company expected to make, could arise only from the current price of their stock being considerably above its real value. By a variety of artifices, and a general stock-jobbing infatuation, it was carried up to the enormous price of 1000 per cent.; the rapidity of its fall, however, exceeded that by which it rose, as it was in a few weeks down to 130 per cent.; involving in ruin persons of all descriptions who were engaged in the wild speculations of the time. (See *BUBBLE*.) Had the transaction completely succeeded, the capital of the company would have amounted to 43,411,399*l.* 6*s.* 11*d.*, but from some of the debts remaining unsubscribed, it became 37,802,487*l.* 14*s.* 0*d.* of which four millions were purchased in 1722 by the bank, and in the following year the remainder was divided into two equal parts, one of which was to be called the trading capital of the company, and the other to be distinguished by the title of "The joint-stock of South Sea annuities," since called old South Sea annuities.

In 1724, the company undertook the Greenland whale

fishery, which turned out very unprofitable: after eight voyages, they sold their ships, stores, and utensils, and found that their whole loss upon this business, capital and interest included, amounted to 237,142*l.* 6*s.* 2*d.*

In 1733, three fourths of their trading capital, which had been reduced by sums paid off in 1727, 1729, and 1732, to 14,651,103*l.* 8*s.* 1*d.*, was converted into an annuity stock called "New South Sea Annuities;" only one fourth remaining as their trading stock; and, in the following year, they petitioned the king to be allowed to dispose of the trade and tonnage of their annual ship under the *Assiento* contract, on account of the little profit they made by it, and to accept of such equivalent as they could obtain from the king of Spain, who at length, to put an end to the many disputes which had arisen from this contract, agreed, in 1750, to pay 100,000*l.* to the company, as a compensation for all claims under the *Assiento* contract, and from that period they have not carried on any trade whatever. The whole business of the company, therefore, now consists in the management of the following public funds.

Their capital stock	-	-	£ 3,662,784	8	6
Old South Sea annuities	-	-	11,907,470	2	7
New South Sea annuities	-	-	8,491,830	2	10
Three per cents., 1751	-	-	1,919,600	0	0

The interest received from government on all these funds, is 3 per cent., but the dividend paid to the proprietors of the company's stock, is 3½ per cent.; on the old and new annuities, 3 per cent.

The company is under the management of three governors, and 24 directors; the qualification required for governor, is the possession of 5000*l.* in the company's stock; for sub-governor, 4000*l.*; for deputy-governor, 3000*l.*; and for a director, 2000*l.* Five hundred pounds stock, gives a right to one vote at the general courts; 2000*l.* to two votes; 3000*l.* to three votes; and 5000*l.* to four votes.

COMPANY, *Scotch Darien*. This was established with good prospect at Edinburgh, in 1695, for the commerce of South America. In 1698, they sent an armament and a colony, which they endeavoured to establish in the isthmus of Darien, which parts North and South America; but the English ministry not thinking proper to avow and support the first successes of the company, which had alarmed Spain, ever jealous of this part of her territories, the Scotch colony was dispersed by the Spaniards in 1699, and thus vanished the best project that ever was formed for disputing with that nation the possession of those countries, from which she pretends to exclude all other nations.

COMPANY, *Hudson's Bay*, was incorporated by charter, dated the 2d of May, 1670, under the title of "The Governor and Company of Adventurers of England, trading into Hudson's Bay," with the exclusive privilege of trading to all parts within the entrance of the freight commonly called Hudson's freights. The charter, however, not being confirmed by act of parliament, the company possess no exclusive rights whatever, any British subject being at liberty to sail into Hudson's Bay, to fish or traffick with the Indians as freely as the company; all the advantage the company have over other adventurers thither is merely the benefit of their own forts, such as they are, by which their agents can reside in inhospitable a country during the winter, preparatory to their trading with the Indians against the arrival of their ships in the summer. According to the evidence given before a committee of the house of commons in 1749, the company then possessed four small factories, erected at the mouths of the principal rivers, in which they employed about 130 persons

fors, and two small houses with only eight men in each; these buildings are necessarily strong, as well to guard against the climate as against other dangers, and are furnished with artillery to command respect from the Indians; they have therefore been generally called forts, although no military force is kept for defending them: their utility in resisting any serious attack, was obvious in 1782, when the French, who at former periods had done the company much injury, destroyed their settlements, forts, merchandize, &c. to the estimated amount of near 500,000*l*.

The capital of the company, it is said, does not exceed 110,000*l*. which is divided among a very small number of proprietors. The commerce carried on by them is not of great extent, as it seldom employs above four or five ships of about 300 tons each. The articles exported by them are coarse duflle cloth or blanketing, guns, pistols, sword blades, hatchets, powder and shot, spirits, tobacco, brass kettles, buttons, fish hooks, looking glasses, &c.; the imports consist of large quantities of beaver skins, and peltry of all kinds, bed feathers, quills, castoreum, walruskins, oil, and a few smaller articles.

The company is under the management of a governor, deputy governor, and a committee of seven members.

COMPANY, *Sierra Leone*, was set on foot in the year 1791, with the philanthropic view of introducing civilization into Africa. The principal means proposed for effecting this end was the establishment of a secure factory for carrying on an extensive commercial intercourse with the interior; but before the arrangements for this purpose were completed, the reception into the settlement of near 1,000 blacks, who had taken part with Great Britain in the American war, and had petitioned the government to be removed from Nova Scotia on account of the coldness of the climate, involved the company in considerable difficulties, and gave a new character to the undertaking. Their expences, from various causes, became much greater than could have been foreseen, amounting in the first two years and a half to 111,500*l*. and were still further increased in 1793 by the war, which at the same time greatly interrupted their trade, and subjected them to depredations. In October 1794, the colony was attacked by a French Squadron, and all the moveable property of the company was either carried off or destroyed, every building belonging to them burnt, and several ships captured. The company's loss on this occasion has been estimated at 52,000*l*. This calamity, combined with their previous expences, so greatly diminished the company's funds, as to lay them under a necessity of contracting their trade, and reducing considerably the scale of their establishment, which had been at all times so limited as scarcely to afford sufficient means of transacting the business and attending to the various wants of an infant settlement.

In the year 1798 the colony had made considerable progress, notwithstanding the many obstacles to its advancement. The town consisted of about three hundred houses, with the necessary public buildings, and had become a place of considerable resort. It was estimated that from one to two hundred natives visited the settlement every day, many of them coming from a distance of eighty or a hundred miles, for the purpose of exchanging articles of African produce, for British manufactures. The total number of inhabitants of the colony at this time was about 1200.

In 1800 the company obtained a charter, creating their settlement an independent colony, and authorizing the directors to frame laws for its government, to appoint a governor and council, and to make other arrangements for the administration of justice; a small military force was at

the same time sent for the defence of the colony. The sum of 7000*l*. being part of the sum granted by parliament for the maintenance of African forts, was paid to the company for the erection of a fort; 10,000*l*. was about the same time received from government as a partial indemnification for the expence to which the company had been put in settling the Nova Scotians; 4000*l*. was also granted for the support of the civil government of the colony. About this time the company agreed to receive in their colony the Maroon Indians, and soon after their arrival, employed them to quell an insurrection among the Nova Scotians, who had endeavoured to possess themselves of the government. A more serious attack on the colony was afterward made by some of the native chiefs in the neighbourhood, which rendered it necessary to adopt additional means of defence.

The sums since granted by parliament for defraying the charges of the civil establishment of the company, and for the erection of fortifications, have been as follow:

For the year	1801	£	4,000
	1802		10,000
	1803		14,000
	1804		14,000
	1805		14,000
	1806		18,000

The trade of the company appears to have been successful, supposing it to have been burthened only with those charges which are strictly commercial, and to have been exempt from the extraordinary losses by fire, and the destruction of the settlement which it has had to sustain. The abolition of the slave trade will remove some great obstacles to the success of this laudable undertaking, and probably enable it to improve and extend its commercial intercourse with the natives very considerably.

COMPANY, *for the Manufacture of Flour, Meal, and Bread*. During the distress occasioned by the great scarcity of corn, in the year 1800, a number of persons formed themselves into a company, for the purpose of establishing in London a manufactory of flour, meal, and bread, to be sold out at reasonable prices. They were incorporated by parliament, and empowered to subscribe a joint capital, not exceeding 120,000*l*. in shares of 25*l*. each; their profits being limited to 10 per cent., and the surplus, if any, to be at the disposal of parliament. They were limited to sell only 120,000 sacks of flour, or meal in a year, to make only 200 sacks into bread in a week, and to sell not more than 1000 quarters of wheat in any one week. The managers of the company were prohibited from dealing in corn, flour, or bread, for their own private account; and were required to lay before parliament an annual statement of their receipts and payments, of the quantities of grain purchased, with the prices paid for the same, of the quantities of grain and flour in store, of the quantities of flour and bread manufactured by the company, and of the debts and credits of the company, with the names of all the members of it, and the number of shares held by each. By these regulations sufficient publicity is given to the concerns of the company to prevent it from ever being perverted from the original principle of the establishment, and made subservient to schemes of monopoly or speculation; and though upon the scarcity ceasing, they discontinued making bread, they have carried on the manufacture of flour and meal, and probably contributed to prevent these essential articles from being unnecessarily enhanced in price.

The total quantity of wheat purchased by the company in the year 1806, was 9182 quarters, for which they paid 32,657*l.* 19*s.*; the quantity of flour manufactured was 10,536 sacks. The number of proprietors of the company was 330.

The king by an order in council may dissolve this company on six months previous notice being given.

COMPANY, *Dock.* See *DOCK.*

COMPANY, *Dutch East India*, had its rise in the midst of the struggle which that people had for their liberty; and the Spaniards having forbid all commerce with them, and shut up all their ports, necessity inspired some Zealanders to seek a new north-east passage to China.

This enterprise proving unsuccessful to three several armaments in 1594, 1595, and 1596, a second company was formed under the name of the "Company of remote Parts;" which, in 1595, took the ordinary route of the Portuguese to the Indies, and returned in two years and a half's time, with little gain, but good hopes.

This company, and a new one just established at Amsterdam, being united, equipped other fleets; and these occasioned other companies at Amsterdam, Rotterdam, in Zealand, &c. inasmuch that the states soon began to apprehend they might be prejudicial to each other. Under this concern they called all the directors of the several companies together, who all consented to the union, the treaty whereof was confirmed by the states in 1602, a very remarkable epocha, as being that of the most solid and celebrated establishment of commerce that ever was in the world.

At this time they obtained a charter from the states; and prevailed upon that body, by administering to its exigencies in the Spanish war, to grant them the exclusive privilege of trading to the southern parts of Africa, for a short term of years. The company's capital of 6,500,000 florins (about 541,833*l.* sterling) was divided into transferable shares, or *actions*, as they are called on the continent, of 300 florins (about 250*l.* sterling each), which were all speedily bought up. The superiority of their trading capital, together with their greater skill in commerce and navigation, enabled them to undersell all other nations, even in the foreign markets of Europe. As they also fixed the prices of their merchandize to all consumers, their profits for some years were enormous. The annual dividends for the 6 years ending in 1610 were as high as 36 per cent.; and in a short time, the *actions* rose from 3000 to 15,000, and at one time stood as high as 24,000 florins, 8 times the amount of their prime cost. The charter, first granted in 1602, and since renewed from time to time, conferred upon them, besides the exclusive right of trading to the East, the sovereignty (under the superintendance of the states-general) of all the territories which they might acquire in that part of the world, by purchase, treaty, or conquest, with the full power of appointing their own servants; of raising whatever force they might deem necessary for the defence of their territories; and of enacting laws for the internal administration of their dominions. In consequence of this charter, the most extensive that was ever granted to any trading corporation, the company proceeded to arrange their establishment, both in Europe and the East Indies. Their affairs were under the management of sixty directors, divided into several chambers; twenty in that of Amsterdam, twelve in that of Zealand, fourteen in that of Delft and Rotterdam, and a like number in those at Sluys and Hoin. As each grant expired the company was obliged to procure a new one, which it has already done, four times since the

first; *viz.* one in 1623, for forty-one years, like the first; another for twenty-one years, commencing in 1643; and a third in 1665, for forty years; a fourth in advance, commencing in 1698, to end in 1740. Each grant cost the company a considerable sum; that of 1647 cost 1,600,000 guilders, and the two following ones more; that of 1698 was confirmed by a placard of the states-general, granted them an exclusive privilege, which was prolonged in 1761, for thirty years more. The average premium paid for these renewals was about 270,000*l.* sterling, or three millions of florins.

Their factories, residences, &c. in the East Indies, were very numerous; reaching from the Persian gulf to the coast of China: the principal was that of Batavia, the centre of their commerce: here resided the general, with the state and splendor of a sovereign prince; making war and peace with the eastern kings and emperors at pleasure. They had also several other considerable factories on the coast of China, in Japan, Malacca, Surat, Amboyna, Banda, Siam, Moluccas, &c. several on the coast of Coromandel, and at Ispahan, Cape of Good Hope, &c. in all, they numbered forty factories, and twenty-five fortresses. They engrossed the whole trade of the spicery in their own hands.

At so early a period as the year 1616, this company had no less than 45 large vessels engaged in war and trade, with 10,000 soldiers and sailors in their service, and 4,000 pieces of artillery. However, the flourishing state of their affairs was of short duration. The mismanagement and plunder of the company's servants, and the disputes in which their cruelties, avarice, and imprudence involved them with the native powers during the 17th century, and the dissensions which arose among the different chambers of the general direction at home, greatly reduced the trade, wealth, and power of the institution. The expence of the military establishment also increased; so that at the end of the 18th century, it amounted to 80 vessels, carrying from 30 to 60 guns, and 25,000 men, soldiers included, while the whole dominions in Java, and its dependencies, were farmed for 361,260 dollars. The directors acknowledged that, in 1780, their loss in the war had exceeded 10 millions of florins, nearly twice the amount of their original capital. In the 18th century the Ostend East India company excited the jealousy of the Dutch company. In 1721, a law was passed by the states, prohibiting their subjects from sailing under the Ostend colours, upon pain of death: and in 1731, this unfortunate association was dissolved in consequence of representations from the different European states interested in the East Indian trade; among which Holland, that is the Dutch company, took the lead. Various precautions have been used to support the credit of this company, some of which were oppressive to the country; nevertheless, its shares have continued to fall with augmented rapidity. In the period from 1605 to 1779, the dividends have varied from 75 to 10 per cent.; and in many years no dividend at all was issued. From 1605 to 1610 (both inclusive), the dividend was, at an average, 36 per cent. From 1610 to 1643, the average was only 21; and from 1771 to 1780, it was no more than 12½ per cent. The price of the *actions*, which had at first risen to 500, and even 800 per cent. of the prime cost, fell, in the period from 1770 to 1780, to about 340 per cent., and during that time continued regularly to fall. The last dividend this once flourishing company made to their proprietors was in the year 1796; but it was not paid till 1799, as their commerce, which had been rapidly declining for the last 30 years, was entirely suspended.

COMPANY, *Dutch West India*, was established in 1621, with an exclusive privilege to trade twenty-four years along the coasts of Africa, between the tropic of Cancer and Cape of Good Hope; and in America, from the fourth point of Newfoundland, through the straits of Magellan, that of Le Maire, or others, to the straits of Anian, both in the north and south Sea.

Besides these commercial privileges, the states conferred upon the corporation the right of governing and defending any new colonies which it might acquire; and made it a present of several large vessels, well manned. They retained to themselves, however, the nomination of the company's governor-general abroad. The original capital of this association amounted to 72,000 florins, in transferable shares, or actions, of 6000 florins each.

The 74 directors were divided into five chambers (as in the East India company), out of which, eighteen, with a deputy appointed by the states, were chosen for the general direction of affairs. In 1647, the company renewed its grant for twenty-five years; but it was scarce able to hold out the term, on account of its great losses and expences in taking the bay of Todos los Santos, Fernambuc, and the greatest part of Brazil, from the Portuguese. The weakness of this company, which had several times in vain attempted to be joined to that of the East Indies, occasioned its dissolution at the expiration of its grant.

In 1674, a new company, composed of the ancient proprietors and their creditors, was settled in the same rights and establishment with the former. It was to undertake the burden of the old company's debt, amounting to six millions, but reduced to 30 per cent.; and was to accredit in its books the proprietors of the old company's stock, at the rate of 15 per cent. The creditors, on their part, were to advance an addition of 8 per cent. on their loans; and the stockholders were to advance 4 per cent. on their shares. The new capital, thus scraped together, amounted only to 630,000 florins. The exclusive commerce of the company was limited to a certain part of the African coast, besides the conquests they should make; and its principal establishments were at Cape Verd, on the Gold Coast, at Tobago, Curaffoa, &c. in America. The rest of the trade monopolized by the former company was now thrown open to all the subjects of the republic. In 1730, when the charter was renewed, the African slave-trade was made free, on condition of a certain lading being paid to the company; and in 1734, the whole African trade was laid open upon the same terms. As the united privileges of the company were not sufficient to counterbalance the various disadvantages under which all fresh institutions labour, they obtained, in 1682, the exclusive management of the colony of Surinam, for the trifling sum of 260,000 florins paid to the states-general. This grant was accompanied by certain conditions, framed with the manifest view of preventing the abuses common to trading corporations. Under these restrictions, the company was not able to delay the expense of the original purchase-money paid for the charter; and, therefore, in the next year, one-third share was sold to the city of Amsterdam, and another to the rich family of Sommelidyk, reserving the remaining third to themselves. The three co-proprietors have since continued to form a society or partnership, under the name of the "Surinam Company," regulated by the charter originally granted to the West India company. Except in the government of Surinam, this association has had no connection with the West India company, which, of course, continued to furnish negroes to the settlement, in its capacity of African company, until the year 1730.

The progress of the dividends and prices of West India stock will enable us to judge concerning the prosperity, not only of the Surinam society, but also of the concerns of the West India company. The average dividend in ten years, ending 1690, was 2½ per cent.; and from 1770 to 1779 inclusive, nothing at all was divided. The actions have never been at par; their price has varied from 92½ to 18 per cent. since the year 1723. The average price during ten years, ending 1732, was about 8½ per cent. During ten years, ending 1779, it had fallen to 3¾ per cent. The settlements of Essequebo and Demerary have been always under the charter of the West India company, as well as Surinam, and governed in the same manner. Berbice, though within the company's charter, owed its origin to the speculations of the family of Van Peere; and all the cultivated part of the colony belonged to them. In 16-8 they obtained a perpetual grant of it from the company, which was confirmed in 1703; and when the French attacked it in 1712, the colony bought them off with a considerable composition. The money was paid by their great mercantile houses, and one fourth of it by the Van Peeres, who thus transferred three-fourth shares of the colony to the other merchants as co-proprietors; and the four houses together formed a copartnery or company at Berbice, administered exactly in the same manner with the Surinam society. The proprietary governments of North America differed from the company administrations of Guiana in many important particulars. They were the consequence of large and thoughtless grants, made by the court to favourites, of waste and uninhabited lands. As the British colonies were subservient to the legislature of the mother-country, the Dutch colonies owed the same allegiance, not to the states-general, but to the proprietors. The ill success of the West India company furnishes an useful example of the manifold evils of company government. This company must of late have been annihilated by the capture of all their settlements.

COMPANY, *Dutch North*, has no exclusive privilege; the advantage of its patent being of another kind, and very considerable.

There are also, in Holland, companies for the Baltic sea, the fishery of Nova Zembla, Davis's Straights, and Greenland; yet none of their fisheries are interdicted to private traders; all the difference between these and the companies consisting in this, that the former may not go ashore to cut their fish in pieces, and meet their lard: but must bring their luggage to Holland.

COMPANY, *Dutch Levant*. In strictness, there is no Levant company in Holland: but the commerce of the private traders is so considerable, that the state has taken the regulation thereof on itself.

To this end, they have established a chamber of direction at Amsterdam, composed of six deputies, and a register; who, under the burgomasters, take care of every thing relating to the commerce of the Mediterranean; especially that of Smyrna and Constantinople.

This company names the consuls, appoints the number and strength of convoys, terminates differences among the traders, and has also a right, on occasion, to add new regulations to the old ones; though those be of no force, till confirmed by the states general.

COMPANY, *French East India*, was established in 1664, with an exclusive privilege to trade for fifty years in all the seas of the East Indies and South Sea; no adventurer to be admitted without a thousand livres in stock; and foreigners, who have twenty thousand livres in stock, to be reputed regnicoles.

The patent grants them the island of Madagascar; and the

the king to be at one fifth of the expence of the three first armaments, without interest; the principal to be refunded in ten years; or, if the company finds it loses on the whole, the loss to fall on the king's side.

The capital fund of the company, which was mostly furnished by the king, was seven or eight millions of livres, but was to have been fifteen millions.

In effect, though no means were wanting to support the company, yet it still drooped, and still struggled; till, having subsisted ten years without any change in its form, and being no longer able to discharge its engagements, there were new regulations concerted, but to little purpose. At length, things not being disposed for a new East India company, nor much good to be expected from the old one, in 1708, the ministry allowed the directors to treat with the rich traders of St. Malo, and resign to them their privilege under certain conditions. In the hands of these last, the company began to flourish.

Its chief factory was at Pondicherry, on the coast of Coromandel; this was the residence of the director-general; the other factories were inconsiderable. The merchandizes which the company brought into France were, silks, cottons, spices, coffee, rice, salt-petre; several kinds of gums and drugs, wood, wax, printed calicoes, muslins, &c. The trade was laid open in 1769, which soon reduced the company to a set of mere holders of the government funds. A new company was established in 1785 with the privilege of an extensive trade to all parts of the East Indies, except the Isle of France and its dependencies. This exception must have prevented the company from succeeding; but the experiment had scarcely been made when the trade was again laid open by the national assembly in 1790. As for the other French companies, such has been the state of the country, they are all, we presume, extinct; and it is needless to give any account of them. Such were the *French West India company*, established in 1664, and possessing by their charter the property and seigniority of Canada, Acadia, the Antilles island, the isle of Cayenne, and the Terra Firma of America, from the river of the Amazons to that of Oroonoko; with an exclusive privilege for the commerce of these places, as also of Senegal, and the coasts of Guinea, for 40 years, on condition of paying half the duties; but in 1674 the grant was revoked, partly on account of the poverty of the company, and partly because it had answered the purpose of its establishment by recovering the commerce of the West Indies from the Dutch:—the *French Mississippi company*, first established in 1684, in favour of the chevalier de la Salle, who failed in search of the Mississippi, but miscarried with his colony, and came to an untimely death. He was succeeded by M. Hiberville, who found the Mississippi and settled a colony there; but this adventurer being poisoned, M. Crozat obtained in 1712 the sole privilege of trading to the French territories called Louisiana, granted to him for 15 years:—*Company of the West*, formed in 1717, when M. Crozat surrendered his grant before mentioned; and obtaining besides every thing granted to the former company the commerce of beaver, enjoyed by the Canada company from the year 1706, but expiring in 1717:—*India company*, formed by a junction of the former company with that of Canada and with that of Senegal in 1718, and also by an union with the East India company, and with those of China and St. Domingo, with the two first in 1719, and with the third in 1720;—the *Bastion company*, arising from the association of two merchants of Marleilles in the 15th century for fishing of coral in the gulf of Storacourcory on the coast of Barbary, on the frontiers of Algiers and Tunis; so called from a small fort called the

“*Bastion of France;*” built in 1561, but it sunk in 1633;—and several other companies, which either fell of themselves, or upon the expiration of their grants, and which it is therefore needless to mention.

COMPANY, Danish North, was established at Copenhagen in 1647. Its establishments are very considerable in Norway; besides which, it sends vessels to Waranger, whence they convey their merchandizes by land into the Danish Lapland; and by sledges drawn by rein-deer into the Muscovite Lapland. It also sends others for Borandai and Siberia; where its agent takes them up, and conveys them, in like manner, on sledges, to Panigorod, the capital of this part of the Muscovite empire.

The commodities it sends thither are six-dollars, tobacco, and linens; it returns nothing but furs and skins.

COMPANY, Danish Iceland, established in the same year with the North Company, its chief factory is at Kirkebar, a large town in that island.

COMPANY, Danish East India, established in the year 1616, and invested not only with the exclusive privilege of trading to the East, but with the powers of civil and military administration; their chief factory was at Tranquebar. In 1634 this corporation was dissolved, and another, with similar privileges, substituted in its place. This also rapidly declined; and in 1686, a third institution was tried for the same purposes; but this too failed in about 23 years; and the project was tried for the fourth time in 1732. The new company was provided with ample privileges and powers; and the possession of these preserved its existence, and increased the profits of the stock-holder, at the expence of the country, and of the Indian settlements. In 1772 the charter expired, and was renewed under restrictions which proved ruinous to the prosperity of the company. In 1777, the king purchased the rights of the company, and the private trade began to flourish. When the charter was renewed in 1792 to 20 years, the private trade was rendered still more free; all Danish subjects, and all foreigners were permitted to trade with the Indian settlements, upon receiving passports, either from Copenhagen or the Asiatic seats of government, and upon condition of returning with the cargoes to Copenhagen.

COMPANY, Levant, of the Genoese, established in 1664, and confirmed by the Porte; notwithstanding the opposition of the French. From 1670 this company has languished and sunk.

For a more particular account of the rise and progress of most of the above mentioned and other companies, see “Anderson’s Hist. of Commerce.”

COMPANY, New River. This corporation consists of a governor, deputy governor, treasurer, and twenty-six directors, who hold a weekly board for appointing officers, granting leases, and redressing grievances. The projector of this canal for bringing water to London, with the assistance of king James I. and the corporation of London, is supposed to have expended 50,000l. upon it: the profits, which are divided into seventy-two shares, for the first thirty years admitted of little more than five pounds to each share; but their value is much increased, and its original shares of 100l. are now estimated at upwards of twelve thousand pounds each.

COMPANY, in French compagnie. A certain number of people of war under the inspection and command of a chief called captain. The number, however, is never fixed, but varies. In the guards, as in the artillery, a company consists of 120 men. In the Austrian service a company consists of 200 men. A *compagnie d'ordonnance* was originally composed of fifteen companies of *gens d'armes* of a hundred

Hommes d'armes each. In former times the word *enseigne* denoted the company of infantry, and the word *cornette* the company of cavalry. A company seldom consists of fewer than 50 men. It generally has three or four sergeants, three or four corporals, and two drums.

COMPANY, *Artillery*. See ARTILLERY.
COMPANY, *of Musicians*, in the city of Westminster. See CHARTER.

COMPANY, in *Sea Language*, denotes the whole crew of a ship, including her officers.

COMPANY of *Ships*, is used for a fleet of merchant vessels, who make a kind of charter-party among themselves; whereby, under several clauses and conditions tending to their common safety, they engage not to quit one another, but to defend each other reciprocally, during their voyage.

These associates, in the Mediterranean, are called *conferres*. The chief conditions of the charter-party are, that such and such shall be owned admiral, vice admiral, and rear-admiral; and those that bear no guns, shall pay so much per cent. of their cargo, for the expences of the admiral; that such and such signals shall be observed; that if they be attacked, the damages shall be reimbursed by the company in general, &c.

COMPANY, *Rule of, or Fellowship*, in *Arithmetic*, is a rule whereby we discover or ascertain the share of the profits, or losses, belonging to the several partners, or associates, in any enterprize, in proportion to the stock each contributed thereto, and the time that stock was in bank. See FELLOWSHIP.

COMPARATES, COMPARATA, in *Logic*, the TERMS or subjects of a comparison; or the two things compared to each other.

COMPARATIONE—*Punctum ex COMPARATIONE*. See PUNCTUM.

COMPARATIONIS *Homogeneousum*. See HOMOGENEUM.

COMPARATIVE *Anatomy*. See ANATOMY.

COMPARATIVE *Degree*, in *Grammar*, is an inflexion between positive and superlative degrees; whose effect is, to set a thing above or beneath the level of another.

The Latins expressed their comparative degree by a particular termination of their adjectives, and particles; wherein they are followed by the English, though by few others of the modern languages.

The French form most of their comparatives by adding the particles *plus*, *moins*, and *aussi*; the Italians, by *piu*, *meno*, &c. as the thing is to be raised, lowered, or equaled to another.

COMPARE, VAL DI, in *Geography*, an island in the Ionian sea, anciently called Ithaca, noted for having been the country and kingdom of Ulysses.

COMPARISON, the relation of two persons or things, considered as opposed, or set against each other, in order to find wherein they agree or differ; or wherein one has the advantage of the other.

COMPARISON of *Ideas*, an act of the mind, whereby it compares its ideas one with another, in respect of extent, degree, time, place, or any other circumstances. This operation of the mind is the ground of relations.

Brutes seem not to have this faculty in any great degree: they have, probably, several ideas distinct enough; but cannot compare them rather than as to some sensible circumstances an end to the objects themselves: the power of comparing general ideas, which we observe in men, they have not, as we may probably conjecture.

COMPARISON, in *Rhetoric*, is a figure, or rather place, in

speech, whereby two things are considered with regard to some third, which is common to them both.

Thus, Cicero, *Topic*. "Catonem licuit sequi bellum civile, igitur et Ciceroni hæcbit." "It was allowed Cato to engage in the civil wars, therefore it may be allowed Cicero:" where, to engage in the civil wars is common to both.

There are three kinds of comparison; the first a *majori*, *i. e.* from the major to the minor, as that of Cicero against Anthony, "Quid feceris domi tuae, cum alienæ tam sis intolens?" Or that of Terence, "Quem feret, si parentem non fessit fœm?" From the same place, Ovid endeavours to appease Cæsar.

"Cur ergo posse negem leniri Cæsaris iram
Cum videam mites hostibus esse Deos?"

The second, a *minor*, *i. e.* from the minor to the major: thus Cicero, "Majoris nostri sæpe mercatoribus, ac navicularibus injuriosus tractatus, bella pesserunt; vos tot civium Romanorum millibus uno nuntio atque uno tempore necatis, quo tandem animo esse debetis?"

The third a *pari*; as when we contend, that what obtains in one thing, ought to obtain in another of the same kind: "It was a law that he who killed his father should be sewed up in a sack, and thrown into a river; therefore, he who killeth his mother deserves the same punishment."

"Capto tuam, pudet heu, sed capto, Maxime, cœnam:
Tu capis alterius; jam sumus ergo pares.

Mane salutatum venio, tu dicis esse,

Ante salutatum; jam fumus ergo pares," &c.

Mart. lib. ii.

COMPARTIMENT, or COMPARTMENT, a design composed of several different figures, disposed with symmetry, to adorn a parterre, a ceiling, panel of joinery, or the like.

The term of compartment is also used in painting. The Turkish and Moorish paintings are only compartments; the fine bindings of books are in compartments, &c.

COMPARTITION, in *Architecture*, the useful and graceful distribution of the whole ground plot of an edifice, into rooms of office, and of reception, or entertainment. Compartment makes one of the great divisions of the art of building.

COMPARTMENTS, in *Gardening*, are beds, plats, borders, and walks, laid out according to the form of the ground, and depend more on a good fancy, than on any set of rules, for their construction. They are also sometimes merely diversities or knots of flower-gardens or parterres, of which there is an infinite variety, according to the fancy of the designer. Plain compartments are pieces of ground divided into equal squares and flower-beds, marked out by lines, and made of regularly equal length and breadth. Some allow to these squares borders of two feet broad, if the plot of ground be small, and if larger of three feet, and edge the borders with box, or with upright hardy thyme; the alleys up between are to be laid with sand or gravel, and kept clean weed.

COMPARTMENT of *tiles*, is an arrangement of white and red tiles varnished, for the decoration of the covering of a roof.

COMPARTMENT, *alley of*. See ALLEY.

COMPARTMENT, in *Heraldry*, is the term for a partition in coat armour, when the arms of several families are borne by one, either on account of intermarriages or otherwise.

COMPASS, the *Mariner's* or *Nautical*. A period of about 500 years is now elapsed, since an admirable property of a natural production was either discovered by, or introduced

duced amongst, the nations of Europe. To the simple application of this remarkable property, mankind is indebted principally for the discovery of a new continent nearly equal to the old one, for an extensive commerce between the most distant nations, and for an accurate knowledge of the shape and size of the world we inhabit. The *magnet* or *loadstone* is the natural production, and its directive property forms the active part of that wonderful guide, the *mariner's compass*, or as it is more commonly called, simply the *compass*, probably from its moving in a circle, or from its compassing the whole horizon. Whatever relates to the history, the construction, the use, and the defects, of this singular machine, is rendered extremely important by the curiosity, the interests, the security, and the wants of the human species.

The time when the attractive property of the magnet was first discovered, is by no means known. The opinions are various, but they are not established upon historical documents of sufficient accuracy and authenticity. Certain however it is, that mankind was acquainted with it at a very early period. Father Kircher, in his work, *De Magnete*, l. i. cap. v., endeavours to prove that the Hebrews were acquainted with the magnet's singular property of attracting iron; and from Plutarch it appears, that the Egyptians were not ignorant of it. Pythagoras, Ptolemy, Hippocrates, Empedocles, Democritus, Lencippus, Epicurus, and several other ancient philosophers, knew and admired this wonderful property of the magnet. Thales and Anaxagoras were so struck with it, as to imagine that the magnet had a soul; and Plato said that the cause of its attraction was divine. Aristotle, Theophrastus, Dioscorides, Galen, and others, were likewise acquainted with this property of the magnet. But its directive property (*viz.* that property by which, if placed upon a piece of cork, or wood, &c. to swim on the surface of water, or if it be suspended by a very flexible thread, so as to have sufficient freedom of motion, it will constantly place itself in a certain situation with respect to the cardinal points of the world) does not appear to have been known to the ancients; and though the time of the discovery of this property is of a much more recent date, yet this too is involved in much doubt and obscurity. It seems, however, that the use of this property, or (what amounts to the same thing) the use of the magnetic needle, was not known in Europe before the thirteenth century. The honour of its discovery has been much contested. The Spanish Jesuit Pineda, and Kircher, affirm that Solomon knew the use of the compass, and that his subjects actually used it in their navigations. Plautus in *Mercatore*, act v. scene ii., has the following remarkable passage, *Huc secundus ventus est, cape modo vorforiam*. Now some authors are of opinion, that by the word *vorforiam* or *versforium*, is meant the mariner's compass; but some learned critics affirm that *versforiam* or *versforium*, meant a particular rope. And Dr. Lorrimer is inclined to believe that it only meant the helm.

By the consent of most writers, it seems that a certain Flavio, or Johs, de Gioja, or Giova, or Gira, a Neapolitan, who lived in the 13th century, has the best title to the discovery. Flavius Blond affirms that about the year 1302, the above-mentioned John de Gioja, a noble citizen of Amalphi, a town of Principato, in the kingdom of Naples, first discovered the mariner's compass; and he quotes the following verse from Antony of Palermo, recorded by the Neapolitan historians, *viz.*

Primo dedit nautis usum magnetis Amalphi.

The arms of the territory of Principato have, it appears, ever since been a mariner's compass. See *Callinas, et Frome-*

bellus de acus magnetica inventore. Inst. Acad. Bonon. tom. ii. p. 3. p. 372.

Dr. Gilbert, an English writer of the 16th century, in his book *De Magnete*, affirms that Paulus Venetus (the Venetian Marco Paulo) brought the invention of the compass to Italy in the year 1260; having learned it of the Chinese. But this cannot be true; for Marco Paulo did not set out for China before the year 1269, nor did he return before the year 1295 (see Purchas's Pilgrim, vol. iii.); whereas the directive property of the magnet, and the communication of that property to steel, was known in Europe before that time; though in all probability it was not used in navigation till some time after, which may very reasonably be attributed to the clumsy mode of suspending the magnetic needle, which must at first have been practised. Ludi Vestomannus asserts, that when he was in the East Indies, about the year 1500, he saw a pilot direct his course by a magnetic needle, fastened and formed like those now in use. And Mr. Barlow, in his *Navigator's Supply*, anno 1597, relates, that in a personal conference with two East Indians, they affirmed that, instead of our compasses, they used a magnetic needle of about six inches in length, suspended upon a pin in a dish of white China earth filled with water, in the bottom of which there were marked two cross lines to indicate the principal winds; the rest of the divisions being left to the skill of their pilots. But these two last observations, being of a date much posterior to the use of the magnetic needle in Europe, conclude nothing with respect to its original discovery; since the use of that magnetic property might have been introduced into Asia by some European.

P. Duhalde, in his "General History of China," vol. i. in the annals of the Chinese monarchy, speaking of the emperor *Hoangti*, when he gave battle to *Tchi Yeou*, says, "He perceiving that thick fogs saved the enemy from his pursuit, and that the soldiers rambled out of the way, and lost the course of the wind, made a carr, which showed them the four cardinal points. By this method he overtook *Tchi Yeou*, made him prisoner, and put him to death. Some say there were engraven in this carr, on a plate, the characters of a rat and a horse, and underneath was placed a needle to determine the four parts of the world. This would amount to the use of the compass, or something very near it, being of great antiquity and well attested." And in another part of the same book, speaking of certain ambassadors, he says, "After they had their audience of leave in order to return to their own country, *Tcheou Kong* gave them an instrument, which on one side pointed towards the north, and on the opposite side towards the south, to direct them better on their way home, than they had been directed in coming to China. This instrument was called *Tchi Nan*, which is the same name as the Chinese now call the sea-compass by; this has given occasion to think that *Tcheou Kong* was the inventor of the compass." This happened in the 22d cycle, above 1040 before Christ. Renaudot adduces strong reasons against the knowledge of the mariner's compass amongst the ancient people of China, and of Arabia. See Kircher, *De Magnete*, lib. i. cap. v.

In the works of Claude Fauchet, entitled, *Recueil de l'origine de la Langue et Poésie François*, fol. 555, there is a quotation from an old French poem, called *la Bible Guict*, in which the mariner's compass is evidently mentioned. This same passage is likewise quoted by Muschenbroeck, in his *Dissertation de Magnete*. The passage in which the compass is mentioned forms part of the above-mentioned poem, contained in a curious quarto manuscript of the 13th century, on vellum, belonging to the royal library at Paris, which was never published. The poem entitled *la Bible Guict*,

Guiot, forms the first article of the volume; the author of which. *viz. Guiot de Provins*, as mentioned in the poem itself, was at the court of the emperor Frederic Barbarossa, held at Mentz in the year 1181, when the emperor's two fons were knighted. See Chron. Abbot. Usperg. p. 311.

Here follows this remarkable passage in its antiquated language, to which is subjoined a literal translation made by a native of Provence.

Extraict from la Bible Guiot.

Icelle estoile ne se muet,
Une arts font qui mentir ne puet,
Par la vertu de la manete
Une pierre laide et brunete,
Ou il fers volenters se joint.
Ont regardet lor droit point
Puez c'une aguile lont toucheie,
Et en un festo lont fishie,
En longue la mette fens plus,
Et il feltui la tient defus;
Puis se torne la point toute
Contre letoile sans doute,
Quant il nuis est tenebre et brune
Cen ne voit estoile ne lune,
Lor font a laguille alumer;
Puiz ne puent ils afferer,
Contre letoile vers le point;
Par ce font il mariner cointe,
De la droite voie tenir;
C'est uns ars qui ne puet mentir.

Literal Translation of the preceding.

This same (the pole) star does not move, (and)
They (the mariners) have an art which cannot deceive,
By the virtue of the magnet
An ugly brownish stone
To which iron adheres of its own accord.
Then they look for the right point,
And when they have touched a needle (on it)
And fixed it on a bit of straw
Lengthwise in the middle, without more,
And the straw keeps it above;
Then the point turns jult
Against the star undoubtedly,
When the night is dark and gloomy,
That you can see neither star nor moon,
Then they bring a light to the needle;
Can they not then assure themselves
Of the situation of the star towards the point (of the
needle?)
By this the mariner is enabled
To keep the proper course;
This an art which cannot deceive.

Francis Cabens, a jesuit of Ferrara, says, that the first thing he knows professedly written respecting the directive property of the magnet, was an epistle of *Petrus Peregrinus Gallus*, about the latter end of the 13th century. A few years after, this epistle was disguised by one John Taffner, who published it in his own name, under the title of *Opusculum perpetua memoria dignissimum de natura et effectibus magnetis*. Some years ago, Mr. Senebier of Geneva sent the following memorandum concerning this letter to Dr. Lorimer in London.

“*Epistola Petri Peregrini de Marcourt, Ad Sigerium de Foucaucourt, Militeni. De Magnete.*”

“The work contains a description of that stone, the means of finding the poles, its property of attracting iron, and proves that the part of the magnet which is turned to the north, attracts that which is turned to the south. It then teaches the manner of employing the magnet in astronomy, and of playing tricks like those of Comus. It deserves to be remarked, that the author knew not that the magnet could be employed in navigation; for though he frequently speaks *de stella nautica*, he never speaks of the use that might be made of the magnetic needle in sea voyages. *Vide Bibliotheca Bibliobecarum, fol. 11. p. 1400.* Catalogue of the manuscripts in the library of Geneva, by Senebier. p. 207.”

Amongst the manuscripts of the university of Leyden, there is a volume containing several scientific tracts, one of which is a Latin letter of Peter Adiger, on the properties of the magnet. It is, in fact, a little methodical treatise, divided into two parts, the first of which is subdivided into ten, and the second into three chapters. This letter, which seems intended for the instruction of some particular friend, is dated in the year 1269. A few years ago, Mr. Cavallo obtained an exact copy of this curious letter, of which he inserted very ample extracts, both in the original Latin and in English, in the supplement to the second and third editions of his treatise on magnetism, from which it appears that the writer, at that early time, was acquainted with all the principal properties of the magnet. The following is the translation of the most remarkable part of the above-mentioned letter, which describes the compass, and mentions the declination of the magnetic needle.

“Part II. Chap. 2. *On the construction of a better instrument to answer the same purpose, viz. to find out the Azimuth of the Sun, the Moon, or any Star upon the Horizon.*”

“In the present chapter, you will be informed of the construction of another instrument of more certain effect. A vessel must be made of wood, copper, or any other material, and let it be turned like a box of small depth, and competently wide. Let a cover of some transparent substance, as glass or crystal, be adapted to it; and if the whole were made of some transparent matter, it would be still better. A slender axis of copper or silver must be adapted to the middle of this vessel, applying its extremities to the upper and lower parts of the box, *viz.* to the cover and to the box; the axis, however, must not be so firmly fastened, as not to be capable of moving very freely. Two holes must be perforated in the middle of the axis, at right angles to each other, and an iron style, like a needle, must pass through one of those holes, whilst another style of silver or copper passes through the other hole in a direction crossing the iron one. The cover must first be divided into four parts, and each of these into ninety parts, agreeably to the instructions given concerning the other instrument in the preceding chapter, and upon it mark the north and the south, the east and the west, points; and let a ruler of some transparent substance, with sights on its extremities, be adapted to it. Then place whichever part of the magnet you please, *viz.* the north or the south, near the glass, until the needle be moved towards the said magnet, and acquires the virtue from it; after which, the magnet being removed, the extremity of the needle will turn itself towards the pole. This being done, turn the box until one extremity of the needle remains directed towards the north part of the instrument, or the north part of the heaven; then turn the ruler towards the sun in the day time, and towards the stars in the night time, after the manner mentioned in the preceding chapter. By means of this instrument, you may direct your course towards cities, and islands, and all other

other parts of the world, either on land or at sea, provided you are acquainted with the longitudes and latitudes of those places; for, if the town or island to which I intend to go is in a lower latitude than the place in which I am, I shall go straight before me, towards that end of the ruler which is directed to the sun or star; but if the latitude of the place be greater, I shall proceed in the opposite way, *viz.* in the direction of the other extremity of the ruler. Observe, that the fourth part of the needle, which is to be used as a guide, must be made to decline towards the west by one point; and this must be done by the declination of the north part towards the east, because the fourth part of the instrument is destitute of divisions."

"Take notice that the magnet, as well as the needle that has been touched by it, does not point exactly to the poles, but that part of it which is reckoned to point to the south, declines a little to the west; and that part which looks towards the north, inclines as much to the east. The exact quantity of this declination I have found, after numerous experiments, to be five degrees. However, this declination is no obstacle to our guidance, because we make the needle itself decline from the true south by nearly one point and a half towards the west."

To this letter, Mr. Cavallo, in his treatise, subjoins the following observation. "It appears that the suspension of the needle in the above description, is a very clumsy one; and that the beautiful suspension by a cap upon a pin, which is now universally used, was unknown to the author. It is likely, therefore, that for want of this suspension, the needles at that time not moving sufficiently easy, were not actually used in navigation, at least in Europe, though the suspension by means of a cap upon a pin, seems not to have remained long unknown after the date of this letter."

Sir G. Wheeler says, that he had seen a book of astronomy older than the year 1502, which mentions the use of the needle in astronomy, but not in navigation.

Gassendus adduces, as an argument of the French having been the inventors of the mariner's compass, that the north point of it is always marked with a flower-de-luce. Lib. x. Diog. Laert. t. 1. p. 139. As for Goriopius's pretence, that the compass must have been invented by the Danes, Dutch, or Germans, because the 32 points on it are written and pronounced in the Dutch, or Teutonic language, it is hardly deserving of a reply. Dr. Wallis attributes it to the English, for no other reason, but for its being called compass. Vincentius Bellucentis, and Albertus Magnus, who lived about the year 1245, also Lavinus Lemnius, make mention of the direction of the poles of the magnet, as from a tract *de Lapilibus*, which had been attributed to Aristotle; but is, with more probability, supposed to have been written by some Arabian author, not long before their own time. This tract has been since lost.

Notwithstanding the foregoing remarks, it is still very doubtful whether the use of the compass in navigation, or even the directive property of the magnet, was known by any people before the Europeans, in or about the 13th century; and it appears, that in the same century, or soon after, the above-mentioned Neapolitan, Flavio, or John de Gioja, if not the original discoverer, was at least the first who used the mariner's compass, or constructed it for the use of vessels in the Mediterranean.

The principle of the construction of the compass is extremely simple. A magnet, or a piece of steel that has been rendered magnetic by means of natural or artificial magnets, must be freely suspended, so as to be able to move without obstruction; for such magnet or piece of steel will,

in that case, direct itself to certain parts of the world, which will of course indicate to the observer the direction of any other place, provided its situation on the surface of the earth be known. Suppose, for instance, that you are at sea near Portsmouth, and wish to go towards Newfoundland, which lies to the west. By looking at the magnetic piece of steel or magnet, one extremity of which looks nearly towards the north, and turning your face to that part of the world, you proceed towards your left hand, at right angles to the direction of the needle; for in that direction Newfoundland is to be found. And after the same manner, you may proceed in any other direction. Such is the simplicity of the principle; but the practical application of it, especially in the present accurate mode of constructing instruments, and of making observations, requires a great degree of mechanical nicety, and a considerable degree of attention to a variety of circumstances, upon which the accuracy of the instrument, and its various applications, absolutely depend. On account of those particulars, and in consequence of various contrivances made at different times, the compass or magnetic needle has undergone innumerable alterations, both in shape and size; and every kind of construction is attended with peculiar advantages, as well as defects; the most essential of which we shall endeavour to point out in the sequel. From its various uses, the compass has obtained different names and different forms. These are reducible to the four following species, *viz.* 1. The *land compass*, which is used either for the pocket, or is adapted to theodolites, to celestial and terrestrial globes, &c.; 2. The *steering compass* for the use of vessels at sea. 3. The *azimuth compass*, which serves to find the sun's or star's azimuth, whence the actual or true direction of the magnetic needle may be ascertained (this seldom being due north and south); and, 4. The *variation compass*, which, being situated in a proper place on land, shews the daily variation of the magnetic needle from its ordinary direction. See *MAGNETICAL Declination*, and *MAGNETICAL Variation*.

A common sewing needle rendered magnetic, and simply laid upon water, or fastened to a cork, or straw, &c. and so laid upon water, in a glass, or earthen or wooden cup; or else suspended by a very flexible thread, which must be fastened to its middle, forms a simple but imperfect compass; and such, in a probability, was one of the first modes of constructing the compass, whence the magnetized steel, wire, or bar, has, ever since, been called the magnetic needle. The defects of the last-mentioned construction are too evident to need any particular remarks. The needle laid upon water is continually running to the sides of the cup, the water is liable to be spilt, or if a thread be used, the stiffness of it will always influence the action of the needle. To avoid these inconveniences, an excellent contrivance was substituted. It is a conical cavity made in the middle of the needle or steel bar, as shewn in *Plate, Magnetism. fig. 1.* the open of which rests upon a pointed wire *a*, which enables the needle to move with the greatest freedom imaginable. The open of this cavity should come as near as possible to the upper surface of the needle, or rather a little above it, as in *fig. 2.* in which case the upper surface of the middle part of the needle is left a little more elevated than the rest. But, in order to avoid any irregularity in the shape of the needle, as well as any difficulty in the mechanical formation, the needles are mostly pierced quite through, with a pretty large hole; a piece of hammered brass is riveted into this hole, and the conical cavity is made into the brass, so that the open of it may stand even with, or very little above, the upper surface of the needle. The upper part of the wire upon which the needle rests, is generally made of hard steel,

while the lower part is made of brafs. This conftruction answers very well for a confiderable length of time; yet, by continual rubbing, a fmall prolongation or irregularity of the cavity, is at length produced, which will in fome degree obftruct the free motion of the needle; hence, in the beft needles, the upper part of the above-mentioned cavity is formed in a piece of agate, which is not in the brafs piece, as fhewn in *fig. 3.* where *AB* is the needle, *cd* the brafs piece riveted in a hole in the middle of it, and *e* is the piece of agate. The needles thus conftructed are faid to have an agate cap. The defect to which thofe agate caps are fubject, is, that on account of the hardnefs of the ftone, the cavity in it feldom runs to a point; the confequence of which is, that the pin which fupports the needle is apt to fhift from one part of the agate cap to another, and of courfe the centre of the needle cannot always coincide with the point of fufpenfion.

The forms of the needles have likewife been very numerous. Some are flender and long, others broad and fhort; feveral needles of the common fort are made broad towards the end, but tapering towards the middle, or they terminate in two very fharp points. Sometimes that extremity of the needle, which points towards the north, is formed like a crofs; but the moft objectionable of all, are thofe which confift of two wires, and may be frequently met with on board of merchant fhips. Two pieces of ftel wire, each bent in the middle fo as to form an obtufe angle, and when fixed under the card, in the centre of which a brafs cap is fattened, form a lozenge. All thofe fhapes may, in great meafure, answer for common purpofes; but they are far from being accurate or regular in their performance, the reafon of which is, that a piece of ftel of irregular form generally has more than two magnetic poles; almoft every corner or protuberance being a fouth or north magnetic pole; in confequence of which the axis of the needle never coincides with its magnetic axis, the latter of which changes its fituation in proportion as fome of the above-mentioned poles become ftronger or weaker than the reft; and this is continually the cafe.

In order to avoid every irregularity of fhape, and even the perforation, needles, for certain purpofes, have been fufpended in the following manner: *AB* (*fig. 4.*) is the magnetic needle of a parallelepipedal form, which is fattened to a piece of brafs *CED*. In the middle of this piece of brafs at *g*, there is a fmall conical cavity, wherein an agate cap is fet. In order to fufpend this needle, a bar *FH* (*fig. 5.*) of brafs, or copper, or wood, is made fall to the box *KL*; in the middle of this bar a fhort pointed wire is fixed, which, when the bar is made to pafs through the brafs piece *CED* *viz.* through *g*, enters the agate cap, and fupports the needle. *Fig. 5.* represents the whole together, where *FH* is the bar fattened to the box, *AB* is the brafs piece, feen lengthways, or in the direction of the needle, which paffes through the hole *AB*, and moves below the bar *FH*. It is evident that in this conftruction the needle cannot turn quite round, confequently this fort of fufpenfion is not ufeful for navigation.

The Chinese method of fufpending the magnetic needle is exceedingly ingenious (fee *fig. 6* and *7.*); the firft of which represents a fection of this fufpenfion as viewed in the direction of the needle; and the fecond exhibits a lateral view of the fame. The letters refer to the fame parts in both figures. *I* is a brafs cap very thin and light, and towards the edge of it there are two holes, oppofite to each other. *BB* is a very flender flip of brafs, the upper part of which *A*, is fhaped like a ring, through which the needle *CD* paffes. The extremities of this flip of brafs go through

the holes in the lower part of the cap, and are fattened to it by being turned over its edge. The magnetic needle *CD* confifts of a cylindrical ftel wire about an inch long, and not above a fortieth part of an inch in diameter; having its northern extremity only painted red by way of diftinction. All this is fupported by the pin *E*, which is fattened to the bottom of the box, and upon which it moves very freely. In this conftruction the needle is above the point of fufpenfion; yet the centre of gravity of all the three pieces (*viz.* cap, needle, and flip of brafs) taken together, is below the point of fufpenfion, which prevents the cap, &c. falling off from the pin when the compafs is fixed in an horizontal pofition; but to prevent the cap with the needle being fhook off by any fudden jerks, or by inverting the inftrument, there is a very thin brafs plate fixed to the box, a fection of which is indicated by *FG*. It has a hole through the middle, which, being fmall than the diameter of the aperture of the brafs cap, prevents its falling off. It appears, from a variety of experiments, that the perforation through the magnetic needle is not attended with any bad confequences. The external fhape of the needle requires to be formed with greater attention, this being more apt to produce a multiplicity of poles. A very broad needle feldom has its magnetic axis coinciding with the axis of its figure. A very flender and long needle almoft always has more than two magnetic poles. There is a certain breadth, proportionate to the length of a needle, which is lefs fubject to an irregular difpofition of the magnetical virtue; this proportion, however, cannot be accurately determined. The little fwelling generally left about the middle of the magnetic needles in order to give them ftrength, where the perforation for the cap would otherwife weaken them, has not been found to produce multiplicity of poles, provided it be made fmooth and free from corners. The lengths of the needles commonly ufed at fea are from three to fix inches, but thofe that are ufed as variation needles are generally made longer, though they need not, however, exceed eight or at moft nine inches. With refpect to the fubftance of the needle, it muft be obferved that certain kinds of ftel are more apt to acquire the magnetic virtue than others; but this muft be determined by actual trial. The common fort of magnetic needles are brought down to what is called by the workmen a blue temper, becaufe in that ftate they are eafily magnetized; but it muft be obferved that if in that ftate they are eafily magnetized, they are at the fame time liable to lofe that power very eafily; therefore the magnetic needles ought to be made quite hard; for in that cafe when they are once rendered magnetic, which is eafily done, they will retain that power almoft for ever after. The magnetic needles, though perfectly balanced before they are magnetized, will, after that operation, incline one of their extremities towards the horizon, which is in confequence of the dipping property of the magnet. See **MAGNETISM**, and **DIPPING Needle**. Therefore after the communication of the magnetifm, it becomes neceffary to balance the needle again; but this muft not be done either by grinding off part of that extremity of the needle, or by adding a fixed weight to the oppofite extremity of it, becaufe the quantity of that dipping varies according to the change of fituation on the furface of the earth. The beft way of adding this weight is by placing a fmall piece of brafs on one arm of the needle, capable of being fud nearer to, or farther from, the centre of the needle, by which means the balance of the needle when loft may be eafily reftored. Upon all thefe confiderations, a needle of the beft form and fize is exhibited at *fig. 8.* and *9.*; the former of which represents a vertical, and the latter a lateral, view of it. *A D*

is the needle of hard steel, C is the agate cap set in a piece of brass, B a mark made on that extremity which points towards the north, in order to distinguish it from the other, and E is the piece of brass which may be slid upon the arm C D, for the purpose of balancing the needle.

The shapes and sizes of the compasses used upon land are very numerous; some being of the usual size of a watch seal, and they are actually fixed in such seals; others are of the size, and externally in the form of a pocket watch; others again are made in a wooden box, square on the outside, but circular within; some are of a larger size, in a brass box. Sometimes a little sun-dial is affixed to some compass boxes, and so forth. But though the shape be different, the principle of the construction is the same in them all. The box, whether of wood, or brass, or silver, or other substance, must have no particle of iron or steel in its construction; and even the brass, when that metallic substance is used, must be tried by presenting the extremity of a very delicate magnetic needle to every part of it; for if any attraction be observed, that brass must be rejected, otherwise the needle would not move with sufficient freedom. Brass is frequently magnetical, especially after being hammered, which is generally done by the workmen, for the purpose of rendering it hard. A pin of hard steel is fixed in the centre of the box, upon the point of which the needle rests; and a glass plate covers the cavity. This glass plate rests upon a shoulder, and stands very little above the piece C (fig. 9.), so as not to touch that piece, whilst at the same time it prevents the needle's falling from over the pin. In several of the compasses a little piece of wire with a button is affixed to the box, which is formed so as to stop the motion of the needle when the compass is not intended to be in action, as when it is carried in the pocket, &c.

The friction which must naturally take place in cleaning the glass cover of a compass, frequently excites its electricity, in which case the needle is attracted more or less by the glass, and its free motion is thereby partly or entirely obstructed, Phil. Trans. N^o. 480. p. 243. This inconvenience may be removed by passing a wet finger in various directions over the surface of the glass. Few needles of land compasses are furnished with cards like those which are used at sea. In general the principal points of the horizon are marked in the bottom of the box, and a divided circle is added to the box, so that the edge of it may be even with, and so near as almost to touch, the extremities of the needle.

The compasses used at sea for ascertaining and directing the course of vessels, differ from the former principally by their having a circular card, whose diameter is equal to the length of the needle, fixed upon the needle, so as to turn with it, and by the box being set in a mechanism on four cross centres, called gimbals, the office of which is to keep the compass box always in an horizontal position, whilst the external box moves with the ship, as the latter rolls and pitches. This construction will be easily understood, by observing fig. 10, which exhibits a steering compass as viewed by an eye placed perpendicularly over it. A B C D is the external wooden box, which is fastened to and moves with the ship, E F is a brass circle having two pivots or axes, G, H, which turn in two holes in the opposite sides of the wooden box; *ic*, in the compass box, which is likewise furnished with two pivots or axes, *r, u*, and these turn in two holes made in the brass ring F E. Now as the direction of these last pivots, *r, u*, is at right angles to the direction of the pivots, G, H, it will be easily understood, that in whatever direction the vessel, and the box A B C D, which is fixed to it, may incline, the compass box, *ic*, re-

mains always in an horizontal position, for it will turn either upon the pivots, *r, u*, or upon the pivots, G, H. K is the card which is fixed to the magnetic needle and moves with it, under the glass cover, through which it may be distinctly seen. The outer edge of this card is divided into 360 degrees, and within the circle of those divisions it is again divided into 32 equal parts or arches, called the *points of the compass*, or *rhumbs*. These rhumbs are usually divided into quarters. Their names, beginning from the north point, and going all round, are as follow: the letters standing N, for north; E, for east; S, for south; and W, for west.

The construction which has been more generally used in the royal navy, is an improvement of the late Dr. Knight, a gentleman of very extensive knowledge in magnetism. In this construction the weight of needle, card, &c. is removed considerably below the point of suspension or centre of motion, by the addition of a brass circle, whose diameter is equal to that of the card, which is made very thin. This ring being fixed below the card, and the needle above it, the centre of gravity of the whole comes low enough to admit of the cap being situated below the needle; hence the needle needs not be perforated. This needle is a perfect parallelopiped. The figs. 11 and 12 represent the lower and upper parts of this (Dr. Knight's) card, needle, &c. about one half of the real size. A B is the needle, and C represents the upper part of its cap, situated below it. The under part of the cap is seen at G; A D D B is the card. The brass edge, or circle, is represented by F E O, and is fastened to the extremities of the needle, (the card being interposed) by means of two screws. H, I, are two sliding weights to balance the card.

A few years ago another sort of construction was contrived by Mr. K. McCulloch, for which he obtained a patent. The figs. 13 and 14 represent this compass, the former being a section, and the latter a perspective view of it. In this compass, both the compass-box and the needle, with the card, are suspended upon pivots, the extremities of which come very near to each other; which construction keeps them horizontal without any gimbals, as will be easily manifested by the following description. Fig. 13. A *aaaa*, is the common wooden box, with its lid; *bb* the brass compass box; *cc* the glass cover to it; *dd* the hollow conical bottom; *e* the prop, upon which the compass is supported instead of gimbals; the spherical top of which is finely polished, and the apex of the hollow cone is fitted to receive it; *ff* is a quantity of lead run round the bottom and cone of the compass box, to balance and to keep it steadily horizontal; *g g* is the card, and the magnetic needle, bent in such a manner as to bring the point of the conical pivot, on which it moves and is supported, very near to the centre of gravity, as well as to the centre of motion; *bb* are two guards, which, by means of the two pins *i, i*, affixed to the compass-box, prevent its turning round, and deceiving the seaman. In fig. 14, both the lid and

the front of the box are removed; *b b* are the guards; *b* the compass-box, and *e* is the prop which supports the box.

The greatest inconvenience that attends the use of the compasses at sea is the irregularity of motion induced by shocks of sudden impulses. In those cases the vessel is suddenly moved out of its direction, and the card of the compass is set vibrating for a considerable time, during which the seaman is unable to regain his course. Several methods have been tried for the purpose of removing this inconvenience, and the above described compass of Mr. M'Culloch's contrivance was supposed to accomplish this end in a considerable degree; but the experience of some years shews that this is not the case. The least skilled seamen do not like the needles of their compasses too powerfully magnetized, because, they say, then the needles are not steady. The fact is, that when the needle is not strongly magnetic, it follows the irregularities of the ship's motion in a great degree; which renders it apparently more steady; but the very same cause which enables it to follow the irregular motion of the ship, prevents at the same time its placing itself in the magnetic meridian. With the same degree of impropriety, some persons have endeavoured to prevent the irregular shocks or vibrations of the magnetic needle by increasing the friction between the cap of the needle and the pointed wire which supports it. Sometimes pieces of paper, like wings, have been stuck to the lower surface of the card, which, by offering a resistance against the air in the box, check in some measure the irregular movements of the card. In the year 1779, Dr. Ingenhousz presented a paper to the Royal Society, which is published in the 69th vol. of the Philosophical Transactions, and in which he describes some experiments, made by magnetic needles in water, where he found that a strong magnetical needle placed itself in the magnetic meridian, nearly as well under water as in the open air, and that by the resistance of the medium, much of its too great versatility was taken away. In consequence of those experiments the Dr. proposed to enclose the magnetic needle in some fluid for the use of vessels. "Common water," he says, "would be, perhaps, the best medium for these different contrivances, if steel was not so easily rusted by it, and if in cold weather water was not so apt to freeze; therefore, I think, that some of the thinnest expressed oils would answer the purpose better. The glass basin containing such a compass should be full of the liquid to the cover, to obstruct undulating motions." But though this proposal appeared at first very promising, and some eminent philosophical instrument-makers were much struck with it; yet it does not appear that it was ever adopted.

The use of the compass in general is to direct a person along any required track, which makes a known angle with the direction of the magnetic needle; and this renders the compass applicable to a variety of purposes; thus it guides travellers in deserts, as in Arabia, in the woods of America, &c.; it enables the navigator to proceed in any required track; it is highly useful to the miner, by shewing the direction of subterranean places; it serves for measuring horizontal angles; hence it is useful in land-surveying, taking plots, finding bearings in dialling, &c. And lastly it serves to set sundials, and other astronomical instruments when no great accuracy is required. The application of the compass to those purposes is so very obvious, as not to require any farther illustration. But for some of these purposes, sights must be applied to it, as in the azimuth compass.

The azimuth compass is a steering compass of any of the above-mentioned constructions, to which two sights are adapted, through which the sun is to be seen, in order to find its amplitude or its azimuth, whence the declination of the

magnetic meridian from the true or astronomical meridian may be determined; those two meridians seldom coinciding. At present (1807) in London, the declination of the magnetic needle is about $24^{\circ} 9'$ west; that is, the northern extremity of the magnetic needle, points to a part of the heavens, which makes an angle of about $24^{\circ} 9'$ with the true North. But this declination is various at different times in the same place, as well as at different places at the same time.

The more usual sort of azimuth compasses is represented in fig. 15, where *F, G*, are the sights, or sight vane, in one of which, *G*, there is an oblong aperture, with a perpendicular thread or wire through its middle; and in the other sight, *F*, there is a narrow perpendicular slit. A thread or wire, *H I*, is stretched from one side of the edge of the box to the other. The ring *A B* of the gimbals rests with its pivots on the semicircle *CD*, the foot, *E*, of which turns in a socket, *f*, that whilst the box, *KLM*, remains steady, the compass may be turned round, in order to place the sights, *F, G*, in the direction of the sun, or other celestial object. The pivots of the gimbals of this, as well as of the steering compass in general, should lie in the same plane with the point of suspension of the needle or card, for the purpose of avoiding the irregularity of its vibrations as much as possible. In the inside of the box there are two lines drawn on its sides perpendicularly down, from the points where the thread, *H I*, touches the edge of the box. These lines serve to shew how many degrees the north or south pole of the needle is distant from the azimuth of the sun; on which account the middle of the apertures in the sight vane, *F* and *G*, the thread *H I*, and the above-mentioned two lines must stand exactly in the same vertical plane. The use of the thread *H I*, which is sometimes omitted in compasses of this sort, is to shew the degrees between the magnetic meridian and the azimuth, &c. when the eye of the observer stands perpendicularly over it. On one side of the box of the azimuth compass, there generally is a nut or stop, which, when pulled in, bears against the card and stops it; and this is done for the purpose of reading that degree, half degree, &c. of the card, which coincides with one of the perpendicular lines in the inside of the box.

Mr. M'Culloch's azimuth compass is represented in fig. 16, where *b* is the compass-box, *b* one of the guards, *e* the prop, which stands in a brass socket, and may be turned round at pleasure, *r* is a brass bar upon which the sight vane are fixed; *2*, a dark glass, which moves up or down on the sight vane; *3*, *4* is a magnifying-glass, which is also moveable on the other sight vane; *5* is the nonius or vernier; *6* a slide for moving the vernier so as to stop the card in taking the azimuth; and *7* a double convex glass, through which the divisions on the vernier may be read with accuracy.

In order to observe at sea the magnetic amplitude of a celestial object (*viz.* its bearing by the compass when in the horizon) with the azimuth compass, place the instrument on a steady place, whence the horizon may be clearly seen; and looking through the sight vane of the compass, turn the instrument round, until the centre of the sun's disk, or other celestial object, may be seen through the narrow slit in one of the sight vane exactly on the thread which bisects the other sight vane; and at the instant that the centre of the celestial object, whether rising or setting, is in the horizon, push the stop in the side of the box, so as to stop the card, then read the degree, half degree, &c. of the card, which stands against one of the perpendicular lines in the inside of the box, and this is the magnetical amplitude sought.—In this observation, some allowance must be made for the height of the observer's eye, above the level of the sea.

sea. The true amplitude of the celestial object is an arch of the horizon contained between the east or west points of the horizon, and that point of the horizon which the centre of that celestial object cuts in its rising or setting. In order to find the true amplitude of the celestial object, the latitude of the place of observation, and the actual declination of that object, must be known; then say, as the cosine of the latitude is to radius, so is the sine of the declination to the cosine of the amplitude sought.

To observe at sea the magnetic azimuth of a celestial object, (*viz.* its bearing by the compass when above the horizon), situate the instrument in a steady place, and looking through the narrow slit in one of the sight vanes, turn the box round until the centre of that object appears to coincide with the thread in the slit of the other sight vane, or till the shadow of that thread, when the sun is observed, falls exactly along the line on the surface of the compass-box, and at that instant stop the card; then read the degree, &c. as above directed with respect to the amplitude, and thus you have the magnetic azimuth of that object.—The true azimuth of that object is an arch of the horizon intercepted between the north or south point, and that point in which a plane passing through the zenith and the celestial object, cuts the horizon. In order to find this azimuth, the latitude of the place of observation, the declination of the celestial object and its altitude must be known; and since to determine the declination of the magnetic needle, this true azimuth of a celestial object must be taken at the same time that its magnetic azimuth is taken; therefore the altitude of that object must be taken with a sextant, at the very instant that its magnetic azimuth is taken; *viz.* at the time the card is stopped; then proceed in the following manner: If the declination and latitude be both north or both south, call the co-declination A; but if they be one south and the other north, add 90° to the declination, and call the sum A. Call the difference between the co-latitude and co-altitude B. Let the half of the sum of A and B be called D; and the half of their difference be called C; then add together the four following logarithms, *viz.* the arithmetical complement of the logarithmic sine of the co-altitude, the arithmetical complement of the logarithmic sine of the co-latitude, the logarithmic sine of D, and the logarithmic sine of C. Half the sum of those four logarithms is the logarithmic sine of half the azimuth sought.

Now, having shewn how to find the true and the magnetic amplitudes as well as azimuths, we shall briefly add the method of determining from them, the declination of the magnetic needle for the time and place when and where the observations are made. Let the amplitudes, as well as the azimuths, be all reckoned from the north point, which is effected by subtracting the amplitude from 90° when it is on the northward of the east or west points; or by adding it to 90° when it is southward of the said points. Then the magnetic amplitude is either smaller or greater than the true amplitude. When the magnetic amplitude is less than the true, and they are both on the same side of the north point, their difference is the declination of the magnetic needle towards the contrary side of the north point. But if they be on different sides of the north point, then their sum is the declination towards the same side with the true amplitude. When the magnetic amplitude is greater than the true, and they are on the same side of the north point, their difference shews the declination towards the same side. But if they be on different sides, then their sum is the declination towards the same side with the true amplitude. Thus, for example, if the magnetic amplitude is 80° eastward of the north point, and the true amplitude is 82° to-

wards the same side; then the declination is 2° west. And if the magnetic amplitude be 76° eastward of north, whilst the true amplitude is 5° westward of north, then the declination is 81° west. The same directions, *mutatis mutandis*, are to be followed for finding the declination from the magnetic and true azimuths.

Ever since the discovery of the declination of the magnetic needle from the true meridian, which appears to have been first observed by Columbus in his first voyage towards the continent of America, in the year 1492, the cause of that phenomenon has been earnestly sought after by inquisitive persons in the scientific world; and especially when it was found that this declination varies continually, in a manner, which has not, as yet, been reconciled to any theory. The most promising method of investigating the subject appeared to be that of observing attentively the daily, and even the hourly, variation of the declination, in order to discover, if possible, any period in it, or any dependence of it upon other natural phenomena. And in fact, the late ingenious Mr. Canton, who made numerous observations relative to the subject, found a periodical increase and decrease of the magnetic variation, in great measure corresponding with the temperature of the different parts of a natural day. For this purpose accurate compasses were fixed in various observatories, and the variation of the magnetic needle has been observed, at least once every day, for a great many years; such observations having frequently been inserted in meteorological journals, and elsewhere.

The variation compass being intended to shew the daily variation of the magnetic needle upon land, is generally made longer than those that are used at sea; and, as it is not necessary to turn it round, the box generally is of an oblong form, so that the angular motion of the needle in it may amount to about 40° or 50° . The divided arches are either within the box, concentric with the point of suspension of the needle; or out of it, on a frame, the particular construction of which will appear from the description of the variation compass of the Royal Society of London, which will be given presently. When the divided arches are within the box, in which case a nonius is often placed on one extremity of the needle, the variation is known by observing the division which coincides with the axis of the needle. In either construction, it is evident that the beginning of the divisions of the arch or arches must be placed exactly in the meridian of the place; or else its deviation from the meridian must be accurately known and allowed for in reading the degrees of magnetic variation. And it is almost superfluous to add that such compasses must be situated in very steady places, out of the influence of iron; so much so that it will be proper for the observer, when he examines the compass, &c. to take out of his pockets, keys, knives, or any other article of steel and iron; for otherwise they will sensibly alter the direction of the needle. We shall now subjoin the particular descriptions of two variation compasses of the best construction, *viz.* of that which is used at the Royal Society, and is described by the honourable Henry Cavendish, in the 66th vol. of the Philosophical Transactions; and of that which was contrived by Mr. Cavallo, and is described in his "Treatise on Magnetism;" the former of which, being much larger, is well calculated for a fixed observatory, whilst the latter is smaller, more compact, and may be easily fixed in any place.

Fig. 17, is a plan of the Royal Society's variation compass. "In this instrument, the box which holds the needle is not fixed, but turns horizontally on a centre, and has an index fastened to it, pointing to a divided arch on the brass frame on which it turns; and the method of observing is to

move the box, till a line drawn on it points exactly to the end of the needle; which being done, the angle that the needle makes with the side of the frame is shewn by the index. *ABba* is the brads frame, the sides *AB* and *ab* being parallel: *Ee* is a circular plate fastened thereto, on which *CDdc*, the box which holds the needle, turns as on a centre; *Nn* is the needle, the pin on which it vibrates being fixed in the centre of the plate *Ee*; *Bb* is the division on the brads frame; and *G* the index fastened to the box, *CDdc*, furnished with a vernier division; the division and vernier being constructed so as to shew the angle which the line, *Ff*, makes with *AB*, or *ab*. The instrument is placed in the meridian by the telescope, *Mm*, the line of collimation of which is parallel to *AB*, and is pointed to a mark fixed due north of it. *Fig. 18*, is a vertical section of the instrument passing along the line *Ff*; *AB* is the brads frame; *CDdc* is the box which holds the needle; *Ee* the circular plate on which it turns; *Nn* is the needle; *P* and *p* are small plates of brads fixed to the ends of it, on each of which is drawn a line serving by way of index. These pieces of brads are raised to such a height that their tops are on a level with the point of the pin on which the needle turns. The use of them is, that it is much easier observing this way, than when the lines, serving by way of index, are drawn on the needle itself, as by this means the inconvenience proceeding from one kind of vibration in the needle is avoided. *S*, and *s*, are two brads plates, on each side of which is drawn a line, to which the index at the end of the needle is to point; there is also a line parallel to these, drawn on the bottom of the box; these three lines form the line, *Ff*, in *fig. 17*. *R* is a double microscope intended to assist us in judging when the index, *P*, points exactly to the line, *F*, that is, to the line drawn on the plate *S*. It is placed so that a wire, *Ww*, in its focus, appears to coincide with this line; and in observing, the box is moved till the wire appears also to coincide with the index *P*. The cap in the centre of the needle is made to take on and off readily, and to fit on upon either face; so that we may on occasion observe with the under face of the needle uppermost. The intention of inverting the needle is to shew whether the axis of the figure of the needle coincides with its magnetic axis.

The *figures 19* and *20*, exhibit a vertical view, and a section of Mr. Cavallo's variation-compass, and those representations are two thirds of the real size of the instrument. The letters of reference indicate the same parts in both figures. *ABD* is a brads bottom with a circular brads piece, *cei*, screwed fast upon it. *FGHK* is a rim likewise of brads, that slides on the outside of the circular piece *cei*, and to which the flat glass, *M*, is fastened; so that when the rim is removed, the glass comes off with it. The shape of the needle is clearly indicated by the figures. It has a hole in the middle to receive the agate cap, which is burnished into a brads socket, and is so situated into the needle, that the apex of its cavity does not rise higher than the surface of the needle; hence the point of suspension upon the pin, *B*, is even with the upper surface of the needle. By this means the pendulum-like oscillations cannot disturb the direction of the fine lines marked on the extremities of this needle. The upper and lower surfaces of this needle are quite alike, and the brads socket, which contains the agate cap, is made so as to admit of the needle's being turned with either of these surfaces upwards. The hole in the middle of the needle is quite cylindrical, and is on the outside of the brads socket, which fits the said hole exactly, but projecting a little way beyond the needle, has

a screw cut on that projection, upon which another circular piece of brads is screwed to fix it, as may be seen in *fig. 20*. It is evident, therefore, that when the last-mentioned piece of brads is unscrewed, the socket with the agate cap, may be put in on either side of the needle, and may be fastened on the opposite side of it. By this means a great source of error may be avoided, namely what arises from the magnetical axis of the needle being not in the axis of its figure, which is frequently the case; for, if the direction of this needle be observed with one side of it upwards and then (the needle being turned) be observed again with the other side upwards; either the second observation coincides with the first, and then we may conclude that the magnetical axis of the needle is truly in its middle; or the observations differ, and thence we shall know that the magnetical axis of the needle is not in the axis of its figure; but in this case we may have the real magnetic direction *By* taking a mean of the two observations; or we may thereby ascertain, once for all, how much the line of direction of the needle deviates from its magnetic axis, which, when once ascertained, becomes a fixed quantity to be either subtracted from, or added to any other observation."

"The upper side of the circular piece *cei* is silvered, and divided into degrees and half degrees; but those divisions, being too minute, are omitted in the figure. The bottom *ABD* has two projections, *A* and *D*, opposite to each other, and on each of their chamfered edges a line is marked, which, being drawn at the same time that the circle, *cei*, is divided by the circular dividing engine, coincide exactly with the commencement of the numeration of the degrees on the opposite sides of the circle, from which places the degrees run on both sides as far as 90°. The needle, therefore, which lies with its upper surface even with the divided circle, points to the same degree and part of a degree with both its extremities."

"We come now to describe the method of measuring the parts of a degree on the circle, which is only divided into half degrees. This is obtained by means of the microscope, *fig. 21*, which is furnished with one of my mother-of-pearl micrometers. (*Phil. Transf. vol. 51.*) The external construction of the microscope, and likewise the manner of placing it perpendicularly upon the compass box, are indicated by *fig. 21*; at *N* in *fig. 19*; and by the dotted lines at *K*, in *fig. 20*. *P* is a short tube supported by the uprights *F*, *R*, the lower parts of which project horizontally. These horizontal projections, *O*, *O*, are not tied at *Y*, so as to fit the mouldings, *H*, *K*, of the rim *FGHK*, when the parts, *O*, *O*, rest upon the glass. By this means the microscope may be moved all round the compass-box, whilst it keeps some of the divisions of the circle always in the field of view. The body of the microscope may be moved up and down in the tube *P*, in order to adjust it for distinct vision. It consists of the tube *SS*, into the upper part of which slides a short eye-tube *T*, and at its lower extremity, *H*, a lens is fastened. Two other lenses are fixed into the tube *T*, which is about nine-tenths of an inch long, and within it; the exact y in the focus of the eye lens, the mother-of-pearl micrometer is situated. Those three lenses are all of the plano-convex sort. The focus of the upper one is about four-tenths of an inch, and the focus of the second and third is about six-tenths of an inch. The divisions of the micrometer are 300ths of an inch, and when viewed through the microscope, and the microscope is placed upon the compass, 15 of them appear to be exactly equal to half a degree on the circle *cei*. But there is no need for those divisions to be exactly

ooths of an inch. It is sufficient if they are nearly so, as, for instance, from about 280 to 320 in an inch; because by pulling the tube T more or less out of the tube SS, and by moving the last mentioned tube up or down into P, the divisions of the circle may be magnified more or less, till 15 divisions of the micrometer appear to be exactly equal to the space between any two contiguous divisions on the circle; *viz.* to half a degree. When the microscope has been once so adjusted, it requires no farther alteration, excepting to be moved round the box until it comes over the end of the needle, in which situation the field of view appears as shewn in *fig. 22*, where the middlemost part is occupied by the micrometers 1, 2, 3, 4; the other large divisions are the magnified divisions of the circle, and W is the extremity of the needle, with its directive line pointing to some division on the micrometer."

"Fifteen divisions of the micrometer being equal to half a degree, or to 30', it follows that each division is equal to two minutes, and as it may be easily discerned whether the line on the end of the needle is directed exactly to one of those divisions or midway between two of them, therefore the direction of the needle in this compass may be read off to a single minute. In order to observe the daily variation, when this compass is properly fixed, the microscope need not be moved, because its field of view takes in about two degrees, which is a much greater space than the needle will go through in ten years time. In moving the microscope round the box, care must be taken to place it so that the divisions of the circle may appear to coincide with some of the long divisions of the micrometer.—N. B. This microscope inverts the objects; therefore what appears to be on the right hand must be understood to lie on the left, and *vice versa*."

"In order to observe the real direction of the magnetic needle, or the daily variation, the compass must be placed so as that the two lines marked on the projections A and D, *fig. 19*, may coincide with a meridian line drawn upon a board, a stone, a block, &c. and then the degrees and minutes, to which the extremity of the needle is directed, will shew the required variation."

Having, in the preceding paragraphs, mentioned all the important particulars relating to the discovery, the construction, and the use of one of the most remarkable, and the most useful, philosophical instruments, we shall conclude by

mentioning a deception which has sometimes been offered to the credulous and unskilled part of mankind. It is a compass, or a magnetical needle which was pretended to point due north and south, without any variation at any time or place; and compasses apparently of this description have actually been offered for trial and have even been sent abroad. But upon examination it has been found either that the north and south points of the card were not placed over the north and south points of the needle; or that the needle, having been made purposely broad, had been magnetized so that the direction of its poles made an angle with the axis of its figure, just equal to the magnetical declination at that particular time and place. The consequence of this artifice is, that though the needle may appear to have no declination at that particular time and place; yet at any other time, or if moved to another place where the magnetical declination is different, its direction will deviate from the true meridian. The declination or variation, like the attraction and repulsion, belongs to every piece of magnet, be it natural or artificial, and the magnetic needle is of the latter sort; nor can, at the same time and in the same place, one needle point to one part of the heavens whilst others point to a different part; provided they are freely suspended, and be uninfluenced by iron or other magnets.

COMPASS of voices, in Music. In early times of counterpoint, human voices of different compass, occasioned by age, sex, and natural organ, were classed and divided into four distinct kinds, at the distance only of a third above each other, which the base, or F clef, placed from line to line, expressed. The lowest of these was called the tenor, the next contratenor, motetus the third, and triplum the highest, or treble; of which term this was the origin.

After this, about the middle of the fifteenth century, as different parts began to be multiplied, the scale received six divisions: base, baritone, tenor, contralto, mezzo soprano, and soprano. The natural pitch of these is about three or four notes above each other, as their several clefs, which originally served as barriers, will discover.

It seldom happens that a voice has more than ten real, steady, and full, natural notes, in its compass, without a mixture of falset, which, being of a different register, is easily discovered. The following are the names and usual extent of the several species of human voice.

But as there are sometimes base voices which go down to double F, and even lower; so there are in the treble, among modern vocal phenomena, singers that go higher than F in altissimo; which make the whole diapason of voices exceed four octaves. And there is at present (1802) in England, a German buffo singer with a base voice that goes down to double gamut in real musical tones; and in falset, up to G on the second line in the treble. No public use was made of this extraordinary voice. He arrived in autumn, when no theatres were open, and remained but a short time.

But though parts in choral music were multiplied, not only to six, but even thirty-six, before the close of the fifteenth century; yet the general, and established number, in the pope's chapel, by which probably all other choral service

was regulated, amounted to no more than four: cantus, altus, tenor, and base; which see severally.

If it be asked why so many clefs are used? It may be answered, to keep the melody of these several voices within the compass of the five line staff; to prevent the perplexity of a great number of leger-lines, which in singing and playing at sight, frequently alarm and embarrass the performer.

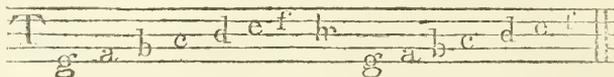

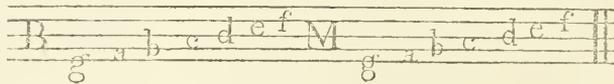

Of all the expedients proposed by speculative and ingenious men, for the abolition of tenor clefs, the only one that seems practicable, and has the merit of great simplicity, was published in our own country in the time of Charles II. under the title of "An Essay on the advancement of Music, by casting away the perplexity of different clefs; and uniting all sorts of music, lute, viols, violins, organ, harpsichord, voice, &c. in one universal character, by Thomas Salmon,

Salmon, A. M. of Trinity College, Oxford." London, 1672. This book is well written, and, though very illiberally treated by Lock, Playford, and some other professors, contains nothing that is either absurd, or impracticable; nor could I discover, says Dr. Burney, any other solid objection to its doctrines being adopted, than the effect it would have upon old music, by soon rendering it unintelligible. At present the tenor clef alone is thought an insuperable difficulty in our country, by Dilettanti performers on the harpsichord; but if Salmon's simple and easy musical alphabet were chiefly in use, the base clef would likewise be soon rendered as obso-

lete and difficult as the tenor; so that two parts or clefs out of three, in present use, would become unintelligible. The author's plan was simply this: instead of the eight or nine clefs that were then in use, as,

to express the whole scale of sounds on the five lines and spaces in this simple manner:

G in every part of the scale being on the first line, *a* on the first space, *b* on the second line, &c. the letters preceding each septenary implying base, mean, treble, supreme. To this proposal there seems no cogent objection; professors would not be humbled by having any thing to learn. The base clef, which every tyro knows, repeated in octaves, without changing a single name or character, would accomplish the whole business. The principal evil, and a great evil it would be, is the certainty of soon rendering all former music, printed or in manuscript, obsolete and unintelligible. This has been effected in a great measure, lately, by new editions of the harpsichord and organ music of the last century, and the total rejection of every tenor clef in music for keyed-instruments; of which we have already pointed out the inconvenience. See ACCOMPANIMENT and CLEF.

COMPASS of proportion. See SECTOR and PROPORTION.

COMPASS dials, are small dials, fitted in boxes, for the pocket, to shew the hour of the day by direction of the needle; which indicates how to place them right by tuning the dial about, till the cock or style stand directly over the needle, and point to the northward; but these can never be very exact, because of the variation of the needle itself. See DIAL.

COMPASS Saw. See SAW.

COMPASSES, or pair of COMPASSES, a mathematical instrument, used for the describing of circles, measuring lines, &c. The common compasses consist of two branches or legs, of iron, brass, or other metal, pointed at bottom; and joined by a rivet, whereon they move, as on a centre. Those are reckoned the best, part of whose joint is steel, and where the pin on, which the joint turns is a steel screw. The points should also be made of hardened and polished steel. In some the points are fixed; in others they may be taken off, and a drawing-pen, pencil, or dotting wheel, substituted in their room.

The invention of compasses is ascribed to Talaus, nephew of Dædalus, by his siler, whom the poets say, Dædalus killed out of envy. We have compasses now of various kinds and contrivances, accommodated to the various uses they are intended for; as,

COMPASSES of three legs, or triangular compasses. Their structure is like that of the common compasses, letting aside the excess of a leg, which has a motion every way: their use is to take three points at once, and so to form triangles: to lay down three positions of a map to be copied at once, &c. Two of the legs A, B (*Plate, Compasses, fig. 1.*) are jointed together like a common pair; the pin *a*, which connects them, has another leg D, jointed to it; the legs, A, B, are first set to two of the points, and the leg D is then moved farther from, or nearer to, the other legs by bending its joint; or it is turned round the pin *a* of the other legs as a centre, as occasion may require.

Fig. 2. is another construction of the triangular compasses. A, B, C, are three arms, at whose ends are jointed the arms *a, b, c*, carrying steel points; they are of such lengths, that when closed they shall nearly meet in one point; by opening them as in the figure, they can be made to coincide with any three points within the reach of the arms.

COMPASSES, Beam, consist of a long branch, or beam, carrying two brass cursors; the one fixed at one end, the other sliding along the beam, with a screw to fasten it, on occasion. To the cursors may be screwed points of any kind; whether steel, pencils, or the like. To the fixed cursor is sometimes applied an adjusting or micrometer screw, by which an extent is obtained to very great nicety. Mr. Ramsden constructed compasses of this kind whose micrometer screw shews very perceptibly a motion of $\frac{1}{1000}$ th part of an inch. It is used to draw large circles, to take great extents, &c. See *Plate, Compasses, fig. 3.* which exhibits a common pair of beam compasses. A A is a five-sided bar, of mahogany, made very straight and true; B, D are two frames of brass, sliding on the bar, that can be fastened at any place by a clamp screw *ab*, at the top of each; *ce, f* are two pieces into which are inserted the points, and are fastened by a screw; the sliding frame B has a collar *g* screwed to it, in which the screw *b*, with a divided head, turns; this screw is tapped into a piece of brass fastened at the end of the mahogany bar, so as to move the point at *f* very slowly when the screw is turned.

COMPASSES, Bow, or Bows, are a small sort of compasses,

passes, that shut up in a hoop, which serves for a handle. Their use is to describe arcs, or circumferences of circles of very small radius. *Fig. 4.* is a small pair of compasses, with a screw for measuring small distances very accurately, and describing small circles: *a* is one of the points fastened to a socket, in which the screw *b* works; *d* is a steel-bar attached to the same socket; *e* is a piece sliding on the bar *d*, and carrying the other point; it has a projection above it, in which the screw works; *f* and *g* are two pieces jointed to the points at one end, and to a small handle *b*. at the other, which is used to hold them by. The head *l* of the screw is divided into equal parts, which divisions are read against a projecting part of the piece, holding the point *a*, and by turning it round one of the divisions, the points are moved some fractional part of an inch, as $\frac{1}{10}$, or $\frac{1}{100}$, according to the number of threads in an inch of the screw's length, and the number of divisions on the lead of the screw.

COMPASSES, *Caliber*. See CALIBER.

COMPASSES, *Clock-makers*, are very substantial, serving to cut pasteboard, brass, &c. jointed like the common compasses with a quadrant, or bow, as the *spring compasses*, only its use is different; as serving here to keep the instrument firm at one opening. See CLOCK.

COMPASSES, *cylindrical and spherical*, used in taking the diameter, thickness, or caliber of round or cylindrical bodies; such as cannons, balls, pipes, &c. They consist of four branches joined in a centre, two of them circular, and two flat, a little bent at the ends.

To use them, one of the flat points is put within the cannon, the other without: the two opposite points shew the thickness. See CALIBER *Compass*.

There are also *spherical compasses*, differing in nothing from the common ones, but that their legs are arched, serving to take the diameters of round bodies, &c. Another sort of compasses has been lately invented, for measuring the diameter of round bodies, as balls, &c. which consist of two flat pieces of metal, set at right angles, in a straight bar or beam of the same; the one being fixed, and the other sliding along it, so far as just to receive the round body between them; and then its diameter, or distance between the two pieces, is shewn by the divisions marked on the beam.

COMPASSES, *Elliptic*. Their use is to draw ellipses, or ovals of any kind: they consist of a beam *AB* (*Plate, Compasses, fig. 5.*) about a foot long, bearing three cursors; to one of which may be screwed points of any kind: to the bottom of the other two are rivetted two sliding dove-tails, adjusted in grooves made in the cross branches of the beam. The dove-tails having a motion every way, by turning about the long branch, go backwards and forwards along the cross: so that when the beam has gone half-way about, one of these will have moved the whole length of one of the branches; and when the beam has got quite round, the same dove-tail has got back the whole length of the branch. Understand the same of the other dove-tail.

Note. the distance between the two sliding dove-tails is the distance between the two foci of the ellipsis; so that by changing that distance, the ellipsis will be rounder or slenderer. Under the ends of the branches of the cross are placed four steel points to keep it fast.

The use of this compass is easy; by turning round the long branch, the ink, pencil, or other point, will draw the ellipsis required. Its figure shews both its use and construction.

COMPASSES, *German*, whose legs are a little bent outwards towards the top; so that, when shut, only the points meet.

COMPASSES, *Hair*, so contrived within side, as to take an extent to a hair's breadth. The outward appearance of the hair compasses is like that of a common pair of compasses; the peculiarity consists in one of the legs *A*, being attached to the brass by a spring *B* (*fig. 6.*), whose action throws the leg inwards, and is counteracted by a small screw *D*; by turning which the leg can be moved small distances, and set to the greatest nicety, without moving the joint.

Fig. 7. represents a pair of pocket compasses, the legs, *a, b*, of which are hollow, and contain, the one a pen, *d*, and the other a port-crayon *e*, at the opposite end of each point, *f* and *g*.

COMPASSES, *Lapidary's*, a piece of wood in form of the shaft of a plane, cleft a-top, as far as half its length; where-with they measure the angles, &c. of the precious stones, as they cut them. In the cleft is a little brass rule, fastened there, at one end, by a pin; but so that it may be moved in the manner of the level; with this kind of square they take the angles of the stones, laying them on the shaft as they cut them.

COMPASSES, *Proportional*, are those whose joint lies between the points terminating each leg: they are either *simple* or *compound*. In the former sort the centre is fixed, so that one pair of these serves only for one proportion.

COMPASSES, *Compound proportional*, consist of two branches (*see fig. 8.*), each pointed at either end with steel: the length of the branches is cut through, for a cursor to slide up and down; in the middle of which cursor is a screw, serving to join the branches, and to fix them at any point required.

On the one leg are divisions, serving to divide lines into any number of equal parts, for reducing of figures, &c. On the other are numbers, for inscribing any regular polygon in a circle proposed.

The use of the first is easy: Suppose *v. gr.* a right line required to be divided into three equal parts; push the cursor till the screw be just on the figure 3; where fixing it, take the length of the given line between the two longest parts of the legs: the distance between the two shortest will be one third of the given line. In the same manner may the line be divided into any other number of parts.

For the use of the line of polygons: Suppose, *v. gr.* a pentagon required to be inscribed in a circle: push the cursor till the middle of the screw be against 5, the number of sides in a pentagon; between the shortest parts of the legs take the semidiameter of the circle: the legs thus opened, the distance between the points of the longest parts will be the side of the pentagon to be inscribed in the circle. And thus for a figure of any other number of sides.

Fig. 9. is a pair of proportional compasses; the brass part of the two legs *A, B*, have longitudinal openings in them, for the pin, round which they move as a centre, to slide in, and can be fixed at any place by a screw *a*, so that the distance from the centre to the points *c, d*, shall be twice, three times, (or any other aliquot part) of the distance to the points *e, f*, and of course the openings at each end will be in the same proportion.

Fig. 10. represents a method of adapting a quick and slow motion to a pair of these compasses; *a* is a brass bar, with an oblong opening cut in it, to receive a screw, *b*, fastened to one leg of the compasses; the other end of the bar, *a*, is cut into a screw, with a fine thread, and has a nut, *j*, on it, turning in a collar jointed to the other leg of the compasses. When the screw, *b*, is loose, the compasses can be set to any opening; but when it is fast, they can only

be moved by turning the nut *f*. The screw, *h*, is put into a hole in one of the legs of the compasses, so that it can easily be removed, and inserted into a hole made in the moveable centre *g*, to give it a slow motion if required.

COMPASSES, *Proportional*, with the *sector lines*. The structure of these is so like that of the common proportional compasses, only a little nicer, that it needs no particular description. See *fig. 11*.

The lines on the first face are the line of lines, marked *lines*: it is divided into 100 equal parts, every tenth numbered: and the line of chords, which goes to 60° , is marked *chords*.

On the other face are a line of sines to 90° , and a line of tangents to 45° . On the other side are the tangents from 45° to $71^\circ 34'$; on the other, secants from 0° to $70^\circ 30'$.

For the use of these compasses: 1. To divide a line into any number of equal parts, less than 100: divide 100 by the number of parts required: slip the cursor till the line on the sliding dove-tail be against the quotient on the line of lines; then the whole line being taken between the points of the compasses most remote from the centre, the aperture of the other will shew the division required. 2. A right line given, supposed to be divided into 100 parts, to take any number of those parts; slip the line on the sliding dove-tail to the number of parts required; the whole line being taken between the points farthest from the centre, the aperture of the other two will include the number of divisions required. 3. The radius being given, to find the chord of any arch under 60° ; slip the line on the sliding dove-tail to the degrees required on the line of chords; the radius being taken between the points farthest from the centre of the cursor, the aperture of the other line will be the chord required, provided the number of degrees be greater than 29 ; if it be less, the aperture taken from the radius will leave the chord required. 4. If the chord of an arch under 60° be given, and the radius required, slip the line on the dove-tail to the degrees given on the line of chords; the given chord being taken between the two points next the cursor, the aperture of the other will be the radius required. 5. The radius being given, to find the sine of any number of degrees. Slip the line on the dove-tail to the degree on the line of sines whose sine is required; the radius taken between the points farthest from the cursor, the aperture of the other will give the sine of the angle required. But if the sine sought be less than $30'$, the difference of the apertures of the opposite points will be the sine required. 6. The radius being given, to find the tangent of any number of degrees under 71° : if the tangent required be under $29^\circ 30'$, then slip the line on the dove-tail to the degree proposed on the tangent line; the radius taken between the points farthest from the cursor, the aperture of the others will be the tangent of the degrees required: if the tangent required be above $29^\circ 30'$, but under 45° , the line on the cursor must be slipped to the degrees given on the tangent line; then the radius being taken between the points farthest from the cursor, the aperture of the others will be the tangent. If the tangent required be greater than 45° , but less than $56^\circ 20'$, slip the notch on the tangent side of the turned check to the degree 0 in the tangent line on the side of the compass; the radius taken between the points farthest from the cursor; the difference between the aperture of the other, and these, added together, will be the tangent required. Thus, for the tangents of other degrees under 71 . After the like manner may the secant of any number of degrees under 71 be found.

Mr. Heath, a mathematical instrument-maker in London,

constructed a pair of proportional compasses in 1746, with a curious and useful contrivance for preventing the shorter legs from changing their position, when these compasses were used. It consisted of a small beam soldered to a screw, and running parallel to the leg of the compasses, nearly of the length of the groove; in this beam a slit was made, which admitted of a sliding nut, the other end of which fell into a hole in the bottom of the screw, belonging to the great nut of the compasses. The screw-pin of the beam passed through an adjuster, by means of which the mark on the slider might be brought exactly to any division. But the proportional compasses have been much out of use since the invention of the *sector*, which see.

COMPASSES, *Spring*, or *Dividers*, are made of hardened steel, the head arched; which, by its spring, opens the compasses; the opening being directed by a circular screw, fastened to one leg, and let through the other, worked with a nut.

COMPASSES, *Triangular*. See COMPASSES of three legs, and TRIANGULAR.

COMPASSES, *Trifsecing*, the invention of M. Tarragon, for the trifsection of angles, geometrically.

The instrument consists of two central rules, and an arch of a circle of 120 degrees, immovable, with its radius; the radius is fastened with one of the central rules, like the two legs of a sector, that the central rule may be carried through all the points of the circumference of the arch. The radius and rule must be as thin as possible, and the rule fastened to the radius hammered cold, to acquire an elasticity; the breadth of the other central rule must be triple the breadth of the radius. In this rule there is a groove, with a dove-tail, to be fastened on it, for its motion; in the centre of each rule must likewise be a hole. See the *Journ. des Sçavans*, Sept. 1688.

COMPASSES, *Turn-up*, a late contrivance to save the trouble of changing the points; the body is like the common compasses; towards the bottom of the legs, without side, are added two other points, beside the usual ones; the one carrying a drawing pen-point, the other a port-crayon; both adjusted so as to turn round, and so be in the way of use, or out of it, as occasion requires.

The points of small compasses are tempered by a lamp and blow-pipe, heating them red-hot; when cold, they are hard: the larger are tempered by a charcoal fire and a blow-pipe, heating them to a cherry colour, then plunging them in water.

See M. Bion's Construction and Uses of Mathematical Instruments, by Stone; and Robertson's Treatise on the same subject.

COMPASSEMENT *de feux*, in *Military Language*, a manner of fixing the distances between the chambers of mines, and disposing of the fauciflons, so as to communicate the fire to them at one and the same instant of time.

COMPASSING, in *Naval Architecture*, a term used to denote such pieces of timber as are incurved into the figure of an arch.

COMPASSING the *king's death*, in *Law*. See TREASON.

COMPASSION, in *Ethics*, a mixed passion, compounded of love and sorrow, and excited by the sight or recital of distress; or, as Dr. Hartley concisely defines it, it is the uneasiness which a man feels at the misery of another. Accordingly he traces it to several associations, both in children and adults, upon which it seems to be grounded; and he observes, that persons, whose nerves are easily irritable, and those who have experienced great trials and afflictions, are in general, more disposed to compassion than others; and that we are most apt to pity in those diseases and calamities

which we either have felt already, or apprehend ourselves in danger of feeling hereafter. A compassionate temper, says this writer, being great matter of praise to those who are endued with it, and the actions which flow from it being a duty incumbent on all, men are led to practise these actions, and to inculcate upon themselves the motives of compassion, by attending to distress, actually present, or described in history, real or fictitious.

Hobbes makes this a merely selfish passion, and defines it, as being fear for ourselves; Hutcheson resolves it into *Instinct*; but Dr. Butler much more properly considers compassion as an original, distinct, particular affection in human nature.

According to Dr. Cogan, in his "Treatise on the Passions," compassion is that species of affection, which is excited either by the actual distress of its object, or by some impending calamity which appears inevitable. It is, says this writer, a benevolent sorrow at their suffering or approaching misery. The etymology of the word expresses this idea with strict propriety, as it signifies "suffering with the object." Compassion is always connected with a disposition to relieve, and will always prompt to vigorous exertion, wherever there is a possibility of success; unless some important considerations should render the endeavour improper or unjust. It has no necessary connection with the character of its objects; their distress being a sufficient excitement. From the great extent and universality of this affection, it may be justly considered as a generic name, comprehending several other affections which have a more specific application, as *mercy*, *commiseration*, *pity*, &c. Dr. Reid remarks, that it seems to be false religion alone that is able to check the tear of compassion. We are told, he says, that in Portugal and Spain, a man condemned to be burned as an obdurate heretic, meets with no compassion, even from the multitude; observing, that they are taught to look upon him as the enemy of God, and doomed to hell fire. But should not this very circumstance, he adds, move compassion? Surely it would, if they were not taught that, in this case, it is a crime to show compassion, or even to feel it. Hobbes of Human Nature, cap. ix. sect. 10. Hutcheson's Enquiry into Moral Good and Evil. Butler's Sermons, serm. v. and vi. Hartley's Observations on Man. Cogan on the Passions. Reid's Essays on the Active Powers of Man, ch. iv.

COMPATIBLE, something that may suit, or consist with another. See **INCOMPATIBLE**.

COMPENDIUM, an abstract, epitome, or reduction of a large matter into a little compass. See **ABSTRACT** and **EPITOME**.

COMPENSATION, an action whereby any thing is admitted as an equivalent to another.

COMPENSATION, in the *Civil Law*, is a kind of right, whereby a debtor pursued by his creditor, for the payment of a debt, demands that the debt may be *compensated* with what is owing him by the creditor. *Compensation* is equivalent to payment, and answers to that which is called *Set-off*, in common law.

COMPENSATION-BALANCE, in *Horology*, is the balance of a chronometer, so ingeniously contrived, that two opposite actions counteract each other's natural effects at all times upon it, and equalise its momentum under all the changes of temperature experienced in different climates and seasons. The opposition of two natural effects, produced by an artificial arrangement of the acting parts, is very properly called the *compensation*, which has been effected in various ways. The most simple compensation that has been produced in a machine for measuring time, is that

which depends upon the variable fluidity of the oil applied to the pivot holes of the balance arbor, and of the arbors of a watch; oil, it is well known, however good, is more fluid in hot weather than in cold, and therefore diminishes the friction at the pivots more in summer than in winter, the consequence of which variation in the friction of a watch with the ordinary crown-wheel escapement, would have its rate accelerated in the former season, and retarded in the latter, by this simple cause, if there were no compensating property in the structure of some part of the mechanism; this property naturally exists in the balance and balance-spring, both which are subject to have their dimensions enlarged by heat, and contracted by cold; and these changes alternately occasion retardations and accelerations in the rate of going; but in such a way, that when the watch is disposed to have its rate accelerated by the most fluid state of the oil, it is also disposed to have the same retarded by the contemporary enlargement of the balance and balance-spring; hence the quantity that one of these dispositions prevails over the other in any watch, when regulated to mean time at a mean temperature, constitutes its liability to vary its rate of going in different months of the year. Berthoud, who attempted to proportion the thickness of his pivots to suit the oil with a given balance, so as to produce an approximation towards a good compensation, has called this the *natural compensation*, which is a very proper appellation, as it exists in a certain degree in all chronometers and watches that have oil applied to them. This natural compensation, however, is found to be a very imperfect one, and unfortunately interferes with the effects produced by the better compensations, which, in opposition to this, may be called the *artificial compensations*. To banish the interference of the variable effects produced by oil, is one of the difficulties, and indeed now the principal one, that opposes the efforts of the chronometer-maker, to make the action of his mechanism permanently uniform.

The mechanism of the artificial compensations may be arranged under three divisions, *viz.* 1st, That which applies exclusively to the balance-spring; 2dly, That which applies exclusively to the balance itself; and, 3dly, That which applies partly to the spring and partly to the balance: for the sake of order, we propose to describe the different compensation-balances agreeably to these divisions, which are also nearly agreeable to the order of time in which they were invented.

Compensations at the Spring.

1. *Harrison's Compensation Curb*.—We have said, under our article **CHRONOMETER**, that Mr. James Harrison of Barton, in Lincolnshire, was the first person who applied a self-compensating piece of mechanism to the balance of a watch, which contrivance, according to his provincial dialect, he called a *curb*, and which we have taken the liberty to name a *curb*. Fig. 1. of Plate XXVIII. of *Horology*, represents the balance, balance-spring, small cocks, and curb, as they would be seen by an eye placed directly over the back of the pillar-plate, when the large cock is taken off, that bears the verge-pivot: AA is the plate on which the mechanism is placed; B the balance of one uniform metal; C the spiral spring of regulation; DE the thermometrical curb, so contrived as to lengthen the effective length of the spring in the different degrees of temperature, without manual adjustment; Gg a double cock to which the curb DE is attached; and F the small cock, or stud, to which the exterior end of the spring is pinned. The thermometrical curb, DE, is composed of two long slender slips, one of brass and the other of steel,

joined together in different places, and is attached to the smaller half *g* of the double cock G *g*, so that it may be brought nearer to G, or removed farther from it at pleasure, before *g* is fixed to G, in order to place it at the requisite point between *a* and *b* of the spiral; the double cock is represented in the figure as though it were fixed fast by a screw and steady pin to the plate; but in the original time-keepers, it was adjustable between two parallel pieces, that allowed it to approach the fluid F, or recede from it, for the purpose of ascertaining particularly the best length of the curb, for effecting the requisite compensation: the side of the curb next to D was steel, and the side next to E brass, and the effect produced by changes of temperature was thus: when the time-keeper was exposed to heat, the balance, and balance spring, had their dimensions enlarged, so that the momentum of the balance was increased, supposing its arc of vibration unaltered, and the force of the spring was diminished, or at least would have been by its elongation, if the curb had not been applied; and the natural consequence would have been for the piece to retard; but the same heat, which naturally produces these changes in the balance and balance spring, produces such a change in the shape of the curb, as counteracts these natural effects; in the case of heat, the brass part, E, of the curb becomes more lengthened than the steel part D, by reason of its superior expansibility; the consequence is, that the compound piece, D E, becomes convex on the brass side E, and concave on the steel side D; that is, the remote or free end of the curb, considered as an index, moves from *a* towards *b*, and as this end carries two pins between which the straight end of the spring passes, these pins, and not the fluid, form the limit of length at all times of the regulating spring, which consequently is curved as to its effective length, under all the variety of elongations, that it experiences from different degrees of heat; so that it may be said to be always both lengthening and shortening in nearly the same proportion: on the contrary, when the piece is exposed to cold, or to speak more scientifically, is exposed to a low temperature, the steel side, D, becomes convex, and the brass side, E, concave from its greater contraction, and the free end of the curb moves from *b* towards *a*, thereby mechanically lengthening the spring, as it naturally contracts, in a degree sufficient to check the velocity which the balance would acquire from its diminished dimensions. Thus, whether it is summer or winter, in hot or in cold climates, the compensation curb is calculated to counterbalance the natural effects of changes of temperature on the dimensions of the balance and of its regulating spring.

It has been asserted, that the *elasticity* of the balance-spring is affected by changes of temperature; but we conceive it to be its *force*, or that power which depends on its *length* that is naturally altered, and not, at least in any sensible degree, that property which depends on its *temper*. This contrivance, we have said, in another place, laid the foundation of modern chronometry, though it was afterwards found to be a better application of the compound bar, that the balance itself should bear it, in order that the dimensions of the balance and of the compensation pieces might be affected in a contemporary manner by the variation of atmospheric temperature, so that the artificial changes going on in the balance itself might compensate the changes naturally produced in it and in the spring, instead of the artificial changes in the spring being made to compensate the natural changes in its dimensions, and in those of the balance. We have before said, that this mechanism was invented and used so long ago as the year 1726, and that it is incapable of the usual adjustment for rate, except at the

fixed fluid, from which the fastening pin must necessarily be taken, to admit of the spring's being lengthened or shortened.

Compensation by F. Berthoud.

In the year 1760, which was about seven years before the Board of Longitude published the principles of Harrison's Time-keeper, Mr. F. Berthoud, the famous clock and watch-maker of Paris, contrived and introduced, into No. 1, of his marine clocks, a compensation-curb, acting on the spiral spring of the balance in a manner similar to the action of Harrison's curb, except that the backward and forward motion of his *pince-spiral*, or curb, was produced by the difference of two direct expansions agreeably to the disposition of the grid-iron pendulum, which Harrison had previously invented, (for the description of which see the section, "Astronomical clock," by Mr. Reid of Edinburgh," under the article Clock.) The mechanism by Berthoud, is represented in *fig. 2. of Plate XXVIII.*, the eye being, as before supposed, to be directly over the pillar plate of the frame; the circle ΔA denotes the plate just mentioned; B B, the grid-iron frame, attached to the said plate, and composed of alternate bars of steel and brass, joined together by end-pieces like the compensation-pendulum alluded to, which therefore need not be again minutely described; the pair of brass bars in the middle of the frame, or grid-iron, are those which act by protruding more or less in different degrees of heat against the tail-piece D, of the double lever D E, moveable on an arbor with pivots borne by the plate and cock G, or by G made as a double cock; H is the principal cock, in which the balance pivot runs in the triangular hole, made by three friction-rollers, not shewn in the figure; the *pince-spiral* *b*, and arm *a* are fast to an arbor which is pivoted into the cock H, and a small cock under it, which is attached to it; this arbor is parallel to the balance verge, and is so contiguous to it, as to be in one of the eccentric points, from which the spiral of the spring which it holds is geometrically described; that is, at half the distance from the verge, that the two nearest spirals are from each other; on each of these two levers, *a* and *b*, is a sliding piece of metal; that on *a* for the lever E to rest against, and that on *b* to have a slit for receiving the thread of the spiral spring; they are both fixed by pressing screws to their respective levers, when adjusted to their proper places thereon; but *b* is prolonged to *d*, which is attached to the graduated L piece by the screw *e*, and this L piece has a pointer, used as an index for the graduations on the bridge I, that lies across the grid-iron frame, when attached to the plate ΔA . K is a spring, pressing against a tail-piece of the lever *a* to keep it always in contact with the lever E; C is the spiral regulating spring, as in an ordinary watch, and F an adjustable fluid, for the exterior end of the spring, with an oblong perforation for the pressing screw; the interior end of the spring being fast to a collet on the verge, which is adjustable by friction. The mechanical action is thus produced; the difference of the expansibilities of the steel and brass rods of the grid-iron frame becomes sensible at the pin D, in the tail-piece of the bent lever D E, moveable in a point of bridge G, between those two letters; the part E, being longer from the centre of motion than the part D, which is acted on, moves faster and carries before it the lever *a*, and together with it the *pince-spiral* *b*, and L piece with the screw *e*; and it is obvious, that, as the sliding piece, borne by lever *a*, limits its effective length from its place of contact with lever E, the relative lengths of these two levers may be varied at pleasure by adjustment, till the effect produced

duced on the spring by the grid-iron frame, through the medium of these levers, is according to its due quantity; and the pince-spiral will go and come in a manner similar to the motion of Harrison's curb, though the law of their motion is different, one depending on direct expansion, and the other on lateral curvature. The graduations of the L piece are for bringing the machine to time, the end, *d*, being the index, and the screw, *e*, the instrument of adjustment; and the index of the L piece shows, on the graduated cock I, the situation of the pince-spiral under all the variations of temperature. Besides Nos. 1, Nos. 3, and 8 of the marine-pieces of this author had the compensation we have here described, which, though complex, would no doubt answer its purpose as well as Harrison's more simple contrivance; and though the idea did not originate with the contriver, yet it will be acknowledged, that there is evident ingenuity in the arrangement and adaptation of the acting parts of the mechanism; the effect also produced by the mechanism before us must be regular and permanent, when the materials are good, and the work well executed. (See "Traité des Horloges Marines" par F. Berthoud. Paris 1773.)

Harrison's Compensation improved by F. Berthoud.

After the Board of Longitude had published the principles of Mr. Harrison's Time-keeper, Mr. F. Berthoud perceived that Harrison's compensation-balance might be improved by introducing the action of a lever, capable of adjustment for any given quantity of effect, without moving the cock that holds the compensation bar; the construction he adopted was thus: A, in fig. 3; of the plate already named, is the cock for the balance pivot, ("Histoire de la Mesure du Temps") which balance is not necessary to be shewn, B is the curb lever, detached from the compensation bar, and turning on a short arbor pivoted into the cock A, and an under cock borne by this not seen, the centre of its motion being at one side of the balance verge, as in Berthoud's former balance; the spring under the cock, that urges it towards the screw C, is concealed from sight; C is the compound or compensation bar, fixed in the chops of a fast bridge D, and having, at its free end, a screw with its point bearing on the tail-piece H of the curb-lever B, which curb-lever has a sliding piece with a narrow groove to admit the thread of the spring, and is fixed by a pressing screw in any given situation; E is what the French call a *piton*, or adjustable frame of the stud, standing on four screws, as feet, which allow it to be brought into the plane of the spiral-spring, so as not to force it from its natural position; the stud F, that holds the exterior end of the spring slides in the *piton*, when under adjustment for distance, and is then fixed by a pressing screw, passing through the contiguous end of the spring G, which turns on a stud or screw, at its remote end when loose. The manner in which this mechanism acts will be readily apprehended from what we have said of Harrison's, and the preceding compensation curb, of which it constitutes an union, thus: when the temperature is high, the compound bar, C, is affected exactly in the way we have just described Harrison's to be affected, and the chops of the bridge, D, allow the lengths of the curb lever B, and of its tail-piece, pressed by the screw, to be adjusted according to any given ratio as they respect each other; and as the quantity of effect to be produced on the spiral spring depends upon this ratio, with a given compound bar balance, escapement, and maintaining power, it is obvious that the adjustment for temperature may be brought to the requisite degree of exactness by a few successive trials in the opposite extremes of temperature.

The Application of Harrison's Curb to a common Watch.

After Berthoud had made the alterations, which we have just described, in Harrison's curb, he turned his mind towards simplifying it so as to become useful in a common watch; the manner in which he succeeded in doing this is shewn in fig. 4 of our present plate, where it will appear by inspection how the action takes place, particularly as we have placed the same letters of reference to the same parts, as in fig. 3; the difference of the two contrivances consists chiefly in the stud, F, being here fixed fast to the circular plate of the frame; in the curb-lever being bent and having its centre of motion on a separate small bridge, H; and in the opposing spring, K, being attached to the face of the plate itself; otherwise the adjustment for temperature is performed as in fig. 3, and is equally capable of taking in the extreme limits of temperature. (For another disposition somewhat similar to the present one, see Berthoud's "Supplément au Traité des Horloges Marines." Plate III. fig. 8.)

Compensation by Mr. Alexander Cumming.

Mr. Cumming published his book on "The Elements of Clock and Watch-work," in the year 1766, in which he has given an ingenious though complex method of compensating the effects of heat and cold on the balance and balance-spring, different from the foregoing ones, and depending on the difference of the direct expansions of two separate and different metals, aided, like Berthoud's, by the introduction of adjustable levers; whether the invention preceded or followed Berthoud's grid-iron frame and lever, is a consideration which does not, perhaps, affect either of their two claims to originality, as Harrison's curb was most probably heard of, if not previously known, by both the mechanists in question; nor does it appear that either of the two complex methods here spoken of has been copied by others in practice. Fig. 1. of Plate XXX. of *Horology*, represents a view of Cumming's mechanism of compensation, without the balance, as viewed by the eye placed directly above it, when fixed to the back of the pillar-plate of the frame. The outermost circular rim, AAA, is of steel, and has eleven small rollers revolving on as many pins or studs inserted into the plane of the rim, and the interior rim, BBB, which rests against the rollers, is of brass, but is not an entire circle: one end of this interior, or brass rim, is screwed fast to the plane of the steel rim, by means of its enlarged extremity being made to lie upon the plane of the steel rim, as shewn in the figure; in this situation it is clear that the excess of the brass rim's expansibility will make its opposite ends approach each other in a high temperature, and recede in a low one, while the friction-rollers will prevent jerks; hence any object opposed to the free end of the brass rim will be pushed forwards by it, as the temperature is raised, which effect affords the means of alternately lengthening and shortening the spiral spring of the balance in the following manner; the free end of the brass rim presses against the end, *a*, of a lever moveable on a stud about the middle of it, and the oblong slit made in the opposite end of the same lever receives a pin inserted into the contiguous end of a second lever *b*, moveable about its remote end round a socket concentric with the balance-verge, or nearly so; the lever, *b*, which may be called the curb-lever, has two pins in underneath, not seen in the drawing, between which the outermost thread of the spiral spring passes; hence it is plain, from an inspection of the figure, that when the end, *a*, of the slit lever is pushed outwards, its opposite end draws inwards the pin of the curb-lever, and with it the curb, so as to shorten the active length of

the spring in this case; and on the contrary, when the brass rim shortens by a low temperature, the contrary effect takes place: for the end, *a*, of the slit lever follows the free end of the said rim as it retires in contracting, in consequence of a spring, not seen, impelling it into contact with this end at all times; the ratio of the two acting ends of the two levers from their respective centres of motion is adjusted by the horizontal arbor, *d*, squared at the end to receive a key; for as the interior end of this arbor is formed into a screw that passes into a tapped hole in a square nut on which is the centre of motion of the slit lever; the said square nut is made to slide in an oblong hole of the plate below the lever; and thus the different parts of the slit may be made, successively, to impel the pin of the curb-lever, as the compensation may be found on trial to require. The balance, of course, is placed above this mechanism, and vibrates free from it. We observe that in the original drawing given by Cumming, (*fig. 5* of his *Plate XIV.*) the spiral is made to turn the wrong way about, so that the effect of heat will be to elongate the spring, which contraction would double the natural effect of variations of temperature instead of compensating them, as the contrivance is intended to do, and would do, if rightly constructed; but we see no reason to doubt this being as effectual and permanent as any of the foregoing modes of producing a compensation, when the spiral is bent the right way round, as we have placed it.

Berthoud's Compensation by a Brass Arch.

Another method of producing a compensation, different from any of the preceding ones, in its mode of application, comes next under our consideration, as another production of the French clock and watch maker, whose name we have had frequent occasion to mention with respect.

Fig. 5, of *Plate XXVIII.* exhibits the plan of all the essential parts of this contrivance, in an intelligible manner; *A*, as usual, is the principal cock over the pillar plate; *B*, the balance of one metal; *C*, the spiral spring; *D*, an arch of brass with its ends resting in two sloping notches filed into the steel bar, *E*, which is fixed by a screw, near *E*, in the middle, to the plate, so that it may be at liberty to yield both ways to the action of increased or diminished temperature on its total length; *F* is, as before, the stud to hold the exterior end of the spring, while the interior one is fast to a collet on the balance-veerge; *G*, is a bent lever, with a pin in its short end, *g*, and its long end pointed as an index, to reach to the divisions, *H*, made on the plane of the plate, which bears the mechanism; the effect is thus produced; the brass arch, *D*, being elongated than the freight steel bar, *E*, with the long increase of heat; this arch carries a small screw, the head of which is just opposite the pin, *g*, already mentioned, between which screw and pin the outermost coil of the spiral spring passes; now if the screw and pin were made to approach, till they both should touch the spring at opposite sides, they would become in place of a curb, and there limit the length of the spring that comes into action; on the contrary, if they were made to recede from each other, till the spring rested up to the stud, *F*, placed on the plate, they would be inopinionous; but when they are placed at such an intermediate distance from each other that the screw limits the opening of the spiral, and the pin its closing, before the part of the spring near the stud is moved by the motion of the balance, then the natural effective length of the spring is contrained, and the pin and screw together become a species of curb, that limits the effective length of the spring from an undisturbed point, lying somewhere between the stud and the said pin and screw; which indiscriminate point will always be nearer to the stud the more the pin and screw are removed

from each other, and *vice versa*; hence it is easy to see, that moving the index, *G*, forwards or backwards, on the graduated portion of a circle, *H*, will bring the pin, *g*, nearer to, or remove it farther from, the screw head, than a mean distance, and will thence affect the rate depending on the effective length of the spiral spring, with a given balance, maintaining power, and escapement; but it is the same thing if the index be suffered to remain, and the screw be brought nearer to the pin; for the one limits the right hand and the other the left hand excursion of the balance; this is the precise operation of the contrivance; the superior elongation of the brass arch over the steel bar shortens the radius of curvature of the arch, and makes the screw-head approach the spring, more or less, agreeably to the change of temperature, to which the acting parts are exposed. The law by which the approach is effected is somewhat different, however, from that by which an expansion-rim is guided, with one of its ends at liberty; and the manner also in which the effective length of the spring is limited, allows a long scale of lengths, in a corresponding short scale of distances between the screw head and pin; the latter of which laws is evidently disadvantageous to the nicety of the adjustment for temperature; besides, when the brass arch and the steel bar are found on trial not to be in their due proportions to each other, the remedy cannot be applied without varying the original proportions, by lengthening or shortening the verfed line, as the case may be, which alteration will require the mechanism to be displaced.

Improvement on the last Compensation.

Berthoud, having discovered the inconvenience and objections to the last described compensation curb, proposes another in his "Histoire du Temps," tom. ii. p. 101 and 102, thus: *A*, *fig. 6*, *Plate XXVIII.*, is the principal cock, mounted as usual on the pillar plate behind; *B* is again the balance of one metal; *C*, the usual spiral spring; *D d b*, a rack moveable on a socket concentric with the balance verge, with some additional apparatus carried by it; *E* is a second cock; and *F* a third, bearing the *pinion*, or sliding stud, with its frame and securing spring as in *fig. 3* of the same plate already described; *G* is a pinion with an arbor squared at the projecting end, to receive a key, which pinion has its teeth formed suitable to impel the teeth of the rack *D d*; *a* and *b* are two compound bars of brass and steel, soldered together with hard solder, inserted at *d* into a bearing piece, and kept fast by a pressing screw *c*, urging them together with the loose piece, *d*, interposed, and kept parallel by a clamping piece *e*; the rack has a circular perforated groove, which allows it to pass backward and forward by the action of the pinion, while the heads of the two screws, *f* and *g*, confine it to the same plane on the back of the plate; and, lastly, the compound bars, *a* and *b*, have each a pin at their free extremities, which contain between them the last coil of the spiral spring, the action of which is limited precisely in the manner described in our last compensation mechanism; here, however, the law of flexure is again the same as in Harrison's, though the law of limitation in the effective length of the spring is different: the latter, as we have seen, depends on the quantum of play between the pins, whereas, in the former, there was no play at all, and the curb itself was the limit; seeing the effective length of the spring diminishes as the pins approach each other, the exterior laminae of the compound bars, *a* and *b*, must necessarily be brass, and the interior ones steel, to shorten the spring in high temperatures, and the contrary; when the effect produced is too great, the clamping piece, *e*, is carried outwards towards the pins, in order to shorten the bars, which have their lengths measured from this clamp; but when the ef-

fect produced is too little, the said clamp must be brought inwards towards *d*, to lengthen the bars; so that the scale of adjustments here runs along the length of the two parallel compound bars, as it relates to the variations of temperature; while the adjustment for a mean rate is made by the index *b*, which shews the quantum on the contiguous portion of a divided circle. Still, we think, that while a small variation in the play, between the curbing pins, produces a great variation in the effective length of the spring; this contrivance can have no pretensions to rank in utility with some of the more recent inventions, that place the compensating parts on the balance itself.

Compensation by Breguet.

A compensation similar in effect to the two foregoing ones by Berthoud, but more simple than the latter, is that which Breguet of Paris has applied with success to his common watches; this compensation is shewn in *fig. 7 of Plate XXVIII.* where the bounding circle denotes the back plate of the frame; *A* the principal cock; *B* the balance of one metal; *C* the common spiral spring; *D* *de* a three armed piece, called by the French a *rateau*, to which is attached the mechanism of compensation thus: the curvilinear fork, *a b*, is composed of two metals: each prong consisting of a slip of steel and a slip of brass, so attached together, that the steel is the exterior, and the brass the interior part in each; the end *a* is screwed to the lever *D*, and the end *b* is loose, consequently at liberty to approach or recede from the spiral spring, as the changes of temperature affect the fork; the interior end, *a*, of the fork bears a pin near the letter *b*, not seen by reason of the lever *D*, which lies over it, and a second pin similar to the other is carried by the lever *D*, between the two largest coils of the spiral: these two pins limit the effective length of the spring exactly in the way that the two preceding compensating contrivances have been explained to do, for which reason we do not repeat what we have already said on this part of the subject; the alternate inward and outward motions of the pin, *b*, regulate the distance between the two pins, on which the play depends, and consequently the length of the spring also, as it has regard to the action; the prong *a* has a tendency to become straight by heat, in consequence of the concave part being brass, but the prong, *b*, has a tendency to become still more convex in consequence of the brass being the convex part; the joint effect of which alterations of shape and position will be, that, as the balance and its spring become enlarged, the space between the curbing pins will become diminished, and the contrary. The watch is regulated for mean time by the index part *d* of the three-armed *rateau*, and the third arm, *e*, contains a pin about the middle of the spiral spring, which we conceive to be the banking pin, though no mention is made of it in the original description. "Histoire de la Mesure du Temps, by Berthoud."

Compensation by Mr. James Scott.

In May of the year 1805, Mr. James Scott, of Grafton Street, Dublin, published an account in Mr. Nicholson's Journal, (vol. XI. p. 19—21., 8vo. series) of a compensation curb which acts in a manner somewhat analogous to that which we have described as the invention of Cumming; but it is evident he had not previously seen the one alluded to, nor yet Berthoud's, otherwise he would not have said in his letter to Mr. Nicholson, that "artists have not been able to invent a compensation curb adjustable to the exact expansion required." The contrivance now before us is ingenious, and we presume might be applied to an ordinary watch with con-

siderable advantage; though we cannot persuade ourselves that any method of curbing the regulating spring, after it has been adjusted for isochronism, affords so good a compensation, as the mechanism of compensation now usually applied to the balance itself. *Fig. 2 of Plate XXX of Horology*, shews all the parts of Mr. Scott's compensation-curb, as given by himself in the original account; but as his description did not seem very intelligible to us at the first reading, we hope to be excused the liberty we take of giving our own account of the contrivance: *A A* is an index of steel, with a circular part embracing a dove-tailed groove that surrounds the balance verge in the upper plate of the frame; to this steel index is attached, by a screw and steady pin, one end of a compound circular bar, *B B*, so formed, that the steel part is the exterior, and the brass part the interior; to this compound bar is fastened a second compound bar *C C*, also circular, by means of a clamping piece and screw at *D*; a loose piece of metal, interposed between the two circular bars, being pressed by the screw, the outer one keeps the inner one close to the shoulder of the clamping piece, which cannot be seen in the figure; but it is easy to conceive that such a clamping piece will apply at any part of the circular bars; the bar, *C C*, has the brass part exterior, and the steel part interior; *E* is the stud in the plate, that holds the outward end of the spiral regulating spring, intended to be curbed; and the interior compound bar, *C C*, passes between two steady pins, inserted in the plate at *a*, a short distance from *b*, where the curbing pins are fixed, that embrace the last coil of the spring: whenever the index, *A A*, is moved, in regulating for mean time, it carries with it the two concentric compound bars, and the curbing pins slide along the coil of the spring, so as to lengthen or shorten it as the case may be; suppose, now, that the regulation for rate be made, and that the balance has its temperature elevated, the tendency of the outer circular bar will be to open, or enlarge its radius of curvature, which action will bring the interior compound bar and its curbing pins nearer to the index, and shorten the balance spring a little; but this action is not sufficient to produce the whole requisite effect; the tendency of the interior circular bar *C C*, on the contrary, is to close, that is, to approach the index, in consequence of its radius of curvature becoming shorter, while its end at *D* is clamped to the free end of *B B*; and it is the amount of these two contemporary motions, produced in the interior compound bar, *C C*, that constitutes the motion of the curbing pins at *b*, along the spiral spring, in a direction towards the index *A A*. In a low temperature, just the reverse takes place; the outer compound bar, *B B*, has its radius of curvature shortened, and the inner one, *C C*, has its radius of curvature, on the contrary, lengthened in this case, so that the joint effect is to make the curbing pins retire from the index to lengthen the regulating spring; which alternate lengthening and shortening of the balance-spring's effective length in heat and cold, form the compensation for the corresponding variations in the momentum of the balance and force of the spring. The excellence of the present contrivance consists in its affording a scale of adjustments; for moving the clamping piece, *D*, forwards, towards the middle of the concentric circular bars of compensation, lessens the effect, and removing them back, towards the open ends, increases the effect to be produced on the balance spring, by giving a greater or smaller range of motion to the curbing pins. The inventor's rule for the thickness of the compound bars is, that each lamina be of the thickness of an ordinary main spring of a common watch, so that the compound pieces may be each of twice the said thickness.

COMPENSATIONS on the Balance.—*Thermometer of Peter le Roy.*

We have said under our article CHRONOMETER, that Harrison was the first person who suggested the idea of the balance carrying its own compensation, and Peter le Roy was the first who in 1766 succeeded in such a construction; in our notice of this invention, however, there is a typographical omission which we beg leave to correct here before we proceed to our description; it is said under the article just referred to, that the compensation was effected "by means of two thermometers, one of mercury and the other of alcohol, attached to, and carried by, the balance itself;" instead of ("one end of each bearing mercury, and the other end alcohol, &c." as will now be more clearly understood. *Figs. 1 and 2 of Plate XIX. of Horology*, exhibit so much of the balance of Peter le Roy as is necessary for explaining its construction; A A, in *fig. 1*, is a portion of the arbor or verge to which the balance B is attached by screws; C is a small ring attached to the inferior part of the verge which holds the two screws of regulation for mean time, and which also clamps the horizontal parts of the two glass thermometrical bent tubes, D and E, placed diametrically opposite to each other, one of which is seen in a detached state in *fig. 2*; these tubes are also held fast by two other clamps, to the middle of the verge, as may be seen in *fig. 1*; the inferior end of the straight vertical part of each tube is open to admit the pressure of the atmosphere on the mercury, which is now seen standing at the same level in both the upright portions of each thermometer. after the inferior or horizontal connecting part is filled; but the bulbs and parts above the letters D, and E, are filled at a mean temperature with alcohol, respectively resting on the columns of mercury: when the balance and balance-spring are enlarged by heat, the alcohol has also its bulk increased, and descends below the letters D and E, for instance, in very high temperatures as low as the horizontal connecting part, in which case the mercury pressed upon by it descends under the alcohol, but ascends in the same proportion at the other end, till it reaches nearly the open superior end of the vertical straight part of the tubes respectively; the mercury which was before in a column parallel to the verge, but at a distance from it, is now also parallel but contiguous, and, as it is a ponderous fluid, the momentum of the balance is considerably diminished by the approach of the mercury to the centre of motion, which change of position of the mercury constitutes the compensation required to balance the effect of an enlargement of the balance itself, and of an elongation of its regulating spring taken jointly: in a low temperature the contrary change takes place in the situation of the mercury, for as the bulk of the alcohol contracts and retires round the acute angular point into the bulb, the exterior vertical branch becomes filled by the mercury. Peter le Roy, we have before said, was disposed to prefer this balance to the balances he made entirely of metal, but the fragility of the bent tubes, and the liability of the fluids to be agitated, if not to be mixed, sometimes constituted objections to its portability, that prevented its being copied by other chronometer makers. The adjustment for the extremes of temperature must have been made by varying the quantity of mercury in a given tube; and probably tubes of various dimensions were tried successively before the exact effect was produced, both at the extremes, and at all the intermediate degrees of temperature. The balance being heavy, was supported by a thread above the superior end, A, and the slender cylindrical part, underneath the same A, rotated in a triangular hole, made by three surrounding friction rollers, not shown in our figure; lastly, two regulating springs, wound in contrary directions,

were placed under the ring, C, near the lower pivot of the verge, which springs are purposely left out, that the reader may not have to view more parts than are necessary for explaining the compensation balance itself.

Compound metallic Balance of P. le Roy.

Peter le Roy, however, was not content with trying his thermometrical tubes, only to effect a compensation on the balance, but he so far adopted Harrison's idea on the requisite construction of a balance, carrying its own compensation in motion, that he tried moreover his compound bars of steel and brass, not, indeed, as curbs, applied to the springs according to Harrison's method, but as rims to the balance itself: *fig. 3 of Plate XXIX.* shews a balance of this contrivance, where A is the diametrical bar fixed to the verge, and BB and CC two separate semicircular portions of the compound rim, which were each composed of laminae of steel and brass respectively riveted together in different places, in such a way that the brass pieces were the exterior or concave ones, and the steel pieces the interior or convex ones; the loads are not given in the drawing, but the inventor says "Memoire sur la meilleure maniere, &c." that his contrivance made a considerable portion of the circumference to approach the centre of the balance in a high temperature; so that either he must have had loads on the ends of the semicircular parts of the rim, or otherwise these parts themselves must have been thick, which would prevent their due obedience to the variations of temperature. *Fig. 4* is a kind of register contrived to examine the law by which the flexure of a compound bar was guided, as compared with a mercurial thermometer, thus; A is the crosses and rim of a balance of one metal, steel, we will suppose, and the compound piece B, screwed at the end *a*, to the plane of the rim, has its end, *b*, at liberty to obey the changes of temperature; near *b* is a small cock into which a roller, bearing the index C, is pivoted above, against which roller the free end, *b*, of the compound bar, B, acts, whilst the interior end of the index points at the divisions made on the portion of a circle, D, near the centre of the balance: the experiments that were made with this instrument, according to P. le Roy's account, shewed that the rim of the index, so circumstanced, corresponded very well with the rim of a mercurial thermometer, in all the different parts of the scale; and if this was found to be really the case, we cannot help thinking it extraordinary that the contriver of the compound metallic balance, which has stability and portability to recommend it, did not prefer it, in actual practice, to the mercurial balance, which was liable to the objections we have stated.

Arnold's Balances.

Some pains have been taken to prove that Mr. Arnold, senior, did not invent his compensation balances himself, but borrowed them from Peter le Roy; we confess that we have not met with any conclusive argument in favour of such a supposition, but, on the contrary, have asserted under our article CHRONOMETER, that, "a variety of different shapes were given by Arnold to his balances, and actually tried in practice, before he adopted the one in present use, some of which balances are yet in existence;" and we have it now in our power to say further, that many of the balances here alluded to are yet in use, as ourselves have witnessed very lately; which balances have been proved to be excellent regulators, and some of which have public testimonies in their favour. We propose therefore now to describe them in succession, or at least such of them as have fallen in our way.

No. 1. In his preface to his printed certificates, Mr. Arnold, senior, says, that his first attempt to improve clocks and watches commenced in the year 1764; but we find it was not till the year 1767, that he turned his mind seriously to the construction of chronometers; the first compensation balance that he actually brought into use, was the one represented in *fig. 5.* of *Plate XXIX.* which was taken from one of the original balances while in our possession. The rim is 2.4 inches in diameter, and is, together with the three radial arms, of slender brass: the compensation bar is of brass and steel coiled round the balance verge, at a little distance from the mechanism which lies between it and the plane of the balance; the exterior part of this compound spiral bar is brass, and the interior part steel; *a b* is a piece of steel moveable round a tube surrounding the balance verge, and having a longitudinal aperture or slit, each way from the centre to nearly each extremity, *a* and *b* respectively; the end, *a*, is turned up a little, and has the exterior end of the compound spiral bar of compensation attached to it, so as to partake of its motion under all the changes of temperature; *c d* and *e d* are two bracket pieces of metal carrying each a pin under them, that exactly fit the longitudinal slit of the piece, *a b*; consequently these bracket pieces also partake of the motion produced by the compound spiral bar; the ends, *e* and *c*, of the bracket pieces are attached to the balance rims at the points, *e a* and *c*, by the straight slender springs, *e e*, and *c c*, respectively; to the ends *d* and *d*, of the said brackets are attached the long pins, *d f* and *d f*, which pass through the small steady bridges on the rim, and carry the sectoral loads of temperature, *f* and *f*; the action produced on this mechanism by the changes of temperature may be thus explained; when the temperature is elevated, the exterior end of the compensation spiral bar, moves in a direction from *a* towards *c*, and carries with it the end, *a*, of the cross-piece, *a b*, at the same time the opposite end of this piece moves from *b* towards the *e* which is contiguous to it; these opposite motions of the ends, *a* and *b*, of the cross piece carry the two brackets in such direction that the loads of temperature, *f*, and *f*, are both made to approach the balance, so as to lessen its momentum when in motion; which is the effect required in the above-named temperature; on the contrary, when the temperature is low, the motion of the ends, *a* and *b*, is towards *d* and *d* respectively, and the loads of temperature are thrown outwards, to increase the momentum of the moving balance. The quantum of effect is regulated by enlarging or diminishing the loads, *f*, *f*, of temperature, as compared with the screws, *g* and *g*, or weights of adjustment for mean time; or otherwise, by screwing them into a new situation, cut or in, as the case may be; the springs, *e e* and *c c*, do not interfere with the inward and outward motions of the loads of temperature, but only confine the brackets to the plane of their action, and limit the direction of their motion. This compensation-balance was applied to ten or twelve different chronometers, between the years 1775 and 1778, but we have not been able to ascertain its comparative merit; its principle is simple, in that there is but one compound bar, to move two loads of temperature, but its mechanism is complex, which was probably the principal reason why it came into disuse.

No. 2. The next balance, which Mr. Arnold contrived, was that which is represented in *fig. 6.* of *Plate XXIX.* in which the mechanism is much more simple than in its predecessor; the rim and diametrical bar, by which it is attached to the verge-collet, are both steel, the parallel bars, *a b* and *a b*, are composed of brass and steel respectively, the brass being here interior and the steel exterior, and

are inserted into pivot-holes made in the rim of the balance; in some of the chronometers, the end, *b*, was fast to the balance, and the end, *a*, of the same bar loose, while the end, *a*, of the other bar was fast, and the end, *b*, of the same was loose, but in other chronometers both the ends of each bar were formed into pivots with shoulders, and were inserted loosely by bending the bars about the middle; the cross pieces, *c* and *c*, which carry the loads of temperature, are of steel, and the rim itself is so notched as to admit of the loads being contiguous, that they may meet with very little resistance from the air, when in motion; the mode of action is obvious from a view of the figure, and from what has been previously said of a straight compound bar, being liable to become convex on the brass side by an elevated temperature, and the reverse in an opposite temperature; the bars, *a b* and *a b*, becoming convex, with increased heat, towards the centre of the balance, draw the loads, *d* and *d*, nearer to the rim, than they are when the bars are straight at a mean temperature, and, on the contrary, as the heat diminishes, the same parallel bars become convex on the sides next the rim, and carry the loads from the balance; and these alternations of motion, keeping pace with the changes made in the dimensions of the balance itself and of the balance-spring, constitute the compensation for the effects of temperature: the exact quantum of effect is adjusted as before, by altering the magnitude of the loads, *d* and *d*, as compared with the weights of the adjustment-screws, *e* and *e*, for mean time; or otherwise have their relative positions altered in regard to their distances from the centre. About twenty of these balances were made and applied as regulators, all of which performed their office, we are told, very well; the famous gold chronometer, No. 36, tried for 18 months by Dr. Maskelyne, at the Royal Observatory, while worn in the pocket, under the different degrees of temperature, agitations of the body, and changes of position, had, and still has, one of these balances; and its rate, which has been published, established its credit so highly, that it was sold for 1000 l. or guineas, notwithstanding the detent of its escapement, after the fashion adopted by the French, is fixed to an arbor revolving on pivots. The balances of the present construction were made from the year 1778 to the year 1783, and the only objection we have heard alleged against them, was the play they necessarily had in their pivot-holes, which we think must have been scarcely perceptible when the pivots were well made and fitted tight into their holes.

No. 3. The objection to the motion at the pivot holes in the last balance, (No. 2.) was attempted to be remedied by the construction exhibited in *fig. 7.* of the same plate, where the expansion pieces are of brass and steel, arranged in the form of a long S, which form was afterwards adopted by Emery, the Swiss watch-maker, who settled in London, and who has been the reputed inventor of this arrangement; the two halves of the S are joined at the middle, and the brass, as before, is interior throughout; the rim and diametrical bar of steel, in the balance we examined, which was 1.2 inches only in diameter, by reason of its having been used in a pocket-chronometer; the exterior end, *a*, of the S is attached to one of the shortened crosses of the balance, and the interior end of the same bears the long pins, *c* and *c*, that carry the loads of compensation *d* and *d*; the long pins, *c* and *c*, do not pass through the rim, but are held to their proper positions by the two slender springs, *e e* and *e e*, as in No. 1, or *fig. 5.* as before, the relative weights of the loads of compensation, *d*, *d*, and *f*, *f*, the loads of adjustment for mean time, constitute the limit of effect to be produced by the expansion bars,

sup^o

supposing their distances from the centre fixed; but if the loads remain unaltered, the effect to be produced may be adjusted by varying the distances of the screws respectively as they regard the centre of the balance. Of these balances about forty were made and applied to use between the years 1779 and 1782, and have been found to perform well.

No. 4. The length of the S pieces in the last balance having been found difficult to execute of uniform thickness and shape, by reason of their great length, the construction represented by *fig.* 8. was substituted, which is very nearly allied to its predecessor, and indeed differs from it only as the bends are united by an interposed piece of solid metal, thereby dividing what was before one half of the S, into two parallel compound bars; in all other respects, the description just given of No. 3, together with the letters of reference, will equally apply to our present balance; which circumstance renders a further detail superfluous.

Of these balances not more than six or eight were constructed, by reason of the more simple form, which is now in general use, having been adopted in 1782, when a patent was taken out for it. The specification, however, contains the drawings of Nos. 2 and 3 (*figs.* 6 and 7), as well as of the common balance, which we have fully described under our article CHRONOMETER, to which the reader is respectfully referred, and which was known to the workmen by the name of the Z balance, by way of distinction from the S balance. Besides the above-described constructions of the compensation balance, Arnold, we are assured, contrived various others which never came into use, one of which had the expansion pieces parallel to the verge of the balance, and borne by it; and others had platina in the expansion pieces, instead of steel; but we conceive it to be unnecessary to pursue the subject of his inventions further, than merely to observe, that to regular a succession of different balances actually made and used, where so many were constructed, and where each was evidently meant to be an improvement on the last preceding, may be taken, if not as a positive, at least as a presumptive proof, that the imputation of plagiarism, unless otherwise fairly made out against him, is in contradiction to the facts we have here adduced; which are all facts open to still further investigation.

For the description of the compensation-balance as made by the Brookbanks and Earnshaw, the reader is desired to turn to the article CHRONOMETER, where this part of our present article has been anticipated. The description of Earnshaw's balance and escapement, however, which we have quoted as the production of this chronometer-maker, it may be proper to state, was not his, but the production of Mr. Firminger, the late assistant of Dr. Maskelyne at the Royal Observatory, as we have been assured by the author himself, since the publication of the pamphlet in which it appeared ostensibly as Mr. Earnshaw's own account. And now that we are on the subject of Mr. Earnshaw's balance and escapement, we beg leave to add further here, an acknowledgment of our misinformation respecting the patent, which we were credibly informed, and said, was never taken out; but which we now find, on more minute examination, was actually taken out and registered. How far his pretensions to originality of invention are warranted by his construction, is not the object of our present enquiry.

A Compensation balance by F. Berthoud.

Berthoud informs us, "Hist. de la Mesure, &c." p. 104 tom. ii., that he had proposed a means of compensation by the balance itself, so long ago as in the year 1754; but that it was not until 1787 that he effected his purpose. The

reader is led to suppose, that he was not indebted to P. le Roy, or any other maker, for the contrivance, but that it was the result of his own inventive genius; and that the contrivance was his own is rendered somewhat probable from this consideration, that in his "Traité des Horloges Marines," two balls only were proposed to be used with two compound bars; but after a calculation of the effect to be produced, contained in page 195 of the Supplement, four balls were found to be necessary with as many compensating bars. The proposed arrangement is shewn in *fig.* 9. of plate XXIX, and is certainly original; A, A, A, and A are four radial bars of metal attached to the verge collet of the balance by two screws, as seen in the figure; the slender bars, a, a, a, and a, attached respectively to the exterior ends of the four radial bars by screws and fixing pieces, are four compound bars of steel and brass, the exterior laminae being of brass; and each of those compound bars has at its free end a stem formed into a screw, upon each of which a ball, B, with a long socket, screws towards or from the verge, to adjust the momentum to the maintaining power, and regulating spring, and also to effect the equilibrium, when the machine is brought to time. From what we have repeatedly said of the flexure of a compound bar, it is easy to see, that the brass portions being exterior, will cause the balls to approach the centre of motion in hot weather, and the reverse in cold; which effect constitutes the compensation. The author acknowledges that the exact effect to be produced depends on the relative length and thickness of each compound bar, and that many trials are necessary to come at the due proportion; consequently, the want of an adjustment for temperature, after the balance is tried, is in this construction a fundamental objection to its general adoption; otherwise we see no reason to doubt its accuracy of performance.

This balance was used in No. 8. of Berthoud's marine pieces.

Another Compensation-balance by F. Berthoud.

The compensation-balance which we have just described being found liable to objection, the same author contrived and used, in his No. 63, a different arrangement of the compensation bars, which he again reduced to two, and introduced two additional screws for adjustment of mean time, placed at right angles to the former; the contrivance is shewn in perspective in *fig.* 10. of Plate XXIX., where all the essential parts may be viewed at once: A A is the balance, made light and of the best brass, having four crosses; B and B are the two compensation bars fixed to the rim of the balance at one end, and bearing the screws or weights of temperature, C and C, at the other respectively; and D and D are the screws or weights of adjustment for mean time, borne by two of the opposite crosses, as shewn distinctly in the figure. The balance as usual is attached to the verge collet by a couple of small screws; the exterior laminae of the two compound bars, B and B, are of brass, and the interior ones of steel, so that a high temperature brings them towards the centre of motion, as the balance itself enlarges, and as its spring elongates and becomes weaker. The adjustment for temperature may be made in two ways; either by altering the relative sizes of the screws of temperature and screws of mean time; or otherwise, which is more readily done, by screwing one pair in and the other out, so as to produce a similar effect without taking either of the pairs entirely out; it is hardly necessary to explain that, in all the constructions, when the momentum of the balance consists more of the moving weights of temperature, than of the moving weights of mean time, the effect of the compensation

compensation bars will be the greater in the same proportion, and the contrary; still, however, the quantity of flexure of the compound bars in the present balance remains unaltered, and consequently the velocity of their inward and outward motions is not capable of adjustment in any other way, than by altering the ratio of their length to their thickness respectively, which may be called an alteration rather than an adjustment.

Compensation balance by J. J. Emery.

We have said, under our article CHRONOMETER, that Emery's balance is one of the varieties previously constructed by the senior Arnold, (see his N^o 3.) and the reader will now judge for himself how far our assertion was founded in fact. We take our drawing from Berthoud's figure of Emery's balance, which Sarron took over into France, and which was much admired for the accuracy and permanency of its regulation. Fig. 11 of Plate XXXIX, presents the plane of Emery's balance to the eye placed over it; A A is the balance made with four crosses, the rim of which is brass; B B is a steel flat ring screwed to two of the crosses; C and C are the two compensation bars, each bent twice over into the shape of a long narrow S; D and D are the weights for mean time, formed into adjusting screws to suit the female screws of the protuberances made on the plane of the balance; the screws, E and E, are the adjustable weights for temperature, but are tapped only at the parts nearest their heads; the points being fast to the exterior ends of the compound bars, and the intermediate pins being without threads and moving steadily in the two sockets respectively fixed to the rims, or rather formed out of them in the solid; the S pieces have the brass laminae as usual on the exterior sides, so that at the middle of the S of each compound bar, the position begins to be reversed, in order that the condition may be fulfilled; the interior end of each compound bar presses against the circumference of the steel ring B B, which we have said is fast to two of the crosses; consequently, whenever a change takes place in the temperature of the parts, the whole motion takes place at the foot of the screw of temperature, at each opposite side of the balance. The small interior circle F is the upper end of the cylindrical spring of the balance, together with the pin that holds one end of it, and the part that forms the banking, which have nothing to do with the compensation. In this balance, as in Berthoud's latter one, the adjustment for temperature must necessarily be made, by altering the relative momenta of the screws of mean time, and of the screws of temperature.

Mr. W. Hardy's Compensation-balance.

Among the most recent improvements in chronometry, may justly be reckoned the new compensation-balance of Mr. W. Hardy of Clerkenwell, communicated to the Society of Arts in the Adelphi, in March 1805, and remunerated with thirty guineas. The balance in common use, that brings the weights of temperature alternately towards and from the verge, by simple flexure of the compound rim-pieces, is objectionable, in the opinion of Mr. Hardy and others, on account of these considerations: 1st, The two metals of the compound pieces of the rim, when united by fusion of the brass, are liable to partial separations, which affect the permanency of the adjustment for temperature; 2^{dly}, The variation of the centrifugal force of the weights of temperature in large and small arcs of vibration overpowers the elasticity of the expansion pieces, and affects the momentum of the balance, as adjusted for mean arcs of vi-

bration; the weights being thrown from the centre more in the long arcs than in the short ones; and, 3^{dly}, The adjustments for rate and temperature, however carefully made, will affect the equilibrium of the balance, and the rate of the machine placed in different positions, without subsequent rectifications; to remove these objections, Mr. Hardy has availed himself of the direct expansion of two different metals, where their difference of expansion produces a mechanical action on the loads of temperature, such as bids fair for general introduction in practice.

Fig. 3, of Plate XXX. of *Horology*, exhibits a lateral view of the balance before us, and fig. 4, the balance inverted; A A is the balance arbor or verge of the ordinary construction; B B is a steel diametrical bar, borne by the collet of the verge, 1.6 in. long, 0.232 broad, and 0.033 thick; this steel bar is made uniformly except at the two extremities, which are made narrow, and in each of which a notch is cut in the inferior surface, so far, that the remaining thin metal constitutes a spring above each notch; beyond these springs, which we have laid form a part of each end of the diametrical bar of the balance, are attached two stems at right angles, so as to be parallel to the verge when the small springs are not acted on by any force; the upper parts of the stems, in the original drawing, are formed into screws with threads adapted to the tapped holes of the two balls C, C, which they support, and which are weights of adjustment for temperature, but in our more recent drawing, the weights slide and are fixed by side screws; D, D, are two similar screws for rate which screw respectively into the inferior or thicker parts of the stems, so as to be capable of increasing or diminishing the effective momentum of the balance according to circumstances; and E, E, are screws of adjustment for equilibrium; each end of the steel diametrical bar has, moreover, a stud or shoulder, pointing downwards under the stem just described, which stud cannot be seen in the figure in a separate state; underneath the steel bar, and exactly parallel to it and to each other, are placed two bars of brass, shorter but broader than the steel bar; the length of each is 1.47 in, the breadth 0.078, and the thickness 0.032, like that of the steel; each of the two brass bars has one of its ends secured to one of the studs described, and pressing with its opposite end against the other, but in such a way, that their positions are reversed with respect to the fixing of the ends; the fixed end of the one being contiguous to the free end of the other reciprocally; a second view is given of these bars in fig. 4, where they are represented in an inverted state. The action of the mechanism it is not difficult to understand, though the author has rendered his account somewhat confused by his mention of short levers, which the reader does not see in the figure. When the balance is exposed to heat, the steel bar elongates a little both ways from the verge in the centre, but the two brass bars separately elongate more, and consequently each detached end, having liberty to move a quantity equal to the difference of the two expansions, pushes against the stud or shoulder that is contiguous, and forces it outwards; the slender spring-parts, above the notches of the steel bars, now yield to the forces impressed respectively on the studs, and the parts of the two springs which yield most may be considered as centres of motion of a pair of levers; the distance from the yielding point of each spring to the point urged by the detached end of its brass bar, may be called the length of the short end of each lever, and the distance from the said point of each spring to the centre of the load carried by the nearest stem, may be taken as the length of the long end of the lever, which two ends suppose as 1 to 20 respectively; then if the difference

of the expansions of the steel and one of the brass bars be called *r* outwards, the quantity of inward motion in the same denomination will be *2r*; consequently, the same heat which elongates the steel bar, and carries the balls from the centre of motion, will, at the same time, by the excess of expansibility of the brass bars, bring the same balls inwards towards the same centre, and the two contrary actions may be adjusted, by moving the loads up or down their proper stems, till the opposite effects exactly balance one another; for as those distances that have been denominated the short ends of the levers are variable in length, or very nearly so, varying the longer end only, viz. the distances of the balls from the yielding points of the springs, considered as centres of motion, will alter the ratios, which may be done in the requisite proportion, till the compensation is found in the tentative adjustments to be perfect. When once the exact compensation is effected, it is obvious, that the law by which it is preserved is uniform and constant, as that according to which the grid-iron pendulum is constructed, which experience has proved to be permanently useful in practice. When the balance has its momentum properly adjusted for rate, with a given maintaining power, escapement, and balance-spring, and when the balance is put into an exact state of equilibrium, the stems being at all times either exactly parallel to the verge, or, if inclined a little by the extremes of temperature, alike inclined, it is self-evident, that, under these restrictions, the adjustment of the loads up or down for temperature will not destroy the adjustments of rate, and of equilibrium for the positions, previously made, provided the two loads be of equal weight, and placed in similar positions on their respective stems; and even if one happen to be left a little higher on the stem than the other, no sensible bad effect will be produced thereby, which circumstance is one of the greatest recommendations of the present balance. The effects produced by variations of temperature, are said to be produced not by jerks, but regularly, notwithstanding the united structure of the parts is sufficiently firm; and, lastly, the construction is so simple, that a common workman may succeed in making and putting together the constituent parts of this balance without difficulty.

Compensation on the Balance and also at the Spring.

Double Compensation by Berthoud.—F. Berthoud having experienced much inconvenience, and lost much time in making the adjustments of his balances for rate, temperature, and position, at length determined to avail himself of the curb, as a supplemental aid, in addition to the compensation carried by the balance itself; the union of the two modes of effecting the due compensation, is represented in fig. 5 of Plate XXX. of *Horology*, in such a way that all the acting parts may be seen and understood: A is the balance-rim of brass, and bears four crosses, besides two projecting bars, B, B; these bars carry each a compound or compensation bar, C, of the usual construction, the free ends of which are perforated and attached to the screws or loads of temperature, D and D, or, more properly speaking, to the sliding sockets on which those loads screw in and out, in making the adjustment; E and E are the screws or loads of adjustment for mean time; FF is the cock, and G a small cock, bearing a jewel mounted on it, to take the pivot of the balance. The action of the compensation bars, C and C, needs no explanation, after what we have said about the effect of such pieces borne by other balances: I, is the compensation bar of the curb for the spiral spring, shewn in the figure, and acts on the bent steel bar, K, which

holds the curbing pins, and which has its centre of motion under the cock, at a short distance from the balance-verge; the quantity of action of I on K is regulated by the holding piece, *a*, sliding in a dove-tailed groove, between the parallel bars, *b* and *b*, screwed to the piece N, which piece, N, is movable round a pin under it, near the part, *a*, in such a way as to admit of a little circular motion, together with the compound bar, I, to regulate for mean time without altering the length of I; and a slow motion may be given to the piece, N, by the graduated piece, M, which is moveable on the pivots of its arbor, in the plate and small cock, L, while the tooth, or rounded part, lies in a concave part at the end of N, and impels it almost imperceptibly as the end, M, moves; the graduations of the piece, M, are seen through a hole made in the interior case of the watch; and the adjustment for rate may be made there without trouble, and without deranging the previous adjustments of the balance itself; but then, if there is an isochronism point in the acting length of the spiral spring, the adjustment made by means of the curb will derange its isochronism, which will become sensible as the arc of vibration varies in use; otherwise the adjustment for temperature might be completed by varying the length of the compound bar, I, after this adjustment has been nearly effected on the balance itself, and after the balance has been brought into a state of equilibrium for the positions; but whether the effect produced by the joint agency of two causes, will be uniform in all degrees of temperature, has not been said by the author.

Compensation for the Spring's want of Isochronism.

That property of a balance's regulating spring which makes the balance perform all its vibrations, long, short, and intermediate, precisely in the same time, is called its *isochronal* or *isochronous* property, from the two Greek words *isos*, equal, and *chronos*, time: it has been asserted that there is a certain proportion between the length and thickness, or between the length and the breadth and thickness taken conjointly, which only ascertains the isochronism in any uniform spring, of whatever shape; this doctrine has been maintained by Dr. Hooke and Peter le Roy separately, and has been subscribed to by Arnold the senior, Berthoud, and others, though Pennington of Camberwell says there are different points in the same spring equally isochronal; now allowing that there is only one point in the length of every spring that determines its isochronism, and that consequently all other lengths of the uniform spring regulate the balance uniformly, only while the arcs of vibration remain unchanged, to determine the isochronal effective length of such spring would be to render all compensations, for want of isochronism, unnecessary; and this point may in most springs be ascertained by repeated trials with long and short arcs successively, and by marking down the respective results; for it is found from experiments, that if shortening the regulating spring makes the long arcs of vibration to be performed in less time than the short ones, and *vice versa*, the spring under trial is capable of having its total length reduced gradually till the isochronal length is determined, but, generally speaking, not otherwise. Another method of managing the spring, which may be said to be effecting a species of compensation for want of isochronism, in the total length of an uniform spring, is tapering it from the outer to the inner end, till, with a given length, the long and short arcs are performed in equal times; this method was strongly recommended by Cumming in his Essay towards the improvement of watch-work, and after him, Earnshaw has laid much stress on this particular, so much indeed, that he considers his skill in the adjustment

of the isochronism, by a tapering spring, as constituting one of his chief claims to public encouragement; nay, he professes to manage the business so nicely, that he can make such a slight deviation from perfect isochronism as will compensate the *latitude* also, in the intensity of his springs in use!

The first notice that we have of a regular compensation, for want of perfect isochronism in a regulating spring, is Harrison's, when he proposed to introduce the cycloid-pin which we have already confessed we do not understand, from the want of shading in the drawing of it, as attached to his compensation curb, in the publication by the Board of Longitude; we may, however, state, that Harrison, not knowing, probably, that there is naturally an isochronal length in most uniform springs, concluded, that the long arcs are naturally performed in less time than the short ones, reasoning from the circumstance of one of his pieces having been observed to go faster in a horizontal position, than in a vertical one, though the arc of vibration was shorter in the latter than in the former position; he therefore applied his cycloid-pin, as Mudge did after him, as may be seen in the drawing of his escapement, in such a way that the short vibrations were accelerated by its push more than the long ones, that were not so long acted on by auxiliary means; but the fact is, the use of such a contrivance would necessarily have an effect just opposite to the intended one, if the balance-spring happened to be pinned to the stud at the contrary side of the isochronal point; that is, if the long vibrations were slower than the short ones, the cycloidal contrivance would make the difference still more sensible.

Berthoud's Compensation for want of Isochronism.

Berthoud has given an ingenious method of compensating the want of isochronism in a balance-spring in his "Supplément au Traité des Horloges Marines," which contrivance he calls an *isochronal compensator*. (Compensateur Isochrone.) The contrivance is represented in *fig. 6. of Plate XXX.* where A represents the balance with three radii; B an eccentric collet of polished steel, placed on the balance-veerge, and pressing against the large roller C, which is carried by and pivoted into a small frame at the end of the slender spring D, attached to the cock, E, on the plate of the watch frame, whenever the long vibrations are found by trial to be performed in a longer time than the short ones, the position of B and C are respectively as in the drawing, at the time when the balance-spring is quietest; for then the pressure of the eccentric piece, B, against the roller urged by the spring, is greater in the smaller arcs than in the long ones; but when the long arcs are performed in the least time, the position of B must be at *b*, and then C will be found by the force of its spring at *c*, where it is evident, that the pressure will be less in the short arcs than in the long ones comparatively; and the quantity of eccentricity of B must depend on the greatest difference of the two extreme vibrations. The principal reason why Berthoud adopted this isochronal compensator in five clocks, and in his portable watch for the longitude, was, that whenever the cock was dismounted the isochronism of his spring, however well adjusted, was generally found to be deranged when re-mounted. The eccentric collet was of course capable of being put to any given eccentricity as well as into any given position for accelerating long or short arcs at pleasure. The English watch-makers have not, that we know of, ever used this contrivance, but depend on their own patience and skill, in ascertaining the best length and

most desirable shape of their regulating springs for effecting their own purpose.

Mr. W. Hardy's Compensation for want of Isochronism.

Mr. W. Hardy published a short account of a new method of making the balance of a chronometer perform its long and short vibration, in the same time, in Mr. Nicholson's Journal for September, of the year 1806, (Supplement of vol. xiv. 8vo. Series) which account, we propose, to copy with some slight verbal deviations, that are more adapted to our figures, as drawn in perspective. The spring *a, b, fig. 8 of Plate XXX.* is screwed to the inferior side of the cock *A, fig. 7.* and lies over the upper part of the regulating-spring, proceeding in a right line to the axis of the balance *B,* and having a bend to clear the verge, from which it passes on to the end of the spring which it holds. This straight spring is made of such a small strength, that it comes into action before the regulating spring. The other piece *c, fig. 8,* is attached to the cock, in a line with the slender one, but on the opposite face of the cock: the part of the piece, *c,* which is bent down, is divided into a fork and admits the part, *b,* of the slender spring, to pass and play between its prongs; at each side of the prongs is a lateral screw, presenting its point to the spring, in such a way, that the play between the prongs, or rather between the points of the two equidistant screws, may be limited according to circumstances, provided they are not farther asunder than the quantity of the escapement angle. The other end of the cylindrical regulating spring, as usual, is attached to a piece of metal carried by the verge of the balance. The effect produced by the compensating spring, *a, b,* is thus, when the balance is first moved from its place of rest, the slender spring, *a, b,* moves first, till it meets with the point of one of the two screws of the fork, then the cylindrical-spring begins to be acted on, as in the chronometers in general; this motion of the stud, at the end of the slender spring, retards the motion of the balance, which begins to be accelerated only, when the stud is at rest; consequently the contrivance before us supposes that the short arcs are in general performed in less time than the long ones; and require on that account, to be checked in their velocity at starting; and the quantity of play in the fork limits the quantum of retardation; but as we have seen the long arcs may be, and often are, performed in less time than the short ones, with springs not adjusted for isochronism; we conceive, therefore, that, like Harrison's cycloid pin, which owed its origin to a contrary supposition, the application of the invention we are describing may happen to be productive of an effect, just opposite to that which it is meant to produce; for it can be used as a compensation for want of isochronism, only in the particular case, when the short arcs of vibration are performed in less time than the long ones, which we have seen is just the opposite application of that adopted by Harrison, and founded, as we have said, on an opposite supposition: whereas the fact is, that sometimes one of the two contrivances may prove to be necessary, and sometimes the other, with a limited length of spring, accordingly as the long, or the short arcs of vibration, may turn out on trial to be performed in the less time; and the trial necessary for ascertaining, whether the spring is too long or too short, will afford the means of ascertaining very nearly, if not quite, the exact isochronal length, such as shall require no compensation at all; to attain which object, though with some additional trouble, we are disposed to think the preferable practice.

COMPENSATION-Pendulum, is a superior kind of pendulum in which the natural effects of two actions are fo opposed to each other, as to counteract or compensate each other's influence on the motion of the going pendulum. We have already described the grid-iron pendulum invented by J. Harrison, and also, Troughton's new arrangement of the metallic bars, under our article **CLOCK**, to which we must here refer; and for the other various constructions of a compensation-pendulum the reader is desired to consult the word **PENDULUM**, where he will find the subject treated at considerable length.

COMPERTORIUM, in the *Civil Law*, denotes a judicial inquest made by delegates, or commissioners, to find out, and relate the truth of a cause.

COMPETENCE, or **COMPETENCY**, in *Law*, the authority, or right of a judge, for taking cognizance of any matter. See **JURISDICTION**.

COMPETENCI Militaire, Fr. military jurisdiction. In France, the officer of the troops took cognizance of and possessed the right of directing the process or proceedings in regard to every thing that concerned military affairs and offences, those excepted, that were punishable by the provost marshal, and to judge of all crimes and offences committed by an officer against an officer, or by a soldier against a soldier, provided a civil individual had no concern or interest in it. And if the civil judges were obliged to cause military persons to be arrested, the commandants could demand them, and in case of refusal complain to the sovereign through the minister.

COMPETENT Witnesses. See **WITNESS**.

COMPETENTES, in *Church History*, an appellation given to the catechumens, when being religiously instructed in the Christian religion they required baptism.

COMPEYRE, in *Geography*, a town of France, in the department of Aveyron, and district of Milhaud; one league N. of Milhaud.

COMPHEDA, a town of Arabia Felix on the Red Sea, S. E. of Mecca, garrisoned by the Turks.

COMPIANO, a town of Italy, in the duchy of Parma; 12 miles from Pontremoli.

COMPIATA, *Ital.* **COMPLICS**, *Fr.* The last prayer or hymn sung in full chorus, at the end of the service of the Romish church.

COMPIEGNE (in Latin, *Compendium*,) a handsome town of France, the chief place of a district in the department of Oise, situated on that river at the distance of two kilometres from the confluence of the Oise with the Aisne and 76 kilometres from Paris. N. lat. 49° 25'. E. long. 3° 12'. A very extensive forest stretches from this town to the department of the North and that of the Lys. Before the revolution of 1789 the kings of France resided occasionally at the palace of Compiègne to take the diversion of hunting. This palace was built by Charles the Bald, repaired by several of his successors, and reconstructed on a grand scale in 1755 by Louis XV. There is also a beautiful bridge over the Oise which formerly was adorned with the arms of France elegantly carved in stone by Coustou; but this fine monument was mutilated in 1793 by a revolutionary stone-cutter, who put a cap in its place. Compiègne has a sub-prefect, two courts of justice, and 6359 inhabitants. The district contains a population of 88,043 individuals, distributed in 165 communes. Its principal trade is in wood, corn, and wool. Its wine is much esteemed. There are but a few manufactures of worsted caps and stockings.

COMPITALIA, or **COMPITALITAS**, feasts held among the ancients in honour of the *lares*.

The word comes from *compitum*, a *cross-way*; because the feast was held in the meeting of several roads.

The *compitalia* are more ancient than the building of Rome. Dionysius Halicarnassus, and Pliny, indeed, say that they were instituted by Servius Tullius; but this only signifies, that they were then introduced into Rome.

Notwithstanding what Di n relates, that the *compitalia* were celebrated a little after the Saturnalia, and that the Roman calendar fixes them on the twelfth of January, it appears that they had not fixed any day, at least not till the time of Varro, as is observed by Casaubon.

The feast being then movable, the day whereon it was to be observed, was proclaimed every year. It was ordinarily held on the fourth of the nones of February, *i. e.* on the second of that month. Macrobius observes that they were held not only in honour of the *lares*, but also of *mania*, madnes. The priests who officiated at them were slaves and liberti; and the sacrifice was a fow. They were re-established, after a long neglect, by Tarquin the Proud, on occasion of an answer of the oracle, "That they should sacrifice heads for heads," *i. e.* that for the health and prosperity of each family, children were to be sacrificed: but, Brutus, after expelling the kings, in lieu of those barbarous victims, substituted the heads of garlic and poppy; thus satisfying the oracle, which had enjoined *capita, heads*, at an easy rate.

During the celebration of this feast, each family placed at the door of their house, the statue of the goddess *Mania*: they also hung up at their doors figures of wool, representing men and women; accompanying them with supplications that the *Lares* and *Mania* would be contented with those figures, and spare the people of the house.

As for slaves, in lieu of the figures of men, they offered balls or fleeces of wool. Servius Tullius ordered, that the slaves who assisted at the *compitalia*, should be free during the whole time of the feast. Augustus ordered the statues of the *Lares*, placed in the cross ways, to be adorned with flowers twice a year.

COMPLACENCY, in *Pathology* and *Ethics*, denotes full and continued satisfaction, connected with a considerable degree of approbation. It has intrinsic value, or some species of worth for its object. Some mental excellencies, or advantages accruing from them; some sentiment, disposition, acquirement, conduct, performance, either of ourselves or of others with whom we are immediately connected, which, upon close examination, we deem deserving of esteem or applause. Complacency may be enjoyed as the reward of our own conduct, or of the purity and benevolence of our motives; and it may also relate to the approved conduct, sentiments, attainments, and dispositions of others, for whom we are deeply concerned. The satisfaction produced by complacency indicates, that we have, in some respect or other, a personal interest in the object of it; and the approbation implied in it conveys the idea of some kind of excellency. In strict propriety of language, complacency is alone applicable to that species of good which originates from some mental or moral excellence; where there is an indication of propriety, ingenuity, wisdom, address, or dignity, in sentiment, design, execution, or of rectitude and benevolence in the motive, this affection will possess different degrees of strength, according to the various kinds and degrees of excellence discernible in the exciting cause; and high complacency is the most grateful of all the affections. It possesses an elevation and a suavity peculiar to itself. It is permanent satisfaction, enjoying the full approbation of reason; and consequently it suffers no alloy from the struggle of contending passions, or opposite desires. When it is in-

fixed

spired by our own conduct, it is accompanied by self-approbation, or the testimony of an applauding conscience, enlivened perhaps by the voice of gratitude, and enriched by the esteem of the worthy. If it proceed from the conduct of others, it augments the pleasures of affection, friendship, and gratitude. This affection, however, has its counterfeit; and an erroneous opinion of ourselves may change the nature of this sublime affection, and render it the parent of vice and folly. Thus false conceptions of our own talents, acquirements, and conduct, may inspire pride, vanity, haughtiness, and arrogance. Cozan on the Passions, p. 71.

COMPLAINANT, in *Law*, a plaintiff, or one who prefers a complaint against another, to be relieved by justice or equity.

COMPLEMENT, in a general sense, denotes what is wanting, or necessary to complete some certain quantity or thing.

COMPLEMENT, *Arithmetical*. See **ARITHMETICAL**.

COMPLEMENT, in *Astronomy*, is used for the distance of a star from the zenith; or the arch comprehended between the place of a star above the horizon, and the zenith. It is the same as the complement of the altitude, or co-altitude; or zenith distance.

COMPLEMENT of the course, in *Navigation*, is the number of points the course wants of 90 degrees, or eight points; viz. of a quarter of the compass.

COMPLEMENTS of the curtain, in *Fortification*, are those parts of the side of the interior polygon, which form the demi-gorges of the two bastions adjoining the curtain.

COMPLEMENT of the line of defence. See **LINE of defence**.

COMPLEMENT, in *Geometry*, is what remains of a quadrant of a circle, or of ninety degrees, after any certain arch has been retrenched from it. Thus, if an arch or angle be 30 degrees, we say its complement is 60 degrees, since $60 + 30 = 90$.

The sine of the complement of an arch is called the *co-sine*; of a tangent, the *co-tangent*; &c.

We sometimes also say the *complement of an angle*; meaning so much as it wants of a right angle, or of 90 degrees.

COMPLEMENT, in *Heraldry*, a term used to signify the full moon, for example, azure, the moon in her complement, argent.

COMPLEMENTS of a parallelogram, are the two lesser parallelograms, made by drawing two right lines parallel to each side of a parallelogram, through a given point in the diagonal.

Such are the parallelograms C and M (*Plate III. Geometry, fig. 50*). It is demonstrated, that in every parallelogram, the complements C and M are equal: for $Z + C + o = R + M + x$; as making up on each side the great triangles, made equal by the diagonal; of which, $Z = R$, and $o = x$ (because the diagonal makes them so); wherefore the remaining parallelogram $C = M$.

COMPLEMENT of life, in the *Doctrine of Life annuities*, denotes the difference, according to M. De Moivre's hypothesis, between the age of any given life, and 86 years; thus, at the age of 30 the complement is 56—at the age of 37 it is 49—at the age of 50 it is 36, and so on. In this hypothesis the probabilities of life through every period of existence, are supposed to decrease in an arithmetical progression, so that out of 86 persons just born, one is supposed to die every year, till at the end of 86 years, which is considered as the utmost limit of human life, the last survivor becomes extinct. M. De Moivre, who formed this hypothesis with the view of facilitating the computations of life-annuities, derived it from Dr. Halley's "Table of Observa-

tions," at Breslaw, which, being the only table of the kind at that time, and making the decrements in the middle stages of life nearly equal, so far supported the truth of the hypothesis, and justified M. De Moivre in adopting it. But in the earlier and later periods of life the decrements are so irregular as by no means to accord with this hypothesis; and since subsequent tables, more accurately formed, and deduced from more extensive observations, have been published by Dr. Price, Messrs. Wargentin, Sufmilch, and other writers on the subject; and the values also of single and joint lives for all ages have been computed from them; this hypothesis is rendered unnecessary, even in cases where it is most correct: in other cases, which involve two or three lives in the question, especially if those lives be very young or very old, it gives solutions so inaccurate as to be altogether unfit for use.

By supposing an uniform decrement in the probabilities of life from infancy to extreme old age, the number of years which a person has an equal chance of surviving is made to be the same with the *expectation* which M. De Moivre by his hypothesis finds to be equal to half the complement of life; so that if the age be four, the expectation will be $\frac{82}{2} = 41$; if the age be 82, the expectation will be $\frac{2}{2} = 1$, while the chance that a child aged 4 survives 41 years is $\frac{4}{82}$, and the chance that a person aged 82 survives 2 years is $\frac{2}{82}$. Now since each of these fractions is $= \frac{1}{2}$, it follows, agreeable to what has been observed above, that the one has an equal chance of living 41, and the other of living 2 years, or such a number as shall be expressed by their respective expectations. But by the Breslaw table the expectations of those lives are severally $40\frac{2}{3}$ and $3\frac{1}{2}$ years, while the chance of the younger living $40\frac{2}{3}$ years is .464, and the chance of the elder living $3\frac{1}{2}$ years is .53; that is, in the first instance, the chance is less, and in the second greater, than an even one, that the person lives such a number of years as shall be equal to his expectation. This is true in all other tables deduced from real observations, and proves that even in the simplest case the hypothesis is incorrect.

Mr. Thomas Simpson, instead of supposing the complement to be the difference between 86 and the age of the given life, assumed this complement to be equal to twice the expectation when computed from a table of the real probabilities of life, and by this means lessened the inaccuracies of those rules which depended entirely on Mr. De Moivre's hypothesis. But had this excellent mathematician been possessed of the present tables of observation, there is no doubt but that he would have adopted a more genuine method of solution. As far as relates to the computation of the probabilities of survivorship between any given number of lives, M. De Moivre's hypothesis in many cases appears to give approximations which are sufficiently near the truth; but as the mere determination of such probabilities is of no use in computing the values of contingent reversions, inasmuch as the discount of money must be blended in each separate year with the chance of survivorship in that year, the investigation of them is a matter of no consequence, and therefore the hypothesis of an equal decrement, which often leads to great errors in the doctrine of life annuities, may be wholly laid aside without injury or inconvenience in any case. (See *Phil. Transactions*, vol. 78.)

COMPLEMENT of a Chord, in *Music*, the note or notes wanting in any chord, to complete its harmony.

COMPLEMENT of an Interval, is the minute quantity it wants in particular temperaments.

COMPLEMENT, is the difference or remainder between an octave or eighth, and any given interval, called also the inversion of that interval, (see **INVERSION**); thus, a

fifth is the complement or inversion of a fourth, and a fourth of a fifth; a minor third is the complement or inversion of a major fifth, and *vice versa*. See THIRD, FOURTH, FIFTH, &c.

COMPLETE, in French *complet*, in *Military Language*, a regiment, troop, or company is said to be complete when it has its full complement of officers, non-commissioned officers, and privates, agreeably to the regulations for the time being.

COMPLETUS. *flor*, in *Botany*, a complete flower, furnished with both calyx and corolla; *incompletus* being used when the latter is deficient, and *nudus* when the former.

COMPLEX, a term ordinarily used as synonymous with *compound*; though, strictly speaking, there is some difference between them.

COMPLEX *object*. See OBJECT.

COMPLEX *opposition*. See OPPOSITION.

COMPLEX *term*, or *idea*, is a term or idea compounded of several simple or incomplete ones.

Thus, in the proposition, *A just God cannot leave crimes unpunished*; the subject of this proposition, *viz. a just God*, is a *complex term*, or stands for a *complex idea*, composed of two simple, or *incomplete* ones, *viz. God* and *Just*. Mr. Locke observes, that though the mind be perfectly passive in the formation of simple ideas, yet it exerts several actions of its own about them, when once formed: and that by this means it is, that they become the materials and foundations out of which all our knowledge is framed.

These acts are chiefly three, *viz.* 1. The combining of several simple ideas into one compound one: and thus it is that all complex ideas are made.

2. The bringing two ideas, whether simple or complex, together; setting them by each other, and so viewing them, without uniting them into one; by which it gets its ideas of relation.

3. The separating several ideas from all other ideas that accompany them in their real existence: and thus all its general ideas are formed.

As simple ideas are observed to exist in several combinations united together: so the mind may consider them as united, not only as they are really united in external objects, but as itself has joined them: ideas thus made up of several simple ones put together, we call *complex*; as man, beauty, army, greatness, &c.

Complex ideas, however compounded and decomposed, though their number be infinite, and their variety endless, may be all reduced under these three heads, *viz. modes, substances, and relations*; which see under their proper heads, MODE, SUBSTANCE, and RELATION. Complex ideas are often considered as single and distinct beings, though made up of several simple ideas; as body, spirit, &c. See COMPOSITION of *ideas*.

COMPLEX *proposition*, in *Logic*, is that in which the subject, or predicate, or both, are made up of *complex terms*: and if the term added to the subject be essential or necessary to it, then it is called *explicative*; otherwise it is *determinative*, the adjoined term limiting the subject to a particular part of its extension. Some logical writers ascribe the complexion of a proposition, in some cases, to the copula, as in modal propositions; but this rather pertains to the predicate. See *Compound* and *Modal Proposition*.

COMPLEX *sylogism*, is that in which the middle term is not connected with the whole subject, or the whole predicate in two distinct propositions, but is intermingled and compared with them by parts: *e. g.* The sun is a senseless being, the Persians worshipped the sun, therefore the Persians worshipped a senseless being.

COMPLEXI *Pars*, in *Anatomy*, a name given by Rio-

lanus, and others, to a muscle called by Albinus *liventer cervicis*, and by some the *complexus*.

COMPLEXIO, COMPLEXION, in *Metaphysics*, the union, or coalition of several things different from each other; either really, or only in our conception. See COMPLEX.

COMPLEXIO, in *Logic*, is sometimes applied to the second operation of the mind, *viz.* the judgment; considered as it affirms or denies any thing; such affirmation, &c. necessarily importing a combination of several things.

Complexio is sometimes also used by logicians in the sense of dilemma.

COMPLEXIO, in *Rhetoric*, &c. is a figure including a repetition, and a conversation at the same time; the sentence both beginning, and ending, with the same word.

Thus Tully: "Quis legem tulit?" Rullus. "Quis majorem partem populi iustitiam privavit?" Rullus. "Quis comitibus profuit?" Rullus.

COMPLEXION, in *Physic*, is used for the temperature, habitude, or natural disposition of the body.

Some philosophers distinguish four general and principal complexions in man, *viz.* the *sanguine complexion*, which, according to them, answers to the air; having the qualities thereof, as being hot and moist. It takes its name from *sanguis*; because the blood is there supposed to be predominant.

The *phlegmatic complexion* takes its name from the pithuita, or phlegm, in which it abounds; and corresponds to water; being cold and moist.

The *bilious*, or *choleric complexion*, takes its name from the bile, or choler; it is supposed of the nature of fire, hot and dry.

Lastly, the *melancholic complexion* partakes of the nature of earth, being cold and dry; but this sort of reasoning is now not much regarded.

Under this article we may introduce a subject that has occasioned much discussion, and considerable difference of opinion among physiologists. It relates to the variety of complexion or of colour that has subsisted amongst the inhabitants of different nations. Some persons, dissatisfied with the several hypotheses that have been suggested for explaining this phenomenon, have been led to conceive that there is a specific difference in the human race, and that the variations of colour are owing to their not having sprung from one common original. But this hypothesis contradicts the most ancient and authentic history extant, which represents Adam and Eve as the progenitors of all mankind; and it is also liable to various other objections which we shall take occasion distinctly to specify in the course of this work. Dr. Hunter, who has published a thesis on this subject, has investigated it with peculiar attention; and he gives it as his decided opinion, that there is no specific difference among mankind. In order to guard against the confusion which has arisen from the use of the term "species," he begins with defining it, and he comprehends under the same species all those animals which produce issue capable of propagating others resembling the original stock, from which they sprung. According to this sense of the term, he considers the whole human race as belonging to the same species. But, as in the vegetable creation, one species of plants includes several varieties depending upon climate, soil, culture, and similar circumstances that are incidental, the case is the same with respect to the human race; the varieties that occur pertain to the same species, and are produced by the operation of natural causes. Of the different colours that subsist among mankind, he enumerates the following, *viz.*

Black,

COMPLEXION.

<p><i>Black</i>, comprehending { Africans under the Line. Inhabitants of New Guinea. Inhabitants of New Holland.</p> <p><i>Copper-coloured</i>, as the East Indians.</p> <p><i>Brown-coloured</i>, to which class belong { Tartars. Persians. Arabs.</p> <p><i>Brownish</i>, including { The inhabitants of the southern parts of Europe; as, Sicilians, Abyssinians, Spaniards, Turks, and also the Samoiedes and Laplanders.</p> <p><i>White</i>, to which belong { Most of the European nations; as, Swedes, Danes, English, Germans, Poles, &c. Kabardiski, Georgians, and Inhabitants of the islands in the Pacific Ocean.</p>	<p><i>Swarthy</i>, including { The Moors in the northern parts of Africa.</p> <p><i>Red coloured</i>, as the Americans.</p> <p><i>Brown coloured</i>, comprehending { Africans on the coast of the Mediterranean. Chinese.</p>
---	--

In tracing the causes of these differences of colour, he sets out with observing that its seat is unquestionably in the skin; that it is confined to the cuticle, consisting of the epidermis and reticulum; and that it chiefly occupies the latter of these. The cuticle, he observes, is much thicker and harder in black than in white people; the reticulum in the latter being a thin mucus, in the former a thick membrane. The seat of colour in whites he conceives to be transparent, and either totally deprived of vessels, or furnished with a very small number; as the yellow colour appearing in the jaundice vanishes when the cause of the disease is removed, which is not the case with stains in the cuticle from gun-powder, or similar causes. He then mentions three causes which contribute to destroy the pellucidity of the cuticle, to give it a brown colour, and to thicken it; *viz.* access of air, nastiness, and the heat of the sun; the effect of these he illustrates by examples; but he apprehends the last to be the most powerful. Admitting such influence of these causes, he supposes that it is sufficient to account for all the diversities of colour, that are observable among mankind. He proceeds to observe, that all the inhabitants of the torrid zone incline more or less to a black colour; and the difference that is perceivable among them may be owing, not to mere heat, but to the other causes also; and if we consider that even in the torrid zone there is a considerable difference of temperature, the existence of a white nation in this climate would not destroy the argument. He is farther of opinion, that the existence of a brown colour, and of considerable varieties from white, in the northern and coldest parts of Europe, may be very easily explained, by adverting to the manner of life of the inhabitants, who of course are either exposed to the inclemency of the air, or to the constant nastiness of smoky houses. If, to this reasoning, it should be objected, that infants are subject to these differences even when they are born, and previously to the influence of the causes above-mentioned, Dr. Hunter replies, that many peculiarities acquired by parents are transmitted to their posterity; in proof of which, he refers to hereditary diseases, which will continue to affect families for many generations. Thus, a parent exposed to causes that destroy the natural whiteness of his complexion, will beget swarthy children; and the same causes continuing to operate upon the son, the blackness will be increased. In this manner, all the different shades may have been at first induced, and afterwards continued. To this objection, however, it might be answered, that the fact is not admissible; as it is now generally allowed, that the children of the blackest negroes are born white.

Mr. Clarkson, in a dissertation introduced in his "Essay

on the Commerce and Slavery of the Human Species," has considered and well illustrated the subject of complexion. In the investigation of this subject, the first question that occurs relates to the precise seat of the colour. As the old anatomists commonly divided the skin into two parts or laminæ, *viz.* the cuticle and cutis or true skin, they must have supposed, that as the latter is the same in all the varieties of mankind, however different their external hue, the seat of colour must have existed in the cuticle or upper surface. Malpighi, however, discovered that the skin is divided into three laminæ; *viz.* the cuticle, the true skin, and a kind of coagulated substance situated between both, which he denominated the "rete mucosum." Accordingly, this discovery served to ascertain the point in question; for it afterwards appeared, that the cuticle, separated from the other laminæ, was semi-transparent; and that the cuticle of the blackest negro was of the same transparency and colour with that of the purest white; and as the true skins of both were invariably the same, the rete mucosum must be the seat of colour. That this is the fact has been also determined by a variety of anatomical experiments and physiological observations. The causes, therefore, that operate in producing difference of colour, must effect it by acting on the rete mucosum, which, from the numberless perforations of the cuticle, is no less accessible than the cuticle itself. These causes are probably those various qualities of things, which, combined with the influence of the sun, contribute to form what is called "climate." Moreover, it is a farther confirmation of this hypothesis, that the mucous substance before-mentioned is subject to variation, according to the difference of climates from the equator to the poles. Thus, the inhabitants of many kingdoms and islands of Asia are found to have their rete mucosum black; those of Africa, situated near the line, are of the same colour; those of the maritime parts of the same continent, are of a dusky brown, nearly approaching to it; and the colour becomes lighter or darker, in proportion as the distance from the equator is either greater or less. The Europeans are the fairest inhabitants of the world: those situated in the most southern regions of Europe, have in their rete mucosum a tinge of the dark hue of their African neighbours. Admitting these facts, we are led to conclude, that climate has a very considerable influence in occasioning a difference of colour. It has, however, been objected to this reasoning, that people of the same climate, geographically considered, or under the same parallels, are not exactly of the same colour. But to this objection it has been replied, that climate, physically considered, depends upon a variety of accidental circumstances. See CLIMATE. It should also be considered, that, although the inhabitants

of the same parallel are not exactly of the same hue, yet they differ only by certain shades of the same colour; and, therefore, if climate has really an influence on the mucous substance of the body, we must expect to find not only a gradation of colour in the inhabitants from the equator to the poles, but also different shades of the same colour in the inhabitants of the same parallel. We might also add another argument of great weight, *viz.* that when the black inhabitants of Africa are transplanted to colder, or the white inhabitants of Europe to hotter climates, their children, born there respectively, are of a different colour from themselves, that is, lighter in the first, and darker in the second case. To this purpose the abbé Raynal observes, that the children, which the Africans procreate in America, are not so black as their parents were; and that after each generation, the difference becomes more palpable. It is possible, he adds, that after a numerous succession of generations, the men come from Africa would not be distinguished from those of the country into which they have been transplanted. If we admit the fact above stated, that climate has an influence on the mucous substance, we may reasonably imagine that this variation of the colour of children from that of their parents must take place; for being born white, and not being subject to the influence of causes equally powerful in colder climates, with those to which their parents were subject in the hotter climates from which they were removed, it must follow that the same effect cannot possibly be produced.

On the other hand, we may here allege an important fact, stated by Dr. Mitchell (Phil. Trans. N^o 476. § 4.). "The Spaniards," he says, "who have inhabited America, under the torrid zone for any time, are become as dark-coloured as our native Indians of Virginia, of which I myself have been a witness; and were they not to intermarry with Europeans, but lead the same rude and barbarous lives with the Indians, it is very probable that, in a procession of many generations, they would become as dark in complexion." Another writer, describing the European settlements on the African coast, observes, that "there are several other small Portuguese settlements, and one of some note at Mitomba, a river in Sierra Leone; the people here called "Portuguese" are principally persons bred from a mixture of the first Portuguese discoverers with the natives, and now become, in their complexion and woolly quality of their hair, perfect negroes, retaining, however, a smattering of the Portuguese language."

Another circumstance might also be mentioned by way of corroborating the argument before us; and this is, that the members of the same family, separated from each other, and migrating into different countries, have not only changed their family complexion, but have assumed as many different colours as the different regions of the globe in which they have settled. The Jews furnish a remarkable instance to this purpose. These people, though scattered over the face of the earth, preserve themselves a distinct people, and never intermarry with any out of their own body, so as to have any mixture of blood in their veins, by which they should differ from each other; and yet it is an undoubted fact, that the English Jew is white, the Portuguese swarthy, the Armenian olive, and the Arabian copper-coloured; and there appear to be as many different species of Jews as countries in which they reside. It appears further from the testimony of the most ancient historians, that the darkest black complexion has actually changed in a succession of years into the purest white. Herodotus informs us, that the Colchi were black and that they had crisped hair. These people were a detachment of the Ethiopian army under Sesostris, who fol-

lowed him in his expedition, and settled in that part of the world where Colchis is said to have been situated. Their descendants probably remained in the same country. If this be the case, they must have totally changed their complexion; or the black inhabitants of Colchis must have acquired the hue of the fair Circassian. If indeed they migrated in any one direction from Colchis and to any distance within 1000 miles of Colchis, still they must have changed their colour; for if they had gone in an eastern or western direction, their colour must have been the same as that of the Circassians; if to the north, whiter; if to the south, of a copper colour. Within the above assigned distance of Colchis, there are no black people.

Professor Zimmermann of Brunswick, in his work entitled "The Geographical History of Man, &c," has satisfactorily proved, that the complexion of the human species uniformly corresponds to the degree of heat or cold to which they are habitually exposed. In establishing this position, he distinguishes between climate, considered geographically and physically, and thus furnishes an answer to the erroneous reasoning of Lord Kames on this subject. At Senegal, and in places adjacent, the thermometer is often at 112 or 117 degrees in the shade; and here we find the inhabitants jet-black with woolly hair. The heat is equally great in Congo and Loango, and these countries are inhabited by negroes only; whereas in Morocco to the north of these regions, and at the Cape of Good Hope, to the south, the heat is not so intense, nor are the inhabitants of so deep a hue. Lord Kames asks, why are not the Abyssinians and the inhabitants of Zaara of as dark a complexion as the Moors on the coast of Guinea; Zimmermann replies that these countries are much cooler. The desert is not only further from the equator, but the winds blowing over the Atlas mountains, which, like the Alps, are covered with snow, and the westerly wind coming from the sea, very much mitigate the heat. Nor is Abyssinia so warm, as either Monomotapa or Guinea. The N.E. winds from the side of Persia and Arabia are cooled by their passage over the Red sea; the northern winds of Egypt lose much of their heat on the chain of mountains that is extended between the countries; the winds from the south and the west are sea winds. Thus the only quarter from which they can derive excessive heat is from the west, as the air on this side must pass over tracts of heated lands. For a similar reason negroes are not found either in Asia or South America, under the equator. These countries, as M. Zimmermann observes, being exposed, from their situation, to sea breezes and cooling winds from the continent. He also observes, in confirmation of this hypothesis, that the mountaineers in warm climates, as in Barbary and Ceylon, are much fairer than the inhabitants of the vallies; that the Saracens and Moors, who conquered the N.E. part of Africa in 1700, from being brown, are become like the negroes near the equator; that the Portuguese, who settled at Senegal in 1480, became black; and it is asserted by Tudela the Jew, that his countrymen in Abyssinia acquired the dark complexion of the conquered nations.

Upon the whole it may be observed, that colour is a kind of habit of the body, which is gradually acquired, and after a succession of ages, fixed and rendered permanent. Thus, the sanguine countenance will be perpetual in the highest latitudes of the temperate zone, and, as we descend to the south, we shall find the swarthy, the olive, the tawny, and the black. The uniformity of the effect in the same climate, and on men in a similar state of society, proves the efficacy and the certainty of the cause. As mankind are for ever changing their habitations by conquest or commerce,

merce, we find that, in all climates, they cannot endure the change, but are to acclimated by time, that we cannot say with certainty, whose ancestor was the native of the clime, and whose progenitor was the intruding foreigner. For a further illustration and confirmation of the general arguments comprehended in this article, we refer to an "Essay on the Causes of the Variety of Complexion and Figure in the Human Species" by Dr. Smith, professor of moral philosophy in the college of New Jersey. See *NIGROE*.

COMPLEXUS MUSCULUS, in *Anatomy*, derives its name from the intermixture of tendon with its muscular fibres, which gives to its surface a confused appearance. It arises from the transverse processes of five, six, or seven of the upper dorsal vertebrae, by so many distinct slips; from the transverse process of the last cervical vertebra; and from the oblique or articulating processes of the sixth, fifth, and fourth vertebrae of the neck. The fasciculi of fibres from these numerous points of origin meet together to form a broad, flat, and strong muscle, which is implanted into the occipital bone, occupying the hollow in front of the external transverse ridge of the bone. It sometimes receives a small fleshy portion from the spinous processes of one or two of the upper dorsal vertebrae; and is generally connected in some degree with the *longissimus dorsi sacrolumbalis* and *transversalis colli*. That portion of the muscle, which is towards the spines of the vertebrae, is divided into two fleshy portions by an intermediate tendon, and is separate from the rest at its origin; this is described by Albinus, Soemmerring, and others, as a distinct muscle, by the name of *biventer cervicis*: we follow Cowper, Douglas, and Winslow, in considering this as a part of the complexus, since it is always connected to the rest of the muscle, for two or three inches before its insertion.

The action of the complexus consists in carrying the head backwards upon the atlas; and in restoring it to the erect position, when it has been bent forwards. Its longest fibres will also have the same effect on the neck, *viz.* that of frightening and carrying it backwards.

COMPLEXUS, Minor, is a name given by Winslow, to the trachelo-mastoideus muscle, which see.

COMPLICATION of *diseases*, a mixture, or combination of several diseases; especially where they have any affinity to one another; as the dropsy, asthma, and jaundice, happening together.

What much perplexes the physicians is, when with a fever there is a complication of some other disorder.

COMPLINE, in *Ecclesiastical Antiquity*, denotes that even-song, which completed the whole service of the day in religious houses, and began at nine of the clock at night.

COMPLUTENSIAN BIBLE. See *GREEK BIBLES*, and *POLYGLOTT*. The Complutensian edition of the Bible, which the reader will find described and particularly noticed, under the articles to which we have referred, has been highly extolled by Mill and Goetze, and as much depreciated by Wettstein and Semler. Michaelis, in the second edition of his "Introduction," &c. endeavoured to steer a middle course between the opposite opinions of Mill and Wettstein; though he believed, on the authority of the latter, that the editors, actuated by religious zeal, had materially altered the Greek text from the Vulgate. But Goetze, he says, in his "Defence of the Complutensian Bible," printed at Hanburgh, in 1765, has enabled him to form a proper judgment of that work; and he acknowledges, that he had too closely adhered to the opinion of Wettstein, after the perusal of the following publications by the same author, *viz.* "Complete Defence of the Complutensian Greek Testa-

ment, with a Collection of the principal Differences between the Greek Text, and the Latin Text of that Edition," printed in 1766, and the "Continuation of the Defence of the Complutensian Greek Testament, &c." published in 1769. Michaelis, having since had access to the Complutensian bible in the university library of Gottingen, has been enabled to speak of it with greater certainty. He has particularly used it in the Greek version of Genesis, the Proverbs of Solomon, and the first book of the Maccabees; and in these books he has found its reading as pure, and as little altered from the Latin, as Goetze had described them. It has been questioned what were the MSS. from which this edition was prepared, and whether the editors had any besides those which were sent to them from Rome; the silence of the editors is no proof of the contrary, for they make no mention of the Codex Rhodiensis, which had been presented to Cardinal Ximenes, though Stunica, in his controversy with Erasmus, frequently applies to it, as a MS. used in the Complutensian edition; and the Codex Bezae Cantabrigiae, which was used in the Septuagint, had been presented to him, by the senate of Venice. Moreover, as the New Testament was begun in 1502, it is wholly incredible that they should have had no other MSS. than those sent from Rome, because Leo X. who communicated these MSS. was not pope before the year 1513, and the subscription at the end of the Revelation bears date January 10, 1514. If, therefore, the MSS. were sent by Leo X., they must have arrived when at least three parts of the Greek Testament were already printed, and yet the editors, at least in the preface, mention no other MSS. One mode, says Marsh, in his notes on Michaelis's translation, of solving this difficulty is, to suppose that MSS. were sent from Rome by Julius II. the predecessor of Leo X., and that the writer of the preface to the Complutensian Greek Testament, who knew that the latter was at that time pope, but, perhaps, was ignorant how long he had reigned, committed an anachronism in ascribing to Leo X. what had been done by Julius II. Or, perhaps, he knew that they were sent by Julius II.; but meant to flatter the vanity of the reigning pope, by attributing to him the act of his predecessor. Or, Leo X. might, before he was pope, have been instrumental in procuring them from the Vatican, and be therefore entitled to the compliment. However this be, it seems probable, that the editors, besides the Codex Rhodiensis, had other MSS. of the Greek Testament, which had been procured by the cardinal. But whether they were ancient or modern, of great or little value, it is difficult to determine, as the editors have given no account of them. Wettstein thinks they were modern, because the readings of the Complutensian bible have a remarkable agreement with those of the MSS. written in the 14th, 15th, and 16th centuries; and this opinion is confirmed by the shape of the types, for they are such as we find in the most modern MSS.; and it is probable that the editors had their types cast in imitation of the MSS., which they employed on the occasion. Michaelis, however, in this account of the types, is not quite accurate; for of all the specimens of Greek hand-writing, which Montfaucou has given in his "Palaeographia Graeca," from the first introduction of the small letters down to the 15th century, none resemble the types of the Complutensian edition more than that which is found in MSS. of the 9th century. On the other hand, letters not very unlike the Complutensian are found in MSS. of the 11th, 12th, and even 13th centuries. Moreover, as no MS. written in such letters, as are used for the Complutensian edition, is without accents, and the editors appeal not to the MSS. which they actually used

but to the poems of Callimachus, and the Sibylline prophecies, there is reason to suspect, that their MSS. had accents, and consequently were modern. Accents, however, if it be allowed that the Complutensian edition had them, though it has been generally said (not justly) that it is printed without them, afford no proof that a MS. is modern; for they are found in several very ancient MSS. written even with uncial letters, as the Vaticanus, Claromontanus, &c. &c. and perhaps, says Mr. Marsh, there are as many ancient MSS. with uncial letters, which have accents as those which have not.

With regard to the main question, whether the MSS. used by the Complutensian editors were ancient and valuable, Mr. Marsh candidly acknowledges that he is too little acquainted with the Complutensian bible to be able to form any judgment: and he therefore contents himself with observing, that Griesbach accedes to the opinion of Wetstein and Semler, and says, in the preface to the second volume of his Greek Testament (p. 16); "Complutenfes non habuerunt codices Græcos, nisi paucos, recentes, exigui fere, si ad lectissimum bonitatem spectes, pretiū."

It has been suggested, that the Complutensian editors, in consequence of a too high opinion of the Vulgate, and a mistaken zeal for the Christian religion, have sometimes introduced into the Greek text readings of the Vulgate, which they did not find in the Greek MSS.

The Greek text of the disputed passage, 1 John, v. 7., in the Complutensian edition, seems to have been a mere translation of one of the editors; because the passage is found in not a single ancient, and in only two modern MSS. the Montfortianus and the Ravianus, the latter of which is only a copy of this edition; and in the former, the text is very different from that in the Complutensian edition. It cannot, therefore, as in the third edition of Erasmus, have been taken from this MS.: though, on the other hand, it is not impossible that they found it in some modern MS., in which the passage, as in the codex Montfortianus, had been already translated. The question can never be decided, because the MSS. which they used are either destroyed, or are at least unknown. For an account of the fate of these MSS., see the article ALCALA. Michaelis candidly explains the conduct of the Complutensian editors so as to remove the charge of dishonesty. They might believe, he says, that this passage was really genuine, and, on account of its supposed importance, take no notice of its alteration from the Greek MSS.; in the same manner as the verse has been inserted by later editors in Luther's version. Or, they might have made some remarks on it, which were afterwards erased by the censors of this edition; for, contrary to their usual custom, they have a marginal note on 1 John, v. 7., which is in itself unimportant, and almost implies that something originally preceded. If they have taken the passage from a modern MS., they have only acted like Erasmus, who has inserted it on the authority of a very modern MS. which he had never seen. In short, many of the best editors have been guided in this passage by a mistaken zeal for the Christian religion, and have acted on principles which they have never admitted in other places. It was the principal object of Goeze to support the authenticity of this passage, and as it occurs in the Complutensian bible, he defended the antiquity and value of the Greek MS. from which he supposed that passage had been taken. On the other hand, Semler's object was to shew the spuriousness of this passage, and at the same time to support the opinion of Wetstein, that the text of the Complutensian Greek Testament, in general, is of little value. The genuineness of this passage is now generally exploded by the most approved biblical critics.

The Complutensian edition is extremely scarce, because only 600 impressions were taken off, and is become too expensive for a private library. That which is now at Göttingen cost 480 Rorins, and the late Münchhausen gave an order to his commissary near as far as 500; and the price of it, says Michaelis, will still increase, in proportion as its great excellence, especially in the Septuagint, shall be better known. Mr. Dangelius, and Wetstein, have collated this edition as a MS with great diligence; but their extracts are by no means complete. Goeze has also given extracts from it, in his "Complete Defence of the Complutensian edition," (p. 277), which, in the proper sense of the word, may be called critical, and which no future editor of the Greek Testament ought to leave unnoticed. Michaelis thinks, that a real service would be rendered to those who are engaged in sacred criticism, if a new edition both of the Greek and Latin Testament was published, that was an exact copy of the Complutensian. From the Greek text of the Complutensian edition were printed the following, viz. seven at Antwerp in 1564, 1573, 1574, 1590, 1591, 1601, 1602; five Geneva editions in 1609, 1619, 1623, 1628, 1632; and, lastly, that of Mayntz, in 1753. These are all described in Le Long Bibl. Sacra, ed. Mafsch. P. i. p. 191—195. See POLYGLOTT.

COMPLUTICA, in *Ancient Geography*, a town of Spain in the Tarragonensis, plac'd by Ptolemy in the country of the Callaici, and thought to be the present village of Complud, in Galicia. It is marked in the chart of M. d'Anville on the right of the Durus, to the south-west of Pallantia.

COMPLUTUM, a town of Spain, in the Tarragonensis, plac'd by Ptolemy in the country of the Carpetani, and marked in the chart of M. d'Anville in Hispania circior, N.E. of Mantua; now *Acuala de Henares*, which see.

COMPOLI, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Lavora; 4 miles E. of Sora.

COMPONE', or *Gobony*, in *Heraldry*, is composed of two colours in equal divisions in a border, or any other ordinary; if it consists of two ranges it is called counter-compony, and if of three, it is then termed chequé, and is generally used in a border to denote illegitimacy.

COMPOS *Mentis*. See NON-COMPOS.

COMPOSED *Balloon*. See BASTION.

COMPOSER of *Music*, a person who invents a melody, and cloaths it with harmony, according to the established rules of the art. Under the word *composition* we shall detail the qualifications requisite to support this character. Yet these are insufficient to form a complete composer, whose productions will be felt and admired whenever they are heard. All the science possible, without the inspirations of genius, is unable to command attention, and interest an audience, at all times, and in all places. They are only gifted men that possess such powers. What is meant here by genius, is not a whimsical and capricious imagination, that quits a flowery road to ramble in thickets, through briars and brambles; that to render harmony piquant, loads it with discord; and instead of grace and elegance, is labouring to surprise by extraneous modulation, and to divide the whole scale into half notes; true genius is that latent fire which inflames the composer, irresistibly forces him to write, and necessarily supplies him with new melodies; always agreeable, expressive, and natural, accompanied by a harmony pure, touching, and majestic, which embellishes melody, without overpowering it. "This was the guide" says the Citizen of Geneva, "that led Corelli, Vinci, Perez, Jomelli,

melli, and Durante. to the sanctuary of harmony; and Leo, Pergolesi, Haffé and Buranello, to that of good taste." We have to add to these, Handel, whose sublime works were never heard by Rousseau; the elder Stamitz, Piccini, Sacchini, Cimarosa, and Pacifello, with Haydn and Mozart, who have gone somewhat further in vocal music, and many leagues in instrumental.

The knowledge of harmony is doubtless the foundation of composition. To fill the chords, prepare and resolve discords, find the fundamental base, and know all the other little elementary rules, is necessary; but with the rules of harmony alone, we are not nearer being composers, than being orators by knowing the rules of grammar. Padre Martini says, that no one can be a good composer without singing in good taste, and playing well upon the organ. His rules are for a real *maestro di capella*, an ecclesiastical composer; but for secular music he would have said it was necessary to sing and play well on the harpsichord or piano forte. In setting words for the stage, he ought to know what passages are difficult, and what easy to execute; what style suits the singer, and what the character he has to represent; he is to know the compass of voices and instruments, and their peculiar genius and powers; how to produce effects, and when to apply them; to feel the character of different measures; to know all the difficulties and pendency of the art: imitations, fugues, canons, double counterpoint, and how to write for double, triple, and quadruple choirs. To these add the mysterious laws of modulation; and all this is no more than preparatory to composition. But he must inherently possess a fund of beautiful melodies, sublime harmony, and grand designs.

Besides correct harmony, correct expression, in lyric compositions, is required. The spirit of three several kinds of composition must be called up in writing for the church, the stage, and the chamber. In the first, solemnity and harmony must be invoked; in the second, a distinct style for each character, strongly marked by the poet; ingenious and spirited symphonies, picturesque accompaniments, a judicious mixture of instruments, and their peculiar powers, occasionally called forth; and for the third species of composition, pieces that require but few hands and few voices; free from all tremendous difficulties, in want of no wind instruments; and, unless catches and glees are in question, no provision need be made for more than one or two voices, and a quartet band. *La musica di camera*, chamber music, requires ease, grace, and elegance, more than force, energy, and feats of execution.

Among the various styles of composition for which an accomplished master should be prepared, is the military, in which wind instruments and drums are chiefly employed. To know the compass, scale, genius, and defects, of the trumpet, horn, clarinet, hautbois and bassoon, both in the orchestra and the field, will require some study, counsel and experience.

Rousseau seems sometimes to regard musicians as mere instruments, incapable of reflexion; and that it is the business of philosophers to think for them; so imagine M. Suard, and all speculative musicians; but in the following advice to a composer, Jean Jaques seems to require more meditation and reflexion than the demon of composition, by which a man of genius is possessed, will allow; who, absorbed in his own ideas, or impelled by the ideas of others, flies to his pen or his instrument, without metaphysical reasoning, or analytical inquiry into the foundation of his art. But Rousseau sums up the article *Compositeur* (*Composer*), in his Dictionary, with the following instruction. "In composing, the author has to consider the physical production

of sound, and that its sole use is to delight the ear; or if he moves it up to imitative music, he has to move the passions by moral effects. In the first instance, he has to seek the most pleasing series of sound, and agreeable harmony; but in the second, he ought to consider music with respect to its similarity with the inflexions of the human voice in speech, and the possible conformity between the harmonical combinations of sound and imitable objects." This is all very fine and profound: but we apprehend, that the most happy effusions of genius have been generated without speculative assistance.

For the mechanical rules by which a composer is to steer, we shall refer our readers to the article COUNTERPOINT; where, though its principal rules are dispersed through the work, we shall collect and form them into a synopsis, and illustrate precepts by examples.

In this musical grammar, we shall perplex the student with no mathematical calculations, no ratios, harmonics, or speculations on the philosophy of sound; but adhere closely to practical knowledge of immediate use in the first stages of study. We shall not even attempt to give new melodies, or harmonical combinations; but endeavour to indicate the foundation on which the best models of composition have hitherto been built. See COUNTERPOINT, CONCORDS, DISCORDS, HARMONY, and MODULATION.

COMPOSITÆ, or COMPOSITI, in *Botany*, the twenty-first natural order in the *Philosophia Botanica* of Linnæus; and the forty-ninth in the *Prælectiones*, published after his death by Giske. The plants with compound flowers are kept distinct by most authors, with only a little difference as to the proper limits and most convenient divisions of the order. But Linnæus observes, that, though it is perfectly natural, its essential character is not easily determined. A compound flower, from the obvious meaning of the term, implies the union of several flowers, or florets, as in this case they are usually called, by some common bond. But this character is not peculiar to the composite plants, nor does it extend to all their genera. For *Cephalanthus*, *dipsacus*, *scabiosa*, &c. have several florets included in a common calyx, but belong to a different family; and *seriphium*, *corymbium*, and *trumpalia*, have only one flower in each calyx, and yet cannot be separated from those which are truly compound. Nor will the united anthers, which Linnæus has taken for the distinguishing character of his artificial class *syngenesia*, exactly apply to this natural order; *jassone*, *viola*, *impatiens*, &c. have such anthers, but cannot properly be arranged with the compositæ.

In the *Philosophia Botanica* the order stands thus:

I. *Scnifistoculofis*, prenanthes, lactuca, cliondrilla, hieracium, crepis, andryala, hypochaeris, picris, yoseris, leontodon, scorzonera, tragopogon, scolymus, foncehus, lapsana, cichorium, catananche, elephantopus. II. *Capitata*, echinops, sphaeranthus, gundelia, arctium, ferratula, onopordum, carduus, cynara, carthamus, carlina, cynicus, atrachylis, centaurea, corymbium. III. *Corymbifera*, roeie, fantolia, chrysofocoma, tanacetum, klema, toechina, xeranthemum, gnaphalium, carpesium, conyza, tarachonanthus, baccharis, erigeron, tussilago, doronicum, solidago, fenecio, inula, aster, gerbera, othonna, chrysanthemum, matricaria, bupththalmum, anacyclus, cotula, anthemis, achilla, eriocephalus, helenium, arctotis, bellis, tagetes. IV. *Helianthus*, rudbeckia, coreopsis, bidens, verbena, figebeckia, milleria, silphium, eupatorium, ageratum, oilcolprium, calendula? chrysoygonum? melampodium? tridax? tetragonotheca?

All these are retained in the *Prælectiones*, except *gerbera*, which has been abolished, and its species referred to *arnica*. Several of them are also placed in different divisions.

The following is the arrangement in the synoptic table annexed to the Praelæfions. Those printed in Italics were added by Linnæus himself; and those marked with asterisks are additions by Giseke.

I. *Capitatae*, gundelia, echinops, sphaeranthus, arctium, ferratula, carduus, ciccus, onopordum, cynara, carina, *gorænia*, atractylis, carthamus, centaurea, *zoega*, elephantopus, removed from semibifolii, *burnadesia*, *veronica, Schreb. *natrix, *Gart.* II. *Semififoliosæ*, feolymus, cichorium, catananche, lapiana, hypochæris, *feriola*, *krigia, Schreb., hyoferis, *rothia, Schreb., andryala, crepis, hieracium, leontodon, prenanthes, chondrilla, lactuca, fonchus, *apargia, *Scop.*, picris, scorzonera, tragopogon, *geropogon*. III. *Difcoideæ*, gnaphalium, xeranthemum, stœchelinum, tanacetum, matricaria, carpeſium, chryfanthemum, *pteronia*, baccharis, *ofmites*, conyza, inula, erigeron, *cineraria*, tuſſilago, doronicum, *arnica*, fenecio, ſolidago, chryſocoma, after, *leſyera*, fantolina, anthemis, anacyclus, cotula, *athanafius*, achillea, *cacalia*, *perdicium*, bellis, age-atum, removed from oppoſitifolii, eupatorium, removed from oppoſitifolii, *ethulia*, *kubnia*, bellium, *unxia*, *mutifia*, *lavenia, *Soland. Sw.* *kleinia *Jacq.* Giseke obſerves, that it is not eaſy to determine why Linnæus has given the name of difcoideæ to this order, which nearly correſponds with his former corymbiferi; ſince the greater part of them are not difcoid, in the uſual ſenſe of the word, but furniſhed with a ray. IV. *Not named by Linnæus*. Corymbium, removed from ſemibifolii, helenium, othonna, and arctotis, removed from corymbifera, calendula, and oſteopermum, removed from oppoſitifolii, *feleroſcarpus, *Jacq.* V. *Oppoſitifoliae*, ſpilanthus, bidens, ver-

befina, ſyſchebeckia, coreopsis, filphium, tetragonotheca, *polymyria*, *trixis, *Swarz.*, helianthus, rudbeckia, milleria, buphthalmum, removed from corymbiferi, chryſogonum, melampodium, tridax, *pedis*, tagetes, removed from corymbiferi, *zinnia*, *calce*, *amelus*, *eclyſia*, *ballimora*, hippia, *cedera*, *clibadium*, *jurgia*, *relhania, *L'Herit.*, *boltonia, *L'Herit.*, *meyera, Schreb., *phaëtula, *Gart.*, *galardia, *Lam.*, *berckheya, *Erb.*, *cralpedia, *Forſt.*, *didelta, *L'Herit.*, *tetranthus, *Swarz.*, *rolanda, *Rottb.*, *shawia, *Forſt.* VI. *Nucumetacea*. ſtoebe, and tarchonanthus, removed from corymbifera, *artemiſia*, *ſcripbium*, eriocephalus, removed from corymbifera. *ſilago*, *microſus*, *iva*, *parthenium*, *ambroſia*, *xanthium*, *ſtrumphia*.

None of the plants of this order are poiſonous, except tagetes, doronicum, and arnica. Moſt of them are bitter and unpleaſant to the taſte, but poſſeſſed of ſtrengthening qualities as a medicine. Some, however, are leſs bitter and aculent; and ſeveral others are rendered fo by cultivation and blanching.

Vaillant, Juſſieu, and Ventenat have divided this order into three: *elictoracea*, *cinarocephala*, and *corymbifera*.

COMPOSITE NUMBERS, in *Ariſmetick*, are ſuch as can be exactly divided by ſome ſmaller number or numbers, without leaving any remainder; ſuch as do not admit of this even diviſion, are called *PRIME numbers*, which ſee. The following table of compoſite and prime numbers under 100, ſhewing all their prime diviſors, will be found uſeful in a great variety of calculations.

Units	1	2	3	4	5	6	7	8	9
0	1	2	3	4	5	6	7	8	9
1	2.5	11	2.3	13	2.7	3.5	2 ⁴	17	2.3 ²
2	2 ² .5	3.7	2.11	23	2 ³ .3	5 ²	2.13	3 ³	2 ² .7
3	2.3.5	31	2 ⁵	3.11	2.17	5.7	2 ² .3 ²	37	2.19
4	2 ³ .5	41	2.3.7	43	2 ² .11	3 ² .5	2.23	47	2 ⁴ .3
5	2.5 ²	3.17	2 ² .13	53	2.3 ³	5.11	2 ³ .7	3.19	2.29
6	2 ² .3.5	61	2.31	3 ² .7	2 ⁶	5.13	2.3.11	67	2 ² .17
7	2.5.7	71	2 ³ .3 ²	73	2.3.7	3.5 ²	2 ² .19	7.11	2.3.13
8	2 ⁴ .5	3 ⁴	2.41	83	2 ² .3.7	5.17	2.43	3.29	2 ² .11
9	2.3 ² .5	7.13	2 ² .23	3.31	2.47	5.19	2 ⁵ .3	97	2.7 ²

In the above table, any number is to be ſought for in the angle of meeting of its *teus*, in the front column, and its *units* in the top line; thus, 23 will be found in the line with 2 at its beginning, and under three at the top. The prime numbers are diſtinguiſhed by larger figures, and the compoſite numbers have their component primes ſtewn, ſeparated by dots to expreſs, in this caſe, the ſign of multiplication, as is frequently done by the writers on ſeries; thus 24 is compoſed of the ſquare of 2 or 2², multiplied by 3 and by 7; 72 is compoſed of the cube of 2 into the ſquare of 3. Matter of curious reflection will be furniſhed by this table to ſuch as ſtudy the properties of numbers, by tracing the parallel lines in which each prime occurs; thus, in

one diagonal of the above table, the whole of the multiples of 11 will be found, while 3² (or 9) will be found in the compoſition of every number in the other diagonal line; parallel to which, in every alternate line, the other multiples of 3 will be found. The fives and the twos will all be found to occur throughout every vertical column in which they occur at top; and under 0, they both occur in every line. This uſeful and curious table we found in M. Overend's manuſcripts, in the library of the Royal Inſtitution, where the moſt copious tables of compoſite and prime numbers may be ſeen, by thoſe who are curious in theſe matters.

COMPOSITE Numbers, in *Muſical Calculations*, are ſuch as are

are composed by the multiplication of the prime integers, 2, 3, and 5; all primes larger than these, or composite numbers into which such enter, are not musical numbers, but are irrational or furd in a musical sense. See **MUSICAL NUMBERS**.

COMPOSITE, or *Roman Order*, in *Architecture*. This name is used to denote a kind of column whose capital is compounded of the Ionic and Corinthian forms; the vase or tambour of the capital being like that of the Corinthian order, and ornamented in the same manner, with two tiers of leaves, and with a similar abacus; but to these are added Ionic volutes which supply the place of the caulicoli and ferules, proper to the Corinthian capital. See the plates of capitals. In other respects, in the shaft base and entablature, there is no uniform and assignable difference between the Composite and Corinthian, and we shall, in a subsequent portion of this article, examine what claims this composite has to be considered as a distinct order.

The principal remains of antiquity in which the composite capital is found, are the following; the arch of Titus, the arch of Septimius Severus, and the arch of the goldsmiths, the building commonly called the Temple of Bacchus, without the gate of Sta. Agnes at Rome, the baths of Diocletian, the Baptiterium of Constantine, which is ornamented with porphyry columns of the most exquisite workmanship, removed from some more ancient edifice; the arch at Verona, and the chapel or basilica at Nismes.

This capital was therefore very popular among the Roman architects, but it does not by any means appear that they admitted a distinct composite order. A passage of Vitruvius will throw some light upon this point; this author, after describing the capitals of the Doric, Ionic, and Corinthian orders, proceeds to observe, that "there are also other kinds of capitals called by various names, which are disposed on the same columns, and which have no proper symmetry or relation to any separate order of columns, but they are all derived and transferred from the Corinthian, Pulvinate (Ionic) or Doric orders, from whose symmetries they only differ in the little novelties of the sculpture." In fact, the remains of Roman antiquity furnish a vast variety of capitals, many of which are more remarkable and remote from the usual orders, as well as more beautiful than the composite capital, and yet no architect has ever thought of erecting any of these into distinct orders. The capitals of the Temple of Concord at Rome, a very entire and considerable remain, are composite, being a mélange of the Ionic and Doric; but no one has claimed the honours of an order for this strange production.

The difference between the pretended Composite order and the Corinthian, exists merely in the capital; for neither in the remains of antiquity, nor in the works of modern artists, is there any decided, uniform, and characteristic difference in any other particular. But the capital, though an important member, is not of itself sufficient to form an order, otherwise we should reckon not five but hundreds; and a composition which has no appropriate proportions, no exclusive character, can only be regarded as a variety of that order with which it is perpetually liable to be confounded. The equivocal nature of this production has caused great embarrassment to the system-mongers of architecture; for while its later origin would lead them to place it last in their systems, and highest in their buildings, its heaviness of appearance, in comparison with the Corinthian order, seems to indicate a contrary arrangement. It is unnecessary; for the three Grecian orders supply all the expressions which architecture is capable of giving with distinctness. The Doric is strong, the Ionic elegant, and the Corinthian rich;

while they admit all the modifications of these qualities that can be required; but as to the Composite, what is it but an exaggeration of the Corinthian, in which the attempt at superior richness has only produced a degree of heaviness.

It has been before observed, that the Romans affected no particular entablature to the composite capital. In the temple of Bacchus the cornice is entirely plain, with a swelled frieze. The arch of Septimius Severus has a cornice enriched with dentils extremely similar to the Ionic of the temple of Fortuna Virilis, and the theatre of Marcellus; while the cornices of the arch of Titus, and the arch at Verona have both dentils and modillions, and the whole profile of the entablature is precisely in the style of the generality of Corinthian examples. Among the moderns, Palladio has imitated the frontispiece of Nero in his cornice and architrave; but he has omitted its beautiful frieze, and substituted a swelled one. Scamozzi's entablature being only one-fifth of the column, and much divided, has rather a trifling appearance, though the details are upon the whole well designed. Vignola's composite has nothing in it remarkable; the architrave differs but little from that of the frontispiece of Nero, and the cornice is nearly the same with that of his Ionic order. Serlio's entablature is extravagantly absurd, being taken from the fourth order of the coliseum, a composition well enough adapted for the termination of that gigantic edifice, but wholly disproportionate to a single order.

COMPOSITE STALK. See **STALK**.

COMPOSITIO MENSURARUM, the title of an ancient ordinance for measures, not printed; it is mentioned in the statute of 23 Hen. VIII. cap. 4.

COMPOSITION, in a general sense, is the uniting or joining of several different things, so as to form one whole, called a *compound*.

The schoolmen distinguish two kinds of composition; the one *entitative*, which is between things of the same nature, *e. g.* two or more drops of water: the other *essential*, when things of different kinds are joined, and thus constitute new things, or essences, different from any of the parts: and thus, say they, from the matter and the form of wood, arises wood; whose essence is very different from either of those ingredients taken separately.

COMPOSITION OF BODIES, in *Chemistry*. See **COMBINATION** and **AFFINITY**.

COMPOSITION, in *Commerce*, a contract between an insolvent debtor and his creditors; whereby the latter agree to accept a part of the debt, in compensation for the whole, and give a general acquittance accordingly.

COMPOSITION FOR TREES, in *Gardening*, a substance discovered, prepared, and applied by Mr. Forsyth, for the purpose of removing diseases, defects, and injuries in fruit and forest-trees. It is directed to be composed in the following manner, in his "Treatise on the Management of Trees."

"Take one bushel of fresh cow-dung, half a bushel of lime-rubbish of old buildings (that from the ceilings of rooms is preferable), half a bushel of wood-ashes, and a sixteenth part of a bushel of pit or river-sand; the three last articles are to be sifted fine before they are mixed; then work them well together with a spade, and afterwards with a wooden beater, until the stuff is very smooth, like fine plaster used for the ceilings of rooms."

It is advised that the trees should be prepared for its application "by cutting away all the dead, decayed, and injured parts, down to the fresh sound wood; leaving the surface of the wood very smooth, and rounding off the edges of the bark with a draw-knife, or other instrument, perfectly

fully smooth, which must be particularly attended to; then lay on the plaster about one eighth of an inch thick all over the part where the wood or bark has been so cut away, finishing off the edges as thin as possible; then take a quantity of dry powder of wood ashes mixed with a sixth part of the same quantity of the ashes of burnt bones, put it into a tin box with holes in the top, and shake the powder on the surface of the plaster, till the whole is covered over with it, letting it remain for half an hour to absorb the moisture; then apply more powder, rubbing it on gently with the hand, and repeating the application of the powder till the whole plaster becomes a dry smooth surface."

And he adds the following directions.

"All trees cut down near the ground should have the surface made quite smooth, rounding it off in a small degree as before-mentioned; and the dry powder directed to be used afterwards, should have an equal quantity of powder of alabaster mixed with it, in order the better to resist the dripping of trees and heavy rains."

Such parts or portions of the composition as may be left for a future use "should be kept in a tub or other vessel, and urine of any kind poured on them, so as to cover the surface; otherwise the atmosphere will greatly hurt the efficacy of the application."

And "where lime-rubbish of old buildings cannot be easily got, take pounded chalk, or common lime, after having been flaked a month at least."

It is further remarked by the author, that "as the growth of the tree will gradually affect the plaster, by raising up its edges next the bark, care should be taken, when that happens, to rub it over with the finger when occasion may require (which is best done when moistened by rain), that the plaster may be kept whole, to prevent the air and wet from penetrating into the wood."

But "as the best way of using the composition is found, by experience, to be in a liquid state," Mr. Forlyth advises that it should "be reduced to the consistence of pretty thick paint, by mixing it up with a sufficient quantity of urine and soapuds, and be laid on with a painter's brush. The powder of wood-ashes and burnt bones is to be applied as before directed, patting it down with the hand."

It is also further advised, that "when trees are become hollow, to scoop out all the rotten, loose, and dead parts of the trunk to the solid wood, leaving the surface smooth; then to cover the hollow, and every part where the canker has been cut out, or branches lopped off, with the composition; and as the edges grow, to take care not to let the new wood come in contact with the dead, part of which it may be sometimes necessary to leave; but to cut out the old dead wood as the new advances, keeping a hollow between them, to allow the new wood room to extend itself, and thereby fill up the cavity, which it will do in time, so as to make it as it were a new tree."

And if the cavity be large, to cut away as much at one operation as will be sufficient for three years. But in this to "be guided by the size of the wound, and other circumstances. When the new wood, advancing from both sides of the wound, has almost met, to cut off the bark from both the edges, that the solid wood may join, which, if properly managed, it will do, leaving only a slight seam in the bark. If the tree be very much decayed, not to cut away all the dead wood at once, which would weaken the tree too much, if a standard, and endanger its being blown down by the wind. It will consequently be necessary to leave part of the dead wood at first, to strengthen the tree, and to cut it out by degrees as the new wood is formed. If there be any canker, or gum oozing out, the infected parts must be pared

off, or cut out with a proper instrument. When the stem is very much decayed and hollow, it will be necessary to open the ground and examine the roots." See DRESSING of Trees.

Various interesting facts and observations on the advantage and utility of this composition in the removal of the diseases of different sorts of trees, may be seen below, as taken from Mr. Forlyth's valuable "Treatise on the Culture and Management of Fruit and Forest Trees."

It is stated by Mr. Forlyth as being "the received opinion and common practice of most professional men, to prune or lop their trees, from the month of October, when the juices have been exhausted by the summer foliage, autumnal fruit, and general nourishment of the body of the tree, until the month of March, when the sap or juices, re-invigorated by nature during the winter's repose, begin to re-ascend and perform the annual function of clothing it with fresh foliage, blossoms, and fruit. The reason of this practice is, he says, that the sap being fallen at that season of the year, it has been considered as the most proper period to lop off all superfluous growths, and the efforts of nature to heal the wounds thus necessarily given (before the rising of the sap in the following spring), have been judged best for the safety and health of the tree. The danger of performing this service when the juices are in a more vigorous flow, as in the months of May, June, and July, has been dreaded, from a fear of its occasioning a waste of the nutritive juices, discharging themselves through the wound, to the impoverishment and injury, if not the ruin of the tree." And it is added, that "the pruning of fruit-trees, and the lopping off large branches from forest-trees during the winter season, has also been frequently attended with great hurt and impediment to their health and vegetation; the wounds being exposed to all the rigours of an inclement season, and thereby contracting those diseases which contain the principles of decay. Hence it is, that such numbers of forest-trees are continually injured in their value for public uses, either by unskillful management, or purposeful depredation, or by the violence of boisterous winds, when their limbs and branches being torn off, the trees are left in that unprotected state to imbibe the seeds of decay and rottenness, which will in time pervade their very heart, and render them unfit for any of those valuable purposes for which nature, by their frame and texture, appears to have designed them." And "it may also be observed, that where branches have been cut off from the body of the tree, even at the distance of two or more feet from the trunk, with a view to prevent injury to the timber, even that method has not been found effectual to save the tree from very material detriment; as the remaining stem of the branch so cut away, dying soon after, becomes a ready conduit for conveying pernicious moisture and disease to that part of the tree with which it is connected; and so on, in time, to the whole."

But he supposes "the practice of others in lopping their trees close to the trunk, and dressing the part smooth and even, has less objections than the former; nevertheless, even according to this method, the tree is liable to injury. The effort of nature to heal the wounds thus given, discovers itself by encircling the wound with a kind of callus or lip, which increasing in size, and swelling out from the annual flow of the juices, forms a hollow or cavity of the central part, where the rain or snow is very apt to lodge; and penetrating between the bark and wood, dried and cracked by a hard frost, or a warm sun, promotes that fermentation with the natural juices, which is the certain source of disease and decay." It is suggested that "young, healthful, and vigorous

gorous trees, when they have been injured by being wantonly cut through the bark, or from other causes, will sometimes recover themselves, and, to all outward appearance, be restored to their original soundness; but when cut into planks and boards, internal blemishes and faults are discovered in them, which appear to have been occasioned by the early injuries which the tree had received; the texture of the wood not uniting where the wound was originally given; though, from the youthful vigour of nature, the bark has closed, and an external cure been evidently performed on such trees.

The composition is a most efficacious remedy to prevent these evils with all their destructive consequences, and to restore sound timber where the symptoms of decay are already apparent, which being applied in the manner directed, "to the wound or injured part, will infallibly prevent the bleeding of trees, or the oozing of juices through the wounds of limbs or branches that have been cut off in the middle of summer, when they are in their highest vigour, and most rapid flow of vegetation; by which means, any wretched discharge of the juices is prevented, and they are duly confined to their natural operations of giving nourishment, growth, and fertility, to their respective bodies. By employing this remedy, trees of all kinds, whether in gardens or orchards, in parks or forests, may, he says, with greater safety and advantage be pruned or lopped in the spring, or early in the summer, than in the winter season; as the composition, when properly applied, repels the flow of the juices through the wound, causes a more active vegetation, and assists nature more powerfully in healing the wound at the time the sap is in full vigour, than when it is on the decline, as in autumn and winter seasons."

The writer considers it also necessary to remark, further, "that both fruit and forest-trees (particularly those which grow in the shade) are very liable to be affected with disorders proceeding from the growth of liverwort, and various kinds of moss, that adhere to the outer bark of the tree, and frequently gain a considerable thickness, that not only prevents the natural flow of the juices, but causes a stagnation in the circulation and brings on decay; which, after destroying the outer bark, penetrates by degrees deeper into the wood. Where this circumstance is observed, care should be taken to clear the whole bark of the tree from these growths; and where it is infected, to scrape or pare it away. When the body of the tree is thus cleansed from infection, the composition may be applied to the parts so cleansed, to close the pores of the wood; when the tree will soon acquire a fresh bark, and improved health and vegetation."

The author is "confirmed in these opinions by the many experiments and various trials that he has made, to ascertain, by the most positive proofs, the properties of this composition, before he ventured to offer it to the public attention." "Indeed, every year's experience has increased his conviction of its general utility, when properly applied to the purposes for which it is recommended." In order to give a more complete illustration of its virtues, and to place the advantages arising from it in a stronger light, he states a few of the very numerous experiments that he has made on the forest trees in his majesty's gardens at Kensington, where the salutary effects of it are extremely evident.

It is remarked that "the first trials of its efficacy were made on some very large and ancient elms, many of which were in a most decayed state, having all their upper parts broken, by high winds, from their trunks, which were withal so hollow and decayed, that a small portion alone of the bark remained alive and sound. Of these trees he

cut away at first a part only of the rotten stuff from the hollow of the tree, and then applied the plaster to the place where the operation had been performed, by way of an internal coat. In a short time, however, the efforts of nature, with a renovated flow of the juices, were clearly discernible in their formation of new wood, uniting with and swelling as it were from the old, till it became a strong support to that part of the tree where the composition had been applied. He then cut away more of the rotten wood from the inside, applying the plaster in the same manner, with the same good effects, and continued to use the knife in proportion to the acquisition of new wood; so that from the tops of the decayed and naked trunks, stems have, he says, actually grown of about thirty feet in height, in the course of six or seven years from the first application of the composition; an incontrovertible proof of its good effects in restoring decayed vegetation in such cases."

And he adds, that "many other elm trees, which had received hurts from bruises and other causes, and where decay and decay were already evident, after cutting away all the infected part, and duly applying the plaster, were so completely healed, that the outline of the wound is scarcely discernible on the bark, and the new wood is as perfectly united to the old, as if it had been originally formed with the tree."

It is stated that "of oak trees also, which had received very considerable damage from various accidents, as blows, bruises, and cutting of deep letter, the rubbing off of the bark by the ends of rollers, or wheels of carts, and mutilated branches, a perfect cure has been made, and sound timber produced. The acidity, or corrosive quality of the juice of oak-trees, when obstructed in their circulation from any of the causes already mentioned, and fermenting with the wet and moisture imbibed by the wounds from the atmosphere, will bring on disease, and promote decay; for, notwithstanding the hard texture of the oak, when once the principles of decay begin to operate, the acrimonious juices feed the disease, and accelerate its progress, as much, perhaps, as in trees of a softer quality and texture, but when the diseased or injured part is entirely cut away to the fresh sound wood, and the composition properly laid on, as perfect a cure has been made as he has already related in the recovery of elm trees."

The writer likewise further states, that "various experiments have also been made on other forest trees, as ash, limes, chestnuts, and sycamores, that had received the several injuries to which they are exposed; as well as many of the resinous kinds, such as the cedar of Lebanon, and others of the pine tribe: in all of which he has experienced a degree of success that exceeded his most sanguine expectations. And as he feels a strong solicitude to render his experiments of the most extensive advantage to the community, and in particular to the proprietors of landed estates throughout the kingdom, he begs leave to recommend to their particular attention, that all forest trees, whether felled with a saw or an axe, may be cut near to the ground; at the same time carefully preserving the stump and roots from any further injury. The surface may then be made quite smooth, and the composition be spread over the whole, according to directions already given. But in these cases the composition should have an equal quantity of the powder of stibacter mixed with the dry powder generally directed to be used after it is laid on, in order to render the surface harder, and of course better able to resist the bad effects of the dripping of trees, of rain, frost, and snow; an addition which is by no means necessary in the usual application to the sides of trees." He concludes that, "in consequence of this pro-

ers, the vigour of the roots will operate so powerfully in the course of the succeeding spring, that a considerable number of buds or branches will shoot forth round the stump, which, with proper care and attention, may be trained to many valuable purposes, either straight or crooked, for knee timber, or other uses; and, by retaining only so many of these shoots as are designed to grow for any particular intention, more than one half will be saved, in point of time, according to the proportions of common growth; for, if a young tree be planted in a soil equal in quality to the state of the old stump, the roots growing from the latter will, in eight or ten years, attain to a size which the single plant will hardly acquire in twice that period. There are also many useful purposes of husbandry, as hop-poles and other poles used on various occasions, for which a number of shoots may be trained from one stump, whose fertile juices will shortly rear a healthy and numerous offspring around it. Very particular attention, however, should, he says, be paid to regulate the number, according to the size and vigour of the stump. It would certainly be proper to leave more of them at first than are intended to be reserved for final use, in order to draw up the sap; if too few are left, they will be liable to burst, from the superabundant flow of the juices from the old stock; to prevent which inconvenience they should be cut away by degrees, always applying the composition as they are cut, and leaving the stump to produce the new tree, and will, in time, cover the old stump, and leave nothing but a faint kind of cicatrix at the junction of the old and new part of the tree."

He thinks it "needless for him to insist on the great advantages which land proprietors and farmers will derive from this method of managing their woods and coppice-grounds, wherever they may be. In many counties of England, coppice, or underwood is an article in very great demand for charcoal, common fuel, or the purposes of particular manufactures, as well as to furnish a variety of articles for husbandry and domestic conveniences." And its advantages in a national as well as ornamental point of view, are still more obvious. See CANKER.

COMPOSITION, in *Grammar*, denotes the joining of two words together; or prefixing a particle to another word, to augment, diminish, or change its signification. See WORD, &c.

COMPOSITION, in *Law*, an agreement or contract made between the owner of lands and the parson or vicar, with the consent of the ordinary and the patron, that such lands shall for the future be discharged from payment of tithes, by reason of some land or other real recompence, given to the parson, in lieu and satisfaction thereof. Land may be exempted from the payment of tithes, where compositions have been made; and real compositions for tithes are to be made by the concurrent consent of the parson, patron, and ordinary. Real compositions are distinguished from personal contracts; for a composition called a personal contract is only an agreement between the parson and the parishioners, to pay so much instead of tithes; and though such agreement is confirmed by the ordinary, yet (if the parson be not a party) that doth not make it a real composition, because he ought to be a party to the deed of composition. (Marsh's Rep. 87.) This kind of composition was permitted by law, because it was supposed that the clergy would be no losers by such composition; since the consent of the ordinary, whose duty it is to take care of the church in general, and of the patron, whose interest it is to protect that particular church, were both made necessary to render the composition effectual; and hence have arisen all such compositions as exist at this day by force of common

law. But, experience shewing that even this caution was ineffectual, and the possessions of the church being, by this and other means, every day diminished, the disabling statute 13 Eliz. c. 10, was made, which prevents, among other spiritual persons, all parsons and vicars from making any conveyances of the estates of their churches, other than for three lives or twenty-one years. So that now, by virtue of this statute, no real composition made since the 13th Eliz. is good for any longer term than three lives, or twenty-one years, though made by consent of the patron and ordinary; which has, indeed, effectually demolished this kind of traffic; such compositions being now rarely heard of, unless by authority of parliament. See MODUS.

Composition is sometimes used for "decisio litis." Accordingly compositions were anciently allowed for crimes and offences, even for murder. By this expedient it was proposed to refrain the violence of private revenge. The custom may be traced back to the ancient Germans (see Tacit. de Mor. German. c. 21.) and prevailed in other uncivilized nations. The nature of crimes and offences was estimated by the magistrate, and the sum due to the person offended was ascertained with a minute, and often after a whimsical, accuracy. Rotharis, the legislator of the Lombards, who reigned about the middle of the 7th century, discovers his intention both in ascertaining the composition to be paid by the offender, and in increasing its value: it is, says he, that the enmity may be extinguished, the persecution may cease, and peace may be restored. About the beginning of the 9th century, Charlemagne struck at the root of the evil, and enacted, "that when any person had been guilty of a crime, or had committed an outrage, he should immediately submit to the penance which the church imposed, and offer to pay the composition which the law preferred, and if the injured person or his kindred should refuse to accept of this, and presume to avenge themselves by force of arms, their lands and properties should be forfeited." Tavernier relates, that in Persia, a murderer is still delivered to the relations of the person whom he has slain, who put him to death with their own hands; and if they refuse a sum of money as a compensation, the sovereign cannot pardon the murderer. Monteq. Sp. of Laws, vol. ii. p. 382. Robertson's Hist. of Ch. V. vol. i. p. 334, &c.

COMPOSITION, in *Logic*, is a method of reasoning, wherein we proceed from some general self-evident truth, to other particular and singular ones.

The method of composition, call'd also *synthesis*, is just the reverse of that of resolution, or *analysis*.

Resolution is the method whereby we ordinarily search after truth: composition, that whereby a truth found, is discovered and demonstrated to others; resolution is the method of investigation; composition, of demonstration.

The method of composition is that used by Euclid, and other geometers; resolution, that used by algebraists and philosophers. The two methods differ, just as the methods of searching a genealogy; which are either by descending from the ancestors to the posterity, or by ascending from the posterity to their ancestors: each have this in common, that their progression is from a thing known, to another unknown.

The method of composition is best observed by the mathematicians: the rules which are, 1. To offer nothing but what is couched in clear and express terms; and to that end, to begin with definition. 2. To build only on evident and clear principles; to that end, to proceed from axioms or maxims. 3. To prove demonstratively all the conclusions that are drawn hence; and to this purpose, to make use of no arguments or proofs, but definitions already laid down,

axioms

COMPOSITION.

axioms already granted, and propositions already proved; which serve as principles to things that follow.

COMPOSITION of ideas, is an operation of the mind, whereby it combines several of its simple ideas into complex ones.

Under the same operation may likewise be reckoned that of enlarging; whereby we put several ideas together of the same kind, as several units to make a dozen.

In this, as in others, brutes come far short of men; for though they take in and retain several combinations of simple ideas; as possibly, a dog does the shape, smell, and voice of his master; yet these are rather for many distinct marks whereby he knows him, than one complex idea, made out of those simple ones.

An ingenious writer has suggested the impropriety of the phrase "composition of ideas," adopted by Mr. Locke, alleging it is merely a contrivance of language, and that the only composition is in the terms; and that it is as improper to speak of a complex idea, as it would be to call a constellation a complex star. He further adds, that they are not ideas, but merely terms, which are general and abstract. Whatever, he says, the immortal author of the "Essay on Understanding," has justly concluded in his reasoning on this subject will hold equally true and clear, if we substitute the composition, &c. of terms, wherever he has supposed a composition, &c. of ideas. If upon strict examination this should appear to be the case, we shall need no other argument against the composition of ideas; it being exactly similar to that unanswerable one which Mr. Locke himself declares to be sufficient against their being innate. For the supposition is unnecessary: every purpose for which the composition of ideas was imagined being more easily and naturally answered by the composition of terms; whilst at the same time it likewise clears up many difficulties, in which the supposed composition of ideas necessarily involves us. This writer further adds, that it is an easy matter, upon Mr. Locke's own principles, and a physical consideration of the senses and the mind, to prove the impossibility of the composition of ideas. Tooke's Diversions of Purley, pt. i. p. 37, &c.

COMPOSITION, in *Mathematics*, is the taking of a given number of quantities, out of as many equal rows of different quantities, one out of every row; and combining them together. Here no regard is had to their places; and it differs from combination, in which there is but one row of things.

1. "The number of compositions of n things taken out of n rows, each row consisting of m things, is m^n , or the n^{th} power of m ."

Let there be any number of rows, such as a, b, c, d , those annexed. It is plain the number of single things as a, b, c, d , is m or m^1 .

Then the number of combinations of every 2 is had by joining each quantity in the second row to all the quantities in the first, which will make as many times m as there are things in the second row, or m times m , that is m^2 , for all the two's. Again, taking in the third row; there will be as many times m^2 , as there are things in the third row, that is, m times mm , or m^3 , for the composition of three things.

After the same manner, if a fourth row was taken in; all the combinations of every four would be m^4 , and so on; and, therefore, universally, when n rows are taken in, the number of combinations will be m^n , which is the number of compositions. Hence it follows, 1. That the number of compositions of

all the one's, two's, three's, &c. to n , is $\frac{m^n - 1}{m - 1} m$. For

$\frac{m^n - 1}{m - 1} = m^n + m^{n-1} + m^{n-2} + \dots + m + 1$. And $\frac{m^n - 1}{m - 1} m = m^n + m^{n-1} + m^{n-2} + \dots + m^2 + m$, as will appear by division, or, in general, $\frac{m^n - 1}{m - 1} m = m^n + m^{n-1}$, &c. to $m =$ compositions of all the one's, two's, three's, &c. to n .

2. Hence may be found the composition of n things out of m , as follows: Involve m to the n^{th} power for the answer.

E. G. 1. How many compositions may be had, of 3 letters out of 20?

Ans. $20^3 = 8000$. In this case there should be three different alphabets.

E. G. 2. How many changes are there on throwing four dice?

Ans. $6^4 = 1296$.

II. "If there be m rows of quantities given, having the same quantities, and the same number of them, as a, b, c, d , &c. to find the number of compositions of m things taken out of the m rows; for any given form of these quantities, as $a^1 b^0 c^0 d^0$, &c.

Rule. Put $V =$ variations of the things $a^1 b^0 c^0 d^0$; and $A =$ variations or alternations of the indexes, $1, v, w, x$. (SEE CHANGES AND PERMUTATION.) Then will $\Delta V =$ the number of compositions required.

For let the different rows in the last proposition be made all alike, or the first row a, b, c, d , m times repeated, as here. And let the number of things proposed be $a^1 b^1 c^1$, and first let the index 3 be fixed to a and 2 to b , &c. Now, since a^3 may be taken out of any three rows, and b^2 out of any two remaining rows; a, b, c, d , and c out of the last remaining row; therefore, there will be so many ways of taking these letters, as each of them can be placed in different rows, that is, in different places or situations; for the varying of the rows is the same thing as the varying of the places of the letters; and, consequently, the different ways of taking them out of the several rows is equal to the number of variations or permutations of these letters; which number is V . And this will hold as long as the indexes are fixed to these particular letters, and to none else. But since, in any one form, as $a^1 b^1 c^1$, that form will comprehend as many cases as there can be variations in shifting the indexes from one letter to another; therefore, there will be so many times V , as is the number of these variations, or alternations, of the indexes, 3, 2, 1; or, in general, of $1, v, w, x$; then ΔV will be the whole number of compositions, which that particular form will admit of.

Hence, 1. In any $a^1 b^0 c^0 d^0$, where the indexes are fixed invariably to their particular letters; the number of compositions V will be $= \frac{1 \times 2 \times 3 \times 4 \dots \text{to } m}{1 \cdot 2 \cdot 3 \dots 1 \times 1 \cdot 2 \cdot 3 \dots \text{to } v \times \&c.}$

2. If $n =$ the number of different letters in any form, $a^1 b^0 c^0 d^0$, &c.; then the whole number of compositions for that form will be $= \frac{1 \cdot 2 \cdot 3 \dots \text{to } n}{R \cdot S, \&c.} \times$

$\frac{1 \cdot 2 \cdot 3 \dots \text{to } m}{1 \cdot 2 \dots 1 \times 1 \cdot 2 \dots v \times \&c.}$ where $R = 1 \cdot 2$, or $1 \cdot 2 \cdot 3$, &c. according as any index is twice or thrice, &c. repeated; and the like for S , and so on.

E. G. 1. How many compositions are in the form $a^1 b^1 c^1$? Here $n = 3$, $m = 6$, $1 = 3$, $v = 2$, $w = 1$; and in this case there is no repetition of indexes.

$$\text{Ans. } 1 \cdot 2 \cdot 3 \times \frac{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6}{1 \cdot 2 \cdot 3 \times 1 \cdot 2} = 6 \times 60 = 360.$$

E. G. 2. How many compositions are in the form $a^2 b^2 c^2$? Here $n = 3$, $m = 5$, $l = 2$, $v = 2$, $w = 1$. The index 2 is twice repeated.

$$\text{Ans. } \frac{1 \cdot 2 \cdot 3}{1 \cdot 2} \times \frac{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5}{1 \cdot 2 \times 1 \cdot 2} = 3 \times 30 = 90.$$

E. G. 3. To find the compositions in the form $a^3 b^3$. Here $n = 2$, $m = 6$, $l = 3$, $v = 3$, $w = 0$. The index 3 is twice repeated; and the letters a, b thrice.

$$\text{Ans. } \frac{1 \cdot 2}{1 \cdot 2} \times \frac{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6}{1 \cdot 2 \cdot 3 \times 1 \cdot 2 \cdot 3} = 1 \times 20 = 20.$$

E. G. 4. To find the number of compositions of the form $a^3 b^3 c^3 d^3$. Here $n = 4$, $m = 10$, $l = 3$, $v = 3$, $w = 2$. The index 3 is twice repeated, and also the index 2. The letters a, b are thrice repeated; and c, d twice.

$$\text{Ans. } \frac{1 \cdot 2 \cdot 3 \cdot 4}{1 \cdot 2 \times 1 \cdot 2} \times \frac{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7 \cdot 8 \cdot 9 \cdot 10}{1 \cdot 2 \cdot 3 \times 1 \cdot 2 \cdot 3 \times 1 \cdot 2 \times 1 \cdot 2} = 6 \times 25200 = 151200.$$

E. G. 5. How many compositions in the form $a^4 b^3 c^2 d^2 e^2 f^2$? Here $n = 6$, $m = 14$, $l = 5$, $v = 3$, $w = 1$. The index 3 is twice repeated, and the index 1 thrice: the letter a five times repeated; and b and c thrice.

$$\text{Ans. } \frac{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6}{1 \cdot 2 \cdot 3 \times 1 \cdot 2} \times \frac{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7 \cdot 8 \cdot 9 \cdot 10 \cdot 11 \cdot 12 \cdot 13 \cdot 14}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \times 1 \cdot 2 \cdot 3 \times 1 \cdot 2 \cdot 3} = 60 \times 20180160 = 1210809600.$$

So prodigiously do the numbers increase in these operations. See COMBINATION and COMPOSITE numbers.

COMPOSITION of motion, in *Mechanics*, is an assemblage of several directions of motion, resulting from powers acting in different, though not opposite lines.

If a point move or slow according to one and the same direction, whether that motion be equable or not, yet it will still keep the same right line; the celerity alone being changed, *i. e.* increased, or diminished, according to the forces with which it is impelled. If the directions be opposite, as one, *e. gr.* directly downward, the other upward, &c. yet still the line of motion will be the same.

But if the compounding motions be not according to the same line of direction, the compound motion will not be according to the line of direction of any of them, but in a different one from them all; and this either straight or crooked, according as the direction or celerities shall require.

If two compounding motions be each of them equable, the line of the compound motion will still be a straight line; and this, though the motions be neither at right angles one to another, nor equally swift, nor (each to itself) equable; provided that they be but similar; that is, both accelerated and retarded alike.

Thus, if the point a (*Pl. XV. Mechanics. fig. 1.*) be impelled equally with two forces; *viz.* upwards, towards b , and forwards, towards d ; it is plain, that when it is gone forwards as far as ac , it must of necessity be gone upwards as far as ce ; so that were the motions both equable, it would always go on in the diagonal ace .

Nay, suppose the motions unequal as to celerity, *v. gr.* as that the body move twice as fast upwards as forwards, &c. yet still it must go on in the diagonal ac ; because the triangles acc , acc , &c. and acd will still be similar, being as the motions are: and it will have described the diagonal in the same time which it would have required to describe either of the sides singly.

But, if the motions be dissimilar, then the compound motion must be a curve.

And, if a body, as b (*fig. 2.*) be impelled or drawn by

three different forces, in the three different directions $ba, bc,$ and bd . so that it yields to none of them, but continues in *equilibrium*; then will those three powers or forces be to one another, as three right lines drawn parallel to those lines, expressing the three different directions, and terminated by their mutual concourse.

Let bc represent the force by which the body b is impelled from b to c ; then will the same right line bc represent also the contrary equal force, by which it is impelled from b to e : but by what hath been said before, the force bc is resolvable into the two forces acting according to the two directions bd and bc , to which the other impelling from b to e , is as bc to bd , and bc or de , respectively.

So likewise two forces, acting without the directions bd, bc , and being equipollent to the force acting without the direction bc , from b to e ; will be to the force acting according to the direction bc , from b to e , as bd, bc , to bc ; and therefore, the forces acting in the directions bd, bc , and equipollent to the force acting in the direction bc , are to the force acting in the direction bc , as bd, bc , or de , to bc : that is, if a body be urged by three different equipollent powers in the directions ba, bd , and bc ; these three forces shall be to one another as bc, bd , and de , respectively.

This theorem, with its corollaries, Dr. Keill observes, is the foundation of all the new mechanics of M. Varignon: by help of which may the force of the muscles be computed, and most of the mechanic theorems in Borelli, *De Motu Animalium*, be immediately deduced. See MOTION.

COMPOSITION of proportion.—If there be two ratios, wherein the antecedent of the first is to its consequent, as the antecedent of the other is to its consequent; then, by composition of proportion, as the sum of the antecedent and consequent of the first ratio, is to the antecedent, or the consequent, of the first; so is the sum of the antecedent and consequent of the second ratio, to the antecedent, or the consequent, of the second.

E. gr. If $A : B :: C : D$; then by composition, $A + B : A$ or $(B) : C + D$ or (D) . See PROPORTION.

COMPOSITION of ratios, in *Arithmetic* and *Algebra*, is performed by multiplying the quantities or exponents of two or more ratios together; the product is then said to be compounded of the ratios whose components were multiplied. Thus, if the quantities or exponents of the ratios a to b , c to d , e to f , be multiplied, we shall have

$$\frac{a}{b} \times \frac{c}{d} \times \frac{e}{f} = \frac{ace}{bdf}. \text{ And the ratio } ace \text{ to } bdf, \text{ is then said to be compounded of the several ratios } a \text{ to } b, c \text{ to } d, e \text{ to } f, \text{ \&c. Thus also the ratio of } 10 \text{ to } 12, \text{ is compounded of the ratio } 2 \text{ to } 3, \text{ and of } 5 \text{ to } 4; \text{ for } \frac{2}{3} \times \frac{5}{4} = \frac{10}{12}.$$

This operation is by some called *addition* of ratios. See RATIO.

COMPOSITION, in *Musick*, implies harmony, music in different parts, according with each other; and by the mixture of concords and discords embellishing melody, and communicating at once, to a well organized ear, the double delight arising from the union of the two great constituent ingredients in music, MELODY and HARMONY. To be able to write down or dictate a melody or single part, does not exalt its author to the rank of composer; though many have assumed that title, who have not been possessed of science sufficient to make a base to a ballad or minuet.

As the term *composition* implies the union of various ingredients we shall endeavour in the important article COUNTERPOINT,

COMPOSITION.

TERPOINT, from our own knowledge, and from the precepts and practice of the greatest masters of the art, to describe these ingredients, and point out their legitimate use. See **COUNTERPOINT**, which is so nearly synonymous with *Composition*, that we know not how to separate them.

We take it for granted, before a musical student is inflamed with the ambition of becoming a *composer*, that he is perfectly acquainted with the elements of the art; that he has read, or at least heard, the principal productions of great masters; that he knows intervals, and their relation to the key note and distance from every other sound of the scale. See **SCALE** and **INTERVAL**. That he knows the different measures or kinds of time in music, nor is unacquainted with rhythm, nor where the accents of each bar should be placed. See **TIME**, **ACCENT**, and **MEASURE**. That he knows and feels the difference between concords and discords; is offended with false intonation, and instruments out of tune; feels something wrong in the regular succession of two sharp 3ds or 6ths; two 5ths or two common chords rising or falling one degree; that he knows the compass and genius of the voice or instrument for which he writes. But we must not take too much for granted, or, in order to save ourselves trouble, tease our readers with too many references to articles connected with *composition*; we shall therefore refer our readers to the article *Counterpoint*, (which we have laboured with great zeal) for the mechanical rules of composition; first reminding the young student, that the scale of eight notes ascending and descending, which represents the whole system in a major key, consists of 5 tones and 2 semitones, the 8th note being a recurrence of the same letter, and nearly the same sound, is included in the same harmony as the key note or principal base.

Keys are denominated major or minor, sharp or flat, from the situation of the semitones. Let C ♯ represent all major keys, and A ♯ the minor. In the major keys, the two semitones lie from the 3d to the 4th, and 7th to the 8th; and in minor keys, from the 2d to the 3d, and 5th to the 6th, ascending in the major, and to avoid accidental sharps, ascending in the minor, thus:

Major key. Ascending.

Minor key. Descending.

A sharp or flat at the clef, or an accidental sharp or flat in the middle of a melody, changes the place of the first semitone; and two sharps or two flats change the place of both,

Of these eight notes, some are termed *concords*, and some *discords*. Of the concords, some are *perfect*, and cannot be changed by an accidental sharp or flat, without becoming discords. These are the 4th, 5th, and 8th, which furnish, when used in the lower part of the scale, a base to the regular ascent in the treble. See **SCALE**, **FUNDAMENTAL BASE**, and **COMPOSER**.

COMPOSITION, in *Oratory*, the order and coherence of the parts of a discourse.

As a part of general *elocution*, (which see) it regards the turn and harmony of the periods: and therefore to *composition* be-

long, both the artful joining of the words, whereof the style is formed, and whereby it is rendered soft and smooth, gentle and flowing, full and sonorous; or the contrary: and the order, which requires things first in nature and dignity, to be put before those of inferior consideration.

Composition consists of four parts: which rhetoricians call **PERIOD**, **ORDER**, **JUNCTURE**, and **NUMBER**, which see respectively. Ward's *Oratory*, vol. i. p. 340.

COMPOSITION, in *Painting*, is that great and important requisite, the knowledge of which enables the artist to dispose all the various objects in his picture, as required by the subject, and furnished by the imagination or invention, in such a manner as to render them, individually and collectively, most conducive to the beauty, the effect, and the expression of the whole work. The objects furnished by the imagination or invention, may be considered as so many unmanufactured materials, which the science of composition teaches us to work up and display, as the peculiar circumstances of each case may require. Composition, in its general sense, may, therefore, be styled the ground-work of painting, upon which the superstructure, expression, design, chiaro-scuro, and colouring, in a greater or less degree depend; and the science of it opens a wide field for our consideration, as it supposes not only the knowledge of all the various combinations or contracts of lines and forms, which are calculated to produce agreeable or striking effects in general, but likewise, that judicious choice in their selection which may be most applicable to the distinguishing character and expression of each subject or work in particular. Composition, thus contemplated, is no longer confined to the artificial pyramid or the forced contrast, but embraces every possible diversity of arrangement and distribution, from the artist's simplicity of Giotto and Masaccio, to the most studied and complex grouping of Buonarroti and Rubens.

In treating this subject we shall follow the same method which we pursued in our inquiries respecting *clair-obscur* and colouring. We shall commence by taking a cursory view of the style of the first restorers of painting, then trace the principles and systems of composition at different periods introduced by their successors, and conclude by recommending such examples, and such precepts, as we conceive may be most calculated to insure the student's improvement.

The efforts of the early artists, Cimabue, Giotto, and their school, were entirely directed to one great point, the appropriate expression of the story to be represented; every kind of artifice was to them unknown, and their pictures may be compared to the simple unembellished diction of the rude but faithful historian, or to the wild but uncouth strains of the untutored muse. These old painters, in their scriptural or ecclesiastical representations in the churches of Italy, seem to have considered the art in no other light than as a means by which to conduce to the devotion of the people, and as they really believed the truth of those stories which they endeavoured to represent, (upon which perhaps a great deal depends), so they described every incident exactly as they supposed, or had been taught by tradition to believe, it had taken place. In their pictures of the Madonna, styled in the Roman church, the Mother of God, and in their attempts to give the image of that eternal being which man never saw, the effect was rendered more awful and impressive by the introduction of choirs of angels and saints, in regular order, disposed on each side and behind the throne; a more picturesque distribution of figures may be found, it is true, in the large altar pictures of the more modern painters, Carlo Maratti, Luca Giordano, and others; but then

solemnity and dignity are sacrificed, where the Virgin Mary, with the saints and angels, her attendants, seem huddled together with as little decorum, as if a group of beggar children, at play in the street, had been the subject to be represented.

In all those pictures of the old painters, which may be more particularly styled devotional, we perceive an attempt to elevate the mind of the spectator to the contemplation of celestial enjoyments; in the pictures of the moderns, beginning from the death of the divine Raffaele, artifice is too apparent, and the subject seems too frequently to have been made subservient to the desire of the painter to display his own academic acquirements. Nature alone seems to have been the preceptress of the old painters in composition, and hence that variety, and at the same time that simplicity in their works which we so much admire; but as they were extremely deficient in many necessary parts of the art, and particularly in the: three, drawing, perspective, and chiaro-obscuro, it is not surprising if, in the eyes of curious observers, their pictures have alone to boast the merit of antiquity, and that interest which is necessarily attached to the early efforts of man in every branch of study.

Instances, however, may be found, even in the works of the oldest painters, of compositions uniting at once propriety of expression, with beauty of disposition: amongst the numerous frescoes of Cimabue still remaining in the church of St Francis, at Assisi, there is in particular one, representing a dead Christ with the Marys and other figures, where, the subject naturally allowing of it, the artist has given such an agreeable form to the groups, by introducing around the recumbent figure of our Lord, the varied attitudes of figures kneeling and standing, as to leave little to be desired, save a greater perfection in the executive and mechanical parts of the art.

The works of Giotto, the scholar of Cimabue, may be studied with abundant advantage as to invention and composition. The church of Assisi, above-mentioned, possesses an extensive series of the frescoes of this extraordinary child of nature, representing stories of the life and miracles of St. Francis; here the compositions, though ever subservient to the expression of their subjects, are in some instances so beautifully grouped, as to leave it almost doubtful whether, in this respect, they ever were surpassed even by the best artists of later periods. One of these represents the story of a nobleman of dissolute character, who having heard of the fame of St. Francis, invited him and his companion, another friar, one day to his table. The holy conversation of the saint had such influence on the nobleman, that he made to him a full and contrite confession of his sins, when, after receiving absolution, he instantly fell down and expired. Giotto has seized this moment. The women, relatives of the deceased, the attendants, all flock, with varied expressions of grief, astonishment, and terror, to the corner of the picture where he lies; an elderly man, (thereby forming the connection between this group and the other) is represented imploring the interposition of St. Francis, who, rising from his seat, seems to pity their sorrow, at the same time that he endeavours to alluage it by the consolatory assurance that the sins of their master are forgiven, and that his spirit is in peace. The friar alone, accustomed to behold miracles, sits unmoved.

In another of these frescoes, Giotto has represented the moment, when, after the death of St. Francis, his body was carried, in the way to the place of burial, to the convent of Sta. Clara. The bearers of the body, surrounded by a concourse of people, have rested the bier on the ground: Sta. Clara is taking a last look at the face of him, who, in her youth, she so much loved, one of the nuns is

kissing the feet of the departed saint, a second bathes his hand with her tears, whilst others, with a gracefulness and tenderness of expression not to be surpassed, are advancing from the three doors of the church to pay these last duties to the object of their affection and veneration. The church itself, beautifully enriched with alto-relievs, gives the most agreeable termination to the group.

We shall mention one more of this series of pictures, which, though not in point of beauty equal to the two first described, is applicable to our present purpose as it strongly exemplifies how much a proper disposition of the groups in a picture contributes to the expression of the subject. The story represented is a miracle which took place some time after the death of St. Francis.

A woman from some cause or other died without making a full confession; she had, however, upon the whole been a good catholic, and especially devoted to St. Francis; the saint therefore made intercession for her, and when the priest with his attendants were upon the point of carrying the body to the grave; she, to the great astonishment of all present, sat up, called a confessor who was present by name, revealed to him her hidden sins, and then once more died and was buried. In the middle of the picture is represented the woman sitting up on her bed, in the act of confessing to a friar, who at once unites in his countenance the strongest expression of terror with the most earnest attention; some women, the friends of the deceased, and a child, form a group on the right; the priest and his attendants are on the left; both these groups are kept at a distance from the two principal figures, in the centre, by which the idea of secret confession, a leading point in the story, is more decidedly given, than could have been accomplished by any other manner of placing the figures. The intercession of St. Francis to our Saviour is represented in the sky; and a little below, the effect of that intercession is unequivocally described, by the introduction of a celestial agent, who is driving before him the infernal spirit, by which the woman is supposed to have been possessed.

Amongst the principal scholars of Giotto we may enumerate, Taddeo Gaddi, and Puccio Capanna: of the former many admirable frescoes are still existing in the church and sacristy of Sta. Croce, and in the cortile of Sta. Maria Novella at Florence, and of the latter, great part of the roof or vault, besides two excellent compositions of the taking down from the cross and the burial of Christ, on the side wall of the lower church of St. Francis at Assisi.

However, the school of painting founded by Cimabue and Giotto, continued with but little variation or advancement, till about 1430, when Masaccio distinguished himself by a correctness and perfection of imitation, hitherto unknown. He began to shew a just notion of perspective, and first succeeded in fore-shortening the feet of his figures, so as to give them the true appearance of standing on an horizontal plane; a difficulty never surmounted by his predecessors, whose figures, except when in profile, beamed generally, as if standing on tip-toe. He gave a greater breadth of light and shadow to his groups, and was an excellent colourist; and the heads of his figures are so finely drawn, so full of nature, and finished with such a delicacy and at the same time such a mellowness of pencil, as to be scarcely surpassed by the finest portraits of Raffaele, Titian, or Del Sarto. In all the executive parts of the art, Masaccio eminently excelled; but we cannot join in the opinion of those who consider him as having equally contributed to the advancement of composition: his aim was to make the most correct possible transcript of the model before him; hence

hence his frescoes, in the celebrated chapel at the Carmine, abound with admirable representations of his friends and contemporaries, portraits that seem almost alive, but they are not always alive to the subject, nor do they express by their actions or gestures, those feelings which the act of which they are represented as spectators, should naturally awaken in them; in the miracle of the boy restored to life by St. Peter, and in the martyrdom of the same saint, the surrounding figures seem no more afflicted than so many indifferent persons met together in the market place, to talk over the ordinary news of the day. However this work of Masaccio greatly contributed to hasten the great era of painting which followed, by exhibiting to contemporary and succeeding artists, a model much more perfect, at least as to the executive parts of the art, than they had hitherto been accustomed to contemplate. Much has been said as to the plagiarisms of Raffaele from this work. The Adam and Eve driven out of paradise in the Loggia of the Vatican, is certainly an improved transcript of that of Masaccio, and the Saint Paul preaching at Athens in the cartoon, bears some resemblance, it must be allowed, to the figure of the same saint visiting St. Peter in prison in Masaccio's chapel; but if Masaccio furnished the body of the saint, it was necessary that the great Raffaele should animate it with the energy of his own soul, ere it could convey the idea of that irresistible torrent of eloquence, by which the apostle combated and overthrew the sophisms and superstitions of his audience at the Atrypagus.

The immediate followers of Masaccio were blind to his greatest excellence, and instead of that mellowness and breadth which we find in his works, adopted a style of execution more crude and unharmonious, than even that of the more early painters; design, however, made a rapid advancement, which, added to a competent knowledge of perspective, now become general, gave to Luca Signorelli, and others of genius, the means of embodying those bold conceptions, which as yet no one had hoped to transmit to the canvass.

The chapel which Signorelli painted in the cathedral church of Orvieto with stories of the End of the World, the Last Judgment, Paradise, Hell, &c. is fraught with the most novel and daring fore-shortenings, energetic expressions and finely contralled groups, inasmuch that the great Michelangelo, is said to have derived benefit from the study of this work, previous to his painting the celebrated Last Judgment in the papal chapel at Rome.

In this work, however, the composition, though fine in its separate parts or groups, is not always judicious in the whole; that essential part of theory, which teaches the artist the policy or necessity of making many small parts of his picture subordinate to the principal figure or chief group, yet remained to be known, nor was it for a long time sufficiently understood, that the great distinguishing prerogative of painting, and that from which arises its decided advantage over every other artificial mode of representation, is its power to give upon a limited plane the appearance of boundless space. Thus, in those two compartments in particular, in which the artist has represented Paradise and Hell; much effect is lost by the figures and groups being ranged as it were in one line parallel to the plane of the picture; and this seems the more surprizing, as in one or two of the other compartments, and especially in that describing the End of the World, and the Destruction of the Wicked by Fire from Heaven, a most happy and striking distribution of the figures into different groups, and on different planes and distances, is to be observed.

Of Domenico Ghislandajo, the master of Michelan-

gelo in his youth, it may be well to note, that although he merited, in the opinion of many, the reputation of being the best painter of his time, yet the style of composition adopted by him in his great work in the tribuna of the church of Sta. Maria Novella at Florence, is by no means such as to rank him amongst those artists whose performances may be studied with profit, as to the branch of art we are now treating of; unless, indeed, that the contemplation of their manifold faults in this particular, may tend to deter the student from pursuing a similar line of conduct. The subject is here made subservient to the rage of the painter for displaying his talents in portrait; these frescoes containing striking resemblances of almost every lord, lady, or literary character of distinction of his time; and as the figures are throughout dressed in the dresses of the time, so this work is valuable, as giving perhaps the best idea of the costume of Florence towards the end of the fifteenth century, of any in existence; add to this, that the whole is admirably executed; but the spectator may long dwell on the various beauties of this work ere he discovers that it is intended to represent the principal stories of the New Testament!

The happy era was, however, fast approaching, when the profound Lionardo, the great Michelangelo, and the divine Raffaele, were destined, not only to unite all the various excellencies of the old painters, but likewise, by an unparalleled and happy exertion of comprehensive and elevated genius, at once to carry all those parts of the art, which most ennoble it, to a height of perfection beyond which the efforts of succeeding artists have never enabled them to reach; if indeed they have ever approached it in the four great points of invention, composition, expression, and design.

It was about the year 1503 that the Florentines formed the idea of decorating their great hall of council with productions of the pencil. Upon this occasion Lionardo da Vinci executed in a cartoon the astonishing Group of Horsemen fighting for the Standard, so well known by the fine print of Edcluk; a composition replete, but not crowded, and which exhibits the utmost energy of action, without extravagance, and the most striking and beautiful variety of contrast, without affectation: this was Raffaele's model for the intricate groups in his "Battle of Constantine," and is the great prototype of all those battles and huntings so daringly executed by the bold pencil of Rubens. That Da Vinci at the age of fifty should have so far surpassed the efforts of preceding painters is, however, less a matter of surprize, than that the youthful Buonarroti, who entered the lists with him, should, as agreed by contemporary writers, have borne away the palm.

The subject chosen by Michelangelo for his cartoon, related to the war between the Florentines and Pisane: the moment taken was an imaginary one, when some of the Florentine soldiers, who had been bathing in the Arno, are hastening out of the river upon the signal of attack, buckling on their armour, and rushing to the assistance of their countrymen, who had already commenced the combat in the distance. This subject naturally embraced a very great variety of character, action, and expression, and was certainly most happily calculated for displaying academic acquirements, and especially that knowledge of the human figure which Michelangelo is universally allowed to have possessed in a greater degree than any other artist of modern times, and which, amongst the Florentine painters, was considered as at least paramount to all the other parts of the art put together. It is perhaps to this last circumstance that we must attribute the very decided pre-eminence given

given to the "Cartoon of Pifa" (as it was called) over that of Lionardo, and which soon after occasioned his quitting his native city in disgust.

Considering these two celebrated works in every other respect, it would be a difficult task to determine to which belonged the preference. The figures in Da Vinci's group, it is true, were somewhat disguised by the introduction of capricious ornaments on their armour; but, on the other hand, the Cartoon of Buonaroti wanted that breadth of chiaro-scuro which that of his rival possessed. Each, however, in its way, is a masterpiece for invention, composition, design, and expression; and each, in its kind, perhaps still remains unrivalled. We refer the reader to a very animated description of the "Cartoon of Pifa" in the third Lecture delivered by Mr. Fuseli to the students of the Royal Academy.

The subjects which Lionardo and Michelangelo had selected for the display of their talents, afforded in their nature the most ample scope for the intricacies of grouping, and the novel charms of contrast: but it was not sufficiently understood by many of the young artists, who flocked to study these works, that that which they so much admired, and which in reality powerfully contributed to expression in the Cartoons before them, might be inadmissible, or at best should be sparingly used, in subjects of a different character. This censure applies not to Fra. Bartolommeo, Andrea del Sarto, and two or three others, rather cotemporaries than followers of Michelangelo; but it is certain, that the indiscriminate introduction of contrasts, fore-shortenings, and naked figures, without regard to propriety or expression, soon became a predominant characteristic of the Florentine school.

In the subsequent productions of Michelangelo's pencil, we almost ever find the happiest concordance of style with subject, nor can he be accused of having at any time sacrificed the invention or expression of his picture, to an ostentatious display of his powers in the executive parts of the art.

The general design of his sublime works, the "Vault of the Sistine Chapel," and the "Last Judgment," will be the subject of our consideration, when we come to treat of invention and expression in painting; we shall, for the present, content ourselves with observing, that there is no part of them which affords not a valuable lesson in composition. The beautiful angels, attendant on the Creator of the sun and moon, give dignity to the subject at the same time that they enrich the composition. The angelic troop, supporting the figure of the Almighty, in the Creation of Man, by furnishing a number of small parts opposed to one large one, produces a delightful effect; whilst the broad dark mantle which surrounds the whole, at once simplifies, whilst it throws out the group; this rich group is again finely contrasted by the simple unembellished figure of Adam. In the compartment where Adam and Eve are represented eating the forbidden fruit, Michelangelo has laid himself open to the accusation of having been guilty of an anachronism, as he has introduced in the same picture their subsequent expulsion from Paradise; but, ere we condemn his conduct, it will be well to consider whether the fault, if it is one, in the case before us, is not amply made amends for by the additional interest and the awful lesson it furnishes—here is at once the cause, and the effect; and the transgression and the punishment. This group of the "Transgression of Man" is particularly deserving our notice, as it furnishes an example in composition different from any other in the chapel; the Eve is sitting in a beautiful posture on the ground, and nearly in front; she

extends her left arm to receive the apple presented to her by the tempter, who is represented, like the Scylla of the ancients, under the form of a female terminating in a serpent: Adam is standing immediately behind the figure of Eve; he extends both his arms to pluck the fruit off the tree, and thus discovers a back view of his figure from the loins upwards, thereby making a most beautiful contrast to the Eve, at the same time that it affords, by its union or connection with the serpent and the tree, in forming a sort of arch over the figure of Eve, which produces a most agreeable and novel effect. In that tremendous group of the "Offending Israelites tormented by Serpents," the low point of sight increases the terror of the scene, at the same time that, by causing the figures to be fore-shortened, it permits the introduction of a greater number of them, and of a larger size than could have been the case, had the horizontal line been supposed higher. The "Prophets" and "Sybils" might each in their turn furnish a lecture; but it would far exceed our limits to attempt to point out the various smaller pieces of composition with which the Sistine Chapel abounds. Each compartment or group contains some principle or essence more or less distinguishing it from every other, and peculiarly adapted to the expression of the subject it represents.

The "Last Judgment" was executed many years after the Vault of the Sistine Chapel. With respect to the composition of this celebrated work, as a whole, there have been various opinions; some highly approving the uniform arrangement of the groups into distinct subdivisions, as contributing to that awful majesty required by the subject; whilst others have regretted the absence of that perspective, that depth, that *sfumato*, employed with so striking and picturesque an effect in the great works of Titoretto, Paolo Veronese, and Rubens. The matchless perfection of the distinct groups has however remained undisputed, and we can therefore with safety recommend the prints from them by Georgio Mantuanus, or those recently published by Mr. Metz, as sources from which the student will best acquire the principles of grand composition, at the same time that he imbibes the antidote to poverty of style, and to every thing trivial or common-place.

We have before observed that the older painters considered a certain degree of uniformity of disposition as indispensable in those representations, which were more especially intended as objects of devotion or religious awe. Michelangelo, though in most other respects he departed from the system of his predecessors, seems to have considered this principle as sacred; accordingly, in his designs of Madonnas, Holy Families, and Pietas, we ever find this uniformity; sometimes effected by the manner of placing the figures, and balancing equally, as it were, one side of the composition with the other; sometimes by the regularity of the architectural decoration. His "Chiril with the Samaritan Woman at the Well" is an instance of this kind, so is the "Flagellation at S. Pietro Montorio," and, more particularly so, his "Representation of the Crucifixion," where the two angels in the clouds and the two figures of the Madonna and St. John, are introduced absolutely at measured distances on each side of the cross.

Fra. Bartolommeo di San Marco has practised a similar uniformity of composition in his great altar pictures, and so has not unfrequently Raffaele, although in many of his numerous small pictures of the Holy Family he seems to have aimed at the expression of domestic felicity or maternal endearment, rather than to elevate the mind to the contemplation of the mysteries of redemption by a sublime image of the Virgin Mother with the Infant God.

If the works of Michelangelo excel in sublime imagery, or in the personification of supernatural agency, those of Raffaele, on the other hand, have ever been considered the most perfect models of that species of painting which is properly termed historical or dramatic. "We stand with awe," says Mr. Fuseli, "before M. Angelo, and tremble at the height to which he elevates us. We embrace Raffaele, and follow him wherever he leads us." The works of Raffaele never fail to exhibit the happy union of a composition every way adapted to the expression of the subject, joined to an inexhaustible variety of well-arranged and beautifully contrasted groups; and yet every part seems to naturally grow out of the story, and comes so home to our feelings, that the spectator is often almost tempted to exclaim, with the countryman when he saw Garrick, "Why I should have done it so myself!"

The productions of Raffaele furnish nothing like a recipe for composition. He well knew there was none, and hence those forcible and distinct impressions which each of his pictures makes on the mind, and leaves indelible on the memory.

If Raffaele can be said to have regulated his compositions by any particular rule or maxim, it was that of making each as unlike the other as possible, consistent with propriety of expression. Thus, in the Cartoon of "Christ giving the keys to Peter," the apostles, all crowding together to be witnesses of the action, occupy the principal part of the picture, and form a group as it were in profile, the Saviour, although in the corner of the picture, being nevertheless rendered evidently the principal figure, by the insulated situation given to him, as well as by the actions of the apostles, who all press forwards towards him, as to the centre of attraction. This Cartoon is finely contrasted by that representing the death of Ananias, where the figures of the apostles form a group in the centre, and are all seen in front. The admirable description of this composition by Mr. Fuseli cannot but prove acceptable to the reader. "In the Cartoon of 'Ananias,' at the first glance, and even before we are made acquainted with the particulars of the subject, we become partakers of the scene. The disposition is amphitheatric, the scenery is a spacious hall, the heart of the action is the centre, the wings assist, elucidate, connect it with the ends. The apocalyptic figure before us is evidently the victim of a supernatural power inspiring the apocalyptic figure, who, on the raised platform, with threatening arm pronounced, and with the word enforced his doom. The terror occasioned by the sudden stroke, is best expressed by the features of youth and middle age on each side of the sufferer; it is instantaneous, because its shock has not yet spread beyond them, and this is done not to interrupt the dignity due to the sacred scene, and to stamp the character of devout attention of the assembly; what preceded and what followed is equally implied in their occupation, and the figure of a matron, entering, and absorbed in counting money, whilst the approaches the fatal centre, and whom we may suppose to be Sapphira, the accomplice and the wife of Ananias, and the devoted partner of his fate. In this composition of near thirty figures, none can be pointed out as a figure of common place or mere convenience; they are linked to each other, and to the centre, by one chain; all act, and all have room to act, repose alternates with energy." The Cartoon of "Peter and John healing the Cripple at the Beautiful Gate of the Temple," is again strikingly different from either of the others, Raffaele having there, with a boldness of which any but a sublime genius would have been incapable, interjected his composition by the columns of the portico. But though divided, it is true, into separate, and

almost equal parts, neither the unity of action, nor the expression of the picture, is impaired, whilst the effect produced is at once novel and beautiful. In the Cartoon of "Paul preaching at Athens," the elevated situation, and energetic action of the apostle, instantly denote him the hero of the piece, whilst the attentive but astonished circle gathered round him, receive, as it were, light from him, their centre, and unequivocally declare him the restless organ of divine truth.

The Series of "Scripture Histories," painted by Raffaele in the Loggia of the Vatican, and his other works, do not less evince the desire of obtaining, as far as consistent with propriety of expression, this diversity in his compositions; but an attentive examination of the prints from them, will better elucidate this point, and indeed every thing relative to composition, than a volume of prolix and laboured description. In short, the works of Raffaele display the most becoming union of natural with acquired talents; strength of conception, and inexhaustible invention, with propriety of disposition in the whole, and careful variety in the component parts.

After the death of this great master in 1520, the art rapidly declined, nor has any one since him trod with equal success the dignified and instructive path of history-painting.

The great reputation of Raffaele, however, even for some time after his death, checked the ascendancy of mistaken principles, at least in Rome, where the great works in the Hall of Constantine, and other rooms of the Vatican, were still continued by Giulio Romano and Raffaele's other scholars, after their master's designs.

Of Polidoro da Caravaggio, one of the most eminent, it might be said that the soul of a Greek animated his pencil, so replete with Attic purity and grandeur of style are his numerous friezes on the facades of the palaces of Rome, now however best known by their prints by Gozzius, Cherubino, Alberti, and Bartoli.

It was not till after the noted sackage of Rome in 1527, when the arts and artists were forced to seek an asylum in distant parts of Italy, that painting was doomed to suffer degradation; Polidoro flew to Messina, Pierino del Vaga to Genoa, and Giulio Romano to Mantua, where, in the palace of the T, he explored the regions of poetry, gave new force to the instructive lessons of fable, or decked the playful charms of allegoric fiction; still however firm to the principles of his great instructor, nor ever sacrificing the true end of his art, the expression of the subject, to a too ostentatious display of his prowess in the means.

We have before observed that Michelangelo's celebrated Cartoon of "Pisa," contributed not a little by its influence to determine the future character of the Florentine school. Blind to its more sublime excellencies, the vigour of its conception, the energy and variety of its parts, and its unity of action as a whole, the young students of Florence ignorantly imagined that a similar introduction of naked and foreshortened figures into their compositions, without any reference to the subject of their picture, would at all times insure them the applause of the artists of their own country, and the envy of those of neighbouring states; nor had Michelangelo the good nature or the good sense to point out their error.

An army of expert mannerists, for the most part joining to a miserable sterility of conception the most audacious rapidity of execution, but proud of possessing what they thought the true secret of the *Grand Gyslo*, now sallied forth; nor can it be a matter of surprize that the palaces, the churches, and the halls of Rome, Florence, and most

of the other cities of lower Italy, were so soon deluged with the common-place productions of mediocrity, since the unrelenting pencils of Giorgio Vasari and Federigo Zuccaro alone, covered more square yards of wall or canvases than had been effected by the honest diligence of perhaps any ten of their predecessors.

The due expression of the subject of a picture was now the last consideration. Provided two or three well drawn academy-figures, however unmeaning, occupied the foreground on the one side, and some women sporting with their children, on the other, whilst the centre displayed a pyramidal group, all was well; the employer was delighted, and the painter applauded. Thus a stranger may pass and repass through the Sala Regia in the Vatican without being struck by, or discovering the meaning of one of those frescoes which occupy its spacious walls, or without being afterwards enabled to call to mind the smallest feature distinguishing one from the other. This subversion of art, this silly fondness for what was erroneously considered picturesque composition, for near a century afterwards degraded the school's of Rome and Florence; we shall therefore leave them, and turn the reader's attention to those of Lombardy and Venice.

If the anatomic studies of the old Florentine artists had rendered them almost exclusively the masters of correct design, the painters of Lombardy could boast a more complete insight into the doctrine of perspective, and were certainly the first who applied it with real effect in large works.

Melozzo da Forlì, in the middle of the fifteenth century, in his fresco in the vault in the tribuna of the church of St. Apollini at Rome, first discovered what the Italians call the knowledge of the *Setto in Sù*, that is, the method of foreshortening figures, so as to give them the due appearance of rotundity and projection when seen from below; and upon the same principle, Andrea Mantegna, in several of his great works, and particularly in a chapel at Padua, where the storied compartments are entirely above the eye, adopted, with equal boldness and effect, an ideal point of sight upon a line with the eye of the spectator, that is beneath the very bottom of the picture.

From sources like these, Antonio Allegri da Coreggio, the splendid meteor of the Lombard school, imbibed the first principles of his art. With a spirit every way conformable to his name, he pictured the "Joyful Assumption of the Madonna amidst Myriads of the Angelic Host," in the cupola of the duomo of Parma, and the "Ascension of Christ," in the church of S. Giovanni in the same city; works which may be justly styled the never-equalled models for that species of composition. In the execution of these, and probably of his other chief works, he was however greatly assisted by his friend Antonio Begarelli, a celebrated Modenese sculptor, who modelled for him in clay all the figures, so that Coreggio, by placing and grouping them together as they were to be represented, was enabled to delineate, with the greatest correctness, every foreshortening, and at the same time to acquire a truth and boldness of light and shade unattainable by any other means. And here it may be well to observe, that the trouble of preparing such models in the first instance, is amply repaid by the great facility, or rather certainty, which it gives the artist in the execution of his work. Moreover, the painter having his modelled figures before him, and being enabled, by varying the situation of his eye, to view them in every direction, will frequently discover beautiful combinations which he never dreamed of, at the same time that he is rendered less liable to the error of too often repeating the

fame view of a figure, or the same action, and is taught to avoid a common-place mode of composition.

Primaticcio, a native of Bologna, in his commerce with Giulio Romano, whom he assisted in his works at Mantua, acquired an admirable talent for treating poetical subjects. Master of perspective, and the *Setto in Sù*, his beautiful fictions on the ceilings, and other compartments, in the palace of Fontainebleau, alike charmed by the fire with which they were conceived, the elegance of their composition, the prodigious boldness and truth of their effect, and the easy grace with which they were executed.

The grandeur and striking appearance of projection and depth, for which the works of Primaticcio were so remarkable, judging as well by their prints as by the writings of those who witnessed them prior to their destruction, was in a great measure occasioned by his having universally chosen, what is called in perspective a *short point of distance*; by which mode of conduct the figures in his near-ground appeared proportionally large, as those behind diminished in a more rapid gradation. This mode of conduct in Primaticcio is the more worthy of remark, as it is the reverse of what we generally find adopted in the works of the great Roman and Florentine painters, his predecessors. It became, however, a favourite doctrine of the Venetian school, particularly of Tintoretto and Paulo Veronese, and was one of the leading principles of the Caracci in the formation of their style.

The composition of Giorgione, Titian, and the older Venetian painters, is simple and dignified, suggested by the subject alone, and of course liable to none of those objections which apply to the works of their followers, Tintoretto, Paulo Veronese, Palma, and a multitude of others, who, like the Florentines, valuing themselves chiefly upon the possession of only a part of the art, sacrificed to their favourite darling all the remainder. No longer expression, but colouring and glitter of effect became their object, and hence, with all their prodigious talents, they soon turned the art into a splendid toy.

The works of these great masters (for great they were in spite of all their faults) may nevertheless be studied with benefit, even as to composition, as they at all times possess a boldness and variety of disposition, which rank them far above the insipid and mannered performances of their contemporaries of Florence and Rome.

About the end of the 16th century, the Caracci of Bologna attempted, by an union of the scattered excellencies of the various schools beforementioned, to establish a perfect system of art: but though they indeed so far succeeded as to form a style in which no particular fault seemed to predominate, still in no one point did they fully reach the purpose of their emulation. Their works present neither the dignified composition, the just and striking expression, the beautiful variety of character, which distinguishes those of Raffaele; the sublime conception, or the learned and grand design of Buonaroti; the grace and enchanting effect of Coreggio, nor the truth and richness of Venetian colour; but seem rather the result of a system founded on the basis of a compromise between the eye and the understanding, the mechanic and the ideal of the art; in forming which compact, however, the former have been evidently allowed the preponderance. This remark is, perhaps, less applicable to the productions of Ludovico Caracci; but with respect to the chief works of Annibale, and particularly his Farnese gallery, we cannot withhold our assent to the critiques of Mr. Fuseli, and the severe but just remarks of Mr. Webb.

Having said thus much, it cannot be expected that we should

should hold forth the Caracci as models for imitation; there is nevertheless a breadth, a concordance of the various mechanical parts of the art, and an ease in their style which render it highly deserving our regard, and would have justly entitled the Caracci to a reputation even greater than that which they have so long enjoyed, had their prodigious powers been made the vehicle of more elevated conception.

With respect to the scholars of the Caracci, and other artists of reputation, who immediately succeeded this epoch, it is only to our present purpose to observe, that grace and beauty rather than grandeur or sublimity, seem to have been their objects, and that whatever eminence they sometimes attained in their Holy Families and devotional subjects, still the dignity of historical painting was evidently on the decline.

Niccolo Poussin alone seems to have considered the art as a language addressed to the mind through the organs of vision. Possessed of a refined and scrutinizing mind, he at all times collected, and, with the greatest ingenuity, inserted in his pictures all those collateral circumstances, probable or possible, which his subject could furnish; and hence his works, more addressed to the imagination than the eye, at once invite and are sure to reward investigation. The greatest defect, however, of his compositions, seems to be that these explanatory or accessorial groups generally appear too principal, and thereby not unfrequently counteract their object, by distracting the attention from the principal figure or group, destroying the unity of action, and weakening that expression which they were intended to augment. Were we to draw a comparison between Poussin and Raffaele, we should liken the former to the cool but subtle reasoner, who by slow degrees brings us to grant his position; Raffaele to the heaven-taught genius who at once darts the ray of truth upon our minds.

The works of Poussin, though esteemed even in his lifetime, had little influence in correcting the corrupt and meretricious taste which was every day gaining ground in Italy. The proper end of the art had been long forgotten or habitually sacrificed, and that bane of painting, pictureque, or artificial composition, which, however varying in its mode, was ever the same in its effect, became every day more deeply rooted.

Poverty of conception, or rather no conception at all, common-place or unmeaning attitude, contrast so often repeated as entirely to lose its effect, and, above all, empty bustle, were now become the elements of what was still called historical composition: if to this we add a brilliant rapidity of execution, joined to gay colouring and tolerable light and shade, with occasionally a madonna's or an angel's head, rather pretty and seductive than devout, we have the sum total of the merits of the most eminent artists who succeeded this period, and the genuine characteristics of the admired Pietro da Cortona, the facile Luca Giordano, and the insipid Carlo Maratti.

It would swell this article beyond our prescribed limits, without throwing much additional light on our subject, were we to attempt to trace the different changes of style which at various periods took place in the schools of painting of Germany, Flanders, Holland, or France. The succession of young students, who at all times considered a visit to Italy as an indispensable part of their education; naturally imbibed in a greater or less degree the principles of those to whom they had been taught to look up as models for their imitation: hence the style of the Florantine and Roman mannerists of the 16th century, unjustly denominated the followers of Michelangelo, was caricatured in the preposterous works of Martin Heemskerck, Van Man-

der, Spranger, and Goltzius; that of Tintoretto feebly imitated in those of his scholars, de Vos and Rottenhamer. Rubens, however, who, though long in Italy, became no wife infected by that poverty of style which then prevailed, broke the fetters of corrupt system, and rescued his countrymen from the effects of such baneful influence. His comprehensive genius, cultured by reading, enlightened by travel, and blest above all, with that envied quality, a just appreciation of its own powers, could not but obtain its object, that object being once clearly defined and steadily pursued. What that object was, the decided character of his works sufficiently determines: it was unquestionably the union of magnificent and expressive composition, with the most splendid colouring and the greatest breadth of chiaro-scuro; for, however enchanted by the spells of colour, Rubens never forgot that painting is mute poetry, and its first great prerogative, the converse, which, through the medium of the eyes, it is permitted to hold with the understanding. It cannot, therefore, be said of Rubens, as of the Venetian painters we have censured, that he sacrificed the ideal to the mechanical part of his art. With the exception of his smaller works, or such as he was sometimes necessitated to undertake, in compliance with the will of his employers, we generally find in his productions the most judicious application, the most happy combination of his powers.—Subjects allowing full scope to the exuberance of his invention, compositions furnishing an ample field for the magic blaze of his tints, and the broad expanse of his masses.

It was the good fortune of Rubens that the burines of the most eminent engravers were employed under his own inspection, to make prints from all his chief works; and indeed so admirably is the character of the originals preserved in those of Bolswort, Vosterman, Pontius, and others, that when the pictures shall be no more, they alone will be sufficient to eternize the claims of this great master of the Flemish school. As an inventor and composer, the "Battle of the Amazons," the numerous "Huntings of Wild Beasts," the "Raising of the Cross," the "Michael combating the Devil and his Angels," and the two tremendous representations of the "Fall of the Wicked," are alone sufficient to place Rubens in the first rank; to say nothing of his celebrated "Garden of Love," and the truly poetic allegories in the "Luxemburgh gallery."

Of Rembrandt, the great head of the Dutch school, it has been justly remarked by Mr. Fuseli, that he was "a genius of the first class, in whatever relates not to form." We have in another place spoken of his chiaro scuro, (see *CLAIR Obscure*.) and we can, with equal propriety, upon the present occasion, recommend the study of his works to all those who feel with us, that the telling of the story, and the appropriate expression of the subject are the true ends of composition; nor will we omit to add, that the works of many of the other Dutch painters, particularly Ostade and Drawers, however the humble representations of low and vulgar nature be their object, abound in admirable examples of composition, and may be studied with advantage, even by such as make the more noble path of historical or epic painting the course of their pursuit.

In the retrospect we have taken of the styles of composition at different periods, adopted by the schools of Italy, it has been our care to point out to the student such examples as are best calculated by their influence to promote his advancement towards the legitimate end of our art; at the same time, that we have cautioned him against that corrupt but specious system of grouping, which, for distinction's sake, we have called pictureque.

COMPOSITION.

The art of painting is a language addressed, through the medium of the eyes, to the understanding; like that addressed to our minds through the ears, it must have some ideas, some truths to communicate; and the perfection of painting, as well as of writing, consists in conveying those truths to the mind in the most clear, the most forcible, and most beautiful manner. A judicious distribution of the arguments in a discourse is of importance, inasmuch as it gives additional force, and sheds increased lustre on the evidence contained; but in a picture this propriety of distribution is itself the argument and the evidence, and is therefore indispensable.

Those who are conversant with the first sketches and drawings of great masters, know that a few simple rude lines are frequently found sufficient to impress the mind with a decisive and immediate idea of the story meant to be represented, and that, in many cases, even the expressions as well as the actions of the chief figures seem evident, although no features of the countenances be delineated.

We may, therefore, safely affirm, that any rule, any mode of composition, except such as is dictated by the subject of a picture, is wrong, and that, were this doctrine sufficiently understood, we should not so frequently pass unmoved by graphic representations, or remain ignorant of the subjects they were intended to express.

To attempt, therefore, to prescribe any general method of distribution would be to insult the understanding of our readers and to degrade the art. The painter, warmed by his subject, must form the ideal picture in his imagination, and from thence transfer it to the canvass: it is only as to the relative economy of the parts of the work that some hints may be suggested: these are the result of observation and experience, and bear the strictest analogy to the precepts we have inculcated respecting clair-obscur and colouring, and, perhaps, to every other part of the art.

As there should be in a picture one principal mass of light, which, however connected with others, should still predominate; so one group or one figure should strike the eye with the same superiority over the secondary groups or figures of the composition; as in clair-obscur there is no rule by which we are obliged to place the principal light in any one given part of the picture; so are we at liberty to give to the chief group or figure of the composition that situation which we judge most appropriate. As in clair-obscur, an inequality of parts, a subordination of several small masses to one large one, never fails to produce richness and beauty of effect; so in composition a similar richness and beauty are the result of an opposition of several small bodies or parts, to one large and simple; as we have before illustrated by the sublime group of the Almighty, supported by a multitude of angels, in the "Creation of Adam," by Michelangelo.

As by the addition of smaller masses of light, connected with the principal mass, that mass acquires at once greater breadth and influence; so the unity of action in a composition is in most cases powerfully augmented by a repetition of nearly the same action in two or three of the accessory figures arranged together, one nevertheless being principal: this was the frequent custom of Raffaele, has its foundation in nature, where similar sentiments must frequently excite similar outward demonstrations, and never fails, if judiciously managed, to produce its effect.

Every thing that has been said relative to contrast of clair-obscur, or relieving dark or light masses immediately by their opposites, equally applies to composition, where strong contrasts of line, of back to front figures, &c. pro-

duce similarly striking and beautiful effects, and must to insure those effects be used with similar discretion and parsimony. The too frequent introduction of contrasts of lights and shadows or of colours, produces a spry and confused effect; the inordinate use of contrasts in composition produces similar confusion, and defeats their end. The moderate introduction of them in both cases gives a zest to the picture. It is like the border or other well-disposed ornament on a piece of drapery; but when indiscriminately used, the work resembles the rich gothic medley of an embroidered petticoat, where the beautiful folds of the stuff are wholly obscured by tinsel and gewgaw.

Having observed thus much, we must refer the reader, who is desirous of obtaining a more complete insight into the subject of this inquiry, to the works of the great masters above-mentioned, or to the numerous prints which have been made from them, by the most eminent engravers of the last three centuries. One hour spent in the study of the Cartoons of Raffaele, or the Last Judgment of Michelangelo, will perhaps teach more than could be inculcated by words in the compass of this volume.

What we have said of historical composition may equally apply to landscape; each work should possess a decided character, distinguishing it from its neighbour, and calculated to incite a train of kindred reflections. This we sometimes find in the simple views of the Flemish and Dutch painters, who painted nature as they found her, and did not think it necessary that every picture should possess a given proportion of fore ground, middle ground, distance and extreme distance, a winding road, a meandering stream, a water mill, a church steeple, a hanging wood, and a mountain.

The works of the two Poussins, some of those of Salvator Rosa, Dominichino, and the Caracci, and the admirable etchings from the drawings of Titian, abound in the finest examples of sublime and characteristic landscape, and are indeed so perfect in their way, that they can never be sufficiently contemplated by the artist who would attain eminence in this delightful branch of art.

Plates illustrative of composition.
No. 1. "The Battle of the Standard," by Lionardo da Vinci.

2. "The Cartoon of Pisa" (or according to Vasari, its chief group) by Michelangelo Buonaroti.

3. "The Creation of Man," the "Transgression at the Tree of Knowledge," and "The Expulsion from Paradise;" frescoes of Michelangelo in the Sistine chapel.

4. "Groups of the Last Judgment," by the same author in the same chapel.

5. "Paul preaching at Athens" from the Cartoon, by Raffaele, at Hampton Court.

6. "The Group of the Assumption of the Madonna," in the cupola of the Duomo at Parma. Coreggio.

COMPOSITION, in *Pharmacy*, the art, or act, of mixing divers ingredients together into a medicine; so that they may assist each other's virtues, supply each other's defects, or correct any ill qualities thereof.

COMPOSITION, in *Printing*, ordinarily called *composing*, is the arranging of several types or letters in the composing-stick, in order to form a line; and of several lines ranged in order in the galley, to make a page; and of several of those to make a form.

The composing-stick is made of iron generally, sometimes brass or wood; of greater or less length or depth, according to the page to be composed, or the compositor's fancy: it hath two sliding pieces, to be fastened by means of a nut and screw, which are slipped forwards or backwards, at the pleasure of the compositor, and according to the space

COMPOSITION.

space which the lines, notes, &c. are to take up. See *Plate Miscellany, Fig. 5.*

The composing-stick ordinarily contains seven or eight lines of a middle-sized letter; these, when set, are taken out, by help of a thin slip of brass, termed a rule, and disposed in the galley; and others composed, till a page be formed. The page being composed, is tied up, and set by; and the rest of the pages of the sheet prepared in the same manner: when done, they are carried to the imposing or correcting-stone; there ranged in order, and disposed in a chase, or iron-frame, fitted with wooden furniture; then, the quoin being struck in, it is carried to the press to be printed.

COMPOSITION, in *Sculpture*, from *Composizioni*, Italian, the art of placing figures or other objects together, whether by entwining them in groups, or forming them into masses more nearly or distantly apposed. The word bears the same meaning in the arts of design as in literature, from which it was most probably received, with many other terms, by the Italian artists at the revival of learning. Although in its most simple sense it is only synthesis, or joining together; yet, in its extended acceptation, it comprehends the production, order, and fitness of all the parts contained in the whole. The first elements, therefore, are invention and sentiment; the invention should be new and copious, affording an abundant choice of beautiful parts according to the subject, whether there be many figures or one only; the sentiment must be just and striking; according to the rule "feel yourself if you would make others feel;" this must pervade every part of the character of the figures; their action or passion expressed to the points of their fingers and toes as well as in the very folds of their drapery.

The order of composition contains the divine, heroic, and historic. The divine contains all sublime and terrific subjects of divinities, angels, departed souls, and infernal ministers. The heroic, according to the ancients, consists of those mortals, said to have one mortal and one immortal parent. The historic class contains the whole series of human life, in which however the most exalted persons and circumstances are always to be preferred.

The arrangement must be dramatic, representing an action; because sentiment only affects the countenance of the figure prior to action, and words cannot be expressed by mute figures; therefore the sentiments and passions must be demonstrated by the action, in which the figures partake. The principal person must have the most distinguished place, whilst the inferiors occupy subordinate gradations; thus in "Prometheus chained;" Prometheus occupies the first interest and place, whilst Force, Strength, and Vulcan are gradually inferior, although linked in the same group. If the hero or heroine of the subject be not entwined in the same group with other figures, he or she will still be distinguished by a preferable situation to those in which the inferior persons are placed; this rule is observed in all the best pictures of the *Herculeanum* collection. In the antique basso-reliefs and painted vases, and in the best works of antiquity, we scarcely ever see more figures introduced than such as are sufficient to tell the story, and for this reason that the expression may be the stronger, being less divided.

Outline. The general outlines of a composition, whether it consist of one or more groups, should be agreeable to the eye, which is produced by a succession of curves of different segments alternately reversed; or, in other words, a succession of S. lines of different curvatures and dimensions. These will be more gentle in tender and graceful subjects, such as the Triumphs of Nymphs, Naiads, and Sea Divinities, the Judgment of Paris, &c. In the antique basso-reliefs,

these curves become more violent with a mixture of angles in subjects of great exertion, such as the War of the Giants, the Battles of the Lapithæ and Centaurs, the Athenians and Persians. See Stuart's *Athens*, vol. iii. *Museum Pium Clementinum*. Basso-reliefs. In the fine antique groups, as the Læocoon, Niobe and her Daughter, Cupid and Psyche, and the Fauns and Nymphs, the lines are intercalated (chained) as it were linked into each other in whatever view they are seen.

Light and Shadow. Sculpture is not like painting, seen and forced on our perception, by the variety and brilliancy of its colours. On the contrary, it has properly no colour at all; and its forms are understood by the effect of light and its privation, with the degrees of their medium called middle tint; these, in fact, produce the all of sculptural forms to the eye, because no such thing as outline really exists, and when we speak of it or use it, it is only to demonstrate form geometrically. Light and shadow will be continually varied in the varied forms of the human figure. If seen abroad in the open air, or illumined from a sky-light within doors, the light will strike most powerfully on the head and breast, and gradually with less force on the lower part of the body and inferior limbs as they approach nearer to the earth. If the figure be recumbent, or in a horizontal position, those parts will have most light which are nearest to the luminary. If the figure be inverted, the bottoms of the feet will have the strongest lights, which will gradually diminish as they approach the head; and consequently all those parts which are shadowed, when the figure is upright, will be lightened in this position, and *vice versa*. It must be remembered that, as the human figure partakes of globular forms, some one part will be lighter than the rest, and that light will be brightest in one point. It will be found that figures in sculpture are almost covered with middle tint, having a small portion of bright light nearest the luminary, with a very few dark and strong shadows which relieve particular projections. Basso-reliefs present the general effect of darkish figures on light back-grounds; in distribution of quantity, of both lines and form, that will be most agreeable which is inherent in the nature of things, which pervades all creation, and is more particularly evident in musical proportion of 3ds, 5ths, and 8ths, with their subdivisions and relative quantities.

We must however observe, that the rules for composition, like all other rules laid down for liberal art, will only assist genius; they will never produce any thing without the vigorous exertion of mental powers and manual industry in the subtle investigation and diligent imitation of nature; all must be done by sympathy and beautiful representation; rules may be compared to the scaffold for raising a building. We must therefore remember that the beauties of nature are also various as they are endless, and from them only we can furnish ourselves with original materials for composition, by continually observing the expression of sentiment and passion in men, women, and children; the characters of their faces, the forms and action of their limbs, their draperies, and the manner in which the direction of the folds obscures or indicates the bodies or limbs, in the grouping of figures; the entwining of the limbs should be carefully observed, and the planes in which the different parts of the bodies and limbs are directed.

In the liberal arts, the sentiment of a composition applies to our sympathetic feelings, as the invention surprises and delights by its novelty, and both together animate the mass as a body is animated by the soul; and as no composition would be complete or interesting without them, so when these vital principles are obtained, great care should

be taken to confine their demonstrative forms within that department of art to which they b-long, in order that the whole may be as pleasing as interesting, without deformity or absurdity. Thus, for example, all those positions which extend the human figure by violent action should in basso-relievo be represented in the flattest view, in which all the lines of the body and limbs may be understood in the fullest and clearest manner, without legs or arms standing out horizontally from the back ground, like scaffold poles driven into a wall. Such extended members belong only to the class of entire sculpture, as statues and groups. The lines and limbs in the composition must be more parallel to the back ground, as the alto-relievo or basso-relievo recedes from entire sculpture, until, in the flattest relief, the most complicated forms and groups are distinguished by little more projection than an outline gives.

COMPOSSIBLES, COMPOSSIBILIA, in *Logic*, such things as are compatible, or capable of subsisting together.

COMPOST, in *Agriculture*, a term signifying that sort of manure which is formed by the mixture or combination of one or more different ingredients with dung or other similar matter, so as to constitute an uniform mass or substance fit for the improvement of the soil.

These composts are usually made by mixing various substances with stable or yard dung; and hence, in some countries, are called *mixens*.

The most common materials for this purpose are turf pared from waste places, virgin earth, peat earth, lime, the scourings of brooks, ponds, and ditches, weeds, sea-sand, rubbish of buildings, coal-ashes, &c. That dung alone, properly managed and applied, is a most valuable manure, is beyond all doubt, but it is certainly not equally useful in all soils and situations. It is much better calculated for active than inactive soils. On lime-stone, chalk, &c. it meets with abundance of active materials; but upon clays, deep loams, &c. it operates best in conjunction with lime or some other stimulating substance. When dung is intended for a compost, no attempts should be made to add a large quantity of lime, earth, &c. till it is properly fermented, every addition of this checking the fermentation. The lime, earth, &c. should be added after the fermentation is finished, and the whole then carefully mixed, and laid up together. In a few days a second fermentation will come on; and if the mixture has been properly turned over and properly incorporated, it will be fit for use in a month or six weeks. Some judgment and attention will be requisite, with regard to the quantity of lime and other active principles employed; for, if the quantity be small, their action upon the rich substances in the dung will be partial and imperfect; and if too great, a considerable loss may be sustained by their over action. If the quantity of earth also be such as to press the dung too hard, the air will be excluded, and the second fermentation be impeded or prevented. It is certainly a right method to lay a good coat of earth as a foundation for the dunghill, into which the moisture of the dung may soak down; and it is no bad way to make a heap of such substances as can be readily obtained, apart from the dung, and to throw the moisture of the dunghill, and the urine of cattle over it frequently.

The composts employed by the farmer are formed in various ways. In some places where there is a head or foot ridge, too high to admit the water being readily discharged from the field, they plough it, then fill it full of lime, dung, or both, and, after frequent ploughings, spread it upon the field. After the lime by this means is sufficiently mixed, the earth may be gathered into a heap with the spade, and

mixed with dung; or the whole operation may be performed with the spade, which is still better.

It is remarked by Mr. Young, that "the farmer may have great advantage from composts; which, when they consist of proper materials, and are skillfully mixed, he may safely depend upon. Where a variety of materials can be had, they may, he says, be laid as follows: first clay or strong earth, next soap ashes, dung, loamy earth, lime, tanners' bark, green vegetables before they run to seed, earth, or as many of these as can be got; also fat chalk, sea-weeds, sea-sand, and several others; which may be so mixed, as not only to raise a general fermentation throughout the whole compost; but likewise to suit the nature of the land on which it is intended to be laid. The common way is to lay the several materials in layers, one over the other, till a large heap is raised; and it is advised by some authors, and the practice of many farmers is, to make these layers from six inches to a foot in thickness; but this he has found by experience is wrong. For the fermentation raised in the compost is not strong enough to penetrate these thick layers, especially those of clay, or strong earth; for after the rest have sufficiently fermented, and the compost is turned, these layers rise almost as whole as when first laid, and must be broken by hand, to mix them with the rest of the compost; whence arise two inconveniences, one an extraordinary expence, and the other that twice or thrice turning is sometimes necessary to dissolve these large pieces; and as a new fermentation is excited every time the compost is turned, the strength of the manure is greatly wasted before it is laid upon the land, where it is then incapable of raising any considerable fermentation, which is, he thinks, one of the principal uses of manure."

It has been suggested, that the best way of making compost is not in thick layers; but after the ground is marked out for the compost, to lay the several materials, after being well broken, in heaps round the space marked out for the compost heap; and to place a man between each two heaps, to throw the manure spreading upon that space. In this manner, the compost heap will soon be raised to the intended height, and the several sorts of manure being thus well mixed, the whole will soon begin to ferment, and will incorporate as fully in two months, as the same manures, placed in layers in the usual way, will in four or five. The owner, therefore, in making such composts, should not prepare them too long before they are laid upon the land; otherwise they will be much wasted, and their best parts evaporated and destroyed. And "composts prepared in this manner need not be turned, or at most not above twice. If the fermentation is observed to abate too soon, holes should be made with a pole from the top almost to the bottom of the heap, upon which throw urine, or the returning of a dunghill, which will fill the holes, force through the whole substance of compost, and soon complete the fermentation." It is added, that "such a compost, by duly proportioning the ingredients, may be made to suit any sort of land, and is excellent for meadow or pasture grounds. A way to improve these, is to cut them five or six inches deep with the five-coiterated cutting plough, or scarifier, which cuts the surface in slips four or five inches asunder, but does not raise or turn them. This cutting of the roots of the grass, and the manure laid on at the same time, sinking into these incisions made by the coulter, cause an improvement in the quality of the herbage, and also make such grass grounds produce much more than they did before. But here it is to be noted, that cutting the ground first, and then laying on the manure,

nure, makes a greater improvement than manuring first, and then cutting; and both are superior to manuring and not cutting; all which have been proved by experiments. The cutting-plough is used with success upon clay grounds, loams, and gravel; but in very strong grounds, the coulters are apt to be thrown out of their work by stones; and therefore, it is not proper to use the cutting-plough where stones abound to any great degree."

It is added, that "in such composts, where it is intended to use a large proportion of earth, that lies at a considerable distance from the limestead, to save the double carriage of it to and from the compost heap, the dung and other materials may be carried to a head land of the field to be manured, and be there mixed into a compost."

It is contended that "the best situation for a compost, is upon level ground; or if made upon a descent, a trench should be cut on the lower side to receive the running of the heap, which is some of the best part of it, and should from time to time be thrown up again, which will quicken the fermentation."

It is supposed that "the richest composts may be made in the farm-yard, which should be made deepening all round from the sides to the middle in form of a hollow ditch or basin. When the yard is made in this form, little of the urine or liquid part of the manure can run off or be wasted. When the dung is carried from the stables, cow-houses, &c. into the farm-yard, it should not be thrown carelessly in heaps, each fort by itself, but carried in carts or wheelbarrows, and laid regularly, and spread all over the yard. Upon this should be spread a thin layer of earth, mud, the sweepings of ditches and ponds, green vegetables before they run to seed, and other such materials as are most suitable to the nature of the land, to be manured with them. The racks and cribs out of which the cattle are foddered, should be frequently moved over the yard, that the offal straw and hay may be equally dispersed, and trod in by the cattle. This method of spreading the dung and other materials being continued, the whole will be incorporated with the urine of the cattle, and make an extraordinary rich compost."

It is supposed that the only inconvenience of this kind of compost, is its being filled with the seeds of weeds, from the earth mixed with it, the hay, straw, and dung of the cattle. It is, therefore, a manure best suited to grass-grounds, and to such arable lands as are to be hoed, as turnips, cabbages, carrots, potatoes, beans, &c. as these weeds will in a great measure be destroyed by good hoeing," or a proper attention to the after culture of the crops. And the earth or mud gathered from the bottom of ditches is excellent for composts. It is usually the lightest part of the soil, carried thither by water, and frequently contains a large proportion of vegetable matter. To this may be added, the cleanings of roads, especially where they are laid with limestone. But one of the best materials for composts is peat-earth: this fills up the pores of a sandy or gravelly soil, without diminishing its friability. Even where applied by itself to such soil, peat increases its fertility. But in a hard clay soil, it should be fermented with lime or dung, or both, and frequently turned, to make it mix properly. Without this precaution it dries, hardens, and cannot be afterwards properly mixed and incorporated with the soil. With regard to the making of composts, if only one sort of manure be used, it is only necessary to put the manure and earth into alternate layers, in a long ridge, and top it so that the rain may not wash through it. When both lime and dung are used, a layer of earth should be interposed between every two beds of lime and dung; for lime, if mixed with dung in the first stage of its putrefaction, corrodes and dissipates its

effluvia. After the first fermentation of the dung is completed, the whole should be turned, to mix the ingredients; and this operation should be repeated until the mass be sufficiently pulverized; which is done by cutting the compost with a spade in perpendicular slices. All the weeds should be collected from the neighbouring fields, before they run to seed, and mixed with the compost. The weeds also that grow upon it should be buried down in it. Such kinds of composts may be used for any crop, and when sufficiently pulverized, are excellent for a top dressing to pastures; the parts being gradually crumbled down, and beaten into the soil by the feet of cattle, or washed in by rains. Some are of opinion, that no advantage results from mixing dung with earth; a bottom of earth, however, will always be useful to detain the moisture that flows from the dung. Quicklime mixed with the dung is useful, by keeping the moisture in a proper state, and preventing the putrefaction from proceeding to too great a length. It has been observed, that making compost dunghills is a general practice in Norfolk. The principal source of them is the shovellings of ditches, which are found there to be singularly fertile. It is not the sediment of water from the inclosures, but it consists entirely of dead weeds, leaves of the hedge, and the mouldering of the bank and sides of the ditch. The most barren sub-stratum, exposed a few years in the face of a ditch bank, is frequently changed into a rich black mould. Perhaps the sea air, acting upon a loose porous soil, may assist in producing this change. Other sources of manure are useless turf, the backs of ditch-banks, the borders of fences in general, the sides of lanes, the nooks of yards, and which, in many places, are suffered to remain the nursery of weeds. These are turned up into ridges, to rot the roots of the grass and weeds, and to receive the melioration of the air; which done, they are carted in due season to the dunghill, to be well incorporated with that substance. It is stated as a good and effectual mode of raising a large quantity of compost manure, to bed the farm-yard about two feet deep with earth, and on this cleanse the stables, cow-houses, hog-sties, &c. and to move the cribs in which loose cattle are fed, with straw about it. This bed of earth will retain the urine, so that, when the whole is mixed together, it will all be nearly of equal goodness, and admirably adapted to gravelly and loose soils in general, through which the effluence of dung alone would be washed in one season; and a top dressing of foot, pigeons' dung, &c. would last but one crop, and very rotten pure dung would be little better. Having the drains from the stables, cow-sheds, and other offices, made so as to discharge themselves into places where these different sorts of earthy materials are deposited, might be a cheap and expeditious method of procuring good compost-manure. And another good method of raising compost dunghills is by making them into clamps. Make a layer of hedge earth from a grubbed border, two feet deep, and about twelve feet square, in the beginning of November; the quantity of earth will be about twenty-six loads of sixteen bushels each; on this clean all the yards and sheds. The yard not being bedded with earth, should be well littered, to soak up the urine, and to be made into dung by the hogs and loose cattle; this may be cleaned once a fortnight, and the sheds once a week, and piled regularly on the foundation of earth, until the heap is about seven feet high; and when one clamp is thus filled up, another foundation of earth may be laid adjoining to it. In order to enrich the compost, the flowings of the heap should be prevented from running off, and thrown up occasionally on it. By thus piling the compost in clamps, it will be in very good order for arable land early in the spring; which will not be the case if it be left to be trodden flat over
the

the whole yard, and every particle washed by the rain. Fermentation goes on much quicker in this method: and it would be better still if the heap were made under a roof, to keep off all water but what is thrown up. Another advantage of this method is, that any part of the compost may be used, by taking a division of the hill that has been the longest finished, and is consequently in the most suitable state for application. See *Dung*.

It is found that all sorts of animal substances, mixed with earth, litter, or any vegetable material, make a rich compost. Saw-dust, mixed in layers with the blood and offal of a slaughter-house, and incorporated till the whole becomes a moist feid mafs, is a rich compost. Two loads of it, with three loads of earth, will be sufficient for an acre of wheat or spring corn. Being a kind of top dressing, it should be put on at the time of sowing, and harrowed in with the grain.

This kind of manure is best adapted to lands of an open texture. Tough clays require lime, and plenty of dung, to break the cohesion of their parts. As this compost takes up little room, it is very convenient for the use of such farmers as are obliged to bring manures from a distance: it is also extremely rich, and will probably continue longer in the land than yard or stable dung. All animal substances being of the same nature, the refuse of whale-fat, after the oil is boiled out, will make a rich compost with fresh dung, which will reduce the blubber speedily into a putrid state, or with earth and dung. Having marked out the length and breadth of your intended dunghill, make a layer of earth, such as moor earth, or that of ant-hills, about a foot in thickness; over this put a layer of yard or stable dung of the same thickness, then a layer of blubber, and over that another layer of dung. Repeat the operation till the heap be raised about six feet, then give it a thick covering of earth, and coat the heap with sods. In about a month, turn the whole in the usual manner; and when turned, coat with earth as before, to confine the putrid steam. In a month or two, the heap will be considerably fallen, when it should have a second turning. This operation must be repeated at proper intervals, till the whole becomes an uniform putrid mafs. In general, this compost should not be used till it is a year old. The heap must be guarded from dogs, swine, &c.

This compost may with great advantage be applied to all purposes where good rotten dung is required. It is excellent for cabbages and for meadow ground. One hoghead of whale refuse will make eight loads of dung; and must be of great importance to such farmers as lie at a distance from manure, but within reach of those places where train oil is prepared. The practice of throwing this kind of offal into the sea was highly wrong and inconsiderate. And it is obvious, that the refuse of all sorts of fish, and fish itself, when in shoals too great for consumption in the way of food, may advantageously be made into a compost in the way above described. These are local advantages; and are mentioned principally with a view to put farmers upon searching diligently for such substances as are within their reach, that are capable of affording the sheepfold and common dunghill, upon which in many places they rely wholly, however inadequate to their wants; abundance of good manure properly managed, being the life and soul of husbandry. Where there is a deficiency of materials for making good composts, proper for the soil in many cases, a mixture of different soils may answer the purpose. Thus, where clay predominates, the addition of sand, where it is happily within reach, is often sufficient to ensure fertility; and where sand prevails, the addition of clay or chalk will answer the same purpose. Gravel enriches peat-moss; and that in return improves gravel. The farmer should, therefore, search every where

above ground and below, for such substances as may improve his several soils, by being properly mixed with them.

In considering the nature of manures, and the methods of applying them to lands, under different circumstances, further directions will be given in regard to the making and applying of composts. See *MANURE*.

COMPOSTELLA, or **ST. JAGO DE COMPOSTELLA**, in *Geography*, a city of Spain, and capital of the province of Galicia, with an archbishop's see and an university, situated in a peninsula formed by the rivers Tambre and Ulla. N. lat. 42° 54'. W. long. 7° 17'. It has a great number of nunneries and monasteries, and contains about 2000 houses. The public squares, the churches, and particularly the cathedral, are magnificent. The Spanish military order of St. Jago derives its origin from this place, where the body of St. James is reported to lie buried, which circumstance likewise used to draw a vast concourse of pilgrims from most parts of Christendom in former times.

The number of pilgrims who went thither from England in 1428, amounted to 916 persons; in 1433 the number was 520; in 1434, 2460, and in 1445, 2100. It was the practice for the crown to grant licenses to masters of ships for carrying out a limited number of these votaries of superstition, who took with them considerable sums of money, not only for their necessary expences, but for offerings and other charges incurred by this pilgrimage. See *ST. JAGO*.

COMPOSTELLA Nueva, or **Nova Compostella**, a rich town of North America, in Old Mexico, or New Spain, in the province of Xalisco, built by Nunez de Guzman in 1531, near the South sea; 400 miles N.W. of Mexico. The soil is barren and the air insalubrious; but it has several mines of silver at St. Peaque, in its neighbourhood. N. lat. 21° 20'. W. long. 110° 12'.

COMPOUND, the result or effect of a composition of different things; or that which arises from them.

Strictly speaking, every new composition does not produce a new compound; but only that from which a new essence arises. Thus, when one drop of water is added to another, there does not arise a new physical compound; the essence being the same now as before the union.

Compound differs from complex, and stands opposed to simple, which see respectively.

COMPOUND, in *Botany*, applied to leaves, expresses their being composed of more than one piece, or leaflet, connected by a common footstalk, which is either simple or branched. *Folium decompositum* is applied to a leaf more than once compounded, and *supra-decompositum* to any greater degree of such conformation. See *LEAF*.

A compound flower is limited by Linnæus to that particular kind of aggregate flower, (see *AGGREGATE*), whose florets are sessile on a common receptacle, within a common calyx, and furnished with anthers united into a tube. These are the exclusive characters of the great natural class *Syngenesia*, the 19th in the Linnæan System, the last order of that class, *monogamia*, consisting of simple flowers, being now, by general consent, diffused. Compound flowers consist either of uniform perfect florets, each furnished with filaments and pistils, and all ripening perfect seed; or of such florets in the disk, with female, or even neutral, ones in the radius; or, lastly, of male florets in the disk and female florets in the radius. Their partial corollas are either tubular and five-cleft, or ligulate, strap-shaped. Their manner of becoming double is for the tubular and perfect florets of the radius to become ligulate and female only, or even neuter, which change is often extended to all the florets, even to the centre, in which case no seed is perfected. Sometimes the ligulate florets become not only abortive, but

tubular,

tubular, or quilled. The prevailing colour of compound flowers is yellow, especially their disk. The ligulate radius is often white, red, or blue, with a yellow disk, but if the radius be yellow, the disk is never of any other colour, except what arises from the anthers or stamens.

COMPOUND *Force, Forms, Poffils, Fractions, Fracture, Gland, Harmony.* See the substantives.

COMPOUND *interest*, called also *interest upon interest*, is that which is reckoned not only upon the principal, but upon the interest itself forborn; which hereby becomes a sort of secondary principal. See INTEREST.

COMPOUND *Larceny.* See LARCENY.

COMPOUND *Machine, Majesty.* See the substantives.

COMPOUND *motion*, that motion which is effected by several conspiring powers.

Powers are said to conspire, if the direction of the one be not directly opposite to that of the other; as when the radius of a circle is conceived to revolve about a centre; and at the same time a point to move straight along it.

All curvilinear motion is compound.

It is a popular theorem, in *Mechanics*, that in an uniform compound motion, the velocity produced by the conspiring powers, is to that of either of the powers separately, as the diagonal of a parallelogram, according to the direction of whose sides they act separately, to either of the sides. See COMPOSITION of motion.

COMPOUND *numbers.* See COMPOSITE.

COMPOUND *pendulum*, in *Mechanics*, that which consists of several weights constantly keeping the same distance, both from each other, and from the centre about which they oscillate. See PENDULUM.

COMPOUND *proposition.* See PROPOSITION.

COMPOUND *quantities*, in *Algebra*, are such as are connected together by the signs + and - : thus, $a + b - c$, and $bb - b$ are compound quantities.

COMPOUND *ratio* is that which the product of the antecedents of two or more ratios has to the product of their consequents. Thus 6 to 72 is a ratio compounded of 2 to 6, and 3 to 12. See PROPORTION and COMPOSITION of ratios.

COMPOUND *Sounds, Sord, Taste, Ulcer, Words.* See the substantives.

COMPOUND *stops* on an organ, are such wherein each finger-key acts upon two, three, four, or even five pipes of different pitches, and causes them all to sound together, whenever a key in this stop is put down. The most common of these are the CORNET, the SESQUIALTER, and the MIXTURE, or furniture stops. (see these articles;) the use of these compound stops with others which are not tuned to the actual note which they represent, or that on the diapason stop, but to the XIIth or XVIIth thereof (see TWELFTH, TIERCE, and LARGOT, Stops) is to introduce an inconceivable number of actual discords into the common chord, even during full performances, as any person may, at leisure, satisfy himself, by writing down the several notes produced by a chord formed of the stops above-mentioned, combined with the diapason and other unisonant stops, or by putting down all the keys on a piano-forte at the same time, to which a chord on these stops answers. No problem in the science of harmonics is more difficult of solution, than to account for the ear's receiving pleasure from such a confused and dissonant assemblage of sounds: and it can only perhaps be accounted for by supposing, that the concordant notes being so many more in number in these kinds of chords, overpower and drown the discords to such a degree, that the ear is able by a sort of mental exertion to pass over and not attend to the latter, any more than to the rattling of the

keys of a badly constructed harpsichord, or the noise of carriages in the street adjoining a concert-room, &c.

COMPOUNDED IDEA, in *Logic*, unites several ideas of a different kind, which are usually considered as distinct single beings, whether those united ideas be simple or complex. See COLLECTIVE idea.

COMPOUNDING FELONY, in *Law.* See THEFT-BOTE.

COMPOUNDING of information upon penal statutes, is an offence of an equivalent nature to CHAMPERTY in criminal causes; and, besides, it is an additional misdemeanour against public justice, by contributing to make the laws odious to the people. At once therefore to discourage malicious informers, and to provide that offences, when once discovered, shall be duly prosecuted, it is enacted by statute 23 Eliz. c. 5, that if any person, informing under pretence of any penal law, makes any composition without leave of the court, or takes any money or promise from the defendant to excuse him, (which demonstrates his intent in commencing the prosecution to be merely to serve his own ends, and not for the public good), he shall forfeit 10*l.*, shall stand two hours on the pillory, and shall be for ever disabled to sue on any popular or penal statute.

COMPREHENSION, in *English Church History*, denotes a scheme proposed by sir Orlando Bridgman in 1667-8, for relaxing the terms of conformity in behalf of protestant dissenters, and admitting them into the communion of the church. A bill for this purpose was drawn up by lord chief baron Hale, but disallowed. A project to the same purpose was proposed and argued in parliament soon after the restoration, in 1661; but the royalists and zealous churchmen formed a majority, and the endeavours of those who wished to avail themselves of the king's declaration to this effect, proved ineffectual. The attempt was renewed by Tillotson and Sillingfleet in 1674, and the terms were settled to the satisfaction of the non-conformists, but the bishops refused their assent. This scheme was likewise revived again immediately after the Revolution; the king and queen expressed their desire of an union: however the design failed after two attempts; and the act of TOLERATION was obtained. Birch's Life of Tillotson, p. 42, 167, &c.

COMPREHENSION, in *Metaphysics*, is that act of the mind, whereby it apprehends, or knows, any object presented to it, on all the sides, whereon it is capable of being apprehended, or known.

To comprehend a thing, is defined by the schoolmen, *rem aliquam totam & totaliter cognoscere.* See APPREHENSION.

COMPREHENSION, in *Rhetoric*, a trope, or figure, whereby the name of a whole is put for a part; or that of a part for a whole; or a definite number of any thing for an indefinite.

COMPREIGNAC, in *Geography*, a town of France, in the department of the Upper Vienne, and district of Bellac; 10 miles N. of Limoges.

COMPRESS, in *Surgery*, from the Latin word *comprimere*, to press together, is a bolster of linen cloth folded several times, and employed on various occasions.

Compresses are formed sometimes of lint or surgeon's tow, but more commonly of half-worn linen without seam or selvage. The size, thickness, and form of them, must be regulated by the part to which they are applied, or the object which the surgeon has in view.

When they are intended to cover other dressings to a wound, &c., they must be always larger than the subjacent plasters, and must lie upon the part in an equal and even manner.

manner, so as to retain the dressings readily on the affected part.

Compresses are divided into simple and graduated. A simple compress consists of linen or flannel folded from two to eight times; and are made quadrangular, triangular, or with pieces cut off a square at the corners, so as to give the compress a crucial form, &c. A graduated compress consists in a number of simple ones laid one above the other, and sometimes sewed together in the shape of a pyramid; these latter are used for compressing a bleeding artery, or they are applied to the bottom of a fistulous sore, or to the sides of a deep fleshy wound, or upon ganglions, and some other tumours, in order to disperse them.

Compresses are employed to fill up inequalities, or hollow parts of the body; they are also used to guard wounds against the contact of irritating substances, and sometimes merely to receive the purulent discharge. They are frequently moistened with different medicated fluids, and are applied either warm or cold according to the surgeon's intention.

Compresses are sometimes of considerable length, and of little breadth, especially when employed to the extremities of the body in a circular form, after the manner of common bandages. (See *BANDAGE*.) The latter kind of bandage is named by the French *longuëte*. The methodical application of such compresses has effected a cure in some aneurisms: they are also found particularly useful in sinusitis and deep sores, where matter is apt to collect and require counter openings. From the various uses of compresses, writers have named them contentive, uniting, diversive, &c.

Tourniquets, trusses, and some other surgical instruments, are only particular kinds of compresses. (See *ANEURISM*, and *HERNIA*.) Compression is now and then more advantageously by means of the finger only, and will often stop a violent bleeding in parts where no surgical apparatus can be employed. Thus the root of the nose is compressed with the fingers, in order to stop violent sneezing, and the crown of the teeth in order to relieve the tooth-ach; and in order to make polypi suppurate, sphacelate, or fall-off, their roots are compressed between the fingers. A great number of the bandages that are used, produce their effects merely by the support which they give to the parts.

The diversity of cases in which a skilful surgeon will employ compression with advantage, cannot here be detailed; but in addition to what has already been said, we may add that by this means alone dropical swellings may frequently be dissipated; and of this, Mr. John Bell records a striking example in his "Principles of Surgery," 4to. vol. i. p. 128, where he treats of bandages in general. By the way, we may mention, that Mr. John Bell has here given some excellent general observations; but (as in other parts of his writings) he affects to have read in authors what no one else can find; and in the instance before us, he pretends to have read "the treatises of Soranus, Glaucus, and Diocles, in which," he says, "I find nothing but what has fallen into deserved neglect;" whereas these authors have not written any treatises upon bandages that have descended to the present generation! Well might this author ask the question, "Why should we go back to the ancients in this pitiful manner?"

COMPRESSED Fossils, this term is applied by naturalists to various extraneous substances found in the earth, which seem to have suffered a flattening or change of shape, from the weight of the superincumbent strata; this is not uncommon with fossil shells, of large size compared with their thickness, as echini, &c., and should be particularly noted

in describing the circumstances of any stratum, where such compressed fossils appear.

The mountains of Quedliac and Portfallet in Norway, contain an argillaceous pudding-stone, the siliceous pebbles of which have been thought by some to be compressed, because those in the lower part of the stratum are progressively thinner than those above (Kirwan's Geo. Exp. 8.); but this probably was their original shape. The small black chert pebbles, which form uniform layers in the lower part of the London clay stratum, are all of them somewhat flat, but certainly not by compression, we think.

Bituminized wood, or the resemblance of trunks of trees in wood-coal, is often found flattened, as at Todt, and near Aqua-Sparta in Umbria, at Thun in Switzerland, in Iceland, &c. Siliceous petrifications have frequently somewhat the appearance of compressed wood, and have been so denominated; but a careful examination of several specimens, in which the transverse section presented two equal segments of circles joined together by their chords, instead of a dilated ellipsis, which would probably be the form of round wood when compressed, has induced us to think that these, and probably many extraneous fossils said to be compressed, may originally not have been round.

Peat-fossils of the present race, such as the trees found in the sea at Sutton in Lincolnshire, and in other places, have without doubt been flattened, by the weight of peat and earth lying upon them, when in a soft and decaying state.

COMPRESSION, from the Latin *compressio*, is the act of pressing, or squeezing matter together, so as to force its parts nearer to one another, and enable the whole to occupy a smaller space; or the effect produced by that cause. *Compression* and *condensation* denote the production of the same effect; that is, the reduction of a certain quantity of matter into a smaller space; with this difference, however, that when the effect is produced by the application of any external force, as by the pressure of a superincumbent fluid, or by means of mechanical engines, it is more properly denominated *compression*; but when the effect is produced by some internal action, as by the escape of caloric in cooling, it is then called *CONDENSATION*, which see.

Compression takes place in various natural processes, and it is also practised by art for various mechanical and economical purposes. The inquiries which may be made concerning it, are, 1st, the principal cases in which compression is produced in nature; 2dly, the mechanical methods which are used for compressing bodies in manufactories and in civil economy; and 3dly, the principal effects which result therefrom. Of the natural compressions, those which arise from the weights of superincumbent solids are sufficiently obvious, and they will, besides, be particularly examined under the articles *GRAVITY*, and *MECHANICS*; but those which are occasioned by fluids, being much less evident, are seldom sufficiently underlooked even by those who are concerned with them.

Water and air are the two fluids with which mankind is naturally and unavoidably conduced; and the pressures of those fluids differ materially from each other. The pressure of water is proportionate to its perpendicular height and not to its quantity, and that pressure is exerted in every direction; for instance, let two vessels of the same height, but of different sizes, as a small pipe and a large reservoir, be filled with water to the same height; then if you measure a square inch in the bottom of the small pipe, and a square inch in the bottom of the reservoir, the pressure upon those two different square inches is the same; though the reservoir

may contain twenty or thirty thousand times more water than the pipe. Also, if you take a square inch on the side of the vessel close to the bottom, the lateral pressure upon it will be equal to the pressure on the square inch of the bottom; excepting indeed a trifling difference which arises from the perpendicular height of the water above the latter, which barely exceeds the perpendicular height of the water above the former.

But though water presses upon every body that is immersed in it in proportion to its perpendicular height, and tends to force the parts of those bodies closer to each other, provided that those bodies have not pores large enough to admit the water; yet water is not itself susceptible of compression, unless it be in a very slight, and scarcely perceptible degree; hence at different depths, water is nearly, if not exactly, of the same density.

The air of the atmosphere, as well as the other aerial fluids, is highly elastic, in consequence of which it not only presses upon all bodies that are immersed in it; but, by pressing upon itself, its own density is rendered different at different altitudes. The bulk of a given quantity of air has been found to decrease in the direct ratio of the force with which it is compressed; hence it has been demonstrated, that if the altitudes above the surface of the earth be taken in arithmetical progression the densities of those altitudes will be in geometrical progression decreasing. If a very long tube, closed at one end be filled with water, and then be inverted in a basin of water, that fluid will remain suspended in it to the height of about 33 feet, that weight of water being counterpoised by the pressure of the atmosphere: (see the articles ATMOSPHERE, PNEUMATICS, and HYDROSTATICS.) Therefore, since a man on the surface of the earth is pressed by the weight of the atmosphere, if he places himself at 33 feet below the surface of the water, he will be pressed by twice the above-mentioned weight of the atmosphere; if he places himself at 66 feet below the surface of the water, he will sustain a pressure equal to three atmospheres, and so on.

If the above-mentioned experiment be tried with a tube filled with and inverted in a cup of quicksilver, instead of water, it will be found that the quicksilver will remain suspended in it to the height of about 30 inches, the specific gravity of quicksilver being much greater than that of water. As the pressure of the atmosphere counterpoises a perpendicular pillar of quicksilver about 30 inches high, or, more accurately speaking, between 28 and 31 inches; for it varies between those limits (see BAROMETER); the weight of such a pillar. Let its base be what it may, shews the pressure of the atmosphere upon a surface equal to that base. A pillar of quicksilver, whose base is an inch square, and whose altitude is a mean between 28 and 31 inches, weighs 14½ pounds avoirdupois; therefore, at a mean, the pressure of the atmosphere upon every square inch on the surface of the earth, is equal to 14½ pounds; and by the rule of proportion, or by simple multiplication, we may determine the weight of the atmosphere upon any other given surface. Thus the pressure of the atmosphere on a square foot, (which is equal to 144 square inches) is 2088 pounds. The pressure on the body of a middle sized man, whose surface is equal to about 12 square feet, is 25056 pounds; and the pressure on the surface of the whole earth is equal to about 1164201684000000000 pounds. For further explanation of the mechanical properties of fluids in general, see the articles referred to above, and likewise the article ELASTICITY.

The artificial methods of compressing substances, either solid or fluid, as employed in the arts, and for economical purposes, are very numerous; different compressing instru-

ments being used for almost every particular purpose. Thus there are hammers, levers, screw-presses, hydraulic presses, condensing engines, rolling or fluting mills, &c. Thus the apothecary obtains his expressed oils by means of a screw-press, the book-binder compresses the leaves of his book, both with the hammer, and with a screw-press of a different form; the gold-beater compresses and flattens his metallic plates first through the rolling (or flattening) mill, and then by the strokes of a hammer, and so forth. Descriptions of those instruments may be seen under their different names.

Besides the above-mentioned mechanical properties, compression produces some remarkable physical effects, of which it will be necessary to give a distinct account. We shall, however, previously to this, briefly state the discoveries that have been made with respect to the compressibility of water, which, as has been already mentioned, is so very slight as to be next to nothing.

Water was, during a very long period, considered as a fluid perfectly unelastic; that is, unyielding, or incompressible; and this opinion was corroborated by an experiment of the Academy del Cimento in Italy. About a century and a half ago the members of that academy endeavoured to ascertain whether water was capable of being compressed in any degree. For this purpose, they filled a hollow metallic sphere with that fluid, and stopped the aperture very accurately. This ball then was pressed in a proper machine, but no contraction could be observed, nor indeed was the apparatus capable of manifesting small degrees of compression. Hence they concluded that water was not capable of compression. This opinion prevailed until the year 1761, when the ingenious Mr. Canton discovered the compressibility of water, and of other liquids, which he immediately made known to the Royal Society. He took a glass tube, having a ball at one end; filed the ball and part of the tube with water, which he had deprived of air as much as it was in his power; then placed the glass thus filled under the receiver of an air-pump; and on exhausting the receiver, which removed the pressure of the atmosphere from over the water and the glass vessel which contained it, in consequence of which the water rose a little way into the tube, viz. expanded itself. He then placed the apparatus under the receiver of a condensing engine, and on forcing the air into it, which increased the pressure upon the water, a diminution of bulk evidently took place; the water descending a little way within the tube. "In this manner," Mr. Canton says, "I have found by repeated trials, when the heat of the air has been about 50°, and the mercury at a mean height in the barometer, that the water will expand and rise in the tube by removing the weight of the atmosphere, one part in 21740; and will be as much compressed under the weight of an additional atmosphere. Therefore the compression of water by twice the weight of the atmosphere is one part in 10870."

"Water has the remarkable property of being more compressible in winter than in summer, which is contrary to what I have observed, both in spirit of wine and oil of olives."

By the same means, and in the same circumstances, Mr. Canton ascertained the property of being compressed in some other fluids, and the results are as in the following table:

Compression	{	of spirit of wine	66	} millionth parts,
		of oil of olives	48	
		of rain water	40	
		of sea water	40	
		of mercury	3	

Mr. Canton was of opinion that the above-mentioned diminution of bulk under the receiver of the condensing engine, is not to be attributed to any air contained in the water, or any of the other fluids; because when he tried the experiment with water which had been forced to imbibe more than an usual quantity of air, the compression did not appear to be greater. Yet it may be observed, that considering the slight degree of compression which water is capable of, and the difficulty of depriving water entirely of air, one might still be induced to doubt whether that compression is not to be attributed to the air. See Canton's account of those experiments in the 52d and 53th vols. of the Philosophical Transactions.

With respect to the effects produced by compression, it is in the first place to be remarked, that certain bodies, when pressed, suffer a derangement of form; but as soon as the pressure is removed, they recover their former shape. Those bodies are said to be *elastic*, and they are distinguished into *perfectly elastic*, when they recover their former bulk and shape entirely, as is the case with common air, and *imperfectly elastic*, when they recover their former shape only in part, which is the case with far the greatest number of bodies.

When the bulk of a body is reduced by compression, the specific gravity of that body is proportionately increased; thus the specific gravity of fine gold, that has been fused only, is 19,258; but the specific gravity of the same, after having been hammered, is 19,362. The specific gravity of pure silver, that has only been fused, is 10,474; that of the same hammered, 10,511. The specific gravity of copper, simply fused, is 7,738; that of the same hammered, is 8,8;8, and so forth.

Whenever the bulk of a body, and especially of a metallic one, is diminished in bulk by hammering, flattening between rollers, or by any other sort of compression, its hardness or rigidity is increased at the same time; thus soft brass, or silver, or copper, by hammering, or pressing, is rendered hard and elastic. By the application of a degree of heat, somewhat lower than incandescence, that hardness or elasticity of the metal is removed, and at the same time its specific gravity becomes equal to what it was before the hammering. This process is called *annealing* or *softening*.

The other remarkable effects of pressure may be reduced to three; namely, a modification of the action of the same degree of heat on bodies, an extrication of heat, and an extrication of light. When heat is applied to any body, the effects differ according as the application takes place under different atmospherical pressures. On the tops of mountains, where the pressure of the atmosphere is considerably less than it is on the level of the sea (in consequence of which the quicksilver does not stand so high in the barometer in the former place as it does in the latter), water boils at a lower temperature; and so do other fluids. At the level of the sea, water boils at about the temperature of 212° of Fahrenheit's thermometer; but Mr. Sauffure found on Mount Blanc (which is reckoned the highest mountain of any in Europe; where the barometer stood at 17,05 English inches), that the heat of boiling was 185½°. From the experiments of Sir George Shuckburgh, and of Mr. De Luc, the following table of the heats of water boiling under different pressures of the atmosphere, which are indicated by the altitudes of the mercury in the barometer, was calculated by Mr. Kirwan.

Heat of boiling water under different barometrical altitudes

Barom.	Heat.	Barom.	Heat.
30	212°	21	195,36
29	210,28	20	193,36
28	208,52	19	191,66
27	206,75	18	189,46
26	204,99	17	187,76
25	203,26	16	184,36
24	201,48	15	180,66
23	199,27	14	176,70
22	197,22		

Mr. Watt observed, that in a very good vacuum water boils, or produces copious vapours, even when its heat is not greater than 70°. On the other hand, when water is caused to boil under a great pressure, a much greater degree of heat must be applied: thus, in Papin's digester (being a strong vessel in which a quantity of water is confined) the water may be rendered nearly red hot; and in that state the dissolving property of water is increased prodigiously. In Iceland a natural discharge of hot water comes out of a deep pit, and when this water falls upon the surface of the earth, it deposits a white powdery siliceous substance, which, it is supposed, the water was enabled to dissolve by the volcanic heat, that acted upon it under a great degree of compression.

Dr. Hutton, like some other geologists, has ascribed the formation of the various minerals chiefly to the action of subterraneous fire; but he thought that that action was modified by the compression of the superincumbent strata of the earth, which rendered it capable of producing such effects as could not be easily imitated on the surface of the earth; for it seemed to him, that under a great degree of compression, volatility would expose to a high degree of heat such substances as generally fly off in our fires, on the slightest application of heat. Hence, by their chemical relations peculiar combinations might arise; such as are dug from the bowels of the earth. What Dr. Hutton supposed, was in a great measure verified by Sir James Hall, bart., who, by his numerous and well imagined experiments, has shewn a variety of remarkable effects, on different substances, by the action of heat modified by compression; but his interesting experiments will be described amongst the effects of heat.

The other two remarkable effects of compression on bodies, are an extrication of heat and an extrication of light. These effects having been observed with all those bodies which may be subjected to decisive experiments; it may be presumed from analogy, that the same effects take place in various degrees, with all bodies which are susceptible of compression, but not with those which are not compressible; and, in fact, liquids which are only compressible in the slightest degree imaginable, cannot be heated by agitation, which is friction amongst their particles; and there is no friction without compression. As heat is evolved from a body when compressed, so when the bulk of a body is enlarged, heat is absorbed, in consequence of which the surrounding bodies are cooled; and this absorption of heat seems to be directly proportioned to the enlargement of bulk. The following instances will illustrate the nature of these remarkable effects. The blacksmith, by about twenty strokes of the hammer upon a piece of iron bar not thicker than a man's little finger, can render one extremity of it red-hot, visible in the day light. But it is to be remarked, that the same extremity of the iron bar cannot be rendered red-hot

COMPRESSION.

red-hot a second time, unless it be previously softened in the fire. The condensation of common air, quickly performed, produces a considerable degree of heat; so much so, that cotton has been set on fire, and so has heated charcoal, by compressing the air quickly upon it. An ingenious mechanic in Paris is said to have kindled tinder in tubes, or compressing pumps, of about a quarter of an inch in diameter, and six inches in length, by a single stroke of the piston. Steam, also, by mechanical compression, may be made to yield its latent heat. A mixture of oxygen and hydrogen gases, if quickly compressed, takes fire and explodes with great force. The discharge of an air-gun is attended with a faint flash of light, visible in a darkened room; and the sudden compression of the air in a tube, to the end of which a strong glass is fitted for the purpose of manifesting what passes within, is likewise attended with light.

In explanation of these phenomena, it is supposed, that independent of the specific caloric, peculiar to every body, a quantity of it is lodged in the pores of each body, and that this may be extricated by compression, in the same manner as water is squeezed out of a sponge. But a farther examination of facts will throw more light upon the subject.

It is well known, that friction amongst solids generates heat, which often occasions actual inflammation and combustion. Thus the axes of wheels of carriages, and other machines, are sometimes set on fire by the violence of the friction; thus, in a turning lathe, the pieces of work are heated to a great degree; thus, the violent collision of a steel against a flint, renders the abraded particles of the former perfectly red-hot. Count Rumford, willing to investigate the origin of the heat produced by means of friction, instituted an intertelling series of experiments in the workshops of the military arsenal at Munich, where cannons are bored; in which case a degree of heat far exceeding that of boiling water is produced. After having examined the temperature of the metallic shavings, their quantity, capacity for containing caloric, &c. and finding reasons sufficient to account for the production of that remarkable quantity of heat which was manifested in the course of the boring, he began to consider which way that heat might be derived, whether from the contiguous metal or from the air, and in order to determine the matter by means of actual experiment, he contrived a suitable apparatus, the principal part of which was intended to turn a piece of metal in a box full of water, whilst a blunt borer acted forcibly against it, so as to produce a considerable degree of friction, without abrading from the piece of metal more than an inconsiderable quantity of it in a fealy powdery state. With this apparatus, in which both the piece of metal and the borer were plunged in water of the temperature of the atmosphere, no heat could be derived from the air. The machine which turned the piece of metal being put in motion, the water in the box, &c. began to be heated soon after, and in 2½ hours time, from the commencement of the operation, the water actually boiled. The result of this experiment shewed, that the heat, which had caused the water to boil, was not derived from the air, and from computation it appeared, that the abraded metallic powders could not furnish it in consequence of the change of their capacity. "Is it possible," count Rumford says, "that the heat could have been supplied by means of the iron bar, to the end of which the blunt steel borer was fixed? or by the small neck of gun-metal by which the hollow cylinder was united to the cannon?" "These suppositions appear more improbable even than either of those before-mentioned, for heat was continually going off, or out of the machinery, by both these

passages, during the whole time the experiment lasted. And in reasoning on this subject, we must not forget to consider that most remarkable circumstance, that the source of the heat generated by friction, in these experiments, appeared evidently to be inexhaustible. It is hardly necessary to add, that any thing which any insulated body, or system of bodies, can continue to furnish without limitation, cannot possibly be a material substance; and it appears to me to be extremely difficult, if not quite impossible, to form any distinct idea of any thing, capable of being excited and communicated in the manner the heat was excited and communicated in these experiments, except in motion." Phil. Transf. for the year 1798.

It seems strange that so distinguished a philosopher as Count Rumford should be induced to admit the immateriality of heat from the result of the above-mentioned experiment, without adverting to the compression which the metal must have received from the action of the borer.

Having mentioned the principal effects which arise from compression, amongst which the extrication of heat has been reckoned the most intertelling; we might now state several instances of the contrary effect, namely, of the absorption of heat attending the enlargement of bulk which takes place in several bodies after the removal of the cause which occasioned their compression. With respect to this, however, we need not be very prolix in this place. The hydraulic engine at Schemnitz furnishes a strong instance of the latter effect. That engine operates by causing a fall of water to compress air in a strong vessel, the re-action of which forces other water to rise in another pipe for certain purposes. Now, in consequence of the great height of the superincumbent column of water, the air in the air-vessel of this machine, is very much compressed, and it is said that if the stop-cock of this vessel is opened, the air, in rushing out of it and expanding itself, absorbs so much heat, and, of course, cools the adjacent bodies so much, as to produce a copious deposition of moisture from the atmosphere, and the actual formation of ice upon the stop-cock. The cold produced by the evaporation of water, and especially by that of spirituous liquors, might be likewise adduced as instances of the above-mentioned property. But the farther investigation of these latter phenomena belongs to other branches of natural philosophy, which will be explained in other places.

The term *compression*, in astronomy and geography, has often been used to denote that diminution of the curvature of the surface of the earth, which has been observed about the poles, as if the earth had been compressed at the poles by some external force, which caused it to lose its perfect spherical form, and to assume nearly that of an oblate spheroid; it being, however, well known that the spheroidal figure arises from the centrifugal force of the parts distant from the poles, which is likewise the case with the other planets. The precise quantity of deviation of the polar regions of the earth from the spherical form, or the difference between the equatorial and polar diameters, has been variously stated by different astronomers. Sir Isaac Newton, supposing the density of the earth to be uniform, has assigned $\frac{1}{230}$ for the difference of the above-mentioned two diameters. Boscovich, taking a mean of all the different measurements, found the difference of the two diameters equal to $\frac{1}{227}$. From other measurements and calculations since made by other able mathematicians, this difference has been reckoned equal to $\frac{1}{17}$ or $\frac{1}{250}$ by De la Lande; to $\frac{1}{17}$ by De la Place; to $\frac{1}{17}$ by Séjour; to $\frac{1}{17}$ by a late anonymous writer. These latter results agree pretty well with the lengths of the pendulums, which have

been found to vibrate seconds in different latitudes; so that upon the whole $\frac{1}{15}$, or a fraction not much differing from this, seems to be the nearest to the true difference of diameters; and the difference between the different measurements probably arises from the imperfection of instruments, from the partial attraction of mountains, and from the unequal density of the earth. See professor Playfair's paper on the figure of the earth, in the Transactions of the R. Society of Edinburgh, vol. v. p. 1.

COMPRESSION, in Surgery, not only signifies the act of compressing, but denotes a class of diseases produced by the pressure of an extraneous body; and, in some cases, a compression will cause the most serious consequences. For example, compression of the brain, arising from a fracture of the cranium, and a portion of the bone in a depressed state, may occasion inflammation, suppuration, and destruction of that part of the brain to which the mechanical effect is applied; which will be, more or less, attended by comatose symptoms, and privation of sense or voluntary motion. In such cases, the surgeon endeavours to remove the cause, by elevating the edge of the bone, or extracting it entirely, either with or without trepanning, as the circumstances may indicate. (See TREPANNING and TREPINI.)

When the symptoms of a compressed brain are evidently marked, no time ought to be lost in setting about an examination of the state of the cranium, wherever appearances point out, or even lead us to conjecture, in what part a fracture may be situated. For this purpose an incision is to be made upon the spot through the integuments to the surface of the bone, which must be sufficiently exposed to admit of a free examination. Some authors have recommended a crucial incision; others one in form of the letter T; while many advise a considerable part of the integuments to be entirely removed. But as it is more agreeable to the present mode of practice to save as much of the skin as possible, a simple incision is generally preferred, unless the fracture run in different directions, and then the incision must vary accordingly. It will frequently happen, that a considerable part of the integuments must be separated from the skull, in order to obtain a distinct view of the full extent of the fracture; but no part of the integuments is to be entirely removed. When blood-vessels of any considerable size are divided, either before or at the time of the examination, they ought to be allowed to bleed freely, as in no case whatever is the loss of blood attended with more advantage than the present. When, however, it appears that the patient has lost a sufficient quantity, the vessels ought to be secured.

After the integuments have been divided, if the skull be found to be fractured and depressed, the nature of the case is rendered evident; but even where there is no external appearance of fracture, tumour, discoloration, or other injury, if the patient continue to labour under symptoms of a compressed brain, if the pericranium has been separated from the bone, and especially if the bone has lost its natural appearance, and has acquired a pale white or dusky yellow hue, the trepan ought to be applied without hesitation, at the place where these appearances mark the principal seat of the injury. Again, although no mark, either of fracture or of any disease underneath, should appear on the outer table of the bone, yet there is a possibility that the inner table may be fractured and depressed. This indeed is not a common occurrence, but it happens perhaps more frequently than surgeons have been aware of; and where it does happen, the injury done to the brain is as great, and attended with as much danger, as where the whole thickness of the bone is beaten in. The application of the trepan is therefore usually deemed a necessary measure.

But if after the application of the trepan, it happens that no mark of injury appears either in the outer or inner table in that part, or in the dura mater below it, and that the symptoms of a compressed brain still continue, a fracture in some other part is to be suspected; or that kind of fracture termed by practitioners *counter-fracture*, where the skull is fractured and sometimes depressed on the opposite side to, or at a distance from, the part where the injury was received. This is fortunately not a very frequent occurrence, and has even been doubted by some; but different instances of it have, beyond all question, been found. If therefore the operation of the trepan has been performed, and no fracture is discovered, no extravasation appears on the surface of the brain; and if blood-letting, and other means usually employed do not remove the symptoms of compression, the operator is to search for a fracture on some other part. The whole head should again be examined with much accuracy; and, by pressing deliberately but firmly over every part of it, if the smallest degree of sensibility remains, the patient will shew signs of pain, either by moans or by raising his hands, when pressure is made over the fractured part. In this way, fractures have been frequently detected, which might otherwise have been concealed.

Having here considered every thing preparatory to the operation of the trepan, we shall point out the means best adapted for the removal or elevation of a depressed portion of the bone, by the use of that instrument, under the article TREPAN. After the operation, the patient should be placed in as easy a position, in bed, as possible, with his head and shoulders elevated a little more than ordinary. If the operation be attended with success, he will soon begin to shew signs of increasing sensibility and the original bad symptoms will gradually disappear. In this state, he ought to be kept as quiet as possible; proper laxatives being occasionally administered, and such as may be least of a nauseating nature. His food ought to be simple and easy of digestion, and his drink of the most diluent kind. If he complain of the wound being uneasy, an emollient poultice should be immediately applied, and renewed three or four times in the twenty four hours. By these means there will commonly be a free suppuration from the whole surface of the fore.

Every time the wound is dressed, the purulent matter ought to be wiped off from it with a fine warm sponge; and if any degree of sloughiness takes place on the dura mater or parts adjacent, it will then be completely separated. Granulations will begin to form, which will continue to increase till the whole arise to a level with the surface of the cranium. The edges of the fore are now to be dressed with some mild cerate, and the rest of it covered with fine lint, kept gently pressed on it by a night-cap properly secured. In this way the cure will go on favourably; luxuriance of granulations will commonly be prevented; the parts will cicatrize kindly; and as all the skin has been preserved in making the first incision, the cicatrix will be but little observed.

But things do not always proceed in this favourable manner. Sometimes, in a few hours after the operation, the patient is seized with a kind of restlessness, tossing his arms, and endeavouring to move himself in bed, while the symptoms of a compressed brain remain nearly the same as formerly. In this case, especially if the pulse be quick and strong, the patient ought to be bled freely, as there will be reason to suspect some tendency to inflammation in the brain. Sometimes, though the trepan has been properly applied, the symptoms are not relieved, on account of extravasated fluids collected internally under the dura mater, or between the pia mater and brain, or in the cavity of the ventricles. The danger in these cases will be in proportion to the depth of the

the collection. Particular attention, therefore, ought always to be paid, to the state of the dura mater after the perforation has been made. If blood be collected below the dura mater, this membrane will be found tense, dark coloured, elastic, and even livid; in which case, an opening becomes absolutely necessary to discharge the extravasated fluid. Gentle scratches are to be made with a scalpel, till a probe or directory can be introduced; upon which the membrane is to be sufficiently divided in a longitudinal, or sometimes even in a crucial, direction, till an outlet to the fluid be given.

After the dura mater has been cut in this manner, there is a possibility of the brain protruding at the opening; but the danger from this is not equal to that arising from effused fluids compressing the brain. A troublesome appearance also now and then follows the operation of the trepan; namely, the excrescences called *fungi* (see FUNGUS), formerly supposed to grow immediately from the surface of the brain, but which, in general, originate from the surface of the dura mater or cut edge of the bone granulating too luxuriantly. After the wound is cured, only a small cicatrix will remain, and, in general, the parts will be nearly as firm as at first, but when much of the integuments hath been separated or destroyed, as they are never regenerated, the lobe will be left covered only by a thin cuticle, with some small quantity of cellular substance. When this is the case, the patient usually wears a piece of silver, copper, or tin, properly fitted and lined with flannel, to protect it from the cold and other external injuries.

This is the method now commonly practised in cases of compression: but it frequently happens, that instead of compression, such a degree of concussion takes place that no assistance from the trepan can be attended with any advantage; for the effects of concussion (see CONCUSSION) are totally different from those of compression, and therefore to be removed in a different manner. In Part III. of his Surgical and Physiological Essays, Mr. Abernethy says, the degree of pressure which the brain can sustain without great injury to the system, probably may vary according to the disposition of that organ to be affected by it, the suddenness of its application, and the direction in which it is made; and although it must be very difficult to obtain any precise knowledge on this subject, yet there is great reason to believe that the brain can bear more pressure without injury to it, than was formerly supposed. The first of these circumstances seems evident; for, in some persons, a slight pressure produces severe symptoms; whilst in others a much greater degree is borne without inconvenience. Where a compressing cause does not, in the first instance, occasion bad effects, if inflammation of the brain ensues, it seems then to act injuriously; which probably arises from the increased susceptibility of the brain. We can rarely judge of the effects of pressure when any part of the cranium is beaten in by a blow; for in that case the shock generally occasions stupor. Internal hæmorrhages, perhaps, afford us the best criterion whereby to determine the effects of pressure on the brain. A case (the seventh) which Mr. Abernethy relates, sufficiently illustrates this remark, for it appears that a considerable hæmorrhage must have taken place before it deprived the patient of his faculties; since he walked home, undressed himself, and went to bed, after the trunk of the middle artery of the dura mater had been ruptured. In cases of apoplexy, also, the hæmorrhage is generally very large, before it produces those consequences which destroy life.

Compression of the brain will sometimes arise from the luxuriant growth of a part of the inner table of the skull, or

a small projecting piece of bone, which may have advanced spontaneously; and it has now and then been discovered that epileptic fits arose from this cause. In apoplexy the common cause of a compression of the brain is effused blood or serum. When persons have a palsy of the lower extremities from incrustation of the spine, the paralysis arises from compression made on some part of the spinal marrow by a disease of the vertebra; and nothing can relieve a patient effectually in this case, unless the pressure be removed by extending the spinal column mechanically. (See CURVATURE OF THE SPINE.)

A dangerous compression may be produced in different parts of the body, by the existence of tumours, by dislocation of the joints, or by fractures, &c. See TUMOUR, DISLOCATION, and FRACTURE.

COMPRESSOR *Naris*, or *Narium*, in *Myology*, is a muscle of the nose, described also under the name of *compressor nasi*. It arises from the root of the ala nasi, where its fibres are strongly connected with the depressor labii superioris et alæ nasi, and are also mixed with those of the depressor alæ nasi. It ascends on the dorsum of the nose, and scatters its fibres between the ala and the ossæ nasi; they are partly joined with the fibres of the opposite muscle, and partly connected with those of the frontal portion of the fronto-occipitais. By drawing down the movable part of the alæ nasi, and bringing it to the septum, it closes the aperture of the nostrils: in this case the depressor alæ nasi must concur with it, in order to render the inferior part of the ala fixed. If this latter muscle does not act at the same time, the compressor naris will elevate the lower portion of the ala, and thereby expand the nostril. Cowper calls it *elevator alæ nasi*: Santorini and Winslow, *transversalis nasi*.

COMPRESSOR *prostatæ*. It seems doubtful whether this should be considered as a distinct muscle, or only as a portion of the levator ani. It arises from the under surface of the arch of the pubis, and is lost between the prostate and rectum. It will therefore have the power of elevating or compressing the former part.

COMPRINT, a surreptitious printing of one book-feller's copy by another person, for gain; which was contrary to common law, and is now, under certain limitations, restrained by statute. See LITERARY PROPERTY.

COMPRISE NIENT. See NIENT.

COMPROMISE, a treaty or contract, whereby two contending parties establish one or more arbitrators, to judge of and terminate their differences in an amicable way.

The regular way of appointing a compromise is by a writing, expressing the names of the arbitrators, the power of choosing an umpire, or super-arbitrator, in case of need, a time limited for the arbitrage, and a penalty on the party who does not abide by the decision.

By the civil law, a slave cannot make a compromise without the leave of his master, nor can a pupil without the authority of his guardian, or a wife without that of her husband. So a slave, a deaf or dumb man, a minor, and the person who is a party in the cause, are incapable of being chosen arbitrators in a compromise.

The occasions on which a compromise is not allowed of, are restitutions, marriage-causes, criminal affairs, questions of state; and, generally, any thing wherein the public interest is more concerned than that of private persons.

In our law, a compromise is not of so much extent. West defines it the faculty, or power of pronouncing sentence between persons at controversy, given to arbitrators by the mutual private consent of the parties, without public authority.

Matters compromised are also matters of law referred, or made an end of. See ARBITER and ARBITRATION.

COMPROMISE is also used in beneficiary matters; where it signifies an act, whereby those who have the right of election, transfer it to one or more persons, to elect a person capable of the office or dignity.

COMPS, in *Geography*, a small town of France, in the department of the Var, and chief place of a canton in the district of Draguignan; ten miles N. of Draguignan. It contains 739 and the canton 2949 inhabitants. The territory includes 525 kilometres and 9 communes.

COMPSA, CONZA, in *Ancient Geography*, a town of Italy, in Samnium, towards the south-east, upon the Aufidus. At the siege of this city was killed Milo, so well known by Cicero's oration on occasion of his murder of Clodius. See CONEZA.

COMPSTATUS, a river of Thrace, mentioned by Herodotus, which ran from north to south, and discharged itself into the lake Bisbonis, near Abdera.

COMPTE, LEWIS LE, in *Biography*, a native of Bourdeaux, and of the order of jesuits, went to China in the character of missionary in the year 1685. Upon his return, he published "Memoirs on the present State of China," &c., in two vols. As an historian he has been accused of a too great partiality for the character and manners of the Chinese, and of attributing to them earlier advances in civilization and improvement than he was warranted by real facts. His work was profcribed, and condemned to the flames, as the best means of refuting his opinions. He died at his native place in the year 1729. *Nouv. Dict. Hist.*

COMPTE, NICHOLAS DE, a French monk, a native of Paris, is known as the author or editor of different works which have met with a favourable reception. Among others, he published "The remarkable Travels of Peter della Valle, a Roman Gentleman, translated from the Italian, in 4 vo s. 4to."—"A new and interesting History of the Kingdoms of Tonquin and Laos, in 4to." translated from the Italian of father Manni, in 1666. In the year preceding this, he published the third volume of father Lewis Coulon's "History of the Jews." He died at Paris in 1689.

COMPTING, or COUNTING-HOUSE, an office in the king's household, under the direction of the lord steward, so called, because the accounts for all expences of the king's household are there taken daily by the lord steward, comptroller, cofferer, master of the household, the clerks of the green-cloth, and the clerks comptrollers. They also there make provision for the household, and make payments, and orders, for the good government thereof.

In the counting-house is the board of green-cloth.

COMPTON, HENRY, in *Biography*, an eminent English bishop, was the youngest son of Spencer, the second earl of Northampton. He was born in the year 1632, and, though deprived of his father by death at a very early age, was initiated with great care in the rudiments of learning, after which he was entered at Queen's college, Oxford, where he prosecuted his studies with much diligence, till the year 1652. From the university he went to the continent, with a view of perfecting himself in the modern languages, and of acquiring an accurate knowledge of foreign establishments, ecclesiastical and civil. On his return, he accepted under Charles II. a cornet's commission in the king's horse guards, which he soon resigned and devoted himself to the service of the church. He was immediately admitted to the degree of master of arts in the university of Cambridge, and afterwards obtained the grant of the next vacant canonry of Christ-church, Oxford. In 1666, he was admitted canon-commoner of that college, and shortly after was in possession of the re-

ctor of Cottenham in Cambridgeshire. He was in the following year made master of St. Croffe's hospital near Winchester, and in 1669 inflated canon of Christ-church. Without farther delay he took the degrees first of bachelor of divinity, and then of doctor of divinity. In 1674, he was nominated to the bishopric of Oxford, where he remained but a single year, when he was appointed dean of the royal chapel, and translated to the see of London. For these valuable and highly important preferments, Dr. Compton was indebted as well to his own excellent character as to his family connections. Soon after he had been made bishop of London, he was sworn in of his majesty's privy council, and undertook the superintendency of the religious education of the princesses Mary and Anne. To the conscientious discharge of his duty as a preceptor may be justly ascribed the zealous attachment of his pupils, afterwards sovereigns of England, to the Protestant religion, as by law established. This worthy prelate endeavoured to devise methods of reconciling the dissenters to his own church; his intentions were unquestionably good, but some of the means which he used to effect his purpose could not be justified on the principles of protestantism. Under the pretence of guarding the church from heresy, he obtained a royal mandate to prohibit certain discussions on the doctrine of the Trinity; he nevertheless shewed himself a decided friend to the Protestant reformation, and encouraged his clergy to defend it with Christian zeal, when the principles of popery, or a more blameable indifference to all religion, were encouraged by the profligate court of Charles II. His conduct, in this respect, which cannot be too highly applauded, rendered him obnoxious to the king and to his brother, who soon after ascended the throne as James II. The name of the excellent prelate was immediately after this event struck out of the list of the privy council, after which he was deprived of his office as dean of the royal chapel. For refusing to become an instrument of ecclesiastical tyranny among his own clergy, and to sanction various unconstitutional measures of the king, he was, in 1686, suspended from his episcopal office. In 1688 the dread of a revolution in favour of the prince of Orange, induced the king to attempt regaining the affection of Dr. Compton, and that of the other clergy, who had been familiarly treated, by restoring them to their office. It was, however, too late to effect a reconciliation, and the bishop shortly after took a decided part in favour of the new order of things. He joined in conducting the princess Anne of Denmark from London to Nottingham; in signing the association begun at Exeter, and in waiting on the prince of Orange at the head of his clergy, to thank him for his interference in preserving the laws and liberties of the nation; and in the house of peers he voted for the prince and princess of Orange in the room of the abdicated king. Immediately after this event had been determined on, he was restored to the office of privy counsellor, and to that of dean of the royal chapel; he had also the honour of performing the ceremony at the coronation of king William and queen Mary, instead of archbishop Sancroft, who refused to take the oaths to the new government. In the year 1689 he was appointed one of the commissioners for reviewing the liturgy, and president of the convocation, in which certain proposed amendments were to be discussed. In this situation he at first joined the moderate party, who were for comprehending dissenters by adapting the liturgy to their minds, but afterwards he united himself with those members who advised and obtained the discontinuance of the convocation session. Dr. Compton was appointed, as bishop of London, a commissioner of trade and plantations, and in this capacity he selected and sent

over to the colonies in America, such clergymen as he thought best adapted, by their talents and zeal, to promote the interests of the church of England. In the year 1690, he attended the king, at his own expense, to the congress at the Hague, where the grand alliance against France was concluded. From this period he united himself more closely with the tory party, in consequence of which his influence at the court of king William was greatly diminished, if not wholly terminated; but in the reign of queen Anne, he recovered his former power and interest. Dr. Compton was in the commission for promoting the union of Scotland with England; he was assiduous in obtaining the act for augmenting small livings, by a grant of the first fruits and tenths; and he maintained a friendly correspondence with the foreign Protestant churches, and the university of Geneva, with a view of impressing them with favourable sentiments towards the Church of England, and of obtaining their disapprobation of those who should dissent from its discipline. He died at Fulham in the year 1713, in the eighty-first year of his age. For some time before his decease he is represented to have been much in the power of others, and to have followed their will rather than the dictates of his own mind. Through the whole of a long life he was exemplary in his moral conduct, and displayed the manners of a gentleman. He was a warm friend, a generous patron, and truly charitable to the wants of those about him. As a bishop he maintained the interests of the church, and was attentive to the conduct and advancement of his clergy, but as a preacher he was extremely dull and inanimate. His character as a literary man was respectable, though his works are not numerous nor of the first rank in merit. He published a translation from the Italian of "The Life of Donna Olympia Maldacchini, who governed the church during the time of Innocent X." "The Jesuits' Intrigues with private Instructions of that Society to their Missaries," translated from the French. "A Treatise of the Holy Communion," and letters to the clergy at different periods, which were reprinted in 1686, under the title of "Episcopalia, or Letters of the Right Reverend Father in God, Henry Lord Bishop of London, to the Clergy, &c." He also published "A Letter on Non-resistance," which may be seen in memoirs of Mr. John Kettlewell. Biog. Brit. Tindal's Continuation of Rapin, vol. vi. &c.

COMPTON, *Little*, in *Geography*, a town of the United States of America, in Rhode island.

COMPTONIA, in *Botany*, (so named by Dr. Solander, in honour of the right reverend Henry Compton, lord bishop of London, who cultivated many exotics at Fulham.) L'Herit. Stimp. Nov. Schreb. 1764. Willd. 1644. Gært. 564. Class and order, *monocia triandria*. Nat. Ord. *Amnaceae*.

Gen. Ch. *Male flowers*. *Catkin* cylindrical; loosely imbricated all round with concave, kidney-shaped, acuminate, caducous, one-flowered scales. *Cal.* Perianth two-leaved; leaves equal, boat-shaped, shorter than the seale. *Cor.* none. *Stam.* Filaments three, shorter than the calyx, forked; anthers six, two-valved. *Female flowers*. *Catkin* egg-shaped, closely imbricated with scales similar to those of the male. *Cal.* Perianth six-leaved; leaves opposite, in pairs, filiform, membranous at the base, many times longer than the seale. *Cor.* none. *Pist.* Germ roundish; styles two, capillary. *Peric.* none. *Seed.* Nut oval, one-celled, without valves. Eff. Ch. *Male flowers* in a catkin. *Calyx* two-leaved. *Corolla* none. *Anthers* forked. *Female flowers* in a catkin. *Calyx* six-leaved. *Corolla* none. *Styles* two. *Nut* oval.

Sp. C. *asplenifolia*. Hort. Kew. 3. 334. Mart. Willd.

Gært. tab. 90. fig. 7. (*Liquidambar asplenifolia*; Lian. Sp. Pl. Myrica. Lina. Hort. Clif. Gale marina. Pat. Mus. 773. Myrta brabantica æstis americana; Pluk. alm. 250. tab. 100. fig. 6, 7.) *Stems* near three feet high, shrubby, slender, hairy, branched. *Leaves* from three to four inches long, half an inch broad, alternately situated almost to the midrib, resembling those of spleenwort, dark green, hairy underneath, fitting close to the stalks. *Males calkins* lateral, erect. *Nut* obscure, tardily lenticular, naked, smooth, shining, obsoletey striated, of a bay colour. A native of New York, Pennsylvania, Virginia, and Carolina; cultivated by the dutchess of Beaufort in 1714; flowering from March to May. Bose was well acquainted with it in Carolina, and observed, that the branches generally died at the end of the third year, the new wood then succeeding to the old, as in the rubi; it was also seldom found in fruit, though it flowered abundantly.

COMPTROL, or CONTROL, is properly, a double register, kept of acts, issues, &c. of the officers or commissioners in the revenue, army, &c. in order to perceive the true state thereof, and to certify the truth, and the due keeping of the acts subject to that enregistrement. See REGISTER.

COMPTROLLER, an officer established to comptrol, or over-see public accounts, and to certify, on occasion, whether things have been comptrolled and examined, or not. Thus, we have a *comptroller of the king's bouhold*, or of the accounts of the board of green-cloth; *Comptroller-general of the customs*; *comptroller of the navy*; *comptroller of the mint*; *comptroller of the excise*; *comptrollers of the accounts of the army*; of the chamber, &c. See CLERK.

COMPTROLLER of the *Artillery*, is the person who inspects the artillery-munitions, makes out the pay bills, takes the accounts of stores and the remains of them, and is accountable to the office of ordnance.

COMPTROLLER is also the name of an officer, who superintends, examines, and inspects the accounts of the army at large.

COMPTROLLER of the *hanaper*, is an officer in chancery, attending the lord chancellor daily in term and seal time. This officer is to take all things sealed from the clerk of the hanaper, inclosed in bags of leather, and to note the just number and effect thereof; to enter them in a book, with all the duties belonging to the king and other officers for the same, and so charge the clerk of the hanaper with them. See CLERK and HANAPER.

COMPTROLLERS of the *peils*, are officers of the exchequer, whereof there are two, *viz.* two chamberlains clerks, who keep a comptrol of the peil of receipts, and gongsgout; originally they took notes of other officers' accounts, in order to discover if they did amiss.

COMPTROLLER of the *pipe*, an officer of the exchequer, who writes out summonses twice a year, to levy the farms and debts of the pipe. See EXCHEQUER and PIPE.

He was anciently called *duplex ingrossator*.

COMPTROLLER'S *bay*, in *Geography*, a bay of the Pacific ocean in the N.W. part of America, situated to the north of Cape Suckling, and of an island, stretching S. E. and N.W. about 3 leagues, and lying on the N.W. side of the N. E. end of Kaye's island. N. lat. 60° 0'. W. long. about 215° 30'.

COMPULSION, and *inevitable Necessity*, in *Law*, constitute a species of defect of will, and they denote such a constraint upon the will, by which a man is urged to do that which his judgment disapproves; and which, it is to be presumed, his will (if left to itself) would reject. As punishments

punishments are only inflicted for the abuse of that free will, which God has given to man, it is highly just and equitable that a man should be excused for those acts, which are done through unavoidable force and compulsion. Of this nature is the obligation of *civili* subjection, whereby the inferior is constrained by the superior to act in a manner contrary to what his own reason and inclination would suggest; as when a legislator establishes iniquity by a law, and commands the inferior to do an act contrary to religion or sound morality. How far the excuse will be admitted "in foro conscientie," or whether the inferior in this case is not bound to obey the divine rather than the human law is a question, which admits of no doubt. Nevertheless, obedience to existing laws is unquestionably a sufficient extenuation of civil guilt before the municipal tribunal. The sheriff, who burnt Lutimer and Ridley, in the bigotted days of queen Mary, was not liable to punishment from Elizabeth, for executing so horrid an office; being justified by the commands of that magistracy, which endeavoured to restore superstition under the holy auspices of its merciless sister, persecution. As to persons in private relations, the principal case where constraint of a superior is allowed as an excuse for criminal misconduct, is with regard to the matrimonial subjection of the wife to her husband; for neither a son nor a servant is excused for the commission of any crime, whether capital or otherwise, by the command or coercion of the parent or master; (1 Hawk. P. C. 3.) though in some cases the command or authority of the husband, either express or implied, will privilege the wife from punishment, even for capital offences. And, therefore, if a woman commit theft, burglary, or other civil offences against the laws of society, by the coercion of her husband; or even in his company, which the law construes a coercion; she is not guilty of any crime; being considered as acting by compulsion, and not of her own will. (1 Hal. P. C. 45.) This doctrine is at least a thousand years old in this kingdom, being found among the laws of king Ina the West-Saxon. (cap. 57.) This rule, however, with regard to crimes, admits of an exception in crimes that are "mala in se," and prohibited by the law of nature, as murder and the like. Also in treason, no plea of coercion shall excuse the wife. In infer or misdemeanors there is likewise an exception; for a wife may be indicted and set in the pillory with her husband, for keeping a *brothel*. And in all cases where the wife offends alone, without the company or coercion of her husband, she is responsible for her offence, as much as any female. Another species of compulsion or necessity is what our law calls *duress per viam*; which see. A third species of necessity, distinguishable from the actual compulsion of external force or fear, is, when a man has his choice of two evils set before him, and being under a necessity of choosing one, he chooses the least pernicious of the two. Of this sort is that necessity, where a man by the commandment of the law is bound to assist another for any capital offence, or to disperse a riot, and resistance is made to his authority; it is in this case justifiable and even necessary to beat, to wound, or perhaps to kill the offenders, rather than permit the murderer to escape, or the riot to continue. 1 Hal. P. C. 53. There is another case of necessity, which has occasioned much speculation among the writers upon general law; viz. whether a man in extreme want of food or clothing may justify stealing either, to relieve his present necessities. Grotius and Puffendorf, and many other of the foreign jurists, maintain the affirmative; alleging that in such cases the community of goods by a kind of tacit concession of society is revived. Some of our own lawyers have held the same opinion (See Binton, c. 10. Mirr. c. 4.

§ 16.); though it seems to be an unwarranted doctrine, borrowed from the notions of some civilians; at least, it is now antiquated; the law of England admitting no such excuse at present. 1 Hal. P. C. 54. However, the founders of our constitution have thought it better to vest in the crown the power of pardoning particular objects of compassion than to countenance and establish theft by one general unadvising law. Blackst. Com. vol. iv.

COMPULSOR, formed of the verb *compellere*, to oblige, *coercere*, an officer under the Roman emperors, dispatched from court into the provinces, to compel the payment of taxes, &c. not paid within the time prescribed.

These were charged with so many exactions, under colour of their office, that Honorius cashiered them by a law in 417.

The laws of the Visigoths mention military compulsors; who were officers among the Goths, whose business was to oblige the tardy soldiers to go into the fight, or to run to an attack, &c.

Cassian mentions a kind of monastic compulsors, whose business was to declare the hours of canonical office, and to take care the monks went to church at those hours.

COMPULTERIA, in *Ancient Geography*, a town of Italy, in Campania. It abandoned the Romans to surrender itself to Hannibal; but Fabius restored it by the sword.

COMPUNCTION, formed from *compungere*, of *purgere*, to prick, in *Theology*, an inward grief in the mind for having offended God.

The Romanists own their confession insignificant, unless attended with compunction, or pricking of heart. See CONFESSION.

Among spiritualists, compunction bears a more extensive signification; and implies not only a grief for having offended God, but also a pious sensation of grief, sorrow, and displeasure, on other motives. Thus, the miseries of life, the danger of being lost in the world, the blindness of the wicked, &c. are to pious people motives of compunction.

COMPURGATOR, in *Law*, one that by oath justifies, or clears, another's innocence. They were introduced as evidence in the jurisdiction of the middle ages, and their number varied according to the importance of the subject in dispute, or the nature of the crime with which a person was charged. In some cases these compurgators were multiplied to the number of three hundred. (Præf. Nicol. ad Wilkins, p. 11.) But the usual number was eleven. It has, indeed, been held by later authorities, that fewer than eleven compurgators will answer the purpose; but sir Edward Coke is positive that there must be this number; and his opinion is founded both on better authority and on better reason, for as wager of law is equivalent to a verdict in the defendant's favour, it ought to be established by the same or equal testimony, namely, by the oath of twelve men. Thus Glanvil expresses it (l. 1. c. 9.) "iurabit duodecima manu;" and in 9 Hen. III. when a defendant in an action of debt waged his law, it was adjudged by the court "quod defendat se duodecima manu." Thus too, in an author of the age of Edward I. we read, "adjudicabit reus et legem tuam duodecima manu." And the ancient treatise, entitled, "Dyve'site des courts," expressly confirms sir Edward Coke's opinion.

This device, which was adopted for rendering the purgation by oath more certain and satisfactory, was found to be in effectual. It was a point of honour with every man in Europe, during several ages, not to desert the chief on whom he depended, and to stand by those with whom the

ties of blood connected him. Whoever then was hold enough to violate the laws, was sure of devoted adherents, willing to abet and eager to screen him in whatever manner he required. The formality of calling comparators proved an apparent, not a real security, against falsehood and perjury; and the sentences of courts, while they continued to refer every point in question to the oath of the defendant, became so flagrantly iniquitous as to excite universal indignation against this method of prevention. See OATH and WAGER of Law.

COMPUTATION, the manner of accounting and estimating time, weights, measures, and money.

The word is sometimes also used among mathematicians in the like sense as CALCULATION.

COMPUTATION of a planet's motion. See PLANET.

COMPUTATION is particularly used in Law in respect of the true account, or construction of time, so understood, as that neither party do wrong to the other, nor the determination of time be left at large, or be taken otherwise than according to the judgment and intention of law.

A deed, dated May 11, to hold from the day of the date, shall be construed to begin on the 12th day of May.

If indentures of demise be ingrossed, bearing date May 11, 1769, to have and to hold the land in S. for three years from henceforth; and the indentures be delivered the 4th of June following; in this case, from henceforth shall be computed from the day of the delivery, and not from the date. And if the indentures be delivered at four of the clock in the afternoon, the said 4th of June, the lease shall end the third day of June in the third year; the law, in such computation, rejecting all fractions or divisions of the day, on account of that uncertainty which is the mother of contention. In writings, ordered by the stat. 27 Hen. VIII. to be inrolled within six months, if such writings have date, the six months shall be accounted from the date, and not from the delivery: if they want date, it shall be accounted from the delivery. Coke, lib. 5.

If a deed be shewn to a court at Westminster, it shall remain in court (by judgment of law) all the term in which it is shewn: for all the term is but as one day in law. Coke, ibid.—If a church be void, and the patron does not present within six months, the bishop of the diocese may collate his chaplain; but these six months shall be computed according to 28 days of the month; and not according to the calendar.

COMPUTATION of Miles, after the English manner, allows 5280 feet, or 1760 yards to each mile; and the same shall be reckoned, not by straight lines, as a bird or arrow may fly, but according to the nearest and most usual way. Cro. Eliz. 212.

COMPUTO, a writ thus called from its effect, which is to compel a bailiff, chamberlain, or receiver, to yield his accounts. It is founded on the statute of W. & M. 2. c. 12.

The same lies for executors of executors; and against the guardian in socage, for waste made in the minority of the heir.

COMPUTO vicemilitis habendo respectu. See RESPECTU.

COMPZA, in Ancient Geography, a town of Italy, in the territory of the Hirpini, towards the frontiers of Lucania. Hannibal, after the battle of Cannæ, was invited into the country of the Hirpini by Statius, who promised to surrender to him the town of Compa. The modern name is CONSA or CONZA. See also COMPSA.

COMRADE is a common appellation for a fellow-soldier in the same regiment, troop, or company.

COMSHE, in Geography. See COMPSHE.

VOL. IX.

COMTAT VENAÏSSIN, a country situated in the south of France, formerly belonging to the pope, by whom it was ceded, together with its chief city Avignon, to the French government, soon after the revolution of 1789. It now forms part of the department of Vaucluse.

COMTE, COUNT. The titles of *comte*, of *duc*, of *vicaire*, of *centenier*, or *thungen* before the time of Charles the Bald, were not hereditary in families. These officers administered the finances and justice in the provinces: they were, at the same time, magistrates and military characters; they convoked the *ban* and *arrière-ban*. They assembled and conducted the troops to the general rendezvous. And when they judged a cause they had their shields on.

COMTE du Palais. See MAJORDOME.

COMUM, in Ancient Geography, a town of Gallia Transpadana, situated towards the north, on the southern bank of the lake Larius. It was founded by the Gauls, became a Roman colony, and was enlarged by Scipio. Julius Cæsar established Greeks in it, and then called it the new Comum, but upon their departure it lost this epithet. It was a municipal town. Pliny founded in it schools and a public library. See COMO.

COMUS, in Mythology, the god of jollity or festivity. There is great reason to believe he was the Chamos of the Moabites; Baal-Phegor, Baal-Peor, Priapus, and Bacchus. He is represented under the appearance of a young man, with an inflamed red countenance, his head inclined, and crowned with flowers; his air drowsy; leaning on a huntsman's spear in his left hand, and holding an inverted torch in his right. His statue was placed at the chamber doors of new married persons; his pedestal crowned with flowers.

CON, Ital. a preposition, placed before many musical terms; as *Con aris*, with the bow, after a *pirricato*, which see. *Con fordini*, with the fordini or mute. *Con affetto*, tenderly. *Con furia*, furiously. *Con discrezione*, discreetly, as to rapidity. *Con violini*, with violins, &c.

CONADIPSAS, in Ancient Geography, an ancient town of Scythia, on the other side of Imaus.

CONAFADOS, an episcopal town of Arabia, under the metropolis of Bosra.

CONAJOHARY, in Geography, a post town of America, on the south side of Mohawk river, in the state of New York, 36 miles above Schenectady, and 318 from Philadelphia.

CONAME, in Botany, the name given by Aublet to a genus formed by him for a shrub found in Cayenne, which has since been considered as a phyllanthus. He gives it the following character. Male and female flowers on different plants. *Calyx* six-cleft. *Cor.* none. *Stam.* numerous. *Pist.* Germ. striated; style bifid; stigma villous. *Peric.* Capsule six-celled.

CONANA, in Ancient Geography, an episcopal town of Asia, in Pamphylia.

CONANICUT, in Geography, an island near the coast of America, a little to the east of Rhode island. N. lat. 41° 25'. W. long. 71° 20'.

CONANT, JOHN, in Biography, was born at Yeatonton, Devon, in the year 1628. He was entered at Exeter college, Oxford, in 1646, where he acquired great reputation for his diligence and for his talents as an able disputant. As a classical scholar he was remarkable for the purity of his Latin style, and for his intimate and extensive acquaintance with the Greek language. He was also well versed in the several oriental tongues. In 1633, he was chosen fellow of Exeter college, where his fame, as a tutor, procured him pupils from many very respectable families. The commencement

commencement of the civil wars obliged him to retire from the university, and he officiated for some time at the living of Lynnington, where he was plundered of his property, and imprisoned. As soon as he was liberated he went to London, and became domestic chaplain to lord Charles. While he continued in his lordship's house at Hanfield in Middlesex, he preached a gratuitous lecture at Uxbridge on a week day to numerous audiences. On the 7th of June 1649, he was unanimously chosen rector of Exeter college, without any sollicitation on his own part. Shortly after this he was in danger of being driven out of all public employment, by the parliament's requiring his subscription to the "engagement," by which a promise was to be given to be true and faithful to the commonwealth of England, without a house of lords. This he at first declined; having however a fortnight given him to reconsider the matter, he submitted; but under a declaration, subscribed at the same time with the "engagement," which rendered that instrument almost nugatory. He now entered upon his office as rector with increased zeal, and discharged the several duties incumbent upon him, with the utmost diligence and fidelity. In December 1654, he was appointed divinity-professor of the university of Oxford, and in three years afterwards he was raised to the dignity of vice-chancellor of that university, which he retained till August 5, 1655. While he held this high office, he was very instrumental in procuring Mr. Selden's valuable collection of books for the public library; he distinguished himself by the correction of abuses, and by the regulation of the public exercises in such a manner, as proved highly beneficial to the interests of solid learning. By some of his biographers, Mr. Conant has been applauded for the share which he took in defeating a project for erecting an university in the county of Durham. Praise on this account to us seems very ill bestowed, because the intended object was worthy of a great nation, whose places of public instruction cannot be regarded as sufficiently numerous, to supersede the necessity of others in distant parts of the kingdom. Upon the restoration of Charles II. Dr. Conant, in his official capacity, came to London, attended by the proctors, and others, and being introduced to the king he made a Latin speech on the occasion, and presented his majesty with a book of verses written by the members of the university. He was appointed, in March 1663, a commissioner with others to review the book of common prayer, and he assisted at the Savoy conferences. After this, upon the passing of the act of uniformity, he was deprived of his preferments, because he refused to conform. During eight years he lived in retirement, when, upon serious deliberation on the nature and lawfulness of conformity, he resolved to comply, and submitted to a re-ordination by Reynolds, bishop of Norwich, whose daughter he had married nearly twenty years before. Preferments were now immediately offered to his choice; and he accepted of the vicarage of All-Saints, Northampton, in which town he had for several years resided, in the highest estimation of the most respectable inhabitants. In Sept. 1675, his church and the greater part of the parish were destroyed by fire; but his own house escaped. In the succeeding year the bishop of Norwich offered him the archdeaconry, with this high compliment, "I do not expect thanks from you, but shall be very thankful to you, if you will accept of it." He condescended to this handsome request, and discharged the office worthily, as long as his health would allow. In December 1681, he was installed a prebendary in the church of Worcester, at the request of the earl of Radnor, who asked for a very desiring person, who never sought any thing for himself.

He had long laboured under a weakness of sight, which terminated in total blindness in the year 1686. This heavy calamity, and the weight and infirmities of old age, he bore with exemplary resignation to the divine will till his death, which happened March 12, 1693. He was interred in his own parish church of All-Saints in Northampton, where a handsome monument was erected to his memory. Dr. Conant was a man of solid and extensive learning, but his great diffidence led him to conceal his acquirements. We have six volumes of his sermons, of which one was dedicated by himself to the inhabitants of Northampton, the others were published after his death, by Dr. John Williams, afterwards bishop of Chichester, and Mr. Coates principal of Magdalen-hall. *Biog. Brit.*

CONARIUM, in *Anatomy*, a term which has been applied to the pineal gland of the brain, in consequence of its conical figure. See *BRAIN*.

CONATUS, *endeavour*, a term frequently used by philosophical and mathematical writers; nearly equivalent to *visus*. Conatus seems to be the same, with respect to motion, that a point is with respect to a line; at least the two have this in common, that as the point is inceptive of the line, or the term from which it commences; so is the beginning of all motion called the *conatus*. Add, that as in mathematical demonstrations, the extension of the point is conceived as if it were nothing at all; so, in the *conatus* of motion, there is no regard to the time wherein, or the length which, it advances. See *Law of NATURE*.

Hence, some define conatus to be a quantity of motion not capable of being expressed by any time or length. Accordingly, all motion tends precisely the same way wherein the moveable is acted on, or determined by the same moving power. See *MOTION*.

CONAWANGO, in *Geography*, a northern branch of Alleghany river, in Pennsylvania, which rises from Chattanooga lake.

CONCA, CAV. SEBASTIANO, in *Biography*, an historical painter of considerable reputation in the 18th century. He was born at Gaeta in the year 1676, and became the disciple of F. Solemene, the most celebrated master of the school of Naples at that period. At the age of forty, Conca established himself at Rome, and spent five whole years in drawing from the finest productions of ancient and modern art, in the vain hope of uniting to the graceful facility he had acquired from his master, a greater purity and correctness of design. But it was too late; bred a mannerist, he had insensibly imbibed those maxims which were to decide his future character; and at length he had the good sense to adopt the advice of the sculptor Le Gros, by pursuing the track which had originally been pointed out to him. He soon became an able machinist (*pittrice di macchina*), in a style not very unlike that of Cortona. He united to facility of invention, and rapidity of pencil, a gay and fascinating distribution of colour; but his flesh has generally too green a hue in the shadows. Amongst his large works at Rome, the "Assumption," at the church of St. Martino, and the "Prophet Jonas," at St. Giovanni Laterano, are of the best. Many of his other productions are at Loreto, Ancona, and other towns of the ecclesiastical state, besides an infinity of cabinet pictures dispersed throughout all parts of Europe. This artist died in 1764. He had a brother, Giovanni Conca, who assisted him in the execution of many of his large works, and is said to have been an excellent copyist. Lanzi, *Storia Pittorica*.

CONCA, in *Geography*, a town of the island of Corfica, 12 miles N. of Porto Vecchio.—A *Lu.*, a market town in a small lake in the Campagna di Roma, in Italy.—Alfo, a small

small river of Italy, which has its source in the duchy of Urbino, and flows into the gulf of Venice.

CONCALE. See CANCALE.

CONCALE Bay, in the channel, on the coast of the department of Ille and Vilaine in France, is a fine bay, in which the English effected a landing in June 1758, and whence they proceeded to the port of St. Malo, where they burnt above 100 vessels of different sizes.

CONCAMERATED, among *Builders*, an appellation given to such roofs as are arched in the vaults.

CONCAMERATIO, was an arched room in our ancient churches, between the east end of the church and the high altar; so formed, that in processions they might surround it.

CONCAN, or COCKUN, in *Geography*, a tract of country on the western coast of Hindoostan, situated between Bombay and Goa, and separated from the rest of the continent by a ridge of high mountains called the Gauts. When the Moguls seized on Hindoostan, they found this coast infested with pirates, and fitted out a fleet to protect their vessels. The Mahrattas, finding their piracies interrupted, armed against the Moguls, ravaged their possessions, and fitted out a fleet to protect their pirates. Conagy Angria, who by his courage had acquired the supreme command, was appointed governor of Severndroog, one of the best fortresses on the coast, where he formed an independent state, and in a little time extended his dominions for the space of 40 leagues along the coast, and six leagues wide towards the mountains. His successors assumed the name of Angria, and made peace with the Mahrattas on paying an annual tribute. They continued to make depredations on the coast, and seize all vessels that passed that way till the year 1756, when their fleet was destroyed, and the strong fort of Gheriah, in which the chief resided, was taken by admiral Watson and colonel Clive. The country now belongs to the Mahrattas. The principal towns are Choul, Fort Victoria, Dabul, Severndroog, Gheriah, Tamana, and Sunderdoo.

CONCANA, in *Ancient Geography*, a town of Spain, towards the north-east of Lucus Asturum, and to the south of Salis, near the sea. Horace says, that the inhabitants of this city took pleasure in drinking the blood of horses: and although a chalice took place in the manners of the people in Spain under the dominion of the Romans, Silius Italicus, who wrote under Trajan, gives an account of them similar to that of Horace.

CONCANGIUM, a Roman station, under the government of the honourable the duke of Britain, not mentioned in the Itinerary, but recorded in the *Notitia Imperii*, and generally believed to have been situated at Watercock, near Kendal, where are visible remains of a Roman station, and where Roman antiquities have been found.

CONCARNEAU, or CONQUERNEAU, in *Geography*, a small, but neat sea-port town of France, in the department of Finistere, and chief place of a canton in the district of Quimper, 42 miles S. E. of Brest. The place contains 2,200, and the canton 6,320 inhabitants; the territory includes 125 kilometres, and 4 communes. Its principal and almost only trade, is in pitchards, of which the average annual shipment is 600 barrels. The price of a barrel varies from 150 to 300 livres. N. lat. 47° 55'. E. long. 3° 45'.

CONCATENATION, in *Philosophy*, a connexion of things, in manner of a chain.

The concatenation of second causes is an effect of Providence. See CAUSE.

CONCAVE is applied to the inner surface of a hollow body; particularly if it be circular.

CONCAVE is particularly understood of mirrors and lenses: concave lenses are either concave on both sides, called *concavo-concave*; or concave on one side, and plane on the other, called *plano-concave*; or concave on one side, and convex on the other, called *concavo convex*, or *convexo concave*, as the one or the other surface is a portion of a less sphere.

The property of all concave lenses is, that the rays of light, in passing through them, are deflected, or made to recede from one another; as in convex lenses they are inflected towards each other; and that the more, as the concavity and convexity pertain to less circles.

Hence, parallel rays, as those from the sun, by passing through a concave lens, become diverging; diverging rays are made to diverge the more, and converging rays are either made to converge less, or become parallel, or go out diverging.

Hence, objects viewed through concave lenses appear diminished; and the more so, as they are portions of less spheres; and this in oblique, as well as in direct rays. See LENS.

Concave mirrors have the contrary effect to lenses: they reflect the rays which fall on them, so as to make them approach more to, or recede from, each other than before, according to the situation of the object; and that the more as the concavity is greater, or the spheres whereof they are segments, less.

Hence, concave mirrors magnify objects presented to them; and that in a greater proportion, as they are portions of greater spheres. See MIRROR.

Hence, also, concave mirrors have the effect of burning objects, when placed in their focus. See BURNING-GLASS.

CONCAVITY. An arch of a curve has its concavity turned one way, when the right lines that join any two of its points are all on the same side of the arch.

Archimedes, intending to include such lines as have rectilinear parts, in his definition, says, a line has its concavity turned one way, when the right lines that join any two of its points are either all upon one side of it, or while some fall upon the line itself, none fall upon the opposite side. Archim. de Sphær. and Cyl. Def. 2. Mac Laurin's Fluxions, art. 180.

When two lines, having their concavity turned the same way, have the same terms, and the one includes the other, or has its concavity towards it, the perimeter of that which includes, is greater than the perimeter of that which is included. Archim. ib. ax. 2.

CONCEALERS, in *Law*, such as find out concealed lands, *i. e.* lands kept privily from the king, by common persons, having nothing to shew for their title, or estate therein.

They are thus called *per antiphrasim*, a *concelando*; as *mons* is a *movento*, &c. Lord Coke calls them *turbidum hominum genus*.

CONCEALMENT of *bastard's death*. See BASTARD.

CONCEALMENT of *Treason*. See MISPRISON.

CONCELHO DE ANCIENS, in *Geography*, a town of Portugal, in the province of Tra-jos-Montes, 8 miles W.N.W. of Mirandela.

CONCELHO DE JAES, a town of Portugal, in the province of Tra-jos-Montes, 10 miles W. S.W. of Mirandela.

CONCELLANA, a town of Naples, in the province of Basilicata; 5 miles S. of Acerenza.

CONCENTEYNA, a town of Spain, in the province of Valencia; 25 miles N. of Alicante.

CONCENTRATION, in general, denotes the retiring, or withdrawing of a thing inwards, towards the centre, or middle.

External cold is said to concentrate the heat within bodies: after meals, the natural warmth retires, and as it were concentrates to promote the digestion.

CONCENTRATION is also used by Dr. Grew for the highest degree of mixture, viz. that wherein two or more atoms or particles touch, by a reception, and intrusion of the one within the other. See MIXTURE.

This he takes to be the case of all fixed bodies without taste or smell; their constitution being so firm, that till the particles be detached from each other by some extraordinary means, they cannot affect those senses.

CONCENTRATION, in *Chemistry*, the act of increasing the strength of fluids, which are rendered stronger by abstracting a portion of the mere menstruum. This is generally effected by evaporation, where the menstruum is driven off at a lower heat than is required to drive off the substance with which it is united. Thus, dilute sulphuric acid may be considered as a mixture of the real acid with water, and by applying a certain heat, the water may be evaporized, leaving the acid behind in a state of concentration. When concentrated as much as possible, its specific gravity is about twice as great as that of water, but it can rarely be obtained denser than 1.85. When concentrated to 2,000 it contains a considerable portion of water, as has been proved by combining it with barytes or potash, in which case water remains behind, and does not enter into the combination. Again, vinegar consists of an acid and water, and brandy of alcohol and water, and in proportion as the acid and alcohol are freed from the water, they are said to be more or less concentrated. This may be performed, 1. Either by simple distillation, in which case the acid or spirit comes over first, leaving the water behind; or, 2. By exposing the vinegar or brandy to severe frost, when the water will be frozen, and the acid or alcohol will be found in a state of concentration in the middle of the ice; the greater the cold, the higher the state of concentration; M. Lowitz has found, that the acid, however concentrated, congeals at -22° . Sulphuric acid, on the other hand, exposed to a much less severe cold, crystallizes, and to effect this, it must not be greatly concentrated. 3. Another mode of concentrating the acetic acid, is by distilling acetate of copper, reduced to powder, in a retort; at first there comes over a liquid nearly colourless, and almost insipid, and afterwards a highly concentrated acid tinged with green; but being distilled a second time in a moderate heat, it is colourless, transparent, exceedingly pungent and concentrated. 4. The most perfect method of obtaining this acid in a concentrated state, was discovered by M. Lowitz of Peterburg; it is thus: distil a mixture of three parts of acetate of potash, and four parts of sulphuric acid, till the acetic acid has come over into the receiver. To separate it from the sulphuric acid, with which it is slightly contaminated, it must be distilled over a portion of acetate of barytes. By the experiments of Adet, Darraacq, and others, on concentrating the acetic and acetic acids, it is ascertained that they differ only in concentration, each containing precisely the same proportion of oxygen. Concentrated acetic acid is capable of an access of oxygen, and in that state it is called oxygenated acetic acid. Sulphuric and nitric acids, whether diluted or concentrated, are still the same sulphuric and nitric acids; but sulphuric, and sulphurous, or nitric and nitrous acids, whatever be the state of concentration, have different properties, and are of course

specifically different acids. Elem. de Chymie. Thompson's Chemistry, Gren's Principles.

CONCENTRATION, in *Distillery*. Dr. Shaw, in his "Essay on the Distillery," is for introducing a method of concentrating the fermentable parts of vegetables from which their spirits are to be drawn by distillation; which, if it can be practised to be practised in the large way, will prove of very great use to the British distillery, as it will greatly shorten the distiller's business; which, at present, including the brewing, fermenting, &c. is much too long. He proposes only to evaporate carefully the wort, or other tinctures or decoctions of vegetables made for the distilling of their spirits, to the consistence of treacle: in this form they might be sold to the distiller, who might keep them by him as long as he pleased, and occasionally use them, by the easy method of reducing them into wort, by mixing warm water with them.

CONCENTRIC, in *Geometry and Astronomy*, something that has the same common centre with another.

The word is principally used in speaking of round bodies and figures, viz. circular, elliptical ones, &c. but may be likewise used for polygons, drawn parallel to each other, upon the same centre.

Concentric stands opposite to excentric.

To find the area of the space included between the circumferences of two concentric circles; see ANNULUS.

Nonius's method of graduating instruments, consists in describing with the same quadrant 45 concentric arches, dividing the outermost into 90 equal parts, the next into 89, &c. See NONIUS.

CONCENTRICITY of the *Strata*, in *Natural History*. The idea has very generally prevailed among geologists and mineralogical writers, that the several layers of matter or strata, which compose the surface of the earth we inhabit, were originally formed or deposited in uniform and level beds, or concentric to the centre or mass of the earth. Among these Mr. Whitehurst, in his "Enquiry into the Original State and Formation of the Earth," 1st edit. p. 192, says, the strata "obtained an uniform concentric arrangement, surrounding the centre of the earth, as so many shells may be supposed to surround an egg." And nearly similar have been the opinions of a large portion of writers on this subject. Mr. Kirwan, "Geological Essays," p. 22, supposes, that the crystallization of strata from the chaotic or polygenous fluid, in some cases, began at the surface, as we see happen to some salts and to lime water under evaporation, and that thus extensive strata might have been formed and sunk to the bottom, mollly in an horizontal position, but often from accidental ruptures during their fall, in an oblique or nearly vertical position. Dr. Townson, "Philosophy of Mineralogy," p. 68, says, "we must not suppose that the strata regularly surround the globe like the concentric circles of an onion; they are rather like the scales of a fish; rather *sguamosus* than *tunicatus*." Though, in general, they are of great extent when not broken and lost, they are known to have a natural termination." In the "Philosophical Transactions," No. 391, Mr. John Stracey gives a figure for explaining a supposition of his on this subject, viz. that the strata were originally formed while in a soft state, as so many wedges, each pointing to and terminating in the axis of the earth; and that by the diurnal revolution of the earth from west to east, these became bent into spirals, each lapping round each other, for some distance, and then ending, in succession.

Whimsical as this last idea must have appeared, when it was first published, now more than 80 years ago, we are somewhat

somewhat surprized that it had not the effect of occasioning subsequent geological observers to notice, more particularly, the endings of the strata, and the remarkable prevalence of their dip towards the south-east, compared with those in any other direction; especially when practical miners must have so often mentioned the dip "towards the 10 o'clock sun," as being the most common. Under the articles COAL, and COLLIERY, the writer of this has endeavoured to shew that the strata of the British islands end in succession in proceeding from the south-eastern part of England towards the north-west; the general dip being towards the south-east or nearly so, except in immensely dilocated parts of the country, as the wealds of Suffex, Kent, and Surry, the peak of Derbyshire and Staffordshire, &c. of which some further and curious particulars will be given under the articles DENUDATION, ELEVATION, and ENDINGS of Strata. From all which, it is expected that it will be made evidently to appear, that the strata were not originally concentric with the earth's centre, but that the same formed planes or zones, inclined eastward in a small angle with the horizon, which were of amazing extent, and were perfectly regular in their position, before they experienced the rude and almost inconceivable violence, which broke and tore the earth in pieces, and left it in its present form.

CONCEPTACULUM, in *Botany*, was originally applied by Linnæus to that kind of seed-vessel which he afterwards termed *folliculus*, and which consists of one valve only, bursting longitudinally, as in the natural order of *asclepiadeæ*. Gartner uses the term *conceptaculum* in a general and lax sense for a seed-vessel, nor is it at present technically applied to any particular kind of fruit.

CONCEPTION, in *Geography*, otherwise called *Penco*, a city of Chili, in South America, and capital of a jurisdiction or bishopric, suffragan of the archbishop of Lima, and having a chapter, consisting of a bishop, dean, archdeacon, and two prebendaries. The ancient city stood at the mouth of the river St. Pierre, E. of Talcahuana, on the S.W. shore of a beautiful bay, and on a small declivity, having a little river running through it, in S. lat. $36^{\circ} 43' 15''$, and in longitude from the meridian of Teneriff, according to Father Feuillée, $303^{\circ} 18' 30''$. The houses were built with mud or burnt bricks, and covered with tiles; the churches, and also the Franciscan, Augustine, and Dominican convents, as well as those belonging to the fathers of mercy, were small and mean, but the college of the Jesuits was constructed in a superior style of architecture. This city was first founded by captain Pedro de Valdivia in the year 1550; but the powerful revolt of the Indians of Arauco and Tucapel, obliged its inhabitants to remove to Santiago. Pedro de Valdivia, its founder, was killed in this contest, and his successor in the command shared the same fate. The inhabitants, however, petitioned the audience of Lima for leave to return to their original city; they were again either slain or dispossessed by the Indians; but those that survived were afterwards restored to their former possession, which they for some time continued to enjoy with apparent security. In 1603 a more general confederacy was formed against the city, by which it was almost wholly destroyed; but receiving fresh succours, it was again repaired. Subject, however, to dreadful earthquakes, and consisting of buildings ill adapted for permanent duration; it was totally destroyed by an earthquake in 1751 and nothing but its ruins are now visible on the spot where it once stood. After the destruction of this town, which, during the earthquake, was swallowed up rather by the sea than by the land, the inhabitants dispersed and encamped in the environs. In 1763 they selected another spot, situated about a quarter of a

league from the river Biobio, and three leagues from the ancient town of Conception, and the village of Talcahuana. On this spot they erected a new town, to which the bishopric, the cathedral, and the religious houses were transferred. The houses consist only of one story, that they may be able more effectually to resist the shock of earthquakes, which occur in those parts almost every year. This town occupies a large extent of ground. The inhabitants are about 10,000; and here is the residence of the bishop and a colonel of horse, who is the military governor. The bishopric is nominally bounded on the north by that of Santiago, the capital of Chili, where the governor-general resides, and on the east by the Cordilleras, and extending on the south as far as the straits of Magellan. But its true limit is the river Biobio, about a quarter of a league from the town. M. de La Pérouse says of this part of Chili, that it is the most fertile spot in the world. Corn, he says, produces sixty-fold, and the vine is equally abundant; the fields are covered with innumerable flocks, which, without requiring any care, multiply beyond all calculation. The only care necessary is to keep separate the different property of individuals; and oxen, horses, mules, and sheep herd together in the same pastures. A large ox is commonly worth eight dollars, a sheep $\frac{2}{3}$ of a dollar; but there are no purchasers, so that the inhabitants kill every year a great quantity of cattle, the skins and tallow of which are sent to Lima. They also cure some provisions for the consumption of the small coasting vessels which navigate the south seas. The climate is remarkably healthy, and M. Pérouse found several in this town that had completed 100 years; but notwithstanding all these advantages, the colony is not thriving, which he attributes principally to the prohibitory regulations that extend through every part of Chili. This kingdom, he says, of which the productions, increased to their maximum, would supply all Europe; whose wool would be sufficient for the manufacture of France and England, and whose herds, converted into salt provision, would produce a vast revenue; has no commerce. Four or five small vessels bring every year from Lima tobacco, sugar, and some articles of European manufacture, which the miserable inhabitants receive after having been charged with heavy customs at Cadiz, at Lima, and, lastly, at their arrival at Chili; in exchange for which they give their tallow, hides, some deals, and their wheat, which, however, bears so low a price, that the cultivator has no inducement to extend his tillage. Unfortunately, says Pérouse, for this country, it produces a small quantity of gold; the annual amount of which in the diocese of Conception is estimated at about 200,000 piastres. The administration of justice is very defective. To these several circumstances it is owing that the land remains uncultured, that commerce is in a low state, that the houses of the most opulent inhabitants of La Conception are almost destitute of furniture, and that the only workmen in the town are foreigners. The dress of the women consists of a plaited petticoat, discovering half the leg, formed of gold and silver luffs, which, being reserved for extraordinary occasions, is transferred, like jewels, from grand-mother to grand-daughter, striped stockings of red, blue, and white, and very short shoes, but such ornaments are only within the reach of a few; the rest having scarcely clothes to cover their nakedness. The idleness, together with the credulity and superstition of the inhabitants, has filled this kingdom with convents, both for men and women. The common people are a mongrel race, much addicted to theft, and the women are very easy of access. Nevertheless, those of a superior class, or the

trus Spaniards, are extremely polite, and hospitable. The inhabitants, and even the women, excel in horsemanship; they are very dextrous in managing the lance and noose; and they rarely miss their aim, though at full speed, with the noose, which they throw 40 or 50 yards, and thus halter the object of their diversion or revenge. The noose is made of thongs of cow-hides, which they twist with oil, till it is rendered supple and pliant, and so strong, as to hold, it is said, a wild bull which would break a halter of hemp of double thickness. De Ulloa's, &c. Voyage to South America, vol. i. Peroufe's Voyage round the World, vol. i.

CONCEPTION, *the bay of*, is one of the most commodious that can be found in any part of the world. The length from Terra-firma, N. and S. is nearly $3\frac{1}{2}$ leagues, and its breadth from E. to W. almost 3 leagues, which is contracted by the island of Quiriquina, forming two entrances; of these, that on the east side is the safest, being two miles broad, and accordingly frequented by most ships. The west entrance is between the island and Talcahuana point, and is near half a league in breadth. In the principal entrance of this bay is 30 fathom water, which depth afterwards decreases to 11 and 10, till within about a mile of the shore, opposite to the entrance. The western entrance, though the numerous rocks and breakers in it make it to appear very dangerous, has a channel with water sufficient for the largest ship, the depth being at first 30 fathoms, and never less than eleven. Within the bay are three roads or harbours, where ships anchor; for though the bottom be every where clear, it is only in one of these three places that ships can ride in safety, being no where else sheltered from the wind. The first, called Puerto Tomez, lies east and west, with the north point of Quiriquina, contiguous to the coast of Terra-firma. The anchoring place is about half a league distant from the land; in about 12 fathom water. But this road is used only when the ships come in during the night; it being difficult to reach either of the other two before day-light, as several tacks must be made for that purpose. In this bay the principal point is that of Talcahuana. It is properly an elbow, and bears S. S. W. from the fourth point of Quiriquina. This is much the most frequented, ships in general anchoring here, as it has not only better ground than any other part of the bay, but is most sheltered from the north winds. Whereas at Cirillo Verde, a little green mountain, situated near the city, they lie exposed not only to these winds, but also to the south winds; the land which should intercept them being low. Besides, the bottom is of a loose mud, so that the anchors in a hard gale of wind generally come home; and consequently the ships are in great danger of being stranded on the coast. From these inconveniences it may be concluded, that the only ships which anchor here are such as happen to be in these parts in the midst of summer, for which this road is most convenient, as it is nearest to the city. Although the tide rises in this bay six feet three inches, the water is smooth, and there is scarcely any current. It is high water here at the full and change of the moon, at 45 minutes past one. The bay is open only to the north winds, which never blow but in the winter, that is, from the end of May to October. Two rivers empty themselves into this bay; one of which passing through the city of Conception bears its name; the other is called St. Pedro. The first is the watering place for ships anchoring at Cirillo Verde; whereas those at Talcahuana supply themselves from streams that flow from the adjacent ennuences; they easily take on board a sufficient quantity of wood, of which there is plenty, and also of all other necessaries.

Ships, before they enter the bay of Conception, endeavour to make the island of Santa Maria, and then coast along it keeping at the same time a good look out for a reef of rocks which stretches out almost three leagues from the north-west point; thence they continue their course, keeping at a little distance from the main, there being no rocks besides those that are above the water. After weathering the rocks on the island of Santa Maria, they steer directly for Talcahuana point, at the distance of about half a league; from which sea-ward is a rock called Quiebra ollas, which should be carefully avoided, as it is surrounded with shoals. After being abreast of this rock, they steer for the north point of Quiriquina; off which lie two rocks swarming with sea-wolves; but as there is a sufficient depth of water all round them, there is no other danger in standing near them besides that which is visible. After passing them, the course is continued as near as possible to the island of Quiriquina, care being taken to avoid some other rocks lying along the shore. In making several tacks to get into Conception-bay, the island of Quiriquina must be avoided on the east and fourth sides, as there is a shoal on the south extending to a considerable distance from the shore. At a third part of the distance between the road at Talcahuana, and the point of the same name, is another shoal, running about half a league towards the east, in the middle of which is a ridge of rocks. To avoid this shoal, it is best at entering the bay with a land wind, to steer directly for the middle of a spot of red earth on a mountain of middling height, situated at the bottom of the bay, continuing this course till the ship has passed the shoal; and then to steer directly for the houses at Talcahuana, till within about half a mile from the shore, which is the usual anchoring place in 5 or 6 fathom water. The same care is also necessary to avoid another reef of rocks, lying between the Morro and the coast of Talcahuana.

CONCEPTION, or *Conception de los Pampas*, a town of South America, in Paraguay, on the S. side of the river Plata. S. lat. $36^{\circ} 30'$. W. long. $57^{\circ} 11'$.

CONCEPTION, *La*, a sea-port town of America, in the province of Veragua, on the Spanish main, with a harbour, formed by the river Veragua; 60 miles W. of Panama. N. lat. $8^{\circ} 52'$. W. long. $81^{\circ} 51'$.

CONCEPTION, a river of America, on the isthmus of Darien, which runs into the Spanish main. N. lat. $9^{\circ} 4'$. W. long. $78^{\circ} 15'$.

CONCEPTION *Bay*, a large bay on the east coast of Newfoundland island, whose entrance is between Cape St. Francis on the southward, and Plamborough head on the northward. It runs a great way into the land in a southern direction, having numerous bays on the W. side, in which are two settlements, Carboniere and Havre de Grace. Settlements were made here in 1610, by about 40 planters, under governor John Guy, to whom king James had granted a patent of incorporation. N. lat. $47^{\circ} 40'$. W. long. $52^{\circ} 40'$.

CONCEPTION *de Salawa*, or of *Salaya*, a small town of North America, in the province of Mechoacan, in Mexico. It was built by the Spaniards, as well as the Nations of St. Michael and St. Philip, to secure the road from Mechoacan to the silver mines of Zacateca. N. lat. 10° . W. long. $83^{\circ} 5'$. They have also given this name to several boroughs of America, to a sea-port of California, &c. &c.

CONCEPTION *de la Vega*, a town of Hayti, in what was formerly the Spanish part of Hispaniola, or St. Domingo. It gave the title of duke to the family of Columbus, the immortal discoverer of America.

CONCEPTION, in *Grammar*. See SYLLEPSIS.

CONCEPTION.

CONCEPTION, in *Logic* and *Metaphysics*, the simple apprehension or perception which we have of any thing, without proceeding to affirm or deny any thing about it.

The schoolmen usually make two kinds of conception; the one formal, the other objective.

The first is defined to be the immediate and actual representation of any thing proposed to the mind: on which footing, it should be the same thing to the understanding, that a word or voice is to the ear; whence some also call it *verbum mentis*.

The second is the thing itself represented by a formal conception. But others explode the notion of an objective conception, as being, in reality, no conception at all; excepting where the mind contemplates its own acts, &c.

Formal or proper conceptions, are subdivided into univocal, where several things are distinctly represented as under some common ratio, or in the same degree of perfection; analogous, where several things are represented as under some proportional likeness; and equivocal, where they are represented immediately as such, without regard to any common ratio or likeness.

Dr. Reid, in his "Inquiry into the Human Mind, on the Principles of Common Sense," and also in his "Essays on the Intellectual Powers of Man," (Ess. iv.), substitutes the word conception instead of the simple apprehension of the schools, and employs it in the same extensive signification. He also uses it, in common with some other writers, as synonymous with *Imagination*, which see. To this purpose, he says, that "conceiving, imagining, apprehending, understanding, and having a notion of a thing, are common words to express that operation of the understanding, which the logicians call "Simple APPREHENSION;" which is defined by them to be the bare conception of a thing without any judgment or belief about it. However, although conception may be exercised without any degree of belief, even the smallest belief cannot take place without conception; for he who believes must have some conception of the object of his belief. Dr. Reid, without attempting a definition of this operation of the mind, explains some of its properties, states different theories concerning it, and points out some mistakes of philosophers in their account of it. In every operation of the mind, says this writer, and in every thing which we call thought, there must be conception. Our senses cannot give us the belief of any object, nor can we remember or reason, nor exert any of our active powers, without this mental operation; but in bare conception, there can, he thinks, be neither truth nor falsehood, because it neither affirms nor denies. In this respect, conception differs from opinion; as an opinion, though ever so wavering, or ever so modestly expressed, must be either true or false; whereas a bare conception, which expresses no opinion or judgment, can be neither; to this purpose, Mr. Locke observes very justly, if we substitute conceptions for ideas, that our ideas, being nothing but bare appearances, or perceptions, in our minds, cannot properly and simply in themselves be said to be true or false, no more than a simple name of any thing can be said to be true or false. Mr. Locke, following the example of Des Cartes, Gassendi, and other Cartesians, has given the name of perception to the bare conception of things; and he has been followed in this respect by bishop Berkeley, Mr. Hume, and many late philosophers, when they are discussing the subject of ideas. They have been probably led into this impropriety, says Dr. Reid, by the common doctrine concerning ideas, which teaches us, that conception, perception by the senses, and memory, are only different ways of perceiving ideas in our own minds; and if that doctrine be well

founded, he thinks that it will be very difficult to find any specific distinction between conception and perception. He adds, there is reason to distrust any philosophical theory, when it leads men to corrupt language, and to confound, under one name, operations of the mind, which common sense and common language teach them to distinguish. This author further observes, when he is tracing the analogies that subsist between the operations of body and those of the mind in the plastic arts, and particularly in painting, that nothing more readily gives the conception of a thing than the seeing of an image of it; and hence, by a figure common in language, conception is called an image of the thing conceived. Nevertheless, the image in the mind is not the object of conception, nor is it any effect produced by conception as a cause, but it is conception itself. In this mode of illustrating conception, Dr. Reid differs from many other philosophers, who have generally maintained, that in conception there is a real image in the mind, which is its immediate object, and distinct from the act of conceiving it. This author proceeds to trace the analogy that subsists, not only between conceiving and painting in general, but between the different kinds of our conceptions, and the different works of the painter. As this artist makes fancy-pictures, or copies from the painting of others, or paints from the life, that is, from real objects of art or nature which he has seen, our conceptions, in Dr. Reid's opinion, admit of a very similar division. Some conceptions may be called fancy-pictures, being commonly called creatures of fancy or of imagination, which are not the copies of any original that exist, but are originals themselves. There are other conceptions, which may be called copies, because they have no original or archetype, to which they refer, and with which they are believed to agree; and we call them true or false conceptions, as they agree or disagree with the standard to which they are referred. There are of two kinds, *viz.* such as are analogous to pictures taken from the life, or such as we have of individual things that really exist; and such as are analogous to the copies which the painter makes from pictures done before, which are the conceptions we have of what the ancients called universals, or of things which belong or may belong to many individuals. These universals are always expressed by general words; and all the words of language, proper names excepted, are general words, or the signs of general conceptions, or of some circumstances relating to them. Such general conceptions are formed for the purpose of language and reasoning.

Having thus stated the three different kinds of our conceptions, and illustrated them at large, our author proceeds to describe their different properties. Accordingly he observes, that our conception of things may be strong and lively, or it may be faint and languid in all degrees. In this connection it is said, that imagination, when it is distinguished from conception, seems to signify one species of conception, *viz.* the conception of visible objects. Again, our conceptions of things may be clear, distinct, and steady; or they may be obscure, indistinct, and wavering. Moreover, when we barely conceive any object, the ingredients of that conception must either be things with which we were before acquainted by some other original power of the mind, or they must be parts or attributes of such things. Thus, a man cannot conceive colours, if he never saw, nor sounds, if he never heard. If man has not a conscience, he could not conceive what is meant by moral obligation, or by right and wrong in conduct. Nevertheless, we are unconfined with regard to the arrangement of the ingredients of our conception; and this last property of the faculty of conception, and that which essentially distinguishes it from

every other power of the mind, is this, that it is not employed solely about things which have existence.

The powers of sensation, of perception, of memory, and of consciousness, are all employed solely about objects that do exist or have existed; but conception is often employed about objects that neither do, nor did, nor will exist. To prevent imposition in this matter, we ought to distinguish between that act or operation of the mind, which we call conceiving an object, and the object which we conceive. When we conceive any thing, there is a real act or operation of the mind; of this we are conscious, and can have no doubt of its existence; but every such act must have an object: for he that conceives must conceive something. For the different theories of conception fluted by Dr. Reid, with his observations upon them, we must refer to the article *IDEA*. This author closes his account of the faculty of conception with an enumeration of what he conceives to be the errors into which writers have fallen in their discussion of the operations of the mind. In all judgment and in all reasoning, he says, conception is included. We can neither judge of a proposition, nor reason about it, unless we conceive or apprehend it; and therefore those are mistaken who so distinguish between conception, judgment, and reasoning, as to imply, that a proposition, or even a syllogism, may not be simply apprehended. Dr. Reid further observes, that the division, commonly made by logicians, of simple apprehension into sensation, imagination, and pure intellect, seems to be, in several respects, very improper. Sensation, and the perception of external objects by the senses, are, in his opinion, very different operations of the mind; and, though commonly conjoined by nature, they ought to be distinguished by philosophers. Neither sensation, nor the perception of external objects, is simple apprehension; because both, as he thinks, include judgment and belief, which are excluded from simple apprehension. Moreover, those who distinguish imagination from pure intellect, by referring to the imagination an image in the brain, and to pure intellect an image in the intellect, ground their distinction upon an hypothesis; since we have no evidence, as he apprehends, that there are images either in the brain, or in the intellect. See *IMAGINATION*. Dr. Reid further observes, that it is a mistake to represent simple apprehension as the first operation of the understanding, and judgment as a composition or combination of simple apprehensions, which mistake probably has arisen from supposing that sensation and the perception of objects by the senses, are nothing but simple apprehension. Although these are very probably the first operations of the mind, they are not simple apprehensions. See *PERCEPTION*. Instead of saying, that the more complex operations of the mind are formed by compounding simple apprehensions, we ought rather to say, that simple apprehensions are obtained by analyzing more complex operations. In this connection, Dr. Reid observes, that a similar mistake pervades the whole of Mr. Locke's Essay. It is this, that our simplest ideas or conceptions are got immediately by the senses, or by consciousness; and the complex afterwards formed by compounding them. He notices also another mistake concerning conception, which is, that our conception of things is a test of their possibility; so that, what we can distinctly conceive, we may conclude to be possible; and of what is impossible, we can have no conception. This opinion has been held by philosophers for more than 100 years, without contradiction or dissent, as Dr. Reid believes; and he considers it as a necessary consequence of the received doctrine of ideas; since it is evident, that there can be no distinct image, either in the mind, or any where else, of that which

is impossible. Our author has investigated this opinion, and urged a variety of objections against it. Whatever, he says, is declared to be possible or impossible is expressed by a proposition; and every proposition, of which you understand the meaning distinctly, is possible. Farther, every proposition, that is necessarily true, stands opposed to a contradictory proposition that is impossible; and he that conceives one, conceives both: thus, a man who believes that two and three necessarily make five, must believe it to be impossible that two and three should not make five. Again, mathematicians have, in many cases, proved some things to be possible, and others to be impossible; which, without demonstration, would not have been believed; "yet I have never found," says Dr. Reid, "that any mathematician has attempted to prove a thing to be possible, because it can be conceived, or impossible, because it cannot be conceived." Moreover, mathematicians often require us to conceive things that are impossible, in order to prove them to be so; and this is the case in all their demonstrations, "ad absurdum." For other particulars connected with the subject of this article, and a fuller view of Dr. Reid's illustration and reasoning, we must refer to his Essays above cited.

A late excellent writer, to whom those who wish to understand the philosophy of the human mind are under great obligation, though they may not admit all his principles and reasoning, has particularly considered the power of conception. By conception professor Dugald Stewart (see his "Elements of the Philosophy of the Human Mind," ch. iii.) means, that power of the mind which enables it to form a notion of an absent object of perception, or of a sensation which it has formerly felt. Although this is not exclusively the proper meaning of the word, yet he thinks that the faculty now defined deserves to be distinguished by an appropriated name. Conception is often confounded with other powers; memory recognizes the features of an absent or deceased friend, and every act of this faculty includes an idea of the past; whereas conception implies no idea of time whatever. Thus considered, the word conception corresponds to what was called by the schoolmen *simple apprehension*; with this difference only, that they included, under this name, our apprehension of general propositions; whereas the professor wishes to limit the application of the word *conception* to our sensations, and the objects of our perceptions. By thus restricting the application of the term, more than Dr. Reid has done, our ideas become more distinct; and for such a restriction the authority of philosophers in an analogous case may be justly pleaded. In ordinary language, we apply the same word *perception* to the knowledge which we have by our senses of external objects, and to our knowledge of speculative truth; and yet an author would be justly censured, who should treat of these two operations of the mind under the same article of perception. "Thus," says the professor, "there is as wide difference between the conception of a truth, and the conception of an absent object of sense, as between the perception of a tree, and the perception of a mathematical theorem." For this reason, he has confined conception to that faculty, whose province it is to enable us to form a notion of our past sensations, or of the objects of sense which we have formerly perceived. The business of conception, thus defined, is to present us with an exact transcript of what we have felt or perceived. The first remarkable fact which strikes us with regard to conception is, that we can conceive the objects of our senses much more easily than those of others. Thus, we can conceive an absent visible object much more easily than a particular sound, a particular taste, or a particular pain, which we have formerly felt. This peculiarity seems to arise from

this circumstance, that when we think of a found, or of a taste, the object of our conception is one single detached sensation; whereas every visible object is complex, and the conception which we form of it as a whole, is aided by the association of ideas, which connects the different parts together, and presents them to the mind in their proper arrangement; whilst the various relations which these parts bear to one another in point of situation equally contribute to strengthen the associations. This power of conceiving visible objects may be much improved by habit. These observations, together with others adduced by our author, are applicable to conception as distinguished from imagination, though the two powers are very nearly allied, and often so blended, that it is difficult to say to which of the two some particular operations of the mind are to be referred. Among logicians, it is a common, and almost an universal doctrine, that conception (or imagination, often used as synonymous with it) is attended with no belief of the existence of its object. To this purpose, Dr. Reid says, "perception is attended with a belief of the present existence of its object; memory with a belief of its past existence; but imagination is attended with no belief at all; and was therefore called by the schoolmen *apprehensio simplex*." Professor Stewart controverts the truth of this principle, and alleges several circumstances in justification of his doubts concerning it. "If it were a specific distinction between perception and imagination, that the former is always attended with belief, and the latter with none; then the more lively our imagination were of any object, and the more completely that object occupied the attention, the less should we be apt to believe its existence; for it is reasonable to think, that when any of our powers is employed separately from the rest, and there is nothing to withdraw the attention from it, the laws which regulate its operation will be most obvious to our observation, and will be most completely discriminated from those which are characteristic of the other powers of the mind. So very different however is the fact, that it is matter of common remark, that when the imagination is very lively, we are apt to ascribe to its objects a real existence, as in the case of dreaming or madness; and we may add, in the case of those who, in spite of their own general belief of the absurdity of the vulgar fables of apparitions, dare not trust themselves alone with their own imaginations in the dark. That imagination is in these instances attended with belief, we have all the evidence that the nature of the thing admits of; for we feel and act in the same manner as we should do, if we believed that the objects of our attention were real; which is the only proof that Metaphysicians produce, or can produce, of the belief which accompanies perception." The author acknowledges, however, that in most cases it is true that imagination is attended with no belief, if by belief we mean a permanent conviction which influences our conduct. But if the word be used in the strict logical sense, he inclines to think, that the exercise both of conception and imagination is always accompanied with a belief that their objects exist. From a variety of observations, which we cannot state within the limits of this article, the ingenious professor infers, that when the conceptions of the mind are rendered steady and permanent, by being strongly associated with any sensible impression, they command our belief no less than our actual perceptions; and, therefore, if it were possible for us with our eyes shut to keep up for a length of time the conception of any sensible object, we should, as long as this effort continued, believe that the object was present to our senses. See NOMINALS, REALISTS, and UNIVERSALS.

CONCEPTION, in *Physiology*, denotes the changes which

take place in the internal organs of generation of the female sex, connected with the development and growth of the embryo. See GENERATION.

CONCEPTION, in *Animals*, is said to be occasioned by something emitted by the male, in the act of coition, impregnating and vivifying the rudiments of an animalcule contained in the female. To explain in what manner this is effected, and to shew

"How the dim speck of entity began
To expand its recent form and stretch to man,"

Gaith.

has been the object of anxious inquiry from the earliest ages. But though much learning has been expended on the subject, and several ingenious theories contrived, to explain the mystery (see GENERATION), yet very little of real knowledge has been obtained.

In this place, without deciding whether the male sperm contains the animalcule, or only a subtle aura, giving life to something engendered in the female, it will be sufficient to observe, that the first effect of impregnation, or conception, will be found in one of the ovaries, or female testicles, as they are called (see Ovary), and not in the uterus, as was generally believed.

That the ovaries are necessary to conception, has been long known, as is evident by the practice of spaying (that is, taking out the ovaries of) sows and other animals, to prevent their breeding. The late Mr. John Hunter took one of the ovaries out of a sow (Obs. on the Animal Econ. &c.), and found the left breeding two years sooner, and produced fewer pigs at each litter, than another sow, kept with her, that was perfect. The perfect sow continued breeding six years, and produced 162 pigs; the half-spayed sow continued to be fruitful only four years, and brought only 79 pigs; whence he concluded, that there is a certain limited number of eggs in each of the female ovaries, and when they are exhausted, the animal is no longer fit for conception.

Anatomists, in the course of their examination of the bodies of females, have found hair, teeth, and other organized parts in the ovaries; and ova, containing fustules, have been found in the Fallopian tubes. (See Fallopian tubes, also FOETUS *extra uterinae*.)

On carefully examining into the contexture of the ovaria, they are found to consist of clusters of vesicles, like bunches of grapes, which are supposed to be ova or eggs.

When one of the vesicles, or eggs, as they are called, become ripe, it enlarges, and puts on a yellowish hue, and it at this time it should be impregnated by the male sperm, it bursts the thin membrane that confines it to the ovarium, enters the fibrinated end of the Fallopian tube, and thence descends into the uterus.

The rent in the ovarium, through which the ovum had passed, forms a cicatrice, which is called, from its colour, *corpus luteum*. (See *Corpus luteum*.) On dissecting the ovaria, there are always found as many of these corpora lutea, as the woman, the subject of the dissection, had borne children.

While impregnation, or conception, is taking place in the ovarium, and the fertilized ovum is descending through the Fallopian tube, a proccis is going on in the uterus, to prepare it for its reception. The vessels of the uterus, which were before so extremely minute, as not to be visible, begin to be conspicuous; the whole organ is enlarged, and a secretion of a mucus takes place, and lines its internal surface. This mucus soon puts on the appearance of a rough and shaggy membrane, destined to become the medium of connection between the ovum and the uterus. The late Dr.

William Hunter called this membrane the decidua, because it is cast off at the birth of the fœtus. He was supposed to have first discovered it: but Needham, who published his "Observations de formato Fœtu," in 1667, gives a clear description of it and of its office, but acknowledges that his account is taken from brutes; he never having had an opportunity of opening the body of a woman who had died undelivered. There are three membranes, he says, lining the uterus of viviparous animals when pregnant; "extima profusa fibrosa est, nulla vena, aut arteria visibili donata," p. 176; it serves as a sheath, he says, to the other membranes. Though he gives no name to this membrane, yet, as he places it between the chorion and the uterus, it can be no other than the decidua. Harvey describes it also still more distinctly. Before any vestige of the conception can be seen, he says, "mucosa quadam filamenta tanquam araneorum telæ, ab ultimo five superiore cornu angulo ducuntur; quæ simul junctæ membranofam ac mucilaginosam tunicam, five manticam vacuum referunt." Exercit. sexagesima nova.

The ovum being received into the uterus, in a little time, pushes out small fibres, or vessels, principally, perhaps, from that part by which it had been connected to its calyx in the ovarium, in a manner not dissimilar to that by which an acorn is joined to its cup, or a hazel nut to its outer green shell. These vessels, piercing the decidua, which affords a support to them, insinuate themselves into the pores of the uterus, and absorb the moisture from it, for the support and increase of the ovum, as the young fibrils, or slender radicles of plants and trees, absorb their nourishment from the earth. Although the uterus is intended by nature, and is thus prepared for the reception of the ovum, yet if it happens to be detained in the Fallopian tube, or to fall into the cavity of the abdomen, it there puts forth its radicles, and attaches itself to the part it happens to fall upon, or be in contact with, and the inclosed fœtus is nourished and comes to maturity nearly in the same manner, as if it had been received in its proper matrix. (See *Poërus extra uterine*, also *Poërus, Nourishment of, in Utero*.)

On examining the ovum, soon after its descent into the uterus, it appears to contain a clear glutinous fluid, like the white of an egg; in a little time a concretion, like a small maggot, is seen in the centre of the fluid, which is the primordium of the embryo. Very minute blood-vessels are now visible, branching upon a part of the chorion, hereafter to become placenta; the little galba, or maggot, being attached to it by slender threads, scarce a line in length, the future funis umbilicalis. At one extremity of the concrete three vesicles are seen, the rudiments of the eyes and brain; and beyond them, a crimson moving point, the punctum saliens, or heart. Soon after, fine white filaments are perceived, variously circumvolved, the intestines. The rest of the viscera are now faintly delineated; then the integuments covering and confining the viscera; then the extremities, or limbs, begin to sprout, at first short stumps, without hands or feet, which at length emerge, complete the transformation. The whole fœtus is said to be completely formed, by the end of the fourth week from the time of conception. See Harvey, *De Generat. Anim.*: and his predecessor, under whom he studied at Padua, Fabricius ab Aquapendente. For the further development and growth of the fœtus, see *EMERYO*, and also *POËRUS*.

CONCEPTION, Symptoms of, in Women. As soon as a woman hath conceived, a train of symptoms commence, which announce some considerable alteration has taken place. "Mulier ubi concipit," Hippocrates says, "statim inhorrescit, et incalcescit, ac dentibus fridit, et articulos reliqu-

umque corpus, convulsiõ prehendit, et uterum torpor." A woman, as soon as she has conceived, shivers, and then becomes hot, her teeth chatter, and she suffers a slight convulsive motion of her whole body. And in another place, "Pregnantem mulierem, si aliter non cognoscas, oculi trahit, et caviores fiunt, et candidum oculorum albicinis naturam non habet, sed lividius exiit." *Op. Om. cura Vaud. Linden*, t. iii. p. 235. In pregnancy the eyes become hollow, the whites of them lose their clearness, and become thick and muddy. If towards the end of the term of uterine gestation, he adds, the eyes become hollow, and the face and the whole body are affected with œdema, if the tips of the ears and of the nose are white, and the lips livid, the child will be found to be diseased or dead. Andreas Laurentius, who was physician to Henry IV. of France, recites the following circumstances, as indicative of a woman having conceived. "Nos mulierem concepitse existimamus," he says, "si in femine concursu totum corpus leviter cohœrerit, aut titulata quodam utero contrahi precepit; si excerptum eum voluptate semen non excedit; si uteri os internum exquisitè convocat; si menstrua subsistat purgatio; si lenis doloris sensus circa umbilicum et hypogastrium oberret; si mammae obdurecant, extuberant, perdolescant; si venenis appetentia languescat; si ocyllimè lactatur, et subinde marore afficiatur; denique si in edulis salidum."

We know a woman to have conceived, if immediately after copulation she is affected with shivering; if the menses, received with pleasure, is not suffered to escape; if the mouth of the womb is found to be completely closed; if a slight sense of pain is perceived about the navel; if she ceases to menstruate, and the breasts become large, hard, and painful; if the appetite for venery abates; if she has frequent and sudden changes from mirth to sadness; and, lastly, if she has a loathing to her usual food, and a desire for things before indifferent, or to which she had an aversion. These observations are in general just, and may serve to shew the accuracy with which the ancients noticed the minutest circumstances; but they are for the greater part such as we can make little use of in practice; as we should neither be permitted to inquire whether a superior degree of pleasure was felt at the moment of coition, or whether the semen was retained, or to examine whether the os uteri was completely closed. Waving, therefore, these minutæ, it will be sufficient to describe the most usual symptoms attendant on conception and pregnancy, in the order they occur, and to make some observations on each of them, with the view of shewing the causes from which they are derived, and the means by which they may be mitigated, or appeased, when they are so violent as to endanger abortion, or are likely to occasion any permanent evil to the constitution.

The first symptom by which women judge themselves to have conceived, is an intermission of the regular discharge of the menses. This is so general, that women who have been accustomed to be regular, always date their conception from the time they first miss their courses, as they are popularly called; and in this judgment, they are almost constantly right, unless fever, or some other cause has intervened, to which the interruption of them may be attributed.

Nausea and vomiting are also pretty constant attendants on pregnancy. These are most troublesome in the morning, and often commence before the period for menstruation arrives. They have been supposed to be occasioned by the subsidence of the uterus into the pelvis, dragging part of the bowels with it. But as they come on before the uterus has obtained sufficient bulk to disturb the bowels by its weight, they are with more propriety ascribed to sympathy,

between

*between the stomach and the uterus. Nausea and vomiting, unless uncommonly violent, are rather to be esteemed salutary than dangerous, and it has been observed, that women, attacked with these symptoms, are less liable to miscarry, than those who are free from them. Blood has even been known to be thrown up from the stomach, from the violence of the straining, without any subsequent ill consequence. When, however, the vomiting is extremely violent, and obstinate, if there are also signs of plethora, or general fulness of the vessels, two or three small bleedings have often proved salutary. In the mean while the body should be kept open, by administering gentle ecoprotics, which the costive state of the bowels, incident also to pregnancy, makes particularly necessary. Infusion of senna, with soluble tartar, or the bitter purging salt; lenitive electuary, rhubarb, magnesia, or castor oil, may be conveniently used, or emollient and opening glysters, administered advantageously for this purpose. In the relaxed state of the bowels, to which some delicate women are inclined, the confection alkermes, or aromatica, given in weak cinnamon water, with three or four drops of the tincture of opium, twice or thrice a day, or from a quarter of a grain to a grain of opium may be given advantageously every night at bed time; where these have failed, the diarrhoea has been removed, by giving occasionally, in addition to the above, small doses of ipecacuanha; or, lastly, by change of air, all other methods having proved unsuccessful.

The disposition to vomiting usually ceases between the fourth and fifth month, or soon after the woman has quickened, (see QUICKENING). The uterus now rising above the brim of the pelvis, and entering into the cavity of the abdomen, is less pressed upon by the neighbouring parts, and has more room for distension; perhaps also having been long used to the irritation, occasioned by the increase of the ovum, it is less sensibly affected by it. In some constitutions, however, the sickness and vomiting continue to harass the women through the whole course of pregnancy; yet even in these cases, although the vomiting is so incessant, that the whole of what is taken into the stomach seems to be ejected that way, yet such women have ordinarily as favourable labours, produce as healthy children, and recover from child-birth as speedily and completely as those who pass through their pregnancy with only the usual sickness.

Subsidence, or falling in of the abdomen, so as to be less prominent than usual, is considered as another of the early symptoms of pregnancy.

Dans une ventre plat
Un enfans il y a,

as the old French proverb has it. This has been said to be occasioned by the descent of the uterus into the pelvis, drawing with it a portion of the bowels, but with little propriety. The real cause seems to be emptiness of the bowels: Women not only vomiting up the greater part of the food they take in, during the first five or six weeks of their pregnancy, but being usually during that time so troubled with nausea, as to have little inclination to take sustenance.

The areola, or circle round the nipple, which in virgins is of a beautiful pink colour, becomes darker, it is said, after conception. It is certain, the areola is darker in women who have had children, than in those who were never pregnant, and in some women who have borne many children, it becomes of a dark chocolate colour, but as that colour continues after child-birth, no indication can be taken thence, whether the woman is actually pregnant, unless perhaps with the first child.

Enlargement, hardness, and tenderness of the breasts, with pains darting through them, and a discharge of a thin palish milk, or whey, are commonly attendant on a pregnant state. This alteration in the state of the breasts usually takes place in the third or fourth month after conception, sometimes earlier, and is indicative of the preparation making in them for the secretion of milk, the future nourishment for the child. If from this plump and firm state, the breasts subside, and become loose and flaccid, unless a violent diarrhoea may have supervened to occasion it, the fœtus may be expected to be weak, sickly, or dead.

Cardialgia, or heart-burn, is a frequent and troublesome attendant on pregnancy. (See CARDIALGIA). This has obtained its name cardialgia, from its being supposed to be an affection of the cardia, or upper orifice of the stomach. A sense of burning, or of intense heat, molests the patient, which demands almost incessant drinking to appease it. As the uterus enlarges, it thrusts the intestines higher into the abdomen, hence the liver, and other viscera, are disturbed and frightened, and thence probably a more plentiful secretion of bile, which flowing into the stomach, is thought to occasion this uneasy sensation, which is observed to be more troublesome in a recumbent, than in an upright posture. Pills with soap and rhubarb, Colombo root, magnesia, and other testaceous powders, are found to be the most useful medicines in this complaint. Milk and water, pyrmont and other chalybeate waters, bark and tonics are also serviceable; but it sometimes resists every medicine, and only subsides after the food is digested, and the stomach is nearly emptied. This points to the only preventive, abstinence. Women subject to this complaint should content themselves with the lightest diet, and that taken in small quantities. In the mean while, the rhubarb, soap, and Colombo, should be persisted in to help digestion, and to cleanse and empty the bowels.

Cramp, attacking the legs, thighs, or belly, is also a frequent attendant on the pregnant state. This is probably occasioned by the pressure of the head, or other part of the fœtus on the iliac or neighbouring nerves, and consequently becomes more troublesome the farther the woman advances in her pregnancy. An unnaturally irritable state of the nervous system seems to be the pre-disposing cause of this complaint. Hence, persons in the higher ranks of life, whose constitutions are debilitated by sitting up late at nights, by large companies, luxurious diet, &c. are most frequently tormented by it. A more simple diet, early hours, exercise in the open air, keeping the bowels empty, bark, and other bitter and tonic medicines, promise most, both in preventing and curing this troublesome complaint.

Of the symptoms here enumerated, many are equivocal, as happening indifferently in the pregnant, or in the unimpregnated state; and none of them are singly of sufficient validity, to enable us to form a decisive opinion from them; but from the conjunction of several of them, a pretty certain conjecture may be formed. If a woman accustomed to be regular, soon after marriage ceases to be so, and about the same time is affected with nausea and vomiting, there would be little hazard in pronouncing such a person to be pregnant. But where the symptoms are equivocal, it is always best to defer giving a decisive opinion, until the commencement of the sixth month, when from the motion of the fœtus, and the increased bulk of the abdomen, we may be enabled to determine with certainty.

About this time, a new train of symptoms succeeds, principally dependent on mechanical causes. The volume of the uterus, daily enlarging, presses on, and flattens the urinary bladder, and diminishes its capacity. Hence a more tre-

quent necessity for making water. The uterus, at the same time, pressing on the rectum, occasions the alvine feces to be discharged with difficulty; hence costiveness, and the return of the blood by the iliac and hæmorrhoidal veins being prevented, by the same cause, the piles; hence, also, oedematous swellings of the legs, thighs, and labia pudendi.

The labia pudendi, consisting almost entirely of cellular membranes, are sometimes so enormously distended as to prevent the person from walking, and to occasion considerable pain. Scarifying the labia, or making two or three punctures with a lancet, the parts being afterwards fomented with warm water, sometimes succeeds in reducing these swellings. Bleeding and moderate purges are also necessary. However formidable the appearance of the labia, when thus enlarged, may be, they offer no impediment to the labour, which is frequently, in these cases, uncommonly expeditious. In these leuco-phlegmatic habits, the fibres seem to have lost their tone or power of resisting, and to give way to the slightest impulse, so that the child is frequently expelled by the most trifling effort. The hæmorrhoids, or piles, are not so tractable, but frequently elude every attempt to cure them, until after delivery, when they usually grow subside.

Varices, or enlargement of the veins of the legs and thighs, being dependent on the same causes, the pressure of the uterus, preventing the return of the blood from the lower extremities, can only be palliated, until after the birth of the child, when they gradually vanish. It will be right, while waiting for this event, to moderate the distension of the veins, and prevent their bursting, by keeping in a recumbent posture, and by wearing bandages around the parts. The piles may be relieved by taking a desert spoonful of cream of tartar every day, and by anointing them with a preparation, consisting of galls of Aleppo reduced to an impalpable powder, and mixed to the consistence of an ointment with cold drawn linseed oil, or green tea, macerated in boiling water, may be applied as a poultice.

An idea prevails among women, that it is necessary they should take a greater quantity of nourishment during the pregnant state, than at other times, as they are then to furnish sustenance to an additional being; and they frequently, at the exhortation of their friends, take in a greater quantity of food than they have any inclination for, lest they should deprive the child of its necessary nourishment. But as no more of the food they swallow can be of use for that purpose, than what is properly digested, and as all the symptoms shew the depressed state of the stomach, it is evident that by loading that organ unnecessarily, all the complaints incident to the pregnant state will be aggravated and increased. The greater part of the bile being discharged by vomiting, during pregnancy, a sufficiency does not remain to complete the digestion of the food, to which it greatly contributes. Hence the chyle, admitted in too crude a state into the vessels, by its stimulus, excites after every meal a kind of hectic, by which the body is emaciated, the face is contracted, or shrunk, and the eyes, as Hippocrates observed, become sunk or hollow. In this state, therefore, an increased quantity of food, by increasing the labour of digestion, adds to the mischief. A moderate diet, with a due quantity of vegetables, and of ripe fruit, with country air, when it can be obtained, are the best remedies, and are to be recommended in every case during pregnancy.

It has been observed, that the cessation of the menses is one of the earlier signs of pregnancy; but some women continue to have a discharge of blood from the pudenda, recurring at longer or shorter intervals, for the first four,

five, or six months of their pregnancy; but the return of these discharges is rarely regular, recurring at the end of the second, third, or fourth week, and sometimes at the end of longer intervals. The quantity also varies, being sometimes more sparing, at others more profuse than the menses usually are. These discharges happen whenever any portion of the placenta, or membranes, is detached from the uterus, and generally terminate in abortion, or the premature birth of the foetus; or if the woman carries her burthen to the end of the ninth month, the child is usually weak, sickly, or dead born. "Si prægnans," Hippocrates says, in the place last quoted, "purgationes menstruæ cursum suum tenent, bene valere factum est impossibile!" A slender diet, with occasional small bleedings, and mild purges are the best preventives, in these cases.

Pica, or an irregular or depraved appetite, exciting women to long for, or intensely desire, some particular kind of food, is sometimes an attendant on pregnancy. (See PICA.) This formerly, from an improper indulgence of the appetites and fancies of pregnant women, was a very troublesome, and sometimes a formidable affection; as not only the health and life of the mother, but the perfection of the foetus, were supposed to depend on gratifying these longings. If a child happened to be born with some mark or blemish on its body, the memory of the female relatives or friends was racked, to recollect some desire of the woman that had been disappointed, to which the accident was attributed. Sometimes, however, these marks were supposed to have been occasioned by the sudden sight of some object, which it was thought to resemble.

This idea of the power of the imagination of the mother, in marking or disfiguring the foetus, is so ancient that we can scarce trace its origin. We read in Genesis, that Jacob placed peeled rods before the ewes when in company with the rams, "and it came to pass, that when the ewes looked at the rods, that the lambs they yeared, were partly-coloured, and streaked." And Hesiod, the most ancient of the Greek poets, says, "Ne quis rediens e funere, liberos operam det, ne imaginatio rei trillis, in proles transeat, easque permuet." Let no one returning from a funeral, embrace his wife, lest the melancholy he had contracted, should make an impression on the foetus. Dr. Daniel Turner, who was an intire convert to the opinion, has made a large collection of stories of monstrous births, all occasioned, he says, by the disappointed longings of their mothers, or by their being frightened by the sight of some hideous or mishappen object. See his Treatise, De Morbis cutaneis. lib. xii. Turner's book was answered by Dr. Blondie, in a masterly and satisfactory manner. The opinion is now wearing away very fast, and bids fair in a little time to be totally obliterated. See IMAGINATION.

When the appetite, during pregnancy, is inordinate or depraved, requiring improper food, it may be remedied by taking small doses of ipecacuanha, of rhubarb and magnesia, of Colombo, and other bitter and tonic medicines.

CONCEPTION, *immaculate*, of the Holy Virgin, is a feast established in honour of the Holy Virgin; particularly with regard to her having been conceived and born immaculate; i. e. without original sin; held in the Romish church on the 8th of December.

The Latin church, says Gibbon, (Hist. of the Decline and Fall of the Roman Empire, vol. ix. p. 265.) has not disdained to borrow from the Koran the immaculate conception of the virgin-mother. It is darkly hinted in the Koran (c. 3. p. 39.) and more clearly explained by the tradition of the Sonnettes. (Sale's Note, and Maracci, tom. ii. p. 112.) In the 12th century, the immaculate concep-

tion was condemned by St. Bernard as a presumptuous novelty. However Allatius, in his *Prolegomena* on Damascenus, endeavours to prove this feast to have been celebrated by several churches in the East, as early as the eighth century. It was first established about the year 1138, though it is not known, with any degree of certainty, by whose authority it was introduced, nor in what place it was first celebrated; about 1140 certain churches in France began to observe it; but it had been observed in England, in consequence of the zeal of archbishop Anselm, before this period.

The church of Lyons in France was one of the first that adopted this new festival, but the canons of Lyons were severely censured by St. Bernard for the innovation, and he vigorously opposed the immaculate conception of the Virgin, because it supposed her being honoured with a privilege which belonged to Christ alone. Thus commenced a controversy, which occasioned two parties in the Christian church that contended with each other for several centuries.

This has been a great subject of controversy between the Scotts and Thomists; the former maintaining, and the latter impugning it.

The Dominicans espoused the party of St. Thomas, and held out a long time in defence of the Virgin's being conceived in original sin. When this controversy was renewed at Paris in 1384, by John de Montefono, a native of Arragon, a Dominican friar and professor of divinity, who publicly asserted that all who believed the immaculate conception were enemies of the true faith, the college of divines, and the whole university of Paris, condemned this and some other tenets of Montefono. Upon this the Dominicans, together with their champion Montefono, appealed from the sentence of the university to pope Clement VII. at Avignon, (the name assumed by cardinal Robert of Geneva, on his election during the pontificate of Urban VI.) and raised an outcry, that St. Thomas himself was condemned by the judgment passed upon their brother. But, before the pope could decide the affair, the accused friar fled from the court of Avignon, went over to the party of Urban VI., who resided at Rome, and thus, during his absence, was excommunicated. Whether or not the pope approved the sentence of the university of Paris is not ascertained. The Dominicans, however, deny that he did, and affirm, that Montefono was condemned merely on account of his flight; though there are many others who assert, that his opinion was also condemned. And as the Dominicans would not acknowledge the sentence of the university to be valid, they were expelled in the year 1389, and were not restored to their ancient honours in that learned body till the year 1404. The council of Trent, sess. v. in the decree of *original sin*, declares it not to be the intention of the council to include the Virgin under it; her conception it calls immaculate; and appoints the constitutions of Sixtus IV. to be observed with regard to it.

This controversy between the Dominicans and Franciscans was revived in the seventeenth century; and a festival was appointed by Clement XI. in 1708, to be celebrated throughout the Romish church: however, the Dominicans persist in denying the obligation of this law, and in maintaining their ancient doctrines.

In the three Spanish military orders of St. James of the Sword, Calatrava, and Alcantara, the knights take a vow, at their admission, to defend the immaculate conception. This resolution was first taken in 1652.

Peter d'Alva and Altorga have published forty-eight huge volumes in folio, on the mysteries of the conception.

CONCEPTION, *Order of*, in Germany, was instituted in 1618, by Charles de Gonzaguez of Cleves, duke of Nivernois and Rheteblais, and was confirmed by pope Urban VIII. in 1624. The badge of this order was a golden cross of eight points enamelled blue; in the centre a medallion rayonnated gold, thereon the image of the Virgin standing on a crescent, holding in her arms our Saviour, and round her head 12 stars all enamelled proper; the reverse was enamelled as the front, and on the medallion St. Michael; the whole of the star environed with the cordon of St. Francis, tied at the bottom: this badge was worn round the neck pendent to a sky blue ribbon.

CONCEPTION, *religious of the order of*. See THEATINES.

CONCEPTUALISTS, in *Logic* and *Metaphysics*, a denomination given to a party of nominalists, who took a middle road between the two sects of nominalists and realists, into which the scholastic philosophers were divided from the beginning of the twelfth century. That universality, which the realists hold to be in things themselves, and the nominalists in name only, the conceptualists hold to be neither in things nor in names only, but in our conceptions, whence they derived their appellation; but being exposed to the batteries of both the opposite parties, they made no great figure. It is not an easy matter, says professor Dugald Stewart (*Elem. of the Philosophy of the Human Mind*, p. 102), to ascertain precisely the meaning of the conceptualists on the point in question, their language on the subject being indistinct and inaccurate; but the professor thinks that, upon the whole, it amounted to the two following propositions: first, that we have no reason to believe the existence of any essences, or universal ideas, corresponding to general terms; and, secondly, that the mind has the power of reasoning concerning genera, or classes of individuals, without the mediation of language. In denying the existence of universals, the conceptualists agreed with the nominalists. To what then, can we suppose, says the professor, that they differed from them, but about the necessity of language, as an instrument of thought, in carrying on our general speculations? Mr. Locke is referred by Dr. Reid (*Essays on the Intellectual Powers of Man*, p. 478) to the class of conceptualists. He does not maintain, that there are things which are universal; but that we have general or universal ideas which we form by abstraction; and this power of forming abstract and general ideas, he conceives, to be that which makes the chief distinction in point of understanding between men and brutes.

If Mr. Locke, says professor Stewart (*ubi supra*), had any decided opinion on the point in dispute, it did not differ materially from what is stated in the general propositions, which we have already cited. The apparent inconsistencies which occur in that part of his *Essay* in which the question is discussed, have led subsequent authors to represent his sentiments in different lights; but as these inconsistencies plainly shew, that he was satisfied neither with the system of the realists, nor with that of the nominalists, they seem to demonstrate that he leaned to the intermediate hypothesis already mentioned, notwithstanding the inaccurate and paradoxical manner in which he has expressed it. Dr. Reid's opinion seems to the professor to coincide nearly with that of the conceptualists; or, at least, to coincide with the two propositions, which are supposed to contain a summary of their doctrine. The absurdity of the ancient opinion concerning universals, as maintained both by Plato and Aristotle, he has exposed by the clearest and most decisive arguments; and by his own very original and important speculations concerning the ideal theory, he has, in the ingenious

ingenious professor's opinion, completely destroyed that natural prejudice from which the whole system of universal ideas gradually took rise. If, even in the case of individuals, we have no reason to believe the existence of any object of thought in the mind, distinct from the mind itself, we are at once relieved from all the difficulties in which philosophers have involved themselves, by attempting to explain, in consistency with that ancient hypothesis, the process of the mind in its general speculations. On the other hand, it is no less clear from Dr. Reid's criticisms on Berkeley and Hume, that his opinion does not coincide with that of the nominalists; and that the power which the mind possesses of reasoning, concerning classes of objects, appears to him to imply some faculty, of which no notice is taken in the systems of these philosophers. However, he has no where positively asserted, that language is not an essential instrument of thought in our general reasonings. At the same time, as he has not affirmed the contrary, and as he has declared himself dissatisfied with the doctrines of Berkeley and Hume, his readers are naturally led to conclude, that this is his real opinion on the subject. His silence on this point is the more to be regretted, as it is the only point about which there can be any reasonable controversy among those who allow his refutation of the ideal hypothesis to be satisfactory. In consequence of that refutation, the whole dispute between the realists and the conceptualists falls at once to the ground; but the dispute between the conceptualists and the nominalists (which involve the great question concerning the use of signs in general speculation) remains on the same footing as before. See CONCEPTION.

CONCERT, an assembly of musicians, or a band of musical performers assembled for the entertainment of musical hearers.

CONCERT Spirituel, Fr. A concert of sacred music, originally established at Paris in 1725, by permission of the manager of the opera; which permission was purchased by the brother of the celebrated Philidor, to perform concerts in Lent, on the days the theatres were closed, at the price of 1000 livres a year, for three years, on condition that no French music or selections from the opera should be performed at these concerts. This first gave birth to the use of foreign music and foreign musicians in France. The licence was renewed from time to time, but always at an advanced price, till it amounted, in 1749, to 9000 livres a-year. In 1734, the two celebrated *Bezzozzi's*, from Turin, performed at the concert spirituel, one on the hautbois and the other on the bassoon, with more applause than any foreign musicians had ever before received in France. The celebrated *Mondonville* had the direction of this concert for several years, and composed expressly for its use motets for a single voice, accompanied by a rapid and difficult harpsichord lesson. It was at the concert spirituel, which, like our oratorios, takes place when no dramatic performances are allowed, that *Giornovich*, *La Motte*, *Viotti*, the *Agujari*, *Madame Mara*, the *Todi*, *Savoi*, and *David*, were first heard in France; and afforded the inhabitants of Paris an opportunity of comparing the music and performance of foreign musicians with their own.

In 1749, during Lent, *Geminiani* had a concert of sacred music at Drury-lane theatre, the vocal pieces were all Italian, and Latin words. *Geminiani* himself led the band on this occasion, and played one of his own solos. This performance, in imitation of the French, was called **CONCERTO SPIRITUALE**.

In Italy and Spain, *academia*, Ital. implies a concert. In

France, *Academie Royale de Musique*, was the title given at Paris to the establishment of the opera under *Lulli* by *Louis XIV.* in 1672, which it retained till the revolution. *Rouffseau*, the scourge of French music and French musicians, traduced both so much in his famous letter on French music, that he was burnt in effigy at the Opera-house door. And in the article *ACADEMIE Royale de Musique*, in the Encyclopedie, and *Dict. de Musique*, he has given great offence by a pun; when after barely mentioning this academy, he only adds—"I shall say nothing further concerning this celebrated establishment, except that of all the academies in the world, this is that which has made the *most noise*," (*le plus de bruit*).

CONCERT-PITCH. This term, among musicians, implies that particular elevation of tone, as to gravity or acuteness, which ought to obtain between different musical instruments intended to be used in concert, which, when thus adjusted, are said to be tuned, or in tune. In concerts entirely vocal, or those wherein adjustable or perfect instruments only are used, as violins, violincellos, &c., any precise pitch being fixed for the notes is immaterial, so that all the instruments derive their notes from some one sound, within moderate limits of the pitch in general use, and for which the instruments were by their dimensions calculated; fingers therefore usually derive their pitch from a simple wind instrument called a **PITCH-PIPE** (see that article), because the same admits of taking their key-note a little higher or a little lower than the note marked on the stopper of the pipe, according to circumstances, and the nature of the piece of music to be performed. Violin performers, when no keyed-instruments are present, usually derive their pitch from a simple steel fork, tuned to the note A, called a **TUNING-FORK** (see that article.)

Instruments, which either from their large and complicated construction, as organs, piano-fortes, &c., or the fixed nature of their notes, as bassoons, oboes, flutes, &c., cannot admit of the occasional variation in the pitch of all their notes which we have mentioned above, are regulated by the makers and tuners of them, to what is called by some the *concert pitch*, and by others the *opera-pitch*; though others maintain that the latter, or that used by the Italian opera band, is higher than the usual concert-pitch of the country. It were much to be wished, that one invariable pitch were adopted and used, but this cannot be hoped for, until the same is accurately expressed by the number of pulses or vibrations excited in the air in a given time by the given note; and the number of these vibrations is essential to be known, before the theory of *beats*, as laid down by *Dr. Robert Smith* in his "Harmonics," the only general and accurate method of tuning instruments to a required temperament, can be applied. We shall therefore first explain the different methods which have been invented for ascertaining the exact number of vibrations made by any given musical sound, and consequently of fixing its *pitch*, and then relate such experiments as have fallen within our knowledge for determining what is the present concert-pitch in this country.

The problem being of considerable importance, we shall enumerate eight different methods of solving it; in order that experiments may be varied in different ways, both for obtaining greater accuracy, and that the coincidence of their results may inspire confidence in the minds of such as have not sufficient mathematical knowledge or patience to go through the investigations, on which the theory of the vibrations of a musical string, and the *beats* of an imperfect consonance are founded: and since the note *C. sol-fa-ut*, or that

that on which the tenor-cliff is placed, being also the ledger

line above the base staff , or the same below the

treble staff of music , is now generally made the

key-note, in flating the notes of the octave, whether diatonic or temperè; we shall adopt each of the formulas, to the finding of the pulses made by this note in ten seconds of time, to be determined by a stop-watch, a second pendulum clock, or a simple pendulum, used for the express purpose of determining periods of 10th each. (See PENDULUM.)

The first method was suggested by Pere Merfenne. It consists in a wire or catgut string, of about 15 to 17 feet in length, over two fixed bridges at its extremities; and after this, dividing the distance between the bridges accurately into eight equal parts; then fixing another bridge at one of those divisions from the end; taking care that the new bridge, which should have a tolerably sharp edge or top, does not strain the string, or force it out of its straight line. The tuning-fork, pipe, or string C, upon the instrument whose pitch is to be determined, is now to be compared with the found of the $\frac{1}{8}$ th part of the string; and if its double octave below nearly agrees therewith, the tension of the whole string is to be altered, as in tuning a stringed instrument, either tightening or slackening it, until the $\frac{1}{8}$ th part is in exact unison with the double octave below the note C, without any beats or undulations: if the found of the $\frac{1}{8}$ th of the string should be found on trial to give a clear musical note, and yet differ very materially from the double octave below C, it may be necessary to assume a greater or lesser length between the extreme bridges, and to determine anew the place of the bridge for the $\frac{1}{8}$ th part thereof: and after the $\frac{1}{8}$ th part has been nicely adjusted to the double octave below the note C, as above, it will be proper again to compare the measure of the $\frac{1}{8}$ th part of the string with its whole length, to see that the points of bearing on the bridges are accurately adjusted to these proportions. Now remove carefully the middle bridge, and cause the whole string to vibrate, which it will be found to do so slowly, as not to cause an audible sound, [if any sound is heard, it will be one of the HARMONICS of that note, see that article, and TRUMPET], but so that its number of vibrations in 10th can be seen and counted, especially if a quill be held so near to the middle part of the string, that it may touch it at each extremity of its vibration; 32 times the number of these vibrations will give the number of pulses or complete vibrations made by C in 10th, and may be called its pitch.

The second method is that which Dr. Robison used, wherein a machine, consisting of a combination of wheel-work, could be so regulated by the motion of a fly, that any given number of the teeth of a wheel should pass and strike a quill projecting against them, during the space of 10th. In using such a machine as this, the velocity of the last wheel should be so regulated, that the sound produced by the snaps of the quill against the teeth, should be in exact unison with the note C; when the known number of teeth which strike the quill in the given time, will determine the pitch.

The third method is by the same learned and ingenious gentleman, who contrived an apparatus, regulated in the manner last described, which opened and shut the passage to an even current of air, produced by a pair of bellows, such as are used in organs, any required number of times in 10th;

this singular apparatus was found to give a clear musical found, which regulated to an unison with C, gave the exact pitch thereof, by the number of alternate openings and shuttings of the cock in 10th.

The fourth method is founded on the following proposition, by the author last mentioned, viz. "An open organ pipe, when sounding its fundamental note, undulates with one node in its middle, and its undulations are analogous, in respect of their mechanism, with the vibrations of a wire of the same length, and the same weight, with the column of air in the pipe, and stretched by a weight equal to that of a column of the same air, reaching to the top of a homogeneous atmosphere, or equal to the weight of a column of mercury, as high as that in the barometer." (See PIPES, Theory of the Sound of, TRUMPET, &c.) Whence this simple practical rule, when the barometer stands at about 30 inches, and the thermometer at about 55°, viz. divide the number 226620 by the length in inches and tenths, of an open cylindrical pipe which sounds C, and the quotient will be the number of pulses or complete vibrations made thereby in 10th.

The fifth method consists in suspending a known weight (equal to W grains) at one end of a wire, such as is used for the lowest notes of a piano-forte, the other end of which is lapped round a thumb-peg, such as is used for tuning a violin, screwed tightly into the waistcoat, near to an instrument whose pitch is to be determined; then by turning the peg, lengthen or shorten the vibrating part of the wire, until when struck it sounds exactly a double octave below C; measure exactly the length of the vibrating part of the string, between its contact with the peg and the loop which sustains the weight; call this L inches. After this, cut off exactly L inches of this same wire and weigh it, call its weight W grains; then will the number of complete vibrations or pulses made by C in 10th be found by the following theorem; viz. $\sqrt{\frac{154463 \times W}{L \times W}}$. See our article CHORDS.

The sixth method is by Dr. Robison, and is as follows. Let a violin-guitar, or any such instrument, be fixed up against a wall with the finger-board downwards, and in such a manner that a violin-string, strained by a weight, may press on the bridge, but hang free of the lower end of the finger-board. Let another string be strained by one of the tuning-pins, till it be in exact unison with C, then hang weights on the other string, till upon drawing the bow across both strings at a small distance below the bridge, they are found to be perfect unisons, taking care that the pressure of the bow on the strings is so moderate, as not to affect the tension of the string first tuned. Then, having noted carefully the weight appended to the first string, add one-fortieth part thereof to the same. Now draw the bow carefully again across the strings as before, and an audible beating will be heard between the sounds of the two strings; count the number of these beats during 10th, and 80 times this will be the number of complete vibrations, or pulses, made by C in 10th.

The seventh method, as well as the best, depends on tuning a major comma; for which several rules are given under the article COMMA. From the octave below C tune upwards three successive perfect fifths upon a single stop of an organ, C G, G D, and D A; and thence tune downwards the perfect major sixth, A C; which last C will be a major comma above the first C, and will beat considerably when sounded therewith; count these beats during 10th, and 81 times this will be the number of complete vibrations, or pulses of C in 10th. See Dr. Smith's Harmonics, p. 195.

The eighth method (Harmonics, p. 197.) consists in tuning a major

a major *sixth*, C A, above C, not perfect, but such that it may beat sharp B times in 10"; from thence tune downwards three successive perfect *fifths*, A D, D G, and G C; which last note will be an imperfect octave below C, the beats of which octave are to be counted during 10", carefully distinguishing whether it beats sharp or flat, and calling the number, if sharp, S, and if flat, F; then will S1S + 16B, or 16B - 81F, according as the case may be, express the number of complete vibrations, or pulses of C in 10".

It is not in our power to give so satisfactory an account of what is the present concert or opera-pitch in this country, as we could have wished; but we hope that experiments will hereafter be multiplied, for fixing it very exactly (at a mean rate of the barometer and thermometer), and after such determination, that the exact number of pulses or complete vibrations from one extreme of the vibrations of a string until its return to the same point, will be resorted to by instrument makers and tuners, for regulating the pitch of their forks, pipes, and instruments.

The vibrations, mentioned in M. Euler's experiment, (after our fifth method, under our article CHORDS) were semi-vibrations, or those made, while a point in a musical string, went from and returned to the axis, or line of rest, between the two points of suspension, and not complete vibrations, or those made while the string went from and returned to the place of its greatest deviation from the axis: therefore $\frac{392}{2}$, or 196, was the number of complete vibrations per 1", made by the A, a minor third below our C; whence this made $\frac{6}{5} \times 196 \times 10 = 2351$ complete vibrations in 10".
