Dr. Robert Smith (Harmonics, p. 220 and 271), calculated about the middle of the last century, that the tenor clef C note, upon the organ in Trinity college, Cambridge, made 232½ complete vibrations in 1", or 2322 in 10", which, he says, was above half a mean-tone lower than the London *opera pitch* at that time, and which therefore probably gave about 2460 or 2470 pulses in 10". The above experiment of Dr. Smith's was made, after Trinity college organ had been depressed a whole tone in its pitch, by making the keys each to act on two pipes lower in the scale than they originally did, by which it was reduced (Harmonics, p. 208, and 218) to the Roman *pitch*, or that to which the pitch-pipes, made about the year 1720, were generally tuned. Dr. Thomas Young, in his lectures at the Royal Institution (Syllabus, p. 95), states our C to make 256 vibrations in 1", apparently only, for the purpose of agreeing with an imaginary C eight octaves below, which is to make but 1 vibration in 1", but which imaginary C, according to the recent determinations of *concert-pitch*, which we are about to mention, ought to make but the $\frac{1}{16}$ part of a vibration in 1", the 8th octave above which will be moved at the rate of 2400 pulses in 10 seconds.

The late Dr. Robison applied our second, third, and sixth methods, for determining the complete vibrations made by C, and relates them all to agree extremely near with 240 in 1", or 2400 in 10". Many other experiments are upon record, but generally some other note than C was selected for the experiment, the exact interval between which and C we are ignorant of, owing to the temperament of the instrument; this is the case with Dr. Smith's determinations (by the fifth and others of the methods above, Harmonics, p. 192, &c.) of the vibrations made by D *la-fel re*, upon the organ above-mentioned.

We were lately present at an experiment by Mr. John Isaac Hawkins, at his house in Great Titchfield-street, where he manufactures the finger keyed viols and double-basses, mentioned under our article CLAVIOL, (see FINGER KEYED VIOL) according to our first method above: two pieces of hard wood, about an inch thick, were sawed down to the floor in his room, at about 22 feet asunder, and were pierced for the two string-pegs of a harpsichord wire; several thin pieces of wood with a sharp edge at top, and fixing a very small height more above the floor, than the fixed pieces of wood, were provided as moveable bridges. A brass wire, called No. 15, by the piano-forte makers, and the largest size which they use in grand piano-fortes, which was found to be .033 inch diameter, was lapped round the pins, and stretched by turning one of them. From a point marked 0 on the floor, 8 or 10 inches from one of the fixed pieces of wood, the several distances 7½ inches, 15, 30, 60, 120, and 240 inches were carefully measured and marked under the string; a bridge was then placed under the string, at the point 0; another at 7½, and another at 240 inches, and one of the tuning pegs was turned until the short portion of the string, 0 to 7½, was in perfect union with Mr. H's snail, or mouth tuning-fork, C; [which is a very considerable improvement upon the large tuning forks which require to be struck upon a table, (see TUNING-FORK) the bridge at 7½ inches was then successively moved to 15 and 30 inches, in order to compare the octave and double octave below with the fork; and which on trial appeared to be accurately in tune. This middle bridge was then removed, and the counting of the visible vibrations of the whole string, 0 to 240, or five octaves below C, was conducted as follows. Mr. H. kneeling down on one knee, placed a seconds watch before him, and held a quill with one hand slightly against the string, about two feet from the bridge, so as to be struck by the wire at each vibration; this was for assisting the sight, in counting the vibrations, by means of the audible strokes thus produced on the quill: for some time Mr. H. continued attentively to notice the vibrations, and to beat down with his toe at every fourth vibration, as a performer on the violin, &c. does in playing in common time; this was pursued, until such a regular rate of beating was obtained by the toe that the experiment was not interrupted by a new twitch or impulse given to the vibrating string by an assidant; the counting then commenced, and was continued during 60 seconds, in the first of which 111 beats of the toe were made, and in a repetition of the experiment, after examining the time of the $\frac{3}{5}$ part of the string, 113 beats were counted; the mean of these, or 112 per minute, gave $112 \times 4 \div 6 = 74\frac{2}{3}$ vibrations for the whole string in 10 seconds, and consequently C, five octaves above, gave $47\frac{2}{3} \times 32 = 2386$ vibrations in 10", which agrees extremely near with Dr. Robison's experiments above mentioned, in shewing, that 2400 may be taken as the present concert pitch.

We have only to add, that an experiment and calculation some years ago by the fifth method above, gave us 2415 pulses in 10" for a tuning-fork then in our possession, marked C, but whether the same had been adjusted to the acknowledged concert-pitch, we are unable to say. The state of the barometer and thermometer should always be noted, at the time of making experiments of this kind, if it is intended accurately to determine the pitch: and it may be well, instead of trusting to the ear alone, in determining the unison or octave of the fork and string, to count and equalize their *beats* with a third found, a little different from both of them, as recommended by Mr. Nicholson, Phil. Journ. 8vo. i. p. 320, for the making of correct tuning-forks.

CONCERT of Ancient Music. This excellent establishment was originally suggested by the late earl of Sandwich in 1776, in favour of such solid and valuable productions of old masters as an intemperate rage for novelty had too soon laid aside as superannuated, was supported with spirit and dignity, by the concurrent zeal and activity of other noblemen and gentlemen of the first rank, who united with his lordship in the undertaking, till 1785, when it was honoured with the presence of their majesties, whose constant attendance ever since has given to this institution an elevation and splendor, which perhaps no establishment of this kind ever enjoyed before. Here the productions of venerable old masters, particularly those of Purcell and Handel, are performed by a select and powerful band, with such correctness and energy, as the authors themselves never had the happiness to hear.

CONCERT, To, in a *Military Sense*, is not only to deliberate upon, but to arrange, form, and agree upon plans of co-operation, for the purposes of either offence or defence.

CONCERTANTE, Ital. from *concertare*, to concert, order, arrange. In the musical technica, it used to be equivalent to harmonizing, adding instrumental parts to vocal. But at present, the term concertante is used substantively, for a symphony or full piece dialogued. In which there are solo parts for the display of great talents on particular instruments. At the concerts of Bach and Abel, solo parts were frequently allotted in these compositions to Cramer, Fischer, the younger Stamitz, Hindmarsh, Shields, Holmes, Tacit, and the elder Florio, Abel, on the viol di gamba, and Bach himself on the pianoforte. Bach's concertante in C \sharp , and Playel's in E \flat , were always heard with rapture; not only from the merit of the composition, but exquisite manner in which they were performed, and the ingenuity of the written cadences, generally furnished by Fischer.

CONCERTATO, a term in *Music*, implying the addition of instrumental parts to a vocal composition; as *motetto concertato*, a motet or anthem, accompanied by instruments.

CONCERTO, synonymous with *concerto*, which long supplied its place. *Concerto* and *suono* implied nearly the same things in the days of Boraccacio, as *concerto* and *sonata* since; but *concertare* and *concertanti* were at first applied to the union of instruments with voices, in motets and madrigals, by doubling the voice-parts. It was not till late in the seventeenth century, that instrumental pieces of many parts, began to be called concertos, and of few parts sonatas.

The earliest compositions which we found in Italy, for three or more instruments of the same species, were Ricercari and Fantasic. But of these none seem to have been printed, when the elder Doni published the second edition of his "Libreria," 1557, as all the instrumental music that appears in his catalogue of musical compositions, which had then been published in Italy, are "Intabolate da organi, et da leuto, d'Anton da Bologna, di Giulio da Modena, di Francesco di Milano, di Jacques Buas, piu di dieci volumi, e la continua."

About the beginning of the seventeenth century madrigals, which were almost the only compositions in parts for the chamber, then cultivated, seem to have been suddenly supplanted in the favour of lovers of music by a passion for fantastics of three, four, five, and six parts, wholly composed for viols, and other instruments, without vocal assistance. And this passion seems to have arisen, from the calling in these instruments to reinforce the voice parts, with which they played in unison, in the performance of motets

and madrigals, thence termed *concertati*. At length the instrumental performers discovered that both the poetry and singing of the times might be spared without any great loss or injury to musical effects; as the words, if good, were rendered unintelligible by fugue, imitation, and multiplicity of parts; and the singing, being often coarse and out of tune, could be better supplied by their own performance. Thus vocal music not only lost its independence, but was almost totally driven out of society; as the ancient Britons, calling in the Saxons to assist them in their conflicts with the Picts, were themselves subdued and forced from their possessions, by too powerful auxiliaries. See FANCIES and BASE-VIOLS.

Simpson in his "Compendium," speaking of fancies, page 118, says: "In my opinion, no nation is equal to the English in this way, as well for their excellence, as for their various and numerous consorts of 3, 4, 5, and 6 parts, made properly for instruments, of which fancies are the chief."

In the MS. "Memoirs of Music," by the hon. Roger North, who speaking of Jenkins, an eminent English composer in the time of Charles I. says, that "of all his concerts, none flew about with his name to it, so universally, as the small piece called his "Five Bell Conforte." And this is only in three parts, so that the import of the term concert or conforte was not then settled.

Montaigne, who travelled through Italy and Germany in 1580, says that the mass in great churches was accompanied by organs and violins. But though the word concerto occurs so early as the year 1587, in the "Trattenimenti" or "Dive'timenti" of Scipion Bargagli, it was only applied to short Fantasic and Ricercari. Salmi concertati was often used when instruments were added to voices, in concerti ecclesiastici.

At the latter end of the 17th century most of Bassani's, Corelli's and Torelli's violin music was composed for the church. The first and third set of Corelli's sonatas, and his first eight concertos, we are certain were thus appropriated. Somis, Veracini, and Tartini, composed their own solo concertos, and performed them likewise in the several churches of Italy. And Pugnani used to accompany the "Messa Bolla," or Silent Mass, at the chapel royal in Turin, with his violin solo concertos.

Concertos merely instrumental, for secular use, seem to have had no existence before the time of Corelli. The honour of the invention has been assigned to Torelli, but from no good authority. Six concertos by Alessandro Scarlatti, manifestly, from the gravity of their style, composed for the church, were printed by Benjamin Cook, in New-street, Covent-garden, about the year 1730. But at the beginning of the last century, besides the concertos of Corelli, Geminiani, and Handel, concertos by Albinoni, Alberti, Tefarini, and Vivaldi, were dispersed all over the kingdom, and heard with great delight at our country concerts, music-meetings, and clubs. These were chiefly on the model of Torelli and Corelli, but with melody of a lighter kind. They were all in seven or eight parts for two choirs; that is, with solo parts for the concertini, or solo instruments, and ripieno parts for the concerto grosso, or chorus of the whole band. But these were soon superseded by great performers on the violin, such as Locatelli, Tartini, Somis, Veracini, Nerla, and Giardini, who, in order to display their superior powers of execution, rendered them too difficult for general use. But these being brought into public favour by the admirable performance of their several authors, were followed by the concertos of Barthelemy, Cramer, La Motte, Lolli, Salomon, Viotti, Giornovich, &c. who, by some peculiar excellence in the knowledge of the finger-board, use of the

bow, or accurate performance of double-stops, seem to have arrived at the acme of perfection in executing solo concertos.

CONCERTO *Croffo*, a grand concerto, or full piece.

CONCERTS, *public*. These were first established in London by Banister, master of king Charles II's new band of 24 violins. The first notice we find of these assemblies is in the London Gazette, No. 742, for Dec. 30th, 1672, in which there is the following advertisement: "These are to give notice, that at Mr John Banister's house, now called the music-school, over against the George Tavern, in White Fryars, this present Monday, will be music performed by excellent masters, beginning precisely at four of the clock in the afternoon, and every afternoon for the future, precisely at the same hour."

There are other advertisements from Banister of the same kind, in 1674, 1676, and 1678. In that for Dec. 11th, 1676, his musical performance is said to be "At the academy in little Lincoln's-inn fields," where it was to begin "with the parley of instruments, composed by Mr. Banister, and performed by eminent masters."

In Mr. North's manuscript "Memoirs of Music," we have a more minute account of these performances. "Banister having procured a large room in White Fryars, near the Temple back-gate, and erected an elevated box or gallery for the musicians, whose modestly required curtains, the rest of the room was filled with seats and small tables, a la mode fashion. One shilling, which was the price of admission, entitled the audience to call for what they pleased. There was very good music, for Banister found means to procure the best hands in London, and some voices to assist him. And there wanted no variety, for Banister, besides playing on the violon, did wonders on the flageolet to a thorough base, and several other masters likewise played solos."

These were followed by other public concerts of a superior kind, at the Crown and Anchor, the Cable in Paternoster row, the Swan and King's Arms, Cornhill, York Buildings, Hickford's Room, &c. &c.

CONCESSI, q. d. *I. herve granted*; a term much used in conveyances, &c. Its effect is to create a covenant in law, as *dedi* (I have given) does a warranty. Co. Lit. 384. This word is of a general extent, and is said to amount to a grant, seoffment, lease, and release, &c. 2 Saund. 96.

CONCESSION, in *Rhetoric*, a figure whereby something is granted or allowed to the adversary, either to prevent being detained by unnecessary incidents, or to make some advantage of. "I will not contend with you the reality of the contract; what I plead for, is relief against the injustice of it." "True, she is fair; but ought the not to shew her acknowledgments to heaven for the favour, by making a virtuous use of her beauty?" See EPITROPE.

CONCESSIT, *Sur*, in *Laws*, a species of *Fine*; which see.

CONCEVEIBA, in *Botany*, Lam Encyc. Aubl. Guian. 924, tab. 353. Class and order, *diancia*. Nat. Ord. *Euphorbie*; Lam.

Gen. Ch. Male flower not known. Female. Cal. one-leaved, fleshy, trigonous near the bottom, with three large glands at its base, terminated by five thick acute teeth, each of which has on the inner side of its base a gland pressing upon the germ. *Pist*. Germ superior, triangular; style none; stigmas three, thick, concave, furrowed, incurved. *Peric*. Capsule globular, trigonous, with three furrows, three-celled, three-valved, each valve dividing into two. *Seeds*, one in each cell, roundish, enveloped in a white pulpy matter which has a sweet pleasant taste.

Sp. C. *guianensis*. A small tree. Trunk ten or twelve feet high, about a foot in diameter, with grey bark and white wood, much branched. Leaves alternate, at unequal distances from each other, oval-oblong, acuminate, toothed, green and smooth on their upper surface, cinereous underneath. *Stipules* in pairs, small, caducous. *Flowers* sessile, alternate, in a terminal spike, common peduncle fleshy, trigonous. A native of Guiana, on the banks of rivers. When the bark is cut, or the leaves torn, a greenish juice issues from the wound.

CONCEZE, in *Geography*, a town of France; in the department of the Correze, and district of Brive; 6 leagues N.W. of Brive.

CONCH, in *Mythology*. See TRITON.

CONCHA *Auris*, in *Anatomy*, is the large hollow of the external ear, included between the tragus, antitragus, and anthelix, and having at its anterior part the commencement of the meatus auditorius externus. See EAR.

CONCHA, *Xoyon*, in *Antiquity*, a liquid measure among the Athenians, which contained two *mystra*, or half an ounce. As much oil as it was capable of holding, weighed five drams one scruple and twenty grains, according to Gor. Defin. Pitisci Lex. & Eisenhom. Others think that the *concha* contained three spoonfuls, ninety-six of which filled a pint vessel (*sestarius*); a *sestarius* was therefore equivalent to thirty-two *conche*, and six *sestarii* made one *congius*, a measure equivalent to our three quarts, according to Salmast. Exerc. Plinian and Bodæus in Theophrast. According to Fernelius, the *concha* was equivalent to two *mystra*, or five spoonfuls; which, according to Jacobus Sylvius, are equivalent to six drams. According to Galen, in his work De Ponderibus & Mensuris, cap. 11, the *concha magna* contained the same quantity with the *acetabulum*, which in liquid measure was an ounce and a half, and in weight fifteen drams. The *concha minor* was in liquid measure half an ounce, and in weight five grams.

CONCHA, in *Conchology*. See CONCHOLOGY.

CONCHA, in *Music*, a trumpet among ancient instruments, or a trumpet-marine, such as Triton used;

— Tritona vocat; conchæque sonaci
Inspirare jubet.

Ov. Met. l.

CONCHA *anatifera*. See ANATIFERA.

CONCHA *anomia*, the name of a fossil shell-fish, found in great abundance, and in a great variety of species, but not known in any of them living, on the shores or in the seas of our own or other countries. In Gloucestershire, and some other of our counties, there are found as common as pebbles on the ploughed lands in other places. They are a sort of bivalve shell, the valves of which are of unequal extent, both of them convex, and the head or beak of the longer valve crooked, and falling over the head of the other.

The great general distinction of this numerous class of bodies, is into those which are of a smooth surface, and those which are of a striated or rough one.

Others also of the same class, or of one very nearly allied to it, are found in many of our inland counties, some very long from the cardo, or hinge, to the margin; and others very short, and very long the contrary way. They are found indifferently in all sorts of strata, in earth, in stone, in sand, and among gravel. See ANOMIA.

CONCHA *fortificata*, a name given by some authors to the genus of shells, called by others the MUREX.

CONCHA *globosa*, the name of a large genus of shells, called by authors the DOLIUM, and in French the *tonne*.

CONCHÆ LAPIDÆÆ, was the name by which some writers

writers distinguished the fossil shells found lodged in the strata of the earth, before the whims of certain authors respecting the *vis plastica, vis formativa, &c.*, by which they attempted to account for the formation of these organic remains, had been entirely exploded, and the truth of their being animal exuvie generally established.

CONCHA margaritifera, a name sometimes used for those *mytili* which produce pearls. See MUSCLE.

CONCHA margaritifera, is the name by which some writers have described a fossil shell, somewhat resembling the recent shells of this genus, in the equality of their valves, the appearance of their guttered and toothed hinges, &c.

CONCHA narium, in *Anatomy*, is a term applied to the turbinated bones of the nose. See SKULLTON.

CONCHA specierorum, in *Natural History*, the *sp. Bre shell*, a name given by authors to a species of voluta, from some odd figures described on its surface, representing rough draughts of terrible phantoms. It is an elegant shell, of a middle size, and is of a white ground, and the figures are reddish; these form three large and broad bands, surrounding the shell at top and bottom, and in the middle; and between these there are several series of small spots. It is a scarce shell, and usually sells at a large price.

CONCHA Veneris, the name by which several species of chama are called. The shell is univalve, wreathed, and has a small longitudinal and denticulated clink, or aperture, in it. It is also called *concha porcellana*, from its aperture in some measure resembling the mouth of a hog; and *concha erythraea*, from its being found in the Red Sea, called *erythraeum*. It is also called *concha cytheriaca*, from Venus, who received the epithet *cytheraea*, from Cythera, a Grecian island. That this fish was used by the ancients as an aliment, we read in Seneca, Ep. 95. Mundius asserts that they prove a stimulus to venery, and provoke urine. Rondeletius informs us, that these shells are an ingredient in the *pitule de bellio*, for removing fluxes, and curing ulcers in the uterus. But instead of the *concha venerica*, the apothecaries generally use cockles. Excellent dentrifices are prepared from this shell, which is also used for curing ulcers in the canthus of the eye, and the *stilla lachrymalis*. It is remarkably drying, without exciting any heat.

CONCHARUM PROMONTORIUM, in *Ancient Geography*, a promontory of Asia Minor, on the Thracian Bosphorus, in the southern part of the Castalian gulf.

CONCHES, in *Geography*, a town of France, in the department of Eure, and chief place of a canton in the district of Evreux, 12 miles S. E. from Evreux, 39 S. from Rouen, and 87 N. E. from Paris. The place contains 2250, and the canton 13550 inhabitants. The territory includes 257½ kilometres, and 33 communes.

CONCHES, a town of France, in the department of the lower Pyrenées, and district of Pau; 6 leagues N. N. E. of Pau.

CONCHITES, or *CONCHITÆ*, in *Natural History*, a name which has been indifferently used by writers, in describing fossil bivalve shells of different kinds.

CONCHITES marmor, a name given by the ancients to a species of marble dug near Megara, and remarkable for containing a great number of sea-shells, and other marine bodies intermixed in it.

CONCHIUM, in *Botany*, from *κόγχη*, a bivalve shell, in allusion to the form of the fruit. Smith. Tr. of Linn. Soc. v. 4. 215. *Donn. Cant. ed. 3. 21. Vent. Jard. de la Malmaison, 110. (Hakea; Schrad. Sert. 27. Cavan. Jc. v. 6. 24.)* Muscle shrub. Clafs and order, *tetrandria monogynia*. Nat. Ord. *Protæe*, Juss.

Gen. Ch. *Cal.* none. *Cor.* of four petals, linear, cohering at their base, somewhat dilated and concave at the summit, nearly equal. *Stam.* four; filaments short, inserted towards the summit of each petal: anthers lodged in the cavity of each petal, erect, oblong, two-celled. *Pist.* Germen superior, small, ovate, oblique; style ascending, recurved, cylindrical, thick, as long as the corolla; stigma turbinate, pointed. *Peric.* Capsule ovate, oblique, gibbous and rugged, pointed, of two hard, thick, woody valves, and one small eccentric cell. *Seeds* two, elliptical, flat on one side, convex on the other, filling the cavity of the capsule, each furnished with a black, membranous, transparent, oblong wing.

Elf. Ch. *Calyx* none. *Petals* four, bearing the filaments. *Stigma* turbinate, pointed. *Capsule*, of one cell. *Seeds* two, winged.

Sp. 1. *C. gibbosum*. *Donn. Cant. 21. (Bankfia gibbosa; White Voy. 224. t. 22. f. 2. Willden. Sp. Pl. v. 1. 536. Hakea gibbosa; Cavan. Ic. t. 534. H. pubescens; Schrad. Sert. 27.)* "Leaves cylindrical, slightly downy, rather longer than the fruit. Corolla smooth. Capsules roundish-ovate, gibbous, rugged." Sm. MSS. *Stem* shrubby, branched, rigid, smooth. Young branches hairy. *Leaves* numerous, evergreen, alternate, sessile, spreading, cylindrical, near two inches long, somewhat downy, especially when young, each tipped with a sharp spine. *Flowers* in small, axillary, hairy umbels, white. *Corolla* nearly or quite smooth. *Capsules* solitary, the size of a walnut, black and rugged, very gibbous underneath; the valves extremely thick, hard and woody, each tipped with a short sharp point; cavity very small, eccentric, uneven, of a mahogany colour. *Seeds* with black wings like gauze or crape. A native of New South Wales, near Port-Jackson. It is now frequent in the more curious European green-houses, but is rather singular than beautiful. 2. *C. sphaeroidem*. "Leaves cylindrical, as long as the fruit, downy as well as the branches. Capsules orbicular, depressed, smoothish." Sm. MSS. A smaller shrub than the last. *Branches* clothed with dense woolly hairs. *Leaves* about an inch long, very hairy. *Flowers* unknown in Europe. *Capsules* of a rusty brown, the size of the last, but much less rugged, and when viewed vertically, almost orbicular, their points scarcely extending beyond the circumference. Sent from Port-Jackson with the preceding. 3. *C. aciculare*. *Donn. Cant. 21. Vent. Jard. de la Malmaison, 111. (Hakea sericea; Schrad. Sert. 27.)* "Leaves cylindrical, smooth, as long as the fruit. Corolla smooth. Capsules roundish-ovate, rugged, elongated at the point." Sm. MSS. Like *C. gibbosum*, but in all its parts about half as large. *Leaves* in every period of their growth quite smooth. *Flower-stalks* and young branches silky. *Fruit* more oblong than in the two preceding, but its lateral protuberances are more glabrous. A native of Port-Jackson, not rare in our gardens. 4. *C. longifolium*. *Donn. Cant. 21. (Bankfia teretifolia; Salisb. Prod. 51?)* "Leaves cylindrical, smooth, thrice as long as the fruit. Corolla clothed with silky hairs." Sm. MSS. *Leaves* three inches or more in length, spinous, as in all the foregoing, always smooth, as well as the branches. *Corolla* clothed with white, close, silky hairs. Perhaps only a variety of *C. pugioniforme* hereafter described, which cannot be determined till the fruit of the present species be known. 5. *C. compressum*. "Leaves cylindrical, smooth, scarcely so long as the fruit. Capsules ovate compressed, somewhat rugged." Sm. MSS. The fruit of this is not more than an inch long, and ovate, partaking but little of the globular protuberant figure of the preceding kinds. *Leaves* small and slender. 6. *C. pugioniforme*. (Hakea pugioniforme; Cavan. Ic. v. 6. 24. t.

533. *H. glabra*. Schrad. Sert. 27. t. 17.) "Leaves cylindrical, smooth. Corolla clothed with silky hairs. Capsules lanceolate, pointed, beset with sharp tubercles towards the base." Sm. MSS. Leaves an inch or inch and a half long, bright green, always smooth, as well as the branches. Flowers white and silky. Capsules very different from the rest of the genus, being much more slender. This, like all the preceding, is found in the country about Port-Jackson, New South Wales. 7. *C. trifurcatum*. "Leaves cylindrical, three-cleft; sometimes dilated, simple, elliptical and flat. Corolla hairy." Sm. MSS. This most remarkable species, discovered by Mr. Archibald Menzies, F.L.S. at King George's Sound, on the west coast of New Holland, is distinguished by its three-forked leaves, but especially by their occasional variation from a cylindrical to a broad flat elliptical figure, on the same branch, and even in the same individual leaf. The flowers and their stalks are clothed with rough, shaggy, not silky, hairs. Fruit unknown. 8. *C. dactyloides*. Vent. Tard de la Malin. t. 112. (*C. nervosum*; Donn. Cant. 21. *Haëca dactyloides*; Cavan. Ic. v. 6. 25. t. 535. *Banksia dactyloides*; Gært. v. 1. 221. t. 47. 1. 2. *B. oleifolia*; Salisb. Prod. 51.) "Leaves obovate-oblong, with a small point, triply nerved, veiny. Capsules ovate, acute." Sm. MSS. Leaves various in length and breadth, flat, thick, rigid, smooth, entire, obovate, tapering towards the base, marked with three principal nerves united above the base, and connected upwards by interbranching veins, forming sometimes spurious nerves. The young leaves and branches are rusty and downy. Flowers numerous, small, white, smooth, on hairy stalks. Capsule ovate, acute, rugged, scarcely gibbous. Common about Port-Jackson, and not rare in our gardens, where the varieties to which it is subject in the leaves, afford the nurserymen an opportunity of furnishing their friends with many new species. 9. *C. ellipticum*. "Leaves elliptical, bluntish, pointless, with five nerves, reticulated with veins. Capsules ovate, obtuse." Sm. MSS. Allied to the last, but distinct. Leaves broad, exactly elliptical, somewhat glaucous, having five ribs, which all spring from the base, and delicate of any terminal point or spine. The spaces between the ribs or nerves are beautifully and copiously reticulated. Capsule more obtuse than in *C. dactyloides*, but otherwise much like it. Found by Mr. Menzies at King George's Sound, but not yet brought alive to Europe. Flowers not seen. 10. *C. oleifolium*. "Leaves elliptical-lanceolate, with a small point, single-nerved. Capsules ovate, gibbous, somewhat rugged." Sm. MSS. Brought by Mr. Menzies from the same country as the last. Full-grown leaves, scarcely an inch and half long, smooth, even and entire, with only one rib, tipped with a little spine. Veins few and obscure. Flowers spiked, smooth, as well as their partial stalks, though the common ones are hairy. Capsule ovate, gibbous on one side, very rugged all over. 11. *C. serotaphyllum*. "Leaves three-lobed, pinnatifid. Capsules ovate, compressed." Sm. MSS. Leaves very fine, large and divaricated, from two to four inches long, smooth, except when very young, hard and rigid, obscurely ribbed, lobes and teeth spinous. Flowers silky. Capsule narrow, ovate, compressed, smooth, apparently fusculent in its outer coat, which seems to be the case with the three preceding species. Gathered at King George's Sound, by Mr. Menzies. It is one of the handfomest of its genus. 12. *C. salignum*. Donn. Cant. 21. (*Embothrium salignum*. Andr. Repof. t. 215.) "Leaves linear-lanceolate, acute, without spine, single-nerved. Capsules ovate, gibbous, recurved." Sm. MSS. A tall elegant shrub, with the habit of a willow. Leaves five or six inches long, smooth and pliable, of

a narrow lanceolate form, entire, acute, but not spinous, with one nerve and a few lateral veins. Flowers copious, white, smooth, in smooth umbels, which, as in all the rest of the genus, are axillary. Capsule linearish, ovate, recurved, very gibbous, and somewhat rugged, at each side, tapering at the base, externally hard and not fusculent, each of its valves tipped with a lateral spine. A native of New South Wales, frequent in gardens.

Propagation and Culture. All the species are shrubby and perennial, easily raised from seeds brought in the capsules from their native country, and requiring with us only the usual shelter of a green-house or conservatory. These from King George's Sound are as yet strangers to our gardens. The others thrive in sandy peat earth, but require regular and rather copious supplies of water. They may be increased by cuttings. *C. salignum* ripens seeds in abundance when planted in the ground under glass, and rises to the height of 12 or 15 feet. S.

CONCHOID, or CONCHILIS, in *Geometry*, a curve line which always approaches nearer a straight line to which it is inclined, but never meets it. It was invented by Nicomedes, and much used by the ancients, as we learn from Pappus, in the construction of solid problems.

It is described thus: draw a right line BD (*Plate, Analysis, fig. 2.*) and another AC, perpendicular to it in E; draw any number of right lines, as CM, CM', cutting BD in Q; make QM = QN = AE = EF: the curve wherein the points, M, M', are found, is the *conchilis*, or *conchois prima*, so called by Nicomedes. The other, wherein the points, N, N', are found, is the *conchois secunda*; the right line BD the *rule*, or *directrix*, the point C the *pole*, or centre of the conchoid. In reality, they are both parts of the same curve, having the same pole C, and four infinite legs, to which the line BD is a common asymptote. The inventor also contrived an instrument, whereby the first conchoid may be described mechanically: thus, in the rule AD (*fig. 3.*) is a channel or groove cut, so that a smooth nail, firmly fixed in the moveable rule CB, in the point F, may slide freely within it: into the rule EG is fixed another nail in K, for the moveable rule CB to slide upon. If then the rule BC be so moved, as that the nail F passes along the canal AD; the style, or point in C, will describe the first conchoid.

Now let $AP = x$ (*fig. 2.*); $AE = a$; $PE = MR = a - x$; wherefore, as x increases, $a - x$, or MR will decrease; and therefore the curve continually approaches nearer to the rule BD.

In the same manner it appears, that the right line NO must continually decrease; and therefore that the second conchoid, also, must continually approach nearer the rule.

But inasmuch as between each conchoid and the right line BD, there will be the right line QM or QN, equal to AE; neither of the conchoids can concur with the right line BD: consequently BD is an asymptote of each conchoid. See ASYMPTOTE.

If from any point, A, of the curve (*fig. 4.*) AH and FTP be drawn perpendicular to the rule, or directrix, HT, and AL parallel to it; and if the quadrant, FGLK, be described intersecting AL in G; we shall have PL \times LG = TL \times LA. For the triangles, AHB, TLG, are similar and equal, as the angles at H and L are right; and $AB = TF = TG$, and $AH = TL$; therefore $BH = GL$. Also the triangles, AHB, ALP, are similar. Whence $AH : HB :: PL : AL$; that is, $TL : GL :: PL : AL$; therefore, $PL \times GL = TL \times AL$. Hence, the same things being supposed, we shall have $AG = BT$, and $GL = HB$. For $AL = HT$, and $GL = HB$.

= HB; therefore, by subtraction, we shall have AG = BT. This proposition is equally true in the inferior conchoid (fig. 5.). In the inferior conchoid $gl = b.b$. Moreover, in the superior conchoid (fig. 4.), if PTF and AH be perpendicular to the directrix HT, and AL parallel to it, $TL^2 : TF^2 = AH^2 : PL^2 = AL^2$. For, by the preceding proposition, $TL : GL :: PL : AL$, and $TL^2 : GL^2 :: PL^2 : AL^2$; but $GL^2 = GT^2 - TL^2 = TF^2 - AH^2$; therefore $TL^2 : TF^2 = AL^2 : PL^2 = AL^2$.

Hence, putting $FT = a$, $PT = b$, axis $TH = x$, ordinate $HA = y$; the equation of the superior conchoid will be $\frac{b+y\sqrt{aa-yy}}{y} = x = AL$, or, by reducing

it, we shall have $b+y\sqrt{a^2-y^2} = yx$, i. e. $\sqrt{b^2+2by+y^2-x^2} = yx$, or $\sqrt{a^2b^2+2a^2by+a^2y^2-b^2y^2-2b^2y^2-y^4} = yx$, and $a^2b^2+2a^2by+a^2y^2-b^2y^2-2b^2y^2-y^4 = y^2x^2$; whence, by transposition, we shall have $y^4+2by^3+b^2y^2-a^2y^2+x^2y^2-2a^2by = a^2b^2$, i. e. $y^4+2by^3+b^2-a^2+x^2y^2-2a^2by = a^2b^2$. Thus also, in the inferior conchoid (fig. 5.), if pf and ab be perpendicular to the directrix bt , and al parallel to it; we shall have $tP : tF^2 = a b^2 :: P P^2 : a l^2$. For $tl : gl :: Pl : al$; and $tP : gP^2 :: P P^2 : a l^2$; but $gP^2 = b b^2 - a b^2 = tF^2 - a b^2$; therefore $tP : tF^2 = a b^2 :: P P^2 : a l^2$.

Hence putting $tf = a$, $tP = b$, axis $tb = x$, ordinate $ha = y$, the equation of the inferior conchoid will be $\frac{b-y\sqrt{a^2-y^2}}{y} = x = al$. And, when reduced, $y^4 -$

$2by^3+bb-a^2+x^2y^2+2a^2by = a^2b^2$. Or, it may be had from the equation of the other curve by merely changing the sign of y , which in this case is negative.

Of the whole conchoid, excorsted by these two equations, or rather by one equation only, with different signs, there are three cases or species; as first, when EF is less than EC, as in fig. 2; when EF is equal to EC, as in fig. 6; and when EF is greater than EC, as in fig. 7, in which latter case the conchoid is called *nodated*. The same equation holds for this nodated conchoid, the whole difference being merely that a is here greater than b .

Sir Isaac Newton approves of the use of the conchoid for trifecting angles, or finding two mean proportionals, or for constructing other solid problems. To this purpose, he says, in the linear construction of equations towards the close of his "Universal Arithmetic:" "The ancients at first endeavoured in vain at the trifecting of an angle, and the finding of two mean proportionals by a right line and a circle. Afterwards they began to consider several other lines, as the conchoid, the cissoid, and the conic sections, and by some of these to solve these problems." Again, "Either, therefore, the trochoid is not to be admitted at all into geometry, or else, in the construction of problems, it is to be preferred to all lines of a more difficult description; and there is the same reason for other curves; for which reason we approve of the trifecting of an angle by a conchoid, which Archimedes in his Lemmas, and Pappus in his Collections, have offered to the inventions of all others in this case; because we ought either to exclude all lines, besides the circle and right line, out of geometry, or admit them according to the simplicity of their descriptions, in which case the conchoid yields to none, except the circle." Lastly, "that is arithmetically more simple which is determined by the more simple equations; but that is geometrically more simple which is determined by the more simple draw-

ing of lines; and in geometry, that ought to be reckoned best, which is geometrically most simple; whereas I ought not to be blamed, if, with that prince of mathematicians, Archimedes, and other ancients, I make use of the conchoid for the construction of problems."

There will be other kinds of conchoids produced, if CE : CQ :: QM : AE; or indefinitely, if CE^m : CQ^m :: QM^m : AE^m; wherefore, if CE = b, EA = a, CQ = x, QM = y; then $ab = xy$; and for infinite conchoids, $a^m b^m = x^m y^m$.

CONCHOLOGY. "The study of shells, or testaceous animals," it has been well observed by a plain, but ingenious writer, "is a branch of natural history, though not greatly useful in human economy, yet perhaps by the infinite beauties of the subjects it treats of, is adapted to recreate the senses, and infensibly lead the amazed admirer into the contemplation of the glory of the Divinity, in their creation." Or, in the more harmonious periods of the poet, we would say,

"Each shell, each crawling insect holds a rank
Important, in the plan of him who framed
This scale of beings;" — STILLINGFLEET.

Shells appear to form a part of the creation not immediately subservient to the purposes of human life. This is granted; but they are a link in the great chain of nature; they constitute a department of rational inquiry worthy the researches of the man of science; and when we consider the amazing diversity of singular and beautiful objects they embrace, are such, we are persuaded, as cannot fail to arrest in a particular degree the regard of every common observer.

A late writer, whose talents we respect, asserts, in undistinguished terms, that the pursuits of the conchologist are frivolous, and tend to no useful purpose. For the credit of the philosophical inquirer in this pleasing department of natural knowledge, we could wish to see this opinion controverted. We shall not indeed endeavour to support the pretensions of conchology to a distinguished rank among the more beneficial pursuits of science, but we do not fear to prove it in a pre-eminent degree entitled to the attention of every contemplative mind. In the present enlightened period, it is not, we should conceive, incumbent to offer any argument in its behalf, because we are unable to prove its utility in the common acceptance of the term. We are not, for this reason alone, to esteem it frivolous; or, in a word, to declare that our ideas are entirely absorbed in the contemplation of interested views and the love of wealth, or that we are studious only to gratify our immediate wants. Our untutored ancestors cultivated the oak, we are told, that they might eat acorns, regardless of the importance of the parent timber; but we are not to imitate their example, and deem it trifling to cultivate any branch of natural science, that is unlikely to afford us some direct benefit; nor are we to be content with ascertaining what may be merely useful as food for ourselves, or fodder for our cattle. How unworthy would this be of the refined conceptions and dignity of intellectual men? But we rest convinced that a more enlarged and liberal idea of this subject will be conceived on the slightest reflection by every intelligent mind; that the science of conchology will be hereafter more successfully pursued in this country than it has hitherto been; and that the observations we have to offer as we proceed, though less abstruse than the science may seem to demand, will to a certain extent facilitate this desirable object.

One clear and most important fact, the truth of which we would wish to impress on the mind of the reader, should be premised, that whatever opinion we may form on this subject,

æd, or however lightly we may be disposed to appreciate its merits, the science of conchology, or in more humble terms the study of shells, has in a greater or less degree attracted the attention of curious and contemplative minds throughout all ages; though, as may be naturally conceived, it has been cultivated with more success in some periods than in others. The beauties of this part of the creation did not escape the observation of philosophers in the first æra of learning, as appears obvious from the writings of Aristotle, of Pliny, and of Ælian, and we may also add of Athenæus and Cicero. The cultivation of this, like all other liberal studies, was neglected in the darker æra that succeeded, or at least no evidence to the contrary has survived to this period; but in after ages, as the mists of Gothic ignorance which had so long overhung the western world dispersed, and the light of science, like the morning twilight, dawned upon the horizon of the human mind, conchology revived, was countenanced, encouraged, and flourished. And if, in later times, it resigned a precedence to other sciences, in conformity to the example of the great Linnæus, who was perhaps less favourably inclined towards the study of shells than any other department of nature, it is pleasing to add, that since his time this subject has been most assiduously cultivated, and that by writers no less eminently qualified to exalt its character than to give stability to the science itself.

The term conchology comprehends the study of all animals which have a testaceous covering, whether inhabitants of the marine element, fresh water, or the land. Testaceous is a term synonymous with conchology, but is of later origin and application.

A precise distinction should be drawn between testaceous and crustaceus animals; they are essentially different; though both are protected by a hard exterior shell or crust, in which they are partially or entirely enveloped; and have been indiscriminately confounded together, for that reason, under the vague denomination of "shell-fish." Some of the old writers, and also Da Costa, distinguish the testacea as a kind of stone-like calcareous covering or habitation, in which the animal, otherwise naked, resides, and from which it can protrude its molluscous arms, or other naked parts of its body, at pleasure. The crustaceus animals of those authors, on the contrary, are not naked, but have every particular limb or part separately covered with the crust, which is thus divided into many joints, inasmuch that the whole animal assumes a loricated appearance, as if inclosed in a coat of mail. Among the crustaceus order, the *canceri*, or crabs and lobsters, were included, a tribe we have endeavoured to shew in another article, to be of a nature altogether distinct from testaceous animals. (See CANCER.) Klein, in his "Nat. Disp. Echinodermatum," sect. r. treats on this subject, and labours to prove that the echini, which are evidently crustaceous bodies, are of the same nature and quality as the testacea; but recent, and we think conclusive observations, testify the fallacy of his opinion. A better definition may be obtained by attending to the chemical properties of the two substances testaceous and crustaceous. Poli, in his work on the shells of the two Sicilies, demonstrates that testaceous bodies consist of calcareous earth united to a small portion of animal matter or gluten; and Mr. Hatchett, whose experiments on the chemical characters of those bodies are inserted in the Transactions of the Royal Society, draws a striking distinction from analysis between the testaceous and crustaceous bodies, ascertaining the shell to consist only of carbonate of lime mixed with gelatinous matter, while in the other the presence of phosphate of lime was detected. The crustaceous body analysed by Mr. Hatchett was the echinus.

All testaceous animals are composed of two parts; one of which, the animal itself, is soft and molluscous; the other is the shell, or habitation, which is hard, of a stony or calcareous nature, and either partially or entirely covers the animal. The animal is attached to the shell by means of ligaments or muscles.

It was long considered as a matter of dispute among naturalists, whether the arrangement of shells should be constituted from the animals or their habitation. No one can deny, that if we proceed on principles strictly scientific, we must regard them as a department of zoology, and should, on that account, dispose them according to the nature and structure of the animals. But the classification formed from the characters of the shells is universally followed, and we must confess too, is for many reasons preferable to any other. Neither is it, in the hands of the skillful conchologist, attended with so much indecision, as might be generally imagined.

In the first place among the vast variety of shells hitherto discovered, how small comparatively is the number of those, whose animal inhabitant is described or known. It is not of species only that we speak, but of whole natural families or genera, not a single species of which has been yet discovered with the animal appertaining, so little are we acquainted with the molluscous orders, or animals inhabiting the shells. Of the shells we daily see in collections few are filled up alive, the far greater number are found on shores, dead or empty. Neither, if they were otherwise, are accurate descriptions of animals whose parts are not easily seen, or anatomical investigations, which are in many cases necessary, within the capacity of every one. Many of their parts, and their respective functions, are not to be ascertained, except by comparative analogy, and which in itself presents an insurmountable difficulty, or a field of critical inquiry so extensive and complicated that few, even with the ability to pursue it with success, could be prevailed upon to devote that attention to the subject which it requires.

Hence it becomes impossible to arrange the far greater number of testaceous productions by the animals; the attempt must ever prove unsuccessful. Our arrangements would be partial, and three-fourths of the shells known must be either excluded from the system, or be placed at hazard; and of course without order or connection with those whose animals we are acquainted with. The latter are chiefly such as are confined to the coasts of the European seas, and some of the terrestrial and fresh water kinds, which, from their abundance and locality, have obtruded themselves upon the investigations of the naturalist. Even our knowledge of those is exceedingly imperfect. For those of the extra European species, we are indebted chiefly to Adanson, Rumphius, Argenville, and Favanne, and for the anatomical discussions on various European kinds to Valerini, De Heide, Lister, and Müller. The investigations of Poli on the shells of the two Sicilies are valuable, in this respect, as also are the observations of Lamarck and Cuvier, and we may also add Olivier; but what is the amount of all these discoveries, we would ask, in enabling us to form a system of conchology.

The best characters upon which to found all systems of natural history, must be those most obvious and accessible. All ranks of animals, as nearly as can be with convenience, should be arranged by apparent and external characters. While we study shells, without regarding the animal, we are aware they are but considered partially. The animals that inhabit them should guide us in our researches; they alone are the fabricators of the shell, and the shell is only their habitation, to which they give the form, the bulk, hardness,

hardness, colours, and all the peculiarities of elegance we admire. If we were to examine these new and almost unknown beings, we should discover a number of parts as remarkable for their structure as their functions, and an infinite variety of curious and interesting particulars relative to their general habits and manners of life. It is a subject worthy of the serious contemplation and attention of the naturalist, and should never be neglected when an opportunity offers. But a system of conchology, founded entirely on the structure of the animals, must, we cannot hesitate in asserting, ever remain one of the desiderata of natural science.

In the superficial arrangement taken from shells alone we are not exempt from difficulty. Shells vary exceedingly in form and colour in the different stages of their growth, and in this case we should sometimes derive material assistance from our knowledge of the animal. Young shells have been described as specifically distinct from the parent or older shells by many writers. It indeed requires a greater degree of caution in determining the species, nay even genera, of shells in the different periods of growth than may be imagined; of this we could adduce many very remarkable instances, a few of it may be necessary to mention to guard the common observer from forming hasty, and erroneous conclusions.

Many of the cyprææ, or cowries, when young, have the appearance of a volute, the thick denticulated fold of the exterior lip being wholly wanting, and the column being only partially plaited as in the true voluta. The young of the alated shells, in general, are destitute of that broad expansive, or furcated lip, called the wing. The spires in many of the turritid kinds of shells, when young, are blunt; obtuse, or terminated in a large globular head, exceeding the size of the whorl beneath, but as the shell advances in growth, it develops itself, extending in a spiral direction, and thus in the old shells the number of spires is greater than in the young ones. The variations in the growth of the patella tribe are often so considerable, as to almost defy the critical observer to determine them. Still however the conchologist by the dint of application, and nice discrimination, will be at last enabled to fix on certain characters peculiar to every species, and be, by that means, enabled to decide on the species of a shell under every stage of growth.

Linnaeus considers the structure of the animal as well as the shell in all his generical distinctions; the idea is excellent, and we should approve the design, but the object itself is unattainable; a lamentable proof of which presents itself to view, when we consider the number of those very animals which he describes that have been ascertained, by recent observations, to be of a very different nature and structure from what he conceived. This error may be easily accounted for when we reflect that the judgment of Linnaeus was guided in many instances by analogy, and the indifferent figures extant in various writers, without himself possessing the means of determining their accuracy, or imperfection. We intend nothing to the disparagement of Linnaeus in this respect; the structure of the animal was of too much importance in his mind to be omitted, and he availed himself of the best sources of authority within his power, some of which, it has since been proved, are not so accurate as we could wish, and others altogether erroneous.

From all that has been advanced on this topic, the result will be obvious, that testaceous bodies may be consistently arranged, or, in other words, can only be arranged by the organization of the shell; that the primary character must be

taken from the shell because this we are acquainted with, while the animal is oftentimes unknown to us. But that the structure of the animal should be regarded in the construction of genera, when it can be ascertained; as a secondary consideration to guide us in the formation of new genera, or in correcting the old, as opportunities of investigating them occur.

Having defined the meaning of a testaceous animal, and endeavoured to prove that the structure of the shell is the most material object to be regarded in a primary view, we shall proceed next to an elementary elucidation of the several parts of which it is composed.

In conchology, as in any other science, the student must necessarily acquire, in the first instance, a distinct knowledge of the terms employed. These, except such as relate to subordinate characters, or specific distinctions, and which require no explanation in this place, may be simplified and reduced to a small number. In the selection of these terms we can abide by no one particular authority; we must be general, deriving our terms from various sources, or inventing new ones. Hitherto in treating on the different articles of conchology, in the progress of this work, it has been our aim to adhere as nearly to the authority of Linnaeus as possible, reserving to ourselves an opportunity of expressing our own sentiments under the present article, and stating generally these points upon which we principally differ in opinion from that author. This will appear more fully in our review of his genera. Our attention is at this time confined to the terms employed in describing the several parts of shells, and as it is well known that Linnaeus laid down a series of terms for this purpose, it will be expected that we should not pass over them in silence. Upon this subject we shall however only trespass lightly. We would willingly adopt those established by Linnaeus, in his "Fundamenta Testaceologie," and other writings; but it must be confessed, with all our respect for the talents of that naturalist, his terms are inadmissible. The warmth of his admirers, and we must, on many occasions, profess ourselves of that number, will not peruse the definitions he has given of the bivalves, of his venus, and some other bivalve genera, of his venus dione, and also of several univalves, without admitting that much of the Linnaean phraseology on this subject is neither applicable to the parts intended, nor if it were, such as modesty would allow us to retain; and that to expunge them is only a necessary sacrifice which the exactness of science imperiously demands. Delicacy will pardon the allusion, and desire no further explanation.

All shells or testaceous bodies hitherto discovered, may be divided into three principal tribes, and which, after the Linnaean manner, may be denominated Multivalve, Bivalve, and Univalve.

Any external part of a shell being of a testaceous substance, and either itself, forming a shield or covering for the animal, as in univalves, or in union with another, or others connected by a ligament, cartilage, hinge, teeth, or other fastening, is denominated a valve. The shells therefore consisting of a single piece, are called univalves, those of two parts bivalves, and those of many parts multivalves. Between bivalve and multivalve no distinction is drawn, shells consisting of more than two such parts, being called multivalve, without any regard to the number. An amendment is proposed by some of the French writers, in a new order under the name of trivalve.

Shells of the simplest form are arranged by some naturalists in the first class, from which they proceed progressively to those possessing the greatest number of valves, and being of the most intricate structure. This is an ancient, and very simple

simple mode of arrangement, and has its advocates in the present day. Linnæus reverses this order by beginning with the chiton, lepas, and pholas, which are shells of the multivalve and most complex structure, and ending with those of the simplest form. We cannot avoid thinking the former preferable, and shall adopt it in the present instance.

Explanation of the Parts of Shells with Reference to the Elementary Plates of Conchology.

Univalve.

In the examination of a shell of this order, the contour, or outline, is the first particular to be regarded. By this the conchologist is guided in his definition of simple, spiral, or turbinated shells, (or as the Linnæan school divides shells, univalves with a regular spire, and univalves without a regular spire); discoid, flattened, or turritid shells; those with smooth or uneven *anfractus*; the ventricose, alated, labiated, rostrated, and many other distinctions, all which strike the eye at the first view. It is indeed, by attending to the contour, that the principal distinctions in shells of this kind are at once perceived, taking into consideration the back and front profile at the same time. Some few shells, as the nautilus pompilius, and others of the same family, have the spire revolving internally, in which the outline offers less assistance in the primary definitions, but the number of such shells is very small. Next to the profile of the shell, the structure of the mouth, the pillar, and expansion of the inner lip, the gutter or canalisation, and the umbilical opening, and operculum if any, are to be considered, and lastly the work on the outer surface, as well as the colours with which it is embellished.

The base or bottom of the shell we consider that part upon which it rests when supported in an erect position, with the summit or tip of the spire standing vertically. In such shells the tip is called the apex. The course of the spires or wreaths is from the left to right in most spiral shells, some few only being of the reversed or heterotrophous kind, the whorls of which are in a contrary direction. When speaking of the right and left sides of a shell, it should be understood as having the aperture downwards, and it will be then seen that in most shells the aperture or opening is on the left side, *i. e.* facing the right hand of the spectator.

Base, the tip of the salient end of the shell, at the extremity opposite the apex of the spire; in the rostrated kind of univalves it implies the tip of the beak. Some say the shell rests on its base when laid upon a flat surface, with the mouth downwards; this is not correct, except in the patella tribe, and some other univalves which have no regular spire, as the dentalium, &c. The base in several shells is denoted in the Plate, *Conchology*, fig. 1.

Apex, the summit of the shell. Fig. 2.

Front, the face of the shell with the aperture placed directly in front of the observer. Fig. 3.

Back, that part of the shell which is immediately opposed to the preceding. Fig. 4.

Sides, those parts seen longitudinally in profile, to the right and left when the shell is viewed either in a front or back position. Fig. 5.

Body, of the shell, (corpus) the first whorl of the spire at the base. Fig. 6.

Belly, is to be distinguished from the body as it implies only the convex or swollen part of the first whorl, formed by the convexity of the aperture near the lip. Fig. 7.

Whorl denotes one of the wreaths, turns, or volutions of the shell. Fig. 8.

Spire, comprehends, in a general sense, all the whorls of the shell, the first or body wreath excepted. Fig. 9.

The form of the spire is of great consideration in the definition of shells as it affords a prominent and distinguished character; it is in general flatish, somewhat depressed or elevated; sometimes convex and slightly pointed; or with the point obtuse; or much elevated and ending in a point; plano-concave, pyramidal, subulate, or truncated. Mr. Adanson observes that the disposition of the spires varies according to the plane they turn on, which is either horizontal, cylindrical, conic, or ovoid. These, he conceives to be the four principal dispositions of the spires, but admits there are many intermediate formations. The number and form of the spires vary in the same species, in their different growths. Young shells have commonly a less number than the old ones, neither have shells of the same age always the like number of spires, a circumstance attributable to the effects of sickness, or the difference of sex. Thus in some turbinated shells we perceive that the males have the spire less numerous, smaller, and of a more lengthened form than in the females.

Suture of the spire or whorls, is the spiral line which separates the whorls, and which is sometimes sulcated, crenulated, or somewhat projecting. Fig. 10.

Pillar or Columella, is the inner part of the left lip, or column, which runs through the shell, from the lower extremity to the tip of the spire, and from which all the spires take their origin; the columella being situated as nearly as possible in the axis of the shell, and serving as its basis and support throughout. It is generally either flat, grooved, folded, or truncated in that part which is visible at the opening. Fig. 11.

Aperture, called in familiar language, the mouth of the shell, is the entrance to the chamber in which the animal resides, and is applicable to the openings of univalve and multivalve shells. The aperture is either entirely open, or closed by the operculum attached to the body of the animal, when the animal retires into its dwelling. This aperture varies in form in different shells, being angular, rounded, semilunar, linear, or otherwise, and sometimes appears double, the inner margin being surrounded by an exterior one. Fig. 12.

Lip, the expansion of the exterior part of the aperture constitutes the lip in the labiated shells, and the wing in the alated kinds. Fig. 13.

Beak, or rostrum, is that part at the base which extends in a straight or slightly oblique direction from the bottom of the aperture, and is larger or smaller in different families. In *murex haustellum* this projection is very conspicuous. Fig. 14.

Canal, or gutter, an elongation of the aperture of the shell descending in a groove or gutter-like process. Some kinds of rostrated shells have the canal remarkably conspicuous, forming a sinus from the aperture throughout the whole length of the beak. Fig. 15.

Umbilicus is the opening, or perforation in the lower part of the body, or first whorl of many spiral univalves, and is very conspicuous in a number of the trochus and nerita genus in particular. This umbilical perforation runs in a straight line from the base to the summit of the shell, forming throughout a spiral groove or gutter, which is wide at the entrance, and tapers gradually towards the apex. In the Linnæan *nerita canrena*, the structure of the umbilicus is well displayed, but is still more obvious in the staircase shell, trochus *perpetuus*. This opening occurs in many shells at the base of the pillar. Fig. 17-

tudinal line is drawn from the beak to the opposite margin, the space on each side the line is distinguished by the appellation of the right and left side; and when the form of both those spaces correspond, the shell is equilateral, as in the scallops (*ostrea*, Linn.): the inequilateral valves are the reverse of this, a line drawn as above described, from the beak to the opposite margin, presenting two sides of a very different shape, as we see in most of the *mastra*, the *donax*, and *tellina* genera, and in the *mya truncata* especially. Sub-equilateral shells, or those having the valves nearly equal at both sides, are sufficiently elucidated by shells of the *cardium*, or *cockle* genus, which are strictly "bivalvis subæquilatera."

All bivalve shells do not completely close their shells, though most of those before mentioned do so, such as the scallop, the *donax*, *tellina*, and *cardium*: in several other tribes of bivalves, when the shells are shut as closely as their form will allow, they still exhibit a kind of hiatus or gaping, either at the anterior or posterior end, or at both; and in some, when the valves are shut, both the anterior and posterior parts are closed, but an opening appears on one side of the beak; this last-mentioned character is very obvious in *chama gigas*.

One of the first circumstances to be considered, is which part of a bivalve shell ought to be deemed the base, because when this is determined, every other part will fall progressively in their relative order under our observation. We name that part of the margin or limb which is situated in a direct line opposite the beak, the base of the shell. Linnæus, in order to establish the characters, and afford some apparent reason at least for the application of the terms he bestows on the different parts of bivalves, reverses this position of the shell, and describes the beaks as the base of the shell. But the fact is, the natural position of the shell is in immediate contradiction to his axiom, for the beaks are always uppermost, being either immediately vertical, or with a slight inclination obliquely, when the animal moves along with its tectaceous covering on the back. A solitary example will perhaps occur occasionally, in which the beaks may be considerably inclined when the animal crawls, but none, we believe, are known which open the valves upwards, and proceed with the beaks under the body. The beaks, if only for this reason, are to be considered as the summit, and the margin opposite as the base. Many of the bivalves are destitute of the locomotive power, or at least do not possess it in any material degree.

Base of bivalve shells, exemplified in *venus verrucosa*. Fig. 22.

Summit, a word applied in a general manner to the top or most elevated part of the two protuberances observable in the greater number of bivalves. Da Costa calls that part of the shell, in which the teeth or hinge is placed, the summit or apex; we regard it as the most elevated part of the beaks. Fig. 23.

Beak, the pointed termination, apex, or tip of the protuberances last-mentioned, and which, in many shells, turn spirally downwards, or obliquely, so that the beak itself is seldom the most elevated part of the shell: though it is so sometimes, as for instance in the *mytilus edulis*, or common *muscle*. Fig. 24.

Sides, the lateral parts of the valves distinguished by the epithet of right and left side; in common language, the two valves of a shell are called the sides, but it is not understood as a term in conchology in this view. Fig. 25.

Margin, or *limb*, the whole circumference or outline of the shell, when laid flat down on one valve. Fig. 26.

Dish, the convex centre of each valve, or exterior surface. Fig. 27.

Anterior slope, that part of the shell in which the ligament is situated; in the front view of the anterior slope, the beaks fall back, or behind. Fig. 28.

Posterior slope, that immediately opposed to the former, and in which the beaks of the shell turn forward. Fig. 29.

Lunule, the lunulated depression below the beaks, either on the anterior or posterior slope, and sometimes on both; they may be distinguished under the appellation of anterior or posterior lunules, according to the slope in which they are situated. Fig. 30, a, b.

Cartilage of the hinge, called also the ligament of the hinge, the substance of a flexible, fibrous, and somewhat horny nature, by means of which, the two valves are united near the beak. Fig. 31.

Ears, the lateral processes near the beaks, as in the scallop tribe: those occur either on one side, or on both. Fig. 32.

Ligament perforation, the opening, or aperture, through which the ligature of the animal passes in the anomia genus, by the assistance of which it fastens itself to the rocks, or other bodies; in some it is situated in the flat valve, in others at the beak of the gibbous valve. Fig. 33.

Length and breadth of the shell. The length is measured from the cartilage or beak to the margin below, the breadth is of course taken in the opposite direction. The breadth of many bivalve shells exceeds their length: some remarkable instances of which occur in the solen tribe. Fig. 34.

Inside of the valves exhibits the concave surface (*concauitas concharum*), fig. 35.

Hinge, the point of union between the two valves, formed by the connection or articulation of the teeth in both valves, or by the teeth in one valve, fitting into hollows or sockets in the valve opposite. The amazing variety of structure observable in the hinge of different tribes of shells renders this one of the most essential characters in the general definitions of shells. The teeth in some are small and numerous, in others thick, solid, and few in number, or sometimes single, long, spatuliform, laminiform, acicular, &c. the principal of which may be divided into *inarticulate* hinge, when only furnished with callosities, or having no visible teeth; *articulate*, when it has teeth, but only a small number; and *multarticulate*, when the teeth are numerous. These variations will be further explained under the respective genera.

Cicatrix, the impression on the inside of the valves indicating the point of connexion between the muscles of the animal, and its shell. In some kinds, as the common oyster for example, there is only one such muscular impression in each valve, in others there are two, and some have more. The cicatrix is not of the same figure in all shells, being either round, semi-ovate, lunate, or elongated, in different kinds. Fig. 37.

Byssus, the appendage called the beard; by means of which some bivalves fasten themselves to the rocks. Fig. 38.

The imbrications, furrows, spines, tubercles, reticulations, striations, or other peculiarities of the same nature, as well as the variations of colours, observable on the exterior surface of bivalves as before stated in speaking of univalves (and which is indeed equally applicable to the multivalves, and consequently to shells of every description), though they afford us the best specific distinctions possible, do not claim our regard as primary characters, and are therefore passed unnoticed in this place.

Multivalves.

The shells of this order are few, compared with either of the preceding; and the terms proposed for those, are applicable for the most part to the multivalves. The following require more explicit mention.

Base, that part of the shell upon which it rests: in the lepas tribe it implies the part immediately seated upon the stem or pedicle; in the balan, the base is generally larger than the summit, and is the bottom by means of which the shell is fixed upon the rocks, or other extraneous bodies. *Fig. 39.*

Ligament, the substance, whether membranaceous or tendinous, which serves to connect the valves together. The connexion of the valves in some multivalves is formed by the parts of one valve locking into another. *Fig. 40.*

Operculum. The balan has the aperture at the summit closed by means of four small pieces or valves, which are commonly called the operculum; these opercula of the balan are, however, very different from those of univalve shells. *Fig. 41.*

The various parts of which testaceous bodies consist being sufficiently considered and explained, our attention is next directed to the different modes of arrangement into which those bodies have been distributed by the principal writers on conchology, and a general inquiry into a variety of other particulars connected with the history of the science. In this investigation we shall avail ourselves in some measure of the method pointed out by the learned author of the "Classes Conchyliorum" (Bergen), the valuable "Bibliotheca Hist. Natur. Bankiana" of Mr. Dryander; "La Conchologie" of Favanne; the "Historical Account of Testaceous writers," by Dr. Maton and Mr. Rackett, inserted in the "Transactions of the Linnæan Society," and the labours of many others, in addition to our own, will appear in the course of the following observations.

The name of Aristotle stands high in the records of philosophy. He is emphatically called by Dr. Pultney, in speaking of testaceous writers, the father of natural science; and by Dr. Maton the inventor of system. Our respect for the Macedonian philosopher is great, nor would we willingly appear to detract from his distinguished merit; yet we must confess we never could conceive it possible, with all the ability this early writer possessed, that, rising as it were from primeval darkness, he could at once survey the multifarious objects of creation, and produce a system of natural objects so complete as that which we are disposed to acknowledge exclusively as his own. He must have derived considerable aid from sources then extant, and which are now for ever lost to the world. The history of mankind throughout all ages will testify beyond a doubt that the acquirement of human knowledge is slow and progressive; and the knowledge of Aristotle in natural science was in particular of that kind which in a great measure could be attained only from the observations of many. Under the patronage of Philip, the Macedonian monarch, and of his son Alexander, the hero of the world, no advantages which Aristotle could derive from the study of books would be denied him, and can it be imagined from so many hundred thousand volumes as were extant in his time, and at his immediate command, Aristotle was unable to obtain information; or that among this immense number there were none on the subject of Aristotle's inquiries? This writer would certainly avail himself of the recorded labours and discoveries of former ages, and especially would not neglect to cultivate an acquaintance with the sciences of the Egyptians, upon all which his own ideas might improve. Indeed, if we mistake not, however visionary it may appear, the latter was the genuine source

from whence his knowledge of natural philosophy was derived. Egypt, not Attica, was the cradle of science.

To the writings of Aristotle the learned world is certainly indebted for the first account we probably ever may possess of the state of natural science at the early period in which he lived; it is a fortunate circumstance for the cause of learning that his labours have survived the havoc of destructive time. This system is a production that would confer credit on any naturalist of the fourteenth century, much less of a period almost two thousand years before. The classification, or division of shells contained in the fourth book of "Aristotle's History of Animals," has stood the test of ages, and, with improvements, rendered necessary by recent discoveries, is in general adopted by very late writers. Linnæus was in a great measure himself indebted to his system for the outlines of his own, for many of his genera, and for the names under which those genera are retained, even in the most improved state of his "System of Testaceology."

The "Oltracodermata" of Aristotle, for such is the title of his conchological productions, present us with a valuable scheme of shells. He divides all shells into two principal classes, *Movibura* and *Δίβυρα*, or univalves and bivalves.

The univalves he separates into two parts; namely, those of the turbinated kind, as *Κοχλίας*, or *limaces*, *Καχλίας*, *cochalis*, the *purpura*, *Πορφύρα*, *buccina*, *Κόρυς*, &c.; and such as are less turbinated, as *Δεπας*, the sea-ears, or haliotis, and *Νηπύρα*, *nerite*. Among the latter, he includes several families of the echinus, or sea-eggs, *Εχμυς*, a tribe of crustaceous animals retained by almost every writer among the shells, till they were separated by Linnæus. He also speaks of the animals inhabiting the coccolia, *purpura*, and *buccina*.

The bivalves he distributes into several families; he has *Κλινας*, or *pelecines*, *Σακμυς*, *solene*, and *Πλωα*, *pinna* or sea-hams, all of which genera have been retained by Linnæus, and later authors.

Aristotle commits one remarkable error, however, in placing the opercula of some turbinated univalves as a genuine tribe of shells. This error, which indeed we think excusable considering the age in which that philosopher lived, is mentioned by several authors as an objection to his accuracy of discrimination, and is commented on by Bergen in the following observation.

"Ex umbilicis *βίς κήχρας* videtur Aristoteles peculiare conchyliorum genus perperam constituisse, sunt enim proprie opercula quorundam turbinatorum, quæ certo anni tempore foribus cochlæarum quasi instar claustris, agglutinata inveniuntur quæque postea decidunt & nullius amplius usus pro ipso animalculo." Aristotle flourished 322 years before Christ.

C. S. Pliny wrote largely upon conchology; the ninth book of his "History of Animals" is very copious: it is more diffuse than that of Aristotle, and the arrangement is unmethodical, but this is still an useful work, and may be consulted with advantage. Many of the terms employed by modern conchologists are to be found in his work. Pliny constitutes thirty-three families, which are distinguished chiefly by the form and superficies of the shell, as *plana*, *convexa*, *longa*, and *lunata*, *levis*, and *rugata*; by the shape of the margin, as *marginè in mucronem emisso*; *marginè fortis effuso*; and *marginè intus replicato*. The sinuosities, or projections of the shell, the connexion of the valves, and other similar characters, were also taken as distinctions of the different families.

In Pliny's time the Romans are supposed to have possessed considerable opportunities of acquiring a knowledge of shells, as their navigation was extensive, at least in the Mediterranean and the Red Sea.

The conchological writings of Ælian are held in less repute than either of the preceding; he dedicates some conchic chapters to this subject in his work entitled, "Ἱστορία Ζῴων ἁδυστησίων."

After the dark ages which succeeded, Vincentius Bellouacensis was one of the earliest writers on this subject. His "Speculum naturale," published in folio, in the year 1494, contains a description of the murex, purpura, ostrea, and a few other remarkable shells, extracted chiefly from the works of Aristotle and Pliny, and intermingled with the absurd and superstitious notions of the times. The works of Albertus Magnus, entitled "De Animalibus," which appeared in folio in 1497, contains descriptions of some shells; and so likewise does that of Adam Lonicerus, "Historia naturalis opus novum," published in 1551.

The first writers who distinguished themselves by any attention to the study of conchology, after the revival of letters in Europe, were Belon, Rondeletius, and Gesner. Belon is celebrated for his travels in the East, and he was perhaps one of the first learned men who travelled principally with a view to natural science; on his return to Paris, in 1553, he published, besides other works, an octavo volume, entitled "De Aquatilibus." The part appropriated to conchology is not extensive, it is rather elementary and philological than descriptive; but contains figures of a few shells engraven on wood. The work of Rondeletius (professor of physic at Montpelier) appeared two years after, A. D. 1555; this bears the title of "Uniuersa Aquatiliu Historia," and contains upwards of one hundred species of testaceous animals. His residence on the coast of the Mediterranean afforded him abundant opportunity of investigating the shells of that sea, and their animal inhabitants, a subject of inquiry to which he paid some attention. This author received much assistance from the labours of Aristotle and Pliny. The "Commentaries" of Matthiolus, embellished with a few cuts of shells, contain nothing of material interest, except what has been collected from former writers; several editions of this work appeared between the years 1506 and 1683, in Spain, Italy, France, and the Venetian States. In 1558, the work of Conrad Gesner, "De Piscium et Aquatiliu Animantium Historia," made its appearance, and acquired much reputation. Dr. Paltney pays a high compliment to Gesner for his unparalleled industry, and ardent love of natural history, and observes, that he not only collected all the philological, historic, and descriptive erudition of the ancients on this subject; but besides his own copious comment on their writings availed himself of what Belon and Rondeletius, his contemporaries, had done, to which he added much original matter of his own, having described and figured many of the Mediterranean shells and several of those discovered in the Indian and Arabian seas. This comment is correct, but of the system proposed by Gesner for the classification of shells, we must speak more fully. This author divides all shells into four classes, *univalvia*, *bivalvia*, *turbinata*, and *anomala*. The first contains only two genera, *lepas* and *auris marina*; or the *Ear*s, and *sea ears* (*lepas* derived from the Greeks, and synonymous with *patella*, being the name applied by old conchologists to the limpets, since called *patella* by Linnæus). His *bivalvia* class contains many genera, as *ostrea*, *spondyli*, *mytili*, *tellines*, *chame*, *pinne*, *solenes*, and eight others. In the third class *turbinata* he has ten genera, as *tr*mbi, *murex*, *buccinum*, *turbo*, *trochus*, *serices*, &c. all which names will be recognized by the Linnæan student as those employed by Linnæus. His fourth class *anomala*, is exceptional, as it contains, besides the *balani*, *penicilla marina*, *tubuli marini*, and *echini*, the *stellæ marinæ*, or

star-fish, and *caput medusæ*, neither of which have ever been considered by other naturalists as appertaining to conchology. Bergen admits this as a material objection to his system, "Peculiarem classem anomalorum condidit, ad quam, ut mihi videtur, adnumerandæ. Idem valet de capite medusæ." His separation of the *balani* from the two first classes is countenanced by all late writers.

Geoffrey Linnœier, in his "Histoire des Poissons," published at Paris in the year 1558, gives an account only of a small number of shells; the work not being devoted to the subject of conchology; neither is that of Imperato, published at Naples in 1599; though it contains an account of some species, this production relating chiefly to fishes; it bears the title of "Dell'Historia di Ferrate Imperato Napolitana."

The work "De Molibus Crustaceis, Testaceis, et Zöophytis," of Aldrovandus, appeared in folio, in 1606, and is well known. His arrangement consists of three classes, *turbinata*, *bivalvia*, and *univalvia*. Among the *turbinata* he includes the *nautilus*, and also the *buccinum*, and other spiral shells, together with the *echini*. The *bivalvia* class is the same with that of all other writers, as *ostrea*, *tellina*, and *pinna*, but besides these includes the multivalve shells of late authors, such as the *balani* and *pholades*. The third class, or *univalvia*, contains the *lepas*, *patellæ*, *auris marina*, *concha veneræ*, *concha perficæ*, and *penicillus marinus*. The figures consist of cuts on wood, and are rudely executed.

Fabius Columna, in 1616, published a treatise on shells, or rather a monograph on the purpura, entitled "De Purpura ab animali testaceo fusa, de hoc ipso animali, aliisque varioribus testaceis quibusdam." A new edition of this work, with annotations, appeared in 1675, by John Daniel Major.

In the year 1616, a work entitled "Fasciculus rariorum et aspectu dignorum varii generis, quæ collegit et suis impensis æri ad vivum incidit curavit," from the pen of Basil Bessler, apothecary at Nuremberg, made its appearance; it is in Latin and German, and two of the plates are appropriated to the subject of shells.

Chiocco, the describer of the "Museum Calceolarium," published at Verona, in 1622, gives a full account of the shells contained in that collection, with specific characters in the Latin language, borrowed for the most part from other authors. This museum was begun by Benedicte Ceruto, a physician, and afterwards enlarged by Calcolari. The figures of the shells occupy six plates. It appears to be the first work that was written professedly as a description of a museum of natural curiosities, the account of the same museum by J. P. Olivier, published in 1584, alone excepted.

A physician of Hamburg, Schonvelde, was author of an account of aquatic animals, both of the marine and fresh water kinds, found in the duchies of Sleswick and Holstein, which contains separate chapters on oysters and murexes. The observations relate chiefly to the culinary uses of the animals. This book bears date 1628.

The work of Nierembergus, "Historia Naturæ," contains an account of a number of shells, but does not present us with any figures. It was published at Antwerp, in 1635.

In the first edition of the "Gazophylacium Rerum Naturalium" of M. P. Bessler, the brother of Basil Bessler before-mentioned, are twenty-four plates, containing, among a variety of other subjects, natural and artificial, a few figures of shells, with a concise description in Latin of each, under the respective figures. The second edition comprises six

ix additional plates and a preface in German. The first was published in 1642, the latter not till the year 1733.

The fynoptical catalogue of Seger, "Synopsis Methodica rariorum tum Naturalium tum Artificialium quæ in Musæo D. Olei Wormiis afferantur," was printed at Copenhagen in 1653; and, as the title informs us, describes both the natural and artificial curiosities in the museum of Wormius. This was succeeded in 1655; by a more ample account of the museum by Olaus Wormius, from which it appears to have contained many of the testaceous tribe, one only of which is however figured; this is the Linnæan *lepas anatifera*, to which is attached the whole of the absurd tale related by credulous writers of that day respecting the bernacle goose, which was supposed to be engendered, and hatched in those shells! The sixth, seventh, and eighth chapters of this work are descriptive of shells; these he divides into univalvia, bivalvia, and turbinata.

In 1672, the "Museum Moscardianum," or "An account of the collection of natural curiosities belonging to an Italian nobleman, Conte Lodovico Moscardo," appeared at Padua. The shells are comprised in twelve plates, and the subjects are noticed specifically. Another edition of this work made its appearance in 1672, at Verona, the city where that noble collector resided, which, besides the twelve plates above-mentioned (and which are engraven on copper) contains some cuts on wood.

The work "Historia Naturalis de Exanguibus Aquaticis" of Jonston, is an extensive production, a compilation for the most part from others, and is embellished with a number of engravings, comprehending altogether twenty copper plates of mollusca and testacea. Like Aldrovandus, he distributes all shells into three principal classes, turbinata, bivalvia, and univalvia. His turbinata are subdivided into two sections, "* in anfractu torta;" and "** in orbem circumacta." In the first of these, we find the nautilus, purpura, buccinum, marex, conchylium, and blatta byzantina; and in the other, turbines, trochi, nerites, cochlæa, and echini. Except the multivalves balani, and pholades, which he includes in his class bivalvia, the bivalves are those of later authors; the class univalvia contains two genera, the *lepas* or patella, and *concha venerca*. This work was published at Amsterdã in 1657. Eight-years after which (1665) the same author described a few of the more remarkable shells in his "Thaumatographia Naturalis."

About this time De Rochfort published an account of the shells of the Caribbee Isles, illustrated with a plate of five species, which he considered most remarkable for shape and beauty. This work bears the title of "Histoire Naturelle et Morale des Isles Antilles." Jean Baptiste du Tertre, also, published on the same subject, "Histoire generale des Antilles habitees par les François." Paris 1667.

The "Museum Gortorpiamum," or "Museum of the Duke of Holstein-Gottorp," was described by Adam Olearius, in 1666. This is in quarto, and of thirty-six plates which it contains, five consist of shells, all which are referred to by Linnæus in various parts of his Systema. Another edition came out in 1674.

In the "Pinax Rerum Naturalium Britannicarum," published in London in the year 1667, by Merret, we are presented with the earliest catalogue of the natural productions of Great Britain, extant. This is in octavo. The conchological part, which he calls "Testacei," occupies about half a page, and contains references to the voluminous works of Rondeletius, Gesner, Aldrovandus, and Jonston.

Charleton, a physician of considerable celebrity, published, in London, in the year 1668, his "Onomasticon Zo-

cum," in which a new arrangement appears. This author divides all shells after the manner of Aldrovandus and Jonston, into turbinata, univalvia, and bivalvia, from whence it will be perceived, he inverts the order of the two last classes. His turbinated genera are literally transcribed from Jonston. The univalves contain ten genera, five corresponding with those of Aldrovandus, *lepas*, *auris marina*, *concha venerca*, *concha perlica*, and *penicillus marinus*, to which are added *tubuli testacei*, *balani*, *conchæ anatifera*, *dentalia* and *entalia*. His bivalve genera are less happily defined: in addition to those established by Jonston, he forms others in imitation of Pliny, taken solely from the scaly aperities, spines, or smooth exterior surface of the shells, after previously dividing the whole class of bivalves into two orders "conchæ aspera, and conchæ læves."

Nothing appeared from this time of material consequence on the subject, till the re-publication of the treatise of Fabius Columna, by Dr. Major. In the interval, Steno published a work, entitled, "De solido intra solidum naturaliter contento Dissertationis Prodrômus," which contains some pages devoted to an explanation of the fabric and texture of testaceous bodies. Boyle described some experiments on the phenomena of shell-fish, particularly of the oyster, under an exhausted receiver, in the Philosophical Transactions of the year 1675; and Willis, in 1672, the anatomy of the oyster, in his "Exercitationes de Anima Brutorum;" but these are only physiological dissertations. The work of Dr. Major includes a new system annexed to the history of the purpura previously published by Fabius Columna, and likewise a "Dictionarium Otracologicum;" and is besides illustrated with a number of wood-cuts. All shells are divided by this system into two classes, univalvia and plurivalvia, the first of which are subdivided into several orders, the characters of which are taken from the form and structure of the opening of the shell, its turbination, ventricosity, protuberances, or general figure. The genera constituted of those shells are few, as *penicillus marinus*, pyramidaliter dentata, *lepas* vel *patella*, *auris marina*, *conchæ natatiles*, *concha venerca*, *nautilus*, *murice*, *turbo*, *turbines terrestres*, and *buccina*. His class plurivalvia is separated into two orders, bivalvia and plurivalvia, the first of which consists of his *conchæ striatæ*, *conchæ verrucosæ*, *conchæ rugosæ*, *pectines*, *ostrea*, and *conchæ anomæ*; the plurivalvia only two genera, *conchæ anatifera* and *balani*, or *glandes*. The two latter genera are those united by Linnæus, under the name of *lepas*, and which, before the time of Major, had been improperly arranged, either among the bivalves, or univalves, except by Gesner, who, aware of this impropriety, places the *balani* at the head of his class anomala. This production of Major's appeared in 1675.

Legati was author of the "Museo Cospiano," printed at Bologna in 1677. The basis of this collection was laid by the celebrated Aldrovandus, whose hand-writing still remains affixed to many specimens that formed the subjects of Legati's description. Ferdinando Cospi, a Bolognese patrician, afterwards augmented it so considerably, that his name became attached to it; and the university of Bologna, to which it was at length presented, considered it one of their most valuable acquisitions. There are not many figures of shells in the "Museo Cospiano," but the descriptions of this tribe are numerous, and very ample.

In the twelfth volume of the Philosophical Transactions, is a "Relation concerning Barnacles," by sir Robert Moray. This credulous observer gives a description illustrated by a rough outline of *lepas anatifera*, from which he asserts, that young geese may actually be seen to emerge.

Harderus,

Harderus, in a dissertation entitled, "Examen anatomica Cochleæ terrestris domiportæ," affords an anatomical description of helix lucorum. This appeared at Basil in 1679. Two years after Grew published his "Museum Regalis Societatis," or "Catalogue and description of the natural and artificial rarities belonging to the Royal Society, and preserved in Gresham college, London." This was the earliest work of its kind that appeared in the English language. The shells are described in two chapters, the first comprehending univalves, the second bivalves and multivalves, illustrated with about forty figures, to which the current English names are annexed.

Buonanni was contemporary with Grew, and in the same year (1681) published at Rome his "Ricreazione dell' Occhio, e della Mente nell' osservatione delle Chiocciolle," a work of very superior merit, and esteemed the first professedly written, at any considerable length, upon the subject of conchology. This was originally printed in Italian; but was three years afterwards re-published, with additions, in Latin, under the title of "Recreatione Mentis et Oculi in Observacione Animalium testaceorum." The first work contains a series of 450 figures, the number of which is augmented to 550 in the Latin re-publication. These are valuable for reference, as being constantly mentioned in the Linnean Systema Naturæ; their greatest fault (and it is certainly a material objection), is that many of the shells are reversed by the inaccuracy of the engraver, so that the apertures of the spiral or turbinated shells turn to the left instead of the right. The subjects were obtained chiefly from the celebrated museum of Kircher; a description of which was afterwards given by Buonanni under the title of "Museum Kircherianum."

The descriptions are not entirely approved by late writers; they are considered too loose and desultory, or too concise and uninformative. His distribution of shells comprehends *univalvia non turbinata*, *bivalvia*, and *turbinata*. In the inferior divisions, this author, Dr. Maton observes, "has strangely separated species naturally allied to each other, as, for instance, the serpule, dentalia, &c. are left out of the first class, and, as well as the porcellanæ, distributed under the third; and, with equal want of consistency, the haliotis and nautilus (genera manifestly turbinated) are placed among those which he terms "univalvia non turbinata." The same objection is urged by Bergen against the system of Buonanni. "Hic A. tres condidit conchyliorum classes; univalvium, non turbinatorum, bivalvium et non turbinatorum, sed partim aliena immiscuit, partim necessaria omisit. Sic in prima classe merito desiderantur penicilli marini et porcellanæ, quas perperam ad turbinatas refert. Sic malo consilio aurem marinum, et nautilium huic primæ sociavit classis, cum manifeste ex turbinatorum gente sint." Buonanni is blamed also for admitting the pholades and conchæ anatifere into his second, or bivalve class; but it should be remembered, in this respect he only imitated the example of most systematic writers; Gesner places the pholades among the bivalves; Aldrovandus gives both the pholades and concha anatifera in that class; and Jonston the former. Linneus, we are to recollect, like the latter, considers the pholades as bivalves in all the early editions of the Systema; even so lately as the tenth edition, they stand under the "bivalvia conchæ." We may still further advert to Charleton, who yet more absurdly arranges the concha anatifera with the univalves, at the same time that he refers the pholades to the bivalve tribe. Major was the only writer before the time of Buonanni who disposed of the conchæ anatifere in their natural order, which he certainly did, by arranging it in his class plurivalvia. In the work of Buonanni will be found many philosophical observa-

tions upon the origin, nature, formation, properties, and other curious particulars relative to testaceous bodies.

The "Scotia Illustrata" of Sir Robert Sibbald, published at Edinburgh in 1684, offers an outline of another system. The author divides shells into two parts, the land and aquatic kinds, or "cochleæ terrestres," and "cochleæ aquatiles." The aquatiles are divided into two sections, the first containing the fresh-water shells, the other those peculiar to the marine element. The shells of both kinds are distributed into three families, turbinatæ, bivalves, and univalves. The subdivisions of those families are rudely defined, but upon the whole there is method in the classification; the genera are selected from the writings of former naturalists, but too sparingly. Sibbald places the echini among the turbinated shells; yet this is even more excusable than his introduction of both the pholades and balani among the univalves.

Marigli's small work on the ova of testaceous animals, appeared at Bologna, in 1683, under the title of "Relazione del Ritrovamento dell' uova di Chiocciolle;" a new edition of which was published at Rome in 1695. Some additional observations on the same subject, by Fulberti, "Riflessioni sopra il medesimo Soggetto," usually accompany this work.

Among the "Osservazioni Naturali" of Paolo Boccone, published at Bologna in 1684, are some remarks not altogether uninteresting on the subject of conchology. He was the first writer who described the pediculus ceti (lepas diadema of late authors) with accuracy.

In the same year Dettelde gave an anatomical description of the common muscle in the Leipzig Commentaries, and which was afterwards re-published in Valentini's "Amphitheatrum Zootomicum."

An elaborate paper on the purple-fish (buccinum lapillus) by Mr. William Cole, pointing out the mode of obtaining, and the nature of this celebrated dye, or Tyrian purple, was inserted shortly after in the Transactions of the Royal Society. This tract was re-printed in quarto in 1689.

A production of very uncommon merit about this period made its appearance before the public, the great conchological work of Dr. Lister, entitled "Historia five Synopsis methodica Conchyliorum;" the publication of which commenced in 1685. The author had previously distinguished himself by some excellent dissertations on the same subject; but our attention is principally directed to this, as his most extensive, if not most valuable, undertaking. It was published in folio progressively from the year 1685 to 1692.

Lister divides his work into four books. 1. "De turbinibus terrestribus." 2. "De Turbi. aquæ dulcis et Bivalvibus aquæ dulcis." 3. "De Bivalv. marinis, et conchis anatifereis." 4. "De Patellis Dentalibus, &c. et de Buccinis marinis."

There is no text to this work, the whole consisting of engravings, with a concise description of the shells, and reference to their native country, where that could be ascertained, in the Latin tongue; and sometimes their current names in English. The plates, which are of various dimensions, are executed with great force and strength of colour by the hands of the author's two daughters, Susanna and Ann Lister. It is an extraordinary circumstance, that no two copies of this work are found alike, which renders it very complex, and ill suited for general reference. The plates in the most perfect copies vary in number from 1050, to 1057, or 1067, the different copies having been augmented or diminished, and the plates transposed or corrected at various times, according to the fancy of the author, or his subsequent discoveries. The most perfect of all the copies extant was that

that presented by Dr. Lister himself to the royal library at Paris. This is ascertained by the observations of Davila and M. de Bure, who have taken considerable pains in the collation of different copies of this work. Da Costa names that in the library of the College of Physicians as the most complete copy in London. This last-mentioned writer appears also to have collated many of the early copies of Lister; he treats on this topic at some length; and, considering the importance of Lister's work to the conchological student, it may not be improper to repeat the result of his observations.

"I do not think it unentertaining (says this writer) to relate some circumstances relative to this useful and costly work, which have occurred to me, on the collation of many copies of the old editions of Lister, and on a collation of numbers of his proof prints dispersed among the curious by Dr. Lister himself before the names and numbers on the plates were added to complete the work; these proof prints, which are what the print collectors style variations, will lead us to some curious particulars that would otherwise be unknown. Dr. Lister in 1678 published his "Hist. Anim. Angl." in which he treats of English shells, and gives excellent figures of them, and good descriptions; he therefore designed this work, (his "Hist. Conchyl.") only for exotic or foreign shells, as evidently appears from the proof head plates of the first book. N. 8, 25, 33, 40, 43, 63, 74, 83, 99, 108, 125, and 136, which are entitled cochleæ, buccina, &c. exotica; but the word exotica was erased when he changed his mind to have a general history of shells, which probably was at the second book, and the erasure of the word exotica is even now plainly seen in all the quoted plates. Dr. Lister, to complete his intended work, carried home all the shells singly to his daughters to engrave on single or detached copper plates, (as is seen by the work) reserving their arrangement till he had a sufficient number, some not being done to his approbation, or getting better specimens afterwards, he had them re-engraved, and therefore many shells appear twice in his work, and in some only the first engraving, while in others only the second engraving is found; this circumstance is also evident from the proof plates, or variations." Da Costa further states it to be a mistaken supposition that there was only one edition of this work; there were, he says, certainly two, and he concludes with these observations in support of his assertion. "However, there are marks by which these editions may be distinguished by an accurate critic, viz. 1. The second edition has seventy-five shells more than the first. 2. In the preface, plate IV. the third paragraph begins "Septuaginta autem, &c." 3. In plate VII. which specifies the places where they are found, the first edition has only one column of names, whereas the second edition has a name, viz. Fret Magel, in a second column. 4. The title and all the head plates, as 1, 2, 3, 100, 106, 139, 140, &c. are printed partly in black and partly in red letters; whereas in the second edition only the title, plate I., is printed in red and black letters, all the others being printed only in black letters."

The plates of this work were bequeathed to the university of Oxford, and were re-published in 1770, under the direction of the Rev. Wm. Huddesford, keeper of the Ashmolean museum, who subjoined two indices, one according to Lister's distribution of the shells, the other after that of Linnæus. This edition differs from the former principally in containing several plates on one page, the whole amount is 1085, comprehending altogether 1153 shells, exclusive of the fossils and anatomical subjects; seven of the plates,

however, which appeared in the original work are omitted in this edition.

After this period, and previous to the work of Rumphius, the first edition of which appeared in 1705, the names of Feir, Norman, Schelhammer, and others, are recorded as contributors to the elucidation of conchology, yet their productions are to be regarded only as subservient to more extensive and important investigations. Fehr wrote a dissertation on the argonauta argo, which was printed in "Eph. Acad. Nat. Cur." A. D. 1686. Normann, in the same year, gave an anatomical dissertation on the purpura, which was published at Upsal. The observations of Schelhammer, published in "Eph. Acad. Nat. Cur.," relate to the subject of fresh water shells. Brachus also treats of the ova of some species of ostra. "Le Cabinet de la Bibliotheque de Saint Genevieve," of Du Molinet contains a few figures of shells. In the Philosophical Transactions, vol. xvii. is a communication on the subject of shells, addressed to Dr. Lister, by Mr. Banister who resided many years in Virginia, and in the same volume is a description of certain shells found in the East Indies by Witzen, but these are confessedly too imperfect to merit further mention. Sir Robert Sibbald also published some curious papers on testaceology about this time, but his system, and best production, on this subject, have been already noticed. Ericus, in a dissertation entitled "Conchæ anatifere vindicatae," refutes the absurd tale of the Bernacle geese hatching in those shells as related by sir Robert Moray. Leeuwenhoek published several treatises on the anatomy or internal structure of shells. Leigh notices a few of the British shells in his "Natural History of Lancashire;" and Wallace an inconsiderable number in his "Account of the islands of Orkney." The works of Petiver, which are dispersed in the 22d, 23d, and 24th volumes of the Philosophical Transactions, and his "Gazophylacium Naturæ et Artis," may be consulted with advantage, being referred to by Linnæus and other late conchologists. This brings us to the time of Rumphius.

The popular work ushered into the world under the immediate patronage of the liberal collector last mentioned, claims particular notice. This valuable acquisition, for so it must be considered, bears the title of "Amboinse Rarite it Kamer," the "Rarity Chamber of Amboyna;" and contains an account of the more remarkable natural curiosities in his museum, the productions of Amboyna, where they had been collected chiefly by Rumphius himself. The descriptive matter is from the pen of M. Schein Voet, and the plates are engraven in a bold style from the designs of Madame Merian. Of sixty plates with which this work is embellished, no less than thirty-three are devoted to the subject of shells, the total number of which amounts to about four hundred subjects, and many of these were of great rarity and price in those days. The passion for collecting and filling cabinets and museums began at this period to be very prevalent in Holland, from whence it afterwards extended over the other parts of Europe. The collection of Rumphius was an object worthy of emulation, and many wealthy individuals endeavoured to excel in this pursuit. The forming a collection of rarities at that period was considered a serious undertaking. Articles of rarity of this description will always obtain a considerable price. It is related as a matter of astonishment that Rumphius himself informs us a shell described in his work cost no less than five hundred florins. The sum is great, yet there are few cabinets of any note that do not include articles of equal or much superior value.

Lyonet

Lvoret estimated the price of his famous "ceño nulli" far higher, namely, 100*l.* sterling; and many instances of great prices being paid for such objects might be adduced. There are two editions of the work of Rumphius, the first written in the Dutch, the other in the German language.

Levin Vincent was one of the most distinguished Dutch collectors. Contemporary with Rumphius, he has left us a description of his museum, dated 1706, and bearing the title of "Waarheitonnel der Nature." This work was printed at Amsterdam entirely in the Dutch language; the various objects are represented as they were placed in cases, drawers, or boxes, in a confined manner in the museum; among which we recognize a pretty considerable number of shells. An abridged account of the museum, with impressions of the same plates, was published afterwards.

The paper of Reaumur, inserted in the memoirs of the French academy between the years 1709 and 1717, deserves the attention of the conchologist; they relate, for the most part, to the formation, growth, and motive powers of testaceous animals. The natural history of the pinnæ, and the formation of pearls, are amply treated of in a memoir which appeared in the volume for 1717.

In 1710 Fredericus Ruyfch published a description of his museum at Amsterdam, entitled "Theaurus Animalium primum;" it relates only in a partial degree to shells, the figures of which are grouped with coral and other substances as they stood in his museum.

Morton, the natural historian of Northamptonshire, describes many shells, for the figures of which he refers to Litter. This work was published in folio in 1712.

Among the plates illustrative of various curious subjects, contained in the museum of Gottwald of Deutzie, dated 1714, forty-three are appropriated to shells. Few of the original copies are complete; that possessed by sir Joseph Banks is perfect.

Three plates of shells are to be found in the botanical work of Barrelier, edited by the elder Jusseu, which appeared in 1714; and the like number in the "Rariora Musei Belliniani" of J. H. Lochner, published two years after. The "Amphitheatrum Zootomicum" of M. B. Valentini, brought forward at Frankfort in 1720, includes many extracts from foregoing authors, and some plates relative to shells, but which are not considered to possess any merit of originality, or execution. Bradley, in his philosophical account of the works of nature, touches on the subject of testaceology though in a superficial manner.

The valuable work of Car. Nic. Langius, "Methodus nova Testacea Marina in suas Classes, Genera, et Species distribuendi," was published in quarto at Lucerne, in 1721. To the writings of this able naturalist Linneus stands highly indebted. "He is an author (says Dr. Maton) not understanding the title of a scientific one, and whose system, so far as marine testacea are concerned, and of these alone he treats, certainly glances at the great clue to simplicity, which was afterwards so successfully and admirably seized by the great reformer of natural history in general."—"He is the first whose generic characters are founded on commodious distinctions; the aperture of univalves, and the hinge of bivalves, being particularly considered. These distinctions are not allowed their due importance throughout, for the contour of the shell is, in many instances, made the exclusive basis of the definition, and the adoption of this naturally led, as in other systems, to a most inconvenient and perplexed multiplication of genera. The parts, classes, and sections, also are far from being well conceived, and em-

barrafs rather than assist the investigation of the other divisions." After perusing these general strictures the curious reader may be desirous of acquiring some knowledge of this author's system. We are inclined to think it entitled to rather higher praise.

Langius divides shells into three parts. 1. Testacea marina univalvia, non turbinata. 2. Cochleæ marinae. 3. Concha marina.

His first part is subdivided into two classes. Class 1. Testacea marina univalvia non turbinata, et in fe non contorta. Class 2. Testacea marina univalvia, non turbinata in fe contorta, ita, ut eorum spiræ non promineant. His cochleæ marinae, or part. 2. consists of six classes, *viz.* 1. Cochleæ marinae longæ. 2. Cochleæ canaliculatae. 3. Cochleæ marinae ore et mucrone simul elongatis, prima spiræ notabiliter ventricosa. Buccina. 4. Cochleæ marinae ore, et mucrone elongatis, prima spiræ notabiliter angustior quam in Buccinis. Strombi. 5. Cochleæ marinae ore admodum brevi mucrone insigniter elongato. Turbines. Trochi. 6. Cochleæ marinae breviores ore et mucrone contractis. The third part, or conchæ marinae, consists of three classes. 1. Conchæ æquilatere. 2. Conchæ inæquilatere. 3. Conchæ anomale s. Valvis inæqualibus. The classes are divided into sections, the distinguishing characters of which are taken from the most prominent features of the various tribes of shells, as the form of the shell itself, the structure of the aperture, the canalication, or lip, &c. in univalves; and the shape of the valves, their dissimilarity, the beaks, hinge, teeth, &c. in bivalves. The sections are divided into many genera, the first class containing seventeen, the second fifty, and the third forty-three. Many of the genera of old writers are divided, and oftentimes not judiciously, into two or more genera, to which new names are assigned, that Linneus and later writers have adopted. We cannot further digress on the merits of this work, but as a system recommend it to the attention of the curious conchologist.

In the work, entitled "Ond en Nieuw Oost-Indien," by Valentyn, are sixteen plates of East Indian, or Amboyna shells. This bears date Amsterdam 1724 and 1726, having been published in folio parts. Those plates were afterwards fold separately with descriptions; the new edition of the plates appeared in 1734.

"Sloane's History of Jamaica" is a valuable work, and relates to conchology, among a miscellaneous variety of other departments of natural history. He was the first person who visited the West India islands for the sole purpose of investigating their natural productions, and his plates and descriptions relate of course to many subjects not before known. His discoveries were submitted to the public in 1725.

In the following year, John Christ. Kundmann published his "Promptuarium rerum naturalium et artificialium," &c. in quarto. He proposes three principal classes for the arrangement of shells. Class 1. Testacea univalvia non turbinata. Class 2. Testacea bivalvia. Class 3. Testacea univalvia turbinata; each of which is divided into a number of genera, somewhat after the method of Buonanni.

A new arrangement of shells, by John Ernst Hebenstreit, appeared at Leipzig in 1728: "Dissertatio de Ordibus Conchyliorum methodica Ratione institutendis." The limits of our observations will not permit us to enter minutely into this methodus testaceorum. The system of this author comprehends several principal classes: namely, Class 1. Univalvia irregularia. Class 2. Univalvia regularia, quæ spiræ carent. Class 3. Univalvia regularia, quæ spiræ gaudent magis turbinata, turbine per totum excurrente. Class 4. De

De vertice tantum turbinata, ore per totum hiant*, turbini-
bus obliquè flexis. Classis 5. Univalvia, vertice tantum tur-
binata, ore per totum hiant, spiris circa centrum flexis.
Classis 6. Minus turbinata spirâ unica brevi. Classis 7.
Bivalvia valvis per ginglynum connexis. Classis 8. Bi-
valvia per ginglynum coherentia. The outline of his
arrangement may be collected from his definition of the
classes. His families, or subdivisions, and genera are nume-
rous, and are characterized by the figure of the shell, the
aperture, hinge, and other remarkable particulars. Dr.
Morton accuses this writer of having introduced an useless,
if not unphilosophical distinction, between testacea and con-
chylia. Bergen previously makes the same objection. "Cl.
auctor distinguit inter testacea et conchylia, et notionem ge-
neraliorum tribuit prioribus, quia et malacollitri, et ostracoderma-
ta; conchylia vero sola ostracodermata sub se se com-
prehendunt, sed non magni momenti mihi videtur hæc distinctio,
si vicissim considero et perpendo sub nozione testæ et duram
et mollem testam intelligi posse."

The "Dissertatio Physica de Polythalamis, nova testa-
ceorum classe," of Breynius, comprehends an arrangement
of recent and fossil shells, but the chief merit of the work
is allowed to consist in the more exact definition this writer
affords of the *belemnites*, *ammonites*, and *orthoceratites*, than
had before appeared. Of the *orthoceras* tribe, he describes
eight distinct species, the two others are treated less copiously.
His classification of recent shells is far from perspi-
cuous. This was published in quarto in 1732.

About this period, the attention of many ingenious writ-
ers was directed to the investigation of the teredo, or ship-
worm, then, as it was believed, very recently imported from
warm climates into Europe; it was first observed in Holland.
The first alarm was given by the persons appointed to take
care of the dykes, who perceived, that the piles which were
of the hardest oak, and had been placed to defend the low
countries from the incursions of the sea, were eaten through
in a few months. The damage occasioned was immense, and
the people of Holland thrown into the utmost consternation,
till remedies were discovered to prevent the evil. Among
the writers on the subject, are Velliscieri, Roussel,
Patonius, Belkmeer, Massuet, and Sellius, the last of
whom particularly distinguished himself by his work en-
titled, "Historia Naturalis Terecinis seu Xylophagi Ma-
rini."

Du Hamel, in a paper inserted in the "Memoirs of the
French Academy," in 1736, treats on the purpura of the
ancients. The work of Swammerdam, "Biblia Naturæ,"
appeared in 1737, and will be found to contain much curi-
ous matter, and anatomical research into the nature of
testaceous animals. In 1739, the work of James Plancus,
"De Conchis Ariminensibus minus notis," appeared in
Venice. This relates principally to the minute shells
found at Rimini in the Adriatic sea. Some of the mi-
croscopic shells described by this author, very much resemble
the cornu ammonis. A second edition was published in
1748, and another at Rome in 1750.

Gualtieri's work on shells is a standard book of reference,
and as such is well known. This is entitled "Index Testa-
rum Conchyliorum quæ adseruantur in Museo Nicolai
Cassini," &c. &c. It was published in Latin at Florence, in
1741, and contains 110 plates of shells; the figures of the
naurales in which are singularly placed on their summit;
they are notwithstanding tolerably correct: the descriptive
matter is less interesting. This author exhibits a system of
shells composed by Tournefort, the celebrated botanist, long
before this time, from manuscripts on the subject that had

been presented to him by professor Targioni. This arrange-
ment is valuable, and highly worthy the perusal of the in-
quisitive conchologist. The Linnaean student, in particular,
will perceive that to Tournefort, as to Linnæus, he is in-
debted for some of the latest amendments of the Linnaean
system, and for many of the subdivisions and terms in pre-
sent use.

"La Conchyliologie" of D'Argenville is a voluminous
work, and contains a vast number of excellent descriptions,
and many figures. The first edition of this work appeared
anonymously, under the title of "L'Histoire Naturelle
éclaircie dans deux de ses parties principales, la Lithologie,
et la Conchyliologie," &c. in 1742; and a second edition,
considerably augmented, in 1754. The last edition was
published in the year 1780, with many additions, correc-
tions, improvements, and a series of plates containing
about 2000 figures, by M. Favanne de Moncervelle and his
son.

The name of Bartram occurs to a paper in the Phi-
losophical Transactions, vol. xliii. A.D. 1743, entitled
"Observations concerning the Salt-marsh Mussels, the Oy-
ster-banks, and Fresh-water Muscles of Pennsylvana," illus-
trated with figures. A copious account was also given
about this time by Needham, of the lepus anatifera. The
"Testaceo-Theologia" of Lefter, is embellished with 137
figures of shells, and abounds with physiological and ana-
tomical observations on the structure of these testaceous
animals.

Some mention is made of shells in Dr. Charles Smith's
"History of the Counties of Waterford, Cork, and Kerry,"
A.D. 1745—1756. Two papers, one relating to mytilus
lithophagus, and the other to pholas pusilla, are inserted in
vol. xlv. and vol. lv. of the Philosophical Transactions. In
sir John Hill's "History of Animals," are an arrangement
of shells, and some figures; it appeared in folio in 1752.

The first work of Klein's that claims mention in this
place is his "Descriptiones Tubulorum Marmorum," con-
taining nine plates, which chiefly represent different species
of belemnites, with various kinds of recent shells, as solenes,
dentalia, &c., and are introduced in order to complete his
arrangement of the tubular coverings of animals. But the
principal production of this writer is his "Tentamen Me-
thodi Ostracologicæ, sive Dispositio Naturalis Cochlidium
& Concharum, in suas classes, genera, & species," &c.,
printed at Leyden in 1753. It has been objected against
this work that the general divisions forming parts, sections,
classes, and genera, are too numerous; and what is worse,
that species are constituted, in some instances, without being
referable to any genus, and that, in one of the parts, there is
a solitary genus without any class. (Dr. Marten)—"Classes,
genera, & species nimium, ut mihi videtur, multiplicavit:
quæ sæpe sunt variationes specierum, species vocavit; quæ
sunt species, generum nomine insigniuit; & ex generibus
quibusdam classes condidit," &c. Bergen.

The outline of an arrangement formed by a naturalist so
eminent as Klein should not be passed over unnoticed. All
shells are divided by this writer into four principal parts, in
the following manner:

Par 1. *Cochlides*, canales testacei, circa principium tenes
& clausi, in gyros gradatim valiores constanti ratione cir-
cumnacti.

Par 2. *Conchæ*. Testæ vasculorum iustar explanatæ & con-
cavæ, variorum animalium exfanguium habitacula, testarum
numero a se invicem differentes.

Par 3. *Polyconchæ*, quæ pluribus valvulis quam duabus
gaudent.

Part 4. *Niduli testacei*, testacea animalium domicilia in forma niduli fœssis catervatim plerumque corporibus marinis superstructa.

The *cochleides* comprehend two sections, "cochlis simplex, ad cochlis composita:" these are again subdivided into families, and lastly into genera. Among the shells included in the first of these, we find the nautilus, cornu ammonis, neritæ, auris marina, trochus, Strombi, turbines, and the buccinum; and in the section cochlis composita, the bulla, porcellana, and murex. The second part, *conchæ*, of this author is comprised in three sections "monocoenchæ, discoenchæ æquales, and discoenchæ inæquales." Among the first of these, we observe the patella, in the second, the ostrea and spondylus, and in the third, the terebratula. Part 3, or *polyconchæ*, consists of "concha anatifera," Part 4, comprehends the baani under the title of "monolopos and polylopus;" and as an appendix to part 4, and as a fifth part, the "echinus marinus, and tubulus marinus."

Although the distribution of shells after the manner of Klein does not meet our ideas of a correct methodical arrangement, it is but candid to say, that many of the genera he proposes have been rejected by later writers without sufficient consideration, and others derived from his labours without acknowledgment. Let us pause and candidly examine this arrangement, and we shall perceive that not only Linnaeus himself derived very considerable assistance from his work, in the latter editions of the "Systema," but that many of the supposed new genera of the French writers, in the present day, are drawn from this very source. This work contains twelve plates, and besides the system above noticed, comprehends a dissertation on the form, growth, and colour of shells "De Formatione, Cremento et Coloribus Testarum."

The "Compectus Sciographicus Testaceorum" of J. H. Cochausen, was printed at Frankfort about the year 1750.

In 1755, a work of considerable importance, the production of Nicholas George Geve, an eminent painter, appeared in quarto at Hamburg, under the title of "Monatliche beschreibungen in reiche der Natur, an Conchylien und Seeegewächsen," or "The monthly arrangement of Shells and Sea Productions." This publication came out in parts, and was favourably received, but being pirated was discontinued. The total number of plates published appears to be 33, the figures in which amount to 434.

The memoirs of the French Academy for 1756, contain a curious paper on the characters of shells, in which fourteen genera are described, founded on the nature of the animal inhabitants; this bears the title of "Observations qui peuvent servir à former quelques caractères des coquillages," and is from the pen of Guettard; another paper also on the subject of conchology, "Sur le Rapport qu'il y a entre les Coraux et les Tuyaux marins, et entre ceux-ci et les Coquilles;" from the same writer appears, in the Memoirs of that Academy for 1760, to which five plates of serpule, dentarie, &c. are annexed. Guettard was besides these the author of two or three ingenious treatises on the same subject, the titles of which do not immediately occur to us. The "Dissertationcula de Cornu Ammonis nativo Littoris Bergenensis in Norvegia," produced in 1757, and "De Tubulis verrucularibus cornu ammonis referentibus" bearing date 1761. are both the performances of J. F. Hoffmann, and appeared originally in the Transactions of the Electoral Academy of Mentz. These, as their titles imply, relate to a supposed discovery of some recent shells of the cornu ammonis tribe, but which, in reality, are only of the nautilus kind, though bearing a remote resemblance to the fossils known by the title of ammonitæ. Shells similar

to those had been before observed by Plancus. Another paper in the same volume as that last mentioned is from this writer, and bears the title of "De Concha Sphærica sphaerulæ, alata ex badio et nigro colore variegata."

"The Civil and Natural History of Jamaica," published in London in 1756, by Dr. Patrick Browne, contains a scheme of shells, which, considering the state of the science of conchology at that period, is less satisfactory than might be expected. Shells are divided by this author into three classes, *univalvia*, *bivalvia*, and *plurivalvia*. The characters of his orders are taken, in the univalves from the hollow of the shell being non-spiral, or spiral, and the situation, and form of the aperture, and the lip; in the bivalves from the ligament of the hinge, and the teeth; and in the plurivalves from the connecting ligament of the valves.

The "Opere Postume" of count Joseph Ginanni of Ravenna, contains a description of the maritime, marsh, and terrestrial shells of the territory of Ravenna, after a system somewhat similar to that of Buonanni. The first of these tribes is illustrated by thirty-one plates, the second by four, and the third by three. The descriptive matter is in the Italian language. It was published in folio, in 1757.

Adanson's "Histoire Naturelle du Senegal," was published at Paris in 1757. This useful work contains a new arrangement of conchology, and a series of about four hundred figures of shells, with the animals appertaining to the principal families. This production of Adanson's is in much esteem with the continental naturalists.

The books of Baister, "Opuscula subseciva, observationes miscellaneæ de animalculis," &c. dated Harlemi, 1759, 1760, 1761, 1762, and two 1756, afford the curious reader much information relative to the anatomical, and physiological nature of testaceous as well as crustaceous animals. In these we find the propagation, and ovaria of shell fish in general, treated of in an ample manner. A translation of the author's dissertation on the teredo navalis appears in the Philosophical Transactions.

A monographie on helix decollata, entitled "Observations sur une espèce de Limacon terrestre dont le femmet de la Coquille se trouve cassé sans que l'Animal en souffre," by M. Brisson, is inserted in the memoirs of the French Academy for 1759.

The testaceological labours of the celebrated Linnaeus should be particularly adverted to in this place. One of the earliest of his productions on this subject is the "Fauna Suecica," the first edition of which was published in 1746, and contains an account of sixty different species of Swedish shells. His travels in Gotland, "Wälgöta resa, föättad år 1746," appeared at Stockholm the year after, and though testaceology had only partially interested the remarks of Linnaeus, we are here presented with a description of several shells observed in his journey, and likewise a plate including a number of figures, rude indeed in the execution, and still more defective in representing all the univalves as heterostrophous shells, but valuable as a plate of reference to conchologists even at this day. (vide Donov. Brit. Shells, murex defectus). The "Museum Tessinianum," published in 1753, and "Museum Adolphi Frid. Suecicæ Regis," in the year following, scarcely demand mention as they contain only three species of the shell tribe. In the description of another museum, that of the queen of Sweden, "Museum Ludovicæ Altricæ Reginae;" Linnaeus possessed a more favourable opportunity of treating on testaceology, as her majesty's collection was particularly rich in shells; this work describes 433 species of shells, and some do not scruple to affirm that it is the best of the Linnaean

Linnæan productions on the subject of testacea; it appeared in 1794. In the interval between the times in which the two last mentioned works were published, Linnæus brought out a second edition of the "Fauna Suecica," in which the number of shells described was augmented from sixty to eighty-nine species.

The "Mantilla Altera" contains thirty-five species not described in the other works already mentioned. The "Fundamenta Testaceologia" is one of his latest tracts, and is to be found among the "Dissertationes Academicæ."

These are valuable books in a limited view, but the classification of shells in the "Systema Naturæ" from the nature of the undertaking is to be considered the most general of all the Linnæan writings on the testacea. Between the year 1735, in which that work first appeared, and 1767, the Systema passed through no less than twelve editions, in all which a progressive improvement, and nearer approach to perfection are manifested, and in no one department is this more unequivocally shewn than in the methodical distribution of the shells.

An opinion is pretty generally prevalent that less attention was devoted by Linnæus to the history and arrangement of the testacea, than any other order of nature; and that he even thought them unworthy of becoming objects of scientific arrangement. These points have been contested. The truth however still appears to be, that Linnæus had not really bestowed much critical attention on this subject. We can easily imagine that the mind of Linnæus might fluctuate between the propriety of establishing his conchological system upon the characters of the animals, and the difficulty, if not impossibility, of accomplishing it, and that in this state of indecision the shells themselves were, in a great measure, disregarded by him. When therefore the completion of the Systema required that some attention should be paid to testaceology, he was unprepared, and resorting to the authorities of others, comprised this department in the smallest compass possible, more with the view of filling up a chasm, which the omission of a tribe so generally admired would occasion, than from any idea of elucidating the subject.—A similar reason is well known to have operated on the mind of Linnæus, with respect to his system of mineralogy, which was added principally, in order that this work should comprehend the three kingdoms of nature.

Whether this conclusion be correct or otherwise, one fact inferred is very obvious, that the early attempts at the classification of shells, which the Systema presents, do not afford that happy result to be expected from the industry, and superior genius, of Linnæus.—It is time we should lay aside the trammels of servile adherence, and speak decidedly:—those early attempts of this celebrated writer we do not scruple to say, if examined with candour, will be found only a slight and ill conceived compendium of what has been handed down to us by antecedent writers; and which, if he had more closely imitated in the outset, as he afterwards found it incumbent upon him to do, would have rescued his reputation as a conchologist from considerable blame. Can we for a moment, dazzled with the splendor of a name, however dignified, deny that merit which is so conspicuously prominent in the classifications of preceding writers, and attribute all the credit of reducing shells into method and order to the genius of Linnæus? or can we, after duly estimating the testaceological labours, even of Gesner, Aldrovandus, and Major, we would almost say of Aristotle, be disposed to commend this naturalist for overwhelming their arrangements in one common ruin; abolishing at the least forty excellent genera

established by the different writers, and in lieu of those presenting us with eight genera for the reception of the whole testaceous tribe! Yet such is the fact, the only genera of shells, included in the first editions of the Systema, are *cochlea*, *nautius*, *cypræa*, *halotus*, *dentalium*, *concha*, and *lepas*.

Linnæus was himself embarrassed in the distribution of shells into such a small number of genera; he even found it impracticable, and hence we perceive, in the later editions of that work, their number progressively augmenting till, in the last publication of the Systema, they were multiplied to thirty-five. Thus from time to time, as his acquaintance with shells became more general, we see him deriving new strength and support, in the aid of his own system, from those very sources which, in the first instance, he too incautiously attempted to subvert; the genera afterwards admitted into the Systema, even to those last adopted, being with scarcely an exception to the contrary, drawn from the labours of naturalists who wrote in the century preceding, or much before.

It is an opinion likewise founded in error, that we are indebted for the outline of this testaceological system (considered in its most improved state) to the native genius of Linnæus. No one will hazard the assertion, we should conceive, who is in the slightest degree acquainted with the writings before-mentioned. His primary divisions were ready formed to his hands. Let us examine further: in the outline of his system, he divides all testaceous bodies into three principal orders, *multivalvæ*, *bivalvæ*, and *univalvæ*. If we take the univalves of Aristotle (retained by later writers under the title of turbinata), the bivalves of all writers, from the time of Aristotle inclusively, and the plurivalves of Major, invert their order, and we at once possess the complete outline of the system attributed to Linnæus. Or we may refer with equal certainty to the principles of Major's system alone, published sixty years before the first edition of the Systema made its appearance, in which this inverted arrangement occurs precisely, univalvia, bivalvia, and plurivalvia. Linnæus, therefore, it may be fairly inferred, was not the inventor of the systematic outline ascribed to him, for it was long in use before his time.

If we next descend from the primary divisions, or orders of the Linnæan system to his genera, these still are to be found in the same, or other early writers, perhaps a solitary transposition (as in *conus* and *strombus*) excepted, and furthermore even under the very names he assigns to them. His obligations to the labours of Langius are too obvious to be concealed. But although, in this particular, Linnæus has only the more moderate merit of adopting, instead of inventing the outlines of his system, he is to be applauded for having condescended to select what it appears he thought, on mature deliberation, superior to his own. And this, in our idea, was so far commendable, that we regret he had not been influenced by the same opinion in his first views of a testaceological classification. Linnæus had assuredly much diffuse and ambiguous matter to wade through in his investigations of former systems in general, and his selections were at length both clear and judicious, though still susceptible of much improvement. We are also to give the celebrated naturalist his full share of credit for having ultimately improved, and more accurately defined, the characters of the respective genera which he has adopted, than any of his predecessors; the characters of his species also, generally speaking, are not to be excelled for expressive simplicity and conciseness. He may be truly said to have reformed the language of natural science, before much too vague, by the introduction of that peculiar brevity of style, so extreme-

ly useful in the nice discrimination of natural objects, and which he seldom fails to apply with the happiest possible effect.

The merits of Linnæus, as a great naturalist, will shine with undiminished splendour, divested of its meteorous lustre; the world feels grateful to his genius. But nothing less than an acquiescence unworthy of his character, and of ourselves, can lead us to conclude he was equally successful in all his endeavours to develope the mysteries of nature. For our own part, attached to no particular system, we would rather "stem the torrent alone, than glide down the stream with many," in contradiction to the evidence of our own mind; we are the friends of Linnæus,—and of truth. We are persuaded, furthermore, that what the result of calm investigation approves, must redound more to the credit of Linnæus than that impetuous obedience which bows down our reason, and rejects inquiry. The celebrity to deservedly acquired by his writings in general, has stamped his system of teleology with respect. Its reputation induces us to examine it with more than ordinary attention. It is in England, what that of Lamarck's is in France, and some others in different parts of Europe; the system best known, and the most admired. We shall for this reason take a comprehensive view of the whole, regarding every genus separately in the same order as Linnæus places them; and offering, as we proceed, a few cursory remarks on each, with a view to enable the common reader to form his own opinion, and judge for himself of the comparative excellence or superiority of the Linnæan system of teleology.

The primary divisions of this system, in the latest edition of the "Systema Naturæ," as before observed, consist of three orders, *multivalves*, *bivalves*, and *univalves*, each of which is subdivided into genera. The *multivalves* contain the chiton, lepas, and pholas; the *bivalves*, mya, solen, tellina, cardium, mastra, donax, venus, bandedylus, chama, arca, ostrea, anomia, mytilus, and pecten; and the *univalves*, argonauta, nautilus, conus, cyprea, bulla, voluta, buccinum, Strombus, murex, trochus, turbo, helix, verita, halotis, patella, dentalium, serpula, teredo, and sabella.

Genera.

CHITON. Animal a doris. Shell consisting of several transverse incumbent valves, disposed in a longitudinal series down the back.

Our knowledge of this genus was very confined till within the last few years; so lately as the period in which the tenth edition of the Linnæan "Systema Naturæ" appeared, only four of its species were known, at least no greater number is described by that writer. To the valuable work of Cuvier, we are indebted for the addition of thirteen other species; to Schuëtter, for three or four; and to Pennant for nearly an equal number; all of which are included in the last edition of the "Systema Naturæ à Gmelin," with a few others, amounting altogether to twenty-eight species. Though we are pleased to see such a number of this curious genus, concentrated in one point of view, we cannot avoid expressing a wish that some few of the species at least were better explained, those especially which are confined to the continental museums; one, if not more of the species described by Pennant, is confessedly erroneous.

LEPAS. Animal a triton. Shell affixed at the base, and consisting of many unequal valves. Linn.

The propriety of separating the balani, or acorn shells, from the anatifera, or as vulgarly denominated the "goose bearing shells," has never yet been questioned by any well-

informed naturalist, although from motives of caution we, have, with others, submitted to the genus established by Linnæus, till our reasons for dissenting from his authority (and which the Linnæan student might deem an innovation) could be explained in its proper place.

We were always at a loss to see the true reason that could induce Linnæus to place these two very opposite natural families together; the only justification seems to be, that the animals of the two genera (for so we shall denominate them) are of the same kind, and that no other multivalve shells are inhabited by this kind of animal, that of chiton being a doris, and of pholas an ascidia. At the same time, it will be remembered, that animals of the same kind inhabit shells of very different genera, and that it is therefore no argument, because all of the Linnæan genus lepas are inhabited by the triton, that they must be of the same genus. We cannot surely infer this from any similitude in the structure of the two kinds of shells. What, for instance, can be more dissimilar than the first very essential particular in which these shells disagree, namely, the manner in which they are affixed; the balani cemented immovably by its base to the rocks, loose stones, or any other extraneous substances, while the anatifera are connected to, and supported at their base by a tendinous tube, which being of a flexible nature, allows the animal an opportunity of writhing or turning in any direction in quest of food. Again, the very striking circumstance, which Linnæus had always himself regarded as of the first consequence in an arrangement of shells, the presence and absence of the operculum; in the anatifera, there is no operculum whatever; while, in the balani, that part constitutes one of the principal features of the shell; it is even the structure, rugosity, or other peculiar circumstances observable in this part, that afforded Linnæus the best of his characters, in defining the species of this family. This operculum or lid of the balani consists of four or six valves. The above characters are so obviously distinct, that it may be almost considered needless to advert to the form of the two shells, though in this also they differ most essentially; the anatifera are wedge-formed, and consist of five or more unequal valves; the balani of six valves, and the general form of the shell is sub-cosmic.

PHOLAS. Animal an ascidia. Shell bivalve, divaricated, with several lesser, differently shaped, accessory ones at the hinge; hinges recurved, and united by a cartilage; an incurvated tooth is the inside beneath the hinge.

These shells were formerly called piddocks by the English; they are found below high-water mark burrowed in hard clay, lime-stone, or sometimes free-stone, and also wood; which they perforate in their younger state, and as they increase in size enlarge their habitations. The animal is somewhat cylindrical in form, and is furnished with two orifices or openings, capable of elongation in the manner of a proboscis; from one of which, supposed to be the mouth, it has the faculty of squirting water. The phosphorescent properties of the pholade are very remarkable; it contains a liquor which shines with uncommon splendor in the dark, and illuminates whatever it touches, or happens to fall upon. This is noticed by Pley, lib. ix. c. 61, and M. Reaumur has also written copiously on this subject, in the Memoirs of the French Academy, for the year 1712.

Only twelve species of this genus are described in the Gmelinian Syst. Nat. The pholades were placed by Linnæus among the bivalves.

MYA. Animal an ascidia. Shell bivalve generally gaping at one end; hinge, with a fold, thick, patulous tooth, or fold on two, and not inserted in the opposite valve.

Many of the shells in this genus were arranged with the muscles till Linnæus separated them; Gmelin in the last edition of the *Systēma Naturæ* describes twenty-one species of the mya tribe.

The Linnæan myæ constitute three distinct genera, in the latest arrangements of the continental writers, as mya, glycymeris, and vullella. The mya is distinguished by a transverse shell gaping at the two ends, and having the ligament within; and one valve furnished with a single, compressed, roundish tooth in the beak, perpendicular to the valve, and having the ligament attached to it. The Linnæan mya truncata is of this kind. In the genus glycymeris the shell is also transverse, and gaping at both extremities, but the hinge is callous and toothless, and the ligament situated on the outside. Vullella has the shell long and somewhat equi-valve; hinge callous, depressed, without teeth, and forming a straight line in both valves; the ligament attached to a roundish cone hollow; beaks bent and very short. This last genus is closely allied in many respects to the oyster.

SOLEN. Animal an ascidea. Shell bivalve, oblong, open at both ends; hinge with a subulate raised tooth, often double, and not inserted into the opposite valve.

Gmelin describes twenty-three species of this genus, several of which are natives of Europe, where they frequent sandy shores. The Greeks were acquainted with some shells of this genus, as were also the Romans, both of whom valued the fish of the inhabiting animal as a dainty. In England they are occasionally eaten either boiled or fried with eggs, but are not found in sufficient plenty to be considered as an article of food. They are called snaths or razor-shells in this country.

The Linnæan solens are divided by late writers on the continent into three different genera, two of which comprehend the recent kinds, the third is established chiefly for the reception of some fossil shells, supposed to be of this Linnæan family. Those genera are solen, sanguinolaria, and corbula.

The solens, according to those writers, have the shells transverse, with the upper and lower margins almost straight, with beaks not projecting and gaping at both extremities; and the two valves together furnish either two or three teeth in the hinge; the ligament of the hinge in this family is placed on the outside. Sanguinolaria differs in having the upper margin curved, the extrinsecus a little gaping, and two approximate teeth in each valve, which lock into each other when the shell is closed. Corbula has the valves unequal, sub-transverse, and regular; with a concave curved tooth in each valve; the ligament of the hinge within, and the inside of the shell marked with two muscular impressions.

TELLINA. Animal a tethys. Shell bivalve, generally sloping on one side; in the fore part of one valve a convex, of the other a concave fold; hinge with usually three teeth, the lateral ones smooth in one shell.

In the Linnæan system the tellinæ are divided into three families, namely, *ovate and thickish, **ovate and compressed, ***lab-orbicular.

A late writer (Dr. Pultney) observes, in his "Catalogue of Shells found on the Coast of Dorsetshire," that the tellinæ genus is one of those of which the species are yet very imperfectly defined, arising from the great similitude among them; and from the insufficient descriptions of authors before Linnæus wrote, who, by deducing their characters of the genus, if indeed such they might be called, almost wholly from figures, were necessarily led to throw together shells entirely different, when examined by the characters Linnæus assigned. Those of this great master, adds

this writer, are yet very imperfect, and since the great additions that have been made to conchological science, by later discoveries, the whole system again wants a total reformation; and the construction of many new genera. The observation of this naturalist is very just; the writers before the time of Linnæus have, with too little caution, derived their characters from figures rather than from the shells, a fault we could have wished Linnæus himself had more frequently avoided; the tellina of Linnæus is a good genus, but requires to be recast; some of the shells included by this genus have certainly no natural affinity whatever with the others, and the character of the genus itself is not laid down with sufficient precision.

Lister is one of the first conchologists who describes the tellens with any degree of accuracy; he defines them to be "shells shaped like wedges," and places them after the pinna, (lib. iii. h. 2. sect. 8.) Woodward says they have a few teeth on the hinge, and are oblong shells, or with the files lengthened. Davila comprehends the tellens as a very large family, and includes the solens as a genus of them. Da Costa, in his "Elements of Conchology," attempts to establish a family of tellens under the character of the shells being more broad than long, rather flat, and the hinge having two teeth left close together. This constitutes his ninth family of bivalve shells; and which he again divides into two genera, the first of which he still calls tellina, and the second corbi; his telline are thus defined. "shells with similar files, whole beak and hinge are central;" his corbi "shells with dissimilar or unequal files, whose beak and hinge are placed near to, or quite at one end."

There is much method, but very little accuracy, or attention to genera, founded on natural affinities and characters, in the arrangements proposed. It was reserved for later writers, by a more strict inquiry into the nature and habits of the animals, as well as the nice discrimination of characters in the shells themselves, to fix upon decisive general distinctions. It has been discovered by Poli, and others of the continental writers, that the animals inhabiting some of the tellen tribe are of a different nature from the others; and another objection to the tellenæ, as they now stand in that genus, is the dissimilitude observable in the hinge, teeth, and other parts of the shell, which Linnæus has himself thought essential to be regarded in constituting genera. The principal of the new genera established by the break of the French writers are *Cyclas* (cyclade) of Lamarck, and *Pandora* (pandore) of Latreille, the animal of which was previously discovered by Poli; the shell is also described by Linnæus under the name of *Tellina inæquivalvis*.

The tellina genus, as now defined, consists of those bivalve shells which are orbicular, or transverse, having a regular fold or rumpie at the anterior end of the shell, with one or two teeth pointed to the beaks; and remote lateral teeth. This will comprehend the true tellinæ. The cyclas is of the Linnæan tellenæ, and is exemplified in the *Tellina cornua* of Linnæus and Pennant. This genus is of a lab-orbicular form, without a regular fold or rumpie at the anterior end; the ligament of the hinge is inflated, and projects out; it has either two or three teeth pointing to the beak, and lengthened lamelliform, or plate-like lateral teeth, which are received into sockets in the opposite valve. The genus pandora, as above intimated, is formed principally of that singular shell the tellina inæquivalvis. This genus is univalve and unequal-lamell, one valve being convex, the other flat, with flattened front; two unequal diverging teeth at the hinge, pointing to the beak in the upper valve, and two hollows in the lower; ligament within, and the inside of the shell marked with two muscular impressions.

CARDIUM. Animal a tethys. Shell bivalve, nearly equi-lateral, equivalve, generally convex, longitudinally ribbed, striated, or fuscated, with the margin denticated. Hinge with two alternate teeth in the middle near the beak. In most incurved; lateral teeth remote, and inserted or locking into the opposite.

Forty-nine species of this genus are described in the last edition of the *Syſtema Naturæ*.

Da Coſta, in his "Elements of Conchology," propoſes to eſtabliſh a new family of cockles, under the title of *pectuncululus*, whoſe character is a curved or ſemilunar hinge ſet with either two or four teeth. Theſe he divides into three genera. Genus 1. *Pectuncululi*, or cockles, with a convex or flatfiſh ſhell, of a roundiſh ſhape, with ſimilar or diſſimilar ſides, whoſe beaks are not very prominent, and curve much upwards towards the hinge; they are the *Chama* of Argenville and Guaiteri; and do not belong to any particular genus in the Linnæan ſyſtem, but are diſperſed throughout his bivalves, and are only mentioned here to introduce the two next genera. Genus 2. *Cordiformes*, or heart-shaped cockles, whoſe beaks are not very prominent, and curve up greatly towards the hinge, thereby forming a figure perfectly like a heart as vulgarly painted. Theſe are ranked by Linnæus in the *cardium* genus, and are thoſe, ſtrictly ſpeaking, of which his genus is chiefly compoſed. Genus 3. *Truncati*, or flat-sided cockles. Theſe laſt are ſuch cockles as are flattened, or have a truncated appearance on one ſide, as we ſee exemplified in *cardium* medium.

The *cardium* genus, as laid down by Linnæus, is far from exceſſionable. It is adopted by the belt continental writers, under the title of *Cardium bucarde*, *Cœvus*, *Conche cordiformes*, and other ſignificant appellations, alluding to the heart-shaped appearance which the ſhells exhibit, in a greater or leſs degree, when viewed ſideways. Theſe ſhells are of a ſomewhat cordiform ſhape, with the valves denticulated or folded at the margin; beaks contiguous; hinge with two oblique teeth in each valve near the beak, locking into each other; lateral teeth remote, and fitting alſo into each other.

MACTRA. Animal a tethys. Shell bivalve, unquilateral; valves equal; middle tooth of the hinge complicated, with a ſmall hollow on each ſide, and lateral remote teeth inserted into each other.

Twenty-seven ſpecies of this genus are deſcribed by Linnæus and Gmelin. Lamarck propoſes to divide the Linnæan *maetra* into two genera, *maetra* and *lutraria*; both ſhells are unquilateral, and gaping at the ends, but the conſtruction and ſituation of the teeth are very different, as we ſee elucidated moſt completely by comparing the *maetra* ſul-torium of Linnæus with the *maetra* *lutraria* of the ſame author.

DONAX. Animal a tethys. Shell bivalve, with the margin in general crenulated, the anterior end very obtuſe; hinge with two teeth, a ſolitary one ſomewhat remote (the latter rarely double, triple, or none). Linn.

This genus, in the Linnæan ſyſtem, contains nineteen ſpecies. The *donax* of the modern continental naturaliſts is rather differently defined; they deſcribe it as a tranſverſe ſhell, with the ſides unequal, a little gaping at both ends, and having two muſcular impreſſions on the inſide of the ſhell; two teeth pointed towards the beaks in one valve, and a ſingle biſid tooth diſpoſed in a ſimilar manner in the other; and the ligament of the hinge on the outside. This character agrees with the *Donax rugoſa* of Gmelin. Another genus is eſtabliſhed under the name of *petricola*, the character of which is exemplified in the Linnæan *Donax irus*, and *Venus lupicida* of Chemnitz. The ſhells of this new genus

are unquilateral, a little gaping at both ſides, and having two muſcular impreſſions in the inſide of the ſhell: two teeth pointing towards the beaks in one valve, and a ſingle biſid tooth in the other; with the ligament of the hinge on the outside.

VENUS. Animal a tethys. Shell bivalve, anterior margin with incumbent lips; hinge with three teeth, all which are approximate, the lateral ones divergent at the tip; "valva et anus diſtincta." Linn.

Theſe are divided by Linnæus into two ſections; * pubentes, and ** impubes, the laſt of which is ſubdivided into three families. † ſubcordata, †† orbiculata, and ††† ovales, ſupra rimam ſubangulate. The total number of ſpecies deſcribed in the "Gmelinian Syſtema," amounts to one hundred and forty-five. It is chiefly in the deſcriptions of the ſhells of this genus that Linnæus has adopted terms which we do not feel at liberty to render into common language for the peruſal of the general reader.

Many of the ſhells of this genus were arranged by writers previous to the time of Linnæus under the title of *chama*. The animal is deſcribed as a tethys differing from that of the *cardium*, chiefly, in having the foot of the animal when protruded lamina-formed, inſtead of hooked, and as a molluſcous animal, taking a variety of forms when the creature moves. It ſhould however be obſerved that we are yet very imperfectly acquainted with the animals inhabiting this extenſive tribe of ſhells.

SPONDYLUS. Animal a tethys. Shell with unequal valves, hard, and rigid; hinge with two recurved teeth, and a ſmall hollow between.

The Linnæan ſpondyli are few in number, the laſt edition of the "Syſtema Naturæ" comprehending no more than four ſpecies. The ſpondyli have been by ſome called thorny oysters. Rumphius, Argenville, Seba, and Davila, rank them as oysters; while Liller, Woodward, Guaiteri, Linnæus, Meuschen and Da Coſta conſider them as a diſtinct genus, under the name of ſpondylus. The ſpondyli are either earleſs or furniſhed with ears; the valves uneven, thick, and rude or uncouth, and forming in their general exterior an intermediate natural family between the oyster and a deſcallop. Lamarck, and other late French writers, divide the Linnæan ſpondyli into two genera, *ſpondylus* and *plicatula*. One eſſential diſtinction between theſe ſhells conſiſts in the ſpondylus having ears, and the *plicatula* being without; but this is not the only difference, a ſtriking character is drawn from the ſtructure and appearance of the beak of the lower valve, which projects beyond the beak of the upper one, and in ſpondylus exhibits a plain triangular flat ſpace, divided by a furrow: while in the genus *plicatula* the beak has no ſuch characteristic ſpace or flat ſurface, and the edges are rumpled or ſolded. Theſe new genera are well exemplified in the two Linnæan ſhells, *ſpondylus gaedareopus*, and *ſpondylus plicatulus*.

CHAMA. Animal a tethys. Shell bivalve, rather coarſe; hinge with a calous gibboſity, obliquely inserted into an oblique hollow; anterior ſlope cloſed (valva clauſa abſque nymphis, Linn.)

In Da Coſta's "Scheme of Shells," the Linnæan *chamae* are divided into two genera, *tridacnae* or baſon conques, and *chamae* or gapers. The *tridacnae* are ſhells of equal valves, and diſſimilar ſides, in hinge and appearance like the heart cockles, but on the longeſt ſide from the beak to near the extreme margin the two valves are open, leaving a large oval or heart-shaped gap, the lips of which are very broad, and turn upon the edges. The *chamae* *gigas* of Linnæus is of this family, and is the largeſt and heaviſt ſhell at preſent known, weighing from ſix to ſeven hundred pounds. The

chamae,

chamæ, or gapers, also called purrs, have a broad, thick, and large tooth at their hinge, and are abruptly cut off on one side, which side is always open or gaping.

The genus *tridacna* is retained by the latest French writers, with some amendment in the definition of the character. They describe it as an equilateral and subtransverse shell, with two compressed teeth in the hinge, and the lunule at the posterior slope gaping. The chamæ of these authors are adherent to other bodies, and have the valves unequal, and the inside of each marked with two muscular impressions; and the hinge consisting of a single thick oblique tooth. *Hippopus*, *cardita*, and *isocardia*, are also new genera formed of the Linnæan chamæ; the last is an excellent genus, founded on the peculiar structure of the *chama cor* of Linnæus: this shell is heart-shaped, with the valve unequal at the sides; the beaks diverging somewhat spirally and remote; in one valve under the beak a flat tooth, locking horizontally between two in the valve opposite, and a single distant tooth in the anterior part, below the ligament.

ARCA. Animal a tethys. Shell bivalve, equivalve; hinge with numerous sharp teeth alternately inserted between each other.

This genus is divided into two principal families, those having the margin entire, and those with the margin crenated; and both families are again subdivided into two sections, the first distinguished by having the beaks recurved, the other inflected; the species described altogether amount to forty-two.

This genus derives its name of *arca*, *ark*, or Noah's ark-shell, from the similitude which most of the species bear when the valves are closed to a boat, or hull of a ship, "*concha rhomboidalis naviculam exprimens.*" Lister places some of these shells among the multarticulate cockles, and the rest with the muscles, under the title of many-toothed muscles. Woodward ranks them among his "*polyginglymi formâ oblongâ;*" Argenville as a family of heart-cockles, and Davila and Gualtieri as a distinct genus: the first under the title of *arca*, the latter as "*concha rhomboidalis.*" These writers were succeeded by Linnæus, who considered these shells as a distinct genus, and called them *arca*.

The principal alteration in the Linnæan classification of the genus *arca* proposed by late writers, is to retain only such shells under the title of *arca* as are unequalvalved, with the beaks remote; and have the line of the hinge simple and straight throughout, with numerous teeth placed parallel to each other, and fitting or locking between those on the opposite valve. Admitting this as the character of the *arca*, and it exactly corresponds with the *arca* *nox*, and most others the title silvery ark; *arca nucleus* of Linnæus, with its analogous species, is excluded. To comprehend the latter, a new genus is recently established by the French writers under the name of *nucule*, or *nucula*, the character of which is remarkably decisive: it is described as a triangular or oblong shell, with the sides unequal; the hinge consisting of an angulated, or broken line beset with numerous teeth, which are transverse and parallel, and a single oblique tooth placed under the beak, and out of the range of parallel teeth before mentioned. The beaks also, instead of being remote, as in *arca* *nox*, are placed close together, and turn backwards.

OSTREA. Animal a tethys. Shell bivalve, generally with unequal valves, and slightly eared; hinge without teeth, furnished with an ovate hollow, and mostly lateral, transverse furrows. "*Vulva anisue nullus.*" Linn.

These are divided into three families, * valves radiated and eared, as in the scallops, ** regged, or rough, as in

the oyster, *** hinge with a perpendicular furrowed line, as in the species *perna* and *isognomum*. The scallops are again subdivided into three sections, namely, those with the valves equilateral, and the ears equal; those with the ears unequal, and having one of them generally ciliated with spines within; and those with the valves gibbous on one side. The two other families are not subdivided.

The difference between the oyster and the peecten tribe is so obviously impressed by the kind of nature on the respective shells which compose them, that few writers on this subject have passed silently over the impropriety of placing them together. If, however, we examine a number of the other shells included by Linnæus in the extensive genus *ostrea*, many will be found, which though less dissimilar at the first view, equally deserving of being considered generically distinct, as well as the two tribes before-mentioned. The form of the shell is sufficient to guide us in an arrangement professedly of shells; but when the peculiar structure of the animal confirms the propriety of constituting new genera, no doubt can remain that such amendment was requisite. With respect to the *ostrea*, the animals of several of its natural families are unknown; some of the oyster and peecten tribe are, on the contrary, well ascertained, and these are proved to be very distinct.

As Linnæus considers these animals the same, and describes them as a tethys, it may not be improper to speak more fully on this subject. The scallop differs from the oyster in being endowed with a higher locomotive power: the animal is different in having the branchiæ ciliated, or fringed; in being furnished with a kind of foot, which it protrudes from the shell near the auricle of the hinge; and in throwing out a byllus like the pinna and the muscle, by which it affixes itself to other bodies. Aristotle, and other ancient writers, attribute to the scallop the power of springing from place to place, a fact pretty correctly ascertained by the observations of the moderns. Argenville describes the process of its movements both in the water and out; he relates, that when left dry, by a sudden and violent closing of its valves, assisted by the foot, it has the power of springing four or five inches at a jerk, repeating this motion in order to regain its element. In the water, it is assisted by this writer, the scallop has the power of rising and sustaining itself near the surface, turning about in various directions, and on any alarm suddenly closing the valves and sinking to the bottom. The oyster has the branchiæ simple, and not fringed, and is unfurnished either with a foot, or with byllus; and its powers of motion consist in turning either the flat or convex side upwards or downwards, and even to effect this, the animal takes advantage of the force of the ebbing or flowing of the water to assist it. Vide Dr. Pultney's Cat.—Lister on Scallop, in Phil. Trans. &c.

Before the time of Linnæus, most writers considered the scallops and oysters as distinct. Gualtieri describes the scallops as a particular family, and divides them into two genera, or those with equal, and those with unequal valves; the first of which he calls *pecten*, the latter *concha pectinata*; and the scallops with unequal or single ears, he calls *pectunculi*. The *ostrea* is ranked as a distinct family by most authors. Da Costa observes that the "head or essential character of the scallop family is a trigonal sinus, and an elastic cartilage for its hinge in the very centre of the top of the shell." "The oysters have unequal valves, though there are some species that have equal valves, but none are eared. The hinge of this family has not any teeth, but consists of one large inarticulate gutter, running the length of the top of the shell, in both shells alike, and is covered and filled with a strong cartilage." We should add, that in the

the felcme of shells proposed by the writer, the spondylus forms an intermediate genus between the pecten and oyster.

In Lamarck's arrangement, the two genera, *huitre*, of *strea*, and *peigne*, pecten, are retained; but four other genera are conflated, under the names of *malcus*, *forma*, *lima*, and *pedum*, into which the Linnaean ostreae are distributed. Latreille forms another genus under the name of *gryphus*, the ostrea gryphus of Linnaeus, a shell fish, and only in a fossil state. We are not exclusively indebted, however, to Latreille for the establishment of this genus. Vide "Donov. Tour South Wales and Monmouthshire," in which the course of an immense stratum of these antediluvian shells is particularly described, with remarks on the genus *ostrea* and *gryphus*.

ANOMIA. Animal, a ciliated strap-shaped body, with bristles or fringe affixed to the upper valve; arms two, linear, longer than the body, connivent, projecting, alternate on the valve, and ciliated each side, the fringe affixed to each valve. Shell inequivalve, one of the valves flatish; the other gibbous at the base with the beak produced, and generally curved over the hinge; one of the valves often perforated near the base; hinge with a linear prominent cicatrix, and a lateral tooth placed within, but in the flat valve on the very margin. Two bony rays for the base of the animal.

Many of the Linnaean species of anomia are found in a fossil state only, and rarely afford an opportunity of inspecting their internal structure; neither is it reasonable to imagine we shall ever become acquainted with the animals by which they were inhabited. Our observations on these points must be confined to the recent kinds only, which, so far as they have been attentively examined, are found to comprehend shells extremely dissimilar in structure, and to be inhabited by animals differing in many essential particulars. It is remarked by Dr. Pultney, that the animal of the anomia is different from that of any other shell-fish, and is not reducible to any of those in a molluscous state hitherto known. Hence, probably, the name Linnaeus imposed upon it, *Anomia*, "quasi irregularis dissimilis a lege discrepans." The animal of the anomia cepa is figured by Murray, in his "Elementa Testaceologiae," t. 2. f. 23; and that of another species, by Forster, in his "Icones Animalium," t. 6. 45. B. under the name of anomia tridentata. The dissimilarity of these two renders it highly probable, that in the different shells which come under the appellation of this genus, the inhabitant animal is various. Linnaeus describes that of the anomia patuliformis as extending from its body a tongue-like process fringed with fine hairs, and furnished with two extensive ciliated arms, by which it is enabled to open and shut the shell. In the anomia tridentata, the animal is furnished with two flat, wedge-shaped, trilobated arms, placed opposite to each other; these it protrudes out of the shell when it moves, and they are the organs by means of which it swims in the sea. Some other kinds of anomia are inhabited by animals which, it is supposed from the structure of the shell, cannot open the valves to stretch forth arms, but are furnished with processes of a different nature, which they protrude through the aperture or perforations at the beak; and other kinds again, instead of arms, have only a ligament passing through the perforations of the shell, by means of which it is firmly fixed to other bodies.

Columna is the first writer who speaks of shells of this kind; he describes some few of the fossil tribe (the only species known in his time) under the title of "Conchæ rarioris anomiae." Hence the term anomia was afterwards

employed by other writers, and has since become the universal name for this family of shells. Lister figures several species of the fossil kinds in his "Appendix de Conchitis" to his "Historia Conchyliorum." Woodward forms an arrangement of them under the name of anomia, ranking them with the shells of unequal valves, not eared, both valves convex, and one of them beaked, and these he divides into three families, the smooth, striated, and fucated. Gualtieri figures some few of the recent kinds as a new genus under the title of terebratula. Argenville places some of the anomia among his heart cockles. Davila treats them as a genus of his oysters; Da Costa as a genus of bivalves with unequal eared valves, the beak of the larger or under valve greatly produced, and rising or curving over the beak of the smaller or upper valve, which is pierced through like a tube; the hinge is in articulation toothless, and they have always a remarkable interior structure. These are the terebratulae of some late writers, and comprehend only part of the Linnaean anomia.

Those shells of the recent kinds among the anomia of Linnaeus, which are most dissimilar in structure, are the species terebratula, placenta, and ephippium; each of which stands at the head of a natural family, and offers characters which may be adapted with facility as distinctions of so many genera. We are persuaded the genera formed by the subdivision of the Linnaean anomia might be extended with much propriety to a greater number still, but we are unwilling to increase them without the most absolute necessity. With respect to the fossil kind, of Linnaean anomia, some may be referred to the genera above mentioned, others are in no manner applicable to them, and for the arrangement of such it is requisite to form new genera. Lamarck proposes one, calcicola, derived from the characters of the anomia sandalium of Linnaeus, and his genus crania formed of the Linnaean anomia cranialaris may be considered as in a great measure appertaining to the fossil shells only. These genera are laid down with pertinacity, but Lamarck we are persuaded might have proceeded farther. We consider Linnaeus sometimes blameable for intermixing the recent and fossil shells promiscuously together, and may be therefore ourselves excused sometimes at least for abating from his example. Lamarck thinks differently; he approves this method, and having ventured from the boundaries of the present into the labyrinths of the antediluvian creation, much was expected; a greater number of new genera might have been established, those at present formed being altogether inadequate to the reception of those numerous remains of the testacea which are admitted among the anomia of the Linnaean conchologist.

Put to return to the recent anomia:—What, we would inquire, could possibly induce Linnaeus to place that singular bivalve, called from its transparency by the English collector "the Chinese glass window" among the anomia?—Or what again can be more remote than the essential character of his anomia ephippium and terebratula?—In the first, which is to be found in his Systema under the name of anomia placenta, both valves are of an equal size and form; in ephippium the valves are unequal, one being flat, and the other convex, as in the oyster; in ephippium the flat valve is perforated with a round hole in the disk near the hinge through which a ligament passes, and by this means affixed it to stones and other bodies; the A. placenta has no such perforation. In A. terebratula there is a perforation; but instead of being situated in the flatter valve it appears at the tip of the long beak into which the head of the convex valve is elongated. Near the hinge in one valve of A. placenta are two longitudinal lamelli-

lamelliform processes, which approach near the beaks, and thence diverge obliquely so as to resemble the letter V, and upon the valve opposite two corresponding processes longitudinally cleft, in which, when the shell is closed, two lamelliform teeth repose. An internal structure of longitudinal processes occurs in the species *terestrata*, but very different from the preceding, and no such internal structure occurs in the *anomia epiplium*. These characters denote sufficiently that they are not only essentially different in the conformation of their shell, but that they are inhabited by animals distinct from each other.

MYTILUS. Animal an ascidia? Shell bivalve, rough, usually affixed by a beard or byssus of silky filaments: hinge in general without teeth, and except in a few species with a fubulate excavated, longitudinal line. Linn.

The Linnæan *mytili* are by no means inconsiderable in number, and as they comprehend many shells very distinct in appearance, and some essential particulars, are necessarily distributed into several sections, or families, such as * parasitic, those affixed by claws, exemplified in *mytilus crista galli*; ** *plani*, &c. flat, or compressed into a flattened form, and slightly eared, as in *mytilus margariferus*; or *** *ventricosuli*, *ventricose*, as in *mytilus edulis*. The older writers appear to be perfectly agreed as to the *mytilus* genus, but the moderns think it necessary to divide them into two or more genera. Lamarck separates them into *mytilus* (*monle*), *modiolus* (*modiole*), and *anodonta* (*anodonte*). In defining the *mytili* he notices in particular the unguiculated, or claw-like termination of the shell at the narrowest end as a peculiar character. We do not perceive the absolute utility of his second genus, *modiole*, though we think it admissible, but we perfectly agree in the adoption of the latter *anodonta*. This last mentioned genus consists of what are vulgarly called the river, or fresh water mussels, shells which we have always conceived it improper to refer to the same genus as the marine *mytili*. In the colour of the valves, and form and situation of the beaks, the most obvious dissimilitude prevails, and a distinction still more evident resulting from the different conformation of the animal occurs in the inside of the shell, which exhibits three impressions of muscles or ligaments by means of which the animal is attached to the shells, while the shells of the common mussel, and its congenères, have only one such impression.

PINNA. Animal limax. Shell sub-bivalve, fragile, erect, gaping, and furnished with a byssus, or beard; hinge without teeth, the valves uniting into one. Linn.

This genus is well defined; the shells of which it consists are wedge-shaped, or of a somewhat triangular form, widening from a pointed or narrow top to a very broad end. The hinge is articulate, the two valves being united in that by part, and thus forming, what Linnæus truly terms it, a sub-bivalve, for it is not strictly of two valves, being thus connected. The *pinnae* are known by different writers under the various appellations of sea-hams, sea-wings, and *pinnae marinae*, or by others silk-worms of the sea, which last they obtain from the quantity of fine strong brown byssus, which the animals produce, and by means of which they affix themselves to the rocks; the byssus consists of fine silky fibres of a brown colour, and which is easily woven into stuff or small articles of dress. Among the ancient Romans this kind of silk was held in considerable esteem: it is even said that there are still manufactories of it at Naples, Messina, and Palermo.

Eighteen species of this genus are described in the last edition of the *Systema Naturæ*.

VOL. IX.

ARGONAUTA. Animal sepia, or clio. Shell univalve, spiral, involute, membranaceous, and unilocular, or consisting of a single cell. Linn.

The principal species in this genus of shells is the Linnæan *argonauta argo*, the celebrated nautilus of Piny, lib. ix. 29, the animal supposed to have taught men the use of sails, and art of navigation in the early ages of society. The ancients knew this species by the name of *nautilus*, as appears sufficiently obvious from many passages to be found in their writings. Linnæus, however, in conformity with Rumpfius, applies the name of *nautilus* to a chambered shell of a very different kind, (see *NAUTILUS*), and retains the *nautili* of the ancients, under the title of *argonauta*, with the essential character above-mentioned.

In the Gmelinian edition of the *Systema Naturæ*, the number of species described under the genus *argonauta* amount to five, *argo*, *vitreus*, *cymbium*, *cornu*, and *arctica*. But the minute observer of nature disposed to descend to the investigation of the microscopic kinds of shells will be able to add considerably to this number; a work published in Germany in 1798, the united labours of our friend L. A. Fichtell, and C. A. Moll, and entitled "Tertacea Microspica aliæque minuta ex generibus Argonauta et Nautilus ad naturam picta et descripta," contains in particular, a number of new species in this curious genus, and a few others are known to us which we have reason to apprehend have not been noticed by any other writers. By the accession of these latter species the genus becomes materially enlarged; but we have, at the same time, to observe that the whole of the Gmelinian shells, described under this generic title, are not strictly admissible among the *argonautæ*, and that the removal of these will occasion a slight reduction of the species already mentioned.

That very rare shell known among collectors by the name of glassy nautilus, the *argonauta vitreus* of Gmelin, is separated by Lamarck from *argonautæ*, and constituted a new genus under the name of *carinaria*. In the Linnæan system it would be difficult to refer it with certainty to any genus. Linnæus was himself in doubt where to place it, and at length referred it to the limpet tribe, under the name of *patella cristata*, but it cannot surely belong to this genus. In the last edition of the *Systema Naturæ*, we see it transferred from thence to the *argonautæ* with more propriety, but we are still persuaded it cannot claim a place in this genus, though it is more closely allied to it than any other of the Linnæan genera; it is certainly of a new genus as Lamarck describes it. The principal distinction between those two genera, the *argonauta* and *carinaria*, is very striking; in the true *argonauta*, (or *nautilus* of the ancients) the spiral involution turns into the opening of the shell, whereas in *carinaria*, the spire is situated at the summit of the shell and the mouth is entire. This character we think alone sufficiently decisive in defining the essential characters of the two genera. The *carinaria* is further distinguished by the shell being conic, and flattened at the sides, the spiral whorl very small, the back furnished with a single denticulated keel, and the mouth, or aperture of the shell, of an oval-oblong form, narrower nearest the angle of the keel. The *argonauta* shell, instead of being conic, is somewhat boat-shaped, and has from this very circumstance been named *cymbium*, both by Gualtieri and Tæstin; and the dorsal carination which is single and denticulated in *carinaria*, is uniformly double and tuberculated in *argonauta*.

In conclusion of our remarks on this genus, it will be proper to observe that the glassy nautilus, or *carinaria vitrea*, is one of the most choice and uncommon of the testaceous tribe;

R r ic

it is not, however, unique, for we know of three specimens, one of which is in the cabinet of Mr. Jennings in England, and the two others in the Museum of Natural History in Paris, one of which was obtained from Lyonet's cabinet. A large fossil shell of the argonauta genus, a singular species, and the only one we are acquainted with, occurs in the London Museum.

NAUTILUS. Shell univalve, divided into several departments, communicating with each other by an aperture or siphunculus.

The Linnæan nautili consist of two principal families, those which are spiral and rounded, and such as are elongated and straight. Of the spiral kinds there are two distinct sections, the first of which have the whorls contiguous, the other the whorls separated; the nautili of a straight form are comprehended in one section only.

Under the general title of nautilus, Linnæus includes the three genera of modern naturalists, nautilus, spirula, and orthocera, with some others which may hereafter, on accurate investigation, be found generically distinct likewise. The nautilus is a spiral rounded shell, having the last whorl very large, and enveloping the others, which are numerous, and divided internally into many chambers by transverse partitions, the disk of which is perforated by a siphunculus or tube. This character is drawn from the nautilus pompilius of Linnæus, a shell admitted by the latest authorities as an amplification of the nautilus genus; of the modern school only we would observe, for it has been previously shewn, under the genus argonauta, that it is not the nautilus of the ancients. The character of the new genus spirula, is derived from the nautilus spirula of Linnæus, (erroneously rendered spicula in Gmel. Syst.) or what we call the ram's horn. This shell is truly of the limax or erozier family, being of a spiral structure with the whorls separated, and the last chamber at the aperture elongated into a straight cylindrical stem. Linnæus describes only the spiral termination of the shell, which being of a concamerated or chambered structure, and perforated with a siphunculus, induced that naturalist to place it with the nautili, notwithstanding the striking dissimilarity of the disposition of the spiral involutions. This shell, when perfect, affords an essential character which at once removes it from the genus nautilus, in which Linnæus places it; namely the last or cylindrical chamber, which is alone sufficient to distinguish it. We may easily presume that no blame attaches to Linnæus in this particular respect, for it is pretty certain that naturalist never saw the perfect shell. In collections we have at various times seen some thousands of the spiral terminations, (for it is a very common West Indian shell,) scarcely one of which has retained the slightest vestige of this chamber, though all appear rudely broken, and different from a natural termination or aperture. This chamber of the shell is extremely thin and brittle, in such a manner that the slightest agitation of the waves will destroy it, and as those shells inhabit the deep waters, and are collected by the curious only from the *rejetments* of the sea cast upon the beach in storms, it is natural to conclude that it is rarely seen complete. It was not till of late years that the true form of the perfect shell appears to have been ascertained. The orthocera is the orthoceros of Gualtieri and Breynius revived. This shell is straight or arched, and a little conic, with distinct chambers formed by transverse simple divisions perforated by a tube, which is sometimes placed centrally and sometimes laterally. We are of opinion this amendment would be improved by forming two genera of the orthocera, one containing the straight and the other the arcuated kinds; and indeed we conceive

still further that those, with the siphunculus placed on one side, should form a distinct genus from those having the siphunculus in the centre. The Linnæan character of the nautilus confounds all these distinctions; they are all nautili of that writer.

Among the testaceous remains of the antediluvian world, are many singular spiral shells, allied to, or of the same genera with the foregoing, and others which, though spiral and concamerated, cannot possibly be reduced to these tribes; such as the ammonites, the orbulites of Lamarck, *helicite* of Guettard, baculites of Faujas, and the belemnites, or "thunder-bolts," of most authors. See article FOSSILS.

CONUS. Animal a limax. Shell univalve, convoluted, and turbinated; aperture or opening effuse, longitudinal, linear, toothless, with the base entire; pillar smooth.

This genus is divided into five distinct families. * *Truncati*, having the spire nearly truncated. ** *Pyriformes*, with the base rotundate and sub-cylindrical; the cylinder half as long again as the spire. *** *Elongati*, with the base rotundate, cylinder twice the length of the spire. **** *Ventricose*, in the middle, and narrow at each end. ***** *Ventricose*; emits a tinkling sound, when thrown on its back upon a board or table. The total number of species included in this genus, in the last edition of the *Systema Naturæ*, amounts to seventy-one. Many of the conus, or cone tribe, are beautiful shells, and bear a high price on account of their rarity; the *cedo nulli* of Lyonet, valued at one hundred guineas, is of this genus. We have no species of this genus upon the English coasts. Some very curious kinds have been discovered in a fossil state in England, chiefly in the chalk cliffs of Hampshire.

CYPRÆA. Animal a limax. Shell univalve, involuted, sub-ovate, obtuse, and smooth; aperture effuse at each end, linear, dentated at both sides and longitudinal.

Linnæus forms several distinct families of the cypræa genus, one of which is distinguished by being obtuse, and without any manifest spire; such, for example, as the species *caput serpentinus* and *tigris*, the last of which is well known by the name of tiger cowry; another kind is perforated, or furnished with an umbilicus, as in *cypræa ziczac*; and a third sort is margined like the common West India cowry, vulgarly called "blackmoor's teeth," *cypræa moneta* of Linnæus. In the young state, the cyprææ have much the appearance of a volute, and are entirely destitute of the thick denticulated lip or margin, so obvious in the adult shells. Writers have been even so far misled by this specious appearance, as to describe the young of several kinds for shells of the volute genus. The *voluta jonesii* of Pennant's British Zoology, is clearly nothing more than the young of the common English cowry, *cypræa pediculus*, which that writer mistakes for a perfect shell.

BULLA. Animal a limax. Shell univalve, convoluted, and unarmed with teeth; aperture somewhat straightened, oblong, longitudinal, and very entire at the base; pillar lip oblique and smooth.

The arrangement of the bulla family is very confused in the works of the old writers. Lister makes them a genus of the cowry, and calls it *concha veneris basi umbilicatâ*. Grew and Bonanni place it with the snails; Argenville and Davila with the cochleæ globosæ; and Gualtieri as a genus between the paper nautili (argonauta) and the cowries. The term bulla implying the bubble-like form, or swollen appearance of the shell, was applied by Rumphius to the bulla ampulla, from whom it was adopted by Klein, and afterwards by Linnæus as a generic appellation. The shells

included by this last-mentioned writer under the name of bulla, are more than commonly anomalous in habit and form; few instances can be adduced of greater dissimilarity than is observable between the bulla ovum, ficus, terebellum, and virginea. The species ovum has the habit of a cowry, the ficus that of a murex, the terebellum that of a cone, or a baccinum, and the virginea of a turbinated helix. The bulla achatina and the bulla cylindrica likewise offer characteristic differences, which may, without any impropriety, constitute generic distinctions.

According to Linnæus, the animal of the bulla is a limax; but if it be such, as Dr. Pultney observes, in any particular species examined by that author, it does not hold throughout the whole genus; nor even in those which were primarily and eminently distinguished by the name of bulla. In some species the animal appears more to resemble an ascidia. The animal of bulla aperta forms a new genus in Lamarck's arrangement, under the title of bullæa. The animal of bulla lignaria is furnished with masticatory organs, consisting of three testaceous bodies placed within the stomach or gizzard, by the help of which it is enabled to break small shells and hard substances. This instrument was first discovered by Plancus in the bulla aperta, in which we have ourselves observed it. An account of that in the gizzard of the bulla lignaria, by Mr. G. Humphreys, is inserted in the Linnæan Transactions. These latter mentioned testaceous bodies were first introduced among conchologists as a new genus of shells by M. Gioèni, a Sicilian naturalist, after whom it was named gioenia, by Bruguière. Retzius also describes it, but under the name of tricola. An account of the discovery of this important error, was published by Draparnaud, in the Bulletin des Sciences, p. 39.

VOLUTA. Animal a limax. Shell single-celled and spiral; aperture without a beak, somewhat effuse; pillar folded or plaited, and generally without lips or perforations.

This extensive genus is dispersed by Linnæus into the following principal families. * Aperture or opening entire. ** Somewhat cylindrical and emarginate. *** Obovate, effuse, and emarginate. **** Puffin. ***** Ventricose; spine papillary at the tip. The whole includes one hundred and forty-two species.

Linnæus has deservedly incurred some blame for having too often transposed long established names from objects to which they were before assigned, and imposed them on others without any apparent or sufficient reason, which were never understood among his predecessors by those terms. An instance of this kind of innovation occurs to us at present. The term voluta, derived "a volendo forte revolutione spirali," was always applied to the cone tribe, and is very expressive of the peculiar rolled, or involuted structure of those shells; Linnæus deprived them of that name, called them conus, and gave the title of voluta to the shells of which we are about to treat. The voluta genus, furthermore, as now laid down, is highly objectionable. Linnæus, in the establishment of this new genus, has been less attentive to the natural families of shells than could have been wished, and has, by that means, brought promiscuously together shells which scarcely agree in any one individual respect, except in having plait or folds upon the pillar.

This error does not rest, however, entirely with Linnæus, for he was not the original projector of the genus; he only adopted it, and gave it the name it now bears, when he might with more propriety have expunged it, or dispersed the shells contained into other genera. In Lister's work, section II. lb. 4, we find a class of shells entitled, "buccina columella dentata," in which that author arranges the buccina and other shells which have the pillar plaited. Lin-

næus, by the adoption of this genus, under the title of voluta, comprehends a number of shells possessing very distinct generic characters, and which had been distinguished by his predecessors under the various names of oliva, rhombus, cylindricus, turricula, mitra, musica, and others applicable either to their figure, or to the essential characteristics of their respective natural families. It is a singular corroboration of the accuracy of the ideas entertained by those writers, that the animals inhabiting the shells above-mentioned, have been recently ascertained to be as dissimilar in structure as the shells. Linnæus considered the animal of all the volutes as a limax or slug; but from the investigation of Adanson and Argenville, and since the time of Müller, Poli, Lamarck, and many others, it appears that no opinion was ever more unfounded; the animal of each family being differently formed, and adapted to the peculiar shape or structure of the shell.

Da Costa, in his "Elements of Conchology," abolishes the Linnæan voluta genus altogether, but the shells are not restored according to his method to their proper or natural families; his definitions want precision, and his scheme is confused and uncouth. But notwithstanding, the scheme of classification laid down by Da Costa was never acceded to by conchologists, and certainly never will now; from the circumstance of its being the only elementary work in the English language (Barbut's Gen. Verm. excepted) it has answered one useful purpose, that of directing the general collector to dispose their shells into particular families, in a more comprehensive manner than could have been accomplished by attending to the Linnæan arrangement. Thus, in the Linnæan volute, the families are distinguished by the title of papal crowns, Persian crowns, melons, olives, midas's ears, mitres, musics, and other trivial appellations, by which they are known even to this day among English collectors. As Da Costa derived his principal distinctions of these families from writers who flourished before Linnæus, so also it has happened with the French conchologists; they disapprove of the Linnæan arrangement, but retain most of the original families described by those earlier writers, and thus we see at the present time the genera olive, turbinelle, mitre, harpe, &c. retain and adopted with some improvements, by the best informed conchologists of that country.

BUCINUM. Animal a limax. Shell univalve, spiral, gibbous; aperture ovate, terminating in a short canal, leaning to the right, with a retuse beak, or tip; inner lip expanded.

The buccina are separated into sections, in the following order: * ampullacea, &c. inflated, rounded, thin, and sub-diaphanous, and brittle. ** Cassidea, caudata, &c.; tail short, exerted, and reflected; lip unarmed outwardly. *** Cassidea, unguiculata, &c. lip aculeated on the outside of the posterior part, otherwise resembling the last division. **** Callosa, &c. pillar lip dilated and thickened. ***** Detrita, &c. pillar lip appearing as if worn flat. ***** Laevigata, &c. smooth, not enumerated in the former divisions.

Linnæus has occasioned strange confusion in his classification of the shells which he denominated buccinum: in the indefinite latitude which his character of this genus admits, he embraces shell every little, if at all, allied to each other, in any other respect than according with his character. Thus the cochleæ globosæ of Rumphius and Argenville, the cochleæ pyriformes of Gualtieri, and other distinct natural families of writers, prior, as well as subsequent, are confounded altogether in this most copious genus. It is not sufficient that these be kept apart by being referred to different families, they should certainly constitute distinct ge-

nera. The French have long distinguished these different shells, by the appellations on tonne, casque, harpe, pourpre, &c.; the English collector will better conceive, perhaps, what is meant by the trivial distinctions of tuns, partridges, harps, and whelks. In Lamarck's arrangement, they assume a more classic form, and are defined generically, under the title of *dolum*, *harpa*, *caffis*, *tebrera*, *purpura*, *buccinum*, and *nassa*, as will be more accurately explained hereafter.

STROMBUS. Animal a limax. Shell univalve and spiral; lip of the aperture often much dilated, and produced into a groove leaning to the left.

Previous to the time of Linnæus, the term *strombi* was applied to shells of a different description from those at present understood by that name. Under the title of *strombi*, the Greeks originally designated all kinds of turbinated shells. Among the older writers, the term *strombi* was indiscriminately employed as synonymous with *turbo*, *trochus*, and sometimes with *murex*. *Strombi* was then a term indefinite, but rather applicable to the slender kinds, *murices*, or *rhombi*.

Linnæus was the first who limited the application of the word *strombus* to those univalve shells, which have the canal or gutter directed to the left, and the lip expanded. He was not, however, the first to establish the genus. Lister describes the shells of this family which have the lip entire, under the title of *purpura seu buccina bilingua*, and classes them in the twelfth section of his fourth book. Rumphius, and after him Meuschen, make a distinct genus of them, under the title of *alatus*; and by this name *alatus*, they are pretty generally known to this day, it being well known that Solander intended to have established such a genus under this name. Davila ranks these winged slate among his *murices*, but independently, and as a distinct genus, consisting of simple or entire winged shells; placing immediately after them another genus, comprehending those which have the expanded lip digitated, or elongated into prong-like processes. Linnæus rejects this arrangement of Davila, including in his genus *strombus*, the whole of those winged or alated shells; not in a promiscuous manner, but in sections or families, as * *Digitati*, *labio in laciniis linearis exeunte*. ** *Lobati*. *** *Ampliati*. The French writers to this time, on the contrary, follow the example of Davila, and form two distinct genera of these shells under the title of *strombus*, and *pteroera*, and to these another has been lately added after our countryman Lister, under the name of *rostellaria*.

On this arrangement, the genus *strombus* is described as being a ventricose shell, terminated at the base by a short canal, sloping off or truncated: the right margin or lip dilating or expanding with age into a simple or entire wing-like lobe, and having a sinus beneath, distinct from the slope of the base, or in the Latin language, the beak. This genus is sufficiently explained by the shell called among English collectors the "pugilist's fist," *strombus pugilis* of Linnæus. The genus *pteroera*, has the shell ventricose, terminated below by a long canal; the right margin, or lip expanding with age into a digitated wing, and having a sinus near the base. The Linnæan *strombus lambis* is of this genus. The generic character of *rostellaria* is drawn from the *strombus fufus* of Linnæus, described by Lister, t. 854. f. 11.; and Martini, t. 159, f. 1500. The shell is fusiform, terminated beneath in a canal, ending in a subulated or pointed beak; right margin entire or dentated more or less dilated into a wing-like process with age, and having a sinus contiguous to the canal or gutter.

We may lastly add, that the young shells of the *strombus* genus do not possess the striking peculiarity of the ample dilated lip before-mentioned, and that in consequence, such shells have been sometimes referred to very different genera, an error committed by some of the best among the early writers.

MUREX. Animal a limax. Shell inequivalve, spiral, rough, with membranaceous futures; aperture ending in an entire canal; either straight, or somewhat ascending.

The Linnæan genus *murex* is very extensive; in the last edition of the *Systema Naturæ* a hundred and sixty three species are described under the following sections. * *Spinosi*, spinous, with the tail (or beak) produced. ** *Frondosi*, futures expanding into crisped foliations; tail (or beak) abbreviated (vulgarly called *purpura*). *** *Varicosi*, futures rounded, protuberant, and thick. **** *Ecaudati*, without tail (or beak) and somewhat spinous. ***** *Caudigeri*, tail (or beak) subulate, clofed, straight and elongated; unarmed with spines. ***** *Turriti*, tapering, subulate, with the tail very short.

The *murices* of the elder writers consisted for the most part of such shells of the whelk or *buccina* kind as exhibited any considerable degree of asperity or ruggedness on the exterior surface, the Latins having employed the word *murex* to express the roughness of rude stones or walls. Many of the Linnæan *murices* are of that kind described by his predecessors under the name of *purpura*, the animals of which are spoken of by the ancients as being furnished with a tongue-like process, by means of which they are enabled to perforate other shells, and derive subsistence from the inclosed animal. The English call the *murices* rocks, and the French in imitation, *rocher*.

Three genera of shells formed of the Linnæan *murices* by the continental writers, claim particular attention; these are *fasciaria*, *pleurotoma*, and a genus, retained under the title of *murex*. The first of these consists of such shells as like the *murex tulipa* of Linnæus are of a somewhat fusiform, or spindle shape; smooth or without rugosities, and having upon the pillar two or three very oblique folds or plicæ. *Pleurotoma* is also of a spindle form, with the aperture terminating below in a long gutter or canal, and has the lip cleft or cut off in a slope near the summit. The third or *murex* genus is of an oval or oblong form, canalculated at the base, and having the outside of the shell constantly beset with prominent longitudinal ridges, and for the most part with tuberculations, spines, or fringes. We cannot refrain observing that this, and perhaps some further amendments in the Linnæan *murices*, were requisite to reduce them to lucid order; it will not we think admit of any doubt that the two first genera before mentioned, ought not to be arranged in the same genus with the *murices*, admitting the Linnæan character of that genus as it stands in the *Systema Naturæ*. Linnæus, it is true, included shells of both these families among the *murices*, but surely without sufficient attention to the generic character he had himself proposed for the *murex* tribe.

TROCHUS. Animal a limax. Shell univalve, spiral, and subconic; aperture somewhat angular, or rounded; upper file transverse and contracted; pillar placed obliquely.

The *trochi* Linnæus divides into three families; * *umbilicati*, &c.; umbilical, erect, and with the pillar perforated; as in the species *nitoticus* and *perpectivus*. ** *Imperforati*, &c.; erect, with the umbilicus clofed; as in *labio*. *** *Turriti*, &c. turritid, with the pillar exerted; shell falling on one side when placed on the base.

This is a long established genus of shells, having been adopted by the principal conchological writers a considerable

time before the *Systema Naturæ* of Linnæus appeared. Notwithstanding this, we perceive no small degree of difficulty arising in a general arrangement of shells from too strict an adherence to this genus as the character is proposed by Linnæus. We do not object to the trochus genus altogether; it is an excellent genus in itself, so far as relates to the greater number of the conic species, which may be readily distinguished by their outline, but we cannot, it must be acknowledged, so easily reconcile our ideas to the propriety of including with these the turritid or tapering trochi of this writer: such as, for example, in the species *telefcopium*, and others in that family. Furthermore, it may be added that some amendment in the distribution of these shells is rendered the more necessary for the sake of perpetuity in the arrangement of a number of new species not strictly according even with the former, and which have been discovered since the time of Linnæus.

Lamarck, and after him Latreille, constitute a new genus of the turritid kinds of the Linnæan trochi, under the title of *pyramidella*, and which they define generically, as being a turritid shell, with the opening entire, and femioval; pillar projecting, raised, with three transverse folds, and perforated at the base. This genus is fully illustrated by the Linnæan *trochus delabratus*.

The new genus *pyramidella* was certainly necessary; but besides this, the continental naturalists above mentioned, have instituted some other genera from the Linnæan trochi, as *solarium*, and *monodonta*. The Linnæan trochus perspective elucidates the character of the first of these three genera, which consists in being of a depressed conic form, with an umbilical opening in the base, crenulated along the inner margin of the spiral volutions, and the opening or aperture almost quadrangular. This is the shell known among English collectors by the name of staircase trochi, from a fancied resemblance of the internal view of the umbilical opening to a well, or spiral staircase. These shells are comprehended by Linnæus in his first family of trochi; but we should rather incline to admit them as a genus distinct from that tribe; the depressed contour of the shell, and singular structure of the umbilical opening, forming an excellent generic distinction. The Linnæan *trochus labio*, and its analogous species, being of an oval or conoid shape, with the opening roundish and entire, but furnished with a projecting tooth, are the description of shells of which the genus *monodonta* consists.

TURBO. Animal a limax. Shell univalve, spiral, and folioid; aperture contracted, orbicular, and entire.

The shells of this genus are divided into five families; *neritoides, &c. having the pillar-margin of the aperture flat, or dilated and imperforate; **solidi, solid and imperforate; ***foliidi, &c. folioid and umbilicated, or perforated; ****cancellati, cancellated; *****turriti proprie dicti, turritid, or tapering.

The turbo genus, as it stands in the Linnæan *Systema*, is much too diffuse, and comprehends shells so very remote from each other in various essential circumstances, that the Linnæan student will find some difficulty in retaining it under its present form. So nearly indeed do the Linnæan turbines, and buccina approach, that the ablest Linnæan is sometimes unable to decide exactly to which of the two genera particular species ought to be referred. The diffusibility, in general appearance, is also very remarkable in the turbo genus. The conoid, and the tapering turbines of this writer, are altogether distinct, and should certainly be assigned to different genera; and a dissimilitude equally striking prevails between those which have a sinus at the margin, and such as have that part entire. In addition to

these, we would mention the Linnæan turbines which have equidistant longitudinal ridges disposed on the outside of the shell, as in *turbo scalaris* and *clathratus*, as affording such a very prominent distinction, that we cannot hesitate to consider them as a genus of themselves.

HELIX. Animal a limax. Shell univalve, spiral, subdiaphanous, and brittle; aperture contracted, femilunar, or roundish.

This genus is divided into several families; as **ancipites*, &c. angulated on both sides, ***carinata*, margin of the whorls acute, ****rotundata*, whorls rounded, and umbilicated, *****rounded* and imperforate, ******turritæ*, tapering, ******ovate*, &c. ovate and imperforate. The whole genus comprehends, according to the last edition of the *Syst. Nat.* two hundred and fifty-two described species.

The animal of the helices seems to be endowed with a more perfect and lively power of motion than most others of the tellacea tribe; this we have abundant opportunity of observing in the common land and garden snail which is of this genus. Before the time of Linnæus the helices were known under the more indefinite title of *cochleæ*, to which family the *neritæ* and several other natural families were also referred.

Late writers divide the Linnæan helices into a number of new genera, as *jauchina*, *bulimus*, *lymnaea*, *melania*, *planorbis*, and *helix*. See LATREILLE, OLIVIER, &c.

NERITA. Animal a limax. Shell univalve, spiral, gibbous, flattish at bottom; aperture semi-orbicular, or femilunar; pillar lip transversely truncated and flattish.

The Linnæan *neritæ* are divided into three families, **umbilicate*, ***imperforate*, with the lips toothless, ****imperforate*, with the lips. No less than seventy-two species are described in the *Systema Naturæ* under these three families.

The *nerita* genus of Lamarck, Latreille, and other late writers, consists of those Linnæan species, which are femiglobule, flattened at the base, and not umbilicated; with the opening entire and semi-circular; and the pillar somewhat transverse, truncated, and often denticulated. *Nerita exuvia* of Linnæus is of this kind. The genus *natica* (notice) of those writers, comprehend the umbilicated *neritæ*, such as the species *caarena*, and its analogous kinds. The *naticæ* are subglobose, umbilicated, with the left margin callous near the umbilicus: mouth or opening of the shell entire; pillar oblique, and not denticulate.

HALIOTIS. Animal limax. Shell ear-shaped, dilated, spire lateral, and nearly concealed, and a longitudinal row of orifices along the disk or surface.

Few species of this genus were known to Linnæus, and in the reference of these, he was peculiarly attentive to the characteristic longitudinal series of orifices so conspicuous in this genus. It was for this reason he referred the *helix halioidea* to the helices, rather than the *haliotis* tribe; the shell being destitute of this striking character, though, in every other respect, it appertains more strictly to this *haliotis* than the *helix* genus. After this we cannot think Gmelin advisable for having admitted the imperforate shells, his *haliotis imperforata* and *perforata*, into this genus. It would have been perhaps better, even in that system, to have constituted a new family for their reception; he conceived the introduction of a new genus an innovation. Chemnitz indeed calls the first of these an *haliotis*, but its impropriety is not lessened by that circumstance.

One of the imperforate kinds, the *haliotis imperforata* of Gmelin, was previously described by Heblins, under the new generic title of *stomatia*, a genus adopted since by Lamarck,

marck, Latreille, and various other writers, and which we cannot hesitate to admit as highly necessary. The distinctions between these two genera are sufficiently characteristic. Stomatia has the shell of an oval form, and ear-shaped, with the spire prominent; the aperture ample, entire, and longer than its breadth; disk imperforate, or without orifice. Halotis shell flat, ear-shaped, with the spire very low, and almost lateral; aperture very ample, and longer than its breadth, and entire; and the disk pierced with orifices disposed in a line parallel with the left margin.

Lillier, in his "Histoire Conchyliorum," places the halotis, or sea-ear tube, among the tubinated shells, between the nerita and trochus; the same mode of arrangement is observed in his work "De Animalibus Angliæ," where he says it is spiral at the clavicle, in the same manner as other tubinated shells, and is therefore placed erroneously by some among the simple shells. Gualtieri ranks them among snails with depressed or flattened spires; Adanson, in the first family of spiral shells; Da Costa immediately after the patella, his first genus of simple shells, and Lamarck between the testacelle, which follows the helices and nerita, and the vermiculaire or serpula.

Some writers admit it as a collateral character of the halotis, that the inside is always of the finest pearl, and pearls are oftentimes produced in these shells. The perforations vary in number in different species. It has been observed, that the animal always closes one of those holes towards the spire, whenever he opens another towards the head as he grows bigger, and by that means that the number of openings are invariably the same in different individuals of the same species. Shells of this genus are very rarely discovered fossil; we much question if any of those described by writers are truly of this genus.

PATHELLA. Animal a limax. Shell univalve, sub-conic, and without spire. Linn.

These are the limpets, and are so named from their resemblance to a little plate, or patella, and are more or less conic without, and concave within. Some have the apex or top entire; others perforated: the chambered limpets are distinguished by a peculiar kind of projecting process, or lip within; most have the margins entire, but some have an indent or fissure in that part; and again others are so completely spiral or wreathed in their exterior appearance that they resemble rather the trochi, or top shells, than the limpet. Linnæus, in order to comprise shells so very dissimilar in appearance under one genus, found it necessary to constitute no less than five distinct sections or families for their reception. These he arranges in the following order.

* **Labiata**, &c. furnished with an internal lip; shell entire.

** **Dentata**, &c. with the margin angulated, and toothed.

*** **Mucronata**, &c. with the pointed tip recurved.

**** **Integerrima**, &c. very entire, and not pointed at the tip.

***** **Perforata**, &c. with the crown perforated.

Lamarck, as being one of the latest writers on this subject, deserves particular attention; he divides the Linnæan patella into six distinct genera, which he calls patella, fissurella, emarginula, concholepas, crepidula, and calyptræza.

The shells retained under the old name of patella (patelle) are defined generically as being univalve, without spire, oval, or suborbicular, shield-form, or bonnet-shaped, concave and simple beneath, with the summit entire, and margin without fissure, as exemplified in patella testudinaria, in the fourth Linnæan family. Fissurella (fissurelle) has the shell shield-form, without any kind of spire, concave be-

neath, and at the summit an oval or oblong aperture. The fissurellæ correspond with the fifth of the Linnæan families perforatæ, and with the genus formed by Da Costa under the name of pierced limpets or molks, in his "Elements of Conchology." The little slit limpet, patella fissura of Linnæus, very clearly illustrates the genus emarginula (emarginule), of Lamarck; the genus is distinguished by the shell being of a conic form, concave beneath, and having the posterior margin cleft. The concholepas has the shell univalve, oval, convex above with the summit obliquely inclined upon the left margin; the cavity within simple; and two teeth and a sinusity at the base of the right margin. This genus is exemplified in the concholepas peruviana of Favanne, and buccinum lepas of Bruguiere. Some other writers admit it as a family of the limpets which they distinguish simply by having the beak produced and somewhat twisted or crooked. The crepidula (crepidule) of Lamarck is of an oval, or oblong form; with the summit inclined upon the margin, and a partial simple diaphragm or division in the cavity. The Linnæan patella porcellana is of this genus. The calyptræza (calyptrée) is of the chambered kind, appertaining to the first of the Linnæan families, and is sufficiently explained by the Linnæan patella questris. The shells of this kind are of a conoid form with the summit vertical, entire, and pointed, and the cavity furnished with a thin pate, or tongue-like process in the centre, which is either detached or connected to one side of the shell, and runs in a spiral direction.

DENTALIUM. Animal a terrella. Shell univalve, tubular, straight, or slightly curved, with the cavity open at both ends, and undivided. Linn.

The simplicity and precision of the generic character of dentalium merits commendation, and, although some late writers on the continent seem too fastidious to admit it, we deem it unexceptionable. The shells of this kind are known in England by the name of tooth shell. (Donov. Brit. Shells.) We have few species, and those are principally of the minuter kinds, in this country. Gmelin enumerates altogether twenty-one species of this genus, some of which are found only in a fossil state.

SERPULA. Animal a terrella. Shell univalve, tubular, and adhering. Often separated internally by divisions at uncertain distances.

By the introduction of a few particular shells the Linnæan serpulæ are rendered altogether incongruous. The genus, as now retained, is extremely vague; and which, indeed, is necessary in order to comprise the whole of the species described by Linnæus under this general head. Nothing absolutely certain is established for its character, except its being an univalve shell, a circumstance common to the greater part of the shell tribe, and its being tubular without a regular spire, which is no less applicable to the dentalia, the terredines, and if, like Linnæus, we admit the genus to be really of the testaceous tribe, the labellæ also. What then remains to fix the character of a serpula? that it adheres to other bodies, but even this is not always the case; and beyond this we are again left in doubt, its character being confessedly indecisive and local, "sæpe illius integris passim intercepta," Linn. There are sometimes internal divisions at uncertain distances in these shells, but what can we infer from these in constituting a generic character: these divisions are in the first place concealed within the shells when entire, and are only to be discovered by destroying them! and can this be considered as a character well calculated to afford a generic criterion? Nor is this all, these internal divisions are by no means constant; they are not as in the nautilus and other regularly formed

formed chambered shells placed at equal intervals, neither are they pierced by a siphunculus, or pipe-like receptacle communicating from chamber to chamber for the reception of the linear body of the animal inhabitant; the creature must remain in the single chamber or enclosure, having no means of extending itself into the rest of the shell. And besides this, the concenterations above-mentioned do not seem conlittant to any particular species, but depend on the age of the shell, and appear to be formed progressively at various intervals as the animal from various causes or its increase of growth finds it necessary to form a larger dwelling. In this case the deserted chamber last occupied being no longer useful is closed up, to render its new habitation more compact. We now advert only to particular shells; there are many species which do not exhibit such a concenterated structure.

One of the first writers upon this subject, after the time of Linnæus, was Da Costa, who in his "Elements of Conchology" takes occasion to notice the manifest impropriety of uniting in the same genus the shell known by the Linnæan student under the name of *serpula penis*, and the simple *vermiculi*.

He proposes to obviate the difficulty by constituting two genera, the *vermiculi*, or tubular worm shells, which have no fixed or regular form, as the common *vermiculi*, (*serpula vermicularis*, Linn.); and *penicilli*, or those worm-shells which, in the whole, or any especial or particular part, have a determinate regular shape or structure. Of this last genus, he observes there are few species; the watering pot (*serpula pluis*, Linn.) from the East Indies is the chief kind, and when perfect is much valued. The propriety of dividing these families of shells is well conceived, but the distinctions are less happily defined than might be expected. The suggestion, however, of this writer has been improved upon by the later French naturalists. The genus *arrofoir* or *penicillus* of Lamarck is the *penicilli* of Da Costa; and yet, in truth, we should add, that though the genus was laid down by Da Costa, we may trace it to Argenville, who had previously, nay, even before the time of Linnæus, described the watering-pot shell under the title of *penicillus marinus*. The genus *arrofoir*, or *penicillus*, as defined by Lamarck, is a good one, and the same may be truly said of the *siliquaria* of Davila, a genus exemplified in the Linnæan *serpula anguina*, which is distinguished by having a longitudinal subarticulated opening or cleft, extending throughout the whole length of the shell. The concenterated *serpulae*, we have seen, are not to be regarded as generically different from the rest.

The *vermiculi* of Gualtieri include the Linnæan *turbo scalaris*, a rare spiral shell, better known in England by the name of winkletrap, and which is esteemed of considerable value on account of its rarity. This writer places it with the *vermiculi*, because, as he observes, the spires of the shell are not produced from or supported by a pillar, as is constantly the case in turbinated shells, but possess, on the contrary, the true character of the spiral worm shells; and there is certainly much truth in the ideas of Gualtieri, though we do not at the same time perceive the absolute necessity of removing it to this genus, and we should anxiously and most scrupulously avoid any needless innovation. Lastly, we shall mention that the author of the "Pellæcia Britannica" proposes as an amendment in the *serpula*, to divide them into two distinct genera; the *serpula* he retains under the old Linnæan character, "shell univalve, tubular, adhering, or affixed to other bodies; in some species divided into celis." The other he calls *vermiculum*, and defines

"shell univalve, shape various; not attached, or adhering to other bodies." This we believe must in candour be admitted as more vague and indefinite than even the Linnæan distinction, and by the laxity of expression may as well apply to the whole tribe of univalve shells, the adherent *serpulae* excepted, as to the particular family called *vermiculum*. But though we disapprove of the character assigned, we perfectly agree with the ingenious author as to the propriety of separating the adhering kinds of *serpula* from those species which constantly occur detached.

TEREDO. Animal a terebella, furnished with two calcareous, hemispherical valves, or maxillæ, truncated before, and two others of a lanceolate form; shell tapering, flexuous, and penetrating wood.

The animal inhabiting this shell is a terebella of a particular kind; the body being of a soft and gelatinous nature, but having the head provided with an instrument of a calcareous substance, which performs the office of an augre, and enables the worm to penetrate the hardest oak. The most destructive of the animals of this genus is the teredo navalis, which penetrates the bottoms of ships. It was originally imported from India into Europe about seventy years ago. Sellus, in the year 1733, published a treatise on this subject under the title of "Historia Naturalis Terebinis, seu Xylophagi marini Tubulo-conchoidis." It was afterwards described and figured by several writers, and among others by Bailler, in the Philosophical Transactions, vol. lxi. It is now too well known by the name of *ship-worm*. See Donovan. Brit. Shells.

Three species only of this singular genus have been yet discovered, and which are named *navalis*, *uricularis*, and *clava*. Favanne and Guettard divide these shells into two genera, *teredo* (*taret*) and *siliularia*; the shell of *teredo* is distinguished as being tubular, cylindrical, and open at both ends, lower orifice furnished with two lozenge-shaped valves, and the upper with two spatulous opercules. *Siliularia* is a genus composed of a single species, *teredo clava*, Gmel.: the shell is tubular, elevated at one end, open at the slender extremity, and containing in the cavity two non-adherent valves. This last is called by Favanne, *siliularia cornicula*, and *siliularia gregata* by Guettard.

SABELLA. Animal a nereis, with ringent mouth, and two thicker tentacula behind the head: shell tubular, composed of particles of sand, broken shells, and vegetable substances, united to a membrane by a glutinous cement.

The *sabella*, according to Linnæus, is inhabited by an animal of the nereis kind. Some of these animals were known among the old writers under the name of sea scolopendæ. Since the time of Linnæus, the number of species has been greatly augmented by the discoveries of Pallas, Fabricius, Müller, and others, and the nature of those animals become better understood; in consequence of which, they have been discovered to be the habitations not only of the nereis, but likewise of the amphitrite and terebella genera. We speak of the marine kinds: with respect to several of the supposed species of *sabella* found in fresh water, it is accurately determined they are not of this race of animals, but the larvae of ephemæra, phryganea, and other insects, which construct cylindrical cells of extraneous matter, in which they reside while they remain in that state in the water. Some naturalists, in order to avoid confounding these larvae with the true *sabella*, have cautiously omitted the whole; and we indeed suspect, that although they may continue to be retained by the Linnæan student among the shell tribe, they will be expunged, or many of the species at least, by future systematists. The Gmelinian system comprehends 25

Species of fabella, the fresh-water kinds, described by Schroetter, included.

The marine fabellæ shells are composed chiefly of sand and the fragments of shells; those of the supposed fabella found in fresh water, either of small fragments of vegetables, or the broken shells of testaceous vermes, those of the helix tribe especially.

Having presented the reader with a detailed view of the Linnæan system of conchology, we shall next proceed as before to speak of the other principal writers on the subject, as nearly in chronological order as circumstances will permit.

The third volume of the extensive and costly work of Seba ("Descriptio Thesauri Rerum Naturalium," was produced at Amsterdam in 1758. This part treats on marine subjects generally, as crustaceans and testaceous animals, corals, &c.; and contains, besides plates in other departments, sixty-one elucidatory of conchology. As a book of reference to the more striking and well known kinds of shells, the work of Seba possesses merit: it has been observed, and with much truth, that this valuable publication might however have been rendered less expensive by the omission of a number of figures, which consist merely of repetitions, and also the specimens of art absurdly introduced, such as the fanciful decorations on the shells of the nautilus, and the examples of "shell work," on which a profusion of engraving is unnecessarily expended.

In the "History of Cornwall," Dr. Borlase presents us with a plate of shells containing about thirty species; the descriptive matter is slight, and is principally copied from some of the oldest writers on the subject. This was published in folio in London, A.D. 1758.

The magnificent work of Francois Michael Regenfus, "Choix de coquillages et de crustacés," appeared at Copenhagen, under the patronage of the king of Denmark, in the same year as the preceding. The work comprises twelve coloured plates in imperial folio, and each plate comprehends twelve shells. The descriptions, which are written both in the French and Danish language, are the joint labour of professor Kratzenstein and Dr. Afcenius. It has been lamented that the talents of this artist were not employed on subjects better deserving of elucidation, as those which are figured by Regenfus fall daily under the notice of the most humble collectors. A second volume was begun, and considerable progress made in it before the year 1776; but as the artist is no more, the undertaking is in all probability relinquished. Twelve plates designed for the second volume are possessed by sir Joseph Banks, and which include shells of greater rarity than those inserted in the first volume.

We have already adverted to the "Class's Conchyliorum" of Carolo Augusto de Bergen, published at Nuremberg in 1760. This little treatise contains a compendious view of the principal systems of conchology which had then appeared, under the heads of "Methodi Universales," and "Methodi Particulares," with concise prefatory dissertations on each. These remarks of Bergen have evidently furnished later writers with many useful criticisms on the several works that fall within the compass of his view, and may, upon the whole, be thought far preferable to many more elaborate observations that have since appeared on the same subject.

The "Amusement Microscopique" of L. d'ermuller relates to minute shells, and contains many figures. The first part was published at Nuremberg in 1764, and in 1766 and 1768 two other parts of the same work.

Davila's "Catalogue Systematique et Raisonné des Conchies de son Cabinet" was printed at Paris, in 1767, in three volumes octavo, preparatory to the dispersion of his collection in the following year. The first volume treats entirely of shells, and contains twenty-two plates of the rarer specimens in his cabinet, many of which are scarce even at this day. This work affords much interesting information, though it is to be considered only as a sale catalogue. The same year a similar production, "Catalogue Systematique des Coquillages de Arnold Leers, de Rotterdam," appeared at Amsterdam, as an announcement of the sale of his valuable collection. This was written by Mr. F. C. Meuschen, German envoy at the Hague, and contains a sheet system of shells.

The work of Geoffroy, "Traité des Coquilles, tant fluviatiles que Terrestres, que se trouvent aux Environs de Paris," was printed in 1767, and forms a valuable acquisition in this department of science. Three plates engraven by Duchesne, contain figures of forty-six shells described by Geoffroy.

A curious and interesting paper by Herissant, occurs in the Mem. de l'Acad. des Sciences, for 1768, entitled, "Eclaircissements sur l'Organization jusqu'ici inconnue d'une Quantité considérable de Productions Animales, principalement de Coquilles des Animaux," with eight illustrative plates, three of which relate to shells. In the same year the "Mémoire sur le Coquillage appelé Datte en Provence" of A. D. Fourgeroux de Bondaroy, was inserted in Mem. Etrang. de l'Acad. Roy. de Sc. together with a plate elucidatory of the subject, which is the Linnæan mytilus lithophagus.

Cotte's observations on the physiology, &c. of the snail tribe, occur in the "Journal de Scavans" for 1770, and in the "Journal de Physique les Découvertes de Yeux, et de l'Esprit" of Knorr, completed in 1773, consist of six parts, and altogether contain 978 figures of shells. The author was a painter at Nuremberg, and his publication commenced in 1760; but not living to finish the undertaking, the last part was brought forward by his executors. Knorr had collected materials for another testaceological work, his "Delicie Nature selectæ," which was afterwards prepared for public view under the direction of Müller and De la Blaquière.

Another conchological work, of still greater extent, "Neues systematisches Conchylien-cabinet," was in a progressive course of publication at Nuremberg, about the same period. The first part appeared in 1769, another in 1771, and a third in 1777. These constitute the first three volumes, which were all its author, Martini, lived to complete. Seven volumes have been since added by F. H. Chemnitz. The body of the work is written in the German language; the embellishments consist of 366 plates, and exhibit a number of figures on each plate. It is highly probable this work will never be extended beyond its present limits; Chemnitz being dead, and his collection of shells, which was very copious, having been dispersed within the last four years by public sale. The catalogue of folio bears date Feb. 7, 1803, it was drawn up by H. S. Holten, in a small duodecimo, entitled, "Enumeratio systematica Conchyliorum J. H. Chemnitzii," &c.

Schöter is the author of many treatises on the subject of shells, and which appear to be little known. He has in particular distinguished himself by his observations on the river shells of Thuringia; the source from whence Gmelin has obtained many of the new-species described in his edition of the Systema; the labellæ of this writer are very numerous. See his "Die geschichte der Flussconchylien, mit vorzüglicher rücksichte auf diejenigen welche in den Thüringischen

gischen wassern leben," 1779. This was preceded by a small publication on the land shells found chiefly in the neighbourhood of Thangelstadt, "Versuch einer systematischen abhandlung über die Erdkonchylien um Thangelstadt." A later production of this writer's is the "Einleitung in die Conchylien kenntnis nach Linné," published in three volumes octavo, 1783—1786. and which to the German scholar forms a valuable introduction to the study of conchology.

The "Zoologiæ fundamenta" of Martinus Thrane Brunnich, was published in 1772, and relates in a partial degree to shells.

In the "Vermium terrestrium et fluviatiliium Historia" of Müller, we are presented with an arrangement of land and river testaceous animals disposed according to the characters of the animals themselves instead of their shells. The first volume was begun in 1773, and the second in the year following. The testaceological productions of Denmark are described in the "Zoolozia Danica" of this author.

The "Viaggia in Dalmazia," or travels in Dalmatia, by Albert Fortis published at Venice in 1774. contains a few figures elucidatory of those shells which he found in the Porto di Dua.

The "Elements of Conchology," by Da Costa, was published in 1776. This work presents us with a new arrangement of shells, and besides contains some judicious observations on the classification of Linnæus, and some other writers; which latter, in our opinion, deserve more attention than his system of shells. The "Elements" of this writer is one of the most inferior of this author's works. His "British Conchology," published in 1775, is more valuable, though it does not take a sufficiently extensive view of the British testacea. Da Costa had intended to publish a second edition of these with considerable improvements; the collection of materials, and the MS. for which are in the possession of Mr. Donovan, and have been in part incorporated into his "Natural History of British Shells." The great forte of Da Costa appears to be in the antediluvian race of shells, and other extraneous fossils, and in the more useful departments of mineralogy, or what he denominated native fossils. Upon these subjects alone, no less than ten folio volumes of unpublished manuscripts are preserved at this time in the extensive collection of original MS., &c. formed by Mr. Donovan, and which are intended to be placed in the library of his museum.

Among the few testaceological works noticed by Da Costa, in the introduction to his "Elements," he speaks of "a new and anonymous conchology, began to be published in this metropolis, in 1750, in folio, illustrated with copper plates." "It was intended (he observes) to be a general natural history of shells, and to include figures of all the known species, common as well as rare, beautiful or otherwise, and some copies were designed to be accurately coloured for the use of the curious. This anonymous production was, to our knowledge, written by Da Costa, and was the joint undertaking of himself and Mr. George Humphrey, by the latter of whom most of the shells were furnished that are described in this work. The numbers of this work that were published comprehend the first three families of his system, limpet, sea-ear, and serpula.

The publication of Ignaz Edler von Born, the celebrated mineralogist entitled "Index Rerum Naturalium Musæi Cæsarei Vindobonensis" presented the public in 1778 with the description of the shells preserved in the museum of the empress queen at Vienna; and was undertaken at the express command of her imperial majesty. Two years after the baron published his "Testacea Musæi Cæsarei Vindobonensis." as a

splendid illustration of his former work; this contains about two hundred coloured figures delineated in eighteen folio engravings.

The early editions of the "British Zoology," as it is entitled by Mr. Pennant, though in reality it embraces only an inconsiderable portion of the zoological productions of Britain, include none of the testaceous tribe: these were added, in a fourth volume published in 1778. This volume contains an enumeration of 163 species of shells with concise descriptions, and 56 plates exhibiting figures of nearly all that are described. Dr. Maton observes in his comments on this work that "most of the plates are valuable for reference, but some of them are executed less carefully than could have been wished. In the descriptive part (says the doctor) the author has translated pretty closely the specific characters, given by Linnæus, whenever they could be had, but there are several species of which the former is to be looked upon as the first describer. It is very remarkable, however, that he should have wholly omitted others which had been noticed by Lister and Pater, and which are unquestionably natives of our island." The number of British species of testacea known to us at present amount altogether to several hundreds more than Mr. Pennant was acquainted with, and it is our knowledge of these which renders his catalogue of little moment. But we ought in candour to allow that considering the very low ebb of natural science in this country at the period Mr. Pennant wrote, his work is a respectable performance: we mean with regard to the number of species contained. The descriptive matter certainly betrays great want of information, as well as science: many of the synonyms are misapplied, and the names erroneous.

The "Observations sur les moules" in the "Journal de Physique," 1779, is from the pen of a lady, Mafoule Coltt, and relates to the reproduction of parts of mussels. Dreuquemare treats upon the locomotive faculty of oysters in the same volume of this journal "Sur la Faculté locomotive des huîtres," p. 241. tom. 28.

In 1780 the "Fauna Gronolandica," of Otho Fabricius was printed at Leipzig. This work contains the description of fifty seven species of shells found in Greenland, among which are a number not previously observed by writers. Fabricius pays considerable attention to the structure and habits of the animal as well as the shell.

The "Zoophylacium Gronovianum," a description of the rich museum of L. T. Gronovius senator at Leyden was published in 1781. There are in this work a scientific description of 589 species of shells, and among the plates, two appropriated to the illustration of the rarer kinds.

Molina's "Saggio sulla storia naturale del Chili," or natural history of Chili, comprehends descriptions of the shells observed by this writer in that part of South America. The work was printed in octavo, at Bologna in 1782.

A small octavo tract was published at Naples in 1784 entitled "Descrizione di una nuova famiglia, e di un nuovo genere di Testacei, trovati nel litorale di Catania, con qualche osservazione sopra una specie di ostriche," by M. Gioeni. The supposed new genus of shells which occurred to the notice of Gioeni on the shores of Catania was no other than the hard testaceous substance found in the gizzard of bulla lignaria, a similar organ to which we have ourselves found in the gizzard of bulla aperta. Some years passed before this misconception was detected: it had been really considered as a shell by professor Ruzizius from whom it obtained the name of triola Gioeni; and it is arranged also in the system of Bruguiere under the name of gioenia

ficula. M. Draparnaud claims the merit of having first ascertained the real nature of this testaceous substance, an account of which he inserted in the *Nouv. Journ. de Physique*. We should add that the same article is described and illustrated with figures in the second volume of the *Linnæan Society* by Mr. G. Humphrey, associate.

A variety of new and very curious experiments by the indefatigable Spallanzani on the reproduction of the head of the common snail is recorded in two memoirs, the first of which was published in 1782, the other in 1784. See "Rifultati di Esperienze sopra la Reproduzione della Testa nelle Lumache Terrestri," *Mem. della Soc. Ital.* t. 1. p. 581.—t. 2. p. 506

The splendid work on shells by Martyn entitled the "Universal Conchologist" was begun in the year 1784, and continued to be published at uncertain intervals till 176 plates appeared, when its progress was finally impeded. This work commenced with the nondescript shells collected in the different voyages of the English circumnavigators in the South Seas; many of which are still esteemed valuable, while others, as may be imagined from our more habitual intercourse at this time with the southern hemisphere, are become common. As a scientific work, this performance will be found altogether defective, and it is besides too barren of general particulars, to render the subject pleasing to the common reader. Much greater praise is due to the plates, which are the productions of Grozier, and many other artists, and are for the most part well executed; it may be indeed added that they are the representations of objects in themselves so beautiful as to afford the artist every facility in the display of talent. A number of the original specimens are in the cabinets of Mr. Wood, apothecary, Mrs. Foster, and others in London.

A small quarto treatise embellished with three plates, the joint labour of Mr. W. Boys, and Mr. G. Walker, appeared in London in 1784. The work treats only of microscopic shells, and the researches of its authors were confined to the sandy shores of Sandwich as the title indicates "Testacea minuta rariora nuperime detecta in arena litoris Sandvicensis." It is dedicated to the late duchess of Portland.

In the *Philosophical Transactions* for 1786 is "an account of some minute shells, either not duly observed, or totally unnoticed by authors." This is illustrated with three plates and is the production of the rev. Mr. Lightfoot, the learned author of the "Flora Scotica," to whom the world is so highly indebted for his indefatigable inquiries respecting the British luci and coniferæ.

In 1786, C. L. Kämmerer described the collection of the hereditary prince of Schwarzburg-Rudolstadt. This catalogue is in the German language, and is embellished with twelve plates: it bears the title of "Die Conchylien in Cabinette der Herrn. Erb.—Prinzen von Schwarzburg-Rudolstadt. An appendix, with four additional plates, was published at Leipzig in 1791, under the title of "Nachtrag zu der Conchylien in Fürstlichen Cabinette zu Rudolstadt."

The "Journal de Physique" for 1787, contains a description accompanied with figures of chiton squamosus by Lefebvre des Hayes.

In the *Transactions of the Russian Academy*, for the year 1787, we find a memoir on testaceology, entitled "Marina variæ, novæ, et rariora," by professor Pallas. The subjects treated are *serpula spirillum*, *lepas cariosa*, *pholas terulella*, *chiton amiculatus*, and *helix coriacea*. This author had previously distinguished himself by his critical writings on conchology, both in his "Spicilegia Zoo-

logica," which appeared in 1780, and his "Miscellanea Zoologica," published some years before.

Retzius in the same year printed his "Nova Testaceorum Genera," a small work in quarto, in which many alterations and improvements on the Linnæan system of conchology are projected. It was previously the subject of an inaugural dissertation at Lund. Retzius was likewise the author of a description of *Venus lithopogoa*, published in the *Memoirs of the French Academy* for 1786.

Cordier's work of "Remarkable Ruins and Romantic Prospects of North Britain," appeared in numbers, and besides the views comprises some plates of natural history, among which are a few of the more remarkable species found on the coast of Scotland, grouped with a variety of other marine productions. Antiquity is however the leading feature of this work. Only part of this production appeared in 1783; some additions have been made to it since that time.

In the year 1789, Bruguière, the well known traveller in the east, commenced the testaceological part of the grand work, carried on in France, under the title of "Encyclopédie Méthodique," but unfortunately for the cause of science, this skilful naturalist lived only to complete the first volume, which does not go beyond the letter C. of the article *vers* (worms). The preface matter to this volume contains the method of an arrangement he intended to pursue, founded principally upon that of Linnæus, with such additions and deviations only, as he conceived to be required by the discoveries of other naturalists since the publication of the Linnæan Systema. This is the principal, though not the only production on the subject of conchology, Bruguière submitted to the world.

A pleasing variety of beautiful and curious species of testaceous tribes, chiefly the extra-European kinds, have been introduced, at various times, to the notice of the English reader, through the medium of that well known periodical undertaking the "Naturalist's Miscellany," of Dr. Shaw. We are not a little surprised indeed to observe, that the greater number of univalve shells in this work are reversed in the plates, and are therefore likely to mislead the incautious observer into a persuasion, that they are in reality heterotrophous. This work commenced in 1790, and still continues in a progressive course of publication.

The "Zoologia Adriatica," of Abbé Olivi, printed in 1791, contains an account of the shells found in the gulf of Venice, with a series of engravings, to illustrate some of the more remarkable species. In the "Ann. de Chimie," for the same year, M. Vauquelin treats of the respiratory process in the helix pomatia, and proves in the course of his observations, that the vermes require vital air for the excitement of their pulmonary system as well as other animals. The species above mentioned (according to this author) will respire azotic and carbonic acid gas, as long as any oxygen remains combined with either. The "Observations sur la génération des Buccins d'Eau douce," by M. Ribaucourt, inserted in the "Journ. d'Hist. Nat." for the same year, tend to prove that all the species of that tribe are viviparous. The last we have to mention in this year are the papers of M. Cuvier, the celebrated comparative anatomist. These relate to the anatomy of the animal of the Linnæan *patella vulgaris*, and *unguis*; and the *bala aperta*, and are to be found in the "Annales du Muséum National."

The first volume of "Testacographia ac Zoophytographia parva et microscopica," by Am. Soldani, is dated 1789; a second volume appeared in 1795. The microscopic subjects, described by this writer, are principally shells discovered

discovered by himself at Porto-Ferrara; the island del Giglio; on the shores of Castiglioneello, la Pollonica, &c. No less than 148 plates embellish this work, in which the shells are represented both of their natural size and magnified.

A number of minute, or microscopic shells, discovered by the late Mr. Adams, on the coast of Pembroke, are described by that ingenious collector in the third and fifth volume of the *Transactions of the Linnean Society*, in which will be also found two plates, containing figures of the shells described.

Among the "Observations sur les Coquilles," inserted in the "*Journ. d'Hist. Nat.*" for 1792, and in the "*Prodomme d'une nouvelle Classification des Coquilles.*" *Mem. Soc. d'Hist. Nat. An. 7*, the curious reader will find much interesting matter relative to the testaceological systems of Linnæus, and Bruguiere, and also a sketch of that proposed by their author, M. Lamarck. These were the prelude to his more important undertaking "*Système des Animaux sans Vertèbres*," in which we meet with a new arrangement of testaceology more comprehensive and satisfactory than has perhaps hitherto appeared upon this interesting subject.

The "*Testacea Microscopica aliisque minuta ex Generibus Argonauta et Nautilus ad Naturam picta et descripta*," published at Vienna in 1798, is the joint production of L. A. Fichtell and J. P. C. Moll. It treats principally on the minute shells of the argonauta and nautilus genera, and contains, besides the descriptions in the Latin and German languages, accurate figures of a great number of species, among which are many that escaped the observations of Plancus, and every other writer.

Mr. Hutchinso's new and enlarged edition of the "*History of Dorsetshire*," includes a catalogue of the birds, shells, and more rare plants of that county, by Dr. Pultney. The testaceological part of this catalogue is that which interests us in the present detail. Dr. Pultney bestowed considerable attention on this department; his remarks on the Linnean genera, which the limits of his views permitted him to notice, are judicious; the species he describes are, however, less numerous than might be expected, nor can we refrain adding, with due respect to the memory of that zealous and well informed naturalist, that all the shells described as species, are not defined in a clear and satisfactory manner. As a local catalogue we admit its general utility with this exception.

The above mentioned catalogue was printed in 1799, and in the *Philosophical Transactions* for the same year, appeared Mr. Hatchet's "*Experiments on Shell and Bone*," in which that accurate chemist relates the particulars of his discoveries resulting from analysis of the component parts of testaceous and crustaceous substances, in the first of which he detected the presence of phosphate of lime, and he found the other to consist only of the carbonate of lime mixed with gelatinous matter. The publication of Donovan's "*Natural History of British Shells*," commenced early in 1799. This work was designed to include all the species hitherto discovered in Great Britain, systematically arranged in the Linnean manner, with scientific and general observations on each. Five volumes have since appeared in a progressive course of publication, comprising altogether 180 plates, with many coloured figures. The writer of this article does not feel at liberty to comment further on a work which he has himself submitted with deference to public opinion. It is allowed by Dr. Maton and Mr. Rackett, in their review of testaceological writers, inserted in the *Linnean Transactions*, "that the author has given several new spe-

cies, and that he has rectified many errors of preceding writers."

The fifth or last volume of Mr. Dryander's "*Bibliotheca Hist. Natur. Bankiana*," was published in 1803. This is an account of the books on the subject of natural history, in the valuable library of Sir Joseph Banks bart., and although only a catalogue, will be found to contain much general information. In the "*Elenchus S. Clionum*," we are presented with a methodical arrangement of the principal testaceological subjects treated of by different writers, named in the other part of the catalogue; and which, in many respects, may prove more acceptable as a mode of reference than a catalogue confining merely of the titles of the books and names of the authors.

A paper describing the hinges of some British shells of the bivalve tribe, by Mr. W. Wood, is inserted in the sixth volume of the *Linnean Transactions*. The attempt is ingenious, but on a very confined scale, and it presupposes, without the slightest countenance of fact, that among the many writers who had previously noticed shells, or even written precisely on them, no one had hitherto paid attention to their hinges. The paper is illustrated by six plates of outlines.

In 1803, the "*Testacea Britannica*" of Mr. G. Montagu, was published in two quarto volumes. The number of shells described in this work is considerable, as it comprehends an account of the microscopic kinds, in addition to those of a larger size. It is embellished with sixteen coloured plates.

"The Historical Account of Testaceological Writers," to which, in the course of our foregoing observations, we have had frequent occasion to advert, appeared in the sixth volume of the *Linnean Transactions*, published in 1804, and is the joint production of Dr. W. G. Maton, and the Rev. Thomas Rackett.

The "*Tableau Methodique des Mollusques*," by Latreille, published in the twenty-fourth volume of the "*Nouveau Dictionnaire d'Histoire Naturelle*," printed at Paris in 1804, affords us an arrangement of shells, founded on that of Lamarck, with some additions that may render it more applicable to general use.

The rise, progress, and general traits of the history of this science may be more readily collected, we apprehend, in the course of the foregoing review of the different works that have appeared on the subject, than from any other mode that might be devised; and, under this idea, we have adhered as nearly as possible to the chronological order of arrangement, this being the most likely to facilitate the purpose intended. From the perusal of this, the reader will at once perceive which are the most considerable and valuable works on the subject, as well as obtain a general knowledge of a number of treatises, tracts, and memoirs, on particular articles connected with testaceology, which, being dispersed through a variety of miscellaneous and voluminous publications, might, without such reference, escape attention. The leading features, or design, of the respective performances, are likewise detailed, and the embellishments which accompany them pointed out; and, in fact, every other particular deemed likely to assist the student in his choice of the best books in forming a testaceological library.

In resuming this subject, as we propose under the article TESTACEOLOGY, we shall be prepared to offer some further, and more general remarks on this topic, and in particular to submit our own ideas as to an enlarged and improved arrangement for the classification of testaceous

bodies, founded on the leading principles of the best authors, with such amendments as we conceive necessary. D.

Miscellaneous Additions relative to Conchology.

The following instructions for collecting, cleaning, and preparing shells, may not be unacceptable.

The testaceous, like all other animals, have their particular resorts; some inhabit only the deep parts of the sea, and are what the old writers distinguished by the name of pelagian shells; others are as constantly found in shallow water, in bays, or those parts of the sea which are contiguous to the entrance of rivers: it has a fo been observed, that many fine and rare shells are sometimes found in the straits between islands, and in shallows near the coast, of four or five fathom water. Some species also are found on rocky, and others on sandy shores. The best shells are those taken alive out of the sea, from whence they may be obtained by means of a trawling-net, such as the fishermen employ, if the depths are not too great; they are also brought up by the cable in weighing anchor, the log-line in founding, and various other means. Sometimes valuable marine shells are found sticking to the bottoms of ships, or the sides of rocks.

After a storm, good shells may be picked up on the sea beach or shore, as the violent agitation of the water in a tempest separates them from their native beds, and often casts them ashore. But such as have lain exposed for some time to the heat of the sun, or beaten by the waves, are of little value, as their colours will be found faded, and the shells worn and broken; those only are worth selecting from the sea-shore, which have the animal alive within, or which have been recently thrown up.

River shells are, in general, of an obscure colour, and remarkably thin and brittle, inasmuch that some have imagined it a peculiar character, by means of which they may be distinguished from the marine or terrestrial kinds. This is not, however, an absolute criterion, for many of the latter are as thin as the river shells, as we observe, for example, in the argonautæ, or paper nautili, some pinæ, and many other sea shells, and in numbers of the shells of the terrestrial kind.

Terrestrial, or land shells, though few in comparison with the former, are oftentimes very beautiful, and not less esteemed than the marine kinds. Those are found most commonly crawling, like the snail tribe, on various sorts of plants, and in warm countries especially abound.

Many shells possess such a smooth, and highly polished surface, and are so beautiful in colour when they are fished up, that art cannot improve their appearance, such as for instance, the cypræa or cowry, and the voluta or volute, with many others. It is the commonly received opinion, that the animals, inhabiting all naturally polished shells whatever, are capable of not only adding to the extent and growth of their shells, but that they are able, from time to time, as occasion may require, to add a fresh polished covering to the whole shell. Should this opinion be unfounded, they can at least extend their organs to such a length, as to clear away all impurities from their shells, as we seldom find any cowries with coral, or any extraneous bodies, adhering to any part of them.

Other shells are covered with an epidermis or membrane, intended no doubt by nature to defend them from accident, and aid their growth. The structure of this epidermis varies very much, being in some laminated, in others fibrous

or brush like, or pilous, and velvety. The epidermis prevents the lepas, and other similar shells, or marine worms, from fixing their habitations on them; it is worthy of remark, that most shells, with a scabrous surface, are covered with an epidermis. Many others, when taken out of the sea, are slimy, and encrusted with fish, coralline, and other extraneous matter.

Immediately after gathering or collecting the shells, and those especially taken from the sea, the first process necessary, is to destroy and extract the animal inhabitant, without injuring the shell, and then to prepare the shell that it may not be damaged by the action of the marine salts, with which they are saturated. As shells are of a calcareous nature, all acids should be as much avoided as possible, both in killing the animal, and preparing the shell; it is usual to boil them in water for this purpose, but as boiling may injure the shells, it will be most advisable to dip them into scalding water, which will be sufficient to kill the animal, after which, let them remain for two or three minutes to cool, and then put them into cold water, in which they may lie till they are taken out to be cleaned. The animal, by being killed in this manner, becomes condensed, and somewhat solid, and may be picked out by any sharp instrument.

Shells encrusted with extraneous matter should be allowed to steep for some time in warm water, both for the sake of softening these substances, and to extract as much as possible the marine salts. They may be suffered to remain in water two or three minutes without any injury. After this brush them well, observing only that the brush must not be too hard. If that proves insufficient to clean them, rub or brush them again with tripoli or emery, or put them into weak acid for the space of a minute and then dip them into cold water; which process may be repeated as often as will be necessary to remove the extraneous matter. Strong soap may also be used with a rag of woollen or linen cloth to rub them, or a ley of pearl-ashes; and when cleaned finish them with a soft brush and fine emery.

Scientific collectors endeavour to preserve one at least of every shell with the epidermis on, to exhibit its natural appearance, together with the uncoated specimens.

The epidermis may sometimes be so thick that it will be necessary to take it off before the shell can be polished. For this purpose pour a quantity of the spirits of nitre, or nitrous acid, into water, in the proportion of about one-sixth or one-tenth part of the former; put this into a shallow basin or saucer, and place the shell or shells therein, in such a manner that the corrosive fluid may act only on the coat, without injuring the orifices or mouth, which in some cases may be coated with bees-wax: change the situation of the shell every two or three minutes, that all the parts may be equally uncoated; wipe off the bubbles as occasion may require with a feather, first dipped in water: when you perceive the enamel in any part free from the coat, take it out, and wash off the aquafortis, and after this process rub them with fine emery powder. If instead of a thick epidermis it is only a pellicle, it is sufficient to steep it in hot water, and then pick it off; or steep the shell in vinegar till it peels off freely, or is corroded away. The epidermis of some shells is so coarse and thick as to resist the corrosive quality of acids diluted, or even of aqua-fortis; emery with strong brushes is then substituted, or sea-skin, and pumice-stone, or the exterior coat may be ground off with a grind-stone, or files of various dimensions. If the matter is too obstinate to be cleared off by this means, pour some spirit of nitre into a cup or other vessel, stop up every

part of the shell that may be susceptible of injury with soft wax, as carefully as possible, and put it into the liquor in the vessel; remove it every minute into cold water, but observe never to shift it into the same water more than once, and wash it every time before you return it into the corrosive liquor. If the shell is warted, irregular, or armed with points, examine it with a common magnifier, and if you perceive on the more prominent parts through the wax any appearance of the polished surface, cover them with wax, and let the shell remain a few minutes longer in the spirit, take it out and wash it again; after which, polish the shell with fine emery, and pass a camel's-hair pencil with gum arabic over them to brighten the colours; the white of egg is sometimes used, but it is very apt to turn yellow in time, though at first it appears glaring; and varnish communicates a disagreeable smell.

Some shells have naturally a slight politure; those may be rubbed by the hand with chamois leather, which will give them a bright glossy appearance; avoid when possible the use of emery powder, as it is apt to detriment the beautiful workings on the shells; it cannot however be often left out of use.

It is desirable as far as can be to point out the impositions which are often practised on those who are not well acquainted with shells, and are therefore not aware that any individual shell may be made to assume a very different appearance by having the first or second exterior coat of the shell removed by acids, or any other means. Thus, for example, we see that though the outer surface of the common cowry, or tide shell, is of a pale colour, with dark spots; when that is cleared off, it is of a fine violet colour: the sea ears are clouded with brown, green, and white; but when that coat is rubbed away it appears of a beautiful pearl colour. Thus also the nautilus shell is externally of a pale brown or ochraceous hue, variegated with streaks of chestnut, but on the exterior coating being taken off, the whole shell will be found of that substance known by the familiar name of mother of pearl. The same circumstance is observed of the true mother of pearl shell, the exterior coat of which is blackish; many of the trochi, or top shells, and an infinite variety of other shells of different genera are of the same description. Among those shells which alter their appearance most, we must not omit the volute, called by us the purple or violet top, and by the French *onyx*; it has a brown epidermis which, being taken off, discovers the ground colour to be a dull yellow. When this is worked down to beneath the crust or surface, it is of a pure white, with the tip of a fine violet. We shall lastly mention the common muscle, the exterior coat of which is dull blueish black, that beneath purple, and the inner one white: sometimes we have seen muscles in the hands of dealers, and in scientific collections, of a fine purple colour, variegated with large distinct spots of white or brown, so dexterously managed as to have all the appearance of a shell in a natural state, though in reality such shells are the work of art, and no other than the common or edible muscle. For this purpose those of the largest size are usually selected, which, being first uncoated down to the brightest purple surface, are afterwards fretted or rubbed with a file, in particular parts, till the white or inner coating is seen through the purple. The spots may be managed however with more certainty, by covering the whole surface with a thin coat of wax, then scraping off the wax in such parts as it is designed should exhibit spots, and lastly suffering the shell to remain in spirit of salts diluted, or nitrous acid, till the outside is corroded in those parts down to the white or inner coat of the shell. After washing the shell, and clearing off

the wax, the spots thus formed may be stained of any colour, according to the fancy of the operator. A preparation of the oxyd of iron, or manganese, are most commonly employed, as these produce a brown colour of different tints, and form an indelible stain. The Dutch, who are great amateurs in conchology, paint shells with a variety of colours, and that to ingeniously, as to render it difficult to detect the imposition. Neither are they less expert in joining broken shells, cementing and filling up holes pierced by marine worms, or fractures, and filling the mouths and tips in such a manner as to entirely alter their appearance.

Fossil shells should be noticed here if any instructions were necessary for their preservation; but these in general constitute the most durable part of a collection, being either chalky, calcis in flint or stone, or replacements of sparry matter, with perhaps only some slight fragments of the shell adhering, and that very rarely. They are dug out of chalk-pits, lime-stone, or other stone quarries, and coal-pits, &c. Vide "Donovan's Instructions for collecting and preserving Subjects of Nat. Hist." from which the above particulars are chiefly extracted.

CONCHUCOS, in *Geography*, a jurisdiction of South America, in the vice-royalty of Peru, subject to the archbishop of Lima, which commences 40 leagues N. E. of Lima, and extends along the centre of the Cordilleras. Its air, therefore, is different according to the height of the situation of its several parts, the middle of which produce all kinds of grains and fruits, and the others, where cold checks their fertility, afford pasture for all kinds of cattle. This jurisdiction abounds with looms: the principal occupation of the Indians being woollen manufactures of various kinds, which constitute the greatest part of its commerce with other provinces.

CONCIATOR, in the *Glass Art*, is for the crystal glass what the founder is at the green glass houses. He is the person that weighs and proportions the salt on ashes and sand, and works them with a strong fire, till they run into lumps, and become white; and if the metal be too hard, and consequently brittle, he adds salt, or ashes; and if too soft, sand; still mixing them to a fit temper, which is only known by the working.

CONCILIO—*Querela eorum rege et CONCILIO*. See *QUERELA*.

CONCINNA, DANIEL, in *Biography*, an Italian Dominican, born in the Venetian territory about the year 1686. He was highly distinguished for his pupil talents, which attached to him numerous admirers in Italy, and even in Rome itself. As a writer he was esteemed, or account of the support which he gave to the institutions of the Papal church. He was author of numerous publications in the Latin and Italian languages, on historical, moral, and critical subjects, among which are "Defensio Concilii Tridentini, et Apoll. Const. Eccle. Rom. in causa Pauperum Montanis, &c." "Usura Contractus trini Dissertationis Hist. Theol. demonstrata," &c. "De Spectaculis Theatralibus Christiano cuiquam, tum Laico, tum Clerico, vetitis, &c." "Theologia Christiana, dogmatico-moralis," in 12 vols. 4to. "The logical, Moral, and Critical Dissertations, relative to the Logic of Probabilities, with Supplementary Observations." "A Defence of Revealed Religion, &c." He died at Venice in the year 1756. *Nouv. Hist. Diet.*

CONCINNOUS *Intervals*, in *Music*, are such as are apt and of use in harmony, as the V., 4^b, III., 3^d, VI., 6th, IV. and 5th, in contradistinction to such as are inconcinuous, as the intervals deficient or r^undant by a comma. See *COMMA-Redundant*, *Fifth*, *Fourth*, &c.

CONCINO

CONCINO CONCINI, MARSHAL D'ANCRE, in *Biography*, was a native of Tuscany, and, with his wife, Leonora Galigai, accompanied Mary de Medici, queen of Henry IV. into France, in 1660. He was made gentleman of the bed-chamber, governor of Normandy, and marshal of France, in 1615. As he was raised by the influence which he attained over the mind of the queen, he held the reins of government during the minority of Louis XIII. and behaved in so haughty a manner to the young king, that he was induced to order his arrest, and in case of resistance, the person sent on the business was commanded to kill him. The captain of the guard demanded his sword as he was passing the drawbridge of the Louvre, and upon his refusing to comply, he shot him dead, April 24, 1617. His body, after it had been buried, was taken up and given to the populace, who treated it with every indignity. His wife was afterwards condemned, by a decree of the parliament, to be hanged and burnt. *Moreri*.

CONCIOLO, an Italian painter, who flourished in the commencement of the thirteenth century. Upon a picture at Sabiaco, in the Ecclesiastical State, representing the consecration of a church, the artist has thus signed his name, *Consiolus pinxit, 1210*. This is one amongst the many proofs, with which the churches and converts of Italy abound, to shew that however low the state of the arts in Europe, previous to Cimabue and Giotto, the intervention of Greek painters was by no means necessary to their establishment. *Lanzi. Storia Pittorica*.

CONCIANTORES, in *Antiquity*, common-councilmen, freemen, called to the hall or assembly, as most worthy. Thus, "quodam tempore cum convissent *conciantores* apud London, &c." *Hist. Elicn. apud Gale, c. 46*.

CONCLAMATIO, a shout raised by those present at burning the dead, before they set fire to the funeral pile. See **SHOUT**. The word was also applied to the signal given to the Roman soldiers to decamp, whence the expression "conclamare vasa" and "conclamari arma" was a signal for battle. It was likewise used for a practice of calling to a person deceased three times by his name, and when no reply was returned, they thus expressed his decease, "conclamatum est." Whence the same term was afterwards applied to the cessation of the Roman empire.

CONCLAMATIO, among the Greeks, Romans, and several other nations, was a spontaneous cry or shout, which all the soldiers of an army made when they understood or heard the third signal for combat.

CONCLAVE, an assembly or meeting of all the cardinals that are at Rome, shut up for the election of a pope; whence it derives its name. See **CARDINAL**.

The conclave had its rise in the year 1270, and on this occasion; Clement IV. being dead at Viterbo, in 1268, the cardinals were nearly three years, *viz.* from the 29th of November 1268, to the 1st of September 1271, without being able to agree on the election of a successor; in effect, things were carried to such pass that they were upon the point of breaking up, without coming to any conclusion at all.

The magistrates of Viterbo, being apprised of their design, by the advice of St. Bonaventura, then at Viterbo, shut the gates of their city, and locked up the cardinals in the pontifical palace adjoining to the cathedral, till they were brought to a better understanding.

Hence arose the custom, which has since prevailed, of shutting up the cardinals in a single palace, till they have elected the pope.

Such was the origin of the conclave, as related by Oneph. Panvinus, Ciaconius, and Papebroch.

Panvinus informs us, that John of Toledo, cardinal

Bishop of Porto, seeing the cardinals daily praying the Holy Ghost to inspire them with the spirit of concord and union, and yet discord continuing to reign among them, said pleasantly, "Let us uncover the room, else the Holy Ghost will never get at us." When this farcalle remark was reported to the magistrates of Viterbo, they immediately ordered the roof of the room in which the cardinals were assembled, to be taken off, hoping that this new inconvenience would oblige them to hasten the election; but their obstinacy prevailed against all inconveniences, till the magistrates bethought themselves of daily lessening their subsistence; and this had the desired effect. For being thus reduced to the alternative of starving or agreeing, they left the election by compromise to fix of their number; and then Gregory X. was elected.

CONCLAVE is also used for the place where the election of the pope is performed; which is now at St. Peter's in the Vatican; though Gregory X. and Clement V. appointed it should always be held in the place where the last pope should die. But if he should die in a borough or village, where the electors could not conveniently meet, the election was to take place in the episcopal city, or in the nearest to it, if that city were under an interdict.

While the affair is in hand, if it be in winter, the walls and windows are all mured up, excepting only a single pane, to give a little light; in summer the windows are not closed; but the great door of the hall is secured with four locks and four bolts; an aperture being, however, left, through which to supply the imprisoned prelates with victuals.

If the election takes place at Rome, the door of the conclave, and all the avenues to it are to be carefully guarded by the city guards, by the Roman nobility, by the ambassadors of princes, and by the bishops and conservators of the city. If the election is to be made out of Rome, the same duty is incumbent upon the temporal lords and magistrates of the place; and it is a duty common to them all to see that nothing be carried into the conclave, or out of it, that has the least tendency to retard or prevent a lawful election.

In the hall, which is very ample, there are cells or stalls erected for as many cardinals as are to be present at the election; the cells being only separated by deal boards, and the room having no outlet, except to the privy.

The cells are marked with letters of the alphabet, and are distributed to the cardinals by lot: each cardinal puts his arms on the cell that falls to his share.

No one shall be allowed to go into the common room or conclave, nor out of it, but in case of sickness, or on some other urgent occasion.

After the assembly has continued three days, they are only allowed one dish for a meal; and after fifteen days more, only bread, wine, and water, though this rule is not very strictly regarded.

Each cardinal is allowed two conclavits, or servants to attend him, and to be shut up with him.

The election is begun ten days after the pope's decease, and decided by a majority of two parts in three of the cardinals present, who vote by ballot; and if, upon scrutiny, no one of the candidates has two-thirds of the votes, the balloting must, after a stated interval, be repeated. And this continues to be reiterated if they should remain shut up for years, till one of them attains the fore-mentioned superiority. Cardinals who arrive before the election is finished, are included with the rest.

These regulations were principally established by Gregory X. in 1274. But as this constitution of Gregory X.

was thought by the cardinals to be too rigorous, they prevailed upon Clement VI. in the year 1351, not long before his death, to mitigate it. Clement allowed them to have each two servants, clerks, or laymen; to have curtains round their beds, and one dish of flesh or fish at dinner, and another at supper, besides bread, wine, fruit, and sweetmeats, so long as they continued in the conclave.

Matthew Paris says, the word conclave anciently signified the pope's wardrobe.

It is a popular proverb in Italy, *chi entra papa, esce cardinale*; he who enters pope, comes out cardinal; q. d. he who according to common report will be elected pope, ordinarily is not.

We have various accounts, both by protestant and popish writers, of the intrigues that have been practised in the conclave, during contested elections. What is said to have passed upon the decease of Alexander VII. is no tale invented by protestants, but related by grave Roman catholics, viz. that on the last day, cardinal Sforza, going into the conclave, asked another cardinal, his intimate friend, what he thought would be the issue? He returned this frank answer: "Signior cardinal, if the French make the pope, he will be cardinal Farneze; if the Spaniards, cardinal Rospigliosi; if he is made by the people of Rome, he will be cardinal Barberini; if the Holy Ghost appoints him, cardinal Odescalchi will be the man; if the devil has a hand in it, he must be your eminence, or myself." Upon this, Sforza replied with a laugh, "then Rospigliosi will be the man;" and he was accordingly chosen by the name of Clement IX. In the year 1724, upon the death of Innocent XIII, the following satirical distinction was made between the candidates for the papal throne:

"Il Cielo vuol Orsini
Il popolo Corsini
Le Donne Ottoboni
Il Diavolo Alberoni."

i. e. "Heaven is for Orsini,
The people for Corsini,
The ladies for Ottoboni,
The devil for Alberoni."

But Orsini was chosen by the name of Benedict XIII. Keyser's Trav. vol. ii. p. 109.

CONCLUSION, in *Law*, is where a man by his own act upon record hath charged himself with a duty or other thing, or confessed any matter whereby he shall be concluded: as if a sheriff returns that he hath taken the body upon a *capias*, and hath not the body in court, at the day of the return of the writ; by the return, the sheriff is concluded from plea of *escape*, &c. Terms de Ley, 153, &c. In another sense the word conclusion signifies the end of any plea, replication, &c. and a plea to the writ, is to conclude to the writ; a plea in bar, to conclude to the action, &c. Conclusion of plea in bar shall be, *et hoc paratus est verificare*:—of other pleas *et de hoc ponit se super patriam*. Kitch. 219, 220. See PLEA.

CONCLUSION of *deeds*, mentions the execution and date of the deed, or the time of its being given or executed, either expressly, or by reference to some day and year before-mentioned. Not but a deed is good, although it mention no date, or hath a false date; or even if it hath an impossible date, as the 30th of February; provided the real day of its being dated or given, that is delivered, can be proved.

CONCLUSION, in *Logic*, the last part of an argument; or the judgement drawn from something either assumed or proved before.

The conclusion of an argument contains two parts: the consequent, which is the matter of it; and the consequence, which is its form, and which, of a simple absolute proposition, renders the conclusion relative to the premises whence it is drawn.

The question and conclusion, say the schoolmen, are the same ideas, only considered in different views, or relations: in the question they are considered as doubtful; in the conclusion as void of doubt.

CONCLUSION, in *Oratory*, consists of two parts; the RECAPITULATION, or ENUMERATION, and the PASSIONS. See also PERORATION.

CONCLUSIONS *d'une procedure militaire*, Fr. See the article JUDGE Advocate.

CONCOBAR, in *Ancient Geography*, a town of Asia, in Upper Media, towards the S.W. of Ecbatana.

CONCOCTION, in the *Animal Economy*, a term used by the older writers to denote the process which the food undergoes in the stomach, and by which it is converted into chyme and chyle. This process is now more usually termed DIGESTION, which see.

CONCOCTION, in the *Pathology* of Hippocrates and Galen, and their numerous followers, was also employed to signify certain changes in the fluids in the course of acute diseases, from a supposed analogy between the changes, and those which the aliments undergo in the stomach during digestion. The process of concoction may be particularly illustrated in the case of a common phlegmon, or boil; the progress of which is marked, according to Galen, by four distinct stages. The first, or *incipient stage*, when these fluids are beginning to collect, is considered as the stage of crude and unchanged humours: in the second, or stage of *increase*, in consequence of the process of concoction, heat is diffused through the part, and the pain, tension, and tumour are increased: when the humours are completely concocted, and converted into *pus*, the stage of the phlegmon is said to be *stationary*, or the disease to be in its vigour: and the fourth stage is that, in which the tension and tumour become less, and which is termed the *decline* of the swelling. A similar progress is observable in almost all inflammatory diseases. Thus in catarrh, affecting the mucous membrane of the nose, the discharge in the commencement is thin and watery, and, in the language of the humoral pathology, *crude*; by degrees a thicker and more opaque matter is discharged, which at length (becoming completely concocted), assumes a very thick and purulent appearance, which betokens the decline of the disease. Such also is the progress of change in the fluids expectorated in inflammations of the lungs and bronchiae, discharged from the eyes in ophthalmia, &c. By an analogy somewhat remote, this doctrine was transferred to febrile complaints, where no local inflammation, or depositary of morbid concocting matter, existed. In an idiopathic fever, as synochus or typhus, the alvine excrements, the urine, and the discharge from the skin, were referred to, as evidence of the process of concoction; and the varieties of the appearance of these discharges are described by Hippocrates, and his commentator Galen, as denoting the states of crudity and of concoction, and hence as affording a prognosis of the future progress and event of the disease. The alvine excrement is said to be well concocted, when it is, as in health, soft and connected, and is discharged with the usual regularity. When it is not in this state, but liquid and watery, partly liquid,

partly solid, &c. it is considered as not concocted, and therefore indicating the unhealthy condition of the bowels, through which it had passed. And thus, with respect to the urine, when it is extremely thin and Empid, it is said to be crude; and when it is slightly tinged with yellow, it is considered as having undergone a small degree of concoction, which is still more complete, if it soon deposits a moderate sediment. But the signs of concoction in the urine were said to be different in the young and the old, and different also in different diseases. Thus in bilious and summer fevers, a light cloud subsiding in the urine was deemed the sign of concoction; in inflammatory fever, a white sediment. See Galen, de Tot. Morbi. Tempor. et de Crisibus, lib. i.

CONCOLIN, in *Geography*, a town of France, in the department of the Isere; 4½ leagues N.E. of Grenoble.

CONCOMITANT, in *Theology*, something that accompanies, or goes along with, another.

Concomitant grace, is that which God affords us during the course of our actions to enable us to perform them; and as the Roman schoolmen say, to render them meritorious.

CONCOMITANT Necessity. See NECESSITY.

CONCORD, FORM OF, in *Ecclesiastical History*, a standard-book among the Lutherans, composed at Torgaw, in 1576, and thence called the Book of Torgaw, and reviewed at Berg, by six Lutheran doctors of Germany, the principal of whom was James Andreæ. This book contains in two parts, a system of doctrine, the subscription of which was a condition of communion, and a formal and very severe condemnation of all who differed from the compilers of it, particularly with respect to the majesty and omnipresence of Christ's body, and the real manducation of his flesh and blood in the eucharist. It was first imposed on the Saxons by Augustus, and occasioned great opposition and disturbance, both among the Lutherans and Reformed.

Several of the most eminent churches of the Lutheran communion rejected it so firmly and resolutely, that no arguments nor intreaties could engage them to admit it as a rule of faith, or even as a mean of instruction. Accordingly, it was rejected for various reasons, by the churches of Hesse, Pomerania, Nuremberg, Hollstein, Silesia, Denmark, Brunswick, and others. Among the Reformed, or Calvinists, the Swiss doctors, at the head of whom was Hôspinian, the Belgic divines, those of the Palatinate, together with the principalities of Anhalt and Bude, declared war against it. This form of concord, however, was patronized in a special manner by Julius, duke of Brunswick, to whom, in a great measure, it owed its existence; and who employed his authority and munificence in encouraging those by whom it was composed, and in commanding all the ecclesiastics, within his dominions, to receive and subscribe it as a rule of faith. But soon after it was published, this zealous prince changed his mind, suffered it to be publicly exposed by the divines of his university of Helmstadt, and to be excluded from the number of creeds and confessions that were received by his subjects. Various means were used to obviate his objections; and particularly in the year 1583, a convocation of divines from Saxony, Brandenburg, Brunswick, and the Palatinate, was held at Quedlinburg for this purpose. But Julius persisted in his opposition, and proposed that the form of concord should be examined, and its authority discussed by a general assembly or synod of the Lutheran church.

In the year 1614, John Sigismund, elector of Brandenburg, following the example of the landgrave of Hesse, renounced Lutheranism, and, under certain restrictions, embraced the communion of the Reformed churches. This event occasioned a dispute, which was agitated with violence,

and which occasioned the form of concord to be suppressed in the territories of Brandenburg, and the subjects of that electorate to be prohibited, by a solemn edict, from studying divinity in the academy of Wittenberg. Towards the close of the 17th century, viz. in the year 1675, a new confession of faith was drawn up by the Helvetic divines, under the denomination of the "form of concord or of agreement," which was also entitled the "Consensus;" but the introduction of it occasioned contests and tumults in several places. It maintained, however, its credit and authority in the church of Geneva, until the year 1706, when, without being abrogated by any positive act, it fell into disuse. In several other parts of Switzerland, it was still imposed as a rule of faith, particularly in 1718, by the magistrates of Bern, who published an order, by which all professors and pastors, particularly those of the university and church of Lausanne, who were suspected of entertaining any erroneous opinions, were obliged to declare their assent to this formulary. Many pastors and candidates for holy orders refused the assent that was demanded by the magistrates, and some of them were punished for this refusal. In consequence of these warm contests and grievous complaints letters were addressed by George I. king of England, as also by the king of Prussia, in the year 1723, to the Swiss cantons, in order to procure the abrogation of this form, or consensus, which was considered as an obstacle to the union of the Reformed and Lutheran churches. Moshem's Eccl. Hist. by Dr. Maclaune, vol. iv. v. vi.

CONCORD, in *Geography*, a flourishing post-town of America, in New Hampshire, pleasantly situated on the W. bank of Merrimack river, in Rockingham county, eight miles above Hookset falls. The legislature has, of late, held its sessions here; and on account of its central situation in the front of a thriving country, it will probably become the permanent seat of government. Much of the trade of the upper country centers here. This town is connected with Pembroke by a handsome bridge across the Merrimack. Concord was incorporated in 1765, and has 1747 inhabitants. Its Indian name was "Penacook." It was granted by Massachusetts, and called "Rumford." The compact part of the town contains about 170 houses, a congregational church, and an academy, which was incorporated in 1790. It is 54 miles W.N.W. of Portsmouth, 58 S.W. of Dartmouth college, and 70 northward from Bolton. N. lat. 43° 12'. W. long. 71° 29'.

CONCORD, a town of America in the state of Vermont and county of Essex, lying on Connecticut river, opposite to a part of the 15 mile falls.

CONCORD, a post-town of America, in the state of Massachusetts, being one of the most considerable towns in Middlesex county, situated on Concord river, in a healthy and pleasant spot, nearly in the centre of the county, and 18 miles N.W. of Bolton, and 17 E. of Lancaster. Its Indian name was Mulqueteguid; and it owes its present name to the peaceable manner in which it was obtained from the natives. It was incorporated in 1635; being at that time the most distant settlement from the sea-shore of New England. In 1791 this township contained 225 dwelling houses and 1590 inhabitants; and as a proof of the fertility of its situation, 80 of the number were above 50 years old; and for 13 years before 1791, the average number of deaths was 17, one in four of whom was 70 years old or upwards. The public buildings are a congregational church, a spacious stone gaol, and a very handsome county court house. The river is crossed by three bridges, of which one is 208 feet long and 18 feet wide, supported by 12

piers, and built after the manner of Charles river bridge. This town, during the revolution, was the seat of the provincial congress in 1774, and the spot where the first opposition was made to the British troops, on the 19th of April 1775. The grand court has been held here, when contagious diseases have prevailed in the capital. N. lat. 41° 25'.

CONCORD, a small river of Massachusetts, formed of two branches, which unite near the centre of the town of Concord, whence it takes its course in a N.E. and N. direction through Bedford and Billerica, and empties itself into Merrimack river at Tewksbury. This river is remarkable for the gentleness of its scarcely perceivable current. At low water mark it is from 100 to 200 feet wide, and from 3 to 12 feet deep. During floods it is nearly a mile in breadth: and when viewed from the town of Concord, exhibits a fine appearance.

CONCORD, a township of Delaware county in the State of Pennsylvania.

CONCORD, a settlement in Georgia, on the E. bank of the Mississippi, about a mile from the fourth line of Tennessee, 108 miles N. from the mouth of Yazoo river, and 218 below the Ohio. N. lat. 33° 55'. W. long. 91° 25'.

CONCORD, in Grammar, that part of syntax, or construction, whereby the words of a sentence agree among themselves, *i. e.* whereby nouns are put in the same case, number, gender, &c. and verbs in the same number and person, with nouns and pronouns.

The rules of concord are generally the same in all languages, as being of the nature of what is in use almost everywhere, for the better distinguishing of discourse.

Thus, the distinction of the two numbers singular and plural obliges us to make the adjective agree with the substantive in number; that is, to put the one either in this or that number, according as the other is: for the substantive being the thing confusedly, though directly, marked by the adjective; if the substantive word mark several, there are several subjects of the form marked by the adjective, and of consequence this should be in the plural; as *homines docti*, &c.

Again, the distinction of masculine, and feminine, renders it necessary to put the substantive and adjective in the same degree.

And verbs should have concord or agreement with nouns and pronouns in number and person.

If any thing occur apparently contrary to these rules, it is by a figure; *i. e.* something is implied, or the ideas are considered more than the words themselves. See SYNTAX.

CONCORD, *Order of*, in *Heraldry*, was instituted by Christian-Ernest, Margrave of Brandenburg, on his return from Spain, in the year 1660, to distinguish the part he had taken in restoring peace and union to many European princes. The badge of the order is a gold cross of eight points enamelled white, surmounted by an electoral crown; in the centre of the cross a medal thereon, two olive branches passing saltierwise through two crowns: around the medal the motto *concordans*. On the reverse the founder's cypher with the date of the institution. This badge is worn pendant from an orange ribbon.

CONCORD, in *Law*, is the agreement between parties who intend the levying a fine of lands to one another, how and in what manner it shall pass. This is usually an acknowledgment from the deforciant (or those who keep the other out of possession) that the lands in question are the right of the complainant. And from this acknowledgment or recognition of right, the party levying the fine is called the *cognizor*, and he to whom it is levied the *cogni-*

zee. This acknowledgment must be made either openly in the court of common pleas, or before the lord chief-justice of that court; or else before one of the judges of that court; or two or more commissioners in the country, empowered by a special authority, called a writ of "dedimus potestatem;" by which judges and commissioners are bound by Statute 18 Edw. 1. ft. 4. to take care that the cognizors be of full age, sound memory, and out of prison. If there be any feme-covert among the cognizors, she is privately examined whether she does it willingly and freely, or by compulsion of her husband.

CONCORD, is also an agreement made upon any trespass committed (betwixt two, or more); and is divided into *concord executory*, and *concord executed*. These concords or agreements are by way of satisfaction for the trespass, &c.

Plowden observes, that the first binds not, being imperfect; but the latter is perfect, and binds the party.

Others are of opinion, that concords executory are perfect, and bind no less than those executed.

CONCORD, in *Music*, denotes the relation of two sounds which are always agreeable to the ear, whether heard in succession or consonance.

If two single sounds be in such a relation, or have such a difference of tone, as that, being sounded together, they make a mixture, or compound found, which affects the ear with pleasure; that relation is called *concord*: and whatever two sounds make an agreeable compound in consonance, those same sounds will always be pleasing in succession, or will follow each other agreeably.

The reverse of concord is what we call *discord*; which is the general denomination of all the relations or differences of tone that have no pleasing effect.

Concord and harmony are, in effect, the same thing; though custom has applied them differently. As concord expresses the agreeable effect of two sounds in consonance: so harmony expresses the same sort of agreement in a great number of sounds in consonance: add, that harmony always implies consonance; but concord is sometimes applied to succession, though never but when the tones will make an agreeable consonance; whence it is, that Dr. Holder, and some other writers, use the word consonance for what we call concord.

Unconsonance, then, being the relation of equality between the tones of two sounds, all the unisons are concords, and in the first degree; but an interval being a difference of tone, or a relation of inequality between two sounds, becomes a concord or discord, according to the circumstances of the particular relation. Indeed some restrain concord to intervals, and make a difference of tone constitute the essential difference of concord and discord; but two unisons cannot form an interval.

It is not easy to affirm the reason or foundation of concordance: the difference of tone, we have elsewhere observed, takes its rise from the different velocity of the vibrations of the sonorous body, *i. e.* of the velocity of those vibrations in their recourses; the more frequent their recourses are, the more acute will be the tone, and *vice-versa*.

But the essential difference between concord and discord lies deeper: there does not appear any natural aptitude in the two sounds of a concord, to determine it to give us a pleasing sensation, more than in the two sounds of a discord: these different effects are merely arbitrary, and must be resolved into the divine pleasure.

We know by experience what proportions and relations of tone afford pleasure, and what do not; and we know also how to express the difference of tone by the proportion

of numbers; we know what it is pleases us, though we do not know why: we know, *v. gr.* that the ratio of 1 : 2 constitutes concord, and 6 : 7 discord: but on what original grounds agreeable or disagreeable ideas are connected with those relations, and the proper influence of the one on the other, are above our reach.

By experience we know, that the following ratios of the lengths of strings are all concord; *viz.* 2 : 1, 3 : 2, 4 : 3, 5 : 4, 6 : 5, 5 : 3, 8 : 5; that is, take any string for a fundamental, which shall be represented by the number 1, and the following divisions thereof will be all concord with

$$\frac{1 \cdot 2 \cdot 3 \cdot 5 \cdot 3 \cdot 5}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 5 \cdot 8}$$

So that the distinguishing character between concords and discords must be looked for in these numbers, expressing the intervals of sound; not abstractedly and in themselves, but as expressing the number of vibrations. Now, unisons are in the first degree of concord, or they have the most perfect likeness or agreement in tone; and therefore have something in them accessory to that agreement which is found, less or more, in every concord: the nearer two sounds come to an equality of tone, the slower are the beats, and the more agreement they have; therefore, it is not in the equality or inequality of the numbers that this agreement lies.

Further, if we consider the number of vibrations made in any given time by two strings of equal tone; on the principle laid down, they are equal: and therefore the vibrations of the two strings coincide, or commence together as frequently as possible, *i. e.* they coincide at every vibration; in the frequency of which coincidence, or united mixture of the motions of the two strings, and of the undulations of the air which they occasion, it is, that the difference of concord and discord must be sought. Now, the nearer the vibrations of two strings approach to a coincidence as frequent as possible, the nearer they should approach that condition, and consequently the agreement of unisons; which is confirmed by experience.

For if we take the natural series 1, 2, 3, 4, 5, 6, and compare each number to the next, as expressing the number of vibrations in the same time of two strings, whose lengths are reciprocally as those numbers; the rule will be found exact, for 1 : 2 is best, then 2 : 3; after 6 the union is unsufferable; the coincidences being too rare: though there are other ratios that are agreeable, besides those found in that continued order, *viz.* 3 : 5, and 5 : 8, which, with the preceding five, are all the concurring intervals within, or less than an octave, or 1 : 2; that is, whose acutest term is greater than half the fundamental.

On this principle, 3 : 5 will be preferable to 4 : 5; because those being equal in the number of vibrations of the acuter term, there is an advantage on the side of the fundamental in the ratio 3 : 5, where the coincidence is made at every third vibration of the fundamental, and every fifth of the acute term: so also the ratio 5 : 8 is less perfect than 5 : 6; because, though the vibrations of each fundamental that go to one coincidence are equal; yet in the ratio 5 : 6, the coincidence is at every sixth of the acute term, and only at every eighth in the other case.

Thus, we have a rule for judging of the preference of concords, from the coincidence of their vibrations: agreeable to which rule, they are disposed into the order of the following table; to which the names of the concords in practice, the ratio of their vibrations, the lengths of the strings, and the number of coincidences in the same, are expressed.

	Ratios, or vibrations.		Coincid.
	Grave	Acute	
Unison	—	1 : 1	
Octave, 8ve	—	2 : 1	60
Fifth, 5th	—	3 : 2	30 ^o
Fourth, 4th	—	4 : 3	20
Sixth, gr.	—	5 : 3	20
Third, gr.	—	5 : 4	15
Third, lesser	—	6 : 5	12
Sixth, lesser	—	8 : 5	12
	Grave	Acute	
	Lengths.		

Though this order be settled by reason, yet it is confirmed by the ear. On this foundation, concords must still be the more perfect, as they have the greatest number of coincidences, with regard to the number of vibrations in both the strings; and where the coincidences are equal, the preference will fall on that interval, whose acutest term has fewest vibrations to each coincidence: which rule, however, is in some cases contrary to experience; and yet it is the only rule hitherto discovered.

Indeed, Kircher, after father Merenne, gives us another standard for settling the comparative perfection of intervals with regard to the agreement of their extremes in tone: and it is this.

The perception of concordance, say they, is nothing but the comparing two or more different motions which in the same time affect the auditory nerve: now we cannot make a certain judgment of any consonance, till the air is as often struck in the same time by two strings, as there are units in each member expressing the ratio of that concord; *v. gr.* we cannot perceive a fifth, till two vibrations of the one string, and three of the other, are accomplished together; which strings are in length as 3 to 2: the rule then is, that those concords are the most simple and agreeable, which are generated in the least time; and those, on the contrary, the most compound and harsh, which are generated in the longest time.

For instance, let 1, 2, 3, be the lengths of 3 strings, 1 : 2 is an octave; 2 : 3 a fifth; and 1 : 3 an octave and fifth compounded, or a twelfth. The vibrations of strings being reciprocally as their lengths, the string 2 will necessarily vibrate once, while the string 1 vibrates twice, and then exalts an octave; but the twelfth does not yet exalt, because the string 3 has not vibrated once, nor the string 1 thrice, which is necessary to form a twelfth.

Again, for generating a fifth, the string 2 must vibrate thrice, and the string 3 twice; in which time, the string 1 will have vibrated 6 times; and thus the octave will be thrice produced, while the twelfth is only produced twice; the string 2 uniting its vibrations sooner with the string 1, than with the string 3; and they being sooner consonant than the string 1 or 2 with that 3. Whence, that author observes, many of the mysteries of harmony, relating to the performance of harmonious intervals, and their succession, are easily deduced.

But this rule, upon examining it by other instances, Mr. Malcolm has shewn defective, as it does not answer in all positions of the intervals with respect to each other; but a certain order, in which they are to be taken, being required: and there being no rule, with respect to the order, that will make this standard answer to experience in every case: so that at last we are left to determine the degrees of concord by experience and the ear.

Not that the degrees of concord depend much on the more or less frequent uniting the vibrations, and the ear's being

being more or less uniformly moved, as above; for that this mixture or union in motion is the true principle, or, at least, the chief ingredient in concord, is very evident: but because there seems to be something farther in the proportion of the two motions necessary to be known, in order to fix a catholic rule for determining all the degrees of concord, agreeable to sense and experience.

The result of the whole doctrine is summed up in this definition.—Concord is the result of a frequent union, or coincidence of the vibrations of two sonorous bodies, and, by consequence, of the undulating motions of the air, which, being caused by these vibrations, are like and proportionable to them; which coincidence, the more frequent it is, with regard to the number of vibrations of both bodies, performed in the same time, *cæteris paribus*, the more perfect is that concord: till the rarity of the coincidence, in respect of one or both the motions, produces discord. See some of the remarkable phenomena of sounds accounted for from this theory, under the word UNISON; see also INTERVAL, &c.

Mr. Carre, in the Memoirs of the Royal Academy of Sciences, lays down a new general proposition, to determine the proportion which cylinders are to have, in order to form the concords or consonances of music. And it is this—that the solid cylinders, whose sounds yield those concords, are in a triplicate and inverse ratio of that of the numbers which express the same concords.

Suppose, *e. gr.* two cylinders, the diameters of whose bases and lengths are as 3 to 2: it is evident their solidities will be in the ratio of 27 to 8, which is the triplicate ratio of 3 to 2: we say then, that the sounds of those two cylinders will produce a fifth, which is expressed by those numbers; and that the biggest and longest will yield the grave sound, and the smallest the acute one.—And the like of others.

Concords are divided into *simple*, or original, and *compound*.

A *simple*, or *original* concord, is that whose extremes are at a distance less than the sum of any two other concords.

On the contrary, a *compound* concord is equal to two or more concords.

Other musical writers state the division thus: an octave 1: 2, and all the inferior concords above expressed, are all simple and original concords: and all greater than an octave, are called compound concords; as being composed of, and equal to the sum of one or more octaves, and some single concord less than an octave; and are usually, in practice, denominated from that simple concord.

As to the composition and relations of the original concords, by applying to them the rules of the addition and subtraction of intervals, they will be divided into *simple* and *compound*, according to the first and more general notion; as in the following table.

Simple Concords	Compound Concords.	
5:6 a 3d less.	4th	} 3dg. and 3dl. } 3ve. com- } 4th. } 3dl. } posed of } 5th g. } 4th. } 3g. }
4:5 a 3d gr.	6th l.	
3:4 a 4th.	5th g.	

The octave is not only the first concord in point of perfection, the agreement of whose extremes is greatest and the nearest to unison; inasmuch that, when founded together, it is impossible to perceive two different sounds; but it is also the greatest interval of the seven original concords; and, as such, it contains all the lesser, which derive their sweetness from it, as they arise more or

less directly out of it; and which decrease gradually, from the octave to the lesser sixth, which has but a small degree of concord.

A remarkable circumstance is the manner wherein these minor concords are found in the octave, which shews their mutual dependences.

For, by taking both an harmonical and arithmetical mean between the extremes of the octave, and then both an harmonical and arithmetical mean betwixt each extreme, and the most distant of the two means last found; viz. betwixt the lesser extreme and the first arithmetical mean, and betwixt the greater extreme and the first harmonical mean; we have all the lesser concords.

Thus, if betwixt 360 and 180, the extremes of octave, we take an arithmetical mean, it is 270; and an harmonical mean is 240: then, betwixt 360 the greatest extreme, and 240 the harmonical mean, take an arithmetical mean, it is 300; and an harmonical mean is 288. Again, betwixt 180 the lesser extreme of the octave, and 270 the first arithmetical mean, it is 225; and an harmonical one 216.

Thus, we have a series of all the concords, both ascending towards acuteness from a common fundamental 360; and descending towards gravity from a common acute term 180; which series has this property, that taking the two extremes, and any other two at equal distances, the four will be in geometrical proportion.

The octave, by immediate division, resolves itself into a fourth and fifth; the fifth, again, by immediate division, produces the two thirds; the two thirds are therefore found by division; though not by immediate division; and the same is true of the two sixths. Thus do all the original concords arise out of the division of the octave; the fifths and fourths immediately and directly, the thirds and sixths mediately.

From the perfection of the octave arises this remarkable property, that it may be doubled, tripled, &c. and yet still will preserve a concord, *i. e.* the sums of two or more octaves are concord; though the more compound will be gradually less agreeable; but it is not so with any other concord less than octave; the doubles, &c. of which are all discords.

Again, whatever sound is concord to one extreme of the octave, is concord to the other also; and if we add any other simple concord to an octave, it agrees to both its extremes; to the nearest extreme it is a simple concord, and to the farthest a compound one.

Another thing observable in this system of concords is, that the greatest number of vibrations of the fundamental cannot exceed five; or that there is no concord where the fundamental makes more than five vibrations, to one coincidence with the acute term. It may be added, that this progress of the concords may be carried on to greater degrees of composition, even in *infinitum*; but still the more compound, the less agreeable.

So a single octave is better than a double one, and that than a triple one; and so of fifths, and other concords.

Three or four octaves form the extremes of all the intermediate sounds; what will afford all the variety of pleasure the harmony of sounds is capable of affording, or at least that we can receive; for we can hardly raise sounds beyond that compass, either by voice or instrument, that shall not offend the ear.

The phenomena attending simultaneous sounds have been considered by Euler, and treated of in so clear and perspicuous

CONCORD.

that such consonances are much more agreeable than perfect discords, whose pulses coincide very often.

We may, indeed, says Dr. Smith (p. 99.) approach as near as we please, and certainly much nearer than the sense can distinguish, towards the exact magnitude of an incommensurable ratio, by the ratios of whole numbers; but as these will grow larger and larger without bounds, so will the time between the successive coincidences, or the length of the approximating cycle of the pulses; by which is meant the time of either of the incommensurable vibrations, multiplied by the heterologous term of the approximating ratio. Let any man tell us then where we may stop, and which of those cycles it is, whose repetition excites the determinate sensation of the consonance.

The like difficulty occurs in approaching gradually even to a commensurable ratio of the vibrations of any perfect consonance. For, if either of its vibrations be pretty much altered at once, and then be made to approach by degrees to its former length, the terms of the several approximating ratios will grow larger and larger without bounds, and in regular order, except when ratios occur whose terms are reducible; and the cycles of their pulses will accordingly be longer and longer, and their coincidences fewer without limit, those interruptions excepted; and yet the consonance will grow better and better by regular degrees, till it arrives at perfection, as is certain by experience. For instance, the ratios 30 to 21, 300 to 231, 3000 to 2001, &c. approach nearer and nearer to 3 to 2, and the Vtths, whose vibrations are in those ratios, grow more and more harmonious, though the cycles of their pulses grow longer and longer to infinity.

It seems indisputable, that coincident pulses are not necessary to such harmony as the ear judges to be perfect. For if any long period of imperfect unisons, intercepted between two beats, be lengthened greatly and indeterminately, as in tuning an instrument, any given part of it, as long as any musical note, will approach indefinitely near to perfect unisons; certainly nearer than the ear can distinguish, as being often doubtful of their perfection. And yet throughout that part (supposed to be small in comparison to the whole period) the pulses of one sound divide the intervals of the pulses of the other very nearly in a given ratio, of any determinate magnitude, between infinitely great and infinitely small, in proportion to the distance of that part from the periodical point or point of coincidence. Nevertheless, the ear cannot distinguish any difference in the harmony of such different parts, as is evident by often repeating the same consonance, which can hardly begin constantly in the same place of the long period; and this argument applies to all other consonances besides unisons.

Dr. Robison supports this train of argument, by a reference to the well known fact, that if two musical instruments, as two organ pipes, tuned so exactly in unison that their pulses may be supposed to begin and end at the same instants, making the most perfect coincidence of pulses, be placed at a given distance from each other, and sounded, the consonance will be perfectly the same, in whatever part of the room or space round the sounding pipes the ear of an auditor may be placed; while, owing to the time taken up by sound in travelling through a given space, it is evident that the supposed coincidence of the pulses in the sounds cannot so affix or reach an ear unless it be placed exactly at equal distances from each of the sounds; whereas, by placing himself exactly in the middle of the right line joining two unison sounds, and gradually approaching one of the sounds, every possible dislocation or deviation of the pulses from coincidence will prevail, in their action upon one of

the ears of an observer, while in most cases the other ear will be very differently acted upon, owing to its relative distances from the sounding bodies being different. And hence, as Dr. Robison concludes, "a musical sound is the sensation of a certain form of the aerial undulation which agitates the auditory organ. The perception of harmonious sound is the sensation produced by another definite form of the agitation. This is the competition of two other agitations; but it is the compound agitation only that affects the ear, and it is its form or kind which determines the sensation, making it pleasant or unpleasant," or in other words, a concord or a discord.

On the supposition that nature has appointed no certain limits between concords and discords, Dr. Smith (Harmon. p. 15.) inquires into the order of simplicity of the consonances between different sounds, perfectly adjusted according to their ratios, on the principle, that one consonance may be considered as more or less simple than another, according as the cycle of times belonging to it is more or less simple than the cycle belonging to the other, or as the sum of the least terms expressing the ratio of the single vibrations is smaller than the like sum in the other consonance; and that, when several such sums are the same, these consonances are simpler in the same order as the lesser terms of their ratios are smaller; and he disposes the consonances in a table, differing little, except in arrangement of the columns, from the following:

Order of the Simplicity	Ratios of the vibrations.	Concords.	Order of the Simplicity	Ratios of the vibrations.	Concords.
1	1 : 1	Unison.	16	1 : 16	XXXIX

15	1 : 15				

The first and second columns of this table can scarcely need any explanation; the third contains the concords, major and minor, expressed as in the second column of the general table of concords, which follows in this article: the blanks in this column denote the discords, such as are marked with a * being computed of primes larger than 5, as 7, 11, 13, &c. and have no existence in music, except in the false notes

of the TRUMPET. HORN, &c.; see those articles: the others, or their octaves, will be found in the table of DISCORDS; see that article.

On the other hand, Dr. Robison and other writers have maintained, and we think justly, that nature has not left the concords without other distinctions than the capricious and uncertain preference given to them by musicians, but in addition to the almost universal delight which concords afford to every description of auditors, that the phenomena of slow and audible beats, accompanying each concord, when slightly tempered either in excess or defect, sufficiently distinguish such from all other musical intervals, comprised properly under the denomination of discords, or imperfect concords; and we cannot but agree with Dr. R. in thinking, that the study of the principles of harmonics would be greatly facilitated by considering the concords as the elements or fundamental intervals of melody fixed by nature, and that we should proceed to supply the other steps wanting in the scale, from their differences or combinations, rather than by assuming the tones and hemitones (which are discords that the most refined ear cannot accurately appreciate) to be the elements for composing the practical intervals of music; which it is not meant to contend, that they cannot accurately do in theory, but that concords of the truth or exact magnitude of which ordinary ears can at once judge with sufficient exactness (while the curious can adjust such in practice, by help of the beats, to any desired degree of accuracy) are better adapted to the purposes of harmonical computations and reasonings, and will admit of more direct and perhaps also of some new applications in practice.

For illustrating this subject, we beg to be allowed to mention an experiment by Dr. Robison, made with a wheel monochord, perhaps improperly so named, because it had two strings, which, by means of a refined revolving wheel, could be made to yield clear and even sounds for any required space of time: one of the strings giving constantly the same sound, while the length of the other, after being accurately tuned in unison therewith, admitted of being shortened in any required degree, without altering its tension.

Beginning with the unison (but which was not exactly the order in the Doctor's experiment), the moveable bridge, which determined the length of the variable string, was slowly and gradually moved forwards; at first a very slow, and by degrees a quicker, beating of the imperfect unison was heard, which increased in rapidity until the beats could no longer be counted, and at length they became a violent rattling flutter, which degenerated into a disagreeable jar. Still advancing the bridge, vile discordant noises resulted from the sound of the two strings, until the variable string had been shortened nearly $\frac{1}{15}$, or when a little more than $\frac{1}{10}$ of the string continued to sound; when a very rapid angry flutter commenced, that became rather less rapid and offensive as the point $\frac{1}{8}$ was approached, and again increased after that, until the discordant jar prevailed again; and this continued, until $\frac{3}{8}$ of the string was approached, when a similar flutter commenced, decreased, and again increased as this point was passed by the bridge; the jar beginning again, and accompanying the motion of the bridge, until it almost arrived at $\frac{1}{2}$ ths of the string's length, when a flutter and rapid beat commenced, decreasing in frequency, until at $\frac{2}{3}$, or when the minor third (3^{rd}) was sounded, they ceased entirely, and the result was a concord rather agreeable than otherwise, but strongly marked by a mournful melancholy in the expression; which, being sufficiently noticed, the bridge was again advanced, and produced the same beating, slow at first, then quicker, and at length

fluttering, until the like grating dissonance succeeded as before. This continued, until near the point marked $\frac{3}{4}$, when the beatings again commenced, having a peculiar fretful expression as they decreased in quickness, owing to the advance of the bridge, to the point of the major third (III), when the beats ceased, and the peculiarly enlivening and gay character of this concord was experienced by the hearers, who noticed an angry and waspish expression to accompany the succeeding beats as the string shortened, but which gave place gradually to the same flutter and jar as before.

When little more than $\frac{2}{5}$ ths of the string's length continued to sound, the flutterings and rapid beats were again heard, and the latter decreased and ceased entirely, at the point marking the fourth (4^{th}) which was noticed as a soft and agreeable concord. To this first flow, and then rapid, beats succeeded, and rapid flutterings, and a jarring noise. Near $\frac{3}{4}$ ths of the string the fluttering commenced again, and decreased until about six of them could be counted in a second of time as the false IV was passed, after which they increased again in rapidity as the bridge advanced, and an indistinct and jarring noise succeeded, which soon again became a flutter that decreased until at $\frac{2}{3}$ ths of the string about eight of these angry flutters could be counted in a second, corresponding to the false fifth, after which they increased in rapidity, and the jarring noise was again heard.

The bridge being progressively moved, the flutterings began, beats succeeded, and passed into a gentle and not unpleasant undulation which ceased entirely at $\frac{1}{3}$ ds of the string, when the fifth (V) with the cheering sweetness which characterizes it, was heard in the accordance of the two flows, neither of which could be separately distinguished: after which the slow and rapid beats, and fluttering, and jar succeeded as before. Some time before the bridge reached the mark for $\frac{1}{2}$ ths of the string the flutter and beats began again, and at that point the minor sixth (6^{th}) a consonance in a slight degree pleasant was heard of a mournful character, without any beatings, but which were heard to recommence and increase as the bridge advanced; and the jarring dissonance continued, until little more than $\frac{1}{3}$ ths of the variable string was left sounding, when flutters and beats succeeded, and such ceased when the true major sixth (VI) was heard, the character of which it was found difficult to express, otherwise than as being greatly inferior to the V in sweetness, and to the III in gaiety, but possessing in a lower degree both of these qualities: shifting the bridge forwards, beats, flutters, and discordant noises succeeded, attended with two perceptible changes to flutters, in its progress towards the $\frac{1}{2}$ of the string; which was not reached without the violent flutters, rapid and slower beats, so often before described; but when the beatings ceased the true octave (VIII) was heard, the treble note being with difficulty distinguished from the bass or fundamental afforded by the other string, and not at all so if the notes were duly apportioned in loudness. After this, if the bridge was still further advanced, beats, flutters, &c. succeeded as before, answering to the octaves of the sounds already described, as the bridge advanced to make half of the lengths of the former strings, respectively.

The doctor concludes his account of this very interesting experiment by remarking, that he has perhaps been rash in ascribing certain moral or sentimental characters to certain concords; because he had seen instances of persons who gave them different denominations, but these were never contradictory to his, but always expressed some sentiment allied to those above assigned. A person capable of a little discriminating reflection was never met with by the doctor, who did not acknowledge a manifest sentimental distinction among the

	Intervals in Half-Tones	Intervals, Major and Minor,	Letters	Ratios	Common Logarithms.	Ratio in their Component Primes.	Tunable Intervals.

The titles of the columns are placed at the bottom of the foregoing Table, because it is intended to be read from the bottom upwards, agreeably to the practice of musicians, who read their notes upwards. Column 1 contains the number of finger-key intervals or half-notes: it will be found of use, in rough calculations respecting musical intervals; thus, suppose a VI were to be added to a 6th, and it was required to know on what note the sum would fall, we have $9 + 8 = 17$, which answers in the Table to the 17th, and which happens to be exactly their sum, as is evident by comparing column 7: suppose again, that it was required to know the interval answering to three III^s, we have in this case $4 \times 3 = 12$; this in the Table answers to the VIII, but it is evident from col. 7, that this is only an approximate value, because this is $4 + III + 3$ instead of 3 III, the difference

being an enharmonic diesis, or the Tierce wolf of earl Stanhope.

Column 2 contains the marks of the intervals, the major intervals being denominated by Roman, and the minor intervals by Arabic characters, or numbers. Column 3 shews the notes of the gamut, distinguishing the seven different octaves, the first or lowest by Roman capitals, the next by Italic small letters, the third by these accented, the fourth by the same double accented, the fifth by three accents, and the sixth and seventh octaves by small figures or indices, to express the number of accents.

Column 4 contains the ratios of the several notes, in their lowest terms. Column 5 contains the common or Briggs's logarithms to eight places of figures, the last being separated by a comma, in order to agree with the common Tables,

Tables,

tables, which have only seven places: whenever this number only is wanted, the seventh figure must be increased an unit, in every case where the eighth figure in the table exceeds 5.

Column 6 shews the ratios, expressed in their component primes, for the convenience of decomposing the same into tuneable intervals, as explained in our article *COMMA*; thus, the second fraction, or $\frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2}$ may be divided or expressed by $\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \frac{1}{2}$, which shews it to be equivalent to 6 VIII + VI, as in column 7. The fraction answering to the 6th, or $\frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2}$ may be thus stated, *viz.* $\frac{1}{2}, \frac{1}{2}, \frac{1}{2}$, or VIII - III, the last term being negative, because the ratio or fraction expressing it is found reversed.

Column 7 contains several different values of each interval in col. 2, all expressed in tuneable intervals, or concords: the first, in each case, is expressed in the concordant elements, or smallest concords 4, III and 3^d; the next expression in each line has one or more VIIIths in its composition; we have next given those tuneable intervals, which are found to express each interval by two terms only; and have then added two others, (being all that our room would admit) of the various expressions in tuneable intervals, which can be had for any concord in col. 2, especially if negative signs are admitted, as we have done in the lowest octave of our table. Matter for curious reflection will present itself to the musical student, who attentively considers the last column of our table, such as; 1st, that the octave is the only concord which admits of being added to itself, without producing a discord; 2dly, that the complement of every concord to an octave (or to 2, 3, 4, &c. octaves,) is a concord; 3dly, that all the simple combinations by one, by two, or by three, of our concordant elements 4th, III and 3^d, produce concords; 4thly, after these simple combinations are made, no farther ones can be made, except the addition of an equal number of each of the concordant elements (as 4 + III + 3, 2 4 + 2 III + 3, &c.) without producing discords; &c. If the difference between any two concords be wanted, as between the XVII and the X, such is readily obtained from column 7th thus; 2 4 + 3 III + 3 - 4 - 2 III - 3 is equal to 4 + III + 3, or the octave. The sum also of any concords, as a VI and 6th, is thus obtained; 4 + III + 4 + 3, or 2 4 + III + 3, which answers to the 11th, as before observed, when explaining the uses of column 1.

It may be of use here to mention, that the differences between each adjoining concord, in each several octave in column 7, will be found to be 3^d, III - 3 (or the minor semitone, $\frac{2}{3}$), 4 - III (or the major semitone $\frac{4}{3}$) III + 3 - 4, or V - 4 (or the major semitone $\frac{5}{4}$), 4 - III, III - 3, and 3^d; and this, whether we begin at the top or at the bottom of the octave, which shews that nature has distributed these six concords, in a surprisingly uniform manner, between the unison and the octave. The intervals which will, in addition to those above, be found by deducting every concord within the octave from each other, are, 4 - 3 (or the minor tone, $\frac{4}{3}$) and 4 + III - 3, or VI - 3 (or the comma deficient tritone or sharp fourth $\frac{13}{9}$).

It has been remarked by Mr. Holder, that the number 6 combined with itself, or with every less integer, produces in every instance a concord, thus $\frac{6}{6}, \frac{6}{4}, \frac{6}{3}, \frac{6}{2}, \frac{6}{1}$, expresses the unison, 3^d, V, VIII, XII and XIX.

CONCORD, or *Concordia*, in *Mythology*, was personified by the Romans, and worshipped as a deity under this appellation. Concord is commonly represented on coins as a graceful female, holding a cup in her right hand, and in her

left sometimes a sceptre, and at other times a cornucopia, to intimate that plenty is the result of unanimity and friendship. Her symbols were two hands joined, as is seen on a coin of Aurelius Verus, and another of Nero; also two serpents twisting round a caduceus. Mr. Spence observes, that concord is sometimes represented with two cornucopias in one of her hands, a thing, says he, which I do not remember to have seen in any figure but her's, and as agreement often doubles the advantages we receive from the world, they seem to be given her with more propriety than perhaps they could be to any other.

CONCORD, *Temple of*, a building erected in Rome, at the expence of the public, upon an eminence at the foot of the capitol; so that it was seen from the forum, and the places where the assemblies were held and justice was administered. This temple was built in pursuance of a vow of Camillus to this purpose. See the article *CAMILLUS*.

Concord had several other magnificent temples, besides this and another erected by Tiberius, at the request of his mother Livia. In one of these temples were deposited the rich spoils of the temple of Jerusalem.

CONCORDANCE, a dictionary or index to the bible wherein all the leading words, used in the course of the inspired writings, are ranged alphabetically; and the various places where they occur referred to; to assist in finding out passages, and comparing the several significations of the same word.

Cardinal Hugo de St. Charo is said to have employed five hundred monks at the same time in compiling a Latin concordance: besides which, we have several other concordances in the same language; one, in particular, called the concordance of England, compiled by J. Darlington, of the order of Prædicants; another more accurate one, by the Jesuit de Zamora.

R. Mordecai Nathan has furnished us with a Hebrew concordance, first printed at Venice in 1523, containing all the Hebrew roots branched into their various significations, and under each signification all the places in scripture wherein it occurs: but the best and most useful Hebrew concordance is that of Buxtorf, printed at Basil in 1632.

Dr. Taylor published, in 1754, a Hebrew concordance in two volumes folio, adapted to the English Bible, and disposed after the manner of Buxtorf. See the preface of this work.

The Greek concordances are only for the New Testament: indeed we have one of Conr. Kircher's on the Old; but this is rather a concordantal dictionary than a concordance; containing all the Hebrew words in an alphabetical order; and underneath, all the interpretations or senses the LXX. give them; and in each interpretation, all the places where they occur in that version.

In 1713, Frommiius published his Greek concordance for the Septuagint at Amsterdam, in two volumes folio; and Schmidius, improving on a similar work of H. Stephens has given an excellent Greek concordance for the New Testament, the best edition of which is that of Leipzig, an. 1717.

Calasius, an Italian Cordelier, has given us concordances of the Hebrew, Latin, and Greek, in two columns: the first, which is Hebrew, is that of R. Mordecai Nathan, word for word, and according to the order of the books and chapters: in the other column is a Latin interpretation of each passage of Scripture quoted by R. Mordecai; this interpretation is Calasius's own; but in the margin he adds that of the LXX. and the Vulgate, when different from

his. The work is in four volumes folio, printed at Rome in 1621.

Of all the helps towards understanding the Hebrew Scriptures, says Dr. Geddes (Prospectus, p. 71.) a good concordance is undoubtedly the most useful. But we yet want a good concordance; and the man who should devote five or six years to the compiling of one from Buxtorf, Calasio, Noldius, Taylor, Kircher, Montfaucon, and Trinius, would do a singular service to biblical studies. Buxtorf's method of arrangement, with very little improvement, should be strictly followed; the errors of orthography rectified from the authority of manuscripts and other sources of emendation; and the various acceptations of the same word in the ancient versions exactly noted and methodically distinguished. Such a work would be worth all the commentaries that have ever been made.

We have several very copious concordances in English; as Newman's, &c. but the last and best esteemed is that in 4to. by Alex. Cruden.

CONCORDANT Elements, in Music, are the fourth (4^{th}) the major third (III) and the minor third (3^{rd}); see CONCORD. Dr. Smith considers the major tone (τ) the minor tone (ι) and the hemitone (ω) as elements; Harmonics, p. 13.

CONCORDANT Verses, such as have several words in common; but which, by the addition of other words, convey an opposite, at least, a different meaning. Such are these,

Et { *Canis* } in *silva* { *venatur* } *Somnia* { *servat*.
 { *Lupus* } { *nutritur* } { *vaflat*.

CONCORDAT, in the Canon Law, denotes a covenant, or agreement concerning some beneficiary matter, as a resignation, permutation, promotion, or the like.

The council of Trent, sess. vi. de reform. cap. 4. speaking of concordats made without the authority and approbation of the pope, calls them *concordias que tantum suos obligant auctores, non successores*. And the congregation of cardinals, who have explained this decree, declares also, that a concordat cannot be valid so as to bind successors, unless confirmed by the pope.

CONCORDAT is also used, absolutely, among the French, for an agreement concluded at Bologna in 1516, between pope Leo X. and Francis I. of France, for regulating the manner of nominating to benefices. The concordat serves in lieu of the pragmatic sanction, which has been abrogated; or, rather, it is the pragmatic sanction softened and reformed. The king went in person to the parliament to offer the concordat to be registered, and letters patent were made out, requiring all the judges and courts of justice to observe this act, and see it executed. The parliament, after deliberating a month upon this important matter, concluded not to register the concordat, but to observe still the pragmatic sanction, unless the former edict was received and established in as great an assembly as that was, which published the latter in the reign of Charles VII. And when, by violence and force, they were obliged to publish the concordat, they joined to the publication a solemn protest and an appeal from the pope to the next general council, into both which measures the university and the clergy entered with the greatest alacrity and zeal. But royal and papal despotism at length prevailed. The chancellor De Prat, who was principally concerned in promoting the concordat, has been generally regarded as an enemy to the liberties of the Gallican church. The illustrious and learned Hainault has defended his memory against this accusation, and justified the concordat as an equitable contract, and as a measure attended with fewer inconveniences, than the pragmatic

sanction. He observes, that by the king's being invested by the concordat with the privilege of nominating to the bishoprics and vacant benefices of the first class, many corruptions and abuses were prevented, which arose from the simoniacal practices that prevailed almost every where, while, according to the pragmatic sanction, every church chose its bishop, and every monastery its abbot. He observes moreover, that this nomination was the natural right of the crown, as the most considerable part of the great benefices had been created by the kings of France; and he particularly insists on this consideration, that the right which Christian communities have to chuse their leaders, cannot be exercised by such large bodies without much confusion and many inconveniences; and that the subjects, by entrusting their sovereign with the government of the state, invest him, *ipso facto*, with an authority over the church, which is a part of the state, and its noblest branch. The most specious objection that was made to the concordat was this: that, in return for the nomination to the vacant benefices, the king granted to the popes the annates, or first fruits, which had too long been complained of as an intolerable grievance. There is, however, no mention of this equivalent in the concordat. And it was by a papal bull that succeeded this compact, that the pontiffs claimed the payment of the first fruits, of which they had put themselves in possession in the year 1316, and which had been suspended by the pragmatic sanction.

As the concordat gave to the kings of France the absolute right of succeeding to all the great, or what are called the consistorial benefices, of the Gallican church; it was a very important edict. Since the establishment of the pragmatic sanction and of the concordat, the clergy of France in general (before the late Revolution) manifested less respect to the decrees of the papal court than the clergy of any other Catholic country. In all the disputes which their sovereign has had with the pope, they have almost constantly taken part with the former. Their independence on the court of Rome seems to have been principally founded on this act.

The concordat between the pope and the republic of Venice resembles the former.

There is also a German concordat, made between the emperor Frederic III. and the princes of Germany, in 1448, relating to beneficiary matters, confirmed by pope Nicholas V.

CONCORDAT, as it is now used in France, is a term that applies exclusively to an agreement or convention exchanged between the pope, Pius VII., and the French government, the 23d Fructidor, an. 9, or September the 16th, 1801. In this agreement the Roman catholic religion is acknowledged to be that of the majority of the French people; and the better to consolidate the reformation of its worship, which had been almost totally neglected since the year 1792, the pope engages not to disturb the proprietors or purchasers of estates, which, before the French revolution of 1789, belonged to the church; and he acknowledges in the first consul of the French government the same rights and prerogatives which the ancient government possessed. By virtue of the said concordat, the whole territory of European France is divided into ten archbishoprics; *viz.* Paris, containing eight bishoprics, Malines seven, Besançon five, Lyons four, Aix four, Toulouse five, Bourdeaux three, Bourges three, Tours seven, and Rouen four; and fifty bishoprics; *viz.* Troyes, Amiens, Soissons, Arras, Cambrai, Versailles, Meaux, Orleans, Namur, Tournay, Aix la Chapelle, Treges, Gand, Liege, Mayence, Autun, Metz, Strasbourg, Nancy, Dijon, Mende, Grenoble, Valence, Chambéry, Nice, Avignon, Ajaccio, Digne, Cahors, Montpellier, Carcassonne,

Carcassonne, Agen, Bajonne, Poitiers, La Rochelle, Angoulême, Clermont, Saint Flour, Limoges, Le Mans, Angers, Nantes, Rennes, Vannes, Saint Brioux, Quimper, Coutances, Bayeux, Siez, and Evreux. The nomination to the sees rests with the French government; the pope only confirms each nomination by his canonical institution, according to the forms anciently established with regard to the Gallican church, whose privileges and immunities continue in full force. The bishops, before they enter upon their functions, shall take before the first consul, in person, the oath of fidelity which was in use before the change of government, expressed in the following terms: "I swear and promise to God, upon the holy evangelists, to preserve obedience and fidelity to the government established by the constitution of the French republic. I also promise to have no correspondence, nor to assist at any council or cabal, either within the country or out of it, that shall be contrary to the cause of the public tranquillity; and if in my diocese, or elsewhere, I shall learn of any plot or machination prejudicial to the state, I shall inform the government of it." The clergy of the second order shall take the same oath before the civil authorities appointed by the government. The following prayer shall be recited at the end of divine service in all the Catholic churches of France:

Domine, salvam fac rempublicam!
Domine, salvos fac consules!

The bishops shall make a new division of parishes in their dioceses, subject to the consent of the government: the bishops shall name the curés, subject to the approbation of the government. The bishops may have a chapter in their cathedral, and a seminary in their diocese, but the government is not engaged to endow them. All the metropolitan, cathedral, parochial, and other churches, undivided of, shall be placed at the disposal of the bishops. The government engages to secure a suitable provision for the bishops and curés, whose dioceses and parishes shall be marked out by the new division. The allowance of the archbishops shall be 15,000 livres annually, and that of the bishops 10,000. Bishops may add to their titles the qualification of "citoyen," or "monseigneur." No man can be named a bishop but a Frenchman, aged at least 30 years, having an attestation of his morals delivered by a bishop, and after an examination of his doctrine by a bishop and two priests: nor shall bishops quit their sees without the permission of the first consul. Bishops are required to visit every year a part of their diocese, and the whole every five years. No clergyman shall be ordained as priest, who is not 25 years of age, and possessed of 300 livres annual revenue. The curés shall reside in their parishes; and priests, who do not regularly belong to any diocese, shall not officiate. The clergy in general shall wear black clothes; and the bishops violet coloured stockings. There shall be a liturgy and a catechism for the French church. The names of the days shall be as in the ancient calendar; and Sunday shall be the day of rest for the public functionaries; nor shall any other holidays, except Sundays, be kept without the consent of the government. The bells shall only be rung for divine service. The same temple shall be consecrated only to one form of worship. The nuptial benedictions shall be only given by the clergy to those who have been married by the civil officers.

With regard to the Protestant religion, no person shall exercise the ministerial functions but a Frenchman; nor shall the Protestant churches and their ministers have any connection with any foreign power. The ministers and their communities shall pray for the prosperity of the French republic, and the consuls. No doctrine, nor alteration of doctrine, shall be published or taught, without being first authorized

by the government. The maintenance of the ministers shall be provided for, wherever the property and oblations of the communities fall short. The articles for the liberty of foundations, in the organic laws of the Catholic worship, shall be common to the Protestant churches. There shall be two seminaries, one in the east of France, for the instruction of ministers of the confession of Augsburg; and the other at Geneva for the reformed churches. The professors are to be named by the first consul, and no minister to be appointed without a certificate of his having studied in the seminary of his religion. The regulations of the seminaries are to be settled by the government. The reformed churches of France shall have pastors, local consistories, and synods. There shall be a consistorial church for every 6000 souls of the same communion. Five consistorial churches shall form the district of a synod. The number of ministers or pastors in the same consistorial church cannot be increased without the authority of government; nor can the pastors resign without stating their motives to government, which shall approve or reject them. The title of election shall be presented to the first consul for his approbation. Each synod shall consist of a pastor and a notable of each church. The synods shall superintend the celebration of worship and conduct of ecclesiastical affairs, and all their decisions shall be submitted for the approbation of government. The synods cannot assemble until they shall have received the permission of government; nor shall any synodal assembly last more than six days.

The churches of the confession of Augsburg shall have pastors, local consistories, inspections, and general consistories. The pastors and consistorial churches shall be subject to the regulations prescribed for the reformed pastors and churches. The churches of this confession shall be subordinate to the inspections. Five consistorial churches shall form an inspection, which is to assemble only by permission of government. Each inspection to choose an inspector, and two laymen of such choice to be confirmed by the first consul. There are to be three general consistories; one at Strasburg, for the Protestants of Augsburg, of the departments of the Upper and Lower Rhine; a second at Mentz, for those of the departments of the Sarre and Mont-Tonnerre; and the third at Cologne, for those of the departments of the Rhine, Moselle, and Rour.

CONCORDAT *Militaire*, Fr., an agreement entered into by officers of the same corps, to establish a fund or provision for one of them that quitted it. This agreement, however, was only tolerated in particular cases and circumstances, to which the chiefs seemed to consent, without either openly, or with their signatures, giving their approbation to the same.

CONCORDIA, in *Ancient Geography*, a town of Italy, with the title of colony; placed by Ptolemy in the country of the Carpi, but by Pliny in that of the Veneti, between Pons Liguentis and Tlavemptus. Eutropius and the Itinerary of Antonine place it in Venetia. It took the name of *Julia*, because a colony had been sent thither by Julius Cæsar.—Also, a town of Spain, placed by Ptolemy in Lusitania, supposed to have been the present *Tomar*.—Also, a town and Roman fortress of Gaul, in Germania Prima, between Brocomagus and Noviomagus, according to the Itinerary of Antonine.

CONCORDIA, in *Geography*, a town of Italy, in the duchy of Mirandola, on the Secchia; 6 miles W. of Mirandola; between which cities there is a fine canal, which facilitates the communication of both.—Also, a town of Italy, in the country of Trulli; which, though in ruins, is the see of a bishop, who resides at Porto Gruato.

CONCOTS, a town of France, in the department of the Lot; 3 leagues S.S.E. of Cahors.

CONCOU, in *Botany*, a name given by the people of Guinea to an herb which is in great esteem with them for killing that troublesome sort of worm called the Guinea-worm, which breeds in their flesh. They bruise the leaves, and mixing them with oil, apply them in form of a cataplasm. The leaves of this shrub somewhat resemble those of the caggow, but they are thicker and stiffer, and are not so full of veins. They are broadest within one third of the base, and from thence they go tapering to each end. They are placed on long footstalks of a fine green throughout. Phil. Trans. N^o 232.

CONCOURS, in *Geography*, a town of France, in the department of the Aveyron, and district of Rhodéz; 7 miles N.N.E. of Rhodéz.

CONCOURSE, or CONCURRENCE, the reciprocal action of divers persons or things co-operating toward the same effect or end.

The schoolmen distinguish two kinds of concurrence; *viz.* mediate, which consists in giving a power or faculty to act; and immediate, which is a contemporary influence of one cause along with another, to produce an effect. Thus, the grandfather concurs mediately to the production of a grandson, as he originally gives the power of generating to the father; but the father concurs immediately with the mother to the production of the same child. With respect to the agency of God, some divines maintain both these kinds of concurrence; others deny the latter. See CAUSE.

CONCOURSE, *Point of*. See FOCUS.

CONCQUE, Fr. A piece of artillery, of which the bore is wider towards the muzzle than towards the breech. It is also the name of a shell, which the ancients made use of in their armies instead of a trumpet.

CONCRESSAUT, or CONCORSAUT, in *Geography*, a town of France, in the department of the Cher, on the Saudre, almost ruined by the civil wars; 25 miles N. of Bourges.

CONCRETE, in the *School Philosophy*, an assemblage, or COMPOUND.

CONCRETE, *Physical*, or a CONCRETE *body*, may denote any mixed body, or body composed of different principles; and consequently, all sensible bodies whatever, as all bodies arise from a coalition of divers elements, or at least of divers principles, matter, and form.

But, in strictness, concrete is only used for those compounds wherein the ingredients still retain their distinct natures, nor are wholly converted into any new common nature.

Authors distinguish *natural* concretes and *artificial* ones: antimony is a *natural* concrete, and soap a *fascitious* concrete.

CONCRETE *Juices*. See JUICES.

CONCRETE, *Logical*, or a CONCRETE *word*, called also *paronymum*, is that which has a compound signification, as denoting both the subject and some quality or accident of the subject, which gives it its denomination.

Such, *e. gr.* are *man, learned, white*; for *man* signifies as much as *having human nature*; *learned*, as much as *having learning*, &c. Hence, the word concrete is chiefly used to express the union of qualities or quantities with the bodies or subjects, without any separation, even in idea. The opposite term, whereby things are separated in thought, is *abstract*.

Concrete properly signifies a subject accompanied with its form or quality; as *pious, hard, white*: *abstract*, on the con-

trary, expresses the form and quality without the subject, as *piety, hardness, whiteness*.

CONCRETE *Numbers*. are those which are applied to express or denote any particular subject: as two men, three pounds, two thirds of a shilling, &c.

Whereas, if nothing be connected with a number, it is taken abstractedly or universally: thus, three signifies only an aggregate of three units; let those units be men, pounds, or what you please.

CONCRETION, the act whereby soft bodies are rendered hard; or an insensible motion of the particles of a fluid or soft body, whereby they come to a confluence.

The word is used indifferently for *induration, condensation, congelation, and coagulation*.

CONCRETION is also used for the coalition of several little particles into a sensible mass, called a CONCRETE; by virtue of which union, the body acquires this or that figure, and these or those properties.

CONCRETION, in *Surgery*, from *concretio*, the adhesion or joining together of parts. This term also denotes the impasting or cohering of substances together, so as to form a mass; as in the sanguineous concretion, the bilious or biliary concretion, the calculous concretion, &c. The coalescence of parts which ought to be separate, as of the fingers and eyelids, might be rather called agglutination or cohesion.

Membranes and other parts may adhere together, either from natural or accidental causes; but the most frequent cause of external concretions is an ulceration or abrasion of the skin, so that two surfaces lying in contact shall unite by inflammation and reciprocal granulation. In all such cases, where an operation is practicable and necessary, the surgeon must separate the united parts with a scalpel, and keep them asunder during the cure. See STONE and CALCULUS.

CONCUBINAGE sometimes expresses a criminal, or prohibited commerce between the two sexes; in which sense it comprehends *adultery, incest, and simple fornication*.

Promiscuous concubinage is productive of a great variety of evils, and tends not only to the corruption, but to the ultimate destruction, both of individuals and of society. It is not only ineffectual to promote love, and the tender affections, either between persons themselves, or towards their offspring, but it contributes towards exciting and maintaining endless jealousies and quarrels among mankind. The great and radical mischief attending unrestrained promiscuous concubinage in a state of society, consists in its tendency to diminish marriages, and thus to defeat the several beneficial purposes resulting from this institution. (See MARRIAGE.) It discourages marriage by weakening the force of a very urgent motive and temptation to it, arising from the intention of the original former of mankind, and the constitution of human nature. "The male part of the species," says Dr. Paley, "will not undertake the incumbrance, expense, and restraint of married life, if they can gratify their passions at a cheaper price; and they will undertake any thing rather than not gratify them."

A just idea may be formed of the magnitude of this mischief, by attending to the importance and variety of the uses to which marriage is subservient; and by duly considering that the malignity and moral quality of each crime are not to be estimated by the particular effect of one offence, or of one person's offending, but by the general tendency and consequence of crimes of the same nature. The libertine may not be conscious that those irregularities hinder his own marriage; from which, as he may allege, he is deterred by different considerations; nor may he perceive, or be disposed to acknowledge, that his indulgences hinder the marriage of others;

others; but it behoves him to reflect, what would be the consequence of universal licentiousness in this respect, and what should prevent its becoming universal, if it be innocent or allowable in him. Moreover, fornication supports prostitution; and prostitution entails on its victims almost certain misery, occasioned by the indigence, disease, and infamy, to which these wretched outcasts of society, who infect populous cities, are subject; the whole aggregate of which is a general consequence of fornication, and to the increase and continuance of which, every act and influence of fornication contribute. Besides, fornication promotes habits of ungovernable lewdness, which introduce the more aggravated crimes of seduction, adultery, violation, &c.; to which we may add, in this connection, that the criminal commerce of the sexes depraves the mind and moral character more than any single species of vice whatsoever; these indulgences prepare an easy admission for every other crime: in low life, they are usually the first stage in men's progress to the most desperate villainies; and, in high life, to that lamented dissoluteness of principle which manifests itself in a profligacy of public conduct, and a contempt of the obligations of religion and moral probity. Habits of libertinism also incapacitate and indispose the mind for all intellectual, moral, and religious pleasures, which would very much contribute to every man's happiness.

It deserves further to be considered, that fornication perpetuates a disease, which may be accounted one of the severest maladies of human nature; and the effects of which are said to contaminate the constitution of even distant generations. This dreadful malady, the severest scourge, says Dr. Robertson, (*Hist. of America*, vol. ii. p. 87), with which, in this life, offending Heaven chastens the indulgence of criminal desires, seems to have been peculiar to the Americans; and he adds, that by communicating it to their conquerors, they have not only amply revenged their own wrongs, but by adding this calamity to those which formerly embittered human life, they have, perhaps, more than counterbalanced all the benefits which Europe has derived from the discovery of the New World.

Dr. Hartley, in his "Observations on Man," (p. 443), remarks, that the shameful, loathsome, and often fatal disease, which peculiarly attends the vice of lewdness, may be considered as a most unquestionable evidence of the Divine Will. This disease, with all its consequences, would soon cease among mankind, could they be brought under the restraints of lawful marriage; but must ever continue, whilst licentiousness continues. Without this check, however, the licentiousness which has always been observed to follow improvements in arts and politeness, and to attend upon bodies politic in their declension, and which the corruption of the Christian religion in some, and the disbelief of it in others, have, in a manner, authorized, would have brought on utter dissoluteness in this western part of the world, such as would have been inconsistent with the very existence of regular government. Nay, it may be, that this will fill be the case, and that we are hastening to our period, through the great wickedness of the world in this respect particularly, though our lives, as a body politic, be somewhat prolonged by this correction.

If we appeal to the Christian scriptures on the subject of this article, it is certain that these sacred writings condemn fornication absolutely and peremptorily, and that they class this crime with murders, thefts, false witness, and blasphemies. Besides, the aggravated sin of idolatry is represented by adultery and fornication in the prophetic writings. Although the scriptures give no sanction to those austerities which have been imposed upon the world under the name of

Christianity, as the celibacy of the clergy, the practice of perpetual virginity, the "prohibitio concubitus cum gravidâ uxore;" yet, with a just regard to the condition and interest of the human species, they have provided, by the marriage of one man with one woman, an adequate gratification for the propensities of their nature, and have *refrained* them to that gratification. The avowed toleration, and in some countries the licensing, taxing, and regulating of public brothels (see *BLVDY HOUSE*), have appeared like a sanction of fornication, and have contributed, with other concurring causes, so far to vitiate the public opinion, that there is no practice, the immorality of which is so little thought of or acknowledged, although there are few in which it can be more easily and more satisfactorily evinced. The legislators who have patronized spectacles of prostitution ought to have foreseen this effect, and also to have considered, that whatever facilitates fornication, diminishes marriage. As to the usual apology for this relaxed discipline, the danger of greater enormities if access to prostitutes were too strictly watched and prohibited, "it will be time enough," says Dr. Paley, "to look to that, when the laws and magistrates have done their utmost." After all, these fears are without foundation in experience. The men are in all respects the most virtuous, in countries where the women are the most chaste.

In its more refrained sense, concubinage is used for a man's and a woman's cohabiting together in the way of marriage without having passed the ceremony thereof.

This species of cohabitation is, without doubt, distinguishable from vagrant concubinage, and by reason of its resemblance to marriage, may be thought to participate of the sanctity and innocence of that state. In modern phrase, it is denominated "the keeping of mistresses," under the supposed favourable circumstance of mutual fidelity. For this practice the following kind of apology has been sometimes alleged:

"That the marriage rite being different in different countries, and in the same country among different sects, and with some, scarcely any thing; and, moreover, not being prescribed or even mentioned in scripture, can be regarded only as a form or ceremony of human invention; and that, consequently, if a man and woman betroth and confine themselves to each other, their intercourse must be the same, as to all moral purposes, as if they were legally married; for the addition or omission of that which is a mere form and ceremony can make no difference in the sight of God, or in the actual nature of right and wrong."

To this specious sort of reasoning, archdeacon Paley has replied:

1. If the situation of the parties be the same thing in marriage, why do they not marry? 2. If the man choose to have it in his power to dismiss the woman at his pleasure, or to retain her in a state of humiliation and dependence inconsistent with the rights which marriage would confer upon her, it is not the same thing. 3. It is not at any rate the same thing with respect to the children. Moreover, as to the marriage rite being a mere form, and that also variable, the same may be said of signing and sealing of bonds, wills, deeds of conveyance, and the like, which yet make a great difference in the rights and obligations of the parties concerned in them. And with respect to the rite not being appointed in scripture, the scriptures forbid fornication, that is, cohabitation without marriage, leaving to the law of each country to pronounce what is, or what makes, a marriage; in like manner as they forbid theft, that is, the taking away of another's property, leaving it to the municipal law to fix what makes the thing property, or whose it is, which also,

as well as marriage, depends on arbitrary and mutable forms. Independently of the injunctions of scripture, the plain account of the question seems to be this; it is immoral, because it is pernicious, that man and woman should cohabit, without undertaking certain irrevocable obligations, and mutually conferring certain civil rights: if, therefore, the law has annexed these rights and obligations to certain forms so that they cannot be secured or undertaken by any other means, which is the case in this instance (for whatever the parties may promise to each other, nothing but the marriage ceremony can make their promise irrevocable), it becomes in the same degree immoral, that men and women should cohabit without the interposition of these forms. Paley's Principles of Moral and Political Philosophy, vol. 1. b. 3. c. 2.

Concubinage was anciently tolerated: the Roman law calls it an allowed custom, *licita consuetudo*. When this expression occurs in the constitutions of the Christian emperors, it signifies what we now call a "marriage in conscience."

The concubinage tolerated among the Romans in the time of the republic, and of the heathen emperors, was that between persons not capable of contracting marriage together: nor did they even refuse to let inheritances descend to children which sprung from such a tolerated cohabitation.

Concubinage between such persons they looked on as a kind of marriage, and even allowed it several privileges: but then this concubinage was confined to a single person, and was of perpetual obligation, as much as marriage itself. Hottoman observes, that the Roman laws had allowed of concubinage long before Julius Cæsar made that law whereby every one was allowed to marry as many wives as he pleased. The emperor Valentinian, Socrates tells us, allowed every man two.

CONCUBINAGE is also used for marriage performed with less solemnity than the formal marriage; or a marriage with a woman of inferior condition, and to whom the husband does not convey his rank, or quality.

Cujas observes, that the ancient laws allowed a man to espouse, under the title of concubine, certain persons, such as were esteemed unequal to him, on account of the want of some qualities requisite to sustain the full honour of marriage. He adds, that though concubinage was beneath marriage, both as to dignity, and civil effects; yet was concubine a reputable title, very different from that of *mistresses* among us.

The commerce was esteemed so lawful, that the concubine might be accused of adultery in the same manner as a wife.

This kind of concubinage is still in use in some countries, particularly in Germany, under the title of a *half-marriage*, *morgengabig marriage*, or *marriage with the left hand*; alluding to the manner of its being contracted, *viz.* by the man's giving the woman his left-hand instead of the right.

This is a real marriage, though without solemnity: the parties are both bound for ever; though the woman be thus excluded from the common rights of a wife, for want of quality or fortune.

The children of concubines were not reputed either legitimate or bastards, but natural children, and were capable only of donations.

They were deemed to retain the low rank of the mother; and were on this ground unqualified for inheriting the effects of the father.

CONCUBINAGE, in a *Legal Sense*, is used as an exception

against her that sueth for dower, alleging thereby, that she was not a wife lawfully married to the party, in whose lands she seeks to be endowed, but his concubine. Brit. c. 107. Braët. lib. iv. tract. 6. cap. 8.

CONCUBINE, a woman whom a person takes to cohabit with him, in the manner, and under the character, of a wife, without being authorized thereto by a legal marriage.

CONCUBINE is also used for a real, legitimate, and only wife, distinguished by no other circumstances but a disparity of birth or condition between her and the husband. Du-Cange observes, that one may gather from several passages in the epistles of the popes, that they anciently allowed of such concubines. The seventeenth canon of the first council of Toledo declares, that he, who with a faithful wife keeps a concubine, is excommunicated; but that if the concubine served him as a wife, so that he had only one woman, under the title of concubine, he should not be rejected from communion: which shews that there were legitimate wives under the title of concubines.

In effect, the Roman laws did not allow a man to espouse whom he pleased; there was required a kind of parity, or proportion, between the conditions of the contracting parties; but a woman of inferior condition, who could not be espoused as a wife, might be kept as a concubine; and the laws allowed of it, provided the man had no other wife.

It is certain the patriarchs had a great number of wives, and that these did not all hold the same rank; some being subaltern to the principal wife; which were what we call concubines, or half-wives. The Romans prohibited a plurality of concubines, and only had regard to the children issuing from a single concubine, because she might become a legitimate wife. Solomon had 700 wives, and 300 concubines: the emperor of China has sometimes two or three thousand concubines in his palace. Q. Curtius observes, that Darius was followed in his army by 365 concubines, all in the equipage of queens; and Diodorus Siculus says, that he maintained as many as the days of the year. Artaxerxes had by his concubines 115 children. The concubines were introduced to the Persian king, each in her turn; whence some have concluded, that the ancient Persian year consisted of 365 days, since several of the Persian monarchs had this number of concubines, who went to their kings in constant courses.

CONCUPISCENCE, among divines, an irregular desire, appetite, or lust after carnal things, inherent in human nature.

The dominion or prevalence of concupiscence, according to F. Malebranche, is what we call original sin.

The origin of concupiscence he ascribes to those impressions made on the brain of our first parents at their fall; which are still transmitted and continued on those of their children; for as animals produce their like, and with like traces in the brain (whence the same sympathies and antipathies in the same kind; and whence the same conduct on the same occasions); so our first parents, after their fall, received such deep traces in the brain, by the impression of sensible objects, that they might well be supposed to communicate them to their children.

The schoolmen use the term *concupiscible appetite* for the desire we have of enjoying any good; in opposition to *irascible appetite*, whereby we eschew what is evil.

CONCURRENCE. See CONCOURESE.

CONCURRING, or CONGRUENT Figures, in Geometry, such as, being laid upon one another, do exactly correspond to, and cover one another, and consequently must

CONCUSSION.

must be equal among themselves. Thus, triangles having two sides and the contained angle equal each to each, appear to be equal to one another in all respects. See CONGRUITY.

CONCUSSION *crimen repetundarum*, in *Jurisprudence*, is the abuse of power by some person entrusted with a public commission or employment; by extorting money from those under his power or command. This crime is taken notice of in the heads of the Digest, or Code—*ad legem Juliam repetundarum*; and it is to be observed, that he who gave a bribe contrary to the oath he had taken, might be prosecuted as well as the receiver: and that the judge who was corrupted was deemed guilty of concussion, as much as he who purchased property which was in a course of litigation. The magistrates were even forbidden to acquire any thing by way of purchase, donation, or otherwise, in the provinces wherein they resided, under pain of being guilty of concussion.

The crime of concussion was not ranked in the number of public offences, except when committed by a magistrate; when committed by a person of inferior station, it was only a private crime; but it is not the quality of the person which renders the crime public or private, but the nature of the crime itself.

CONCUSSION, in *Surgery*, from *concutio*, a shaking together. This term is mostly applied to a violent commotion of the body, and especially of the brain; but a concussion of the nervous system in general, or of the spinal marrow in particular, may produce the same train of symptoms in a partial degree, as a commotion of the brain does in the whole body. A concussion of the brain may be occasioned not only by blows on the head, but also by violence inflicted upon other parts of the body. It is frequently occasioned by a fall upon the thighs when stretched out straight, or upon the breech; it is also observed in cases of contusion of the face, and fractured bones, occasioned by a fall from a considerable height, in gun-shot wounds attended with a splintering of the bones, and, in general, in every case of external violence attended with considerable commotion of the whole body. However, from whatever cause it may arise, it always requires surgical treatment.

Most of the symptoms attending compression of the brain occur also in concussion; but in a compressed state of the brain they are more permanent. See COMPRESSION.

There is no discharge of blood from the eyes, nose, or ears, which frequently happens in compression; and instead of that apoplectic stertor in breathing which accompanies compression, the patient seems to be in a sound and natural sleep. The pulse is irregular and slow in compression, and grows stronger and fuller by blood-letting; but in concussion it is weaker, being soft and equal, and sinks by blood-letting. There are besides, convulsions in compressions, which are not observed in a state of concussion. The symptoms arising from concussion come on immediately after the injury is received. In the violent degrees of these, the patient remains quite insensible; the pupils are much dilated, and do not contract though the eyes be exposed to the strongest light.

In more violent accidents, especially when the patient is rendered insensible, it is extremely difficult to distinguish between concussion and depression; for symptoms which have been supposed to arise entirely from concussion, have, after death, been found to be owing to extravasation or undiscovered fracture; and extravasation has been blamed, when, on dissection, not the least morbid appearance could be discovered.

The symptoms consequent upon concussion of the brain

are various, in proportion to the different degrees of the violence inflicted. In its slightest degree, it produces stupor and inclination to sleep, debility of the intellectual and corporeal faculties, insensibility, or paralysis of some particular part. In the second degree, the patient lies without sensation and motion in a state of profound coma, from which he cannot be roused. But at the same time he is generally restless, tosses about, speaks much in his sleep, sometimes looks up, flares wildly, raves, is affected with convulsions, and generally his pulse betokens irritation. In the third degree, death supervenes, either immediately, or as the symptoms increase in violence.

These symptoms, however, are not always of the same nature and origin, and therefore require different methods of treatment. Thus the blood-vessels of the brain may be weakened in consequence of the violence inflicted; the blood may be preternaturally accumulated in them, and dilate them, to which sometimes also a congestion in the head contributes. Sometimes, also, the external violence acts upon the substance of the brain itself and the whole nervous system, either by the irritation or by the debility and paralytic state which it induces: in the first of these cases spasmodic affections, restlessness, want of sleep, or come attended with delirium and convulsions, are observed, and in the second the patient is thrown into a state similar to syncope.

Before the external violence has been inflicted, it may happen that the patient may have been in a state of great anxiety and fear, and he may have been greatly terrified by the danger whilst it was still impending, in which cases the consequences of these violent emotions of the mind, may be mistaken for effects of a concussion of the brain. The patient is in a very different state when the injury has been inflicted whilst he was intoxicated, or in anger, or when his stomach was full. Not unfrequently also some of the symptoms proceed from lesions of other parts of the body more remote from the head, or from collateral causes, especially from inflammatory, and bilious complaints in the viscera; which frequently produce not only a determination towards the head, but also various other symptoms indicative of irritation.

All these symptoms the surgeon must take into mature consideration, in order to be able to form a proper judgment concerning the state of the patient in whom he discovers symptoms of concussion of the brain. These symptoms are commonly of a fourfold nature; that is, they are symptoms indicative of compression of the brain, and arise from the congestions in the vessels; or they are symptoms of debility and inactivity of the concussed nervous system; or they are symptoms of irritation in the nervous system; or finally, they are consequences of preternatural irritating causes in the abdominal viscera. Commonly the symptoms belonging to each of these four different heads are combined; but frequently those of one class are more violent than those of the rest, and to this circumstance the surgeon must especially attend in regulating his method of treatment.

With respect to the cure, much also depends upon making the proper distinction between the symptoms of concussion and those of extravasation. In many cases this may easily be done; for the symptoms of concussion come on immediately after the violence has been inflicted, whilst those of extravasation generally supervene within a longer or shorter time after. This criterion is however not always to be depended upon, nor discoverable in every case; for when the patient was alone at the time when the accident happened, and is now deprived of his senses, the surgeon cannot

ascertain whether the symptoms followed the accident immediately.

If the symptoms abate after the use of antiphlogistic remedies, such as blood-letting, evacuations, glysters, washing with cold water, &c. they ought to be continued; but in the contrary case, they are to be relinquished and an opposite method of treatment adopted. The effects of blood-letting alone sometimes form an important criterion; for in cases of concussion of the brain it frequently lowers the pulse to a great degree, nay, even aggravates the symptoms; whilst in extravasations, even though it be frequently repeated, it produces a far less decided effect upon the pulse, and frequently alleviates the symptoms:

Amongst the various remedies that have been recommended in concussions of the brain, blood-letting is most generally employed; but it ought to be moderate. Topical detraction of blood from the head has sometimes been found useful. Purgatives are always very serviceable, but in general it is necessary to administer them in large and repeated doses. Still more beneficial are emetics, and amongst these tartar emetic and vitriolated zinc commonly prove the most efficacious; though, on account of the insensibility of the patient, they must usually be administered in very large doses, in order to produce their effect. Many recommend also stimulating glysters, and various other stimulating remedies; such as the volatile alkalis, blisters applied to the head, and it is affirmed that some have even administered wine internally with the best effects. Cold fomentations are here particularly useful, as they are adapted to all cases, as are likewise all the remedies usually employed in syncope. Where there are symptoms of irritation, spasms, and convulsions, antispasmodics are frequently found to produce great benefit; and in these cases Dover's powder is particularly recommended. Before using it, the warm bath, and when the patient is plethoric, blood-letting is prescribed. This remedy must be continued as long as the symptoms remain, and it must be repeated when they return. Also a mixture of three parts of Vin. Antimonii and one part Tinct. Theb. given in doses of ten drops every four hours, is found very useful. The use of laudanum alone has sometimes removed the symptoms of concussion.

Notwithstanding that all the above mentioned remedies stand recommended by authentic experience, yet as they are so opposite to each other in their properties, it cannot possibly be advisable to prescribe them all together, or any single one in all cases; and the surgeon has therefore in every single case to choose those remedies that are particularly adapted to remove the most urgent symptoms of the disease. Thus, when the symptoms of preternatural repletion of the vessels of the brain are urgent, he must employ blood-letting, cold fomentations, evacuations, and glysters; to the latter of which it has been particularly recommended to add powder of squills: when the urgent symptoms are those of debility bordering on syncope, he may use volatile alkali, wine, epispastics, cold fomentations, emetics, and other tonic remedies; when the spasmodic symptoms are the most prominent, Dover's powder, Tinct. Antimon. and laudanum; when the symptoms of bilious effusions prevail, emetics and purgatives.

As there is always reason at first to suspect an accumulation of blood, and to apprehend inflammation, it will almost always be advisable first to draw blood, unless it should be contraindicated by any peculiar symptoms. Stimulants and tonics will produce more benefit after the symptoms have continued for some time, than if administered at the beginning. If after the first or second blood letting, the pulse sinks whilst the other symptoms remain the same, or

are even aggravated, it ought not to be perfited in, but a contrary mode of practice is to be attempted. We may expect advantage from blood-letting, purgatives, and emetics, when the pulse is full, hard, and quick; from antispasmodics, when it is small and hard; and from stimulant and tonic remedies, when it is small and soft. Neutral salts, gentle purgatives, and blood-letting, may be employed when the patient is strong, vigorous, plethoric, and fluid; stimulant antispasmodics, when he is weakly, very irritable, pale, and cold.

Finally, we must also attend to the state in which the patient has been before the injury: should he have received it whilst in a state of intoxication, cooling evacuations, and blood letting are necessary; if he has received it whilst his stomach was full, or whilst in a paroxysm of anger, emetics and purgatives are indicated; if whilst under the influence of great fear or apprehension, tonic and antispasmodic remedies will be proper. Moreover, the head of the patient must be carefully guarded against all motion and concussion during the course of the cure.

Should the patient recover under the use of the above-mentioned remedies, he must still for some time after carefully avoid all commotion of the head, and whatever tends to accelerate the circulation, as anger, wine, violent bodily exercise; it is also proper to continue still for some time, to wash or bathe the head in cold water; and sometimes to take tonic remedies, such as Peruvian bark, acid of vitriol, &c. When the patient, though in other respects recovered, still continues to labour under debility or paralysis of particular parts, these complaints may sometimes be removed by the continued use of internal and external tonics and stimulants, especially volatile alkali, emetics, blisters, electricity, &c. But when the symptoms increase in spite of the most careful treatment, the surgeon is authorized, especially when the diagnosis is doubtful, to suppose an extravasation, and to trepan the part that has been injured. And supposing even that the surgeon has drawn a false conclusion, the operation of the trepan, if skillfully performed, will do no harm, nay, may even in some instances be productive of benefit, in consequence of the discharge of blood which it occasions.

On this important subject Mr. Abernethy's observations deserve particular attention. He is of opinion that the effects of concussion have not been justly described by authors, nor the symptoms related by them those which usually occur. In his Surgical Essays, he, therefore, selects two cases out of many others, in order to shew what really are the common consequences of this injury named concussion.

"The whole train of symptoms following a concussion of the brain," says he, "may, I think, be properly divided into three stages. The first is, that state of insensibility and derangement of the bodily powers which immediately succeed the accident. While it lasts, the patient scarcely feels any injury that may be inflicted on him. His breathing is difficult, but, in general, without stertor; his pulse intermitting, and his extremities cold. But such a state cannot last long; it goes off gradually, and is succeeded by another, which I consider as the second stage of concussion. In this, the pulse and respiration become better, and though not regularly performed, are sufficient to maintain life, and to diffuse warmth over the extreme parts of the body. The feeling of the patient is now far restored that he is sensible if his skin be pinched; but he lies stupid, and inattentive to slight external impressions. As the effects of concussion diminish, he becomes capable of replying to questions put to him in a loud tone of voice, especially when they refer to his chief suffering at the time, as pain in the head,

head, &c. otherwise, he answers incoherently, and as if his attention was occupied by something else. As long as the stupor remains, the inflammation of the brain seems to be moderate; but as the former abates, the latter seldom fails to increase; and this constitutes the third stage, which is the most important of the series of effects proceeding from concussion.

"These several stages vary considerably in their degree and duration; but more or less of each will be found to take place in every instance where the brain has been violently shaken. Whether they bear any certain proportion to each other or not, I do not know. Indeed this will depend upon such a variety of circumstances in the constitution, the injury, and the after treatment, that it must be difficult to determine.

"With regard to the treatment of concussion, it would appear, that in the first stage very little can be done; and perhaps, what little is done, had better be omitted, as the brain and nerves are probably insensible to any stimulants that can be employed. From a loose, and, I think, fallacious analogy between the insensibility in fainting, and that which occurs in concussion, the more powerful stimulants, such as wine, brandy, and volatile alkali, are commonly had recourse to, as soon as the patient can be got to swallow. The same reasoning which led to the employment of these remedies in the first stage, in order to recal sensibility, has given a kind of sanction to their repetition in the second, with a view to continue and increase it.

"But here the practice becomes more pernicious, and less defensible. The circumstance of the brain having so far recovered its powers, as to carry on the animal functions in a degree sufficient to maintain life, is surely a strong argument that it will continue to do so, without the aid of means which probably tend to exhaust parts already weakened by the violent action they induce.

"And it seems probable that these stimulating liquors will aggravate that inflammation which must sooner or later ensue. The access of it, in the cases which I have related, is sufficiently evident; and its cure is to be effected by the common methods. The great benefit of evacuations was, in those cases, very evident."

After some further remarks in opposition to the cordial plan of treatment, and the relation of a fatal case of simple concussion, in which that system would have been manifestly hurtful, Mr. Abernethy adverts to the very desirable object of pointing out the marks by which we may distinguish between compression and concussion of the brain; for these, he apprehends, may in general be distinguished.

"As far as my observation goes," says he, "the insensibility is much less in concussion, especially after a short time has elapsed. Patients in this case, though they seem reluctant to answer questions, yet complain much if their heads are moved; and in those instances where it was judged necessary to inspect the bone, I have generally found they made great complaint during the operation. The pupils also are usually more contracted than in compression of the brain, the muscles of the limbs retain their natural state of tone, and respiration is performed with little or no stertor, though the pulse generally intermits in a very considerable degree. In the slighter cases of concussion, the sickness of the patient is often very great.

"But, in cases of compression of the brain, circumstances very much the reverse of those just related take place; the sensibility is much diminished in proportion to the degree of the injury; from this cause also the pupils are dilated, and the limbs relaxed; the respiration is attended with stertor; and the pulse is subject to much less intermission."

COND, CON, or CONN, in *Sea Language*, signifies to guide or conduct a ship in her right course.

He that conds her, stands aloft with a compass before him, and gives the word of direction to the man at the helm how he is to steer. See **STEERING**.

If the ship go before the wind, or, as they call it, be-tween the sheets, the word is either *starboard*, or *port the helm*; according as the conder would have the helm put to the right or left side of the ship, upon which the ship always goes the contrary way.

If he says, *helm a mid/ship*, he would have the ship to go right before the wind, or directly between her two sheets.

If the ship sail by wind, or on a quarter wind, the word is, *aloof, keep your luff, fall not off, wear no more, keep her to, touch the wind, have a care of the lee-latch*: all which expressions are of the same import, and imply that the steersman should keep the ship near the wind.

On the contrary, if he would have her sail more large, or more before the wind, the word is, *ease the helm, no near, bear up*.

If he cries *steady*, it means, keep her from going in and out, or making yaws (as they call it), howsoever the sail, whether large or before a wind; and when he would have her go just as she does, he cries *keep her thus, thus, &c*

CONDA, or KOND, signifies fortrefs, and often occurs as a termination of words in the fourth part of India, in this sense, as *colta* and *cote*, which have the same signification, do in the north.

CONDABORA, in *Ancient Geography*, a town of Spain, placed by Ptolemy in Celtiberia.

CONDALIA, in *Botany*, Cavanilles, Icon. tab. 525. Clafs and order, *pentandria monogynia*. Nat. Ord. *rubrami*.

Gen. Ch. Cal. one-leafed, with five lanceolate divisions, permanent. Cor. none. Stam. five. Pijl. Germ superior, egg-shaped, surrounded by the glandular disk of the calyx; style one; stigma emarginate. Peric. Drupe egg-shaped; nut one-celled.

Sp. C. *parvifolia*. A shrub. Branches numerous, spinous. Leaves small, egg-shaped, acute, clustered in the axils of the spines. Flowers yellowish, very small, axillary. Ruiz and Pavon, in their Flora Peruvienfis, have given the same name to another genus, consisting of some herbaceous plants discovered by them in Peru. Clafs and order, *tetrandria monogynia*.

Gen. Ch. Cal. one leafed, four-toothed, permanent. Cor. monopetalous, funnel-shaped; tube inflated; border with four lanceolate divisions. Stam. four, very short. Pijl. Germ inferior; style bifid. Peric. Berry egg-shaped, crowned by the calyx, hollow, spongy, two-celled. Seeds several, attached to a pedicelled receptacle, adnate to the interior of the partition.

CONDALUS, in *Antiquity*, a kind of ring usually worn by slaves.

CONDAMINE, CHARLES-MARIE DE LA, in *Biography*, a celebrated traveller. was born at Paris in the year 1701. In early life he distinguished himself as a military man; but quitting the profession of arms for the purpose of indulging a laudable curiosity, and a thirst for natural science, he diligently surveyed all the countries bordering on the coasts of the Mediterranean, and travelled into various parts of Lesser Asia, Egypt, and Turkey. He was elected a member of the Academy of Sciences, and proposed a voyage to the equator, in order to measure a degree of the meridian. In 1736 he went, with other mathematicians, to Peru for this purpose, and exhibited the greatest assiduity and skill in accomplishing the work. On his return he descended the celebrated river of the Amazons; in this enterprize

he suffered many hardships, which were, however, more than requited by the instruction, which regions so remote, and so fruitful of the wonders of nature, afforded him. Here he compared the number of vibrations made by the same pendulum, which he had used at Paris, at Quito, and other places, and he found that for 100,000 vibrations at Paris, 68,770 were made by the same pendulum at the side of the Amazon, 68,740 at Quito, and 68,720 on Pinchincha. He published in the year 1745 an account of his travels, under the title of "Relation Abrégée d'un Voyage fait dans l'Intérieur de l'Amérique Méridionale;" and in 1751, a "Journal du Voyage fait par Ordre du Roi à l'Équateur, avec un Supplément, en deux Parties." Condamine, after a short residence at home, went to Italy, where he was honoured with the particular notice of the pope, who granted him a dispensation to marry his own niece. In 1762 he published some remarks on what he had seen in his tour through Italy. He then visited England, and, among other interesting objects, he became warmly attached to the new practice of inoculation for the small-pox. On his return he published in two volumes "Mémoires et Lettres sur l'Inoculation." About this period he was elected member of the French Academy of Belles Lettres; he likewise received the same honour from several foreign learned societies, as those of London, Petersburg, Berlin, and Bologna. He died in February 1774, in consequence of an operation for the hernia. "The acquisitions of M. de la Condamine," says one of his biographers, "were more extensive than profound; and he possessed rather an ardour for making researches on a variety of subjects, than patience completely to investigate any." *Nouv. Dict. Hist. Gen. Biog. See also the article BOUGUER.*

CONDANORE, in *Geography*, a town of Hindoostan, in the country of Golconda; 15 cosses E. of Adoni. N. lat. 15° 40'. E. long. 78°.

CONDAPILLY, a town of Hindoostan, and capital of a circar of the same name, near the bay of Bengal; 142 miles S.E. of Hydrabad. N. lat. 16° 40'. E. long. 80° 40'.

CONDAPILLY, a circar of Hindoostan, bounded on the N.E. by the circar of Ellore, on the S.E. by the bay of Bengal, on the S.W. by the river Kistnah, which divides it from Guntoor, and on the N.W. by the country of Golconda; about 60 miles long and 25 broad.

CONDATCHY, a bay of Ceylon in the East Indies, lying on the west side of the island, six miles southward from Arippo, and about 12 miles from Manaar. N. lat. 8° 45'. E. long. 80°. In this bay all the boats are collected for the pearl-fishery. The bay forms nearly a half-moon; the beach which surrounds it is an extensive sandy waste, with only a few miserable huts scattered along the shore between the bay and the woods which skirt the beach. Such is the appearance which this bay presents at most seasons of the year; but during the fishery the scene is entirely reversed. At that time the bay is crowded with small vessels, and the beach presents an astonishing multitude of people from every quarter of India. The principal bank for the fishery is opposite to Condatchy, and lies out at sea about 20 miles. See PEARL-Fishery.

CONDATE, in *Ancient Geography*, an appellation, probably of Celtic original, bearing relation to the idea of *Confluent*, and giving name to several towns, such as follow.

CONDATE, or REDONES, *Rennes*, a town of Armenia, the capital of the Redones, according to Ptolemy.—Also, *Montreau*, a town of Gaul, between Melodunum and Agedinnium, which afterwards bore the name of Monactiolum.—Also, *Combe*, a place of Gaul between Noviomagus

and Darocasses.—Also, *Cone*, a town of Gaul, between Nevirnum and Brivodurum.—Also, *Coignac*, a town of Gaul, between Medio anum Santonum and Velu na, according to the table of Peutinger.—Also, a place of the isle of Albion, between Manucium or Manchester and Deva or Chester in, Antonine's Itinerary; generally placed at Congleton; but Mr. Horsley hath made it very probable that it was somewhere near Northwich.

CONDAT-EN-FERRIERES, in *Geography*, a town of France, in the department of the Tarn; 10 miles N. of Murat.

CONDATOMAGUS, in *Ancient Geography*, a place of Gaul, marked in the Peutingerian table between Ségodunum and Luteva.

CONDAVIR, in *Geography*, a fortified place of Hindoostan, and a principal post in the circar of Guntoor; strongly situated on a mountain, eight cosses to the west of Guntoor, and ten from the bank of the Kistnah. Not far from Condavir is Colore, a diamond mine on the southern bank of the Kistnah. Condavir is distant S. E. from Hydrabad 131 miles; from Madras 276 miles; from Nagpouur, S. 385 miles; and N. E. from Seringapatam 414 miles.

CONDE, LEWIS I. *De Bourbon*, in *Biography*, was the son of Charles of Bourbon, duke of Vendome, and born in 1530. He distinguished himself when very young at the battle of St. Quintin, and behaved with great gallantry till the death of Henry II, when he became a leader of the Huguenots. He was accused of having been the principal contriver of the conspiracy of Amboise, but, in the presence of the king, he vindicated his honour with all the intrepidity natural to him, and offered to maintain his innocence in single combat against his accuser. He was set at liberty, but engaging in another plot, he was condemned by his judges to have his head struck off on a scaffold before the king's apartment. To the sudden death of the sovereign he was indebted for his freedom a second time; he now openly put himself at the head of the Huguenots, and was admitted, with Admiral Coligny, to share their full confidence. After many and very important instances of success, he was wounded and taken prisoner in the battle of Dreux in 1562. At the battle of Jarnac 1569, he encountered the enemy with his arm in a scarf, and as he marched to the attack, the horse of his brother-in-law reared and broke his leg; superior however to this painful accident, he thus addressed his followers: "Nobility of France, know, that the prince of Condé, with an arm in a scarf, and broken leg, fears not to give battle, since you attend him." The village of Jarnac has been rendered memorable by the courage and constancy with which the Huguenots disputed the day; but their leader Condé, exhausted with fatigue, was surrounded and taken prisoner. Those to whom he had yielded his sword, had placed him at the foot of a tree, when Montsieu, captain of the duke of Anjou's guards, shot him dead, in cold blood, in revenge of a private quarrel. This savage, and truly infamous deed has affixed an indelible stain on the character of the duke of Anjou who was supposed to have authorized it. The body of Condé, thrown upon an ass, was carried to the castle of Jarnac, and after being exposed to the view of the victorious army, was delivered to the duke of Longueville, his brother-in-law, who caused it to be interred with those of his ancestors at Vendome. In his person, the prince of Condé was ungraceful and diminutive, yet his wit and vivacity rendered him a great favourite with the ladies. His amours gave occasion to the conclusion that he engaged in the cause of the Huguenots more as a party-man, than as a religionist. This trait in his character was a foil to qual-

ties the most splendid, and to virtues the most heroic. Of high and determined courage, he was formed to shine in camps as well as courts, and though his income was narrow, he displayed a magnificence of temper worthy his birth and station. *Nouv. Hist. Dict. Hist. de France.*

CONDÉ, *Lewis II. de Bourbon*, was born at Paris, Sept. 7, 1621. He was styled Duke d'Enguien, and is known in history, under the appellation of the *great Condé*. He succeeded to the rank of prince by his father's death in 1646. In his infancy he was of an extremely delicate constitution, and was sent into the country for the sake of pure air. At a proper age the prince took upon himself the task of governor, and selected, as his assistant, in this important business, M. de la Bouffière, a private gentleman, upon whom he could depend for the most exact attention to the orders given him. Two jesuits were likewise assigned to him as preceptors, who, with some officers of high rank and eminent probity and discretion, formed the household of the young prince. With these attendants he went to Bourges, where he frequented the college of jesuits, and became distinguished in every branch of learning. His inclination was evidently turned towards the military art, and at the age of eighteen he made a campaign under Marshal de la Meillcraye, that laid the foundation of that renown by which he was afterwards distinguished as the greatest general of his age. In the year 1643, he was entrusted with the command of the army opposed to the Spaniards who had invaded France; by a signal victory which he at that time gained, he was looked upon as the guardian genius of his country. So much coolness did he display on this occasion, that on the night preceding the battle, after he had made all the proper dispositions, he slept so soundly that it was necessary to awaken him when it was time to begin the attack. He next formed the project of besieging Thionville, and proposed the scheme to the council of regency, who unwillingly consented to it. The duke, contrary to expectation, carried it into execution with so much skill that the town soon surrendered. After this he was engaged in many combats in Germany, in one of which he threw his general's staff into the enemies' trenches, and led on a regiment, sword in hand, to recover it. The victories of the duke d'Enguien, and his great and growing reputation rendered him an object of jealousy to Cardinal Mazarin, who did every thing in his power to thwart his ambitious projects. The treachery of the cardinal, and the artifices of the leaders of the country party, excited cabals and troubles, and the duke d'Enguien, who, by the death of his father, had succeeded to the title of the prince of Condé, was carested by both parties. He at length took part with the court, though he felt it was an ungrateful task, and he protected the miller without feeling for him the least esteem.

The royal family left Paris privately, and went to St. Germain, upon which the parliament sent deputies to learn from the queen the causes of her departure; but Mazarin dismissed them contemptuously and without an answer. Exasperated at this, the people made a common cause, and resolved to defend themselves against the power of the court. With about 8000 men, the prince of Condé formed a design of reducing above 500,000 entrenched behind walls. He had neither money nor magazines; nevertheless he triumphed over Paris, and this success added not a little to the glory he had already attained. During the siege he constantly defeated the troops of the malecontents; he prevailed on the army that marched to their assistance under Turenne, to abandon their general; he stopped the progress of the duke de Longueville, who had caused an insurrection in

Normandy, and got the start of the Spaniards who were advancing to give him battle. Peace was at length concluded, but Condé alone acquired glory by this war, and after the treaty was signed, the prince traversed the streets in his coach alone. All persons of any rank paid their compliments to him, and he received a vote of thanks from the parliament. The people, however, were uneasy at the king's absence, and Condé at length brought the royal family to Paris amidst the acclamations of the public: for this he was not recompensed in the manner which he had anticipated; he accordingly united with the malecontents, was arrested in 1650, and detained a year in prison. Soon after his liberation, he broke out into open revolt, and a civil war followed which was attended with various success. Condé exhibited great prowess, and sustained his military reputation through the whole of this unhappy warfare, though he was engaged in the service of the malecontents, the inveterate foes of his country, whom he had formerly obtained so much glory in resisting. At the peace of the Pyrenees in 1659, the re-establishment of the prince of Condé was made a condition. In 1668, he contributed very materially to the conquest of Franche-Comté. He took part in the invasion of Holland in the year 1672, and received a wound at the famous passage of the Rhine. He fought the bloody battle of Seneff against the prince of Orange, in which he had three horses killed under him, and was anxious to lead to a fourth attack, but as an officer observed, "No one but the prince of Condé was desirous of fighting any longer." After the death of his great rival Turenne in 1675, Condé was sent to check the progress of the imperial army, in Alsace, and displayed as much caution in this business, as he had before exhibited ardour and impetuosity. By his consummate prudence and judgment he forced the enemy to cross the Rhine, and then, full of glory, he resigned the military profession, and retired to Chantilly, where he spent the remainder of his days in cultivating and patronizing letters and the fine arts, to which he had been always attached. During the last two years of his life his faculties had so much declined, that scarcely a trait was left of the *great Condé*. He died in 1686 at Fontainebleau, leaving behind him two sons, by his wife, the niece of cardinal Richelieu. *Nouv. Dict. Hist. Heme.*

CONDÉ', in *Geography*, a small town of France, in the department of the Aisne, and chief place of a canton in the district of Chateau-Thierry, 9 miles S.E. from Chateau-Thierry. The place contains 508 and the canton 9613 inhabitants. The territory includes 235 kilometres and 27 communes. — Also, a fortified town of France, in the department of the North, on the confluence of the Haine and Scheldt, 9 miles N.E. from Valenciennes, known at present by the name of Nord Libre, which it took under the republican government of France. After a blockade of nearly four months, it surrendered to the Austrians on the 11th of July 1793, but was soon evacuated. It is the chief place of a canton in the district of Donay, and contains 5978 inhabitants. The territorial extent comprehends 87½ kilometres, with 10 communes, and 139,621 inhabitants. Before the revolution of 1789, Condé was a principality from which the princes of Condé derived their title. There are in France several other small towns of the name of Condé, which signifies confluence, from the Latin *condare, circumdare*, and means a place built on the spot where two rivers meet. See CONDÉ.

CONDÉ *sur Noireau*, a town of France, in the department of Calvados, on the river Noireau, or Noireux, chief place of a canton in the district of Vire, 24 miles S. from Caen, and 150 W. from Paris. The place contains 3030,

and the canton 10,681 inhabitants. The territory includes 122½ kilometres, and 12 communes. The inhabitants carry on a considerable trade in cloth, leather, and cutlery.

CONDE' sur Non, or *CONDE' l'Evêque*, a town of France, in the department of the Eure; 12 miles S.W. of Evreux.

CONDEAU, a town of France, in the department of the Orne, and district of Bellefme; 10 miles E. of Bellefme.

CONCEDDO, a cape or promontory of North America, in the province of Yucatan; 100 miles W. of Merida. N. lat. 26° 50'. W. long. 91° 27'.

CONDEMNATION, the act of passing, or pronouncing sentence, or giving judgment against a man; whereby he is subjected to some penalty or punishment; either in respect of fortune, reputation, or life.

CONDEMNATION to the galleys. See GALLEYS.

CONDEMNATION of prizes taken from the enemy. See PRIZE.

CONDENSATION (from *condensatus*, and *condensate* from the Latin *condensatus*), denotes the contraction of a given quantity of matter into a smaller space, and in this sense only the word condensation ought to be used; however, in common language, the inspissation, the thickening, or hardening of certain compound substances, in consequence of the escape of some of their component ingredients, is frequently expressed by the same term; thus the juices of fruit, of plants, of meats, &c. are often said to be condensed over the fire. Compression and condensation (though sometimes used the one for the other) differ in this; *viz.* that the former denotes a diminution of bulk, occasioned by the application of external force; whereas the latter expresses the same effect, when produced without that external application, as is the case with most bodies in cooling. But the word condensation has been more commonly used for denoting the conversion of vapour into water, or of vapours in general into liquids.

The particulars which might be noticed with respect to condensation are, the quantity and rate of contraction in different bodies, the causes which produce it, and the limits of that contraction. These particulars, however, will, with more propriety, be stated under the articles EXPANSION, THERMOMETER, and PYROMETER, which see.

Notwithstanding the above-mentioned definition, it is to be remarked, that in every case of condensation, or of the contraction of a body into a narrower space, the effect is produced by the escape of something; and in bodies, which seem to be the simplest in nature, the contraction which they undergo in cooling, is occasioned by the escape of the caloric, which the present state of philosophical knowledge reckons amongst the elementary substances. But the reverse of this proposition is not always true; *viz.* bodies are not always contracted in their dimensions when the caloric escapes from them; and such has been found to be the case with water, with iron, and with some other substances, in certain temperatures. This will be rendered more evident in the sequel.

Most bodies are susceptible of three successive states of existence; namely, the solid, the liquid, and the elastic or vaporous; and all these are effected by the introduction of different doses of caloric. During every one of those states, a different degree of condensation is produced by the intermediate gradations of temperature; *viz.* such as are not quite sufficient to induce a different state of existence in the body concerned. Thus, a quantity of the vapour of water, which, at the temperature of 212° (Fahrenheit's thermometer), and under the mean gravity of the atmosphere, occupies the space of 3600 cubic inches; if it be gradually cooled until the temperature becomes equal to about 212°,

its bulk will be contracted so as to occupy the half of the space it did before, *viz.* about 1800 cubic inches. If the temperature be lowered below 212°, the vapour will be condensed into liquid water, which will occupy the space of not more than a single cubic inch. If the cooling be continued, the water will be contracted in its bulk, but not very regularly (that is, the decrements of bulk will not be exactly proportional to the decrements of heat); until the temperature descends to about 42°. Below that degree, the water, instead of contracting its bulk, is expanded by further cooling; *viz.* by a further abstraction of caloric. This is a very remarkable property of water, upon which some interesting phenomena of nature are depending. The water, though expanding below the temperature of 42°, still continues fluid as far as about the temperature of 32°; but below this last mentioned point, by farther cooling it becomes a solid; namely, ice; and in this state water occupies a greater space than it did in a liquid state. (See CONGELATION.) Similar irregularities have been observed in the condensations of several other bodies, both solid and fluid; and it is to be wished that experiments capable of determining the laws of condensation were instituted with all those bodies which are at all susceptible of the trial.

The causes of condensation are by no means thoroughly understood. It may seem, at first sight, sufficient to say, that since caloric is an elementary substance, which is combined in various proportions with every other known body, the separation of part of that element from the other bodies, naturally enables the particles of the latter to come closer to one another in virtue of their mutual attraction. But that this cannot be the sole cause of the condensation in its whole extent, is easily pointed out by the following queries. 1st. How are the particles of bodies disjoined, that they may be capable of approaching, or of receding from each other? 2dly, Why the degrees, or quantities, of condensation are not always proportional to the degrees of caloric that are abstracted from bodies? And, 3dly, Why clouds, fogs, mists, &c. (which consist of the vapour of water suspended in the atmosphere) are not always condensed into liquid water below the temperature of 212°; which is actually the case in the atmosphere?

It has for a long time been an opinion prevalent amongst philosophers, that the particles of bodies do not actually touch one another; for otherwise it seemed impossible to comprehend how a body could be expanded and condensed. But the least consideration will easily suggest a variety of dispositions of the particles, which, whilst they actually touch one another, will readily admit of the dilatation and condensation of the aggregate. Conceive, for instance (as professor Prevost of Geneva justly observes), the particles to be elongated, and united at their extremities like the legs of a pair of compasses, and they may turn, with regard to this point of union, as a centre, and produce condensations and dilatations of the whole apparent mass of the body. A sponge likewise will dilate in water without interrupting the continuity of its parts. One may also conceive the particles of bodies arranged in the form of rings; that is, many of them to be in absolute contact, one with the next, and this with the following, &c., so as to form circular or oval rings. With this disposition of particles, the dilatation and condensation of the aggregate is nothing more than an alteration of the form of those rings; *viz.* they become more like circles when the body is expanded, and more oblong when the body is condensed; it having been demonstrated by mathematicians, that the circle comprehends an ampler space than any other figure of the same periphery. Though the general disposition of the particles of a body is not known, yet a variety

riety of phenomena clearly indicate that they are not confusedly placed; but that some arrangement, probably a peculiar one, for the particles of each different body, actually takes place; and to this peculiar arrangement some of the effects of dilatation and condensation, at least the irregularities of those alterations, must undoubtedly be attributed. Thus the particles of water crystallize in freezing; that is, they dispose themselves with a peculiar regularity, somewhat resembling the filaments of a feather. These filaments of water form angles of about 60 degrees with a larger filament, which is, as it were, the stem of the feather; and to this crystallization the enlargement of the bulk of water in freezing is with propriety attributed. Such is the force with which the particles of water endeavour to arrange themselves in that particular order, and of course to enlarge the bulk of the aggregate, that several astonishing effects are produced by their united efforts. Pieces of timber, stones, and other bodies, are burst by the freezing of inclosed water. Even iron mortar-shells, such as are used in war, filled with water, and accurately flopped, have been burst by the freezing, and the consequent enlargement of the inclosed water.

Since the enlargement of the bulk of water commences at about the temperature of 42°, which is 10 degrees above the point of melting ice, commonly called the *freezing point*, which is 32°, it is evident that the particles of water begin to arrange themselves in a particular order long before the freezing takes place. And, by following the analogy, it may be supposed, that in every state of existence the particles of bodies have, more or less, a tendency to arrange themselves in a certain order; to which tendency the irregularities in the condensations of bodies are probably to be attributed.

The above-mentioned particulars, respecting the condensation of water, must in great measure be understood to belong to a great variety of bodies; for all those which have been subjected to decisive experiments have been found to contract or to enlarge their bulk with irregularity, in some part at least, if not throughout, the whole scale of heat.

The condensation of vapour in the atmosphere, which is not always accompanied with a proportionate degree of temperature, forms another difficulty, which the present state of philosophical knowledge is not entirely capable of explaining. We shall, however, briefly state certain facts and certain considerations, which ought to be kept in view by those who are willing to investigate this intricate and interesting subject. The conversion of water into vapour is attended with an increase of its capacity for containing heat, or caloric, and likewise with an increase of its capacity for containing electric fluid; so that if a quantity of water, held in an open and insulated vessel, be suffered to evaporate, the vapour will deprive the vessel of part of its heat, and of part of its electric fluid: consequently, the vessel will be cooled and electrified negatively. Now that which philosophers wish to ascertain is, whether the influx of the caloric and of the electric fluid produces the evaporation, or the conversion of the water into vapour draws the caloric and the electric fluid from the contiguous bodies. In the first case, we see no reason why the caloric and the electric fluid should spontaneously quit the contiguous bodies, and run to the water in order to force it to evaporate, because both the water and the contiguous bodies are in an equilibrium; that is, in the same state with respect to temperature as well as of electricity. In the second case, if the influx of heat and of electricity does not force the water to evaporate, what other cause can produce that effect?

The same reasoning which has been applied to the conversion of water into vapour, may, *mutatis mutandis*, be

adapted to the contrary effect; *viz.* to the condensation of vapour into water, it being equally difficult to comprehend how the vapour can remain in the elastic state, that is, without being converted into water, at a temperature much lower than 212°, which in the atmosphere is generally the case. There is one consideration, however, which may throw some light upon this remarkable phenomenon; *viz.* that in order to deposit the caloric and the electric fluid, which must necessarily take place in the condensation of vapour, there must be a body or bodies ready to receive both. But in the atmosphere, the only body which can receive them is the air, and it is well known, that air is a bad conductor of heat as well as of electricity. The last remark which we have to subjoin is, that it has been observed with several substances, and especially with water, that though placed in a colder temperature, they do not part with their caloric so easily as it might be expected, and this is particularly the case when they are to undergo a change in their state of existence; thus water will sometimes continue fluid when its temperature is 4 or 5 or even more degrees below 32°; though when once formed into ice, this will not melt at a temperature lower than 32°, and yet it will evaporate if exposed to the air whilst its temperature is many degrees below 32°.

CONDENSER, from *condense*, is an instrument capable of collecting, or of drawing into a smaller space any scattered matter, or quality, or effect. In philosophy and in mechanics, three different instruments have obtained the name of condensers; *viz.* the *condenser of air*, the *condenser of electricity*, and the *condenser of forces*.

The *condenser of air*, in pneumatics, is a syringe, by means of which a considerable quantity of air may be forced into a vessel fitted for the purpose. Fig. 1 and 2, Plate XIV. *Pneumatics*, represent two constructions of this sort of condenser, which differ but little from each other. They are generally made of brass or of iron. A B, fig. 1, represents a cylindrical tube, at most, two inches in diameter, and from 8 to 12 inches in length, or even longer. Its flat bottom B is perforated with a hole, on the outside of which, a valve, (consisting of a piece of oil silk, or rather of leather, stretched over a small flat piece of brass), is adapted, so that if any air be forced from the inside of the cylinder A B, that fluid will easily lift up the valve, and make its exit through the hole at B. But should any suction take place within the cylinder A B, the air cannot possibly enter through the hole at B, because the valve on the outside prevents it by stopping that hole. The piston *cd* fits the cavity of the cylinder A B pretty tightly, by means of leathers soaked in oil; and it may be moved up or down by the handle E which is fastened to its rod. This piston is perforated with a hole *d*, the lower part of which is furnished with a valve *d*, which, when the piston is drawn upwards, will permit the air to enter the lower cavity of the cylinder; but if the piston be pushed downwards, the air which is contained in the lower cavity of the cylinder, cannot pass through the hole *cd*, on account of the valve at *d*; therefore it will come out through the hole at B. At the extremity of the cylinder, a brass or iron cap F G is screwed over the valve, allowing however a little room for its free motion. The end G of this cap is perforated quite through, and its outside is formed into a screw.

Fig. 2 represents a condensing instrument simpler than the preceding, and such indeed is at present mostly used. Neither the cylinder nor the piston of this instrument is furnished with any valve. There is a hole through the screw at the bottom B of the cylinder, and a hole at C through its side, and at about two or three inches below its upper end; the piston has no perforation.

When

When the condenser, *fig. 1*, is screwed into the aperture of a glass or metal vessel, and the piston is moved alternately up and down, it will be readily understood, that the air will be forced into the vessel to which the condenser is adapted; for when the piston is pulled upwards, that is, towards *A*, the air cannot enter the cylinder through the hole at *B*, but it can easily pass through the hole *cd*; and when the piston is pushed in, the air which is contained in the cavity of the cylinder, cannot go out of it through the hole *cd*, but it can pass through the hole at *B*; hence it is forced to enter the vessel to which the condenser is applied. Thus by repeating the movements of the piston, more and more air is condensed into the vessel, until the latter is burst by the elasticity of the condensed air, or the same force pushes so hard against the valve at *B*, that the strength of the operator is no longer able to overcome it. The condenser, *fig. 2*, is used exactly in the same manner; this, however, must be adapted to such vessels as are furnished with a valve within their aperture, which permits the entrance, but not the exit of the air. When the piston of this condenser is drawn towards *C*, a vacuum is formed in the lower part of the cylinder, until the lower part of the piston is raised above the hole *C*; then the air rushes through that hole, and instantly fills the cavity, &c.

These instruments are generally used for condensing the air into the air-holders of wind-guns, of certain water fountains, and other machines. By this means, the air has sometimes been condensed to such a degree, as to become six, eight, and even more times, denser than common atmospheric air. The vessel, in that case, is said to contain respectively six, or eight, or a greater number of atmospheres.

In a variety of philosophical experiments, substances are frequently placed in a glass vessel in which air is condensed, in order to observe its effects upon the enclosed substances. For this purpose, one of the above-mentioned condensers is affixed to a frame and apparatus, as is represented in *fig. 3*; and this apparatus, all together, is called a *condensing engine*.

CD is a brass condenser, which is worked by applying the hand to the handle *Z* of the piston, and by moving the latter alternately up and down, the air is forced through the brass pipe *DNF* into the glass receiver *AB*. This receiver, which must be very thick and well annealed, is set with its smooth and flat edge upon the brass plate of the machine, which is similar to the plate of an air-pump. A thick piece of brass *LM*, is applied in a similar manner to the upper aperture of the glass receiver, and a slip-wire passes through a collar of leathers in this brass piece. In order to prevent the lifting up of the brass piece *LM* from over the glass vessel, or the latter from the plate on the frame of the machine by the force of the condensed air, two pillars of wood with a cross piece *GH*, likewise of wood, are annexed, for the purpose of keeping down the glass vessel, and the piece of brass *LM*. The cross piece *GH* is pressed upon *LM* by means of the screw-nuts on the pillars *I, K*. There is a gage *E, F*, annexed to this machine, which indicates the condensation of the air within the glass vessel, and tube of communication. It consists of a strong and narrow glass tube, hermetically closed at *E*, and connected with the brass tube of communication at *F*. A small quantity of mercury fills up a short part of the cavity about the middle of the tube, and the space between the mercury and the closed end *E* of the tube, contains air of the usual atmospheric density. It is by the contraction of this small quantity of air, that the degree of condensation in the glass receiver is indicated; for in proportion as the air is condensed into the receiver, or tube of communication, &c., so the air between

the mercury and the closed end of the gage becomes contracted more and more; and the quantity of that contraction is indicated by a scale annexed to the glass tube; for instance, if that air is, by working the machine, compressed into the half of the space it occupied at first, it shews that the air within the receiver is as dense again as it was before the working of the machine. If the air in the gage is compressed into a quarter of its original space, the air within the receiver is shewn to be four times as dense as it was before the working of the machine, and so forth; the condensations in the glass receiver being inversely as the spaces occupied by the air in the extremity *E* of the gage. These degrees of condensation are commonly expressed by saying, that the receiver contains two, or three, or four, or more atmospheres, when the air within it, is twice, or three times, or four times, or more times, denser than the usual air of the atmosphere.

There are certain air-pumps, as those of Smeaton, of Haas and others, the construction of which renders them capable of being used for condensing, as well as for exhausting the air. See *AIR-PUMP*. In certain forcing water pumps, in fire engines, and some other hydraulic machines, there is a vessel, in which the air is condensed by the action of the machine itself; the object of which is to produce a constant stream of water out of the engine, whilst the piston of it is moved up and down in the usual way. This vessel is called the *air vessel*, and often the *condensing-vessel*, or simply the *condenser*. See *PUMP*, and *FIRE-ENGINE*.

The head of an alembic, wherein the vapours are condensed into a liquid, has sometimes been called the *condenser* of the alembic.

CONDENSER of Electricity. This is an instrument capable of collecting, or of condensing into a small space, such quantities of weak and diffused electricity, as would otherwise remain unperceived, or be insufficient to affect even the most sensible electrometer. It was originally invented by a very distinguished philosopher, Mr. Volta of Como, and is by himself described in the 72d vol. of the *Philosophical Transactions*. But, since its original invention, this instrument has undergone several improvements and alterations, which we shall now describe, together with their peculiar advantages and defects.

The action of electric atmospheres is the principle which suggested the construction of this most useful electrical instrument. Though the nature of these atmospheres will be treated of in the article *ELECTRICITY*; it will, nevertheless, be necessary to give, in this place, some idea of their action, by means of an easy experiment, in order to render the principle upon which the electrical condenser acts, manifest to the reader. Affix an electrometer of pith-balls to an insulated metallic plate; that is, a plate of tin or brass, or other metal, having a glass handle. Communicate some electricity to it, and observe the divergence of the electrometer. In this state, bring the electrified plate near a conductor which is not insulated, such as the wall of a room or another metallic plate, and you will find that the electrometer collapses in proportion as the electrified plate comes near to the uninsulated conductor. Remove the electrified plate, and the electrometer will diverge again, nearly as much as it did at first; which shews, that by the vicinity of the uninsulated conducting body, which could easily acquire the contrary electricity, the intensity of the electricity in the electrified plate was diminished; or, which is the same thing, that the capacity of that plate for containing electricity was increased. Hence, when an insulated metallic plate is situated near another metallic plate not insulated,

CONDENSER.

the former will thereby be enabled to absorb a much greater quantity of electricity than it otherwise would, from any source whatever; and if the electrified plate be removed from the other, then that absorbed electricity will be manifested by the divergency of the electrometer, or even by affording a spark. It naturally follows, that according as the conductor which is opposed to the insulated plate, is nearer to, or farther off, so the capacity of the plate will be increased more or less. Such an insulated plate, placed upon an imperfectly insulating, or an imperfectly conducting plane, for the purpose of collecting weak and scattered electricity, was called a *condenser* by Mr. Volta. The reason of using an imperfectly conducting, or imperfectly insulating plane, is, that when the insulated condensing plate is placed upon it, the electricity will not pass from the latter to the former. In short, the following particulars should be attended to in the construction of this, Mr. Volta's, condenser. The metal plate should be about six inches in diameter, with the edge well rounded, and furnished with a varnished glass handle. The inferior plane must be of a very imperfectly conducting nature, such as dry marble, very dry and slightly varnished wood, a common piece of wood covered with oiled silk, or such like substance; but be its substance what it may, its surface must be very smooth, and such as to coincide as well as possible with the surface of the metal plate, *viz.* the receiving plate; on which account, if a marble slab be chosen for the inferior plane, it will be proper to fit the surface of the metal-receiving plate to that of the marble, by grinding one against the other.

The apparatus, consisting of the above described two planes, being properly constructed, lay the receiving plate upon the other plane, connect the former with an atmospheric conductor, not much elevated above a house, or with the vapour of boiling water, or, in short, with any weak source of electricity, such as could not be discovered by any other means, and after a certain time lift the receiving plate from over the other plane, holding it by the glass handle, and present it to an electrometer, which will be caused to diverge sufficiently to ascertain the presence and the quality of the electricity. Sometimes the receiving plate will even be able to afford a spark. Yet, in several cases, the receiving plate is electrified so slightly, as not to occasion the divergency of the most delicate electrometer. A contrivance of Mr. Cavallo, which is described in his *Treatise on Electricity*, (fourth edition, vol. ii. p. 265) rendered this weak state of electricity capable of affecting the electrometer in a very sensible degree. His description of this contrivance is as follows:

"I naturally thought that, for the same reason which enabled the condensing plate of Mr. Volta's apparatus, to manifest such small degrees of electricity as could not otherwise be observed, another smaller plate, or small condensing apparatus, might be employed to collect and to render sensible the weak electricity of the large metal plate. Accordingly, I constructed a small plate of about the size of a shilling, having a glass handle covered with sealing-wax; and when the large metal plate seemed to be electrified so weakly as not to affect an electrometer sensibly, I placed the small plate upon the inferior plane, and touched it with the edge of the large plate; then, after removing the large plate, I took up the small one from the plane, holding it by the extremity of the glass handle, and presented it to the electrometer, which generally was so much affected by it as to diverge to its utmost limits.

"In this manner I have often obtained electricity, more than sufficient to ascertain its quality, from a single stroke of the corner of an handkerchief; *viz.* the large plate being laid

upon the proper plane, was stroked once with the handkerchief; then, being removed and presented to an electrometer, it appeared not electrified; but by touching the small plate with the edge of it, that small plate acquired thereby electricity sufficient to make an electrometer diverge."

With this condensing apparatus Mr. Volta, and other philosophers, made several discoveries; yet the use of it was not always attended with the desired effect, which was principally owing to the changeable nature of the semiconducting plane, upon which the receiving plate was placed; it being difficult to obtain, and much more difficult to preserve, such plane in a middling or semiconducting state; for sometimes it would carry off the electricity from the superimposed receiving plate, and at other times it was not of a conducting nature sufficient to enable the upper plate to condense the electricity. It, likewise, often happened that this plane would acquire some electricity either in consequence of the slightest friction, or by communication, which rendered the action of the upper plate quite equivocal. With a view to remove these inconveniences Mr. Cavallo contrived an instrument capable of answering the same purpose, but quite free from all the above-mentioned objections. The principle of this instrument is like that of Mr. Volta's condenser; excepting that the receiving plate does not touch the other plane, though it comes very near it, and it likewise opposes another plane to the other side of the receiving plate. Those planes are of metal, and by their not touching the receiving plate, enable the latter to act with certainty and without obstruction. Upon this principle, *viz.* of the two plates not actually touching, but approaching one another very nearly, the present electrical condensers are constructed, however they may have been varied in size, in name, and in shape. By the aid of these condensers various important discoveries have been made in electricity, and especially in that branch of it, which is called galvanism. The original description of this instrument of Mr. Cavallo, is in the 78th. vol. of the Philosophical Transactions, for the year 1783, from which we make the following extracts.

"The properties of this machine, which from its office may be called a *collector of electricity*, are first, that when connected with the atmosphere, the rain, or in short with any body which produces electricity slowly, or which contains that power in a very rarefied manner, it collects the electricity, and afterwards renders both the presence and quality of it manifest by communicating it to an electrometer. Secondly, this collecting power, by increasing the size of the instrument and especially by using a second or smaller instrument of the like sort to collect the electricity from the former, may be augmented to any degree. Thirdly, it is constructed, managed, and preserved with ease and certainty; and it never gives, nor can it give, an equivocal result, as I have proved experimentally, and as will appear by considering its construction."

"The figures 4 and 5, *Plate II. Electricity*, exhibit this instrument, *viz.* *fig.* 4 shows the instrument in the state of collecting the electricity, and *fig.* 5 shows it in the state in which the collected electricity is to be rendered manifest. An electrometer is annexed. The letters of reference indicate the same parts in both figures. A B C D is a flat tin plate, thirteen inches long and eight inches broad; to the two shorter sides of which are soldered two tin tubes, A D and B C, which are open at both ends. D E and E F, are two glass sticks covered with sealing wax by means of heat, and not by dissolving the sealing wax in spirits. They are cemented to
the.

the lower apertures of the tin tubes, and also in the wooden bottom of the frame or machine, at E and F, so that the tin plate, ABCD, is supported by those glass sticks in a vertical position, and is exceedingly well insulated. GHIKLM and NOPV, are two frames of wood, which being fastened to the bottom boards, by means of brass hinges, may be placed so as to stand in an upright position and parallel to the tin plate, as shewn in *fig. 4*. or they may be opened, and laid upon the table which supports the instrument, as shewn in *fig. 5*. The inward surfaces of those frames from their middle upwards are covered with gilt paper, X, Y; but it would be better to cover them with tin plates, hammered very flat. When the lateral frames stand straight up, they do not touch the tin plate; but they stand at about one-fifth part of an inch asunder. They are also a little shorter than the tin plate, in order that they may not touch the tin tubes, AD, BC. In the middle of the upper part of each lateral frame is a small flat piece of wood, S and T, with a brass hook; the use of which is to hold up the frames without the danger of their falling down when not required, and at the same time it prevents their coming nearer to the tin plate than the proper limits. It is evident that when the instrument stands as shewn in *fig. 4*, the gilt surface of the paper, X, Y, which covers the inside of the lateral frames stands contiguous and parallel to the tin plate."

"When the instrument is to be used, it must be placed upon a window, a table, or other convenient support, a bottle electrometer is placed near it, and is connected, by means of a wire, with one of the tin tubes, AD, BC; and by another conducting communication the tin plate must be connected with the electrified substance, the electricity of which is required to be collected on the plate, ABCD: thus, for instance, if it be required to collect the electricity of the rain, or of the air, the instrument being placed near a window, a long wire must be put with one extremity into the aperture, A or B, of one of the tin tubes, and with the other extremity projecting out of the window. If it be required to collect the electricity produced by evaporation, a small tin pan, having a wire or foot of about six inches in length, must be put upon one of the tin tubes; so that the pan may stand about two or three inches above the instrument. A lighted coal is then put into the pan, and a few drops of water poured upon it, will produce the desired effect."

"The quantity of electricity, which the tin plate, ABCD, is capable of collecting, principally depends on three circumstances, *viz.* 1st. On the distance between the tin-plate and the conducting lateral surfaces: the smaller that distance is, the greater being the collecting power; 2^{dly}. On the size of the instrument; and 3^{dly}. On the quantity of electricity possessed by the body from which it must be collected or taken away."

"I need not expatiate on the principle upon which the action of this instrument depends; this being the same as that of the electrophorus of Mr. Volta's condenser, and of many other electrical experiments; namely, that a body has a much greater capacity for holding electricity, when its surface is contiguous to a conductor which can easily acquire the contrary electricity, than when it stands not in that situation."

Though this original condenser, which, by way of distinction, its inventor called a collector, answers the purpose for which it was intended perfectly well; yet for the common run of experiments, its size may be dispensed with, as it takes up too much room on the table of an electrician. On this account, not only the size of the instrument has

been reduced, but its shape also has been varied according to the fancy of almost every philosophical instrument maker. For the sake of simplification in the condensers which are at present in general use, one conducting plane only is opposed to the receiving plate, which answers the purpose sufficiently well; for if the electricity collected by the receiving plate happens to be too weak to affect the electrometer, a smaller condenser may be used, which will condense the electricity of the former, &c.

The forms of the condensers that are mostly used at present, are represented in *figs 6, 7, 8, and 9*. *Fig. 6* exhibits a vertical section of the condenser constructed by Mr. John Read of Knights-bridge; *aa* is a circular flat plate of brass, about eight inches in diameter, standing insulated, by means of the glass stick *f*, on the wooden foot *g*; *gb* is a hollow brass cylinder, terminating in the hollow brass cone *ecdb*; and to this cone the flat perforated brass plate *bccb* is affixed. The glass stick *f*, which, by means of a brass ferril, is fastened to the plate *aa*, has its lower extremity cemented in a cylindrical piece of wood, and this piece of wood is fixed in the bottom *g*. Now it will be easily perceived, by inspecting the figure, that the hollow cylinder *bg* may be moved up or down by sliding it upon the cylindrical piece of wood; and that, by so doing, the plate *bccb* may be brought near to, or removed from the plate *aa*, which is the receiving plate of this condenser; *i* is a milled-head screw, which serves to fix the plate *bb* at a proper distance from *aa*, where a stop is made for that purpose; when *i* is loosened, the plate *bb*, with *cbg*, which is all one piece, falls in the situation represented in the figure, and in that state an electrometer is put in contact with the plate *aa*, in order to manifest the electricity which *aa* condensed whilst *bccb* stood near it.

Fig. 7 represents a condenser of another form, as made by Mr. Cuthbertson. This sort of condenser is both simple in its construction, and commodious in practice; *ab* is a brass plate of about 8 inches in diameter (the instrument being shewn in profile), which is screwed tight into the wooden head *c*, which is cemented on the glass stick *d*, and this is cemented with its lower extremity into the wooden stand *ee* of the instrument; *fi* is a similar plate of brass, fastened to the brass head and pillar *gi*, the lower part of which turns round a pin at *h*, so that it may either stand upright, or it may be inclined after the manner of the dotted representation *hm*. It is almost superfluous to add, that *ab* is the receiving plate of this condenser. *Fig. 8* shews a front view of a condenser of this sort, placed close to a gold leaf electrometer, furnished with a smaller condenser, *viz.* such as is represented by itself in *fig. 9*. The small condenser, *fig. 9*, is similar to the one represented in *fig. 7*; saving that in *fig. 9* the receiving plate is affixed to the cap of a gold-leaf electrometer; so that this apparatus, *viz.* *fig. 9*, may be used by itself in most experiments; but in certain cases it will be necessary to employ the condenser *fig. 7* first, and afterwards the electricity may be farther condensed by means of the apparatus *fig. 9*, as shewn in *fig. 8*.

There is an instrument contrived by Mr. Wilson, which he calls "a compound electrical instrument for condensing and doubling." But as the construction, as well as the principal use, of that instrument properly belongs to another class of electrical instruments, its description will be found in another part of this work. See DOUBLER, and MULTIPLIER of electricity.

CONDENSER of forces. This name was given by Mr. R. Prony to a contrivance for obtaining the greatest possible effect from a first mover, the energy of which is subject to augmentation

augmentation or diminution within certain limits; and in general to vary at pleasure the resistance to which the effort of the first mover forms an equilibrium in any machine whatever, without changing any part of their construction. (Bulletin of the Philomathic Society at Paris, No. 83.)

The general problem in mechanics, of which this condenser is intended as a practical solution, is enunciated by Mr. PROY in the following terms:

"Any machine being constructed, to find, without making any change in the construction, a means of transmitting to it the action of the first mover, by fulfilling the following conditions; viz."

"1. That it may be possible at pleasure, and with great speed and facility, to vary the resistance (against which the effort of the first mover must continually make an equilibrium) in limits of any required extent."

"2. That the resistance, being once regulated, shall be rigorously constant until the moment when it is thought proper to increase or diminish the same."

"3. That in the most sudden variations of which the effort of the first mover may be capable, the variation in velocity of the machine shall never undergo a solution of continuity."

Mr. PROY applies this solution of this problem to the dynamic effect of wind; but it will be easy to make the same general, when other first movers are used. *Fig. 10 (Plate XVI. Mechanics)* represents the plan, and *fig. 11* the elevation of the machine. *OO* is the vertical arbor to which windmill-fails are adapted; *eeee* is an assemblage of carpentry, of which one of the radii, *Oe*, bears a curved piece, *bd*, of iron or steel: vertical axes of rotation *aaa*, being placed round the axis *OO*; they also divide the circumference in which they are found, into equal parts. Each of these axes carries a curve *af*, of iron, steel, or copper; so situated, that when the wind acts upon the fails, the curve *bd* presses against one of the curves *af*, and causes the vertical axis to which this last curve is affixed, to make a portion of a revolution. The curves *bd*, and *af*, must be so disposed, that when *bd* ceases to press on one of the curves *af*, it shall at the same instant begin to act upon the following curve: the number of axes which are provided with these curves, must be determined by the particular circumstances of each case, and it is also practicable to substitute, instead of *bd*, a portion of a toothed wheel having its centre in the axis *OO*, and to place portions of pinions instead of the curves *af*; but the dispositions represented in the figure are preferable. Each of the axes *aaaa* (which are all fitted up alike, though, for the sake of clearness, only one of them has its apparatus represented in the drawing), carries upon it a drum or pulley, *tttr*, on which is wound a cord that passes over a pulley *p*, and serves to support a weight *Q*, by means of the lever *FG*, upon which this weight may be slid and fastened at different distances from the point of motion *G*. The same axes, *a, a*, pass through the pinions *q, q*, to which they are not fixed; but these pinions carry clicks or ratchets, which bear against *rr*; so that when the weight *Q* tends to rise, the ratchet gives way, and no other effect is produced on the pinion *qq*, either by the motion of the axis or of the drum *tttr*, excepting that which causes the ascent of the weight *qq*. But the instant that the curve, or tooth *bd*, ceases to bear against one of the curves *af*, after having caused the corresponding weight *Q* to rise, that weight *Q* tends to re-descend, and then the toothed wheel *rr* acts against the ratchet, so that *Q* cannot descend without turning the pinion *qq* along with the drum *tttr*. The pinion *qq* takes in the wheel *ab*, from

the motion of which the useful effect of the machine immediately results; so that the effect of the descent of one of the weights *Q* is to solicit the wheel *AB* to motion, or to continue the motion in concurrence with all the other weights *Q*, which descend at the same time. This wheel, *A B*, carries beneath it oblique or bevelled teeth, *G D*, which take in a like wheel, *C E*, and cause the buckets at *S* to rise.

From the preceding description, it is seen that the machine being supplied to start from a state of repose, the wind will at first raise a number of weights, *Q*, sufficient to put the machine into motion, and will continue to raise new weights, whilst those before raised are fallen, so that the motion once impelled will be continued.

Among the numerous advantages of this new mechanism, the following may be remarked:

1. No violent shock can take place in any part of the mechanism. 2. The useful effect being proportioned to the number of weights *Q*, which descend at the same time, this effect will increase in proportion as the wind becomes stronger, and causes the sails to turn with greater velocity. 3. The weights, *Q*, being moveable along the levers *FG*, it will always be very easy to place them in such a manner as to obtain that ratio of the effort of the first mover to the resistance, which will produce the maximum of effect. 4. From this property it results, that advantage may be taken of the weakest breezes of wind, and to obtain a certain product in circumstances under which all other windmills are in a state of absolute inactivity. This advantage is of great importance, particularly with regard to agriculture: the windmills employed for watering lands, are sometimes inactive for several days, and this inconvenience is more particularly felt in times of drought. A machine capable of moving with the slightest breeze, must, therefore, offer the most valuable advantages.

CONDENSING OF WINES. See WINES.

CONDEON, in *Geography*, a town of France, in the department of the Charente; 25 miles S.E. of Saintes.

CONDER, a river of England, in the county of Lancaster, which runs into the Irish sea; 3 miles S. of Lancaster.

CONDERCUM, in *Ancient Geography*, a station of Britain on the line of Severus's wall at Benwell-hill, where the prefect of the first wing of the Alti was placed. Not. Imp.

CONDERS, from the Fr. *Conduire*, to conduct, persons who were employed in the fishery to give notice where shoals of herrings were passing; otherwise called *Balkers*; which see.

CONDESCENSION, in *Ethics*, denotes that species of benevolence, which designedly disregards the supposed advantages of birth, title, or station, in order to accommodate itself to the state of an inferior, and diminish the restraint which the apparent distance is calculated to produce. Accordingly, it greatly enhances the value of every other species of benevolence.

CONDESUYOS DE AREQUIPA, in *Geography*, a jurisdiction of South America, under the bishop of Arequipa, 30 leagues distant from that city; which extends about 30 leagues, with different temperatures of the air, and consequently produces grains and fruits. In this jurisdiction is bred the wild cochineal, with which the Indians carry on a kind of trade with the provinces in which the woollen manufactures flourish. They first pulverize the cochineal by grinding it, and after mixing four ounces of it with twelve of violet maize, they form it into square cakes called

"mango," each weighing four cunes, and sell it for a dollar per pound. This country abounds in gold and silver mines, which have of late been much neglected.

CONDETTA, a town of France, in the department of the fruits of Calais, and district of Boulogne; $1\frac{1}{2}$ league S. of Boulogne.

CONDICA, in *Ancient Geography*, a town of Asia Minor, in Lycia, and in the country called Mylas, according to Ptolemy.

CONDIGNITY, MERIT OF, in *Theology*. See MERIT.

CONDIGRAMMA, in *Ancient Geography*, a small town of Asia, on this side the mouth of the Indus, upon the coast of Gedrosia, according to Pliny.

CONDILLAC, STEPHEN BONNET DE, in *Biography*, a French metaphysician, member of the Academy, and preceptor to the infant Don Ferdinand, prince of Parma, an honour to which he arrived from the high reputation that he had gained from his writings. The work by which he was first known was an "Essay on the Origin of Human Knowledge," in 2 vols. published in 1745; in which he endeavours to develop the faculties of the mind, by giving a sort of historical account of its several functions. In 1754, he gave to the world a "Treatise on Sensations," in 2 vols. 12mo.: here he considers what would be the conceptions of a statue, provided at first with a single sense, and successively with the others; and hence he undertakes to account for the origin of memory, judgment, and the mental affections, and the gradual formation and correction of sensible ideas. In the course of the following year he published a "Treatise on Animals;" in which he refutes the notions of Descartes and Buffon concerning the merely mechanical nature of brutes, and shews in what manner their faculties are acquired. In 1776 his great work, entitled, "A Course of Study drawn up for the Instruction of the Prince of Parma," was published in 16 vols. 12mo. As an introduction to these volumes, we have a discourse on the different modes of communicating instruction; giving a decided preference to the gradual advance from particular facts up to general principles, instead of the contrary method. Metaphysical lectures, logic, and the philosophy of the human mind, are among the earlier parts of this course of study; and from these, as preliminary steps, he proceeds to the study of history, of which he has given an ample and well-arranged abridgment, in eleven volumes. As an appendix, is added a volume consisting chiefly of political reflections. This ingenious writer published also a small work, entitled, "Commerce and Government considered relatively to each other." In all his works he exhibits an extensive knowledge, a mind well imbued with the principles of humanity, and with the most liberal notions of government. He died in the year 1780, highly respected by his countrymen, and characterized for the soundness of his judgment, for the clearness of his ideas on every subject which he undertook to discuss, and for his general knowledge in almost every department of literature. Nouv. Dict. Hist.

CONDITION, in the *Civil Law*, an article of a treaty, or contract; or a clause, charge, or obligation, stipulated in a contract, or added in a donation, legacy, testament, &c.

The donee does not lose his donative, if it be charged with any dishonest or impossible conditions. Lawyers distinguish three kinds of conditions, under which a legacy or donation may be made: these are the *casual*, which depends merely on chance; the *potestative*, which is absolutely in our power; and the *mixed condition*, which is both casual and potestative together.

CONDITION, in *Common Law*, is a manner, quality, or restriction, annexed to an act; qualifying or suspending the same; and making it precarious and uncertain, whether or not it shall take effect.

Accordingly, it is defined to be what is referred to an uncertain chance, which may or may not happen. Or, condition is a modus, or quality, annexed by him that hath estate, interest, or right to the land, &c. whereby an estate, &c. may be either created, defeated, or enlarged upon an uncertain event; and it differs from a *limitation* (which see), which marks the bounds or compass of an estate, or the time how long the estate shall continue.

A condition is also considered as one of the terms upon which a grant may be made; and in this sense a *condition in a deed* is a clause of contingency, on the happening of which the estate granted may be defeated; as "provided always, that if the mortgager shall pay the mortgagee 500*l.* upon such a day, the whole estate granted shall determine;" and the like.

Of conditions there are various kinds; *viz.* conditions in deed or express, and in law or implied; conditions precedent and subsequent; conditions inherent, and collateral, &c.

CONDITION *in deed, or express*, is annexed by express words to the feoffment, lease, or grant, either in writing, or without. As, if a man make a lease of lands to another, reserving a rent to be paid at such a feast; *upon condition*, if the lessee fail in payment, it shall be lawful for the lessor to re-enter.

CONDITION *implied*, called also *condition in law*, is when a man grants to another the office of a steward, bailiff, keeper of a park, &c. for life: though there be no condition expressed in the grant, yet the law makes one covertly; which is, that if the grantee do not justly execute all things belonging to the office, it shall be lawful for the grantor to discharge him.

CONDITION *precedent*, is when a lease or estate is granted to a person for life, upon condition of the payment of a certain sum by the lessee to the lessor at a certain day, when he shall have fee-simple: in this case the condition precedes the estate in fee, and on performance gains the fee simple.

CONDITION *subsequent*, is when a man grants to another his manor in fee, upon condition that the grantee shall pay to him a certain sum on such a day, or that his estate shall cease: so that here the condition follows the estate, and the performance preserves it. From these definitions it appears, that a *condition precedent* gets or gains the thing or estate made upon condition by the performance of it; and that a *condition subsequent* keeps and continues the estate by the performance of the condition. If one agree with another to do such an act, and for the doing of it the other shall pay so much money; here the doing of the act is a *condition precedent* to the payment of the money, and the party shall not be compelled to pay till the act is done; but when a day is appointed for the payment of money, which day happens before the thing contracted for can be performed, there the money may be recovered before the thing is done; for here it appears, that the party did not intend to make the performance of the thing a *condition precedent*. For a further account of these conditions, see the article *ESTATE upon condition*. There are other conditions, besides those already mentioned: such are conditions *inherent*, being such as descend to the heir with the land granted; and *collateral condition*, being that which is annexed to any collateral act. Conditions are likewise *affirmative*, which consist of doing; *negative*, which consist of not doing:

some are said to be *restrictive*, for not doing a thing, and some *compulsory*, as that the lessee shall pay the rent, &c. Some conditions are *single*, to do one thing only; some *copulative*, to do divers things; and others *disjunctive*, where one thing of several is required to be done. Co. Litt. 201.

CONDITIONS in *restraint of Marriage*, have not been generally favoured, as contrary to sound policy; but where a legacy hath been given over to another, the condition has been held valid; and it seems, that such conditions as only reasonably restrain children from imprudent marriage will be always supported;—that is, when they operate only as particular, not as universal restrictions. Where a legacy is given on consideration that the legatee should not marry without consent, and there is no devise over, the condition is void. 4 Burr. 2055. Com. Rep. 739. The rule of the ecclesiastical law is, that where a portion is given in consideration that the daughter should never marry, the condition is void. As the intent of the testator chiefly governs in wills, such construction is always made of the words, as will best support his intent; and therefore these words *ad faciendum, faciendum, ea intentione, ad effectum*, &c. in a will create a condition. Co. Litt. 204. a. A grant to one to the intent he shall do so and so, is no condition, but a trust and confidence. Some words in a lease do not make a condition but a covenant, upon which the lessor may bring his action. A covenant not to grant, sell, &c. may be a condition; and covenant, that, paying the rent, the lessor shall enjoy the land, is conditional. 2 Danv. 2. 6. Where words are indefinite, and proper to defeat an estate, they shall be taken to have the force of a condition. Palm. 503. For the performance of conditions and relief against the breach of them, see Jacob's Dict. by Tomlins, art. CONDITION.

CONDITION of a *Bond*. See BOND.

CONDITION *without which, sine qua non*, is used in *Philosophy*, in speaking of some accident or circumstance, which is not essential to the thing, but is yet necessary to its production. Thus, light is a condition without which a man cannot see objects, though he have good eyes; and thus fire, though considered in itself, may burn without wood; yet is its presence a condition without which the wood cannot be burnt.

CONDITION, *applied to Horses*, is used to signify that a horse is well fed and of good appearance; it also has another signification, that of his being brought by suitable treatment into a state of body, that gives him the fullest use of all his faculties in performing any very difficult or arduous exertion or exercise, as for hunting, racing, trotting, or the arts of the manege.

A horse that is moderately fat may be said to be in good condition, and so he is for sale, or for slow heavy draught-service; but such a one would be totally out of condition for any of the above exercises. To condition a horse for these a proper share of clean nourishing food and exercise is necessary, as much only as would confer the utmost point of strength and power, without adding any useless incumbrance of matter to the body that might clog the freedom of respiration, or increase the weight and bulk of the animal, and impede rather than assist the functions of the organs, viscera, and limbs. This art, if properly understood, should impart the greatest facility of wind, and join to lightness of the body the greatest possible elasticity and strength of the muscular system. Such is properly the art of *training*, to which we refer the reader, and in which, though great things have been done, more wonderful might be yet effected; if to a well-founded view of nature in these animals was added all that consummate and well-placed art

could bring to her assistance, for nature we are led to believe has been but too often thwarted instead of assisted by the arts of stable-men, jockies, and smiths.

Though mere practice alone will teach much, yet when combined with a just system or knowledge of cause and effect, the art, whatever it be, may be carried to much higher perfection than it can otherwise.

For the present, we only treat of condition in horses, for the common and ordinary purposes to which they are applied.

To stable servants is left in general the physicking, dieting, and conditioning the horse; and a mystery has often, with the ignorant, more charms than the clear face of truth herself. The effects of drugs upon horses are very little known, perhaps, except the purgative effect of aloes, and the diuretic effect of soaps and turpentine, and neutral salts; we have scarcely any medicine whose effects we really know upon the horse, or that appears at present likely to be known, yet are grooms ever physicking their horses with some drugs or other; good clean food in plenty, dry lofty stables, gentle exercise, and attention to the skin in keeping it clean, will bring almost any horse that is out of condition into condition, unless there be some lurking disease; yet nauseous drugs are added to their food, and they are pleased to fancy that the effects they experience result from these, though it is more probable, as far as they go, and in the uncertain and often idle doses in which they are exhibited, that they prevent, rather than assist, the purpose they have in view, and rather disturb their digestion, and weaken the stomach, than assist it; or more certainly render nauseous and loathsome the food they could otherwise relish; antimony, nitre, brimstone, cleampare root, &c. are among their secrets for this purpose. Antimony is, however, believed, by better judges than these, to affect the skin of the horse, and promote perspiration; this it may possibly do. We may, however, just remark, that where it affects the skin, it has the power of affecting the stomach; but with pigs, horses, and a variety of other animals, it does not affect the one, and one should doubt whether, in these cases, it would affect the other; for in no quantity whatever, and we have given 4 oz. at a dose, does it appear to affect the stomach; nitre in larger quantities than they are used to give, will increase the urine; but how this promotes condition, we have not yet been informed. The rest of their nostrums are obviously inert, at least their actual effects, when pushed, till they become externally sensible, have never been exhibited; and unless they are, we cannot know them. There is, however, another, and a more certain purpose answered, in the administration of their drugs, and to which the science of medicine, in ignorant hands, is but too frequently made subservient; and without which, we believe, there would not be so much anxiety about the administration of them.

There is one instance, however, in which we rejoice to have it in our power to concur with these men in the use of medicine, and that is on horses coming from grass; this appears to be a really useful practice, and we think, from sufficient experience, we can vouch for the fact, though to give medicines without a direct indication for their use, would at first appear repugnant to reason, yet it is usual with grooms to give one, two, or more doses of physic, on the horse being brought from grass "to clear him out," as they say; but if such were the only effect, there would be no occasion for it, as the grass would very naturally come away from him without its good effects: we shall give a different account of the sudden change of life, from green relaxing watery food, as grass, to dry hay and stimulating corn; from free open air and nightly dews, and all kinds of weather, to a

close, low, foul, and crowded stable, the air of which is heated to an excess, and filled with stimulating exhalations from the dung; the water which had been received in quantities unrestrained, is now portioned out (though it is really more necessary) in miserable pittaunces. The body, before exposed, is wrapped in rugs and cloths, and the whole system becomes heated and inflamed by the sudden changes, inflammatory complaints of the lungs, eyes, palate, throat, intestines and feet, are produced; and it is therefore useful on this account, in keeping off these attacks, to lower the habit by physic, after the horse has been a few days in the stable, and to pass by slow degrees to the excessive use of these vigorous stimuli. Dealers like to mix carrots with their corn, and bleed occasionally, and give bran mashes, which has the same effect.

In turning out also, grooms are again for physicking their horses, and under the same pretence of clearing them out, and preparing them for grafs. They will, however, be sufficiently lowered and reduced by the grafs itself, without any additional reduction by physic. It may not be an useless precaution, however, to withdraw by deprees the use of corn, previous to turning out, and the removing all sort of clothing, to give water in greater abundance, that the change may not be too suddenly felt, and bring on broken wind, farcy, and the diseases induced by too great debility.

In Arabia, where the finest horses of the world are produced, a late traveller in those countries, (Mr. Barker), informs us of the extraordinary simplicity of their treatment of them. They do not use any instrument for dressing or cleaning them. They merely fasten them to a picket by the leg or a halter, to give them their food, which, during the spring, consists only of grafs; and when the earth no longer produces that nutriment, they supply the want by camel's milk, which, he says, is most assuredly preferable to any kind of grain.

Beans, malt, oats, clover, hay, and meadow hay, are the general food of horses in England, and are supposed to be stimulant or invigorating to the system of the horse, in the order in which we have placed them. Barley was the ancient food for horses, the discovery of oats being comparatively of modern date.

In the north of Holland, they feed their horses principally on the black four bread called bumpnickle, made of buck wheat, and there it is eaten also by a large share of the inhabitants; for this purpose, they alight from their vehicles, and, without taking the horses out of their hempen traces, cut it in slices, and give them to eat. We observed that they appeared relaxed by it, but apparently without much debilitating them, as they seemed to do their work very well.

In the "Museum Rusticum" is a proposition founded apparently on actual experiment of feeding horses on carrots, vol. i. p. 333. The following remarks we think worth recording from that communication: "I have a couple of hunters which I value as being very good horses, and these I feed in the season with very little else besides carrots well cleaned from the dirt, and loaves made of the meal of barley and oats, mixed sometimes with a small admixture of coarse but good wheat meal; and if they require to be loosened in their bodies, I now and then give them some bran. As to hay, they eat at this season but little of it, of oats none at all, yet they go through their work to admiration."

Furze or whinns has been found useful food in sustaining horses, after it has been bruised, and the spines or prickles crushed; this some horses will naturally do with their feet.

Dr. Darwin relates, that on one particular common, all the horses do it; and that fresh comers starve, till by imitation they learn this practice, as the common, in other respects, is very barren. In Wales, mills, we understand, have been used for crushing the furze for cattle.

Sainfoin is a food that horses are very fond of; but as they eat it very greedily, too much should not be allowed at once for fear of indigestion, and it serves better for horses of slow draught, being a coarse heavy food.

Salt is imagined an useful addition to the food of horses, Salt marshes have often a preference given them over other ground for horses and cattle; whether it is the salt that in itself operates beneficially, or whether the herbage itself is altered by it, and is rendered more salutary to the cattle, is not known. The same correspondent, in the Museum Rusticum, says that salt in substance is abundantly distributed in the mountains by the Swifs, for the use of their cattle and horses, who become excessively fond of it, and more healthy in consequence; it is conceived to be an antidote to worms and other formations in the body, and the long continued use of it to cure them when formed, vol. i. p. 99. Horses, he observes, are fond of it with their oats.

Horses when at liberty are almost ever feeding, therefore long fasting must be injurious to the stomach, and should be as much as possible avoided; they would also naturally, there is reason to believe, feed principally during the night, and sleep during the day; their sleep, however, is hardly ever, in health, profound and fast, but is a state of watchful dozing.

Horses are naturally gregarious, and though they will do very well alone, company, where there is an opportunity for it, is preferable for their health. The stable should be lofty, so as not to confine an atmosphere about them, loaded with exhalations from their own bodies and their dung; the loftiness alone of the stable is their best airing; all partial draughts from doors, windows, or holes into the loft, as far as they affect them, are injurious; for we have often remarked, that though they bear the coldest weather of our seasons when turned out, yet they easily take cold from partial draughts in stables, inasmuch, that persons not attentive to these effects would hardly believe their facility.

In cleaning the skin, the curry-comb is considered as a necessary implement. In warmer climates, where the scurf comes away more freely, this instrument is not so much used; and here it is often used to horses whose skins are particularly thin and sensible, yet no difference is made; and though the animal expresses, in every way he can, the excessive torture it occasions, yet it is persisted in, and violence is often had recourse to, to enforce it, and horses are thus rendered vicious and untractable. Where this is found to be the case, it would save much trouble and inconvenience to use a milder kind of comb, or to lay it aside altogether, and use a stiff brush made for the purpose. It is more easy by violence and punishment to create vice, than to overcome a natural dislike by it.

Warm clothing, on account of its keeping up a free perspiration, tends to render the skin cleaner, makes the coat lie better, and have a more glossy appearance, and saves trouble. It is too often, however, carried to an excess, and two or three hot rugs keep the horse in a perpetual fever; and as they are all taken off, when he is most exposed, on going out, the sudden check given to the perspiration by the elements without, lays the foundation of disease, and occasions inflammations of the lungs, catarrhs, and coughs, that might as well be avoided by more moderate and judicious proceedings, besides the weakening effects of such violent perspirations.

There is a principle in feeding them that ought not to be overlooked; which is, that good food may be carried too far, till, instead of condition, it produces fever and disease, and destroys the condition it is meant to promote. Green vegetable food fills out the body; and from its weight and watery nature weighs down the abdomen, giving an unrightly appearance. Some horses, however, can work with this, that more stimulating food does not suit so well. The dry diet braces the system, and draws up the abdomen. The food is longer retained in the large intestines, which occasions the flanks to appear full and rounded, and greatly adds to the beauty of the horse's make in these parts.

Some horses we have noticed have voracious appetites, and devour great abundance of corn, and whatever is set before them, yet always look meagre and out of condition. When this has been the case, we have been led to believe that by too much food, and of too heating a quality, the stomach and intestines have been paralyzed, and lost their powers of forming chyle, or absorbing it. Turning out to the green pasture will often bring them into condition, and they fall off again in the stable. Horses of small make and fiery temper are, we have thought, more particularly subject to this disease.

Water, like the food, should be given often, and not in too large quantities: stinting horses is a dangerous custom; it induces them, where there is an opportunity to take enough at once, to break their wind, or otherwise injure themselves. See art. *BROKEN WIND*.

The skin, to look well and healthy, should be smooth, supple, and easy upon the muscles, free from knots, and by no means tight about the ribs. The hair clean, bright, and glossy, lying to the skin, and not distorted, or turning away from it, or twisted, dry, or thrady. The effects of cold air on the skin of the horse, in setting up the hair, is well known to the grooms, who cautiously avoid it.

Exercise to animals by nature born to be fleet, is particularly necessary; besides the good it does in moving and forwarding all the secretions and excretions. This should be gentle or vigorous, proportioned to the strength and state of the horse, without distressing or too much fatiguing him. A gentle perspiration loosens the scurf, and makes him clean better.

The hide soon gets foul, and a groom that has much pride in the appearance of his horse, is almost incessantly currying, brushing, and hard rubbing the coat.

It is a customary thing with the dealers in horses, in forming a judgment of the actual state of the horse, and whether his condition will admit of farther advancement, to handle the crest, or upper part of the neck which carries the mane: if this be lax in the hand, and easily pliant, it is presumed the condition may be carried farther; if, on the contrary, this part has a stiff tense feel, it is considered that farther improvement is not to be expected. Among the acknowledged indications also of poverty and good condition, is the poor mark in the buttock, that is the channel, or depression running down the buttock, at its posterior part; being a depression formed between the muscles. If this channel is very visible and deep, the horse is out of condition; if obliterated, so as to be hardly visible, he is considered in condition.

Blood horses are more easily cleaned than the common kind of horses; their coat is not so thick, it does not retain the perspiration so much, and the hair takes a better polish; which makes an experienced groom always prefer them.

Too great excitement from the food, and undue fever, may be known by the heat of the mouth, the fulness of the

veils of the eyes, the strength of the pulse, and diminished appetite; the skin also, and extremities, are found too hot or too cold, languor and weakness follow: the remedies are before stated.

CONDITIONAL, something not absolute, but subject to limitation.

Conditional legacies are not due till the conditions are accomplished.

The Arminian divines maintain, that all the decrees of God, relating to the salvation and damnation of man, are truly conditional; and the Calvinists, that they are all absolute. See *ARMINIAN*, &c.

CONDITIONAL conjunctions, in *Grammar*, are those which serve to make propositions conditional. As, *if, unless, provided that, in case of, &c.*

Mr. Horne Tooke, in his "EHEA HTEPOENTA, or Diversions of Purley," &c. has given us a new system, with regard to these conditionals, as well as other conjunctions. Our conjunction *if*, he says, is merely a verb; being the imperative of the Gothic and Anglo-Saxon verb *ΓΙΨΑΝ*, *Giþan*. And in those languages, as well as in the English formerly, this supposed conjunction was pronounced and written as the common imperative, purely *ΓΙΨ*, *Liþ*, *giþ*. In proof of the truth of this etymology of the word *if*, the author observes, that when-ever the datum upon which any conclusion depends, is a sentence, the article *that*, if not expressed, is always understood, and may be inserted after *if*. But the article *that* is not understood, and cannot be inserted after *if*, where the datum is not a sentence, but some noun governed by the verb *if* or *give*. This, he says, will hold universally, not only with *if*; but with many other supposed conjunctions, such as, *but that, unless that, though that, lest that, &c.* which are really verbs, put in this manner before the article *that*. *An*, now indeed obsolete, but formerly often used to supply the place of *if*, is also a verb; being nothing else but the imperative of the Anglo-Saxon verb *Anan*, which likewise means to *give* or *grant*. If recourse should be had for consulting the author's opinion on the conditionals of the Greek and Latin, and Irish, the French, Italian, Spanish, Portuguese, and many other languages, he obviates the objection by alleging, that those words which are called conditional conjunctions, are to be accounted for in all languages in the same manner as he has accounted for *if* and *an*. Not that they must all mean precisely as these two do—*give* and *grant*; but some word equivalent: such as, *be it, suppose, allow, permit, put, suffer, &c.*; which meaning is to be sought for from the particular etymology of each respective language. "To put this matter of doubt," he says, "I mean to discard all supposed mystery, not only about these conditionals, but about all those words also which Mr. Harris and others distinguish with prepositions, and call conjunctions of sentences. I deny them to be a separate sort of words or part of speech by themselves. For they have not a separate manner of signification; although they are not devoid of signification. And the particular signification of each must be sought for amongst the other parts of speech, by the help of the particular etymology of each respective language. By such means alone can we clear away the obscurity and errors in which grammarians and philosophers have been involved by the corruption of some common words, and the useful abbreviations of construction." See **CONJUNCTION**.

CONDITIONAL propositions, in *Logic* are such as consist of two parts, connected together by a conditional particle. Of these, the first, wherein the condition lies, is called the antecedent, and the other the consequent.

Thus, "if the soul be spiritual, it is immortal;" is a conditional

conditional proposition, wherein, "if the soul, &c." is the antecedent, and "is immortal" the consequent.

The truth of these propositions depends on the truth of the connection of them, and they may be properly denied or contradicted when the negation affects their conjunctive particles. See PROPOSITION.

CONDITIONAL *syllogism*, is that whose major or minor, or both, are conditional propositions: *e. gr.* "If there be a God, the world is governed by Providence; but there is a God, therefore the world is governed by Providence." See SYLLOGISM.

CONDITIONAL *estate, fees, pardons, and resignations*. See the SUBSTANTIVES.

CONDITIONALS, *science of*, i. e. of *conditional truths*, imports that knowledge which God has of things, considered, not according to their essence, their nature, or their real existence; but under a certain supposition, which imports a condition never to be accomplished.

Some of the schoolmen deny, that God has the knowledge of conditionals: the Thomists maintain, that God's knowledge of conditionals depends on a predetermining decree; others deny it.

F. Daniel observes, that the truths which compose the knowledge of conditionals, being very different from those which compose the knowledge of intuition, and that of understanding; a third class must be added, and the knowledge of God be divided into *intuitive, intellectual, and conditional*. See KNOWLEDGE.

CONDIVI, ASCANTO, in *Biography*, an artist whose works of painting and sculpture are now unknown. He is indeed said to have possessed but an humble share of talent, inasmuch that although he had the good fortune to be the inmate and disciple of the great Michelangelo Buonaroti for many years, he never attained eminence.

The world however has obligations to Condivi for the life which he wrote of his master, in somewhat the form of a journal, and which he published in 1553, ten years prior to the death of Michelangelo. Mr. Mariette, the celebrated connoisseur, was decidedly of opinion that the greater part of this narrative was written absolutely under the immediate instigation and guidance of Michelangelo himself, and of course considered it as infinitely more authentic than the florid, but hasty, composition of Vasari. Vasari had published a life of the great Florentine artist in his first edition of 1550. Condivi points out and corrects many of his errors. This Vasari indignantly resents in his second edition of 1568; but as Michelangelo was then no longer alive to decide their respective claims, the veracity of Condivi should suffer no imputation. Vasari however relates many things which the other omits, dwells more largely upon others, and in his second edition gives us the sequel of Michelangelo's life, with a long description of his magnificent funeral, &c. it was therefore desirable to unite these and other scattered materials into one work: this has lately been done by Mr. Duppa in a handsome quarto volume.

The first edition of Condivi is in quarto and become rare. Another edition, with copious notes by Antonfrancesco Gori and Mariette, together with extracts from Vasari, was published in Florence, 1746, in folio.

CONDIVICNUM, in *Ancient Geography*, Nantes, a town of Gallia Lyonenfis, according to Ptolemy, and capital of the Namneti, from whom it took its name.

CONDOCHATES, a river of India, on the other side of the Ganges, according to Pliny and Arrian, which discharged itself into the Ganges, about the 26th degree of latitude.

CONDOLENCE, in *Ethics*. See COMMISERATION.

CONDOM, in *Geography*, a town of France, in the department of the Gers, and chief place of a district, situated in a beautiful valley on the river Baïse, 27 miles N.W. from Auch, and 60 S.E. from Bourdeaux. It has a sub-prefect and a court of justice. The place contains 6917, and the canton 13,232 inhabitants. The territory of the canton includes 247½ kilometres and 16 communes. The whole district counts 128 communes and 67,103 inhabitants, upon a territorial extent of 1662½ kilometres. Its soil is in general fertile, except in the southern part, which is an extensive barren heath; but as there are many mud pits, the waste land is improved with mail, which renders it tolerably fertile for a term of 20 years, at the end of which the ground is suffered to lie waste again, and another extent of heath is rendered productive upon the same plan. Corn, wine, and brandy are the chief articles of trade, most of which are sent to Mont de Marsan and Bourdeaux.

CONDOMOIS, a country of France, before the revolution, of which Condom was the capital.

CONDOMA, in *Zoology*, the name given by Buffon to the striped antelope of Pennant, the antelope strepticeros of Gmelin's Linnæus, the cervus capensis, or cape deer, of Collin. Aët. Ac. Theod. Palat. 1. 487, the bos strepticeros of Aldrovand, the strepticeros of Cams, Gesner, and Jonston, and the wild goat of Kolben, &c. It has long, compressed, wrinkled, tapering, sharp-pointed spiral horns, with a ridge on one side which follows the wreaths; the body has a white line along the back, and several white stripes across from that down the sides towards the belly and thighs. This animal inhabits the country near the Cape of Good Hope. It is near nine feet long from the nose to the rump, and four feet high at the shoulders; the body is long, slender, and of a reddish-grey colour; the face is brown, having a white line from the corner of each eye, running forwards and uniting above the nose; the transverse stripes above-mentioned are, in general, seven in number, four of which point towards the thighs, and three to the belly; it has a short mane on the neck, and long hairs hanging down from the throat to the breast; the breast and belly are grey; the tail, two feet in length, is brown above, white on the under side, and black at the end; the horns are of a dusky colour, and naturally wrinkled, though such as are brought to Europe are highly polished; they are near four feet long, close at the bases, above two feet and a half distant at the points, and have two spiral screw-like turns. The female has no horns. It is said to leap with surprising activity to a great height.

CONDORCET, JEAN ANTOINE, NICHOLAS CARITAT, *Marquis of*, in *Biography*, celebrated as a writer and political character, was descended from an ancient family in Picardy in France. He was born in 1743, and was educated at the college of Navarre, where he exhibited an ardent thirst for physical and mathematical pursuits, and acquired the reputation of a hard student. Condorcet first attracted public notice as a mathematician, by his treatise "On Integral Calculations," which he wrote when he was only twenty-two years of age, and in which he proposed to exhibit a general method of determining the finite integral of a given, differential equation, either for differences infinitely small, or finite differences. D'Alembert and Bezout, the commissioners of the academy, employed to examine the merits of this performance, declared that the greater part of the methods were of the author's own invention, that the production itself indicated a degree of knowledge very seldom to be met with at so early an age, and that it afforded a preface of talents worthy of being excited by the approbation of the academy. This was followed by his "Essay on Analysis," and other works, which shewed his skill in
analytica

analytical researches. In the year 1769, he was admitted member of the Academy of Sciences, the memoirs of which were enriched by various dissertations presented by him on the most abstruse subjects. During the administration of Turgot, celebrated no less for his integrity, than for his high talents, Condorcet was applied to for assistance in arranging plans for economical reforms in the state. In 1773 he was appointed secretary to the Academy of Sciences, when he composed eulogies upon several deceased members who had been neglected by Fontenelle. At this period he was the friend and intimate associate of Voltaire, D'Alembert, and other distinguished characters. Like D'Alembert he united in himself the reputation of an elegant writer, and of profound science; and in 1782 he was received into the French Academy, on which occasion he delivered a discourse concerning the influence of philosophy. In the following year he succeeded D'Alembert as secretary to that academy, and pronounced an able eulogy to the memory of his deceased friend, whose literary and scientific merits are set forth with great ability. The death of Euler afforded Condorcet another opportunity of displaying his own talents by appreciating those of the departed mathematician. In his discourse on this occasion, he exhibited a clear and scientific statement of the improvements and inventions introduced into one department of knowledge by the exertions of an individual. The lives of Turgot and Voltaire, and the eulogy pronounced upon the death of the celebrated Franklin, were decided testimonials to the abilities of Condorcet as a biographical writer. Turgot had occupied much of his time and attention with moral and political sciences, and was particularly anxious, for the good of his fellow creatures, that the certainty of which different species of knowledge are susceptible, might be demonstrated by the assistance of calculation, hoping that the human species would necessarily make a progress towards happiness and perfection, in the same manner as it had done towards the attainment of truth. To second these views of Turgot, Condorcet undertook a work replete with geometrical knowledge. He examined the probability of an assembly's rendering a true decision, and he explained the limits to which our knowledge of future events, regulated by the laws of nature, considered as the most certain and uniform, might extend. If we do not possess a *real*, yet he thought, we have at least a *mean* probability, that the law indicated by events, is the same constant law, and that it will be perpetually observed. He considered a forty-five thousandth part as the value of the risk, in the case when the consideration of a new law comes in question; and it appears, from his calculation, which we cannot go into, that an assembly consisting of 61 votes, in which it is required that there should be a plurality of nine, will fulfil this condition, provided there is a probability of each vote being equal to four-fifths, that is, that each member voting shall be deceived only once in five times. He applied these calculations to the creation of tribunals, to the forms of elections, and to the decisions of numerous assemblies; inconveniences attendant on which were exhibited by him. This work furnished a grand, and at the same time, an agreeable proof of the utility of analysis in important matters to which it had never before been applied.

Condorcet at this time flattered the idea of a dictionary, in which objects are to be discovered by their properties, instead of being searched for by their respective names; he also intimated a scheme for constructing tables, by which ten milliards of objects might be classed together by means of only ten different modifications. The talents of Condorcet

were very various, and he distinguished himself by many philosophical and economical discussions, which it is supposed, with great justice, had a great share in producing the subsequent important revolution in France. Without pretending to decide upon the motives of those who were active in achieving the downfall of the French monarchy, we shall bring before the reader a brief account of the part which Condorcet took in this business. Almost all his writings tended to pave the way for that most important change in government which took place in the year 1789. At this period, and in the following two or three years, he engaged in several periodical publications, with a view, no doubt, of guiding the public mind. He was a member of the popular clubs at Paris, particularly that of the jacobins, celebrated for democratic violence, where he was a frequent but by no means a powerful speaker. He was chosen a representative for the metropolis, when the constituent assembly was dissolved, and joined himself to the Brissotine party which, in point of real talents and integrity, were not inferior to any of the contending factions of the day. But they wanted energy to control the people, and finally fell victims to that revolutionary spirit which they had excited. Condorcet at this period was the person selected from the party to draw up a plan for public instruction, which he comprehended in two elaborate and very striking memoirs; the principles laid down were, perhaps, too abstract for general use, and too refined for the present state of society. He was the author of a manifesto addressed from the French people to the powers of Europe, on the approach of war; and of a letter to Louis XVI., as president of the assembly, which was dictated in terms desultory of that respect and consideration to which the first magistrate of a great people has, as such, a just claim. Condorcet attempted also to justify the insults put upon the sovereignty by the lowest, the most illiterate, and most brutal part of a delirious populace. On the trial of the king, his conduct was equivocal and unmanly; he had declared that he ought not to be arraigned, yet he had not courage to defend his opinion or justify those sentiments which he had deliberately formed in the closet.

After the death of Louis, Condorcet undertook to frame a new constitution, which was approved by the convention, but which did not meet the wishes and expectations of the nation. A new party, calling themselves the MOUNTAIN, were now gaining an ascendancy in the convention over Brissot and his friends. At first the contest was severe; the debates, if tumult and discord may be so denominated, ran high, and the utmost acrimony was exercised on all sides. Condorcet always timid, always anxious to avoid danger, retired as much as possible from the scene. By this act of prudence he at first escaped the destruction which overwhelmed the party; but having written against the bloody acts of the mountain, and of the monster Robespierre, a decree was readily obtained against him. He was arrested in July 1793, but contrived to escape from the vigilance of the officers under whose care he was placed. For nine months he lay concealed in Paris, when dreading the consequences of a domiciliary visit, he fled to the house of a friend on the plain of Mont-Rouge, who was at the time in Paris. Condorcet was obliged to pass eight-and-forty hours in the fields, exposed to all the wretchedness of cold, hunger, and the dread of his enemies. On the third day he obtained an interview with his friend; he, however, was too much alive to the sense of danger to admit Condorcet into his habitation, who was again obliged to seek the safety which infrequented fields and pathless woods could afford. Worn at length with fatigue, and want of
 necessary

necessary sustenance, he went to a public-house, and asked for an omelette, which he devoured with so much greediness as to induce the suspicion of a municipal officer who was present. At this period, suspicion and guilt were divided by very narrow boundaries; the unfortunate man was seized and thrown into a dungeon, in order that he might, on the following day, be conducted to the bloody tribunal at Paris. The precaution was, however, unnecessary. Condorcet was found dead in the morning; and as it was generally understood that he was never without a concealed dose of the most active poison, to this cause his melancholy end was generally ascribed. Such was the concluding scene of the career of a man who had sustained a brilliant part on the stage of life. He died March 28, 1794.

His character has been variously estimated. His manners were mild, and his talents were unquestionably of the first order. He is said to have been destitute of those fine feelings which distinguish great and generous minds; and it is allowed on all hands that he was a prey to timidity; a passion which at length induced him to commit the act of suicide. By Madame Rolande, his contemporary and intimate, he was, in his life-time, thus described: "The genius of Condorcet is equal to the comprehension of the greatest truths; but he has no other characteristic besides fear. It may be said of his understanding, combined with his person, that it is a fine essence absorbed in cotton. The timidity which forms the basis of his character, and which he displays even in company, on his countenance and in his attitudes, does not result from his frame alone, but seems to be inherent in his soul, and his talents furnish him with no means of subduing it. Thus, after having deduced a principle, or demonstrated a fact in the assembly, he would give a vote decidedly opposite, overawed by the thunder of the tribunes, armed with insults, and lavish of menaces. The properest place for him was the secretaryship of the academy. Such men should be employed to write, but never permitted to act." Condorcet was married, and lived on the most affectionate terms with his wife. He left one daughter, who has, during the present summer (1807), been married to Arthur O'Connor.

Condorcet was the correspondent of the great Frederic, and of Catherine, the empress of Russia. "Letters to the King of Prussia," he published during his life; and he left behind him, which appeared as a posthumous work, "A Sketch of a Historical Draught of the Human Mind." In this work, he considers man as he has been, as he is, and as he may be; and he inculcates, with great energy, his favourite idea of the perfectibility of the human species, and of its advance to actual perfection. He left behind him also "A Treatise on Calculation," and "An Elementary Treatise on Arithmetic." His work on the human mind was written during the months that he secreted himself from the savages who were seeking for his blood, with more than inhuman fury; and it is remarkable, and to the credit of the writer, that under such circumstances, dreading death at every instant, he could compose so able a treatise, and feel the conviction of the progress of his fellow creatures towards moral improvement. *Memoirs of the French Revolution.* Rolande's *Memoirs.*

CONDORE, or PULO CONDORE, in *Geography*, an island of the East Indian ocean, about 20 leagues from the coast of Cochinchina, taking its name from two Malay words, *Pulo* signifying an island, and *Condore* a calabash, of which it produces great quantities. This island is high and mountainous, and surrounded by several smaller islands, some of which are less than one, and others two miles distant. It is of the form of a crescent, extending, says Capt. King,

near 8 miles from the southernmost point, in a N.E. direction, and its breadth no where exceeds 2 miles. Sir Geo. Staunton says, it is 11 or 12 miles in length, and about 3 in breadth, confining of a ridge of peaked hills. From the westernmost extremity, the land trends to the S.E. for about 4 miles, and opposite to this part of the coast there is an island, called by Mons. D'Après "Little Condore," which runs two miles in the same direction. This position of the two islands forms a safe and commodious harbour, the entrance into which is from the north-west. The distance between the two opposite coasts is $\frac{3}{4}$ of a mile, exclusive of a border of coral rock, which runs down along each side, extending about 100 yards from the shore. The anchorage is very good, from 11 to 5 fathoms water, but the bottom is so soft and clayey, that great difficulty occurs in weighing the anchors. Toward the bottom of the harbour, there is shallow water for about half a mile, beyond which the two islands approach so near each other, as to leave only a passage at high water for boats. The most convenient place for watering is at a beach on the eastern side, where is a small stream that furnishes 14 or 15 tons of water a day. Sir George Staunton says, that beyond the beach, which stretches across two-thirds of the entrance, at the southern extremity of the spacious bay on the eastern side of the island, there is a safe passage to the inner part of the bay, the north of which is sheltered by a small island lying to the eastward. The whole of the bay, he says, is formed by four small islands, which approach so nearly to each other as to appear, from several points, to join. They all seem to be the rude fragments of primitive mountains, separated from the great continent in the lapse of time. This island has convenient anchoring places in either monsoon; and Sir Geo. Staunton stopped there, on the 17th of May, in a spacious bay on the eastern side of the island. Capt. Gore, on the 20th of January, stood for the harbour on the S.W. end of the island, which, having its entrance from the N.W. is the best sheltered during the N.E. monsoon.

This island, both with respect to animal and vegetable productions, is considerably improved, since the time when Dampier visited it. Neither that writer, nor the compiler of the East Indian Directory, mention any other quadrupeds besides hogs, which are said to be very scarce, lizards, and the guanoes; and the latter, on the authority of Mons. Dédier, a French engineer, who surveyed the island about the year 1720, says, that none of the fruits and esculent plants, so common in the other parts of India, are to be found here, except water melons, a few potatoes, small gourds, *chibbols* (a small species of onion), and little black beans. At present, besides the buffaloes, of which there are large herds, it supplies remarkably fine fat hogs, of the Chinese breed. There are also some of the wild tort in the woods, which also abound with monkeys and squirrels. One species of the squirrel is of a beautiful shining black colour, and another species is striped brown and white, which is called the flying squirrel, from its being provided with a thin membrane, resembling the wing of a bat, extending on each side of the belly, from the neck to the thighs, which, in stretching out the legs, spreads, and enables it to fly from tree to tree, to a considerable distance. Lizards are found in great abundance; but Capt. Gore says, that none of his company discovered the guano, and another animal described by Dampier as resembling the guano, only much larger. Among the vegetable improvements of the island are fields of rice and tobacco, and groves of cabbage palm-trees, plantains, various kinds of pumpions, cocoa-nuts, oranges, shaddockes, and pomegranates. These improvements are ascribed to the French, for the purpose of making

It a more convenient refreshing station for any of their ships that may be bound for Cambodia, or Cochin-china; and for this purpose it is well situated. The woods are well stocked with feathered game; and particularly with wild hens and cocks, resembling those of our own country. The land in the neighbourhood of the harbour is a continued high hill, richly adorned with a variety of fine tall trees, from the summit to the water's edge; and among others the tea-tree described by Dampier.

The town in this island is situated near the sea side, at the bottom of a retired bay, which affords a safe roadstead during the prevalence of the S.W. monsoon. It consists of between 20 and 30 houses, built close together; besides six or seven others that are scattered about the beach. The roof, the two ends, and the side fronting the country are neatly constructed of reeds; the opposite side, facing the sea, is entirely open; but by means of a fold of bamboo screens, they can exclude or let in as much of the sun and air as they please. There are other large screens or partitions, for the purpose of dividing, as occasion requires, the single room, of which the house properly speaking, consists, into separate apartments. The largest house of the town, belonging to the chief or captain, had a room at each end, separated by a partition of reeds from the middle space, which was open on both sides, and provided with partition-screens like the others. It had, besides, a pent-house, projecting four or five feet beyond the roof, and running the whole length on each side. At each end of the middle room were hung some Chinese paintings, representing men and women in ludicrous attitudes. In this apartment Capt. Gore's companions were civilly desired to seat themselves on mats, and they were presented with betel. In one of the apartments, visited by Sir George Staunton, was an altar decorated with images; and the partitions were hung with figures of monstrous deities; but the countenances and deportment of the people exhibited no idea of religious awe, nor was any person observed in the posture of prayer or adoration. A few spears stood against the wall with their points downwards, together with some match-locks, and a swivel-gun.

The inhabitants of this island, who are fugitives from Cambodia and Cochin-china, are not numerous. They are of a short stature, very swarthy, and of a feeble, unhealthy aspect, but seemingly of a gentle disposition. The dress of these people is composed chiefly of blue cotton, worn loosely about them; and their flat faces and little eyes indicate a Chinese origin or relation. Their colloquial language is altogether different from that which is spoken in China, but their written characters are all Chinese.

The English settled in this island in 1702, when the factory of Chusan, on the coast of China, was broken up, and brought with them some Macassar soldiers, who were hired to assist in building a fort; but the president not fulfilling his engagement with them, they watched an opportunity, and in one night murdered all the English in the fort. Those without the fort, hearing a noise, took the alarm, and ran to their boats, very narrowly escaping with their lives; but not without much fatigue, hunger, and thirst, to the Johore dominions, where they were treated with great humanity. Some of them afterward went to form a settlement at Banjer-Massin, in the island of Borneo. Since this event, no Europeans have ever resided in this island. The latitude of this island, calculated from a meridional observation, as stated by Sir Geo. Staunton, is $8^{\circ} 40' N.$; and its longitude, according to a good chronometer, $105^{\circ} 55' E.$ The harbour in which Capt. Gore was stationed, is in N. lat. $8^{\circ} 40' E.$ long., deduced from a great number of lunar observations, $106^{\circ} 18' 46''$; dip of the N. pole of the mag-

netic needle, $2^{\circ} 1'$; variation of the compass, $0^{\circ} 14' W.$; high water at the full and change of the moon, $4^h 16'$ apparent time. The water rose and fell 7 feet 4 inches perpendicular. Voyage to the Pacific Ocean, by captains Cook, Clerke, and Gore, vol. iii. p. 450. &c.

CONDOR, in *Ornithology*, the *Vultur Gryphus* of Latham, (Ind. Orn.) Klein, Brisson, Borowski, the condor of Lact and Ray, the conder of Prezier, Condamine, Buffon, and Molina, and the condor of Latham (Syn. and Sup.) is a bird of enormous size, having a longitudinal warty excrescence on the crown of the head, and a naked throat. It inhabits South America; and its size is so enormous that the wings, when extended, measure 9, 12, or even 16 feet from top to tip; the largest quill-feathers of the wings sometimes measure $2\frac{1}{2}$ feet in length, and the quill-part $1\frac{1}{2}$ inch in circumference. The body is of a black colour, with a white back; the neck is surrounded with a collar of longish white feathers; the chin is reddish; the head is clothed with brown down or wool; the eyes are black, with chestnut or light reddish irides; the bill is black, with a whitish point; the legs and feet are black, and the claws are straightish; the tail is small. The female is considerably larger than the male, which it resembles, except in having a crown crest or tuft on the scrag, or hinder part of the neck. The condore builds its nest on the highest mountains, under the shelter of some projecting shelf of a rock, in which the female lays two white eggs. It preys on calves, sheep, goats, and such animals, and when very much pressed by hunger, it has been known to carry off children of ten years of age; and two of them are said to be able to devour the carcase of a cow at one meal. When it alights upon the ground, or rises from it, the noise it makes with its wings is such as to terrify, and almost to deafen, any one who happens to be near the place. Don Ulloa informs us, that he actually saw one of them rising with a lamb in its talons. The Indians have various ways of catching them: besides traps and snares laid for them near any carion, they kill a cow or other animal, and moisten its flesh with the juice of some strong intoxicating herbs, and then bury the body till it putrefies. In this state they take it up and lay it on the ground; and when the condores come near to devour it, they are intoxicated and rendered motionless, when the Indians fall upon and kill them.

CONDORMIENTES, religious sectaries, whereof there have been two kinds. The first arose in Germany, in the thirteenth century; their leader was a native of Toledo. They held their meetings near Cologne; where they are said to have worshipped an image of Lucifer, and to have received answers and oracles from him: the legend adds, that an ecclesiastic having brought the eucharist to it, the idol broke into a thousand pieces; which put an end to the worship. They had their name from their *lying all together*, men and women, young and old.

The other species of Condormientes were a branch of Anabaptists in the sixteenth century; so called, because they lay, several of both sexes, in the same chamber; on pretence of evangelical charity.

CONDOTTIERI, in the Italian *Policy*, denoted leaders of bands, who, in the 15th and 16th centuries, made a trade of war, and raised soldiers in order to hire them out to different states.

CONDREN, CHARLES DE, in *Biography*, superior general of the fathers of the oratory, was born near Soissons in the year 1588. By his father, who was in high estimation in the court of Henry IV., he was designed either for a

pest about the king, or for the military profession. His own inclinations, however, led him to think of the church, as most suited to his talents, to which, after some hesitation, his father gave an assent. He accordingly prosecuted his studies in the college of the Sorbonne at Paris, was ordained priest, and admitted a doctor of that society in the year 1614. In the following year he became a member of the congregation of the oratory, and founded some houses belonging to that order. He was not long in obtaining a distinguished reputation for integrity and prudence as a man, and for piety and benevolence as a priest. On account of these traits in his character he was fixed upon as the most proper person to be confessor to the duke of Orleans, only brother to Louis XIII. In this situation he was successfully employed in confidential business between the duke and the king, and was the happy means of restoring these princes to a mutual good understanding with one another, after long and violent disagreements. For these services he was offered the archbishopric of Lyons, and a cardinal's hat; but he declined accepting offices of honour and emolument for having performed those acts, which, his religion taught him, were binding upon every Christian. He died in the year 1641, leaving behind him many pieces which evidenced superior talents, and a sincere piety. His principal works are, "Discourses and Letters," 2 vols. 12mo. 1648; and "An Explanation of the Priesthood of Jesus Christ," published in 1677. Father Amelotte drew up an account of his life, in which there is a collection of his letters and maxims with an exposition of his opinions. *Nouv. Dict. Hist.*

CONDRIEUX, in *Geography*, a small town of France, in the department of the Rhône, at the foot of a hill on the river Rhône, 21 miles south from Lyons. This place is celebrated for its excellent sweet wine.

CONDROS, **CONDROTZ**, in *Geography*, is a tract of land in the circle of Westphalia, situated in the bishopric of Liege, which formed part of the German empire, and is now incorporated with France. Condruz, in ancient geography, was reckoned part of Belgica. Huy, which was considered as the principal town of Condros, is, at present, the chief place of the district of the same name in the department de l'Ourthe. See *Huy*.

CONDUCT, *verb.* See *SAFE-conduct*.

CONDUCTOR (from *conduct*, and to *conduct* from the French *conduire*) *prime*, in *Electricity*, is a body of a conducting substance, (*viz.* such as will transmit the electric power or fluid) placed immediately before the glass cylinder, or globe, or plate, or other excitable body, of an electrical machine. Its office is to collect the electricity, and to convey it either in the form of sparks, or silently, to other bodies that may be presented to it in the course of experiments. Without this prime conductor no large sparks could be drawn immediately from the excited electric, because the electric body, being in its nature incapable of conveying the electric fluid through its substance, discharges, on a body which is presented to it, that quantity of electricity only which is accumulated upon a small part of its surface. But when the prime conductor is placed before the excited electric, the former successively collects all the electricity from the surface of the latter, whilst revolving; and if a proper body be brought near its surface, the electricity which has been accumulated, will rush from every part of the surface of the prime conductor in a copious stream, or in a full spark, to that body.

The forms of prime conductors have been continually varied from the very first invention of electrical machines, according as new discoveries, or the progress of experience, have either detected former defects, or suggested more ad-

vantageous forms. A gun-barrel, or a metallic chain, supported by silk strings, formed the prime conductor of the earliest electrical machines, *viz.* such as were used towards the beginning of the last, or eighteenth century. And in consequence of this usage some distinguished late writers on the continent, have retained the name of *chain* for the prime conductor, long after the shape of that instrument had undergone a total alteration. See "L'Électricité artificielle del P'Beccaria."

Though the gun-barrel or the chain would be highly improper for the modern electrical machines, either of them was quite sufficient for those of the old construction, in which the excitation was very slight and difficultly obtained. But when the glass globes or cylinders began to be made much larger, when a better method of excitation was discovered, and especially when Mr. Canton's amalgam was introduced, to which the great power of the modern electrical machines is principally owing; then the chain or the gun-barrel was found incapable of retaining the electric power, so that every narrow edge, or point, or curvature of the same, was found to dissipate the electricity into the surrounding air, as could be easily perceived in a darkened room. This suggested the idea of enlarging the size, and smoothing the irregularities of the prime conductor, in consequence of which some prime conductors were made of brass, others of tin, or even of gilt paper; and their shape became much more regular and compact. A cylinder with spherical terminations has been the most usual form of prime conductors. A few were made spherical; Dr. Priestley used one of a pear-like figure, and some have also been made of other fanciful shapes. But amongst all those forms, that which the practice of the best electricians has found to be, upon the whole, the most eligible, is the abovementioned one of a cylinder with hemispherical terminations. Those terminations, in small prime conductors, sometimes are made a little larger in diameter than the cylinder; but in the prime conductors of the larger kind, they do not project beyond the surface of the cylindrical part. As the conducting nature of their substance must be of the best kind, the prime conductors are made of metal, at least on their surface. The small ones are made of hollow brass, or tin plates, or of wood covered with tin-foil. But the large ones are almost always made of wood, or paste-board covered with tin-foil. The prime conductors of tin are frequently covered with a black varnish, which is preferred cleaner than the surface of the tin, and may perhaps in some measure prevent the dissipation of electricity from their surface. In any construction, care must be had, that the surface of the prime conductors be quite free from points, and sharp edges; and if holes are to be made in them, which indeed are necessary for the performance of various experiments; these should be well rounded off and their edges burnished. The prime conductor is generally supported in an horizontal position, by one or two glass sticks, which proceed from the bottom board of the electrical machine, or from separate wooden stands; the extremities of those glass sticks entering a little way within the surface of the conductor. The direction of the prime conductor is mostly perpendicular to the axis of the glass cylinder of the machine; but in some electrical machines, the conductor, or two conductors, are situated parallel to the abovementioned axis. When two conductors are affixed to the machine, one of them, which collects the electric fluid from the excited glass, is called the *positive conductor*, and the other, which is connected with the rubber, is called the *negative conductor*. At that extremity of the prime conductor, which stands nearest to the glass globe or cylinder, when the former is perpendicular to the

axis of the latter, or on the side when it stands parallel, lie collector is affixed. See COLLECTOR.

To the opposite extremity of the prime conductor which stands farthest from the glass cylinder or globe, a thick brass wire, with a pretty large and smooth brass ball, is usually affixed, and from this ball the longest and densest spark can be drawn; the greatest endeavour of the electric fluid to escape from the prime conductor being made at that extremity. In plate machines, viz. where glass plates are used instead of a globe or cylinder, the extremity of the prime conductor is furnished with two semicircular projections, which carry the collecting points at their extremities. The size of the prime conductor must be proportionate to the size of the machine; for if the prime conductor be too small, the sparks that are drawn from it will not be of the largest size possible to be obtained with that machine; and, on the other hand, if the prime conductor be too large, the dissipation of electricity from its surface will be very considerable. It is difficult to determine the exact size which might be the most advantageous for a given machine; for even with cylinders of the same size, different prime conductors might be used, according as the glass cylinders are more or less capable of a vigorous excitation. With one of the largest glass cylinders ever made in this country, which measured two feet in diameter, a prime conductor of wood covered with tin-foil was used, which measured six feet in length and 18 inches in diameter. With a small machine, the cylinder of which was seven inches in diameter, a prime conductor of two feet by three inches and a half was found the most advantageous. When the electrical machine is to be used only for charging a battery, then it will be better to use a very small prime conductor.

The forms of the above-mentioned prime conductors are represented in the various plates relating to electricity that are contained in this work.

CONDUCTOR of *Lightning*. See CONDUCTORS.

CONDUCTOR, in *Surgery*, is an instrument which serves as a guide for a scalpel, in several operations which do not allow the surgeon's discerning the exact course or extent of a wound. For instance, in opening a fistulous orifice, or dilating the abdominal ring in a strangulated hernia.

Conductors are either made of steel or of silver; and always have a groove on one side, to direct the cutting instrument. That which surgeons employ in cutting for the stone is named a GORGET. This is an instrument generally made of steel, and introduced, in the operation of Lithotomy, through the artificial orifice, into the bladder, in order to widen the neck of the bladder, and facilitate the introduction of the forceps, with which the stone is to be extracted. There are two species of this instrument; the one, which is provided with a knob at the top, is termed the male gorget; and the other with an excavation, the female gorget. See LITHOTOMY.

There is also a machine invented by Mr. Walker, by means of which, a patient labouring under a simple or compound fracture of the leg, may be conducted with safety and convenience from one place to the other, and the extremities of the bones kept in their proper situation during the progress of the cure.

To this head belong the conducting apparatus invented for the same purpose by Mr. Theden of Prussia, which are used in fractures of the superior and inferior extremities. Machines adapted for fractures of the femur have been described by Mr. Schmucker, and those for other parts by Mr. Theden himself. Mr. Richter conceives that these

machines may be rendered more serviceable, by constructing them of tinned iron, instead of walnut-tree wood.

CONDUCTORS. In two important branches of natural philosophy, a marked distinction has been observed between the various known bodies of the earth; and upon the peculiar properties of the two different classes of bodies, which are discriminated from each other by the above-mentioned distinction, numerous phenomena, of consequence to the human species, are absolutely depending. The two branches, of natural philosophy, above alluded to, are the science of electricity and the subject of heat. In electricity, if an excited piece of glass, or an electrified conductor, be touched with the extremity of a stick of sealing-wax, which a man holds by its other extremity; or if it be touched with the extremity of a silk string, the electric power will not be dissipated; but if the electrified body be touched with the extremity of a rod of iron or brass, held in a manner similar to the stick of sealing-wax, the electric power will be instantly dissipated; viz. it will pass through the metallic rod, and through the person that holds it, &c. Hence it evidently appears, that iron or brass will permit the transition of the electric power through its substance; whereas sealing-wax or silk will not permit it. Therefore, iron, brass, and all those substances through which the electric power can be transmitted, are called *conductors of electricity*; and all those substances, which, like the sealing-wax or the silk, will not permit the passage of the electric power, are called *non-conductors of electricity*.

A similar distinction has been remarked in the subject of heat and cold. Take a small piece of charcoal, make it red hot at one end, and in that state it will be found that a person may hold it with his fingers within about a quarter of an inch of the red hot extremity, without feeling any unpleasant degree of heat; but if an iron rod as thick as the charcoal be rendered red hot at one end, a person will not be able to hold it within less than four or five inches, at least, of that end; and such is the case with all metallic bodies, as well as with some other substances; which shews that heat will pass through certain bodies much more easily than through others. Hence those bodies which, like the iron rod, will easily transmit the heat through their substance, are called *conductors of heat*; and those which will convey it with great difficulty, are called *non-conductors of heat*. It must be observed, however, that though heat will pass incomparably more easily through certain bodies than through others; yet there are no bodies that are known to be either perfect conductors or perfect non-conductors of heat. And indeed, the like observation, though in a much more limited manner, may be made with respect to the conductors of electricity.

In magnetism also, the name of *conductor of that power* has been given to a single substance, namely, to soft iron; but the peculiar nature of iron in that respect, or rather the passage of the magnetic power, will be explained under the article MAGNETISM. We shall now in an orderly manner state the various particulars which have been ascertained with respect to the above-mentioned two classes of bodies; viz. first with respect to electricity, and then with respect to heat.

CONDUCTORS of *Electricity*. In endeavouring to point out the true nature of electrical conductors, it becomes necessary to give a list likewise of the non-conductors of that power, since these two classes of bodies gradually approach each other, in proportion as they are less perfect of their kind, as far as certain substances, which seem to stand in an intermediate state between conductors and non-conductors, so as to participate of both. Glass, sealing-wax, amber,

CONDUCTORS.

fluk, and several other bodies, which, by means of friction with a dry and clean hand, are capable of being excited, so as to exhibit electrical phenomena, are called *electrics*; and these identical bodies have been found to be non-conductors of electricity; hence *electrics* and *non-conductors* mean the very same class of bodies. In the same manner it has been found, that those bodies, which will easily transmit the electric fluid through their substance, cannot be excited in the above-mentioned manner; hence *conductors* and *non-electrics* do also denote the same bodies.

Strictly speaking, as we have already hinted above, there is no substance which may be called a perfect conductor or a perfect non-conductor of electricity; the electric power finding some resistance in its passage through the best conductors, and being in some degree capable of passing through the best electrics, at least under certain circumstances. The following lists contain the conductors and the electrics, or, which is the same thing, the non-electrics and the non-conductors. They are disposed in the order of their perfection; that is, the best conductors and the best electrics are placed at the heads of their respective lists; and those which participate of both, meaning those which are partly electrics and partly conductors, will be found towards the end of each list. In this, however, no great accuracy must be expected; first, because a very accurate discrimination is impracticable when substances are expressed under general denominations; and, secondly, because the precise degree of conducting or non-conducting power in most substances cannot be determined on account of their fluctuating nature.

Conductors.

Gold.
Silver.
Copper.
Platina.
Brass.
Iron.
Tin.
Mercury.
Lead.
Semi-metals.

Metallic ores; of which the best are those which contain a greater proportion of metallic parts, and nearest to a genuine state.

Charcoal, either of animal or vegetable substances. The conducting power of charcoal is very equivocal; for some pieces of it will hardly conduct at all, and others will suffer the passage of the electric fluid over their surface only, and not through their substance. The reason of this difference is not quite understood; but it seems owing to the degree of heat that is applied in the process of making them. See Priestley's second volume of Observations on different Kinds of Air, sect. xiv.

Animal fluids.
Acids.
Saline substances.
Hot water.
Cold water.

Salt water.
All other liquids excepting oils.

Red-hot glass.
Melted resin.
Flame, or the effluvia of flaming bodies.

Ice and snow; but not below a certain temperature; for Mr. Achard, at Berlin, in January 1776, observed that

frozen water, or ice, at the temperature of 25° below 0° of Reaumur's scale (equal to -13° of Fahrenheit's) was become an electric. He tried his experiments in the open air, where he found that a rod of ice two feet in length, and two inches thick, was a very imperfect conductor at the temperature of 6° below 0° of Reaumur's thermometer, and that it would not conduct in the least at 20° below 0°. By whirling a spheroid of ice in a proper machine, he even electrified the prime conductor, so as to attract, repel, give sparks, &c., like any other electric.

Most saline substances, of which the metallic salts are the best.

Earthy and stony substances, of which the hardest are the worst.

Glass filled with boiling water, as mentioned by Kinnelley.

Smoke.

Vapour or steam of boiling water.

All compounds, in which different proportions of the above-mentioned substances enter, are conductors in different degrees.

An imperfect vacuum, or the absence of air produced by the action of an air-pump. But a perfect Torricellian vacuum is not a conductor of electricity. Mr. Walsh, assisted by Mr. De Luc, having made a double barometer, in which the mercury had been accurately boiled, so as to expel all the air from the tube, found that the vacuum in the arched part of this double barometer was not a conductor of electricity, nor any electric light could be seen in it. (Priestley's Experiments and Observations on Elastic Fluids, vol. i.) This remarkable discovery was afterwards confirmed by the experiments of Mr. Morgan. (Phil. Trans. vol. lxxv.)

Electrics.

Glass, and all vitrifications, even those of metals.

All gems, of which the most transparent are generally the best.

All resins and resinous compounds.

Amber.

Sulphur.

Baked wood, if not suffered to imbibe moisture.

All bituminous substances.

Wax.

Silk.

Cotton.

All dry and external animal substances, as feathers, wool, hair, &c.

Paper.

White sugar and sugar-candy.

Air, and other gases.

Oils.

Dry and complete metallic oxides.

The ashes of animal and vegetable substances.

All dry vegetable substances.

All hard stones, of which the hardest are the best.

Soft stones when heated, according to Delaval.

Powders not metallic, according to Delaval.

Ice, at the temperature of -13° of Fahrenheit's thermometer, according to Achard.

According to Mr. Walsh's, and Mr. Morgan's experiments, the Torricellian vacuum ought to be placed at the head of the list; but the singular nature of a vacuum, though a non-conductor, will hardly entitle it to the name of an electric. We must, however, refer all farther observations, respecting *electrics*, to the article of that denomination; the

the above list having been inserted in this place merely to elucidate the nature of conductors.

Thus far we have stated the number of conductors, and their gradation, with respect to common electricity; but that lately discovered branch of this science, which is at present assiduously cultivated under the title of Galvanism, has pointed out a peculiar arrangement of conductors with respect to the order of their capability of conducting that power which affects the limbs of a prepared animal, and of conveying the power of a galvanic, or rather a Voltaic, battery. See the article GALVANISM. Concerning the former of these powers, we transcribe a list, followed by a few remarks, from Cavallo's Treatise on Electricity, 4th ed. vol. iii. p. 20; and with respect to the latter, we subjoin an abridged extract from a paper of Erman, in the *Annales de Chimie*, Feb. 1807.

Conductors of Animal Electricity, according to Dr. Lind's and Mr. Cavallo's experiments, which however are arranged with diffidence by the latter, considering the difficulty of making the arrangement, and that, in this branch of electricity, the metals do not seem to act merely as conductors—The list begins with the best.

“ Malleable platina.

Silver.

Gold.

Quicksilver.

Copper.

Brass.

Tin.

Lead.

Iron.

The human body.

Salt water.

Fresh water.”

“ The metallic ores are not so good conductors as the purified metals themselves, and their conducting power is various according to the nature of the ores, but even the metallic salts are tolerably good conductors.

“ It is very remarkable, that the flame of tallow candle, which is a good conductor of common electricity, will not conduct the animal electricity, when placed in a short interruption made in the circuit of communication. Charcoal, placed in the same situation as the flame of the candle, was also found to be a non-conductor, except when it was actually burning, in which state it conducted tolerably well; but Mr. Volta says that he has found some pieces of charcoal that acted as well as the metals. Dr. Valli observed, that human bodies are not all equally good conductors. Out of four persons in a company, he found that when two of them formed the circuit of communication between the nerve and the muscles of a frog, the motions took place very readily. When a third person formed the circuit, the motions were very weak; but that when the fourth person formed the communication no motion took place. This experiment, he adds, was often repeated with the same success. The effect, however, may be owing to the different dryness of the skin. Vitriolic acid, and what is very remarkable, alcohol, appear to conduct this property rather better than water.

“ The arteries and the veins are not so good conductors as the nerves; for when a blood-vessel forms part of the circuit of communication, the contractions will take place only when nervous ramifications are adhering to it, and if these be carefully separated, the motion will not take place. The same thing may be said of the tendons, the bones, and the membranes; for when either of those parts

is separated from the body, and is introduced in the circle of communication between the muscles and nerves of a prepared frog, no motion will ensue, excepting, indeed, when those parts are full of moisture, and are in immediate contact with the nerve of a prepared frog. Dry nerves are not conductors of animal electricity. Dr. Valli found that the internal substance of a nerve conducts much better than its external, or coat.”

Silver and zinc, professor Aldini says, will produce contractions in the muscles of a frog, many hours after it has become insensible to the action of either of them, separately used.

Mr. Erman, in his paper on two new classes of galvanic conductors, says that the bodies which may be applied to the poles of a galvanic pile are, I. *Non-conductors*. II. *Conductors*. The conductors are either *perfect* or *imperfect*; and the imperfect conductors are so, either with respect to both poles, or with respect to one of the poles of a galvanic battery.

I. The *perfect non-conductors* prevent the communication of the power of both poles effectually; and such are glass, resins, ice, and the vapour of water, sulphur and its flame, amber, but not its flame.

II. The *perfect conductors*, which discharge both poles completely, are the metals, and all in the same degree.

The *imperfect conductors of both poles*. These, though capable of forming the galvanic circuit, exhibit in their extent effects of two different kinds. Fluid water and bodies impregnated with water are of this nature.

The *imperfect conductors of the positive pole only*. These are incapable of forming the galvanic circuit; for when interposed between the two poles of the pile, they insulate the negative power and conduct the positive; whence it follows, that the negative becomes charged, whereas the positive is conducted. The flame of hydrogen gas, and the flame of the hydrocarbonated bodies, have this property.

Lastly, the *imperfect conductors of the negative pole only* insulate the power of the positive, and conduct the power of the negative pole. Of this sort are the flame of phosphorus and of alkaline soaps.

There now remain two other particulars, which demand our examination with respect to the conductors of electricity. These are the method of ascertaining their peculiar degrees of conducting power, and their uses. The simplest method of determining whether any given body be a conductor or not, is to affix an electrometer to the prime conductor of an electrical machine, and when the machine is in action, and of course the electrometer is diverging, to touch the prime conductor with one extremity of the given body, which the operator holds in his hand by the other extremity; for if, in so doing, the electrometer collapses, the body in question is a conductor; but if the electrometer continues to diverge, that body is a non-conductor. Its degree of conducting power may also be, in great measure, estimated from the quickness with which the electrometer loses its divergency. In the performance of this experiment, the operator should take care that the electric fluid does not run over the surface of the body under trial to the hand that holds it, which generally takes place when the machine acts powerfully, and the body in question is not much extended. In this case, it becomes proper to stop the revolution of the glass globe or cylinder, when the body is to be put in contact with the prime conductor. But if the body be very small, it will be sufficient to use a simple electrometer only, which may be easily caused to diverge by means of an excited stick of sealing-wax, and may then be touched with the body in question. Yet all this is not sufficient,

sufficient to discriminate the peculiar powers of substances that are of the same class, such as the various metallic substances, the different stones, &c. And for this purpose various other means may be adopted, according to the nature of the bodies under examination. The best way of determining the peculiar conducting powers of metallic substances, is to have wires of the different metals drawn through the same hole, so as to be precisely of the same diameter, and then melt them by the discharge of a battery; *viz.* take a wire, of about one-fiftieth of an inch in diameter, and connect it with the outside of a battery, containing at least thirty square feet of coated surface, and connect the other extremity of the wire with one branch of the discharging rod. Then, when the battery is charged, touch the wires which proceed from the inside of it with the other branch of the discharging rod, which will force the explosion to pass through the wire that has been interposed between the battery and the discharging rod, generally melting a greater or a smaller part of it, according to the nature of the metal. Thus by repeating the experiment successively with wires of the same length and diameter, but of different metallic substances; charging the battery constantly to the same height, which may be easily accomplished by means of a quadrant electrometer; and measuring the length of each wire that has been melted by the explosion; their various conducting powers may be ascertained; observing that the worst conductors are more easily melted, and *vice versa*. Mr. Henley found that the same charge melted $\frac{1}{4}$ inches of gold wire, 6 of brass, 8 of silvered copper, 10 of silver, and rather more than 10 of iron. In melting wires of a considerable length, as for instance two or three feet, it often happens that the force of the explosion barely renders it red hot, without actually melting it. In this case, it is curious to observe that the redness appears first on that extremity of the wire which communicates with the positive side of the battery, and thence proceeds towards the other end of the wire, which shews an ocular proof of the theory of a single electric fluid; the wire, however, is not rendered red hot at one extremity before the other, in consequence of the progressive motion of the electric fluid through it, but because that fluid loses some of its impetus in going through the wire, so that the wire suffers the greatest effect of the shock on that end which the electric fluid enters; in consequence of which, that same end will be rendered red hot much sooner, and in a greater degree, than those parts which are more remote from it.

When the conducting powers of different fluids are to be ascertained, the best method of performing the experiment is to fill very narrow glass tubes, such as are used for spirit thermometers, with the fluids in question, introducing a pin at each end of the tubes; and to present them successively to the prime conductor, after the manner already described. For other kinds of bodies other methods may be adopted for ascertaining their conducting powers. These, however, need not be particularly described; first, because they may be easily derived from those that have been described above; and, secondly, because they must be varied according to the nature of the bodies in question. After all, it must be acknowledged, that the metals excepted, no very great degree of accuracy can be expected with other substances; since the fluctuation of their conducting powers arises from a variety of slight, and almost imperceptible differences, such as the difference of temperature, of moisture, of admixture with other substances, &c. Thus, glass itself becomes a conductor, when heated to a certain degree; and the very same body will conduct more or less readily, even by being placed nearer to or farther from certain other bodies.

In considering the conducting power of natural bodies, one may naturally ask, whence does that property arise; or how is it, that certain bodies will, whilst others will not, conduct the electric power? The present state of knowledge, however, does not afford a satisfactory answer to this question. Various suppositions have been offered by the late Dr. Priestley and others; but as they are insufficient for the explanation of the phenomena, we shall not attempt to state them in this place.

The uses of conductors are remarkable and extensive, though they are not yet fully ascertained to the entire satisfaction of the speculative philosopher. In the first place, the science of electricity, or the existence of the electric power, would be absolutely unknown, were it not for the difference of conducting and non-conducting bodies; for otherwise the electric fluid which is manifested to us, and operates merely by its passage from one body to another, could neither be confined nor accumulated in any place; in consequence of which, its uniform dispersion throughout the universe would remain inactive and unperceived. But the movements of conducting and non-conducting bodies in the world, their contact, or even their approach without any actual contact, condenses the electric fluid in one place, and rarefies it in another; and this takes place between the clouds and the earth, &c. By the change of their states of existence, some bodies absorb from other bodies; and others deposit upon other bodies considerable quantities of electric fluid. Thus, a perpetual and ample circulation of that fluid is continually kept up amongst all the substances of the terraqueous globe, whence thunder and lightning, vaporization, and probably several other important operations of nature, are derived. In order to understand the action of conductors when opposed to each other, see the nature of electric atmospheres under the article ELECTRICITY.

The greatest advantage which mankind have derived from the knowledge of the present subject, is the adoption of a conductor for the preservation of buildings and vessels against the dire effects of lightning. The identity of electricity and lightning proved by Dr. Franklin, and his subsequent introduction of conductors for preserving buildings, form two of the greatest discoveries of the last century. It was proposed by the above-mentioned philosopher to raise a metallic conductor some feet above the highest part of the building, to continue the same down along the outside of the wall, and below it, deep into the earth, or, which is preferable, to connect it with some well or drain. By these means the house would have little to apprehend from a stroke of lightning; for, since an electrified body is well known to strike the nearest and best conductors that may happen to be in its way, it is evident that the conductor situated in the above-mentioned manner, being of metal, and higher than any part of the building, would naturally be struck by the lightning in preference to any other part, and would conduct it to the ground, without any damage to the building.

This reasonable proposal was no sooner offered by the sagacious Franklin, than it was adopted in America, in Europe, and elsewhere. Numerous facts soon proved the usefulness of such conductors, and extended its adoption; by shewing that several houses, which before had been repeatedly struck by the lightning, escaped unhurt after the application of the conductor; that, in many places, the conductors of houses were actually struck by the lightning, which melted them about their extremities, yet the houses themselves received no injury; and so forth.

Though the conductors were instantly adopted, yet their
most

most useful form, especially with respect to their upper termination, has been much controverted; and it is but lately that the true state of the question has been elucidated. The question was, whether the conductors should terminate in a point, according to Dr. Franklin's original proposal, or in a ball. Mr. B. Wilson exhibited some experiments, in which a point was struck at a greater distance than a ball; whence he concluded, that as the point would attract the lightning from a greater distance, a blunt termination ought to be preferred, since, in certain cases, it would avoid a stroke of lightning, which the pointed termination would not. (Phil. Transf. for 1778). Mr. Nairne, on the other hand, shewed some experiments, in which a ball was struck in preference to a point. And this indeed is confirmed by a great variety of other experiments. In short, a pointed conductor will draw the electric fluid from an incomparably greater distance than a blunt one; but it will draw that fluid gradually, in a stream, or silent manner; whereas the blunt termination will receive it in a full spark, or at once; hence a pointed conductor will tend to diminish the quantity of electricity in a cloud, previous to its coming too near, and thus it may protect a greater extent of building than a conductor with a blunt termination, since the object of fixing a conductor to a house is to protect the house from the effects of lightning, and not the conductor from transmitting the matter of the lightning.

Upon the whole, considering the immense quantity of electricity in a thunder cloud, and the little difference between the action of a blunt or a sharp conductor with respect to that quantity, the difference of those terminations seems to be of less consequence than it was apprehended in the fervour of the dispute. After all the experiments and the discussions made for the purpose, "A conductor," Mr. Cavallo observes, "to guard a building, as it is now commonly used in consequence of several considerations and experiments, should consist of one iron rod, (copper would do much better, it being a more perfect conductor of electricity, and at the same time not being subject to contract rust so soon as iron), about three quarters of an inch thick, fastened to the wall of the building, not by iron cramps, but by wooden ones. If the conductor were quite detached from the building, and supported by wooden posts at the distance of one or two feet from the wall, it would be much better for common edifices; but it is more particularly advisable for powder magazines, powder-mills, and all such buildings as contain combustibles ready to take fire. The upper end of the conductor should be terminated in a pyramidal form, with the edges, as well as the point very sharp; and if the conductor be of iron, it should be gilt or painted for the length of one or two feet. This sharp end should be elevated above the highest part of the building, (as above a stack of chimnies, to which it may be fastened), at least five or six feet. The lower end of the conductor should be driven five or six feet into the ground, and in a direction leading from the foundations; or it would be better to connect it with the nearest piece of water, if any be at hand. If this conductor, on account of the difficulty of adapting it to the form of the building, cannot conveniently be made of one rod, then care should be taken, that where the pieces meet they be made to come in as perfect a contact with one another as possible; for the electricity finds considerable obstruction where the conductor is interrupted. For an edifice of a moderate size, one conductor, in the manner already described, is perhaps sufficient; but, in order to secure a large building from sustaining any damage by lightning, there should be two, three, or more conductors, in proportion to the extent of the building.

"In ships a chain has often been used for this purpose,

whence, on account of its pliability, has been found very convenient, and easy to be managed among the rigging of the vessel; but as the electricity finds a great obstruction in going through the several links, for which reason chains have been actually broken by the lightning, so their use has now been almost entirely laid aside; and in their stead, copper wires, a little thicker than a goose-quill, have been substituted, and have been found to answer very well. One of those wires should be elevated two or three feet above the highest mast in the vessel; this should be continued down the mast, as far as the deck, where, by bending, it should be adapted to the surface of those parts, over which it may most conveniently be placed, and, by continuing it down the side of the vessel, it should be always made to communicate with the water of the sea."

Another precaution must be added to the above directions, which is, that a communication should be made between the conductor, and all other pretty large pieces of metal in the building, such as leaden spouts, large iron clamps, &c.; for otherwise a lateral explosion may take place between those detached pieces of metal, at the time that the lightning is conveyed by the conductor, and thence the building may receive some damage, though not in a very great degree, unless indeed in case of powder mills and powder-magazines. See LATERAL EXPLOSION.

It is owing to this circumstance, that some buildings furnished with a conductor or two, are said to have been struck and to have been damaged by a stroke of lightning. See Phil. Transf. vol. lxxii.

The size of the conductor, as recommended in the preceding paragraphs, has by some been thought too small for the purpose; and an instance is recorded of a conductor of iron, four inches wide, and half an inch thick, which is said to have been made red hot by a stroke of lightning. But with respect to this remark, we shall briefly observe, that should any person think that the conductor, as directed above, is not large enough, the enlargement of its size is attended with no other inconvenience than an increase of expence. However, though a conductor be made red hot, and even melted by a stroke of lightning, yet it will essentially convey that stroke of lightning to the ground without any material injury to the building, as has been sufficiently proved by experiments with artificial electricity, as well as with cases of conductors partly melted by the lightning.

CONDUCTORS of heat. When a congeries of bodies remains long in a given degree of temperature, these bodies will all acquire the same apparent degree of heat; that is, the thermometer placed in contact with any of them, will rise to the same degree; and in this case of equilibrium there is no reason to believe that any heat, or of caloric, passes from one body to another; but if a body, at a certain temperature, be placed amongst bodies of a different temperature, the caloric will, in this case, be communicated from the former to the latter, or *vice versa*; according as the temperature of the former is higher or lower than that of the latter. This communication or passage of heat from one body to another, is made either by *contact* or by *radiation*.—By *contact*, when the bodies, which are contiguous to the hotter one, are progressively heated; *viz.* the nearest first, and then those which are farther off, without any interruption; as when a red-hot piece of iron is placed amongst other pieces of colder iron, the heat is gradually communicated from the red hot one to the others.—By *radiation*, when the heat from a hot body passes through a vacuum, or through transparent bodies, which are not heated by it, yet it elevates the temperature of bodies placed at some distance. Thus, the solar heat radiates freely through
air,

air, glass, water, &c., and heats opaque bodies without sensibly affecting the transparent bodies through which it passes. Thus also, a thermometer suspended under the exhausted receiver of an air-pump, or in the Torricellian vacuum, continues to vary its temperature with that of the surrounding bodies.

In the communication of heat from one body to another, when a third body is interposed, it has been observed that the transition of heat is much quicker when certain bodies are interposed, than when other bodies are placed between; but there are no bodies known which prevent that transition effectually; hence the bodies of the universe are distinguished into more or less perfect conductors of heat, but they afford no instance of a perfect non-conductor.

The transmission of heat from a solid at a higher degree of temperature, to another at a lower one, in a given time, is nearly proportional to the difference of their temperatures. But the velocity with which heat is propagated through the substance of different bodies, varies considerably according to the nature of those bodies. In general, metallic bodies are the best conductors of heat; stones, or hard earthy bodies come next; then the vitreous substances, and the resinous. Dry animal parts, excepting bones, and especially dry and light vegetable bodies, are bad conductors of heat. The conducting power of liquids is of a particular nature, which will be mentioned presently. But the different bodies of the same class differ considerably in conducting power. Thus the metals possess it in different degrees, and their proportional powers were thus estimated by Dr. Ingenhousz. He procured equal cylinders of several metallic substances, and having coated them with wax, he plunged their extremities in hot water, and judged of the conducting power of each, by the length of the wax-coating that was melted. The result of these experiments is expressed in the following Table, which commences with the best conductors. Journ. de Phys. 1789, p. 68.

Silver.	} nearly equal.
Gold.	
Copper.	
Tin.	
Platina.	
Iron.	} much inferior to the others.
Steel.	
Lead.	

In the same paper, the proportional conducting powers of three fluids are stated in the following manner:

	<i>Equal bulks.</i>	<i>Equal weights.</i>
Water - - -	1.	1.
Mercury - - -	2.	4.8
Linseed oil - -	1.111	1.085

The conducting power of the same body does not remain invariably the same in all circumstances; but it differs, according as the body changes its state of existence, so that the conducting power of a body in a solid state is different from that of the same body in a fluid state. And at the time of changing its state of existence, the conducting power in most cases ceases altogether. Thus, at the temperature of 60°, sulphur is a conductor; but when heated to 212°, at which point it melts and becomes volatile, it is no longer a conductor. Thus also, ice conducts at the temperature of 20°, or at any other temperature below the freezing point, which is 32°; but at that point it ceases to be a conductor, because the heat which may be communicated to it is absorbed as an ingredient necessary to its fluid state, which it assumes at, or little above, that point.

Rarefaction or condensation alters the conducting powers of several bodies. Yet the rarefaction of air is by no means accompanied with a proportionate diminution of its conducting power.

Professor Pictet supposes that heat ascends within solid bodies more readily than it descends; viz. that in communicating heat to a solid body by the lateral application of a hotter body, the upper parts of the former are heated sooner than the lower. This effect, however, may with propriety be attributed to the ascending current of heated air which rises along the surface of the body, and causes colder air to approach the lower part of the body; hence the heat is continually carried upwards.

The conducting power of a body changes likewise, in consequence of an alteration of the surface; so that polish and figure are likewise concerned in the reception as well as in the propagation of heat. These particulars, however, together with the reflection and refraction of heat, from the surface or through the substance of bodies, will, with more propriety, be explained under the article HEAT.

Fluids are, upon the whole, very imperfect conductors of heat, and Count Rumford was led, by his experiments, to conclude that heat is not at all propagated through them by contact, as it is in solids. (See Rumford's paper on the Conducting Property of Fluid, &c. Phil. Trans. 1805.) Whatever permits or promotes the motion of the particles of a fluid, contributes to the propagation of heat;—whatever obstructs that motion, retards the propagation of heat through them. The particles of air which come in contact with an heated body, being thereby heated and rarefied, become specifically lighter than the surrounding air, and of course ascend; other air then comes in contact with the heated body, and this also being heated is caused to ascend, and so forth. Thus is heat conveyed from the original hot body, by the air, to a distance from it; but if that motion of the air be obstructed, as by the interposition of partitions of paper, wool, cotton, furs, and the like, then the communication of heat is prevented more or less effectually. It is principally on this account, that furs, feathers, eider down, cotton, and other similar things, form warm coverings; viz. because, by preventing in great measure the motion of the air between their filaments, they prevent at the same time the dissipation of heat.

The like observations are applicable to water, and perhaps to all other fluids. When a vessel full of water is set upon the fire, the particles of water that are close to the bottom of the vessel are first heated and rarefied; in consequence of which they ascend, and other colder particles take their place, which, being heated, likewise ascend, and so on. If the fire be applied to the upper part of the water, the fluid will not be heated, or at most it will in a very slight degree. Count Rumford (see his 7th Essay) confined a piece of ice at the bottom of a pretty tall glass vessel full of water nearly boiling, and noted the time it took up to melt the ice. The experiment then was repeated with this difference, viz. that a similar piece of ice was placed on the surface of the hot water, instead of the bottom. It was found that the ice melted more than eight times quicker in this last situation than in the former. The result of this remarkable experiment is explained in the following manner. When the ice swims on the surface of the hot water, the particles of the latter, that are contiguous to the ice, being cooled by it, descend, and other hot particles of water take their place, which deposit their heat upon the ice, and being thereby rendered specifically heavier than the next particles of water also descend, and so forth. But when the ice is confined a,

the bottom of the vessel, the particles of hot water which come first in contact with it, are cooled, and are rendered specifically heavier, in consequence of which they remain in their place, and no motion will take place within the water; hence the ice is not melted nearly so readily as in the former situation. Now count Rumford contends that it is by means of the above-mentioned motion only that heat is propagated through fluids, and not otherwise. This conclusion was no sooner published to the scientific world, than it was opposed in an able manner by very skillful philosphers. See Dalton's paper. Nich. Journ. vol. iv. p. 75. Traill's paper, *ibid.* for 1805, p. 133; and Murray's paper, *ibid.* vol. i. From these papers we shall make the following abridged extracts, which seem necessary for the elucidation of the subject; and in the first place we shall state Mr. Murray's experiments.

Into a glass cylindrical vessel water was poured, till it covered the bulb of a thermometer; its temperature was 46°, which was likewise the temperature of the air of the room. One ounce of olive oil, heated to 140°, was poured on a small piece of cord, suspended on the surface of the water, and the cord was slowly withdrawn. Any motion of the water was thus avoided. In the course of a minute the thermometer began to rise slowly; in five minutes from the commencement of the experiment, it had risen 4°, in ten minutes 6½°, in fifteen minutes 8°. It then became stationary, and continued so for seven minutes, before it began to fall. Its descent was slow. This experiment was repeated with a hot metallic ball (instead of oil) immersed in the water above the thermometer, and it was attended with a similar effect.

From these results the conclusion might seem just, that the fluid must possess a conducting power. Yet this is rendered doubtful by the circumstance, that in all experiments of this kind, a quantity of caloric must be conveyed by the sides of the vessel. In order to avoid this source of error, Mr. Murray employed a vessel of ice. But water could not be used in this case, because that fluid expands from 40° to 32°; therefore oil and mercury were used.

A quantity of almond oil was poured into the ice vessel, so as to cover the bulb of the thermometer a quarter of an inch. A small cylindrical iron cup, two inches in diameter, and having a flat bottom, capable of holding two ounces by measure, was suspended so as merely to touch the surface of the oil, and was filled with boiling water. At the beginning of the experiment, the thermometer stood at 32°. In a minute and a half it had risen to 34½°, in three minutes to 34½°, in five minutes to 36½°, in seven minutes to 37½°. At this point it became stationary, having risen 5½° in seven minutes. The temperature of the water in the cup had in this time fallen to 66°. The thermometer, after remaining stationary at 37½° for six minutes, began to fall, and it continued to descend at the rate nearly of a degree in a minute and a half, till it returned to 32°. The experiment was repeated with this variation, *viz.* that the thermometer was placed lower, so that half an inch of oil stood over its bulb. It was also repeated with mercury instead of oil. But in both cases the results were similar to that of the first experiment.

"This rise," Mr. Murray says, "it appears to me impossible to ascribe to any other cause than to a power in the fluid to conduct caloric. Thus it is evident, that the sides of the vessel could not convey to the fluid in contact with the bulb of the thermometer any part of the caloric it received. Ice, in common with any other solid, may, at temperatures below its melting point, conduct caloric; but as it cannot possibly exist with a temperature above 32°, it cannot communicate any temperature above that to a fluid in contact with it, and consequently it could not contribute in the

above experiment to raise the thermometer above that temperature. Caloric does not radiate through transparent fluids, and it cannot even be supposed capable of passing by radiation through an opaque fluid as mercury.

If it be proved that oil and mercury are capable of conducting caloric, it will be admitted as sufficiently probable, that other fluids may have a similar power. Of these two, mercury, it is probable from these experiments, is the best conductor, as the rise of the thermometer took place in it much more rapidly than in the oil."

Dr. Traill's experiments for ascertaining the conducting powers of divers fluids, were performed in the following manner.

A cylindrical vessel was turned out of wood, having its sides half an inch thick, its height four inches and its diameter two. It has a moveable wooden top or cover, perforated with a hole in its centre, a little more than an inch in diameter, into which an iron cylinder, of one inch in diameter, could be easily introduced. This cylinder is supported by a slight flanch, or shoulder-piece, and can be taken up by means of a string attached to its top. When the iron bar is in its place, its flat lower extremity is half an inch distant from the bulb of a delicate mercurial thermometer, which is fixed by wax in a hole perforating the cylinder near its bottom. This thermometer is bent to a right angle, so that its bulb and part of its stem lie in the axis of the wooden cylinder. This shape was preferred, because the stem could be little affected by the caloric transmitted by the sides of the vessel, till after the bulb was acted on by the caloric of the iron bar.

A variety of experiments was performed with this apparatus in the following manner: The temperature of the room being steadily 67° Fahr. therm.; during the trials, a kettle of water was kept boiling over the fire. Its temperature was between 210° and 212°, and in this the cylinder of iron was suffered to remain, at each experiment, for fifteen minutes. The liquid to be examined, and all the apparatus (but the iron bar) were at each experiment ascertained to be at 67°. The liquid was poured into the wooden vessel, till it could rise 1/16 of an inch on the side of the iron cylinder when in its place. The wooden top was put on, and the iron was drawn out of the kettle of boiling water by means of the attached string, and instantly let down through the hole of the cover. The time the thermometer took to rise through 3° (*viz.* from 67° to 70°) was accurately marked by means of a stop-watch, and the results of the experiments on several fluids, are exhibited in the following table.

Liquids.	Minutes.	
	Minutes.	Seconds.
Water	7	5
Cow-milk	8	25
Proof spirit	8	nearly
Alcohol. Lond. Pharmac.	10	45
Transparent olive oil	9	50
Mercury	9	15
Solution of sulphate of iron. Salt 1. Water 5.	8	
Saturated solution of sulphate of alumine	9	40
Saturated solution of sulphate of soda	6	30
Aqua potass. pura. London Pharm.	8	15
Saturated solution of sulphate of soda, but the liquid not touching the iron cylinder, by 1/16 of an inch, or nearly so	19	20

"If I am not deceived," says Dr. Traill, "we may conclude, from what I have above adduced, that liquids, as well as solids, are conductors of caloric; that the transmission of it through them follows a particular law depending on the properties of the particular liquid; but which is not in the exact ratio of any of their mechanical properties, though nearer that of their density, than any other."

A circumstance, deserving the attention of the speculative philosopher, respecting the conductors of electricity and of heat, has been observed; *viz.* that most of those bodies which are good conductors of the one, are likewise good conductors of the other. This law, however, is not without exceptions. Thus, metallic bodies are good conductors of both; but charcoal is a good conductor of electricity, though a very bad conductor of heat.

The last particular, which we shall briefly notice, with respect to the conductors of heat, is their use. This, on the least examination, will be found to be very extensive. Nature and art avail themselves of these peculiar properties of bodies, and without them both animal and vegetable life could not subsist. The atmospherical fluid which envelops the earth, is a very bad conductor of heat, undoubtedly created for the purpose of not dissipating the heat of the earth and terrestrial bodies. The coverings of animals, such as furs and feathers, being extremely bad conductors, confine the heat on the animal body. The bark and ligneous part of plants, in consequence of their imperfect conducting powers, tend to prevent the freezing of vegetable juices. The industry of man has not omitted to use the worst conductors of heat for coverings, for the defence of his habitations, for the confinement of heat in certain furnaces, &c. In short, numerous and admirable effects are deduced by Providence, and several essential advantages are obtained by art, from a proper application of the various conducting powers of natural bodies.

CONDUCTORS, in the *Military Art*, are assistants to the commissary of stores in conducting depots and magazines from one place to another. They take charge of the ammunition waggons in the field, make their reports to the commissary, and are under his authority and command.

CONDUCTOS *ad profectendum*, in *Law*. See *CAPAS*.

CONDUIT, a canal, or pipe, for the conveyance of water, or other fluid matter.

In the earth are several subterraneous conduits, through which the waters pass that form some *SPRINGS*; and through which also pass the vapours which form *METALS* and *MINERALS*.

Artificial conduits for water are made of lead, stone, cast iron, potter's earth, &c. See *PLUMBERY*.

In the province of New Mexico, there is said to be a subterraneous conduit, in form of a grotto, extending six hundred miles in length. See *DUCT. TUBE*, &c.

CONDUITE *d'une Troupe*. A *troop* that marches with always an officer, who commands independently of the other officers that may accompany it.

CONDUSKEEG, in *Geography*, a settlement of America, in the district of Maine and Hancock county, containing 567 inhabitants.

CONDYLÆ, in *Ancient Geography*, a town of Arcadia, near Caphia, and N.W. of Orchomenæ. In this town was a temple of Diana, and near it a grove. Pausanias.

CONDYLE, in *Anatomy*, an appellation bestowed on several projections of the bones.

CONDYLOMA, from *κόνδυλος*, *digitii articulus*, in *Surgery*. By this term is understood almost every hard excres-

cence or sarcoma, that appears in the parts about the anus and the pudenda of both sexes; which is generally painful, or at least troublesome, and sometimes of a venereal origin. According to the different forms which these excrescences assume, they are termed *condylomata venerea, verrucæ, framboesias*, &c.; however they do not essentially differ, being all of the same nature, and requiring the same mode of treatment. They are distinguished from the hemorrhoids by their situation, irregular form, the constant profuse which they produce, their generally fungous texture, and the foul matter which is frequently discharged from their surface, or by the venereal symptoms with which they are accompanied. In some cases they are not harder than the parts upon which they are situated; sometimes, however, they are harder than the most complete ferrinus. With respect to their colour, they are, in some cases, of a pale white, in others more or less red. Sometimes they are found single; but generally the whole of the parts about the anus becomes covered with them. Frequently they are not larger than common warts; which, when the disease has proceeded to a great height, become more numerous, and adhere to or are in contact with each other. In other cases, these excrescences are from the beginning broad and flat, and frequently of the size of a large bean split in half. Sometimes they hang, like figs, on a slender stalk. These excrescences are in general more troublesome than dangerous; however, the syphilitic virus by which they may have been produced is what is most to be feared.

In the cure of these excrescences, the principal object is to remove the cause, especially when of a venereal kind; and they are either local affections, or, which is sometimes the case, effects of a depraved state of the body. After the appropriate internal remedies (see *DYPHILIS*) have been administered, they frequently dry up of themselves, and when they remain, they must be treated with topical corrosive applications. When these excrescences are of a softer consistence, and their surface sore or ulcerated, we may mix *Aq. calcis*, with *Spir. vin. Camph.* and *Tinct. myrrhæ*, and apply this mixture several times a day to the excrescences, by means of a hair-pencil, or cover them with compresses dipped in it. Still greater effects are produced by the fine powder of faine sprinkled frequently upon them; this powder may also be mixed into an ointment with precipitate of mercury, and spread upon the excrescences. Or they may be sprinkled once or twice a day with the powder, and a saturnine cerate with opium afterwards applied. In various cases, the following corrosive wash of Mr. Pienk has been found the most effectual remedy: *R. Spir. Vin. rect. Acet. vin. concentrat. aâ ʒss. Merc. sublim. corrosiv. ʒj. Alum. crud. Camph. Ceras. aâ ʒss. M. D. S.* To be rubbed twice or thrice a day upon the excrescences, which are to be covered during the intervals with *Ungt. ex Hydrargyro*.

Frequently the excrescences disappear without suppurating, and the sound skin is not injured. Mercurial fumigations with cinnabar are likewise recommended as powerful remedies. The aqua phagedænica has sometimes been found very effectual in removing very small venereal warts.

If the excrescences do not yield to the use of any of these remedies, but remain hard, callous, and fungous, we may apply the following: *Triturate Merc. sublim. corrosiv. ʒss. in a marble mortar, and add gradually Spir. nitr. fumant. ʒss.* The application of this remedy, which is to be applied every day, or every other day, must be performed with the utmost caution, by means of a hair-pencil, with which it is to be rubbed upon the summit of the excrescence. We may also employ the *lunar caustic*, also the *lap. infern.* or *Butyr. antimon.*, which are likewise to be applied in a very cautious manner; and we ought particularly to take care

are not to let any part of them come into contact with the restum, which would produce very dangerous consequences. The extirpation by means of ligatures may be employed when the number of the excrescences is but small, and they hang by small stalks to the surface; for otherwise it is a painful remedy. The most certain method of removing them is by means of the knife, only they frequently grow again within a short time; nor ought this remedy to be employed in venereal cases, till a sufficient quantity of mercury has been administered. In cutting them off, all the adjacent diseased parts must be taken away: and in order to prevent inflammation, the blood may be suffered to flow for some time, after which the parts may be covered with lint, and treated as a common wound.

CONDYLON, in *Ancient Geography*, a fortress of Greece, between Connas and Tempé, towards Thessaly.

CONE, in *Geometry*, a solid body, having a circle for its basis, and terminated at the top in a point, or vertex. See *Plate I. Conics, fig. 4.*

The cone is generated by the motion of a right line, KM, round an immoveable point, K, called its *vertex*, along the circumference of a plane, called its *basis*, MN: or it may be conceived as generated by the revolution of the triangle, KLM, about the right line, KL, which is called the *axis* of the cone, and KM its *latus* or *side*. If the axis be perpendicular to the base, it is said to be a *right cone*: and if inclined, or oblique, an *oblique* or *scalenus* cone. *Scalenus* cones are again divided into *obtusè-angled*, and *acutè-angled*.

An *equilateral* cone, is a right cone, whose side is equal to the diameter of the base.

Euclid defines a cone a solid figure, whose base is a circle, as CD (*fig. 5.*), and is produced by the entire revolution of the plane of a right-angled triangle CAB, about the perpendicular leg AB.

If this leg, or axis, be greater than CB, half the base, the solid produced is an *acute-angled* cone; if less, it is an *obtusè-angled* cone; and, if equal, a *right angled* cone.

But Euclid's definition only extends to a *right cone*; that is, to a cone whose axis is at right angles to the base; and not to oblique ones, whose axis is not at right angles to the base.

For a more general and comprehensive description of a cone, which may take in both right and oblique ones, suppose an immoveable point A (*fig. 6.*), without the plane of the circle BDEC; and suppose a right line, AE, drawn through that point, and produced infinitely both ways, to be moved quite about the circumference of the circle; and the two superficies that will arise from this motion are each called *conic superficies*; but, taken conjunctly, they are called *superficies vertically opposite*, or only *opposite superficies*. The immoveable point, A, common to both the superficies, is called the *vertex*; the circle BDEC, the *base*; the right line AC, drawn through the vertex A, and C, the *centre of the base*, and if infinitely produced, the *axis*; and the solid, comprehended under the conical superficies and the base, is a *cone*.

CONE, *Properties of this.*—1. *The area or surface of every right cone, exclusive of its base, is equal to a triangle whose base is the periphery, and its height the slant side of the cone.*

Take the very small arc IK (*fig. 7.*), and draw AI, AK. Then the part of the surface AIK coincides with the small isosceles triangle AIK, whose base is IK, and height AI. In like manner, the whole surface of the cone may be supposed to consist of such triangles whose common height is AI, and bases so many KPs as are contained in the circumference of the base, all which triangles are equal to the triangle whose height is AI, and base, the sum of

all the KPs, or the circumference BKDB. Hence, the curve surface of a right cone is equal to half the rectangle of the side AB, and circumference of the base, BKDB. For the half of that rectangle is equal to a triangle of the same base and height. Moreover, the curve surface of a right cone is equal to a circle, whose radius is a mean proportional between the side AB, and the radius of the base BC. For the conic surface is = $\frac{AB \times BKDB}{2}$, and the

area of the base BD = $\frac{BC \times BKDB}{2}$ (see *CIRCLE*).

Let the radius, R, represent the mean proportional between A B and B C, or let $R = \sqrt{AB \times BC}$; and the area of the circle whose radius is R = A. Then the conic surface : circle BD :: $\frac{AB \times BKDB}{2}$: $\frac{BC \times BKDB}{2}$::

A B : B C :: A B × B C : B C²; and the circle B D : circle A :: B C² : R² or A B × B C : consequently the conic surface : circle A :: A B × B C : A B × B C, which is a ratio of equality: therefore the conic surface = circle A, whose radius is $\sqrt{A B \times B C}$. Hence also, the curve superficies of a right cone is to the area of its circular base, as AC (*fig. 5.*), the length of the hypotenuse of the right-angled triangle describing it, is to CB, the base of the same triangle: that is, as the slant side of the cone, to the semidiameter of the base.

Hence also, the surface of a right cone is equal to a sector of a circle described on the slant side of the cone, as a radius, whose arc is equal to the periphery of the base of the cone: and has therefore the same proportion to its periphery, which the diameter of the base has to twice the side of the cone. Hence we have a method of describing a net or cage that shall just cover a cone.—Thus, with the diameter of the base AB (*Plate, Conics, fig. 8.*), describe a circle, and produce the diameter to C, till AC be equal to the side of the cone. To 2 AC and AB, determined in numbers, and 360°, find a fourth proportional: and with the radius CA, on the centre C, describe an arc DE equal to the number of degrees found: the sector CDE with the circle AB will be a net for the right cone.

If, then, the side of a truncated cone be set off from A to F, and an arc GH be described with the radius CF; by finding a fourth proportional to 360°, to the number of degrees of the arc GH, and to F C; and thence determining the diameter of the circle IF, we shall have a net or cover of the truncated cone.

For CDBAE is a net for the entire cone; CGFHH for the cone cut off; therefore, DBEHIG for the truncated cone.

2. *Cones and pyramids, having the same bases and altitudes, are equal to each other.*

Now, it is shewn, that every triangular prism may be divided into three equal pyramids; and therefore, that a triangular pyramid is one third of a prism, standing on the same base, and having the same altitude.

Hence, since every multangular body may be resolved into triangular ones, and every pyramid is a third part of a prism, having the same base and altitude; since a cone may be esteemed an infinite-angular pyramid, and a cylinder an infinite-angular prism; a cone is a third part of a cylinder, which has the same base and altitude. Hence, cones of equal bases are as their heights; cones, and also frustums of cones, of equal altitudes, are as the bases: cones are to one another in the compound ratio of the bases and heights: and in equal cones, the bases and heights are reciprocally proportional.

Here we have a method of measuring the surface and Solidity of a cone. Thus, for the solidity: find the solidity of a prism, or cylinder, having the same base with the cone, or pyramid, or, multiply the base by the altitude: then divide by 3: the quotient will be the solidity of a cone, or a pyramid. Thus, *v. gr.* if the solidity of a cylinder be 605592960, the solidity of the cone will be found 201864320.

For the surface: that of a right cone is had by multiplying the semi-periphery of the base into the side, and adding the product to the base.

All cones, which have their altitudes and the diameters of their bases reciprocally proportional, are in the triplicate ratio of their altitudes, being to each other in the same proportion with prisms of equal base and altitude, of which they are like parts. See PRISM.

Suppose, *e. gr.* the diameter of the cone NM (fig 4.) 56, the periphery will be 175.9256, and the base 2403.0144. Suppose the altitude or axis KL, 216; since $LM = \frac{1}{2} NM = 28$, and $KM^2 = KL^2 + LM^2 = 60516 + 784 = 61300$, $KM = 247.5$, &c. Consequently the superficies of the cone, exclusive of the base, is 21771,288; and the whole together 24234,3224.

The solidity of an oblique cone is obtained in the same manner with that of the right cone: but it is much more difficult to find its surface, since it cannot be reduced to the measure of a sector of a circle, because all the lines drawn from the vertex to the base are not equal. See a Memoir on this subject, by M. Euler, in the *Nouv. Mem. de Petersburgh*, tom. i. Dr. Barrow has demonstrated, in his *Lectures Geometricæ*, that the solidity of a cone with an elliptic base, forming part of a right cone, is equal to the product of its surface by a third part of one of the perpendiculars drawn from the point in which the axis of the right cone intersects the ellipse; and that it is also equal to one third of the height of the cone multiplied by the elliptic base: and therefore that the perpendicular is to the height of the cone, as the elliptic base to the surface.

For the measure of the surface, and solidity of a truncated cone, or frustum, ABCD (fig. 8). Its altitude CH, and the diameters of its bases AB and CD, being given, find their circumferences; to the square of the altitude CH, add the square of the difference of the radii AH, and from the aggregate extract the square root, which will give the side AC: the semi-sum of the peripheries, multiplied by that side, gives the superficies of the truncated cone or frustum.

To find the solidity: as the difference of the semi-diameters AH, is to the altitude of the truncated cone or frustum CH, so is the greater semi-diameter AF to the altitude of the entire cone FE. This being found, subtract the altitude of the truncated cone GF, which will leave that of the cone taken off, EG.

Find the solidity of the cone CED and AEB; subtract the other from this; the remainder will be the solidity of the truncated cone or frustum ACDB. Or, add into one sum the areas of the two ends of the frustum and the mean proportional between them; multiply that sum by the perpendicular height, and $\frac{1}{3}$ of the product will be the solidity. For the method of finding the surface and solidity of a cone, &c. by fluxions; see SUPERFICIES and SOLIDITY.

CONe, *Ungula of.* See UNGULA.

For the sections of the CONE, see CONIC SECTION.—For the ratio of CONES and CYLINDERS, see CYLINDER.—For the centre of gravity and of oscillation of a CONE, see CENTER.

CONES of the higher kinds, are those whose bases are circles of the higher kinds; and are generated by supposing a right line fixed in a point, on high, though conceived capable of being extended more or less, on occasion; and moved or carried round the said circle of the higher kind.

CONe of rays, in *Optics*, includes all the several rays which fall from any point of a radiant, on the surface of a glass.

CONe, *duble, or spindle*, in *Mechanics*, is a solid formed of two equal cones joined at their bases. If this be laid on the lower part of two rulers making an angle with one another, and elevated above the horizontal plane, it will move towards the raised ends, and seem to ascend, though it really descends. Let ABD (*Plate XVI. Mechanics, fig. 7.*) be the common base of the two cones, its centre C will be the centre of gravity of the whole solid: therefore, if DF represents one of the rulers elevated to an angle FDG, whose sine FG is less than the semidiameter of the cone CD, it is plain that the centre of gravity C at the position of the cone in D, is more distant from the centre of the earth, to which all heavy bodies tend, than in its position between the legs of the ruler at F; and therefore it will descend, as on an inclined plane CFE, from C to F, where it will stop, being supported on the raised ends of the rulers.

CONe, in *Assaying*. See MELTING-cone.

CONe, in *Botany*, a hard dry seed-vessel of a conical figure, consisting of several woody parts; and is, for the most part, scaly, adhering closely together, and separating when ripe.

CONe-stone, in *Natural History*, the name given by many to a species of *Tubulus marinus*, not known to us in its recent state, but frequently found fossil in the Swedish stones used in pavements.

CONe and key. *Bracon*, lib. ii. cap. 37. num. 3. says, *Femina in tali etate (i. e. 14. et 15. annorum) potest disponere domui suæ, et habere cone et key.*

The words come from the Saxon *colne*, i. e. *calculus*, and *key*, *clavis*; so that a woman was then held to be of competent years when she was able to keep the accounts and keys of the house: and *Glan*, lib. vii. cap. 9. has somewhat to the same purpose.

CONe, in *Conceology*. See CONUS.

CONECTE, THOMAS DE, in *Biography*, a monk of the order of the Carmelites, born in Bretagne, towards the close of the fourteenth century, and distinguished as the most popular and impressive preacher of his time. In his discourses he did not confine himself to subjects of religion and morality, but he attacked with vehemence the reigning follies and fashionable foibles of the age. The head-dress of the ladies in particular was the subject of his repeated remonstrances. At this period, says Bayle, "the head-dresses were of such a prodigious height, that the highest top-knots now are but dwarfs to them." Conecte reformed that excess, and obliged the ladies to dress themselves modestly and with a strict regard to decorum. It was not, however, so much by the force of the reasons with which he represented the evangelical duties, as by exciting boys and the commonalty to insult those of the other sex, who would not introduce a reform into their dress. Whether, however, he aimed at vice or folly, he was so famed as an orator, that no churches were sufficiently spacious to contain the crowds, that followed him wherever he went; he therefore chose as theatres for the display of his eloquence, public squares and other places where immense scaffolds were erected, from which he could make himself heard by many thousands.

sands at the same time. When he travelled from place to place, it was on a mule attended with many monks and priests on foot. As soon as he arrived in the vicinity of any town, the most considerable persons for rank and property came out to meet him, in order to conduct him to the house provided for his lodging, which was commonly the best in the place. His labours were not confined to his own country; from France he proceeded to the Netherlands, and Italy, exciting every where the same attention which he experienced in his native land. At Venice he gained so much reputation, that the ambassadors from that republic to the pope, invited him to accompany them to Rome. But the freedom and asperity of his declamations against the corruption of the clergy and the court, roused the resentment, and passions of the papal see; he was accordingly tried and condemned for heresy, and burnt at Rome in the year 1434. His motives were questioned by some of his contemporaries, but the readiness with which he submitted to a cruel death, in defence of his conduct, rather than retract the charges which he had exhibited against the profligacy of the Romish hierarchy, was sufficient evidence of his sincerity in a good cause. Bayle.

CONEGLIANO, GIO BATTISTA CIMA, called *Il*, from the place of his nativity, a small city in the state of Venice, became, under the tuition of Giovanni Bellini, a painter of considerable eminence; and indeed so entirely did Conegliano possess himself of the style of Bellini, that the works of the scholar are frequently confounded with those of the master; even by good judges. It was however much the custom with the older Venetian painters to subscribe their names to their works; many therefore of this artist are still known, as well by the inscription as by the mountainous view of the town of Conegliano with which he usually enriched his back grounds. A juvenile performance of this master with the date 1493, is in the duomo of Conegliano: a more excellent picture by him is in the church of Santa Maria dell'Orto, at Venice. It represents St. Peter, St. Paul, St. Mark, and St. Jerome, with a magnificent architectural back-ground. But in the opinion of Lanzi, the chef-d'œuvre of Conegliano is an altar-piece in the duomo at Parma, the subject of which however he has neglected to mention. This master is supposed to have died shortly after 1517. Lanzi. Storia Pittorica. Zanetti, Pittura Veneziana.

CONEGOCHEAQUE CREEK, in *Geography*, a creek of America, which rises near Maricburg, in Franklin county and state of Pennsylvania, runs southerly in a winding course, and after supplying a number of mills, discharges itself into the Potowmack at William Port, in Washington county, Maryland; 19 miles S.E. of Hancock, and 8 miles S. of the Pennsylvania line.

CONEI or COWNE, GEORGE, a native of North Britain, and a zealous catholic, went to reside at Modena, in Italy, at an early age. He afterwards settled at Rome, and was celebrated, during the pontificate of pope Paul V., for his profound knowledge of the Greek and Latin languages. His own good character recommended him to the patronage of the cardinals Montalto and Barberini. The latter being nephew to pope Urban VIII., Canei soon obtained so much of the favour and confidence of the pontiff as to be entrusted with the office of nuncio to Maria Henrietta, queen of England, which he discharged completely to the satisfaction of the papal court. As a reward for his conduct he would have been raised to the dignity of cardinal, had not death cut off his prospects. He died in 1640, at the age of forty-two; leaving behind him, among other works

of merit. "The Life of Mary Stuart;" "De Institutione principis;" "De Duplici Statu Religionis apud Scotos," &c. &c.

CONEMAUGH RIVER, and *Little Conemaugh*, in *Geography*, are the head waters of Kilkennantas, in Pennsylvania. After passing through Laurel hill and Chestnut ridge, Conemaugh takes that name, and discharges itself into the Alleghany, 29 miles N.E. of Pittsburgh. It is navigable for boats, and there is a portage of 18 miles between it and the Franktown branch of Juniata river.—Also, a town of Pennsylvania, 15 miles E. of Fort Ligonier.

CONENTOS, LAS, a city of La Plata or Paraguay, in South America, in the diocese of Buenos Ayres.

CONEPATL, in *Zoology*, an American animal of the weasel kind mentioned by Hernandez; and also by Ray under the title of *Tesquipatl*. It is described as bearing a strong resemblance to the racoon in shape, but variegated with two long streaks of white, one on each side of the ridge of the back, which run even into the tail. This animal is said to be of a harmless disposition, but of a stinking smell, and when pursued, or provoked, will discharge its excrements at the person who offends it to fix or eight feet distance; these have a very bad smell and spoil peoples cloaths by leaving indelible yellow spots on them. Little more is known of this animal than is above related. It inhabits New Spain, and was placed by Linnæus in his Systema as the same species with his *Viverra Memphisita*, the memphitic weasel, and chinchel of Buffon. Gmelin considers it as a distinct species, and describes it specifically under the name of conepatl. This animal may prove to be a variety only of the striated weasel, or perhaps only of the memphitic weasel to which Linnæus at first assigned it. See *Viverra*.

CONERFREIT, in *Geography*, a town of Germany, in the circle of Bavaria, and Upper Palatinate; 34 miles N.N.E. of Amberg.

CONESSI, or CONESTI, in the *Materia Medica*, a bark brought from the East Indies. It is frequent in Ceylon, and Malabar, where the natives take it in diarrheas, henteries, and dysenteries. We use it in powder for the same purposes, the dose being from half a dram to a dram. It is proper to give a dose of ipecacuanha before taking it.

This tree grows also on the Coromandel coast, in the East Indies, and is not unlike the *cadogopa* of the *bortus Malabaricus*. The bark should be fresh powdered, and the electuary prepared with syrup of oranges every day or every other day. Med. Ess. vol. iii. art. 4.

CONESTEO, in *Geography*, a north-western branch of Tioga river in the state of New York, America.

CONESTOGA, a township of America, in the county of Lancaster and state of Pennsylvania.

CONESUS, a small lake of America, in the county of Genesee and state of New York, which conveys its waters N.W. to Genesee river.

CONFARREATION, a ceremony among the ancient Romans, used in the marriage of persons whose children were destined for the honour of the priesthood.

Confarreation was the most sacred of the three modes of contracting marriage among that people; and consisted, according to Servius, in this, that the *pontifex maximus* and *flamen dialis* joined and contracted the man and woman, by making them eat of the same cake of salted bread; whence the term, *far* signifying meal or flour.

Ulpian says, it consisted in the offering up of some pure wheat bread; rehearsing, at the same time, a certain formula,

formula, in presence of ten witnesses. Dionysius Halicarnassus adds, that the husband and wife did eat of the same wheat bread, and threw part on the victims.

CONFECTION, in *Pharmacy*, a kind of compound remedy, of the consilience of a soft electary, or electuary.

Confections and electuaries are composed chiefly of powders, mixed up with syrups or honey, into such a consistence, that the powders may not separate by keeping. They are chiefly the milder medicines, and such as are not very ungrateful to the palate, that enter into the composition of the electuaries: for as they are taken somewhat "ad libitum," it would be unsafe to trust this mode of exhibition of the more active drugs. The lighter powders require about twice the weight of syrup to be brought to the proper consistence of an electuary. The ordinary dose is a piece about the bulk of a nutmeg. See **ELECTUARY**.

Several electuaries were formerly distinguished by the name of confections; some of which, in the medical language, are *corroborative*, and others *purgative*.

Of the number of the corroborative confections, were those of *alkermes*, of *hyacinth*, and the *anacardine*: a purgative one is the confection *Hamech*. The confection of *alkermes* has its name from the principal ingredients therein; which is the *kermes*, or *alkermes*, or scarlet-grain. The other ingredients were pearls, musk, cinnamon, ambergris, leaf-gold, juice of pippins, and rose water. It was ranked among the best cardiacs, and frequently used for the palpitation of the heart, or syncope; and sometimes in the small-pox and measles.

The confection of *hyacinth* was said to have nearly the same virtues with that of *alkermes*; but, besides, it was frequently used as an astringent. It consisted of nearly triple the number of drugs; whereof the precious stone, called the *hyacinth*, was esteemed the principal; the chief of the rest were, red coral, bole armoniac, terra sigillata, myrrh, the fanials, burnt hartshorn, camphire, sapphires, emerald, topaz, and most of the ingredients of the confection of *alkermes*. The *anacardine* confection was composed chiefly of *anacardiums*; whence the name. The other drugs were long pepper, black pepper, most kinds of myrobalans, castoreum, &c. It was used to purge the blood, and deemed proper in cold diseases.

The confection *Hamech*, took its name from that of its inventor, an Arabian physician. Its ingredients were, poly-pody, myrobalans, agaric, fenna, tamarinds, red roses, manna, colocynth, &c. It was applied as a drastic for the purging of the grosser humours and viscidities; it was also of some reputation in vertiges and cancers. But all these, though we have thought it proper to mention them, are excluded from the modern dispensatories.

CONFECTION AROMATICA. See the next article.

CONFECTION CARDIACA, a name given in the late London Dispensatory to the so much esteemed medicine commonly known by the name of the *confectio Raleighiana*, and now denominated *confectio aromatica*. The composition is also altered, as well as the name, and is ordered now to be made in the following manner: Take zedoary, in coarse powder, and saffron, of each half a pound, and of distilled water, three pints. Macerate for twenty-four hours, and then press out and strain. Evaporate the strained liquor to a pound and a half, and add of compound powder of crabs-claws, sixteen ounces by weight; cinnamon and nutmeg, of each two ounces by weight; cloves, one ounce by weight; lesser cardamom, half an ounce by weight; and double refined sugar, two pounds.

Powder the spices together very finely, and adding the sugar, make a confection. This is an improvement of the *confectio cardiaca* of the former dispensatory. The essential oil of the cardamom appeared, on an experiment made at the Hall, to be lost in the evaporation of the tincture; and, therefore, the cardamom is now more properly added in powder.

CONFECTION DAMOCRATIS. See **MITHRIDATE**.

CONFECTION FRACASSORII. See **DIASCORIDIUM**.

CONFECTION JAPONICA, was prepared of Japan earth, three ounces; tormentil root, nutmeg, and oilbanum, of each two ounces; opium, dissolved in Lisbon wine, a dram and a half; simple syrup and conserve of roses, of each fourteen ounces. An electuary of these ingredients supplied the place of *diacordium*; and the dose was from a scruple to a dram.

CONFECTION OPIATA, confection of opium, is prepared in the following manner: Take of hard purified opium, powdered, six drams by weight; long pepper, ginger, and caraway, of each two ounces by weight; syrup of white poppy, boiled to the consistence of honey, three times the weight of the whole. Mix the purified opium with the heated syrup, and add the rest in powder.

CONFECTION PAULINA, a name given in the late London Dispensatory to the composition which used to be called *confectio archigenis*. It was ordered to be made in the following manner: Take costus or zedoary, cinnamon, long pepper, black pepper, strained storax, galbanum, opium, and Russia caltor, of each two ounces; of simple syrup, boiled to the consistence of honey, an equal weight to thence the species. Pemberton's London Pharm. p. 339.

CONFECTOR, among the *Ancient Romans*, a sort of gladiator, hired to fight in the amphitheatre against beasts; thence also denominated *bestiarius*. See **GLADIATOR**.

The confectors were thus called *ad conficiendis bestias*, from their dispatching and killing beasts.

The Greeks called them *αυροβοτοι*, q. d. *daring, rash, desperate*; whence the Latins borrowed the appellations *parabolani*, and *parabolarii*. The christians were sometimes condemned to this sort of combat.

CONFECTS, or **CONFITS**, a denomination given to fruits, flowers, herbs, roots, and juices, when boiled and prepared with sugar, or honey, to dispose them to keep, or render them more agreeable to the taste.

The ancients only confited with honey; at present, sugar is more frequently used. Confects half-sugared are those only covered with a little sugar, to leave more of the natural taste of the fruit.

Confects are reduced to eight kinds; viz. *liquid confects*, *marmalades*, *jellies*, *pastes*, *dry confects*, *conservees*, *candies*, and *drages*, or *sugar-plums*.

Liquid confects are those whose fruits, either whole, in pieces, in seeds, or in clusters, are confited in a fluid transparent syrup, which takes its colour from that of the fruits boiled in it. There is a good deal of art in preparing these well; if they be too little sugared, they turn; and if too much, they candy. The most esteemed of the liquid confects are plums, especially those called mirabels, barberries, quinces, apricots, cherries, orange flowers, little green citrons from Madeira, green cassia from the Levant, myrobalans, ginger, cloves, &c.

Marmalades are a kind of pastes almost liquid, made of the pulp of fruits, or flowers, that have some consistence; such as apricots, apples, pears, plums, quinces, oranges and ginger. Marmalade of ginger is brought from the Indies by way of Holland: it is esteemed good

deliberate separately, he presides in the college of kings, and the duke of Nassau in the college of princes.

XI. The fundamental statute is to be framed by the prince primate.

XII. The French emperor is protector of the confederation, and names the successor of the prince primate.

XIII. to XXI. Enumerate the cessions made by members of the league: thus, Nassau cedes to Berg the town of Dous and its territory; Bavaria acquires the imperial city of Nuremberg and its territory; and

XXII. The prince primate receives Frankfort on the Mayne, and its territory, as his property.

XXIII. and XXIV. Enumerate the lordships over which the members of the confederation exercise the rights of sovereignty.

XXV. They also enjoy the sovereignty over the imperial knightdoms included within their boundaries.

XXVI. The rights of sovereignty consist in legislation, administration of justice, military conscription or recruiting, and levying taxes.

XXVII. Regulates the patrimonial or private property of the subordinate princes and counts. Their domains cannot be sold or given to any prince out of the confederation, without being first offered to the prince under whose sovereignty they are situated.

XXVIII. These subordinate princes and counts preserve the privilege of being tried by their peers. Their fortune cannot be confiscated, but their revenues may be sequestrated during the life-time of the criminal.

XXIX. and XXX. Regulate the payment of debts.

XXXI. The subordinate princes or counts may take up their residence where they choose, and draw their rents or capitals without any reserve.

XXXII. Public functionaries not retained by the new sovereign, receive a pension proportionate to the situation they held.

XXXIII. The same takes place with respect to religious orders losing their income.

XXXIV. The confederates renounce all reciprocal claims, except the eventual right of succession.

XXXV. Between the French emperor and the confederated states there shall be federatively and individually an alliance, by virtue of which every continental war in which either is engaged shall be common to all.

XXXVI. In the event of any power making preparations for war, the contracting parties, in order to prevent surprise, shall, upon the requisition of the minister of one of them at the assembly of the league, arm likewise. And as the contingent of the allies is subdivided into four parts, the assembly shall decide how many are to be called into activity. The armament, however, shall only take place upon the summons of the French emperor to each of the confederates.

XXXVII. The king of Bavaria binds himself to fortify Augsburg and Lindau, and to form and maintain artillery and baking establishments in the said places.

XXXVIII. The contingent of each confederate is: France 200,000 men, Bavaria 50,000, Wirtemberg 12,000, Baden 8000, Berg 5000, Darmstadt 4000, Nassau, Hohenzollern; and others 4000.

XXXIX. Admits of the accession of other German princes; and,

XL. as the concluding article, stipulates the exchange of the ratifications.

Of the two principal articles of the new constitution of the confederation of the Rhine, one relates to the establish-

ment of a superior court of appeal, in which all causes between the sovereigns and their subjects shall be finally decided. The other stipulates that the manufactures of each state shall be allowed to be freely imported into all the other states of the confederacy. Several new roads are to be made in order to facilitate commerce.

CONFERENCE, in its first and primary sense, denotes mutual discourse, and more especially such discourse on serious and important subjects. It also denotes an appointed meeting for discussing some point, by personal debate; of this kind was that held at Ratibon, in 1601, at the joint desire of Maximilian, duke of Bavaria, and Philip Lewis, elector Palatine, between some eminent Lutheran doctors on one side, and three celebrated Jesuits on the other. The dispute turned upon the two great points, to which almost all the contentions between the Protestants and the Roman Catholics are reducible, *viz.* the rule of faith and the judge of controversies. In 1615, another conference was held at Newberg between James Heilbronner, a learned Lutheran, and James Keller, a celebrated Jesuit, by the appointment of Wolfgang William, prince Palatine, who had a title before that time embraced the Romish faith. But the most famous of all these conferences was that held in the year 1645 at Thorn, by the express order of Uladissus IV. king of Poland, between several eminent doctors of the Romish, Lutheran, and reformed churches. As this meeting was intended to heal the divisions that prevailed among these churches, and to discover some method for healing their differences, and for effecting their reunion, it was on this account called the "Charitable conference." But the issue of this conference was very far from being favourable to the projected union. Some time after this, Ernest, landgrave of Hesse, in order to give a plausible colour to his apostacy from the Protestant religion, and make it appear to be the result of examination and conviction, obliged Valerianus Magnus, a learned capuchin, to enter the lists with Peter Habereorn, a reformed minister, in the castle of Rheinfield. Besides these public conferences on the continent, there were others of a more private nature held, during the 17th century, between the doctors of the contending churches. The most remarkable of these was the famous dispute between John Claude, the most learned of the Reformed divines in France, and Jaques Benigne de Bossuet, whose genius and erudition placed him at the head of the Romish doctors in that country. This dispute, held in the year 1683, terminated, like all the rest, in widening the breach instead of healing it. Neither of the contending parties could be persuaded to yield; but, on the contrary, they both returned from the field of controversy more riveted in their own opinions, and more averse from those of their adversaries. Another conference was held at Leipzig, in 1631, between three Saxon doctors on the one side, and some of the most eminent divines of Hess.-Cassel and Brandenburg on the other, with a view of representing, with fidelity and precision, their respective doctrines, and for the purpose of discovering the obstacles which prevented the union of the Lutheran and Reformed churches. The conference, however, though amicably conducted, broke up without having contributed in any respect to promote the salutary work of peace. The conference held at Cassel in 1661, by the order of William VI., landgrave of Hesse, between two professors at Rintelen, on the side of the Lutherans, and two others of the university of Marburg on that of the Reformed, was attended with much greater success than that of Thorn above mentioned: for, though it did not bring about a perfect uniformity of opinion, it produced an effect, which

was in reality, much better, a spirit of Christian charity and forbearance.

The most famous conferences of a similar kind, held in England, were those of *Hampton-Court* in 1604, and of the *Savoy* in 1661. The former was held by order of James I., on pretence of finding expedients, which might terminate the religious disputes between the church and the puritans, and reconcile both parties. The professed design of this conference was to examine the objections of the puritans against the doctrine, government, and discipline of the established church, and to rectify its abuses. But the progress and result of it evidently shew, that it was the design of the king to make an ostentatious display of his learning, and to mortify the puritans, who had favourable expectations from James's education in Scotland, and his professed attachment to the church established in that country, but who found, in the event, that he had conceived invincible prejudices against them. The disputants on both sides were nominated by the king. For the church, there were nine bishops, and about as many dignitaries; and for the puritans, there were only four ministers. This conference continued three days, viz. Jan. 14th, 16th, and 18th. The first day's conference was with the bishops and deans; the puritan ministers not being present; when the king made a speech in commendation of the hierarchy of the church of England, congratulated himself, that he was now come into the "promised land," &c. &c.; and informed them, that the reason of his consulting them by *themselves* was to receive satisfaction from them: 1. About some things in the Common Prayer. 2. Concerning excommunication in the ecclesiastical courts. 3. About providing some well qualified ministers for Ireland; that if any thing should be found meet to be redressed, it might be done without their being confronted by their opponents. After some alterations of no great importance, agreed on between the king and the bishops, with regard to the confirmation of children, the absolution of the church, private baptism, and baptism by women, and excommunication for lesser crimes, his majesty's scruples were satisfied; and thus ended the first day's conference. On the second day, Jan. 16th, the four ministers on the side of the puritans, together with Patrick Galloway, minister of Perth in Scotland, and two bishops and six or eight deans on the other side, were convened. The king, seated in his chair, with his nobles and privy counsellors around him, informed the puritanical ministers that he was ready to hear their objections against the establishment. Upon which Dr. Reynolds, one of their number, in the name of his brethren, humbly requested: 1. That the doctrine of the church might be preserved pure, according to God's word. 2. That good pastors might be planted in all churches, to preach in the same. 3. That the book of Common Prayer might be fitted to more increase of piety. 4. That church government might be sincerely ministered according to God's word. In the discussion of these points, Bancroft and the king took an active part. At the close of this day's debate, his majesty highly incensed at the complaints stated by Dr. Reynolds, told the ministers, that he found they were aiming at a Scots presbytery; "which," says he, agrees with monarchy as well as God and the devil; there Jack and Tom and Will and Dick shall meet and censure me and my council. Therefore I reiterate my former speech: "Le Roi s'aviviera." Stay, I pray, for one seven years before you demand; and then, if you find me grow purple and fat, I may perchance hearken unto you. For that government will keep me in breath, and give me work enough. I remember how they used the poor lady, my mother, in Scotland, and me in my minor-

ity." Then turning to the bishops, he put his hand to his hat and said "I beseech you, I may thank you that these puritans plead for my supremacy; for if once you are out and they in place, I know what would become of my supremacy, for *no bishop, no king*." When Dr. Reynolds said he had nothing more to offer, the king said, "if this be all your party have to say, I will make them conform, or I will hurry them out of this land, or else worse." On the termination of this day's conference, some asserted that the puritans had been grossly insulted and ridiculed, and that they had not been allowed freedom of speech; but the bishops and courtiers flattered the king's wisdom and learning, and called him the Solomon of the age. Bancroft fell upon his knees, and said, "I protest my heart melteth for joy, that Almighty God of his singular mercy, has given us such a king, as since Christ's time has not been." Chancellor Egerton said, "he had never seen the king and priest so fully united in one person." The king was no less satisfied with his own conduct, and boasted of his victory over the puritans. At the third day's conference, Jan. 18, the bishops and deans were first called into the privy-chamber with the civilians, to satisfy the king about the high commission and the oath *ex officio*; and when the king expressed his satisfaction with the latter, the old archbishop (Whitgift) was so transported as to exclaim, "undoubtedly your majesty speaks of the special assistance of God's spirit." A committee of bishops and privy-counsellors was then appointed to consider of lessening the charges in the high commission, for planting schools and proper ministers in the kingdom of Ireland, and on the union of England and Scotland. After which Dr. Reynolds and his brethren were called in, not to dispute, but only to hear the few alterations or explanations in the Common Prayer Book, that had been adopted; but when they expressed their wish that something further might be done, or at least that the surplice and cross might not be urged, the king replied with a stern countenance, interrupting the bishops who were about to answer, "We have taken pains here to conclude in a resolution for uniformity, and you will undo all by preferring the credit of a few private men to the peace of the church; this is the Scots way; but I will have none of this arguing; therefore let them conform, and that quickly too, or they shall hear of it; the bishops will give them some time, but if any are of an obstinate and turbulent spirit, I will have them enforced to conformity." Thus ended this conference, and the opportunity for conciliation and union was lost; and this was chiefly owing to the king's pedantry and love of adulation, to his high and arbitrary principles, and to his inveterate hatred of the Puritans.

The *Savoy* conference was held in pursuance of the declaration of Charles II. Oct. 25, 1660, concerning ecclesiastical affairs, when 12 bishops and nine assistants were appointed on the part of the episcopal church of England, and as many ministers on the side of the presbyterians, to assemble at the bishop of London's lodgings at the Savoy; "to review the book of Common Prayer, comparing it with the most ancient and purest liturgies; and to take into their serious and grave consideration the several directions and rules, forms of prayer, and things in the said book of Common-Prayer contained; and to advise and consult upon the same, and the several objections and exceptions which shall be now raised against the same; and if occasion be, to make such reasonable and necessary alterations, corrections, and amendments, as shall be agreed upon to be needful and expedient, for giving satisfaction to tender consciences, and the restoring and continuance of peace and unity in the churches under his majesty's government and direction."

They were to continue four months from the 25th of March 1501, and then present the result of their conferences to his majesty under their several hands. When the conference opened on the 15th of April, some difficulties occurred about the proper mode of proceeding; some of the presbyterian party were for insisting only on a few matters of importance, judging that if these were gained, and an union followed, it might be more easy to obtain the others afterwards. But the majority, by the influence of Mr. Baxter, were for extending their desires to the utmost, and thought themselves bound by the words of the commission, to offer every thing which they thought might conduce to the peace of the church; but when they were put in mind, that the king's commission gave them no power to alter the government of the church, nor to insist upon archbishop Usher's model, nor so much as to claim the concession of his majesty's late declaration, they were much discouraged; for they were now convinced that all they were to expect were a few amendments in the liturgy and Common-Prayer Book. They wished also to have consulted their absent brethren, and to have received from them a commission in form; but this was denied. Instead of drawing up a few supplemental forms and making some amendments to the old liturgy, Mr. Baxter composed a new one, in the language of scripture, which he called "The Reformed Liturgy;" not with a design entirely to set aside the old one, but to give men liberty to use either according to their own choice and approbation. This was presented to the bishops in the conference, together with exceptions to the "old liturgy." This gave great offence, partly because a liturgy, composed by a single person in fourteen days, was set in competition with one which had been received in the church for a whole century; and partly, because it was inconsistent with the commission, and the bishops' declaration of varying no further from the old standard than should appear to be necessary; and, therefore, the reformed liturgy was rejected at once without examination. When the presbyterians presented their exceptions to the liturgy, they accompanied them with "a petition for peace," beseeching the bishops to yield to their amendments; to free them from the subscriptions and oaths in his majesty's late declaration, and not to insist upon the re-ordination of those who had been ordained without a diocesan bishop, nor upon the surplice, the cross in baptism, and other indifferent ceremonies, enforcing their petition by various arguments and motives. These exceptions were canvassed, and produced a variety of alternate objections and replies. The bishops, however, would make no concession to the prejudices of the presbyterians; upon which they sent them a large expostulatory letter, in which, after having repeated their objections, they lay the wounds of the church at their door. The term for the treaty being almost spun out in a paper controversy, about 10 days before the commission expired, a disputation was agreed on, to argue the necessity of alterations in the present liturgy. Three of each party were chosen to manage the argument. The dispute, however, terminated without effect. From arguments the presbyterian ministers descended to intreaties, and besought the bishops to compassionate scrupulous minds, and not to despise their weaker brethren; to all which the bishops replied, that they were only commissioned to make such alterations in the liturgy as should be necessary, and such as should be agreed upon. Mr. Baxter says, that the bishops would not abate the smallest ceremony, nor correct the grossest error, for the peace of the church. Thus the king's commission expired July 25, and the conferences ended without any prospect of accommodation. It was agreed at the conclusion, that each party

might represent to his majesty, that they were all agreed upon the ends of the conference, which were the welfare, unity, and peace of the church, but still disagreed as to the means of procuring them. The bishops thought they had no occasion to represent their case in writing, but the presbyterian commissioners met by themselves, and drew up an account of their proceedings, with a petition for that relief which they could not obtain from the bishops. Hume's Hist. vol. vi. 10. 13., vol. vii. 369.

CONFERVA, in Botany, a name occurring in Pliny for a water plant, supposed to be *C. rivularis* of Linnæus, so called, he says, a *conferrumianum*, because it closely adheres together, Linn. gen. 1207. Schreb. 1672. Juss. 6. Vent. 2. 32. Clafs and order, *cryptogamia alga*. Nat. Ord. *Alga*. Linn. Juss. Vent.

Gen. Char. Fibres simple, uniform, capillary, filamentous." Linn. "Filaments capillary, simple or branched, jointed; joints numerous, often unequal." Lam. Vent. "Seeds produced within the substance of the capillary or jointed frond, or in closed tubercles united with it." Dr. Smith.

Species. I. Simple.

* Immersed.

+ In salt water.

1. *C. confervicola*. Conferva upon conferva. Dillw conf. 8. Dill. Musc. 552. tab. 85. fig. 21. "Filaments simple, minute, somewhat crowded, acute; partitions obscure; joints cylindrical, unequal in length." Dillw. *Filaments* rarely more than an eighth of an inch long, of a dark glaucous colour, tapering. Common in the latest months of autumn on various tuci and confervæ. 2. *C. flaccida*. Dillw. 49. "Filaments simple, very slender, minute, flaccid; partitions transparent; joints very short." Growing in loose patches of a green colour, about half or three-fourths of an inch long. Joints scarcely half so long as broad. Parasitical on confervæ, and the smaller tuci in the neighbourhood of Swansea. 3. *C. fucicola*. Vellej Mar. Plant. Pl. 4. Dillw. 66. With. 4. 156. "Filaments clustered, simple, obtuse; partitions transparent, slightly contracted; joints rather long." Dillw. *Filaments* very numerous, thickly clustered at the root, diverging while in the water, from four to six lines long, of a dirty yellow or brown colour, somewhat glossy when dried. Joints about twice as long as broad, filled with minute granules. Parasitical on fucus vesiculosus, and sometimes on nodosus. 4. *C. curta*. Dillw. 76. "Filaments clustered, simple, somewhat cartilaginous or horny, erect, short, attenuated at both ends; partitions transparent, slightly contracted; joints rather short." *Filaments* seldom more than three or four lines long, of an olive-brown colour, obtuse, growing in roundish stiff tufts. Joints not much longer than thick. Parasitical on fucus. 5. *C. carnea*. Dillw. 84. "Filaments simple, clustered, somewhat knotty, flesh-coloured; joints rather short, attenuated at both ends; juice collected into solitary globules." *Filaments* from a quarter to half an inch long, rather obtuse. Partitions dark-coloured. Joints sometimes about twice the length of the diameter, sometimes little more than the length; colourless, except where the juice is collected. Parasitical in loose tufts on other confervæ. 6. *C. capillaris*. Linn. Sp. Pl. 14. Lam. 14. Dill. p. 25. tab. 5. fig. 25. A. Dillw. 9. (C. limum; Flor. Den. 771. *C. palustris*, five filum marium Anglicum. Rai. Syn. p. 60. n. 16.) "Filaments simple, cylindrical, rather rigid, curled, entangled, brittle; partitions transparent; joints cylindrical, short; capsules sessile." *Filaments* three or four feet long, about the thickness of large thread, pale yellowish green, entangled, but never adhering together; perfectly flaccid after it has been exposed a few minutes to the

the air. *Partitions* quite transparent, with a thin blackish line on each side. *Joints*, when dry, generally appearing alternately compressed. Found in the ditches and stagnant pools of salt marshes. 7. *C. tortuosa*. Dillw. 46. "Filaments simple, rather rigid, entangled, slender; partitions transparent; joints cylindrical, rather long." Resembling the preceding species in miniature. *Filaments* as fine as human hair, less brittle than those of *C. capillaris*; joints nearly twice as long as broad. Found in salt-pools, and on rocks in the sea. 8. *C. arca*. Dillw. 80. "Filaments simple, rather rigid, nearly straight; partitions glassy-transparent, contracted; joints oblong, short." *Filaments* several from the same root, from six to fifteen inches long, sometimes nearly the thickness of a crow quill, generally about that of large thread, dark or bluish green, brittle. *Joints* not so long as broad, rounded at each end. On stones in the sea.

†† *In fresh water.*

9. *C. foetida*. Dillw. 60. "Filaments simple, slender; partitions ring-like; joints rather long, transparent." *Filaments* very long, extremely slender, entangled. *Joints* about four times as long as thick. In ponds, pools, and ditches frequent. In ponds forming a semi-transparent cloud-like mass round the grass or reed on which it grows, of a yellowish-green colour. In small currents, floating, in denser masses, on the surface. 10. *C. inflata*. Smith Eng. Bot. 1670. *Conjugata inflata*; Vaucher conf. 68. tab. 5. fig. 8. "Filaments simple; joints three times as long as broad; when fertile, swelling and elliptical." *Filaments* but the seventh part of an inch in diameter, transparent, almost colourless. *Joints* at first exactly cylindrical, marked with green colouring matter in spiral lines; afterwards swelling, elliptical, each protruding a lateral tube, so as to unite with similar tubes of a neighbouring plant. The colouring matter of one joint passes into the other, its spiral appearance being entirely lost. At length each joint which has received it swells still more, growing quite elliptical, and filled with a solid green body, which M. Vaucher has proved to be a single seed, producing in due time a solitary young plant. These appearances cannot be perceived without the aid of a microscope. Found by Mr. W. Boner at Hensfield in Sussex. 11. *C. punctalis*. Dillw. 51. "Filaments simple, slippery, very slender; partitions obscure; joints rather short, cylindrical; juice finally collected into solitary globules." *Filaments* from one to two inches long, so slender, as, when single, scarcely to be distinguished by the naked eye. In ditches and pools not infrequent. 12. *C. bipunctata*. Dillw. 2. Smith Eng. Bot. 1610. Roth Cat. Bot. ii. p. 204. (*C. bellina*; Muller in Nov. Act. Pet. iii.) "Filaments slippery, yellowish, joints short, cylindrical, with two spots." *Joints* remarkable in having each two dark spots, frequently furnished with a green longitudinal streak running through them; these spots sometimes fill nearly the whole, sometimes only a small portion of the joint, and, when verging upon decay, assume a stellated appearance; but are not visible without the aid of a microscope. 13. *C. nitida*. Dillw. 4. Flor. Dan. tab. 519. (*C. rivularis*; Hudf. Flor. Ang. 1. β. *C. ferrea* crassior & varie. extensa. Dillw. p. 13. tab. 2. fig. 2. *C. decima*; Mull. nov. act. Pet. iii. *C. fetiformis*; Roth. Cat. Bot. Fasc. 1. p. 171. 2. p. 103. *Byssus palustris confervae* des. Mich. Gen. tab. 89. fig. 6.) "Filaments simple, shining, slippery; joints rather long, cylindrical; granules of the fructification doubly spiral." *Filaments* a foot or more long, about the thickness of a human hair, dark green, growing at the bottom of the water in loose irregular patches, not sufficiently matted as to contain air bubbles, nor so much entangled as in many others. 14. *C. spiralis*. Dillw. 3. Smith Eng. Bot. 1656. Roth Cat. Bot. ii. p. 202. (*C. quinina*; Mull. act. nov. Pet.

iii.) "Filaments simple, slippery; joints cylindrical, rather long; granules of the fructification, simply spiral." *Filaments* longer and more slender than those of *nitida*, anatomising like those of *C. inflata*. 15. *C. jugalis*. Dillw. 5. Flor. Dan. tab. 883. (*C. fcalaris*; Roth. Cat. Bot. ii. p. 196.) "Filaments simple, flaccid, often conjugate by pairs; granules of the fructification doubly spiral; finally collected into globules." In pools and ditches. Mr. Dillwyn strongly suspects, that *C. nitida* (n. 13.), is only the present plant in an earlier period of its growth. 16. *C. geniflexa*. Dillw. 6. Roth. Cat. Bot. ii. p. 199. (*C. serpentina*; Mull. nov. act. Pet. iii.) "Filaments simple, very slender, brittle, here and there knee-bent and conjugate; joints rather long, cylindrical; granules collected into lines." *Filaments* as far as can be judged, considering their brittleness, not more than one or two inches long, anatomising occasionally at very uncertain distances, and only where they are geniculate, not regularly paired as in *C. jugalis*, but connecting themselves with any other that is near them, and manifesting a strong affinity to the next species. In pools and ditches. 17. *C. reticulata*. Linn. Sp. Pl. 11. Lam. 21. Smith Eng. Bot. 1687. Dillw. p. 20. tab. 4. fig. 14. (*Hydrodictyum*; Vaucher Conf. 88. tab. 9.) "Filaments united into the form of a tubular net." *Filaments* green, tubular, forming a very delicate net, open at both ends; meshes generally with five sides, sometimes with four or six. M. Vaucher found the old plants in a stationary condition during winter; but in spring the joints swelled, and gave out simple cylindrical masses of green matter. Each mass soon became a reticulated tube, which in two or three months grew to the full size of the parent plant. It grows loosely, floating in still water; but not very common. 18. *C. rivularis*. Linn. Sp. Pl. 1. Lam. 1. Dillw. 29. Smith Eng. Bot. 1654. (*C. compacta*; Roth. Cat. Bot. i. p. 170. *C. fluviatilis terrea, vulgaris & fluitans*; Dillw. p. 12. tab. 2. fig. 1. *C. Pinni* Rai. Syn. p. 58.) "Filaments simple, dark green, slender, very long, very densely compact, frequently twisted; joints rather short." *Filaments* often two or three feet long. 19. *C. hucus*. Dillw. 47. Smith Eng. Bot. 1655. "Filaments simple, slender, glaucous, slippery; joints shortish; granules collected in fasciae." *Filaments* seldom more than three inches long, tapering. On rocks and stones in clear rapid rivulets. 20. *C. diffusus*. Dillw. 63. "Filaments simple, straight, brittle; partitions but little contracted, often loose; joints short, with a dark spot in the middle." *Filaments* from three to six inches long, less than a human hair in diameter, dark green, often breaking at the partitions and remaining connected at one extremity; joints about half as long as thick. In ditches on reeds and other aquatic vegetables. 21. *C. pectinalis*. Dillw. 24. Smith Eng. Bot. 1611. Mull. nov. act. Pet. iii. (*C. bronchialis*; Roth. Cat. Bot. i. p. 186.) "Filaments simple, transparent, broken, acuminate; partitions often loose; joints very short, crystalline-transparent in the middle." *Filaments* seldom half an inch long, dirty green, to the naked eye resembling decayed vegetable matter, when entire gradually tapering to a point, and bearing some resemblance to the antennae of a lobster, frequently breaking at the partitions, and remaining connected at one extremity. *Joints* appearing coloured at each end by a green fluid, which, as the plant approaches to decay, collapses, sometimes forming into small globular masses, and sometimes disappearing entirely. In rivers and stagnant waters, adhering to decaying wood and vegetables. 22. *C. flocculosa*. Dillw. 28. Roth. Cat. Bot. p. 192. tab. 4. fig. 4. and tab. 5. fig. 6. "Filaments most commonly simple, minute; partitions loose; joints prismatic, alternately refracted." *Filaments* seldom more than a quarter of an inch long

CONFERRA.

varying from a pale to a greenish brown. *Joints* with a double line running through the middle, and frequently with some transverse bands; as they adhere to each other only in a single point, and always at alternate ends, they give the plant the appearance of a string of parallelograms, united at the corners. It might be taken for a much broken piece of *C. pectinatis*, but the joints cannot be so disposed as to form one regular line. In pools and slow streams, adhering to decaying vegetables and to other conferræ, especially to *C. glomerata*. 23. *C. fontinalis*. Linn. Sp. P. 2. Lam. 2. Flor. Dan. tab. 651. fig. 2. Dillw. 64. (*C. minima* byssif. facie; Dill. p. 14. tab. 12. fig. 3.) "Filaments simple, cylindrical, truncate, dark green, fasciated; partitions obscure; joints very short." *Filaments* without any apparent root, equally obtuse at both ends. Common in rivers, pools, and ditches, generally floating in irregular masses on the surface. 24. *C. limosa*. Dillw. 20. (*C. gelatinosa*, omnium tenerrima et minima aquarum limo innascens; Dill. p. 15.) "Filaments simple, very slender, short, mucous, densely compact, bluish green, slippery; partitions indistinct." Common on the muddy edges of rivers, ditches, and ponds, representing to the naked eye, except at the margin, where it is fibrous, a widely expanded, thin, shapeless gelatinous mass, sometimes floating at the top of the water. In either case the only mode to examine it, is to carry it home, without allowing it to dry, and to put it in a pan of water, where, in the space of a night, it will shoot out an immense number of threads, visible to the naked eye only from their number; these viewed through a microscope appear obtuse at each end, and crossing each other without any regular order. Mr. Dillwyn is inclined to think that this is only the last species in a younger state; the principal difference is in the size and colour; in *C. fontinalis* the filaments are much larger, browner, and not glossy; the joints also are far more distinct, and more regularly disposed. 25. *C. violacea*. Hudf. Flor. Ang. p. 592. (*C. confragosa*; Lightf. Flor. Scot. p. 976. Dill. p. 15. tab. 2. fig. 4.) "Filaments simple, equal, violet." *Filaments* about half an inch long, of a beautiful violet or indigo colour, of a slippery mucous substance, so extremely fine as to be undistinguishable by the naked eye, and so crowded together as to form, when moist, a gelatinous mass, and when dry, a membranous lamina. Found by Lightfoot on the rocks in the waterfalls of the mountain of Goatfield in the Isle of Arran, and said by Dillenius to grow in Alpine rivulets near Llanberis. 26. *C. e-lino-lata*. Smith Eng. Bot. 1378. "Glaucous, stems simple, spreading every way from a centre, and forming a globe." Sent by the Rev. Mr. Davies from a lake in Anglesea. It covers the surface of the water in the months of June and July, and consists of innumerable minute globules of a glaucous or verdigrise green, all nearly of a size. When examined with a microscope each globule appears to be composed of a number of simple cylindrical short filaments apparently springing from a solid centre. Under a very high magnifier these filaments are found to be formed of short uniform joints, each of which is of an equal thickness throughout, but the upper ones gradually diminish in size. Mr. Davison Turner suggests that this minute vegetable ought probably to be referred to Roth's new genus *uvularia*, to which *ulva incrassa* and *U. pruniformis* of English botany belong. Those species are of a pulpy substance, clothed with jointed filaments.

**Not immersed.*

27. *C. ericetorum*. Dillw. 1. Smith Eng. Bot. 1553. Roth Cat. Bot. ii. p. 206. "Filaments simple, slender, prostrate, densely entangled; partitions scarcely contracted;

joints about as long as they are broad." *Filaments* from half an inch to an inch long, of a dull purple colour, covering the moist sandy earth in large patches. Common on moist heaths. 28. *C. muralis*. Dillw. 6. Smith Eng. Bot. 1554. "Filaments simple, very slender, prostrate, densely entangled, somewhat rigid; joints very short, slightly swelled; partitions obsolete." *Filaments* about an inch long, scarcely discernible by the naked eye, covering the substances on which they grow with a fine close green mat. Common upon damp walls, flowers, and neglected shady walks. 29. *C. decorticans*. Dillw. 26. "Filaments simple, closely interwoven, glaucous; partitions obscure; joints short." *Filaments* growing in large patches so intimately interwoven as to peel off in flakes, bearing a considerable resemblance to a piece of silk or ribbon. It differs from *C. muralis* in its much greater tenacity and darker colour. Not frequent on damp walls and flowers.

II. Compound.

* *Immersed.*

† *In salt-water.*

30. *C. polymorpha*. Linn. Sp. Pl. 17. Dillw. 44. (*C. marina* geniculata nigra palmata; Dill. p. 32. tab. 6. fig. 35. *Ceramium fastigiatum*. Roth Cat. Bot. ii. p. 175.) "Filaments dichotomous, fastigiate, somewhat cartilaginous; joints short; capsules on the upper branchlets, egg-shaped, sessile." *Filaments* about the thickness of horse hair, repeatedly dichotomous, with rather acute angles, of a dark purple colour when young, afterwards becoming black. Common on the larger fuci, most commonly on *F. nodosus*, in thick tufts, two or three inches long. 31. *C. lanuginosa*. Dillw. 45. "Filaments nearly simple, very minute; of a rusty colour; joints rather long, pectinid in the middle; capsules sessile, unilateral." In the sea, adhering to other conferræ. 32. *C. nigra*. Hudf. Flor. Ang. p. 595. "Filaments equal, branched, very long; branches alternate, many-cleft, very short." *Filaments* five inches long, black, fissile; branches fasciculated. On the Yorkshire coast. 33. *C. byssoides*. Dillw. 58. Eng. Bot. 547. "Filaments more than twice pinnated; branches and branchlets alternate; uppermost ones extremely short, somewhat fasciculate; partitions from the union of the veins; joints rather long; capsules egg-shaped, sessile." *Filaments* extremely flaccid, zig-zag, transparent, beautifully striated by longitudinal veins, each of which arch over at or near the same place, and appear to form the partition. Common on most of our shores, from three to five inches long, varying in colour from a reddish brown to a light or purplish red. 34. *C. parasitica*. Hudf. Flor. Ang. p. 604. Eng. Bot. 1429. "Filaments branched; branches doubly and alternately pinnated; capsules axillary, solitary, oblong." *Filaments* an inch long or more, purplish brown, slender, cylindrical, with the same jointed and tubular structure as the preceding. Parasitic on fuci, found rarely on the coast of Yorkshire, Devonshire, and Cornwall. Dr. Smith observes that the last two species have the jointed structure of conferræ, but agree better with the character of fuci in their fructification. The same observation will apply to several of the following species. 35. *C. nigrescens*. Hudf. Fl. Ang. p. 602. Smith Eng. Bot. 1717. "Filaments much branched; branches alternate, elongated; ultimate ones short, crowded, awl-shaped; joints rather broader than long, compound." *Filaments* from four to six inches long, blackish. *Joints* a little contracted, consisting of a circular double series of numerous parallel tubes, similar to those of *C. byssoides*. Mr. Stackhouse is said to have found the fructification in small lateral nodules on the coast of Scotland, Devonshire, and Cornwall. 36. *C. fistula*. Hudf. 603. "Fila-

"Filaments much branched; branches and branchlets a ternate, simple." *Filaments* three or four inches long, dark brown or reddish; branches long; branchlets short, dilant, *Fruifications* terminal and lateral, sessile, small, roundish, clustered. 37. *C. mertensii*. Smith Eng. Bot. 999. "Filaments much branched; branches opposite, pinnated; joints short; capsules minute, acorn-shaped, on short peduncles." In habit resembling *fungus wigii*. *Filaments* about three inches long, pale yellow, pinnated from their very origin; pellucid; branches short, ditichous, horizontal, generally simple. *Partitions* darker, and thence visible. *Capsules* visible on γ with a good glass. Found on the beach near Yarmouth. Mr. Dawson Turner. 38. *C. fusoides*. Hudf. Fl. Ang. p. 603.—Dillw. 75. Eng. Bot. 1743. "Filaments capillary, somewhat cartilaginous, much branched; partitions from the union of the nerves; joints compound, shortish, striated; capsules solitary, egg-shaped, sessile." *Filaments* from two or three inches to a foot long, reddish-brown, becoming darker and almost black with age, remarkably thick and bulky in its growth, ultimate branches awl-shaped, all alternate. *Joints* of the stem and principal branches three times as long as broad; of the branchlets about as long as broad, each consisting of a simple circular series of numerous parallel tubes. *Capsules* terminal and lateral, small, obtuse, discharging their seeds at the summit. On rocks and stones in the sea, frequent. 39. *C. atrorubescens*. Dillw. 70. "Filaments branched, striated; branches elongated, generally alternate, branchlets short, awl-shaped, fasciculated; capsules egg-shaped, peduncled." *Filaments* from four to nine inches long, the thickness of small thread, growing separately, varying from a light purple to a dusky red, and becoming black with age or by drying, striated under the microscope by longitudinal spiral veins, which arch over at or near the partitions, and at first sight appear to form them. *Joints* in the principal branches often more than twice as long as broad, in the branchlets about equal in length and breadth. *Capsules* either lateral or terminal. In the sea, adhering to rocks, stones, and shells. 40. *C. rosea*. Smith Eng. Bot. 966. Dillw. 17. (Ceranium roseum. Roth Cat. Bot. ii. p. 182.) "Filaments repeatedly branched; branches and branchlets alternate, approximate; partitions transparent, a little contracted; joints oblong; capsules unilateral, sessile, somewhat globular." *Filaments* from an inch and a half to three inches long, in their thickest parts nearly as fine as human hair, so fine near their tips as to be scarcely visible, very flaccid, when floating in water resembling beautiful feathers, rose-coloured. In the sea, on rocks, fuci, and other substances. 41. *C. coccinea*. Hudf. Flor. Ang. p. 603. Eng. Bot. 1035. Dillw. 36. (C. plumosa. Lightf. 995. Ellis Philos. Transf. vol. lvin. 425. tab. 18. fig. c. c. d. D. Ceranium bifurcum. Roth Cat. Bot. ii. 169. tab. 4.) "Filaments somewhat cartilaginous, much branched; main stem rough with hairs; branches alternate, more than twice alternately pinnated; extreme branchlets fasciculated, pencil-shaped; partitions obscure; joints short; capsules egg-shaped." *Main stem* nearly as thick as common twine, solitary, mostly of a darker red than the branches. *Partitions* scarcely perceptible in the main stem and larger branches, but very apparent in the smaller ones, dividing them into short transparent joints. *Capsules* bright red early in spring, becoming gradually darker, and in May discharging the seeds by an aperture at the tip. On rocks and stones in the sea common. 42. *C. turneri*. Smith Eng. Bot. 1037. "Repeatedly branched, very slender, tufted; ultimate branches all pectinated on the upper side; joints transparent, cylindrical; capsules globular, sessile between the teeth of the branches, unilateral." Pectinated branchlets opposite;

Capsules deep red, scattering the seeds over the branches. *Seeds* large. In the sea, off the Isle of Wight. 43. *C. plumosa*. Ellis Phil. Transf. vol. lvi. p. 426. Dillw. 50. "Filaments much branched; branches alternate, pinnated; pinnæ opposite; ultimate branchlets unilateral; joints longish; capsules short, pedicelled." Whole plant deep red, pellucid. *Partitions* dark. *Capsules* very numerous, unilateral on the ultimate branchlets, discharging the seeds at the tip. In the sea, adhering to conservæ. 44. *C. tetrica*. Dillw. 81. "Filaments repeatedly pinnated; pinnæ and pinnulæ alternate; ultimate ones curved; joints rather long; capsules generally only one on each ultimate branchlet, globular, peduncled." *Stems* several from the same callus, forming thick entangled tufts of a brownish-red colour, six or eight inches long, about the thickness of horse hairs. On rocks and fuci in the sea. 45. *C. diaphana*. Lightf. Flor. Scot. 996. Hudf. Flor. Ang. 653. Dillw. 38. Smith Eng. Bot. 1742. (C. nodulosa. Hudf. Flor. Ang. 600. C. marina nodosa lubrica, ramossissima et eleganter rubens. Dill. 35. tab. 7. 40.) β C. purpurascens. Hudf. "Filaments capillary, repeatedly forked, divaricated; ultimate divisions like a pair of forceps; partitions obsolete; joints short, pellucid in the middle, deep red at each end; capsules lateral, solitary, globular." From two to six inches high, presenting to the naked eye the appearance of a series of small heads, alternately coloured and pellucid. Common in the sea, on rocks, stones, and fuci. 46. *C. rubra*. Hudf. Flor. Ang. 600. Smith Eng. Bot. 1166. Dillw. 34. (C. nodulosa. Lightf. Flor. Scot. 944. C. geniculata, ramossissima lubrica longis sparsive ramulis. Dill. 35. tab. 6. fig. 38. A. Ceranium virgatum. Roth Cat. Bot. i. 148. tab. 8. fig. 1.) "Filaments repeatedly branched, thread shaped, thickly jointed; ultimate branches bristle-shaped, forked; capsules somewhat globular, sessile, solitary, lateral." Eighteen or twenty inches high, light red or purple, very liable to bleach. *Filaments* one or more from the same callus, about the size of sewing-silk; partitions dark red, more or less contracted; joints beautifully reticulated, pellucid towards the centre. Common on rocks and stones in the sea. 47. *C. tetragona*. With. Bot. Arr. 34. 495. Dillw. 65. Eng. Bot. 1690. "Filaments much branched; branchlets fasciculated, short, generally simple; joints ovate-cylindrical; capsules sessile, somewhat globular." Seldom more than two inches long. *Stems* several from one callus, straight, branched on all sides, forming an irregular ovate general outline, of a light purplish-red colour; branches square. Parasitical on fungi. 48. *C. elongata*. Hudf. Flor. Ang. 599. Dillw. 33. (Fucus distichus. Hudf. Flor. Ang. 589.) "Filaments much branched, cartilaginous; branches and branchlets elongated, diffuse, bristle-shaped veined; partitions obscure; joints very short; capsules egg-shaped, sessile." Exceeding in size every other British conservæ. *Main stem* as thick as common twine, purplish-red; branchlets paler; partitions dark-coloured. *Capsules* scattered sparingly on the ultimate branches. On rocks, oyster-shells, &c. 49. *C. littoralis*. Linn. Sp. Pl. 6. Lam. 6. Dillw. 31. (C. marina capillacea longa, ramossissima, mollis, Dill. 23. tab. 4. fig. 19.) "Filaments much branched, very slender, zig-zag, thickly matted; branches and branchlets acuminate; partitions obscure; joints cylindrical, short." *Filaments* from six to nine inches long, of a dull olive-green colour; branches generally alternate, making an acute angle with the stem. *Capsules* globular, scattered irregularly on the branches, rarely found. On rocks and fuci, common. 50. *C. conoides*. Dillw. 27. Smith Eng. Bot. 1700. "Filaments capillary, zig-zag, branched; branches scattered, sharp-pointed, but little spreading; partitions scarcely visible." Nearly allied to the preceding. *Filaments* seldom

more than an inch long, purple-brown. lying one over another, on the round pebbles in the sea. so as to have a striking resemblance to an infant's head. 51. *C. tomentosa*. Hudf. Flor. Ang. 594. Dillw. 56. (*C. marina* tomentosa, minus tenera et ferruginea. Dill. 19. tab. 3. fig. 13.) "Filaments much branched, very slender, thickly matted, divaricated, extreme branchlets simple; joints long." *Filaments* from three to five inches long, of a pale greenish or russet-brown colour; branches so slender as to be scarcely visible without a microscope, issuing at right angles. *Joints* at least three times as long as thick. *Partitions* dark brown. Frequent, generally parasitical on *fucus vesiculosus*. 52. *C. allida*. Hudf. Flor. Ang. 595. (*C. marina* tomentosa, tenerior et albicans. Dill. 19. tab. 3. fig. 12. *C. tomentosa* ß. Roth.) "Filaments much branched, very slender, equal; branches simple, fasciculated, white." *Filaments* scarcely separately visible to the naked eye, pale green, soft, resembling cotton. Found in salt water, ditches, and pools in the island of Selsey in Sussex. 53. *C. fetacea*. Hudf. Flor. Ang. 599. Smith Eng. Bot. 1689. Dillw. 82. (*C. marina* gelatinosa, corallinæ inlar geniculata, tenuior. Dill. 33. tab. 6. fig. 37.) "Filaments alternately and repeatedly branched, taper-pointed, fasciculated, slippery; joints a little swelling, at least four times as long as broad; lateral shoots bearing tufts of filaments containing many globular seeds. Seldom exceeding four or five inches in length, of a rich crimson colour. On rocks and stones in the sea, not unfrequent at the latter end of summer and beginning of autumn. 54. *C. borrieri*. Smith Eng. Bot. 1741. "Filaments capillary, repeatedly branched; branches alternate, spreading in two directions, zig-zag; ultimate ones fattigiate; joints cylindrical, about twice as long as broad." *Filaments* in tufts, about two inches long, of a delicate pink colour, turning orange when dry. *Fertilisation* unknown, but conjectured by Dr. Smith to resemble that of *C. fetacea*. Gathered on Yarmouth beach by W. Borrer, etcq. F. R. S. 55. *C. stricta*. Dillw. 40. "Filaments somewhat dichotomous, fasciated, veined; joints long." *Filaments* in thick bundles, many from the same root, seldom more than three inches long, of a dull crimson colour, repeatedly divided. *Joints* about three times as long as broad. On rocks in the sea, at Dover and Swansea. 56. *C. rothii*. Turton's Syst. Nat. 6. 1806. Dillw. 73. Eng. Bot. 1702. (*C. violacea*. Roth. Cat. Bot. i. 190. tab. 4. fig. 1.) "Filaments erect, dichotomous, short, densely tufted, crimson; branches alternate; joints very short." *Filaments* very slender, from three to twelve lines long. *Joints* cylindrical, about twice as long as broad. On rocks by the sea-shore. 57. *C. corallinoides*. Linn. Sp. Pl. 15. (*C. marina* gelatinosa corallinæ inlar geniculata crassior. Dill. 33. tab. 6. fig. 36.) "Filaments dichotomous; joints thicker at the top." *Filaments* bright red or white, slippery, very tender, almost disappearing when dry. On stones on the sea-shore. 58. *C. tubulosa*. Hudf. Flor. Ang. 600. (*C. marina* filitulosia. Dill. 34. tab. 6. fig. 39. *Ulva* confervoides. Linn.) "Filaments much branched; joints oval, alternately compressed." *Filaments* from two to four inches long, yellowish green; branches knotted, hollow. On rocks, stones, and fuci. 59. *C. catenata*. Linn. Sp. Pl. 16. Lam. 16. (*C. ramosa*, geniculis longioribus cateniformibus. Dill. 27. tab. 5. fig. 27.) "Filaments branched, green; joints oblong, forming a kind of chain, with links alternately broader and narrower." On the coasts of Carolina, the Bahama islands, and the south of Europe. 60. *C. scoparia*. Linn. Sp. Pl. 9. Lam. 9. Smith Eng. Bot. 1552. Dillw. 52. (*C. marina* pennata. Dill. 24. tab. 4. fig. 23.) "Filaments much branched, rigid; branches fasciculated, ultimate divisions alternate, acuminate; partitions obscure; joints short."

Whole plant of a brownish olive, changing when dry to a russet-brown colour. *Filaments* from two to six or nine inches long; upper branches longer and more clustered than the lower, giving the plant a brush-like appearance. *Joints* about as long as thick. Frequent on the sea coast on stones and pebbles. 61. *C. pennata*. Hudf. Flor. Ang. 604.—Dillw. 85. "Filaments branched; upper branches pinnated; pinnae nearly opposite, nearly horizontal, approximate, stiff and straight; partitions obscure; joints short; tubercles fissile, spherical." Often confounded by botanists with the preceding. *Filaments* in bushy tufts from half an inch to two inches long, olive green, brown when dry. On rocks, fuci, & corallines. 62. *C. verrucosa*. Smith Eng. Bot. 1688. "Branches irregularly scattered and subdivided, scarcely jointed, studded with rough warts." *Filaments* three or four inches long, pale reddish brown, capillary, but uneven, somewhat twisted, not perceptibly jointed, except in the youngest shoots, where an interruption of colour is sometimes perceived at intervals. Found on the coast of Hampshire and Cornwall. 63. *C. villosa*. Hudf. Flor. Ang. 603.—Smith Flor. Ang. 546.—Dillw. 37. "Filaments branched; branches and branchlets opposite, distant; joints very short; partitions obscure, villous." *Stem* from six inches to three feet high, greenish yellow, seldom more than thrice divided; hairs in whorls on about every fourth or fifth joint, extremely slender, brittle; partitions not readily discoverable except in the verticillated hairs. On submarine rocks and stones. 64. *C. ciliata*. Ellis in Philof. Trans. vol 57. p. 425. tab. 18 f. 4. H.—Dillw. 53. (*C. plicata*; Roth Cat. Bot. 2. 225. tab. 5. fig. 2.) "Filaments dichotomous, incurved at the tips in a forceps-like manner; partitions beset with verticillated cilia, reddish at each end, pellucid in the middle; capsules somewhat globular, lateral." *Filaments* in bushy tufts, seldom more than two inches long, varying from a bright to a purplish red. On rocks, stones, and fuci, frequent. 65. *C. equisetifolia*. Lightf. Flor. Scot. 984.—Smith Eng. Bot. 1479.—Dillw. 54. (*C. imbricata*; Hudf. Flor. Ang. 603, and multicauda. Hudf. 603, as appears from an authentic specimen communicated by Dr. Goodenough to Mr. D. Turner.) "Filaments much branched; branches acuminate, elongated; branchlets verticillated, short, dichotomous; joints of the branchlets long." From three to eight inches long, the thickness of a crow's quill, bright red when young, afterwards dull brown. *Stem* and branches very where clothed with numerous whorled branchlets, which, being longer than the joints, are tiled upon each other, and give the plant a rough spongy appearance. On rocks and stones in the sea, not unfrequent. 66. *C. spongiosa*. Hudf. 596.—Dillw. 42. (*Fucus hirtutus*; Linn. Mant. 134.—*Mucus marinus* hirtutus; Morif. 3. 650. tab. 9. fig. 6.) "Filaments branched, branchlets very short, simple, imbricated on all sides; joints short; capsules oblong, pedicelled." Seldom more than three inches long, olive-coloured. *Branchlets* not whorled but disposed without any regular order, not dichotomous. *Capsules* small, on rather long pedicels, discharging the seeds at the summit. Rocks in the sea, not uncommon. 67. *C. verticillata*. Lightf. Flor. Scot. p. 984.—Smith Eng. Bot. 1718.—Dillw. 55. (*C. Myriophyllum*; Roth in Schrabers Journ 3. 335.) "Filaments cartilaginous, variously branched; branchlets at the partitions, verticillated, very short, incurved, frequently forked; joints about as broad as long." Four or five inches long, of a dull olive colour. On rocks and stones in the sea. 68. *C. arbutula*. "Primary filaments thick, not jointed, naked near the bottom, much branched above; branchlets crowded, somewhat verticillated,

lated, short, branched, jointed; joints cylindrical, short." About three or four inches long, of a beautiful deep-red brown colour when fresh, dull brown when dry without glos. On submerfed calcareous rocks in the north of Ireland. 69. *C. cancellata*. Linn. Sp. Pl. 10. Lam. 10.—Hudf. Flor. Ang. p. 596.—Dill. 24. tab. 4. fig. 22. "Filaments branched; joints short, much divided, digitate." Three or four inches long, of a pale dirty colour, irregularly branched; branches an inch and half or two inches long; branchlets capillary, numerous, incurved, leaving a hollow space between them and the branch. On stones and rocks in the sea. 70. *C. repens*. Dillw. 18. Smith Eng. Bot. 1608. (*C. fulva*; Hudf.?) "Filaments minute, creeping, densely matted; partitions scarcely contracted; joints cylindrical, twice as long as they are broad." Seldom more than three or four lines long, the thickness of human hair, of a more or less vivid red colour, investing the larger fuci and confervæ in minute dense tufts like velvet or plush; branches and branchlets generally unilateral. 71. *C. flexuosa*. Dillw. 10. "Filaments dichotomous, rather rigid; branches zig-zag; branchlets generally simple, very slender, alternately unilateral, spreading; joints cylindrical; partitions obsolete." Filaments in closely entangled masses, from four to eight inches long, finer than human hair, pale yellowish green in the branchlets, very dark green in the main shoots. On the sea coast and in salt-water pools at Yarmouth. 72. *C. late virens*. Dillw. 48. "Filaments much branched, rather rigid, curved; branchlets twice alternately unilateral; partitions pellucid; joints long." Filaments from three to six inches long, light green, irregularly branched, growing in a bushy manner. On rocks, fuci, and corallines on the Welsh coast. 73. *C. diffusa*. Dillw. 21. Roth Cat. Bot. 2. 207. tab. 7. "Filaments branched, diffuse; branches somewhat dichotomous, zig-zag, remote; branchlets short, approximate, obtuse; partitions pellucid; joints rather long." Filaments in loosely entangled bundles, from two to six inches long, pale green, more rigid than in most other species, not collapsing when drawn out of the water. On rocks in the sea. 74. *C. rufescentis*. Linn. Sp. Pl. 20. Lam. 20. Dillw. 23. Smith Eng. Bot. 1699. (*C. glauca*; Roth Cat. Bot. 2. 208. tab. 6. *C. trichodes ramiflor.* Dill. 28. tab. 5. fig. 29.) "Filaments much branched, fasciculated, rigid, straight, obtuse; joints long, even; partitions but little contracted, colourless." From three to six inches long, dull green, in dense tufts upon rocks, pebbles, or dead shells. 75. *C. pellucida*. Hudf. p. 601. Smith Eng. Bot. 1716. "Filaments erect, much branched; branches mostly ternate, cylindrical; joints even, cylindrical, four times as long as broad." Filaments about six inches long, green, shining, pellucid, somewhat wiry and elastic to the touch, naked and stem-like towards the bottom. On the coast about Yarmouth. 76. *C. feniculacea*. Hudf. p. 594. Dill. 16. tab. 2. fig. 8. "Filaments square, much branched; branches and branchlets very long, scattered." Filaments irregularly divided like the leaves of fennel, soft and greenish when young, brownish and stiffer when old. On the shores of Cornwall and the Isle of Man. 77. *C. aruginosa*. Linn. Sp. Pl. 7. Lam. 7. (*C. marina capillacea brevis, viridissima mollis*; Dill. 23. tab. 4. fig. 20.) "Filaments branched, soft, shorter than the human finger, very green." Filaments numerous, very fine, shining and silky when dry, retaining their elegant cereulean green colour. On fuci, not very common. 78. *C. vagabunda*. Linn. Sp. Pl. 18. Lam. 18. (*C. marina trichodes, lance inflar expansa*; Dill. 30. tab. 5. fig. 32.) "Filaments zig-zag, much branched; branch-

lets very short, horizontal." Floating in the water without root, pale green, joints so small towards the extremities, as scarcely to be seen with a common lens. In salt water marshes and ditches. 79. *C. sericea*. Hudf. p. 601. (*C. trichodes virgata sericea*; Dill. 31. tab. 4. fig. 33.) "Filaments much branched, elongated; branchlets crowded, very slender." From four to eight inches long, pale green in salt water, fine green, softer and smoother in fresh water. On submarine rocks; also in the new river near London and other fresh water rivulets.

†† In fresh water.

80. *C. dichotoma*. Linn. Sp. Pl. 8. Lam. 8. Smith Eng. Bot. 932. Dillw. 15. (*C. dichotoma fetis porcinis similis*; Dill. 17. tab. 3. fig. 9. *Ceraminum dichotomum*. Roth Cat. Bot. i. 153.) "Filaments fasciculated, straight, fastigiate, dichotomous, hollow, somewhat jointed; partitions obsolete; joints very long, capsules elliptical, sessile." Filaments in dense masses, about two feet long, considerably thicker than horse-hair, dark green, most dichotomous near the top; angles of the divisions acute; partitions scarcely perceptible, except in the dried plant. Capsules scattered, sometimes single, sometimes five or six together. In ditches common; also according to Dillenius in ditches, between Greenwich and Woolwich, filled every tide with the brackish water of the Thames. 81. *C. furcata*. Hudf. Flor. Ang. p. 592. (*C. capillacea, filamentis bifidis et trifidis*.) "Filaments branched at the extremity; branches simple." Filaments long, simple, the greatest part of their length, once or twice branched at the end, of a dull pale colour, white when dry. 82. *C. fraida*. Flor. Dan. tab. 946. Dillw. 14. (*C. divaricata*; Roth Cat. Bot. i. 179. tab. 3. fig. 1.) "Filaments much branched, matted; branches and branchlets divaricate; older joints oblong; younger ones cylindrical; capsules sessile, roundish." Filaments from one to four inches long, the thickness of human hair, dark green, rather rigid, generally floating, in densely entangled masses, on the surface of stagnant water; branches abruptly terminated, so as to give the plant a broken appearance. 83. *C. vivipara*. Dillw. 59. "Filaments dichotomously branched; branches zig-zag, bulbiferous at the partitions; bulbs terminated by a long hair; joints long; capsules lateral, sessile." Filaments in small, slender, bushy tufts, commonly not more than two lines long, never exceeding half an inch, yellowish green; joints five times as long as thick. Capsules at some of the partitions; bulbs at the others. In boggy rivulets on stones, moss, and other substances. 84. *C. gelatinosa*. Linn. Sp. Pl. 13. Lam. 13. Smith Eng. Bot. 689. Dillw. 32. (*C. fontana nodosa spermatifera ranaum inflar major et fusca*; Dill. 36. tab. 7. fig. 42. *Chara batrachosperma*; Weis Gott. 33. tab. 1. *Batrachospermum moniliforme*; Roth Cat. Bot. 2. 187.) "Filaments much branched, beaded, slippery; branchlets very slender, pencil-shaped, somewhat vertically lated, very compound, bearing the fruit; partitions obscure, joints rather short; capsules roundish with many seeds." From one to six inches long, resembling frogs spawn, dark purple or yellowish green. β minor et viridis; Dill. 37. tab. 7. fig. 43. δ Hudf. *C. filamentis nodosis et cæruleis*; Dill. fig. 43. But from some specimens gathered in an alpine lake on Saowden, Mr. D. Turner is dubious whether it be not a distinct species; its stems being quite hard, and its moniliform appearance very faint. In clear springs and streams. 85. *C. mutabilis*. Roth Cat. Bot. 1. 197. Dillw. 12. Smith Eng. Bot. 1740. (*C. gelatinosa* γ Hudf. *C. itagnalis, globulis virefcentibus mucosus*; Dill. 38. tab. 7. fig. 44.) "Filaments much branched, gelatinous, somewhat beaded; branchlets compound,

pound, twisted; partitions contracted; joints short." Vanius in length from half an inch to three inches, and from a light to a dark green. Main stems remarkably pale and pectinate; branches darker. Joints short. In pools and ditches, not uncommon. 86. *C. atra*, Hudf. p. 597. Smith Eng. Bot. 67. Dillw. 11. (*C. fontana*, nodosa, lubrica, filamentis; *musculus nigris*; Dill. 3, tab. 7. fig. 46.) "Filaments much branched beaded, somewhat gelatinous; branchlets bristly-shaped; joints dilated towards the tip, ciliated; edge verticillated, imbricated." Varying in colour, during different stages of its growth, from a pale to a dark green, and finally becoming black. In clear rivulets and springs, but rare. 87. *C. fluviatilis*. Linn. Sp. Pl. 12. Lam. Pl. Dillw. 29. (*C. lubrica*, fetosa, equifolia facie; Dill. 3, tab. 7. fig. 47. *C. nodosa*, *faunus molans*; Dill. 37. tab. 48. *C. torulosa*. Roth Cat. Bot. 1. 202.) "Filaments branched, rather rigid; branches and branchlets generally alternate, attenuated each way; partitions swollen, tubercled; joints long, dilated at both ends." *Filaments* six or eight inches long, dull olive or greenish purple; sometimes nearly simple, when they are shorter, thicker, and more rigid. Dill. 48. Dillwyn has seen these different filaments growing from one root. In rapid, rocky streams. 88. *C. lubrica*. Dillw. 77. "Filaments much branched, slender, very long, shining, slippery; branches thorn-like; joints rather short." *Filaments* from six inches to near a foot long, green, with a slight tinge of blue, branches scattered, forming an acute angle with the stem. In clear rivulets attached to stones and wood in large gelatinous masses. 89. *C. proterva*. Dillw. 67. "Filaments much branched; branches diffuse, much lengthened out, pellucid at the tip; joints rather long." *Filaments* from two lines to a half or three quarters of an inch long, light green. In rivulets and springs, on stones and aquatic plants. 90. *C. glomerata*. Linn. Sp. Pl. 19. Lam. 19. Flor. Dan. tab. 65. fig. 2. Dillw. 13. (*C. fontinalis ramosissima glomeratim congesta*. Dill. 28. tab. 5. fig. 31. *C. cristata*; Roth Cat. Bot. 1. p. 193. 2. p. 220.) "Filaments much branched; branches alternate; branchlets unilateral, fasciculated, pencil-form; partitions pellucid; joints cylindrical, rather long." *Filaments* from two or three inches to a foot long, yellowish green. On stones and wood in clear rivers and streams. 91. *C. rigida*. Hudf. Flor. Ang. 594. (*C. fluviatilis fibrillosa subrigida*; Dill. 21. tab. 4. fig. 16.) "Filaments much branched, rather rigid; branchlets alternate, very short." *Filaments* several from the same base, so as to have a clustered appearance, and sometimes to cover the pebble to which they are attached, dull green, often inclining to brown. Somewhat hairy; branchlets most numerous near the summits of the filaments. In clear streams. 92. *C. canaliculata*. Linn. Sp. Pl. 4. Lam. 4. (*C. rivulorum capillacea densiflora conglobis ramulis*; Dill. 21. tab. 5. fig. 15.) "Filaments most branched near the base; branches long." *Filaments* one or two inches long, slender, deep green, simple or but little branched above the middle, of a spongy soft substance, densely matted together so as to resemble a piece of velvet, soft and herbaceous when fresh, but when dry blackish, and acquiring almost a stony hardness from the mud adhering to it. In pure streams and mill-pool water spouts. 93. *C. bulbosa*. Linn. Sp. Pl. 3. Lam. 3. (*C. palustris bombeyana*; Dill. 18. tab. 3. fig. 11.) "Filaments branched, matted inclosing air bubbles." *Filaments* from three to nine inches or a foot long, slender, dull yellowish green. In clear waters, soft, somewhat silky, and of a livelier green; in stagnant muddy waters, paler, tomentous, resembling dirty cotton. Professor Martens is of opinion that *C. fracta* is the plant intended by Linnæus, and since called *C. bul-*

lofa; but Mr. Dillwyn observes that the specimen in Dillæus's herbarium, here described, is certainly another species, and agrees with Mr. D. Turner in thinking, that several distinct plants which have the property of retaining bubbles of air have been confounded by authors, and consequently that the confervæ bulbosa are a family and not a species. These confervæ when dried have been used as wadding for stuffing garments, and have been woven into coarse household linen. 94. *C. dispersa*. Flor. Dan. tab. 820. Dillw. 22. "Filaments branched, jointed, fasciated with transverse lines; branches and branchlets distorted; partitions obsolete; joints short." *Filaments* about half an inch long, extremely slender, of a beautiful dark green colour varying to a lighter colour as they approach to decay; branches seldom numerous, but with a very peculiar twist at their ramifications. Parasitical in short thick tufts on decaying grass, attached to small pieces of which it frequently floats on the surface of the water. Hitherto found in Great Britain, only by Mr. Dillwyn, in a boggy pool on Sketty Burroughs, near Swansea. 95. *C. agagropia*. Linn. Sp. Pl. 21. Lam. 21. Smith Eng. Bot. 1377. Dillw. 87. "Filaments much branched, clustered into a globe and divaricating from the centre; branches and branchlets nearly unilateral, straight, obtuse; joints long, cylindrical." From the size of a pea to three or four inches in diameter, always pretty exactly spherical, hollow within, without any solid body, or root, to which the filaments might originally have been attached. The specific name alludes to the hairy balls found in the stomach of goats. In lakes lying in great abundance at the bottom of the water. 96. *C. nana*. Dillw. 30. "Filaments branched, very minute; branches and branchlets generally alternate, acuminate; partitions pellucid; joints cylindrical." *Filaments* seldom much more than half a line long, of a pale brown colour tinged with brown, resembling *C. littoralis* in its ramification, and remarkably acuminate branches. Parasitical on decayed confervas, &c. in rocky rivers. 97. *C. typhlodermis*. Dillw. 83. "Filaments nearly simple, densely matted; partitions obscure; joints short." The extreme tenacity and entangled growth of the filaments makes it impossible to ascertain their length; their colour is a dull olive green. Observed in a bottle which contained a solution of gum dragon in water, the surface of which was covered with a mass of filaments so densely interwoven as to form a film about two lines in thickness, bearing a considerable resemblance to the skin of a mole. 98. *C. ochracea*. Dillw. 62. Roth Cat. Bot. 1. 65. tab. 5. fig. 2. "Filaments much branched, very slender, very brittle, closely compact, constituting an ochraceous jelly, which at length breaks into fragments of separate filaments." The filaments are so extremely fragile that the slightest touch or any considerable agitation of the water breaks them into a thousand pieces, which at first remain suspended, and afterwards sink to the bottom in the form of an ochraceous powder. In this state only can the plant be examined, but the fragments are so small that it is impossible to ascertain their original length, and under the highest magnifiers their thickness scarcely seems equal to that of the human hair. In pools and ditches common, of a dull yellow colour. 99. *C. laeta*. Dillw. 79. Roth Cat. Bot. 1. p. 216. 3. p. 292. (*C. pusilla*; Roth Flor. Germ. 1. 524.) "Filaments much branched, gelatinous, slippery; branches rod-like, alternate from each partition; partitions contracted; joints very long, glassy-transparent." *Filaments* growing in gelatinous masses at the bottom of ditches and rivulets, from half an inch to three or four inches long, of a dirty white colour; branches clustered, so as to give them a brush-like appearance; partitions of a dusky colour. *Joints* at least ten times longer than

than thick. 100. *C. myoceros*. Dillw. 19. Smith Eng. Bot. 1555. "Filaments very densely matted, branched; branchlets simple, generally unilateral, in pairs, incurved." *Filaments* sometimes quite simple, generally branched, seldom more than half an inch long, as fine as the finest wool. On the rocky beds of torrents in the vale of Beddgelert, in Caernarvonshire, matting the stones with a velvety covering, three or four lines in diameter, of a dark glossy brown colour, soft to the touch, which, when taken out of the water, might be compared to the skin of a mouse. 101. *C. vesicata*. Dillw. 74. Müller in Nov. Act. Pet. 3. "Filaments branched, somewhat jointed, rigid; vesicles innate, solitary, elliptical, broader than the filament; capsules generally in pairs, pear-shaped on short peduncles." *Filaments* in bushy masses at the bottom of the water, so extremely brittle that their length cannot easily be ascertained, yellowish green, cylindrical, filled with minute granules which issue from them when broken; very rough to the touch; branches few, distant, generally making an obtuse angle with the stem. *Stems* and *branches* frequently swollen, with bladder-like vesicles, four or five times thicker than the filaments, resembling those of *fucus nodosus*. *Partitions* irregularly disposed, always at a great distance from each other. 102. *C. amphibia*. Linn. Sp. Pl. 5. Lam. 5. Dillw. 41. (*C. amphibia fibrillosa* et *spongiosa*; Dill. 22. tab. 4. fig. 7. B and C). "Filaments somewhat jointed, branched, densely matted; branches spreading, remote; branchlets, when not immersed, collecting into sharp bristly points; partitions but little contracted; capsules sessile, somewhat elliptical." β . branches elongated (*C. furecata*; β . Huff. Ceramium coespitosum; Roth Cat. Bot. 1. p. 154. 2. p. 186. *C. palustris filamentos brevioribus et crassioribus*; Dill. 17. tab. 3. fig. 10.) Filaments very various in length, according to the situation, bright green, becoming ash-coloured with age; α is the plant as it grows on the edges of ditches, and in shallow water, where it is not wholly immersed. In such situations, it frequently occurs in masses, so densely matted as to hold water like a sponge, with its surface beset by erect branches, which give it a bristly appearance. In floods, when the waters overflow the plant, the length of the filaments is gradually increased, and forms Mr. Dillwyn's β ; but when the waters subside, the filaments, again exposed to air, take of course an horizontal direction, and again throw out erect spreading branchlets, which, on being dried, collapse so as to form rather stiff points. In rivers, the branches are frequently carried out by the force of the stream to a great length, and in that case do not assume a bristly appearance when exposed to air; probably owing to the less spongy nature of the mass, in consequence of which the water is not so readily transmitted to the upper surface, as to enable it to make fresh shoots. The plant has a mouldy ungrateful smell, and is much used as a shelter by aquatic insects.

** Not immersed.

103. *C. atrovirens*. Dillw. 25. "Filaments rather rigid, branched; branches divaricated, somewhat unilateral, attenuated at both ends, rather obtuse; partitions pellucid; joints very short, marked with three points." *Filaments* from a quarter to half an inch long, growing in thick bushy tufts, of a blackish green colour, not unrequently intermixed with mucus. On the wet rocks, forming the banks of the river Dylais, near Neath. 104. *C. frigida*. "Filaments not jointed, creeping, branched; Dillw. 16. (Ceramium Dillwynii; Roth.) "Filaments not jointed, creeping, branched; branches alternate; capsules sessile,

round." *Filaments* about an inch long, a little finer than human hair, of a pale green colour, growing in loose irregular patches, two or three inches in diameter, very slightly adhering to the soil. On the ground in moist shady places, particularly in turnip fields, with a northern exposure, during the winter and early months of spring. The frigidia of Dr. Roth is a different plant, referred by him to Dill. tab. 4. fig. 17, A. 105. *C. umbrosum*. Dillw. 61. Roth Cat. Bot. 1. 191. tab. 4. fig. 3. (*C. arcuaria*; Roth Cat. Bot. 2. 217?) "Filaments branched, creeping, fragile, short-obtuse; branches curved, simple, somewhat unilateral; joints long, sometimes cylindrical, sometimes inflated." Growing in smaller patches, and of a darker colour, than *C. frigida*. *Filaments* scarcely half an inch long; joints varying greatly in shape and length. 106. *C. pallida*. Dillw. 78. "Filaments dichotomous, curved, zig-zag, fastigate angles of the divisions roundish; joints very long." *Filaments* considerably finer than human hair, a light yellowish brown, matted together into dense leathery masses, about an inch long, and the thickness of a shilling; joints at least eight or ten times broader than thick. Found on some yellow ochre, in a pot of singlass size. 107. *C. multicaespularis*. Dillw. 71. "Filaments minute, creeping, olive-coloured; branches erect, generally simple, short, thickened towards the top, and bearing the capsules; capsules clustered, spherical." *Filaments* very minute, thickly entangled, growing in small irregular patches. *Joints* in the creeping item very long; in the branches shortest at the base, and longest towards the summit. *Capsules* terminating the branches, discharging the seeds at the orifice. On clayey banks, in high exposed situations. 108. *C. rubiginosa*. Dillw. 72. Smith Eng. Bot. 1701. "Filaments creeping, branched, entangled, alternately bipinnate; branches divaricated, tapering, acute; joints elongated, cylindrical." *Filaments* creeping in loose entangled masses, among mosses, over dead stalks and sticks, and along the ground, of a brown chestnut colour; branches from a quarter to half an inch long; pinnæ and pinnulæ variously curved, nearly at right angles with the stem and branches; partitions almost black; joints in the stem and main branches three or four times longer than broad. On hedge banks. 109. *C. rubiginosa*. Dillw. 68. "Filaments much branched, rigid, rather erect; branches zig-zag, spreading, matted together so as to form nearly a solid mass; joints long." *Filaments* very minute, growing in irregular patches, about an eighth of an inch in thickness, of a rusty brown colour, entirely destitute of gloss. *Joints* visible only under the highest powers of the microscope, about four times longer than broad. On rotten wood, secluded from the light. 110. *C. volutina*. Dillw. 77. Smith Eng. Bot. 1556. "Filaments creeping, branched, matted; branches erect, alternate, or unilateral, curved, obtuse; joints slightly swelling, at least twice as long as broad." Distinguished by its sweet scent. (See *Byssus volutina*.) Jointed structure first discovered by Mr. J. D. Sowerby. 111. *C. aurea*. Dillw. 35. "Filaments branched, gold-coloured, minute; branches long, spreading, rather rigid, somewhat incurved; partitions pellucid; joints longish." (See *Byssus aurea*.) Jointed structure, first discovered by Mr. Dillwyn. 112. *C. purpurea*. Dillw. 43. "Filaments dichotomous, flexible, minute; dichotomous, branches approximate; partitions obscure; joints longish." (See *Byssus purpurea*.) 113. *C. licheniola*. Smith Eng. Bot. 1609. "Filaments red, upright, crowded, alternately branched; roughish; joints swelling, about as long as broad." *Filaments* scarcely a line long, forming thick tufts, and appearing to the naked eye like brick-dust. Parasitical on crustaceous lichens.

Jchens. 114. *C. musficola*. Smith Eng. Bot. 1738. "Filaments rusty brown, upright, crowded, much and irregularly branched; joints cylindrical, twice as broad as long." Filaments two or three lines long, crooked, divaricated, of equal thickness throughout, glossy, like human hair under a microscope; branches ascending, obtuse, frequently unilateral. Paratitcal on orthocornum striatum.

Obf. The term confervæ occurs, we believe, first in the Natural History of Pliny, and was applied by him to a fresh water species of the present genus. The name was extended to two or three species by the elder modern botanists. But this part of the science was not at all studied before the time of Dillenius, who, in his admirable "Historia Muscorum," has described and figured forty-eight species, partly marine, and partly growing in fresh water. These he has distributed under three orders, as he calls them, viz. 1. Equabili filo protensa seu non geniculata. 2. Geniculata; and 3. Nodosa; dividing the first order into simple and branched; succeeding authors, for a considerable time, seem to have supposed that Dillenius had exhausted the subject. Linnæus has given only twenty-one species, adding only *C. ægropila* to those which are already described by that great cryptogamist, omitting such as he was not able to identify, and considering some as mere varieties. La Marck, in *Encyclopédie Methodique*, has done nothing more than copy the Linnæan species, in exactly the same order. Hudson, in the second edition of his "Flora Anglica," has introduced several species, not known either to Dillenius or Linnæus. Lightfoot, in his "Flora Scotica," has also made one or two additions. But it is not more than six or seven years since rapid advances have begun to be made in the knowledge of confervæ. Mr. D. Turner and Mr. Dilwyn are now diligently employed in the investigation of the British species; several foreign botanists, professor Roth in particular, are successfully engaged in the same pursuit; and we are informed by Bosc, in "Nouveaux Dictionnaire d'Histoire Naturelle," that professor Draparnaud of Montpellier is now busy in preparing a Monographie Confervarum, and has already determined several hundred species. We have been induced to confine ourselves, with a single exception, to the British species; partly by our inability to procure all the works which are necessary for a complete account of what has hitherto been done by foreign botanists; but chiefly by the consideration, that the species which belong to the Flora of the British islands, are the only ones accessible to the greater part of our readers. Our knowledge of these plants is indeed still very imperfect, and no generic character has yet been formed, which is sufficiently discriminating and comprehensive. The jointed structure of the filaments has generally been considered as an essential character; but we have been led by the high authority of Mr. Dilwyn to admit one species (n. 104.) which has not this conformation. We have already seen that the fructification of several species does not consist of *closed tubercles*, as it is described even in Dr. Smith's last improved generic character, but of *capsules opening at the apex*, and discharging the seeds in a manner similar to that observed in many fungi. These have been separated by Dr. Roth into a distinct genus which he calls *ceranium*; and it is probable that further researches will prove the propriety of making other separations. M. Vaucher of Geneva thinks, that he has discovered five different modes of propagation in the plants usually called confervæ; which has induced Decandolle to form them into six genera. *Conferva*. Filaments cartilaginous or herbaceous, divided by partitions; seeds enclosed between the partitions, and not escaping but

by the destruction of the tube itself. *Ceranium*. Filaments membranous, cartilaginous, without partitions; capsules monoperiform, adhering to the external surface of the filaments. *Vaucheria*. Filaments herbaceous, simple or branched, without partitions; seeds attached to the exterior side of the filaments, and generally peduncled. *Batrachospermum*. Filaments knotty, jointed, gelatinous; knots formed of filaments, simple or compound, between which are found seeds or spores (æyexis) detaching themselves, and consisting of filaments already jointed. *Chantrania*. Filaments solid, knotty; knots separating and becoming new plants, in the way of slips or cuttings. *Hydrolytium*. Tube cylindrical, closed at the two extremities, and anastomosing into pentagonal meshes; filaments of the pentagon swelling at their extremities, separating and becoming themselves cylindrical tubes, closed at the ends, and composed of pentagon meshes. The last three genera, according to his ideas, have no proper seeds.

See some curious experiments by Dr. Priestley on a species of conferva or water-moss of a peculiar kind, the manner of its production, and its effect, by the concurring action of light upon it, in dephlogisticating or dephurating the air to which it has access, and thereby increasing the quantity of it; in "Observations on Air," vol. iv. p. 335, &c. vol. v. § 2, 3, 4, 5. The seeds of this plant, says Dr. Priestley, float every where; in the air, on the earth, on the sea, on the Alps, in the plains, under the poles and the equator, in summer and winter, and in all seasons; and they are received into the water, insinuating themselves into vessels of water through the smallest apertures, where they germinate. Dr. Ingenhoufz made a variety of experiments on this singular substance; from which he concludes, that the water itself, or some substance in the water, is converted into this kind of vegetation. It is a real transmutation, which may appear incomprehensible to the philosopher, but which, in reality, is not more extraordinary than the change of grass and other vegetables into grease in the bodies of granivorous animals, and the change of the aqueous juice of the olive into oil. Dr. Priestley, however, observes, that the change of water into an organized plant is a thing of a very different nature from these, and tends to revive the long exploded doctrine of evocative or spontaneous generation. Dr. Girtanner of Gottingen (see *Annales de Chemie*, No. 100.) traces its formation from azot, which is a constituent principle of bodies, in the following manner. When water is exposed to the sun the light decomposes it, and disengages the oxygen in a large quantity. The hydrogen then retains the last portions of the oxygen; azot is formed, and announces itself by its green colour; the water is more and more decomposed; more of the oxygen, which, in the opinion of this writer, is the principle of life and irritability in organized nature, becomes fixed; and this azot, produced from water by means of the sun, is an organized body, the "conferva fontinalis;" a plant which lives, expands, and perpetuates its species. The influence of the solar light is, he conceives, absolutely necessary for this conversion of water into a plant or organized azot. No degree of heat can supply its place. Mr. Senger of Reck, in Westphalia, has lately discovered, that the conferva affords next to sage, one of the fittest materials for the making of paper; in consequence of which he obtained the honour of a gratuity from the court of Berlin, and also a patent for the manufacture of paper from this substance. From his experiments it likewise appears, that the conferva, after a previous preparation, might be made a substitute for cotton-wool, and a succedaneum for feathers in beds.

CONFESS and *avoid*, in *Law*, a species of **REPLICATION**, in which the plaintiff introduces some new matter or distinction, consistent with his former declaration; as, in an action of trespass upon lands of which the plaintiff is seized; if the defendant shews a title to the land by descent, the plaintiff may either deny the fact, or *confess and avoid* it, by replying, that such descent happened, but that the defendant hath since demised the lands to the plaintiff for the term of life. Blackf. Com. vol. iii. p. 310.

CONFESSION, **CONFESSIO**, in *Rhetoric*, the same with what is otherwise called **PARHOMOLGY**.

CONFESSION, in a *Civil Sense*, a declaration or acknowledgment of some truth, though it be against the interest of the party who makes it; whether it be in a court of justice, or out of it. It is a maxim, that in civil matters, the confession is never to be divided, but always taken entire; and that a criminal is never condemned on his simple confession, without other collateral proofs; nor is a voluntary extra-judicial confession admitted as any proof. A person is not allowed to accuse himself, according to that rule in *law*, *non auditer perire volens*.

CONFESSION of Action, in *Law*, is a species of plea to the action, in which the merits of the complaint are answered, by confessing either wholly, or which is most common, in part. A confession of the whole complaint is not very usual, for then the defendant would probably end the matter sooner; or not plead at all, but suffer judgment to go by default. Yet sometimes, after tender and refusal of a debt, if the creditor harasses his debtor with an action, it then becomes necessary for the defendant to acknowledge the debt, and plead the tender: adding that he has always been ready, "tout temps prêt," and still is ready, "uncore prêt" to discharge it: for a tender by the debtor, and refused by the creditor, will, in all cases, discharge the debts, (1 Vent. 21.) but not the debt itself; though in some particular cases the creditor will totally lose his money. (Litt. § 338. Co. Litt. 200.) But frequently the defendant confesses one part of the complaint (by a "cognovit actionem" in respect of it,) and traverses or denies the rest; in order to avoid the expence of carrying that part to a formal trial, which he has no ground to litigate. A species of this sort of confession is "the payment of money into court;" which is for the most part necessary upon pleading a tender, and is itself a kind of tender to the plaintiff; by paying into the hands of the proper officer of the court as much as the defendant acknowledges to be due, together with the costs hitherto incurred, in order to prevent the expence of any farther proceedings. This may be done upon what is called a "motion;" which is an occasional application to the court by their parties or their counsel, in order to obtain some rule or order of court, which becomes necessary in the progress of a cause; and it is usually grounded upon an "affidavit" (the perfect tense of the verb "affido") being a voluntary oath before some judge or officer of the court, to evince the truth of certain facts, upon which the motion is grounded: though no such affidavit is necessary for payment of money into court. If, after the money paid in, the plaintiff proceeds in his suit, it is at his own peril; for, if he does not prove more due than is so paid into court, he shall be non-satisfied and pay the defendant's costs; but he shall still have the money so paid in, for that the defendant has acknowledged his due. Blackf. Com. vol. iii.

CONFESSION of Indictment, is a prisoner's acknowledgment of the offence, when he is brought to the bar to be arraigned: upon a simple and plain confession, which the court is backward in receiving and recording, nothing re-

mins; but to award judgment. This confession is made before the judge; in consequence of which, the prisoner submits to the legal penalty annexed to his crime; or the prisoner, by confession, becomes an approver, or accuser of others. See **APPROVEMENT**.

There was also a third sort of confession, formerly made by an offender in felony, not in court before the judge, but before the coroner in a church, or other privileged place, upon which the offender, by the ancient law of the land, was to abjure the realm. 3 Inst. 192. See **ABJURATION**.

There is also a confession indirectly implied, as well as directly expressed, in criminal cases; as if the defendant, in a case not capital, doth not directly own himself guilty of the crime, but by submitting to a fine owns his guilt; upon which the judge may accept of his submission to the king's mercy. (Lamb. lib. iv. c. 9.) By this indirect confession, the defendant shall not be barred to plead "Not guilty" to an action, &c. for the same fact; the entry of it is, that the defendant "puts himself on the king's mercy;" and of the direct confession, "that he acknowledges the indictment." This last confession carries with it so strong a presumption of guilt, that being entered on record, on indictment of trespass, it stops the defendant to plead "Not guilty" to an action brought afterwards against him for the same matter; but such entry of a confession of an indictment of a capital crime, it is said, will not stop a defendant to plead "Not guilty" to an **APPEAL**, it being in case of life. And where a person upon his arraignment actually confesses himself guilty, or unadvisedly discloses the special manner of the fact, supposing that it doth not amount to felony, where it doth; the judges, upon probable circumstances, that such confession may proceed from fear, weakness, or ignorance, may refuse it, and suffer the party to plead "Not guilty". 2 Hawk. P. C. c. 31. § 2.

A confession may be received, and the plea of "Not guilty" be withdrawn, though recorded. (Kel. 11.) The confession of the defendant, whether taken upon an examination before justices of peace, in pursuance of the 1 and 2 P. & M. c. 13. or 2 and 3 P. & M. c. 10. upon an offender's being bailed or committed for felony; or taken by the common law, upon an examination before a secretary of state, or other magistrate, for treason or other crimes, is allowed to be given in evidence against the party confessing; but not against others. Also two witnesses of a confession of high treason, upon an examination before a justice of peace, were sufficient to convict the person so confessing, within the meaning of 1 Ed. VI. c. 12. and 5 & 6 Ed. VI. c. 11. which required two witnesses in high treason; unless the offender should willingly confess, &c. But the stat. 7 W. c. 3. requires two witnesses, except the party shall *willingly*, without violence, confess, &c. *in open court*. 2 Hawk. P. C. c. 41. § 3.

A demurrer amounts to a confession of the indictment as laid, so far, that if the indictment be good, judgment and execution shall go against the prisoner. (Bro. 86. S. P. C. 150. H. P. C. 246.) And in criminal cases, not capital, if the defendant demurs to an indictment, &c. whether in abatement, or otherwise, the court will not give judgment against him to answer over, but final judgment. (2 Hawk. c. 32. § 7.) See **ABATEMENT**. Where a prisoner confesses the fact, the court has nothing more to do than to proceed to judgment against him. "Confessus in judicio pro judicato habetur." 11 Rep. 30. 4 Inst. 66. 2 Hawk. P. C. c. 32.

CONFESSION, in *Theology*, denotes the verbal acknowledgment which a penitent makes of his sins to God: in a

more partial and restricted sense, it is a declaration of a person's sins, made to a priest, in order to obtain absolution for the same. The Romish church makes confession a part of the sacrament of penance.

Confession was anciently public and general, in the face of the church; though the Romanists have since altered it, and made it private and auricular.

Confessors are to be buried in eternal silence, under pain of the greatest punishment to the priest who reveals them. Bellarmin, Valentin, and some other Romish controversial writers, endeavour to trace up auricular confession to the earliest ages; and thus contend for a point given up by the rest. M. Fleury owns, that the first instance of auricular confession he can meet with, is that of St. Eloi, who, being grown old, made a confession to a priest of all his sins from his youth upwards.

Secret confession was first decreed and established in the 4th council of Lateran, under Innocent III., in 1215, cap. 21. And the decree of this council was afterwards confirmed and enlarged in the council of Florence, and in that of Trent (sess. 14. cap. 5.), which expressly ordains, that confession was instituted by Christ, and that by the law of God it is necessary to salvation; and that it has been always practised in the Catholic church. Hard. Concl. tom. vii. p. 35. and tom. x. p. 92. See **POPERY**.

The Indians, according to Tavernier, have a kind of confession; and the same may be said of the Jews: these last have formulas for those who are not capable of making a detail of all their sins: the ordinary form is in alphabetical order, each letter containing a capital sin. This they usually rehearse on Mondays and Thursdays, and on fast-days, and other occasions; some every night and morning. When any of them find themselves near death, they send for ten persons, more or less, one of them a rabbin; and in their presence recite the confession. See Leo de Modena.

CONFESSION of faith, denotes a list, or enumeration and declaration of the several articles of belief, in a church. See **ARTICLES of faith**.

In the council of Rimini, the Catholic bishops found fault with dates in a confession of faith, and observed that the church never used to date them.

CONFESSION, Augsburg or Augustan. See **AUGUSTAN Confession**.

CONFESSIONAL, or CONFESSORIAL, in *Church History*, a place in churches, usually under the main altar, wherein were deposited the bodies of deceased saints, martyrs, and confessors.

CONFESSIONAL is also used in the Romish church for a little box, or desk in the church, where the confessor takes the confessions of the penitent.

CONFESSO, Pro-CONFESSO. See **PRO-CONFESSO**.

CONFESSOR, a Christian, who has made a solemn, and resolute profession of the faith, and has endured torments in its defence. A mere saint is called a confessor, to distinguish him from the roll of dignified saints; such as *apostles, martyrs, &c.*

The title of confessors was given in the early ages of the church, and particularly towards the commencement of the first century of the Christian era, to those, who, in the face of death, and at the expence of honour, fortune, and all the other advantages of the world, had confessed with fortitude, before the Roman tribunals, their firm attachment to the religion of Jesus.

In ecclesiastical history we frequently find the word confessors used for martyrs; in after-times, it was confined to those who, after having been tormented by the tyrants, were permitted to live and die in peace. And at last it was also

used for those who, after having lived a good life, died under an opinion of sanctity. According to St. Cyprian, he who presented himself to torture, or even to martyrdom, without being called to it, was not called a *confessor*, but a *professor*; and if any out of a want of courage abandoned his country, and became a voluntary exile for the sake of the faith, he was called *exterris*.

The veneration that was paid to both martyrs and confessors in the early ages of the Christian church is hardly credible. The distinguishing honours and privileges they enjoyed, the authority with which their counsels and decisions were attended, would furnish ample matter for an interesting history. Without doubt it was both wise and just to treat with respect, and to invest with extraordinary privileges, those Christian heroes, since nothing was more adapted to encourage others to suffer with cheerfulness in the cause of Christ. Nevertheless, as the best and wisest institutions were generally perverted by the weakness or corruption of men, from their original purpose; so the authority and privileges granted, in the beginning, to martyrs and confessors, became, in process of time, a support to superstition, an incentive to enthusiasm, and a source of innumerable evils and abuses. See **MARTYR**.

CONFESSOR is also a priest, in the Romish church, who has a power to hear sinners in the sacrament of penance, and to give them absolution. See **SHROVE-TIDE**.

The church calls him in Latin *confessorius*, to distinguish him from *confessor*, which is a name consecrated to saints. The confessors of the kings of France, from the time of Henry IV. have been constantly Jesuits: before him the Dominicans and Cordeliers shared the office between them. The confessors of the house of Austria have also, ordinarily, been Dominicans and Cordeliers; but the latter emperors have all taken Jesuits.

CONFESSOR to his Majesty. See **CLERK of the closet**.

CONFIDENCE, in *Military Language*, denotes a firm reliance on the skill, courage, conduct, &c. of an individual. It is of the first importance for the commander of an army to have the entire confidence of the officers and soldiers under his command. This was remarkably the case with Hannibal, Julius Cæsar, &c. among the ancients, and with the marshal de Turenne, John duke of Marlborough, &c. among the moderns. A general, in whom his troops have confidence, may gain a victory without employing much military skill; and on the other hand, the most skillful general may lose one, who has lost the confidence of his army.

CONFIGURATION, the exterior surface, that bounds bodies, and gives them their particular figure.

That which makes the specific difference between bodies, is the different configuration, and the different situation of their parts. A short, or a long light, depend on the different configuration of the crystalline.

CONFIGURATION of the planets, in *Astronomy and Astrology, is a certain distance or situation of the planets in the zodiac, whereby they are supposed to aid, or oppose each other. See **ASPECT** and **SATELLITES**.*

CONFIGURATIONS of salts, a term used by some to express the combinations of the particles of the salts of plants, and other substances, into certain figures, on evaporating the water in which they had been dissolved, so hastily as not to admit of their shooting into their own regular crystals. See **CRYSTALLIZATION**.

CONFINEMENT to the realm. See **NE EXEAT REGNUM**.

CONFIRMATION, in a general sense, the act of ratifying or rendering a title, claim, pretension, report, or the like, more sure and indisputable.

CONFIRMATION,

CONFIRMATION.

CONFIRMATION, in *Law*, denotes the conveyance of an estate, or right in *esse*, which a person hath in or to lands, &c. from one man to another that hath the possession or some estate in it, whereby a voidable estate is made sure and unavoidable, or a particular estate is increased, or possession made perfect; and it is particularly used for the strengthening or homologating an estate of one already in possession of it by a voidable title. Thus, if a bishop grant his chancellorship by patent, for term of the patent's life; this is no void grant; yet it is avoidable by the bishop's death, except it be strengthened also by the confirmation of the dean and chapter. 1 Inst. 205.

CONFIRMATION is also defined to be the approbation or assent to an estate already created: which as far as it is in the power of the confirmer, makes it good and valid; so that the confirmation doth not regularly create an estate, yet such words may be blended in the confirmation as may create and enlarge an estate; but this takes place by the force of such words as are foreign to the business of confirmation, and by their own force and power, tend to create the estate. Gilb. Ten. 75. A confirmation, says judge Blackstone, is of a nature nearly allied to a release; and the words of making it are these "have given, granted, ratified, approved, and confirmed." (Litt. § 515. 531.) An instance of the first branch of the above definition is, if tenant for life lease for 40 years, and dieth during that time; here the lease for years is voidable by him in reversion; yet, if he hath confirmed the estate of the lessee for years, before the death of the tenant for life, it is no longer voidable but sure. (Litt. § 516.) The latter branch, or that which tends to the increase of a particular estate, is the same in all respects with that species of release, which operates by way of enlargement.

Madox says, that most ancient confirmations, made after the conquest, often run like feoffments; and are distinguishable from them, chiefly by some words inserting a former feoffment or grant. In former times, when feoffees were frequently disseised of their lands upon some suggestion or other, charters of confirmation seem to have been in great request. Possessors of lands, &c. seemed not to have thought themselves secure against the king, or the great lords who were their feoffors, or in whose lands their fees lay, unless they had repeated confirmations from them, their heirs or successors. And these ancient confirmations seem to have been sometimes made, either by precept or writ from the king, or other lords, to put the feoffees, or their heirs or successors into seisin, after they had been disseised, or to keep them in their seisin undisturbed, or else by charter of express confirmation. Confirmation is "*perficiens, crescens, or diminuens*;" *perficiens*, as if feoffee upon condition make a feoffment, and the feoffor confirm the estate of the second feoffee;—*crescens*, which always enlarges the estate of a tenant; as tenant for years to hold for life, &c.—and *diminuens*, as when the lord of whom the land is holden, confirms the estate of his tenant, to hold by a less rent. 9 Rep. 142.

The lord may diminish the services of his tenant by confirmation; but not reserve new services, so long as the former estate in the tenancy continues; and therefore if he confirm to the tenant, to yield him a hawk, &c. yearly, it is void. (Litt. § 539. 1 Co. Inst. 296.) Leases for years may be confirmed for part of the term, or for part of the land, &c.; but an estate of freehold, being entire, cannot be confirmed for part of the estate. (5 Rep. 81.) There may be a confirmation implied by law, as well as express by deed; where the law by construction confirms a grant made to another purpose: and a confirmation may enlarge an estate,

from an estate held at will to term of years, or a greater estate, from an estate for years to an estate for life; from an estate for life, to an estate in tail, or in fee; and from an estate in tail to an estate in fee-simple. (1 Inst. 305. 9 Rep. 142. Dyer. 263.) But if the confirmation be made to lessee for life or years, of his term or estate, and not of the land, this doth not increase the estate; though if the lessee confirm the land, to have and to hold to the lessee and his heirs, this will enlarge the estate, and so of the rest. Co. Litt. 299. Plowd. 40.

In every good confirmation, there may be a precedent rightful or wrongful estate in him to whom made, or he must have the possession of the thing as a foundation on which the confirmation is to be established; the confirmer must have such an estate and property in the land, that he may thereby be enabled to confirm the estate of the confirmee; the precedent estate must continue till the confirmation come, so that the estate to be increased comes into it; and it is required that both these estates be lawful. Co. Litt. 296. 1 Rep. 146. Dyer. 109. 5 Rep. 15. If tenant for life make a lease for years to one person, and afterwards lease the land to another person for years; and he in reversion confirms the last lease, and after that the first lease, this is not good; the second lessee hath an interest before by the confirmation of him in reversion. But in a like case, confirmation of the first lease, after the second was confirmed, has been held good; for the lease takes no interest by the confirmation, but only to make it durable and effectual. Moor. c. 150. 1 Inst. 296. Plowd. 10. If a disseisee confirm the land to the disseisor but for one hour, one week, a year, or for life, &c. it is a good confirmation of the estate for ever; and if he confirm the estate of the disseisor without any word of heirs, he hath a fee-simple; and if a disseisee make a gift in tail, and the disseisee doth confirm the estate of the donee, it shall enure to the whole estate. (Co. Litt. 291, 297, 299.) But where the estate is divided it is otherwise; and if there be an estate for life, the remainder over, there the confirmation may be of either of the estates; and if the lessee of a disseisor of a lease for 20 years, make a lease for 10 years, the disseisee may confirm to one of them and not to the other. (1 Cro. 472. 5 Rep. 81.) The tenant in tail of land hath a reversion in fee expectant; in this case, the confirmation of the estate tail will not extend to the reversion: &c. (Co. Litt. 297, 298.) If lessee for years, without impeachment for waste, accept a confirmation of his estate for life, he hath by this lost the privilege annexed to his estate for years. (8 Rep. 76.) Acceptance of rent in some cases makes a confirmation of a lease. (2 Danv. 128, 129.) What a person may defeat by his entry, he may make good by his confirmation. (Co. Litt. 300.) But none can confirm, unless he hath a right at the time of the grant: he who hath but a right in reversion cannot enlarge the estate of a lessee. (2 Danv. 140, 141.) As confirmation is to bind the right of him who makes it, but not alter the nature of the estate to him to whom made, it shall not discharge a condition. (Poph. 51. 1 Rep. 147.) A confirmation will take away a condition annexed by law; and by confirmation, a condition after broken in a deed of feoffment is extinguished. (1 Co. Rep. 146.) Confirmations may make a defeasible estate good; but cannot work upon an estate that is void in law. (Co. Litt. 295.)

A confirmation of letters patent, which are void as they are against law, is a void confirmation. (1 Lil. Aur. 295.)

Grants and leases of bishops, not warranted by the l. t. 32 Hen. VIII. c. 28. must be confirmed by dean and chapter;

CONFIRMATION.

chapter: and grants and leases of parsons, &c. by patron and ordinary. (1 Inst. 247, 300, 301.) Bishops may grant leases of their church-lands for 3 lives, or 21 years, having the qualities required by the fore-cited act, and concurrent leases for 21 years, with confirmation of dean and chapter. (See 1 Eliz. c. 4, 19.) If a prebend leases parcel of his prebendary, and the bishop, who is patron, confirms it; this shall not bind the succeeding bishop, without confirmation of dean and chapter, because the patronage is parcel of the possessions of the bishopric; but it shall bind the present bishop, &c. (2 Dav. 139.) If a parson grants a rent, the confirmation of the patron and bishop is sufficient without the dean and chapter, and shall be good against the succeeding bishop. (Ibid. 140.) The dean of Wells may pass his possessions, with the assent of the chapter, without any confirmation of the bishop. (Ibid. 175.) See LEASE.

To the grants of a "sole corporation," as parson, prebendary, vicar, and the like, the patron must give his consent; because such a sole corporation has not the absolute fee; but a "corporation aggregate," as dean and chapter, master, fellows and scholars of a college, &c. or any sole corporation that has the absolute fee, as a bishop with consent of the dean and chapter, may by the common law make any grant of their possessions without their founder or patron. (1 Inst. 300 b.)

A confirmation, as we have already observed, is in nature of a release, and in some things of a greater force: and in this deed, it is good to recite the estate of the tenant, as also of him that is to confirm it, and to mention the consideration; the words *ratify and confirm*, are commonly used; but the words *gives, grants, demises*, &c. by implication of law, may enure as a confirmation. (1 Inst. 295. West. Symb. 1. p. 457.)

CONFIRMATION, in *Rhetoric*, is, according to Quintilian, the third part, but according to Cicero, the fourth, of an oration, wherein the orator undertakes to prove, by laws, reasons, authorities, and other arguments, the truth of the propositions advanced in his narration. Cicero, *De Invent. lib. i. cap. 14. 24.* *Quint. Inst. Orat. l. iii. c. 9.*

Confirmation is either *direct*, or *indirect*: he first confirms what the orator has to urge for strengthening his own cause; the second, properly called *confutation*, refels the opposite arguing of the adversaries. The two parts together are sometimes placed under the head or title of CONFUTATION.

As to the forms of reasoning used by orators, for the purpose of confirmation, the Greek writers distribute them under four heads; *viz. Syllogism, Enthymeme, Induction, and Example.* (See each article, and also ARGUMENT and ARGUMENTATION.) Cicero reduces the rhetorical modes of reasoning to two, which he calls *ratiocination and induction*, comprising both syllogism and enthymeme under ratiocination, and example under induction; so that the difference lies in their manner of dividing them. As to the use of these modes of reasoning, it is proper to vary them in a discourse, and not to adhere too closely to the same form; for want of variety in this, as well as in other cases, will soon create disgust. With regard to the disposition of arguments, or the order of placing them, some advise to put the weaker, which cannot wholly be omitted, in the middle; and such as are stronger, partly in the beginning, to gain the esteem of the hearers, and render them more attentive; and partly at the end, because what is last heard, is likely to be retained longest; and if there are but two arguments, to place the stronger first, and then the weaker; and after that to return again to the former, and insist principally upon that. But this must be left to the prudence of the speaker,

and the nature of the subject. Nevertheless, it can never be proper to begin with the strongest and to gradually descend to the weakest; for this would be a kind of anticlimax in reasoning, which would be likely to destroy its effect. Arguments ought not to be crowded too close upon one another; for then their force would be weakened, and the attention of the hearers would be so distracted, that they could not have sufficient time duly to consider them. Besides, more arguments than are necessary should not be used, because the fewer they are, the more easily they are remembered. In this respect the observation of a great master of eloquence is very just, that "arguments ought rather to be weighed than numbered." *Cic. de Orat. lib. ii. c. 76.*

The confirmation is, as it were, the life and soul of the oration: in this the main stress of the argumentation lies. Whence Aristotle, properly enough, calls it *συστησις, fides*.

CONFIRMATION OF BISHOPS. See BISHOP.

CONFIRMATION, in *Theology*, is the ceremony of laying on of hands, for the conveyance of the Holy Ghost. When the apostles at Jerusalem heard that many of the inhabitants of Samaria had embraced the Gospel, and had been baptized, they sent thither Peter and John, who laid their hands on these new converts, and prayed that they might receive the Holy Ghost, and the Holy Ghost descended upon them. (*Acts, viii. 14, &c.*) And when the men of Ephesus had been baptized, "Paul laid his hands upon them, and the Holy Ghost came upon them." (*Acts, xix. 6.*) And St. Paul, in his epistle to the Hebrews, (*vi. 2.*) mentions the doctrine of the laying on of hands immediately after the doctrine of baptism. Upon these authorities was founded the practice, which prevailed in the primitive church, of persons receiving from the bishop immediately after baptism, a solemn benediction, accompanied with imposition of hands, unction upon the forehead with the holy chrism (made of oil and balsam), the sign of the Cross, and a prayer for the descent of the Holy Ghost.

Among the ancients it was conferred immediately after baptism; and was esteemed, in some measure, to be a part thereof: whence the fathers call it the *accomplishment* of baptism. The ground of the practice was an opinion of the imperfection of baptism, which in their apprehension only prepared persons for the reception of the graces of the Holy Spirit, which were actually conferred in confirmation. To this purpose Tertullian says, "when we come out of the water, we are anointed with a blessed ointment, according to that ancient rite by which men used to be anointed for the priest's office with oil out of a horn, ever since the time that Aaron was anointed by Moses; so that Christ himself had his name from chrism." (See CHRISM.) Then we have the imposition of hands on us, which calls down and invites the Holy Ghost." (*Tertull. de Baptism. c. 7.* King's Hist. of the Prim. Church, chap. v. p. 80, &c.) This ceremony was called confirmation, as it completed the admission of the person into the Christian church, and qualified him to partake of the Lord's Supper. It was not confined to adults, but infants also received confirmation as soon as they were baptized, and an opportunity offered of presenting them to the bishop.

Among the Greeks, and throughout the East, it still accompanies baptism; but the Romanists make it a distinct independent sacrament. The first express institution of this ceremony as a sacrament occurs in the decree of pope Eugenius in 1439, in which he says, "the second sacrament is confirmation, the matter of which is chrism blessed by the bishop, and though the priest may give the other unction, the bishop only can confer this." Peter Lombard, however, who lived in the 12th century, seems to have been the first

who

CONFIRMATION.

who reckons seven sacraments, and mentions confirmation as one of them. Although this ceremony was generally performed by bishops, yet in some countries, and at some periods, it was performed by presbyters; but in that case it was necessary that the chrism should have been previously consecrated by the bishop. St. Cyprian, and many of the fathers, speak of it in such terms as to imply, that the administration of it was confined to the bishop alone. Jerome tells us, that in his time, confirmation was always performed in the Latin church by bishops, as it had been in earlier times; and some have supposed that the custom of receiving the imposition of hands after baptism, to be performed by the bishop alone, commenced in the time of this father; though he himself did not think that the Holy Spirit was given by the imposition of the hands of the bishop only: and he says, they are not to be lamented, who, being baptized by presbyters or deacons in little villages, and castles, have died before they were visited by bishops. Hilary says, that in Egypt the presbyters confirmed in the absence of the bishop: the same was also determined by the council of Orange: and this was the practice of the Greek church, which did not allow confirmation to be a sacrament. From one of the canons of the council of Nîmes we learn, that, in the time of Cyprian and of Augustine, confirmation was performed by bishops. Hence Fleury, and many of the moderns, lay it down as a distinguishing character between the offices of a priest or deacon, and that of a bishop, that the former might baptize, but the latter alone might anoint and confirm; by virtue of their succession to the apostles, to whom it originally belonged. But from some passages in St. Gregory, &c. others gather, that the priests, on occasion, had likewise the power of confirming.

It has been alleged, that, as confirmation always succeeded baptism, and made a necessary part of it, and several of the primitive Christians esteemed both necessary to salvation, it must have been performed by presbyters as well as by bishops; because the bishop of a church might be absent for a very considerable time, as was the case with Cyprian, or the see might be vacant: and as presbyters baptized, it is reasonable to conclude that they also confirmed. Lord King has shewn that confirmation and absolution were the same thing; and that presbyters, sometimes with the bishop, and sometimes without the bishop, did absolve by imposition of hands: and he has cited several ancient authorities in order to prove, that confirmation was frequently repeated with respect to the same persons. (Hist. Prim. Church, p. 91, &c.)

It is certain, among the Greeks, the priest who baptizes, also confirms: which practice, Lucas Holstenius shews, is of so old a standing among them, that it is now generally looked on as belonging properly, and of right, to the priest: though some will have it to have been borrowed by them from the bishops. Hence, some of the Latin divines acknowledge, that though the bishop be the ordinary minister of confirmation, yet, that the priest, in his absence, may also confer it, in quality of minister extraordinary.

The council of Rouen, held in 1072, decrees that confirmation must be conferred fasting, both on the side of the giver, and that of the receiver.

The ancients, and in this respect they are followed by the moderns, did not think this rite of confirmation so absolutely necessary, that the want of it would exclude from the kingdom of heaven those who had already been baptized; but they attributed to it so much importance, that they punished the neglect of it with marks of disgrace and

public censure; and denied the privilege of ecclesiastical promotion and holy orders to such persons as had voluntarily and carelessly omitted it.

"After this example of the primitive Christians," says Dr. Tomline, the bishop of Lincoln, "our church requires all who have been baptized to appear publicly in the congregation, and renew their baptismal vow according to the form prescribed in our liturgy." The order of confirmation requires, "that none shall be confirmed but such as can say the Creed, the Lord's Prayer, and the Ten Commandments, and can also answer to such other questions as in the Short Catechism are contained, &c." The bishop then questions them, whether they renew the solemn promise and vow that was made in their name at their baptism; ratifying and confirming the same in their own persons, and acknowledging themselves bound to believe and to do all those things which their god-fathers and god-mothers then undertook for them? The bishop in his general prayer declares before God that he hath vouchsafed to regenerate these his servants by water and the Holy Ghost, and hath given unto them forgiveness of all their sins; and then laying his hand upon the head of every one severally, offers a prayer for each individual. Moreover, in the collect which forms a part of this service, he prays for those that are confirmed, saying, "upon whom, (after the example of thy holy apostles), we have now laid our hands, to certify them (by this sign) of thy favour and gracious goodness towards them." The order forbids any to be admitted to the holy communion, but those who have been confirmed, or who are ready and desirous to be confirmed. This order of confirmation does not mention the proper age of the person to be confirmed.

This ceremony, says the bishop, "falls within the authority of the church, and may be considered as included in the general precept of doing all things 'in order and unto edifying;' especially since the now universal practice of infant baptism makes confirmation more necessary than it was in the primitive church, when chiefly adults were baptized. It seems highly reasonable that they, who, at the time of their baptism, were incapable of making any engagement, should, when they arrive at a proper age, ratify and confirm those promises which were made in their name: And to give this ordinance the greater solemnity, it is performed only by the higher orders of the church, the archbishops and bishops. Thus far our church receives confirmation, confining it to prayer and imposition of hands, without the chrism, or the sign of the cross, and believes it to be derived from the practice of the apostles. But as it is not a regular constitution of Christ and his apostles, like baptism and the Lord's supper, with a written command that it should be continued in future ages, and a promise that it will be attended with inward grace, we reject it as a sacrament. There is, indeed, not a single precept upon the subject in the New Testament; nor is there any scriptural authority for the use of the chrism or the sign of the cross; and Bingham thinks that the chrism made no part of confirmation before the latter end of the second century; though other writers attribute an earlier date to it. It must be admitted by all, that imposition of hands was not peculiar to confirmation (see Matt. xix. 13. Mark, x. 16. Luke, iv. 40); and that no separate efficacy is ascribed to it distinct from the prayers which accompanied it; and prayer and imposition of hands are not sufficient to constitute a sacrament: we, therefore, consider confirmation as nothing more than a solemn manner of persons' taking upon themselves their baptismal vow; and as such, it is a ceremony of high importance, calculated to impress youthful minds with a just sense of the great obligations of the Christian profession, and to

excite

excite in them an earnest endeavour "faithfully to observe such things as they, by their own confession, have assented unto." Elements of Christian Theology, vol. ii. p. 416.

It has been urged, however, that this ceremony, with respect to the real importance and utility of it, was peculiar to the days of the apostles; and though it is retained among Protestants, it is doubted whether it be a necessary instrument of grace.

Some have thought it a remnant of the popish sacrament of confirmation; and that there is no more authority for retaining this remnant, than for any thing that is omitted in the ceremony. It has been said that the texts of scripture, repeatedly alleged in favour of this rite, have no weight. To this purpose it has been argued, that Peter's and John's going down to Samaria to pray, and to lay their hands on those whom Philip had baptized, furnishes no precedent, no direction, no institution, nor command for our bishops, to do likewise. The end for which the apostles did it, as it is expressly said (Acts, viii. 15, 17.), was, "that they might receive the Holy Ghost;" i. e. its miraculous gifts, such as prophesying, speaking with tongues, &c. necessary for forming them into a church; in proof of which it is urged, that they were something visible and obvious to sense; something which excited the wonder and ambition of the wicked forerger; for it is said, "When Simon saw that through laying on of the apostles' hands the Holy Ghost was given, he offered them money." Besides, Dr. Whitby has observed, that if they laid not their hands on *all* who were baptized, it makes nothing for confirmation; if they did, then Simon Magus also was confirmed, and received the Holy Ghost: which is not admissible. Our bishops, it has been said, disclaim the powers exercised by the apostles. As for the open and solemn renewal of the baptismal covenant before God, which baptized persons ought to make, when they come to years of discretion, this, it is said, is done in the sacrament of the Lord's Supper, which Christ himself has appointed, and which is the *only* institution his wisdom has thought fit to appoint for this purpose. It has also been alleged that the ceremony of confirmation, however solemnly practised, has a tendency, the more from the solemnity of its administration, to cherish in men's minds a presumptuous and false hope, and to decide them into wrong notions as to the safety of their state, and as to the terms of acceptance and favour with God. What warrant, it has been asked, has the bishop to pronounce a man's "sins all forgiven," and himself "regenerated by the Holy Ghost," upon no other grounds than his being able to repeat the Lord's Prayer, Creed, and Ten Commandments, and the answers of the Short Catechism? Can it be said, that this is the Christian doctrine concerning the terms of acceptance and favour with God? Are good vows and resolutions, declared in the church, infallible or proper proofs of a regeneration by the Holy Ghost? Is a man's professing that he repents, and promising that he will live a godly life, that actual repentance and amendment of life, which *alone* can ensure the divine pardon and favour? The multitudes, it is further said, who come to be confirmed, are taught to consider the bishop, in the exercise of that part of his office, as an ambassador of Christ, a successor of the apostles, and a special minister of God; and therefore, when they hear this sacred person, solemnly declaring that they are fully justified, pardoned, and regenerated by the Holy Ghost, can they be blamed if they believe it, and rest satisfied with regard to the safety and happiness of their state? And as full remission of sins, and the favour of God are to be had on such easy terms, is it matter of wonder, that thousands should eagerly flock from all quarters to accept it?

Or that persons of very vile and profligate characters should too often thrust themselves in to partake of this benefit, and be seen receiving upon their knees episcopal absolution, and solemn assurances of God's favour and peace?

It has been further argued by those who object to the continued practice of this ceremony of confirmation in the Christian church, that Tertullian is the most ancient author who has mentioned it, and that in his time, a great variety of superstitions, and ridiculous and foolish rites, had been introduced and actually subsisted in the Christian church. Confirmation was then always performed, as we have already mentioned, (not as it is with us, but) immediately after baptism. The expression in our order of confirmation, by which the bishop declares to God, "that he hath vouchsafed to regenerate these his servants by water and the Holy Ghost, and to give them the forgiveness of all their sins," was probably taken from some ancient liturgy, and was suitable and well adapted to the practice of those times, but is incongruous and unsuitable to ours. Then, as Dr. Cave observes, (Primitive Christianity, pt. 1. p. 194, 288.) "although infants were undebatedly taken into the church by baptism, yet the main body of the baptized were adult persons; who, flocking over daily in great numbers to the faith of Christ, were received in at this door. Usually they were for some considerable time catechized, and trained up in the principles of the Christian faith; till having given testimony of their proficiency in knowledge, and of a sober and regular conversation, they became candidates for baptism," or, as lord King says, (Inquiry into the Constitution, &c. pt. i. p. 102.) "the catechumens enjoyed not the privileges of the faithful, till they had, in a sense, merited them, which was when, through a considerable time of trial, they had evidenced the sincerity of their hearts, by the sanctity and purity of their lives. And then, as Origen says, *we initiate them in our mysteries, when they have made a proficiency in holiness, and according to the utmost of their power have reformed their conversation.* When they had changed their manners, and rectified their irregular carriage, then they were washed with the water of baptism, and not before. For, as Tertullian observes, *we are not baptized that we may cease to sin; but because we have already ceased.*" In these circumstances, it is said, the bishop or the presbyter might use an expression similar to that already cited with propriety; but the case is different, say the objectors to the permanent use of this rite, with the multitudes who flock to modern confirmations. Pierce's *Vindicia Frat. Diss. Towgood's Dissent* justified.

CONFISCATE, in *Law*, is applied to goods forfeited to the exchequer, or public treasury.

The word is derived from *secus, a hamper, panier, or basket*, wherein the emperor's money used to be kept.

The title to goods, which are not claimed by any other, is given by law to the king. If a man, indicted for stealing the goods of another, in which case they become, in effect, the proper goods of him indicted, be asked about them in court, and disclaim them; he thereby loses the goods, though he be afterwards acquitted of the theft; and the king shall have them as confiscated; but otherwise, if he had not disclaimed them. Thus also, when goods are found in the possession of a felon, if he disavows them and afterwards is attainted for other goods, and not for them, the goods which he disavows are confiscate to the king; but if he had been attainted for the same goods, they would have been said to be "forfeited and not confiscated." So if an appeal of robbery be brought, and the plaintiff leaves out some of his goods, he shall not be allowed to enlarge his appeal; and because there is none to receive the goods so left out, the

king shall have them as confiscate, according to the rule, "Quod non capit christus, capit nescius." Staundf. P. C. l. 3. c. 21. See FORFEITURE.

CONFISCATION, a legal adjudication of goods or effects to the fisc, or treasury.

Thus, the bodies and effects of criminals, traitors, &c. and merchandizes that are contraband, prohibited, or brought aboard or ashore, without paying the duties, when seized, are confiscated.

It is an axiom in law, that he who confiscates the body, confiscates also the effects, to the profit of the king, or the lord of the fee, *i. e.* he who is condemned to lose his life, must also lose his goods; yet the widows of criminals do not lose their dowries, nor their share in the goods of the community, by the forfeiture of their husbands. See FORFEITURE.

CONFLAGRATION, a general burning of a city, or other considerable place. In which sense, Nero is said to have procured the Christians to be accused of the conflagration of Rome, which was done by his own order.

But the word is more ordinarily restrained to that grand period, or catastrophe of our world, wherein the face of nature is expected to be changed by a deluge of fire, as it was anciently by that of water. The ancient Chaldeans, Pythagoreans, Platonists, Epicureans, Stoics, Celts, and Etrurians, appear to have had a notion of the conflagration; though whence they should derive it, unless from the sacred books, it is difficult to conceive; except perhaps, from the Phœnicians, who themselves had it from the Jews.

The Celts, whose opinions resembled those of the eastern nations, held, that after the burning of the world, a new period of existence would commence. The ancient Etrurians, or Tuscans, also concurred with other western and northern nations of Celtic origin, as well as with the Stoics, in asserting the entire renovation of nature after a long period, or great year, when a similar succession of events would again take place. The cosmogony of an ancient Etrurian, preferred by Suidas, limits the duration of the universe to a period of 12,000 years, 6000 of which passed in the production of the visible world, before the formation of man. The Stoics also maintained, that the world is liable to destruction from the prevalence of moisture, or of drought; the former producing an universal inundation, and the latter an universal conflagration. These, they say, succeed each other in nature, as regularly as winter and summer. When the universal inundation takes place, the whole surface of the earth is covered with water, and all animal life is destroyed; after which nature is renewed, and subsists as before, till the element of fire, prevailing in its turn, dries up all the moisture, converts every substance into its own nature, and at last, by an universal conflagration, reduces the world to its pristine state. At this period all material forms are lost in one chaotic mass, all animated nature is reunited to the Deity, and nature again exists in its original form, as one whole, consisting of God and matter. From this chaotic state, however, it again emerges, by the energy of the efficient principle; and gods and men, and all the forms of regulated nature are renewed, to be dissolved and renewed in endless succession. The doctrine of conflagration is a natural consequence of the general system of Stoicism. For, since, according to this system, the whole process of nature is carried on in a necessary series of causes and effects, when that operative fire which at first, bursting from chaos, gave form to all things, and which has since pervaded and animated all nature, shall have consumed its nutriment, that is, when the vapours,

which are the food of the celestial fires, shall be exhausted, a deficiency of moisture must produce an universal conflagration. This grand revolution in nature is, after the doctrine of the Stoics, thus elegantly described by Ovid, (*Metam. l. i. v. 256*):

"Effe quoque in fatis reminiscitur affore tempus
Quo mare, quo tellus, correptaque regio cœli
Ardeat, et mundi molis operosa laboret:"

or, as Dryden has translated the passage,

"Rememb'ring in the fates a time when fire
Should to the battlements of heaven aspire,
When all his blazing worlds above should burn,
And all th' inferior globe to cinders turn."

Seneca, speaking of the same event, (*Ad Murciam, c. ult.*) says expressly, "Tempus advenit quo sidera fideribus incurrent, et omni flagrant materia uno igne, quicquid nunc ex deposito lucet, ardebit," &c. *i. e.* the time will come when the world will be consumed, that it may be again renewed, when the powers of nature will be turned against herself; when stars will rush upon stars, and the whole material world, which now appears resplendent with beauty and harmony, will be destroyed in one general conflagration. In this grand catastrophe of nature, all animated beings (excepting the universal intelligence), men, heroes, demons, and gods, shall perish together. Seneca, the tragedian, who was of the same school with the philosopher, writes to the same purpose, (*Here. Oâ. iii. 1112.*)

"Cœli regia incidens
Ortas atque obitus trahet,
Atque omnes pariter deos
Perdet mors aliqua, et chaos."

i. e. "The mighty palace of the sky,
In ruin fall'n is doom'd to lie,
And all the gods, its wreck beneath,
Shall sink in chaos and in death."

During the course of this vast conflagration, the Stoics conceived that the world would expand, and in its chaotic state continue to fill a much larger portion of infinite space than it had required, or would again require, in a state of orderly arrangement. After an interval of rest, says Seneca, (*Epist. 9. Qu. Nat. c. ult.*) in which the Deity will be intent upon his own conceptions, the world will be entirely renewed; every animal will be reproduced; and a race of men, free from guilt, and born under happier stars, will repeople the earth. Degeneracy and corruption, will, however, again creep into the world; for it is only while the human race is young, that innocence remains upon the earth. The grand course of things, from the birth to the destruction of the world, which, according to the Stoics, is to be repeated in endless succession, is accomplished within a certain period. This period, or fated round of nature, is probably what the ancients meant by the "Great Year."

From this brief account of the doctrine of the Stoics concerning the final conflagration, it evidently appears, that it differs in several essential particulars from the Christian doctrine on this head. It is the work of fate, performed by natural and mechanical laws, and repeated eternally at certain periods, without any good reason, since with every revolution the same disorders and vices return. Philo justly ridicules this dogma; remarking, that the Stoics make their deities act like children, who raise up piles of sand only for

the pleasure of beating them down. Several of the Stoics themselves were aware of the absurdity of this system, and rejected it; particularly Boethius, Posidonius, Diogenes the Babylonian, and Paretius. This general dissolution the Stoics call *extremis, cyprosis*. The Pythagoreans also maintained the dogma of conflagration. To this purpose Hippafus, of Metapontum, taught that the universe is finite, is always changing, and undergoes a periodical conflagration. Philolaus, who flourished in the time of Plato, maintained that the world is liable to destruction, both by fire and water.

Mention of the conflagration is also several times made in the books of the Sibyls, Sophocles, Hyftapes, Lucan, &c.

Dr. Burnet, after F. Tachard, and others, relates, that the Siamefe believe, that the earth will at last be parched up with heat; the mountains melted down; and the earth's whole surface reduced to a level, and then consumed with fire. And the Bramins of Siam do not only hold, that the world shall be destroyed by fire; but, also, that a new earth shall be made out of the cinders of the old.

The sacred scriptures announce this event in a variety of passages; some of which, however, have been applied by Dr. Hammond, and others, to the destruction of Jerusalem; but others are universally allowed to refer to this awful catastrophe. See 2 Pet. iii. 10—13, referred by Dr. Hammond to the destruction of Jerusalem, and the dissolution of the Jewish state, but generally, and, with just reason, applied to the end of the world. (See Ray's Discourses, p. 311, &c.) 2 Theff. i. 7, 8. Rev. vi. 12, 13, 14. Rev. x. 6. Rev. xxi. 1. Heb. xii. 26, 27. All these passages, and others, which more immediately relate to the time of this event, are applied by Dr. Hammond to the destruction of the city, temple, and polity of the Jews: and, indeed, he leaves only one place in the New Testament, as a proof of the general conflagration of the world; *viz.* 2 Pet. vii. 7. The other passages have been cited from the Old Testament that seem to indicate and foretell the dissolution of the present globe: such are Job. xiv. 12. Pl. cii. 5, 6. Isai. li. 6. Joel, ii. 31. Malachi, iv. 1. Deut. xxxii. 12. But it must be allowed that the prophetic books abound with figurative expressions, the precise object of which cannot be so satisfactorily ascertained. The ancient fathers of the church, and Christian writers, in successive periods of its duration, have frequently referred to this event, and testified their belief of its advent. Some of the first Christians apprehended it to be near at hand; and many of the ancients conceived that it would take place at the end of 6000 years. In this number we may class Justin Martyr, Irenæus, Lactantius, Eusebathius, &c.; but their opinion, with regard to the precise time of this event, is proposed by them not as an undoubted truth, but only as a modest conjecture. It was the general opinion of the ancient Christians, that this world shall not be annihilated or destroyed, but merely renewed and purified. To this purpose we might cite the testimonies of Eusebius, Cyril, Oecumenius, Jerome, and others.

Various are the sentiments of authors on the subject of the conflagration; the cause whence it is to arise, and the effects it is to produce. Divines ordinarily account for it metaphysically; and will have it take its rise from a miracle, as a fire from heaven. Philosophers contend for its being produced from natural causes; and will have it effected according to the laws of mechanics: some think an eruption of a central fire sufficient for the purpose; and add, that this may be occasioned several ways; *viz.* either by having its intensity increased; which, again, may be effected either by being driven into less space by the encroachments of the superfluous cold, or by an increase of the inflammability of the

fuel whereon it is fed: or by having the resistance of imprisoning earth weakened; which may happen, either from the diminution of its matter, by the consumption of its central parts; or by weakening the cohesion of the constituent parts of the mass, by the excess or the defect of moisture.

Others look for the cause of the conflagration in the atmosphere; and suppose, that some of the meteors there engendered in unusual quantities, and exploded with unusual vehemence, from the concurrency of various circumstances, may be made to effect it, without seeking any further.

The astrologers account for it from a conjunction of all the planets in the sign Cancer; as the deluge, say they, was occasioned by their conjunction in Capricorn. This was an opinion adopted by the ancient Chaldeans.

Lastly: others have recourse to a still more effectual and flaming machine; and conclude the world is to undergo its conflagration from the near approach of a comet, in its return from the sun. Those wandering bodies do indeed seem to menace us a little; being able, both by their transverse motion across the earth's way, by the hugeness of their size, and the intense fire wherewith they glow in their recess from the perihelion, to produce the most signal changes and revolutions in the system of things.

Mr. Whiston has shewn, that they are extremely well fitted to produce the phenomena of the deluge; and has gone a good way towards proving, that the comet of 1680, was the very body to which that event was owing; as being then in its approach towards the sun, and its atmosphere crowded with the watery vapours, which it had gathered in those inconceivably cold regions, into which it had fled off in its aphehon.

This same comet, sir Isaac Newton has calculated, when in its perihelion, December the 8th, was heated, by the vicinity of the sun, to a degree two thousand times more hot than red-hot iron: he shews, likewise, that it would scarce be cool again in fifty thousand years.

This same comet, Dr. Halley observed November the 11th, was not above a semidiameter of the earth from the earth's way: so that had the earth, at that time, been in that part of its orbit, something very extraordinary might have been apprehended; but whether in the way of fire, or water, may, perhaps, to some, leave room to doubt. But it is scarcely conceivable, that the comet should bring any vehement degree of heat, out of those regions it comes from, whatever heat it might carry thither. See COMET. See on the subject of this article *Theory of the Earth*.

CONFLANS, in *Geography*, a small town of France, in the department of Mont-blanc, and chief place of a canton in the district of Moutiers, 18 miles N.E. from Moutiers. The place contains 1313, and the canton 5512 inhabitants; the territory includes 182½ kilometres and 10 communes.—Also, a small town of France, in the department of Moselle, and chief place of a canton in the district of Briey, situated at the confluence of the Iron and Orn, 15 miles E. from Metz. This place contains but 347, and the canton 7145 inhabitants, and 31 communes, upon a territorial extent of 240 kilometres.—Also, a town of France, in the department of the Upper Saone, in the district of Lure; 4 leagues N. of Vesoul, and 2½ W. of Luxeuil.—Also, a town of Savoy, near the conflux of the Isere and Doron; 18 miles E. of Chambéry.

CONFLANS, or *Constant*, was, before the revolution, the name of a valley of France, in Rouffillon, surrounded by the Pyrénées, and watered by the river Tet. Villefranche sur le Tet was its capital.

CONFLANS *St. Honorine*, a town of France, in the department of the Seine and Oise; 5 leagues S.W. of Paris.

CONFLICT. See **COMBAT**.

CONFLUENCE, **CONFLUX**, the place where two rivers join, and mix their waters.

CONFLUENT, in *Medicine*, literally *flowing together*, is a term applied to cutaneous eruptions, which, though confining, on their first appearance, of separate and distinct spots, form themselves subsequently into extensive patches, by the spreading of the individual spots, which coalesce with each other. This epithet is most frequently applied to the small pox, which, when confluent, becomes a very formidable and fatal disease, and requires a treatment in its latter stages, different from that which is beneficial in the mild form of the disease, when the pustules are few and distinct. See **SMALL-POX**.

CONFLUENTA, in *Ancient Geography*, a town of Spain, belonging to the Vaccæans, S.E. of Pallentia.

CONFLUENTES. See **COBLENZ**.

CONFOLENS, in *Geography*, a town of France, in the department of Charante, and chief place of a district, situated on the river Vienne, 30 miles N.W. from Limoges, and 36 N.E. from Angoulême. It has a sub-prefect, a court of justice, and a register-office. It is divided into north and south, and has a population of 2025 inhabitants. Its northern canton comprises 7391, and the southern 11,385 inhabitants, distributed in 18 communes, upon a territorial extent of 342½ kilometres. The district reckons 58,503 inhabitants and 70 communes, on a territorial extent of 14,32½ kilometres. Its soil in general is a barren heath, except on the banks of the Vienne, which afford some good corn land and excellent pastures. Corn and cattle are the principal articles of commerce. N. lat. 46° 2'. E. long. 0° 34'.

CONFORMATION, the particular texture and consistence of the parts of any body, and their disposition to make a whole.

We say, light of different colours is reflected from bodies, according to their different conformation; in opposition to the Cartesians, who pretend, that reflected light becomes of different colours, according to the different conformation of the bodies that reflect it. The conformation of the members of an embryo is not perfect enough to allow of distinction.

CONFORMITY, in the *Schools*, is the congruency, or relation of agreement between one thing and another: as between the measure, and the thing measured: the object, and the understanding; the thing, and the conception; the thing, and the division thereof, &c.

CONFORMITY, *Non*. See **NON-CONFORMITY**.

CONFORMITY, *Occasional*. See **OCCASIONAL CONFORMITY**.

CONFRERES, from *con*, and *frere*, *brother*; denote brethren in a religious house, or the fellows of one and the same society. 32 Hen. VIII. c. 24.

CONFRONTATION, the act of bringing two persons, in presence of each other, to discover the truth of some fact, which they relate differently.

The word is chiefly used in criminal matters; where the witnesses are confronted with the accused; the accused with one another, or the witnesses with one another.

CONFUCIUS, or **KONG-FU-TSE**, in *Biography*, the most celebrated ancient philosopher of China, descended from the imperial family of the dynasty of Shang, was born in the reign of the emperor Lu, about four centuries and a half before Christ. He was accordingly a contemporary with Pythagoras, and flourished at a period prior to that in which Socrates rose to celebrity. At fif-

teen years of age, he engaged in the study of the ancient learning of his country; and, before he had arrived at the years of manhood, he had made astonishing proficiency in the doctrines attributed to the legislators Yao and Chun, which the Chinese consider as the source of all their science and morality. The reputation which Confucius acquired, and the uncommon wisdom which he discovered, were the means of advancing him, while he was yet but a youth, to the office of minister of state. The duties of this, and of other posts assigned to him, he performed with honour to himself, and signal benefit to the kingdom. The rank which he held in public life, enabled him to form an accurate judgment of the state of morals among his countrymen.

He devised a plan for a general reformation, which he endeavoured to carry into execution, as well by inculcating a strict and pure morality, as by using the influence of his authority in recommending it. His efforts were crowned with so much success, that the whole nation became, at first, a pattern of order, decorum, and strict justice. This reformation was not, however, permanent; the business of the state was abandoned to men of licentious habits, and in a short time an universal effeminacy and dissoluteness of manners prevailed. Confucius exerted all his powers to stem the torrent of vice; and when he found that his endeavours were fruitless, he resolved to quit his station and country, and seek an asylum in some other kingdom where his efforts in the cause of virtue might be more availing. He, at length, devoted himself to the task of private instruction in philosophy and morality. His great celebrity, and his personal virtues, soon procured him many scholars; and he is said to have had several thousand disciples to whom he taught morals, the art of reasoning, and the principles of policy. From these he selected seventy-two, who were distinguished from the others on account of their superior attainments. These were divided into classes, destined for different purposes. The business of the first class was the study of morals; of the second, that of reasoning and eloquence; of the third, that of the rules of good government; and the immediate province of the fourth was something similar to our public preaching. The exertions of Confucius in the cause of virtue, were too great for the frame of body with which he was endued; his natural strength became impaired, and his mental powers failed. During his last sickness, he declared that his heart was overpowered with grief, on beholding the disorders which prevailed in the empire, and which he had in vain endeavoured to suppress: "The kings," said he, "will not follow my maxims; I am no longer useful on earth; it is, therefore, time that I quit it." This exclamation was followed by a lethargy from which he never recovered. He died in his seventy-third year. B. C. about 479, (Blair.) By his sage counsels, his moral doctrine, and his exemplary conduct, he obtained an immortal name as a reformer of his country. After his death, his name was held in the highest veneration, and his doctrine is still regarded among the Chinese, as the basis of all moral and political wisdom. His natural temper was excellent, and his conduct irreproachable and exemplary. He was particularly praised for his humility, sincerity, temperance, disinterestedness, and contempt of riches.

Confucius seemed designed by heaven to reform, both by his doctrines and example, the corruptions which prevailed, as well in the civil, as in the religious establishments of China. He condemned the idolatry which he found existing among his countrymen, and endeavoured to introduce a purer form of religion. He did not attempt to dive into the impetrate secrets of nature, nor bewilder himself in abstruse researches on the essence of a first cause, the origin of good

and evil, and other subjects which seem beyond the limits of the human mind. He maintained that the Deity was the most pure and perfect principle, and fountain of all things; that he is independent and almighty, and watches over the government of the universe, so that no event can happen but by his command; that our most secret thoughts are open to his view; that he is holy without partiality, and of such boundless goodness and justice, that he cannot possibly permit virtue to go unrewarded, or vice unpunished.

So high is the respect paid to the memory of this great man, even in the present day, that his descendants enjoy, by inheritance, the title and office of mandarins, and are allowed the privilege in common with the princes of the blood, of exemption from the payment of all taxes to the emperor. The works which Confucius composed for the use of his disciples, and the preservation of his philosophy, are looked upon by the Chinese as of the first authority, next to the classical books, styled by way of eminence, "the Five Volumes;" and to these, indeed, he declares himself indebted for the information and wisdom which his own are calculated to convey. Moreri. Hist. Univer. D'Anquetil. Es. field's Hist. of Philosophy.

CONFUSED Notion and Vision. See the substantives.

CONFUSION, in a general sense, is opposed to order; in a perturbation whereof, confusion consists: *e. gr.* when things prior in nature do not precede; or posterior do not follow, &c.

In a logical sense, confusion is opposed to distinctness, or perspicuity; and may happen, either in words, as when misconstrued or misapplied; or in ideas, as when the idea of any thing presents something along with it, which does not properly belong to that thing.

In a physical sense, confusion is a sort of union, or mixture by mere contiguity. Such is that between fluids of contrary natures; as oil and vinegar, &c.

CONFUSION, property by, in Law, denotes the intermixture of the goods of two persons in such a manner, that their respective portions cannot be ascertained. If this be consent, they have a common interest, both by the English and civil law, in proportion to their shares. But, if one wilfully intermixes his money, corn, or hay, with that of another person, without his approbation or knowledge, or casts gold in like manner into another's pot or crucible, the civil law, though it gives the sole property of the whole to him who has not interfered in the mixture, yet allows a satisfaction to the other for what he has so improvidently lost. (Inst. 2. 1. 28.) But our law, to guard against fraud, gives the entire property, without any account, to him, whose original dominion is invaded, and endeavoured to be rendered uncertain, without his own consent. Foph. 38. 2 Bulltr. 325. 1 Hal. P. C. 513. 2 Vern. 516. Bl. Comm. ii. 455.

CONFUSION of tongues, in the History of the World, is a memorable event, which happened in the one hundred and first year, according to the Hebrew chronology, after the flood, B. C. 2247, at the overthrow of Babel; and which was providentially brought about, in order to facilitate the dispersion of mankind, and the population of the earth. Until this period, there had been one common language, which formed a bond of union, that prevented the separation of mankind into distinct nations; and some have supposed, that the tower of Babel was erected as a kind of fortress, by which the people intended to defend themselves against that separation, which Noah had projected.

There has been a considerable difference of opinion, as

to the nature of this confusion, and the manner in which it was effected. Some learned men, prepossessed with the notion that all the different idioms now in the world did at first arise from one original language, to which they may be reduced, and that the variety among them is no more than must naturally have happened in a long course of time by the mere separation of the builders of Babel, have maintained, that there were no new languages formed at the confusion; but that this event was accomplished by creating a misunderstanding and variance among the builders, without any immediate influence on their language. But this opinion, advanced by Le Clerc, &c. seems to be directly contrary to the obvious meaning of the word *שפה*, *shapha*, *lip*, used by the sacred historian; which, in other parts of scripture, signifies *speech*. (See Pl. lxxx. 5. II. xxvii. 11. xxxiii. 19. Ezek. iii. 5.) It has been justly remarked, that unanimity of sentiment, and identity of language, are particularly distinguished from each other in the history; "the people is one, and they have all one language." (Gen. xi. 6.) It has been also suggested, that if disagreement in opinion and counsel were the whole that was intended, it would have had a contrary effect; they would not have desisted from their project, but strenuously have maintained their respective opinions, till the greater number of them had compelled the minority either to fly or to submit. Others have imagined, that this was brought about by a temporary confusion of their speech, or rather of their apprehensions, causing them, whilst they continued together and spoke the same language, to understand the words differently: Scaliger is of this opinion. Others again account for this event, by the privation of all language, and by supposing that mankind were under a necessity of associating together, and of imposing new names on things by common consent. Another opinion ascribes the confusion to such an indistinct remembrance of the original language which they spoke before, as made them speak it very differently; so that by the various inflections, terminations, and pronunciations of divers dialects, they could no more understand one another, than they who understand Latin can understand those who speak French, Italian, or Spanish, though all these languages arise out of it. This opinion is adopted by Causabon, and by bishop Patrick in his Commentary in loc. and is certainly much more probable than either of the former: and Mr. Shuckford maintains, that the confusion arose from small beginnings, by the invention of new words in either of the three families of Shem, Ham, and Japhet, which might contribute to separate them from one another; and that in each family new differences of speech might gradually arise, so that each of these families went on to divide and subdivide among themselves. Others, again, as Mr. Jos. Mede and Dr. Wotton, &c. not satisfied with either of the foregoing methods of accounting for the diversity of languages among mankind, have recourse to an extraordinary interposition of divine power, by which new languages were framed and communicated to different families by a supernatural infusion or inspiration; which languages have been the roots and originals from which the several dialects that are, or have been, or will be spoken, as long as this earth shall last, have arisen, and to which they may with ease be reduced. This opinion is adopted and vindicated by Dr. Hartley, in his "Observations on Man," p. 179, who says, that it seems impossible to explain how the human languages should arise from one stock. Upon the whole, we may observe, that there evidently seems to have been something miraculous in the transaction; and if it be supposed that nothing more was meant than a confusion of designs, counsels, and opinions; so that they could not agree

agree together in the execution of their scheme (which, as we have shewn, is not very probable); this would be sufficient to answer the purpose of Divine Providence, which was to prevent the children of Noah from preserving their union in one body, and to spread them over the face of the earth, that it might be peopled and cultivated. If the confusion of tongues was an actual change of languages, it was probably accomplished by degrees; nor does it appear to be so fundamental and radical an alteration as some have imagined. In proof of this, we may allege the free intercourse which subsisted in early times between persons of different ages and countries; the uniformity of the Eastern languages, which plainly shews that they have one common radix; and the manifest derivation of the Greek and Latin from the same source.

As to the number of languages thus introduced, many opinions have been adopted. If there were no more than three were nations or heads of nations, then the number would be seven for Japhet, four for Ham, and five for Shem; but if there were as many as there were families, which is the more probable opinion, their number cannot be certainly assigned. However, the Hebrews fancy they were seventy, because the descendants from the sons of Noah, enumerated Genesis x., were just so many. Allowing then the languages of the chief families to have been fundamentally different from each other, the sub-languages and dialects within each branch would probably have had a mutual affinity, greater or less, as they settled nearer or farther from each other. But whichever of these hypotheses is adopted, the primary object of the confusion at Babel was the separation and dispersion of mankind. Cleric. Com. in Gen. x. i. Scaliger Exerc. in Cardan. § i. Casaubon. Distrib. de Ling. Heb. Mede's Works, vol. i. p. 276. Wotton's Disc. and Brett's Ess. on the Confusion of Languages. Univers. Hist. vol. i. part i. chap. 2. § 5. Shuckf. Conn. vol. i. p. 146.

The ingenious and learned Dr. Bryant has, in the third volume of his "Analysis of Ancient Mythology," advanced a new and singular hypothesis, both with respect to the confusion of tongues and the dispersion. He supposes that the confusion of language was local and partial, and limited to Babel only. By כַּל-הָאָרֶץ Gen. xi. 1 and 8, which our translators render the *whole earth*, he understands *every region*: and by the same words in ver. 9, the *whole region*, or province. This confusion was occasioned, as he supposes, by a labial failure; so that the people could not articulate. Thus their speech was confounded, but not altered; for as soon as they separated, they recovered their true tenor of pronunciation, and the language of the earth continued for some ages nearly the same. The interviews between the Hebrews and other nations, recorded in Scripture, were conducted without an interpreter; and he farther observes, that the various languages which subsist at this day retain sufficient relation to shew, that they were once dialects from the same matrix, and that their variety was the effect of time. See DISPERSION.

CONFUTATION, in *Rhetoric*, &c. a part of an oration, wherein the orator seconds his own arguments, and strengthens his cause, by refelling and destroying the opposite arguments of the antagonist. This is done by denying what is apparently false, by detecting some flaw in the reasoning of the adverse party, by granting their argument, and shewing its invalidity, or retorting it upon the adversary.

Confutation makes a branch of what we call *confirmation*.

The confirmation and confutation are sometimes called *confirmation*.

Rhetoricians generally place confutation after confirmation, which seems agreeable to the natural method of thinking on any subject. For persons first endeavour to find out such arguments as are proper to maintain that side of a question which they espouse, before they consider what objections may be offered against it: although in speaking it may be necessary to vary the order, according to the nature of the discourse. The method prescribed by Quintilian (Inst. Orat. l. v. c. 13.) is this, that, "if we bring a charge, we should first prove it, and then answer objections; but if we stand upon the defence, we ought to begin with confutation." The forms of reasoning are the same here as those that occur under *confirmation*. But it is of importance to know the different modes of confutation practised by orators, which is often the more difficult task; because he, who is to prove a thing, comes usually prepared; but he, who is to confute it, is frequently left to a sudden answer. Hence Quintilian says, that, in judicial cases, "it is as much easier to accuse than to defend; as it is to make a wound than to heal it." In all disputes it is of the greatest consequence to observe, where the stress of the controversy lies; and in confutation, what the adversary has advanced ought carefully to be considered, and in what manner he has expressed himself. Those things, which relate to the merits of the cause, may be confuted either by contradicting them, or by shewing some mistake in the reasoning, or their invalidity when granted. There are various ways in which things may be contradicted; what is apparently false may be expressly denied; and things which the adversary cannot prove may be likewise denied. A thing may be also contradicted by shewing that the adversary himself maintained the contrary. When you can fix contradictions on an adversary, you effectually silence him; for this is stabbing him with his own weapon. Sometimes a thing is not in express terms denied, but represented to be utterly incredible; and this method exposes the adversary more than a bare denial. There is, likewise, an ironical way of contradicting a thing, by retorting that and other things of the like nature upon the adverse party. A second mode of confutation is by observing some flaw in the reasoning of the adverse party. The last method of confutation is, when the orator does in some sense grant the adversary his argument, and at the same time shews its invalidity. This may be done in a variety of ways, according to the different nature of the subject. Sometimes he allows that what was said may be true, but pleads, that what he contends for is necessary. At other times the orator pleads, that although the contrary opinion may seem to be attended with advantage, yet that his own is more just and honourable. Another way of confutation is by retorting upon the adversary his own argument. The orator takes this advantage, when an argument proves too much, that is, more than the person designed it for, who made use of it. See INVERSION. Sometimes orators in confutation raise such objections themselves to what they have said, as they imagine may be made by others; which they afterwards answer the better to induce their hearers to think, that nothing considerable can be offered against what they have advanced, but what will admit of an easy reply. See PROLEPSIS. See the several modes of confutation above recited illustrated by apposite citations from Cicero's Orations in Ward's Oratory, vol. i. lect. 17.

As to the order and disposition of the arguments, proper to be used in confutation; whether to follow the adverse party, or alter his method, and range them in a different manner

manner, as likewise whether to attack the weak-st or strong-st arguments first; these things must be left to the discretion of the speakers.

CONG, in *Geography*, a village of the county of Mayo, Ireland, situated in the neck of land between the Loughs, Mask, and Corrib. Large caverns and subterraneous waters are frequent in the neighbourhood; especially at the back of the village, a very broad river rushes at once from beneath a gently sloping bank, and after a rapid course of about a mile loses itself in Lough Corrib. It is supposed to be the outlet of a subterraneous channel, through which the superfluous waters of Loughs Mask and Carrah are discharged into Corrib. Cong is about 108 miles west from Dublin, and 20 south from Castlebar.

CONG, a town of China of the third rank, in the province of Honan; 15 miles south of Hoi-king.—Also, a town of China of the third rank, in the province of Szechuen; 25 miles south of Sou-tcheou.

CONGA, a town of Persia, in the province of Irak-Agemi; 100 miles N. W. of Ispahan.

CONGAREE, a considerable river of America, in the state of S. Carolina, formed by the confluence of Saluda and Broad rivers. The union of the waters of Congaree and Wateree forms the Santee.

CONGAUTATA, in *Ancient Geography*, a station on the line of Severus's wall in Britain, mentioned in the Notitia Imperii, and supposed to be at Stanwix.

CONGE, APOPHYGE, Gr. *Στοπος*, Lat. in *Architecture*. The extremities of the shaft of a column when they are worked circularly to unite gradually with the fluted of the base and capital are thus named.

CONGE, in the *French Law*, a licence, or permission, granted by a superior to an inferior, which gives him a dispensation from some duty to which he was before obliged. The word is French: Menage derives it from the Latin *committus*, used for *commensus*, and *commencare*, often seen among ancient writers: the Italians say, *congedo*.

A monk cannot go out of his convent, without the conge of his superiors.

CONGE *d'accorder*, i. e. *leave to accord*, or *agree*, is used in the statute of hies, anno 18 Edw. I. to the following purpose. "When the original is delivered, in presence of the parties before justices, a pleader shall say this: sir, justice, *conge d'accorder*; and the justice shall say to him, What saith sir R. and shall name one of the parties, &c."

CONGE *d'elire*, is the king's permission royal to a dean and chapter, in time of a vacancy, to choose a bishop. See BISHOP, CANON, and COLLATION.

Gwyn observes, that the king of England, as sovereign patron of all bishoprics and other benefices, had anciently the free appointment of all ecclesiastical dignities; investing, first, *per baculum & annulum*; and afterwards by letters patent: but that, in process of time, he made the election over to others, under certain forms and conditions; as, that they should at every vacancy, before they chose, demand of the king *conge d'elire*, i. e. leave to proceed to election; and after election to crave his royal assent, &c. He adds, that king John was the first who granted this; which was afterwards confirmed by stat. Westm. 3 Edw. I. cap. 1. and again in the Articuli Cleri, 25 Edw. III. cap. 1.

CONGE, in *Military Language*, leave of absence granted to an officer or soldier from his corps, from the army or altogether from the service. The old service of France admitted of two kinds; namely, the *congé limité*, a specific or limited leave, and the *congé absolu*, or an absolute discharge. In the latter case there was delivered to the soldier a *car-*

tourte, with all the signatures on it necessary for the good order and regularity of the service, and for the tranquility of the person, who obtained it. The *congé absolu* was always suspended in time of war.

CONGEABLE, from the French *congé* (i. e. *leave, licence, or permission*), signifies as much as lawful, or lawfully done, or done with leave or permission; as, *then entry of the diffidite* is congeable.

CONGELATION (from the Latin *congelare*), means the transition of a liquid into a solid state, in consequence of the abstraction of heat; thus metals, butter, oils, water, &c. are said to *congeal*, when, from a fluid state, they pass into that of a solid.

Congelation and freezing mean, in fact, the same effect; yet the term congelation is indiscriminately applied to all the above-mentioned transitions; whereas the word freezing is more commonly used for denoting the congelation of water, of vinegar, of brandy, of mercury, and in short of all those substances which, in order to become solid, must be cooled below 32° of Fahrenheit's thermometer. We shall, however, in this work, divide the subject of congelation under the two above-mentioned denominations; stating, under the present article, whatever relates to natural congelation, and under the article FREEZING, whatever relates to the artificial methods of freezing.

Another important process, much connected with congelation, has been improperly separated from it. And this is *crystallization*, or the arrangement of certain substances into regular figures, in their transitions from the fluid into the solid state; but water and several other bodies likewise crystallize in congealing, which shews that the two processes can hardly be separated; and this is rendered still more evident by a due consideration of other phenomena that accompany both processes. Allowing therefore that crystallization and congelation are essentially of the same class, a slight discrimination may be formed by applying the term crystallization to the formation of those regular forms or crystals, which are of a compound nature, and which, when once formed, generally require a much greater degree of heat for their liquefaction, than that in which they were formed.

By far the greater number of liquids we are acquainted with, have been found capable of congelation in a proper temperature; and on the other hand most of those solids which are such in the usual temperature of the atmosphere may be rendered fluid by the application of certain appropriate degrees of heat; hence we are led by analogy to suppose, that every fluid might be congealed, if it were possible to cool it sufficiently; or that fluidity is the effect or consequence of heat. Every particular kind of substance requires a different degree of temperature for its congelation; hence it appears why certain substances remain always fluid, whilst others remain always solid, in the ordinary temperature of the atmosphere, and why certain other substances are sometimes fluid, and at other times solid, according to the vicissitudes of the weather, the difference of seasons, and the variety of climates.

Heat, or sensible caloric, continually tends to pass from those bodies which have more of it than their proper share, to those contiguous bodies which have less of it than their proper share; hence, when a body is placed amongst other bodies of a lower temperature, its heat gradually passes to those other bodies, until the whole acquires the same temperature; and this transition proceeds regularly, excepting, however, when the body is in the act of assuming the solid state; for at that moment a sudden extrication of heat is observable. Place a thermometer in a glass full of water,

CONGELATION.

and place the glass in a freezing mixture of broken ice, and common salt, the thermometer will be found to descend gradually as low as 30, or 28 degrees of Fahrenheit's thermometer, and sometimes even much lower, whilst the water remains fluid; but, at last, the water begins to freeze, and at that very moment the thermometer rises suddenly to 32°, and it remains at that point until the whole of the water is congealed. If then the application of the freezing mixture be continued, the thermometer will sink gradually several degrees below 32°, according to the activity of the freezing mixture. We may, Dr. Black observes, easily satisfy ourselves, that the water, while congealing, is continually imparting heat to the surrounding air; for, if we suspend a delicate thermometer immediately above the water, we shall find the instrument affected by an ascending stream of air, less cold than the air around.

Not only pure water, but all aqueous fluids, may be cooled down 7, or 8, or 10 degrees without freezing; but if in that state they be affected with a tremulous motion, or if they be touched with a slender piece of ice, they will instantly shoot into beautiful spicules, the thermometer in it rising at the same time. This striking phenomenon of the sudden rising of the thermometer at the moment of congealation, which has also been remarked in wax, spermaceti, and other substances, has not yet been fully or satisfactorily explained. It is true that ice has not so great a capacity for containing heat as water has; (see the capacities of bodies under the article CALORIC and HEAT); but why should water so reluctantly part with that superfluous quantity of heat as to suffer itself sometimes to be cooled several degrees below 32, before it will assume the solid form?

Since water, when it has once begun to congeal, remains at the apparent temperature of 32° until the whole of it is congealed; and since water cannot remain congealed in a temperature higher than 32°; therefore the congealed point of water has been fixed at 32°, of Fah.

The congealing points of several other substances have also been ascertained with considerable accuracy. In some, however, it is not the congealing, but the melting, point that has been ascertained. These two points, if they be not quite the same, may naturally be supposed not to differ more than about a degree or two; hence from the latter the former may be easily deduced. In the following table, however, we shall set down the one or the other of those points, according as either of them has been more accurately determined.

Table of the congealing, or melting points of different substances, expressed in degrees of Fahrenheit's scale; the high degrees of which have been estimated by the equivalent degrees of Wedgwood's thermometer;

Platina melts	-	-	-	23177° F.
Manganese melts	-	-	-	28877.
Iron melts	-	-	-	21637.
Nickel melts	-	-	-	20577.
Pig iron begins to melt	}	-	-	17977.
Cobalt melts		-	-	
Fine gold melts	-	-	-	5237.
Settling heat of flint glass	-	-	-	4847.
Fine silver melts	}	according to Mr. Wedgwood	-	4717.
		according to Sir James Hall	-	3937.
Swedish copper melts	-	-	-	4587.
Brass melts	-	-	-	3807.
Zinc melts	-	-	-	700.
Lead melts	}	according to Newton	-	540.
		according to Seconat	-	535.
		according to Irwin	-	594.
		according to Parker	-	612.

Lead fixes, according to Crichton of Glasgow	612° F.	
Bismuth melts	460.	
A mixture of one part of tin and four of lead, melts	according to Irwin	470.
	-	476.
Tin melts	according to Irwin	408.
	according to Crichton of Glasgow, it congeals at	442.
	-	413.

The last mentioned gentleman says, "it melted in the thermometer sunk gradually till it arrived at 442°; then it instantly sunk to 439°; and as instantly rose to 442°." At this temperature the mercury remained perfectly stationary for five minutes, at which time the metal became solid to the centre of the crucible."

A mixture of three parts of tin and two of lead	}	melts	-	334.
A mixture of two parts of tin, and one of bismuth melts		-	-	
A mixture of tin and bismuth, in equal parts, melts	-	-	-	283.
Sulphur melts	-	-	-	234.
A mixture of five parts of bismuth, three of tin, and two of lead, melts	-	-	-	212.
A mixture of three parts of tin, five of lead, and eight of bismuth, melts	-	-	-	219.
Serum of blood begins to coagulate at	-	-	-	156.
Albumen, or the white of an egg, coagulates at	-	-	-	156.
Bees wax melts	-	-	-	142.
Tallow melts	-	-	-	127.
Spermaceti melts	-	-	-	112.
Ice, or congealed water, begins to melt	-	-	-	32.

The increase of the bulk of water previous to, as also following, its point of congealation is a remarkable property, which has been more or less observed with all aqueous fluids, viz. they are contracted by cold, until a certain limit, which generally is about 7 or 8 degrees higher than their congealing point; they then expand again as they are cooled farther, and if they are not agitated, they will remain liquid at a temperature lower than their congealing point. The greatest density of water, Count Rumford says, is somewhat lower than 40°. Professor Hope of Edinburgh places it between 39°.5 and 40°. Mr. Dalton says, that the greatest density of water is at the temperature of 42°.5. And that the expansion of water is the same at the distance of the same number of degrees above and below 42°.5. Thus the expansion is the same at 32° and 53°; the same at 10° and 75°, &c. The increase of bulk in freezing water is not owing to the formation of air bubbles, for water, which has been deprived of air, will also expand in freezing. The bulk of ice, at a mean, is to that of the water which it produces, as 9 to 8. This enlargement of bulk is attributed to a crystallization; the particles of water in freezing tend to arrange themselves so as to form angles of about 60 and 120 degrees; and this tendency is exerted with a prodigious force. Mr. Leslie says, "water necessarily discharges its air previous to the act of congealation; a circumstance which sometimes retards that species of crystallization. Hence it is, that water freezes sooner which has been boiled. When exposed to cold, crude water will present a cake of ice crowded with large bubbles entangled in the mass; but boiled water will contain a solid lump, almost pellucid, with only some minute specks or strag floating from the centre." Dr. Black says, that boiled water begins to freeze as soon as the air has cooled it to 32°. Iron likewise occupies less room when fluid than when solid. And the same thing has been asserted of two or three other metallic substances.

CONGELATION.

Vinegar congeals at about	28° F.
Human blood congeals at	25.
Strong wines congeal at about	20.
A mixture of one part of alcohol and three of water congeals at	7.
A mixture of alcohol and water, in equal parts, congeals at	minus 7.
A mixture of two parts of alcohol and one of water, congeals at	minus 11.
Mercury congeals at	minus 39.

Mercury exposed to cold, and at about the point of congelation, contracts its bulk irregularly. This substance may be cooled some degrees below its freezing point, before it assumes the solid form; but as soon as it begins to harden, the thermometer rises to its freezing point, which, from a variety of experiments made by Mr. Hutchins at Hudson's Bay, appeared upon his thermometer to be -40° . "But (Mr. Cavendish observes in the Phil. Transf. vol. lxxiii. p. 321.) as it appeared from the examination of his thermometer, after it came home, that -40° thereon answers to $-38\frac{3}{4}$ on a thermometer adjusted in the manner recommended by the committee of the Royal Society; it follows, that all the experiments agree in shewing that the true point at which quicksilver freezes, is $-38\frac{3}{4}$, or in whole numbers 39° below nothing."

In becoming solid, mercury sometimes shoots into crystals or longitudinal filaments like pins. The first observations concerning the natural congelation of mercury were made by Mr. Gmelin about the year 1735, at Yeneseick in lat. $58\frac{1}{2}^{\circ}$ north, at Yakutsk in lat. 62° north, at Rivengo, lat. $57\frac{1}{2}^{\circ}$ north, and elsewhere. (See the Peterburg Commentaries for the years 1756 and 1765). Professor J. A. Baux, of Peterburg, in the year 1759, first accomplished the congelation of mercury by art, viz. by means of snow and aqua fortis. But with respect to the artificial methods of congelating mercury, and their history, see the article FREEZING.

Nitric acid is said to congeal at - - - minus 66.

With respect to the congelation of the sulphuric, or vitriolic acid, the greatest number of experiments seems to have been made by Mr. Keir, and from those experiments he infers: "1. That the vitriolic acid has a point of easiest freezing, and that this is when its specific gravity is to that of water as 1780 to 1000. 2. That the greater or less disposition to congelation does not depend on any other circumstance than the strength of the acid. 3. That the freezing and thawing degree of the most congelable acid is about 45° of Fahrenheit's scale. It is, however, to be observed, that this degree is inferred from the temperature indicated by the thermometers immersed in the freezing and thawing acids; but the congelation of the fluid acid could never be accomplished without exposing it to a greater degree of cold, either by exposing it to the air in frosty weather, or to the cold of melting snow. 4. Like water, this acid possesses the property of retaining its fluidity when cooled several degrees below the freezing point; and of rising suddenly to it when its congelation is promoted by agitation, or by contact even with a warmer thermometer. 5. That, like water and other congelable fluids, the vitriolic acid generates cold by its liquefaction, and heat during its congelation, though the quantity of this heat and cold remains to be determined by future experiments. 6. That the acid, by congelation, when the circumstances for distinct crystallization are favourable, assumes a regular crystalline form, a considerable solidity and hardness, and a density much greater than it possessed in its fluid state."

The heat of the earth, at least on the surface of it, is de-

rived entirely from the sun; for the heat arising from combustion, as about volcanos, or from decomposition of bodies, is trifling and partial. The direct rays of the sun on the same spot of the surface of the earth heat it more or less, according to the time of the year, clearness of the atmosphere, state of the winds, colour and quality of the spot. In Great Britain, during the hottest time of the summer season, the direct rays of the sun seldom raise the mercury in the thermometer so high as 110° . But in other climates, especially within the tropics, the mercury is raised considerably higher by the like exposure. Yet we must not believe the idle stories of the sun's heat melting lead, or setting fire to gun-powder, without the assistance of lenses, speculums, or other artifice.

It is not on account of the sun's being nearer or farther from the earth, that we receive much more heat in the summer than in the winter time; since the difference of those distances is too small to be sensibly felt; but we receive more heat in the summer than in the winter season. 1. Because the sun comes nearer to our zenith in the summer than in the winter time, in which situation its rays pass through a shorter portion of the atmosphere, and of course are less intercepted by it. 2. Because, when the sun is nearer to the zenith, a greater quantity of its rays falls upon a given horizontal part of the surface of the earth, than when that luminary stands lower, and its rays fall more obliquely upon the same spot. 3. Lastly, because the sun remains longer above the horizon during a summer day than a winter one.

The hottest part of the day is not at noon, nor that of the year when the sun passes nearest the zenith of a given country; but the hottest part of the day, when no accidental circumstance intervenes, is some time in the afternoon, and nearer to noon in the winter than in summer. In this country and in summer, the hottest part of the day generally is either precisely at, or a little before, two o'clock. The hottest time of the year in this country generally takes place in July, viz. after the solstice. The reason of this, is that though the rays of the sun give more heat when the sun stands higher, and of course at two o'clock they must give less than at noon; yet the earth, and the air contiguous to it, are hotter at two o'clock, because, besides the heat which they are actually receiving from the sun, they retain a considerable portion of the heat acquired before that time; so that as long as they acquire at any particular time, a greater quantity of heat than they lose of that which they had previously acquired, their temperature must continue to increase. The same thing must be understood with respect to the communication of cold, which, for similar reasons, is greatest some time after midnight, and some time after the shortest days of the year. The earth acquires heat in the day time, and loses it during the night. In the summer season the loss of heat during the night is less than the acquisition of it during the day; therefore that excess of heat is gradually communicated from the surface to the more internal parts of the earth. But when the above-mentioned summer heat has penetrated a certain way, the winter cold begins to counteract it; and when that cold has penetrated a certain way, the next summer heat begins again to counteract it, and so on; hence, below a certain depth there is no alteration of temperature at any time of the year; unless some local combustion or other source of heat should interfere, which, however, seldom occurs. This fixed degree of temperature at a certain depth below the surface of the earth, varies in different countries, and nearly coincides with the mean temperature of the particular country. Thus in London the mean temperature is 50° ; and if a bucket of water be drawn from a pretty deep well, and a thermometer

CONGELATION.

be instantly placed in it, the temperature of that water, (which is the same as that of the ground furrounding the bottom of the well) will also be found to be 50°. In products of time the mean temperature of a country is liable to some alteration arising from cultivation, clearing of grounds, draining of marshy grounds, &c. See CLIMATE.

With respect to the temperature at different altitudes, it has been found that a thermometer placed close to the ground is sometimes affected by heat or cold, sooner, or in a greater degree, than a thermometer placed 20, or 30, or 60 feet, higher up; and that at other times the latter is affected sooner, or in a greater degree, than the former. In the night time, especially when the air is still, and the sky quite free from clouds, a thermometer close to the ground generally indicates a greater degree of cold than in a higher situation. The true cause of this phenomenon is not fully understood; though it is attributed to evaporation, or according to Mr. Six, to the coolness which the dews or vapours may acquire in their descent.

At great heights above the surface of the earth, either in the free air, or on the summit of high mountains, the cold is much greater, and it increases more suddenly; it, because they are much more exposed, and 2dly, because they are more remote from the body of the earth, which, as has been observed above, tends to equalize the temperature, by retaining in the winter time a considerable degree of the heat acquired in the course of the summer. The winds to which mountains are exposed, especially those which, after having blown over the plains below, rise along their sides, have a peculiar refrigerating power, arising from the expansion of the ascending air, which becomes capable of absorbing more heat in proportion as it is more rarefied. See Dr. Darwin's Paper, Phil. Transf. for 1788.

Thus we have briefly stated the natural sources, and the principal causes which check or promote the heat and the cold, that are usually experienced in the world, at different times of the day, of the year, and in different countries; whence alone one may pretty well conceive where and when natural congelation may be expected to take place. Yet it is necessary to subjoin some farther observations, that have been made with respect to natural congelation at different times and different places.

The greater obliquity with which the sun's rays fall upon the northern and southern parts of the earth, than they do upon such parts as are near the equator, undoubtedly produces the variety of the mean temperatures that are observed in different latitudes; the higher latitudes being generally colder than the lower, and *vice versa*. But this gradation is partly counteracted by a variety of local circumstances; and such are the vicinity of large tracts of land or great extent of sea, the face of the country being flat or hilly, the disposition of the hills and mountains, the prevalence of rain and of certain winds, the state of cultivation, &c. The influence of winds in certain latitudes is so very great that a frost or thaw is brought on within a remarkably short time by a change of the wind. The action of winds on the temperature of a country principally depends upon three circumstances, *viz.* on their bringing a quick succession of new air in contact with the bodies that are exposed to it, on their having passed over the surface of hotter or colder tracts of water or land, and upon their increasing the evaporation. Saussure found that when the wind moves at the rate of forty feet per second, it triples that quantity of evaporation that would take place in calm air; hence it follows that frequently unusual heats or colds come on at unexpected times, and that the higher strata of the atmosphere are often warmer than the lower; for the heat

of the atmosphere is derived not from the immediate action of the sun's rays which pass through it, but from the warmer and more solid bodies with which it has been, or is, in actual contact. In consequence of these various circumstances, it has been observed that the north Pacific Ocean, above latitude 40°, is much colder than the north Atlantic, between the same parallels of latitude. The interior parts of Siberia, east of longitude 100°, are much colder than the parts equally distant from the meridian on the western side. The coast and interior parts of the western regions of America are much colder above the latitude of 40°, than the corresponding tracts of the continent of Europe. Large seas, which are agitated by winds and currents, are thereby so little affected by cold winters or hot summers, as to preserve a temperature nearly uniform in every season, like the internal parts of the earth.

With respect to the mean temperature of places at different altitudes above the level of the sea, but in the same country, or nearly about the same spot with respect to latitude, the heat diminishes nearly one degree of Fahrenheit for every 200 feet of elevation, according to Dr. Black. Other writers find reasons to assert, that the diminution of one degree takes place at every 299 feet of elevation.

From the statement of all the above, particulars the reader may form some idea of the time and place when natural congelation may be expected, and he will at the same time be able to perceive that close to the surface of the earth, no great regularity can be expected. On the continent of Europe congelation formerly took place at a lower latitude than it does at present, when natural congelation is seldom observed lower than the latitude of 40°. In America congelation has been observed at a much lower degree; and it is remarkable that great degrees of heat, as well as great degrees of cold, are alternately experienced on the same spots of that continent. In the more northern parts of the world the degrees of cold are very extraordinary. At Torneao, Reaumur's spirit thermometer fell to minus 34°. In Siberia the spirit thermometer has been known to descend as low as minus 121°. Even at the Glasgow observatory in the year 1780, the mercury of the thermometer exposed to the ambient air was found to stand at minus 14°.

The altitude on the sides of mountains, at which constant congelation takes place, seems to be less fluctuating, though not accurately ascertained. This altitude varies with the latitude; but even in the torrid zone perpetual congelation has been observed (according to Bouguer and others) at the altitude of about 15600 feet. This altitude, at which the congelation is constant, or where water ceases to be a fluid, and beyond which visible vapour does not seem to ascend, is called the *upper line of congelation*. The *lower line of congelation* is where it freezes at night only. The upper line of congelation, within the tropics, has been observed at the altitude of 15600. Near the tropics, on the sides of the temperate zones, it lies at the height of about 13428 feet. On the island of Teneriffe, in lat. 28° N., it lies at the altitude of about 10000 feet. In Auvergne, lat. 45° N. the line of congelation is at the altitude of 6740 feet. In latitude between 51° and 54° N. it seems to be at the altitude of about 5800. In latitude 80° north, lord Mulgrave found the line of congelation at the altitude of about 1200 feet above the level of the sea; whence, if the progression continues uniformly, as general Roy observes, we may conclude that the surface of the earth, at the pole itself, is for ever covered with congelation. Mr. Kirwan, however, places the upper line of congelation considerably higher. See his paper on the variations of the atmosphere, in the 8th vol. of the Transf. of the Royal

Royal Irish Academy. He reckons the altitude of the line of congelation from 0° to 10° of north latitude, at about 27700 feet; from 10° to 15° at about 26,00 feet; from 15° to 20°, at about 25200 feet; from 20° to 25°, at about 24000 feet; from 25° to 30°, at about 23000 feet; from 30° to 35°, at about 20000 feet; from 35° to 40°, at about 17000 feet; from 40° to 45°, at about 15000 feet; from 45° to 50, at about 12500 feet; and for every one of the other degrees of latitude, at the altitudes which are annexed to them in the following table. These results, however, he deduced by computation from a few ascertained particulars.

Degrees of N. lat.	Altitude of the line of congelation.	D egrees of N. lat.	Altitude of the line of congelation.

CONGENERES *musculi*, in *Anatomy*, are such muscles in an animal body, as serve together to produce the same motion; and they are so called because they assist one another in their action.

CONGER, or **CONGER EEL**, in *Ichthyology*, the largest of the *Muraena* tribe. This voracious fish grows to the length of five or six feet, and the thickness of a man's thigh. The colour of the upper part is dark grey, sometimes inclining to olive, and the belly pure white; but it is principally distinguished from the other species of the *muraena* genus by having the lower jaw rather shorter than the upper; nose with two tentacula, and the lateral line whitish, with a row of spots. See *MURENA*.

CONGERIES, a Latin word, sometimes used in our language for a collection or heap of several particles, or bodies, united into one mass or aggregate.

CONGERIES, in *Rhetoric*. See *SYNATHROISMUS*.

CONGESTION, in *Medicine*, has been used to denote an enlargement of any part of the body, especially when accompanied with hardness, or alteration of structure, which, in the opinion of the humoral pathologists, was produced by a collection of morbid humours, deposited in the part. The term is still employed, chiefly to express the morbid increase of distention in the blood-vessels in inflamed parts, or morbid effusions of blood or lymph in the viscera. Thus, a *congestion* of blood in the vessels of the brain is said to have produced apoplexy, when, on dissection, vessels which are usually invisible, are observed to be filled with red blood; and congestion is said to exist in the lungs, when the circulation of the blood through the minute ramifications of the

blood-vessels is impeded, or when lymph is poured out into the cells of the bronchæ, as in the catarrhus semis, and p^{ne}pneumonia.

CONGHEVE LAKE, in *Geography*, a Lake of Thibet, which intervenes between the Maagarvar lake, and the head of the river Sampo.

CONGLIARUM, **CONGIARI**, among *Malaïis*, a gift or d native, represented on a medal.

The word comes from the Latin *congius*; because the first presents made to the people of Rome consisted in wine and oil, which were measured out to them in congi. The congiary was properly a present made by the emperors to the people of Rome. Those made to the soldiers were not called *congiaries*, but *donatives*.

The legend on medals representing congiaries, is *congiarium*, or *liberalitas*.

Tiberius gave a congiary of three hundred pieces of money to each citizen: Caligula twice gave three hundred sesterces a head. Nero, whose congiaries are the first that we find represented on medals, gave four hundred. The congiarium of Nerva had on its reverse five figures.

CONGIO, or **CONGIO**, **CAMILLO**, in *Biography*, was a designer and engraver of considerable talents. He was born at Rome about 1604. Little is known of his life, except that he followed his profession at the place of his nativity, and at Florence. About the year 1650, he engraved several of the plates for the Galleria Justiniana. Most of the twenty plates for Tasso's Jerusalem, from the designs of B. Caselli, are by Congio, as likewise several of the engravings in the fine work entitled *Odes Barberine*. Besides the above, we have many prints by him executed in a bold and firm manner, from the designs or pictures of Tempella Larifianco, Pomerancio, and other masters, and some from his own drawings. His plates are generally marked with two C's, the top of one joined to the bottom of the other; or in this manner: C. C. F. the F. standing for fecit. Strutt. Huber, Manuel des Arts.

CONGIATELLA, in *Antiquity*, half a congius.

CONGIUM, in *Ancient Geography*, a town of Spain, placed by Ptolemy in the Tarragonensis territory; the country of the Vaccæans, supposed to be the present Cabçon.

CONGIUS, an ancient Roman measure of capacity, or for things liquid, = $\frac{1}{4}$ of a cubic Roman foot, = 8 sextaries, = 197.137 cubic English inches, = .1141 cubic English feet.

From the original standard of Vespasian extant at Rome, Graves deduced the value of the Roman pound to be 5256 Troy grains. See *DENARIUS*. But Mr. Raper, in an excellent paper on this subject, has suggested several objections against the accuracy of this conclusion. Phil. Trans. vol. lxi. part ii. p. 456.

The congius has also been used in England, as appears by a charter of king Edmund in 946.

CONGLETON, in *Geography*, a small corporate town in Cheshire, England, is situated near the upper part of the river Dane, on the borders of Staffordshire, and governed by a mayor and six aldermen. It possesses two churches, both subject to the mother church of Athbury, a village two miles distant. The town was formerly celebrated for the manufacture of tagged leather laces, called Congleton points; but the chief employment of the poor is now derived from a very capital silk mill erected on the river; and from a ribbon manufactory. In the church-yard of Athbury are two ancient stone monuments, ornamented with the insignia of Knighthood; but the families whose memory they were intended to record are now unknown. Congleton is 163 miles N.W. from London; has a market on Saturdays.

In the return under the late act the houses were estimated at 855; the inhabitants at 3861, of whom 1713 were males and 2148 females.

CONGLOBATE glands, in *Anatomy*, those glands whose substance is not divided, but firm, entire, and continued; and their surface smooth and uniform.

They are thus called, in opposition to *conglomerate glands*. Conglobate glands have each of them an artery which brings them blood, a vein which carries it back again, after the proper juice has been filtrated, and several excretory ducts.

Some of them have a cavity in the middle, with lymphatic vessels, which discharge themselves into a common reservoir, or canal.

CONGLOBATE flowers, are those with globular heads.

CONGLOMERATE glands, are those which are composed of several little ones; or they are several glandulous bodies joined together under the same common membrane. See **GLAND**.

Such are the salival glands, lachrymal glands, the pancreas, &c. which see under their proper articles.

The conglomerate glands, besides their arteries, veins, and nerves, are also furnished with an excretory vessel, ramified throughout their own substance; by means whereof they discharge the liquors they have filtrated into reservoirs.

CONGLOMERATE flowers, are those which are irregularly crowded together.

CONGLOMERATION, in *Minerology*, is the term used to express confused mixtures or concretions of different mineral substances. Kirwan's *Geol. Essays*, p. 303 and 306.

CONGLUTINATION, the act of gluing, or fastening two bodies together, by the intervention of some third, whose parts are unctuous and tenacious, in the nature of a glue, *gluten*; from whence the word is formed.

In the animal economy, the parts of the body are said to be conglutinated by means of their natural moilures; by the help of bandages, as in several cases of surgery; or by the supply of viscid particles. In which last acceptation, conglutination differs little from accretion, or nutrition.

CONG-MOU-ING, in *Geography*, a town of China, in the province of Setchuen; 42 miles N.W. of Hoi-li.

CONGO, or **KONGO**, a name given to the country of Africa, otherwise called *Lower-Guinea*, which see. It is commonly divided into Loango, Angola, Benguela, and Congo Proper.

Congo, or **Kongo**, *Proper*, a kingdom of Africa, bounded on the north by the famous river Zair or the river of Congo, which divides it from that of Loango, on that side; on the south by that of Dando, which separates it from the kingdom of Angola; on the east by the kingdoms of Fungoo and Metamba; and the burnt mountains of the sun, those of crystal or salt-petre and silver, and by the rivers Verbeia and Chilenda; and on the west by the Ethiopic sea, called the sea of Congo. Its extent from N. to S. and from E. to W. has not been accurately ascertained; but according to the relation of John Anthony Cavazzi de Monte Cuculo, a Capuchin missionary, the dominions of the kings of Congo were much extended towards the east and the south, before the introduction of the Christian religion; but since this event, many of the remote provinces in these directions have been dismembered, so that Congo was reduced from above 600 leagues in circuit to less than one-half of that extent. Being situated under the torrid zone, it is subject to the excessive heats peculiar to that climate; however, they are considerably mitigated by winds and breezes, rains and constant dews; as well as by the more equal length of days and nights. Their summer and winter, which compose their year, are divided into six sea-

sons, which they call *massanza*, *neasu*, *ecundi*, *quitombo*, *quifiso*, and *quimbangala*. The first commences with the month of October; which is the beginning of their spring, when the rains begin to fall; and they continue during the two, and sometimes the three, next months. The floods that are thus occasioned are commonly followed by a famine. Their second season begins about the end of January, which is followed by harvest and new sowing; their lands commonly yielding them two harvests. The third and fourth seasons are frequently blended towards the beginning of March, when the more gentle rains begin to fall and continue till the month of May; at which time the air is clear and dry, but occasional clouds burst forth into tremendous lightning and thunder without rain; these two seasons last till about the beginning or sometimes till the end of September. The two last seasons constitute their winter, which consists not in frost or snow, for these are unknown in this climate, but in dry blasting winds, that strip the earth and trees of their verdure, till the next *massanza*, or spring, restores their vernal bloom. The Congoes divide the year into twelve lunar months, commencing like that of the Jews, in September. Their week consists of four days; three of which are appointed for labour, and the fourth for rest or religious exercises. The general indolence of the inhabitants prevents their deriving any substantial benefit from the fertility of their soil, which duly cultivated would yield a double, and sometimes a triple, crop yearly. But the negroes, averse from labour, spend their time in dancing, leaping, hunting, and shooting, or in smocking and more listless indolence; whilst they commit to their slaves, or their wives, the operations of digging, sowing, reaping, cutting woods, grinding corn, and fetching water. Their ground produces variety of grain, but no corn or rice besides that which is cultivated by the Portuguese. Of their maize, of which they have regularly two crops, they make their bread. They have three other sorts of grain, which they apply to the same purpose. They also cultivate a variety of pulse, as beans and pease of different sorts, which serves them for part of their food. Their fruit-trees have been chiefly trees planted there by the Portuguese; and of palm-trees, which are exotic and brought from America, they have no less than eight sorts, which are all excellent in their kind. If we may credit the accounts that are given of the productions of the country, which sometimes border on the fabulous, they have a tree called *Aliconda*, so large that ten men cannot fathom it, yielding a fruit which resembles a gourd, and which serves for vessels of various uses; the bark of which furnishes them with a coarse thread, which they form into ropes and into a cloth, with which the natives cover their middle from the girdle to the knees; and the small leaves of which supply them with food in a time of scarcity, while the large ones are used for covering their houses, or by burning for the manufacture of good soap. Of the bark of the insana tree, and also of the *mulemba*, resembling in many respects our laurel, they form a kind of stuff or cloth, which is fine and used for cloaks and girdles by persons of the highest rank. The oil of their palm-trees is used instead of butter; with the moss that grows about the trunk, the rich commonly stuff their pillows; and the *Gia-gas* apply it to their wounds with good effect: with the leaves the Moors cover their houses, and they draw from these trees, by incision, a pleasant liquor like wine, which however turns sour in five or six days. From the Congo palm-tree, so called, because it thrives better in that country than any of the other sorts, they obtain a liquor, which is reckoned as valuable as the wine that is brought from Europe, though it is rather a kind of milk, sweet and agree-

ably tart, which will become four in three or four days, and is so strong and heady, that a pint of it will produce intoxication. The fruit of this tree, not unlike a peeled chestnut in colour, taste, and substance, is the common food of the poorer class. With the oil that is drawn from it the natives dress their vicinals: but the Europeans only burn it in their lamps. Of their shrubs we shall only mention that which they call capano, or "the fig of hell," from the nut of which they extract an oil for the lamp, and which they also use in the composition of their ointments and plasters. The leaves burnt to ashes, afford a good lye, with which the natives wash their bodies. The Portuguese have cultivated to plant several other fruits, as oranges, lemons, citrons, granates, cedars, and others, which thrive as well as in their native soil. Vines have also been brought thither from Candia; and they yield excellent grapes twice a year. They have also plants of the aromatic kind, which yield substitutes for cinnamon and pepper. Their manioc, of which they make bread, is the same which is used in Asia and America; their potatoes and other roots of a like kind yield a grateful nourishment. Wheat is the only grain which the ground will not produce, as it shoots up into straw and ear, the former being high enough to hide a man on horse-back and the latter being unfiled. Their grass grows to a great height, and affords sheltering places for a variety of wild and voracious beasts, and venomous insects; so that it is dangerous to travel through the country on this account. Their lilies, tulips, tuberoses, hyacinths, &c. grow wild, and are singularly beautiful.

The principal rivers of this country are the Zair, into which fall the Bancaro, Vambra, Congouo, and Barbelo or Vervel, the Dando, which see respectively. Between the Zair and Dando, are the Ichunça, Doce, Ambriz, Leze, Ouzi, and Lutana, with several others of less note.

Congo is divided into six large provinces, under the titles of duchies, counties, and marquises, and these again are subdivided into lesser signories or lordships. The situation of these provinces is as follows; along the sea coast lie the county of Sogno, and the great duchy of Bamba; on the north, the duchy of Sandi, the marquise of Pango; on the west, the duchy of Batta; and within land, the marquise of Pemba. See each respectively. The capital of the whole kingdom is Banza, or St. Salvadore, which see. Independent of the six districts above enumerated, Congo has several other lesser provinces, most of which are covered with forests or mountains, and inhabited by a race of men in a barbarous and savage state: their names, as we learn from Cavazzi, are Zuionz, Zujamazondo, Ndamba, Nfusso, Nkellajua, Alombo, Niolo, Nzanga, Marlinga, and Mor-tonda; the three last of which border upon the country of Ajacoo, a nation more barbarous than any of the rest.

The kingdom of Congo, like most other parts of Africa, breeds a prodigious variety of living creatures, both wild and tame, and particularly those of the former sort; such as elephants and lions, of a monstrous size, leopards, tigers, wolves, and other voracious animals. The zebra of this country is a beautiful animal, which the natives hunt, on account of its flesh, which they esteem a dainty food, and for its hide which they send to Europe as a valuable commodity. In this country they have also a great abundance of buffaloes and wild asses. The "Dante" seems peculiar to this country; in shape and colour it resembles an ox, but is not so large; its horns are like those of a he-goat, but very smooth and shining, and of a blackish hue, of which the natives make a variety of pretty bangles; the skin is commonly bought by the Portuguese, and sent into Germany, to be tanned and made into targets, called

"Dantes;" and of the raw hide dried, the natives make their shields, which are impenetrable to arrows and darts, and so large as to cover the whole body. Camelons swarm in Congo; and it has several sorts of wild rats, as the ningi, nssoli, and maimoni; whose furs excel those of the finest tigers, in the beauty, variety, and regularity of their streaks and spots. The forests also swarm with wild dogs, which are extremely fierce and voracious. It has also one singular quadrupel, which abides constantly in the trees, and which is said to die immediately upon letting its feet on the ground; it is called "entingia," and is very small; its skin is so beautifully spotted, that none but the kings of Congo, the princes of the blood, and such nobles as obtain the privilege from him, have the liberty of wearing it. And even the kings of Lovango, Cucongo, and Gay, receive this extraordinary fur, as a valuable present.

The tame animals of Congo, such as oxen, sheep, hogs, horses, mules, and asses, which might be rendered useful and profitable, are much neglected. The Portuguese, however, have directed their attention to the cows, sheep, and goats, chiefly on account of their milk, though they have not learned to make butter or cheese. The land and sea fowls of this country are very numerous; its ostriches are very large and beautiful; the feathers of which, mixed with those of peacocks, no less numerous and beautiful, are used, instead of ensigns and standards, and made into umbrellas. Turkeys, geese, hens, and ducks, both wild and tame, and also pheasants, pigeons, doves, woodcocks, and other smaller birds, abound in this country. Of parrots there is a great variety, distinguished both by their size and colour; the most esteemed of these are such as they denominate, by way of excellence, the birds of music, which are kept by persons of rank in cages and aviaries, for the sake of their surprising melody. Here are other birds which the superstitious natives regard with horror; the sight or cry of which throws them into a general panic, and occasions them to disperse with the utmost precipitance and confusion. The most dreaded of the ominous kind are crows, ravens, bats, owls, and especially the great owl, which they call, in their language, "kariam pempa," the name they give to the devil. Birds of prey, such as eagles, vultures, falcons of various sorts, sparrow-hawks, and others of a similar kind, are found in great numbers. Herons, bitterns, and some others of the like voracious kind, commonly abound in their marshes, lakes, and other waters. Among these they have a bird, in shape and size like a crane, and one in particular, called by the Portuguese the pelican, of a large size and whitish colour; and also another called the fisher, which darts from a surprising height in the air on the fish which he perceives in the sea or in rivers. Of fish, the sea adjoining to this country, and its rivers, afford great plenty and variety. The inhabitants are likewise infested with a great variety of serpents, very long and thick, rattle-snakes, vipers, and other venomous reptiles, scorpions, and other venomous insects, both flying and reptile, of various kinds, are found in this country. This country is said to possess mines of silver and gold, as well as of iron and copper; but the people are too indolent to work them, or to derive any great advantage from them.

When the Portuguese first discovered this country, in the reign of John II., in the year 1484, they found it for the most part covered with towns and villages, swarming with inhabitants; the cities being well filled with people, and particularly the metropolis, which contained above 50,000 persons. We may form some judgment of the population of the country by this circumstance, *viz.* that the army of the king of Congo, in the year 1665, consisted of no less than

than 900,000 fighting men; and, besides, the number of converts to Christianity, which a small number of Capuchin friars made among the more civilized part, within the space of a few years, is affirmed to have amounted to 60,000. The surprising fecundity of their women, the hardiness with which they bring up their children, and the robust healthy constitution of their men, if we may credit Cavazzi, and the missionaries, are such that their villages and hamlets swarm with men, women, and children, that a father will exchange one or two of the latter for some commodity he wants, or even some trifling bauble which he fancies; inasmuch that the number of slaves they sell abroad, both seldom, communibus annis, fall short of 15 or 16 thousand. Notwithstanding the indolence and consequent poverty of the Congoese, they entertain the most extravagant conceit both of themselves and of their country; so that it is one of the articles of their belief, that the rest of the world was the work of angels, but that their kingdom of Congo, in its full and ancient extent, was the immediate production of the Supreme Architect himself, and must of course enjoy singular advantages and prerogatives above all others; and that their monarchs must be the most opulent, wise, and powerful, and their subjects the noblest, richest, most ingenious, and happiest in the universe. They imagine also, that the natives who traffic with them are forced to undertake that servile employment by their poverty and the sterility of their respective countries, rather than induced to it by their luxury and avarice; whilst they themselves, with the utmost ease and content, can indulge their natural indolence, though attended with hunger and misery, rather than disgrace the nobleness of their blood by any kind of industry; which, however laudable and beneficial, is regarded by them as a lesser degree of slavery. However, since the settlement of the Portuguese, they have been roused by their example from this kind of fantastic pride and shameful sloth into occasional and partial exertion; in weaving nets, and other coarse stuffs, sawing of boards, several branches of carpentry, and other manufactures and trades. But though they think it beneath their dignity to apply to any useful work, they deem it no disgrace to beg and steal.

The complexion of the genuine natives, that both of the men and women, is black, but some of them are of a deeper dye than others. Since their intermarriages with the Portuguese, they have varied from their native hue; some to a dark brown, some to an olive, and others to a blackish red. Their hair is black and curled, and in some cases of a dark sandy; their eyes are generally of a fine lively black, but some are of a dark sea-colour; they have neither flat noses nor thick lips, like the Nubians and other negroes; their stature is mostly of the middle size; and, excepting their black complexion, they much resemble the Portuguese, though some of them are more fat and fleshy. In their disposition, they are generally mistrustful, jealous, envious, and treacherous, and much inclined to revenge. They are so far devoid of natural affection, that a father will sell his son or daughter, and perhaps both, for a piece of cloth, a collar or girdle of coral or beads, and often for a bottle of wine or brandy. A husband may have as many wives, or if a Christian, as many concubines, as he pleases, and repudiate, or even sell them, though with child, at his pleasure. The religion of the country, before the Portuguese introduced their Christianity into it, was, and still is, among the unconverted, a monstrous compound of idolatry and superstition, and of the most absurd and detestable rites and customs, invented by their "gansas," or priests, for the purpose of keeping the people in a state of the most abject subjection, and

cruel tyranny and wretchedness. They do, indeed, acknowledge one supreme being, called "Nzambiamponga," believed to be all-powerful, and to whom they ascribe the creation of their country; but they suppose that he has committed the care and government of all subsidiary things to a great variety of subordinate or inferior deities, appointed to preside over the air, sea, and earth; lakes and rivers, winds and storms, rain, lightning, drought, heat and cold, men, beasts, fowls, and fishes, trees, fruit, and other productions of nature, fertile and barren, healthy and sickly, &c. Hence proceeds that immense multitude of false deities, idols and altars, and that prodigious variety of gansas or priests, and superstitious rites, still found in those parts of the kingdom, where Christianity has not been introduced. These imaginary deities are represented under various forms, at the pleasure of the worshipper, either of living creatures, as serpents, crocodiles, lions, tigers, he-goats, &c. or of trees and plants of different kinds, or of statues and images, skilfully carved or painted, some of which they worship in their houses, and others in temples of mean construction. Their worship consists in genuflexions, prostrations, fumigations, and other such superstitious rites; and also, agreeably to the injunctions of the gansas, in offerings of their most valuable effects, for food, apparel, &c. from which the principal revenue of the gansas is derived, who contrive to sell the favour of these deities at the most exorbitant price. Such is the superstition of the people, and the unbounded influence of these gansas, that they will not attempt to build a house or hut without consulting some gansa, and putting the edifice under the protection of a deity; nor can the owner take possession of it without employing the gansa to make the necessary sacrifices and fumigations, and performing other ceremonies, in order to secure that protection. Even the gansas, who are the most barbarous people of this kingdom, never venture to begin their harvest till they have offered various, and even human victims to their gods, and gorged their gansas themselves with human flesh. Excepting their new moons, they have no set festivals or seasons of worship, besides those which the president of the gansas appoints, after a victory, a good harvest, &c. to whom it belongs, to appoint the attendant sacrifices and rites, to receive the offerings of the people, and to prescribe the various ceremonies which accompany them. The highest power and dignity, pertaining to the priestly tribe, are those which are vested in the "shalome" or "chalombe," whom the people reverence as a kind of deity, and to whose rank and office various privileges belong. The influence of the gansas is so extensive and so powerful, that the kings of Congo, though desirous of extirpating idolatry from their dominions, have been unable to effect it. With regard to the establishment of Christianity in the kingdom of Congo, the first preachers commissioned by the court of Portugal for this purpose, were priests and monks of the church of Rome; so that the Romish religion became the established religion of all the conquered provinces of the kingdom. But Christianity, even under that form of it, has been so much neglected, that in the greater part of these extensive dominions, nothing now remains but the mere name of Christian. It is said, indeed, that the catholics in the duchy of Sogno, are better Christians than others, as they pay a peculiar regard to the external forms of the popish worship. The princes of this province, as well as those of Lamba and Pemba, have always distinguished themselves by their zeal for the Christian religion, under that external mode of it in which they have been instructed; and they have been careful to preserve their respective governments from being corrupted by the heathenish gansas or priests;

priests; and if any such are ever found within their dominions, they are treated with a severity, which prevents their attempting to repeat their visits.

The government of Congo is monarchical and despotic. The kings are the sole proprietors of all the lands within their dominions; which they parcel out to individuals on condition of a certain tribute and of the performance of particular services. The tribute is ordered to be brought in once in three years at the furthest; and the rigorous demand of it is the cause of many cruel extortions, which often terminate in a revolt, or open rebellion. The crown is partly hereditary, and partly elective, so that no candidate can be chosen, unless he be of the royal blood; and since the introduction of Christianity, a Christian of the church of Rome. The whole process of his coronation and his mode of living after his advancement to the throne are attended with various circumstances of splendour and magnificence. Whenever he goes abroad, which is seldom the case, he is attended by a numerous guard, consisting of Ansiki (See ANSIKO), and some others of neighbouring nations in whom he reposes the greatest confidence, musicians, knights of the holy cross, (an order instituted by the first Christian king of Congo) and a number of officers, richly accoutred. The respect that is paid him approaches to idolatry. His court is numerous and brilliant; and the royal palace is spacious, grand, and commodious. His seraglio, in which he keeps a great number of concubines, though he is allowed only one wife, is a kind of prison; as the women that enter it are confined during the remainder of their lives. His lawful wife presides in the seraglio over all the other women; who ingulf themselves in the most licentious gratifications. The royal revenue consists chiefly in the tribute that is paid him by several vassal princes; free-will-offerings, in acknowledgment of the lands which are held under him; the property of all the zimbis, or cockle-shells, that constitute the current coin of this and other neighbouring kingdoms; mines of silver and gold, which, however, are much neglected; and the renewal of siefs and investiture, fines and confiscations. He has also the prerogative of levying taxes upon his subjects whenever he pleases. His standing forces are neither numerous, nor well-disciplined, and very badly armed and clothed. Their mode of fighting is tumultuous and ferocious, nor do they give any quarter. Those that are taken alive are hurried to the sea-side, or to some inland market, where they are sold for slaves to the Europeans. The funeral obsequies of the monarchs of Congo before they were converted to Christianity, consisted of various kinds of sacrifices and superstitious ceremonies, accompanied with music, howling, dancing, and feasting, which lasted a whole week, and were resumed once a year, on the anniversary of the king's demise. It was also the custom to bury alive a certain number, nor exceeding twelve, of his favourite concubines, or young ladies belonging to his court; but Christianity has abolished this inhuman custom, though it has not suppressed the drunken revels that take place on this occasion.

It is considered as a great crime and liable to punishment on conviction to shed tears even for the king. But certain persons are kept in pay to go to all the public places of the city or town, to remind the subjects of his death by the mournful sound of their ivory cornets. The princes and nobles are interred in waincoated vaults hung with black; and two of their old domestics destined alternately to guard the entrance, and to pray for the deceased. Other prayers are to be offered on the anniversary of their decease, and on All-souls day, at which times their graves are opened, and the hangings exchanged for new ones. The giagas dance

about the graves of the deceased in a frantic manner, and bring them victuals, drink, and other conveniences. The dances that are performed at the funeral of their great men last eight whole days, without intermission: and upon these occasions, they never fail sacrificing a number of human victims, the flesh of which they devour with peculiar relish. Mourners of the common class shave their whole heads, and anoint themselves with oil, upon which they rub such a quantity of earth and dust, and dried leaves, as to give them a shocking appearance. Those of higher ranks have only the upper part of their heads and bind it with a list of cloth, linen, or leather, and confine themselves to the house for eight whole days. The Congoese conceive concerning dying persons that they are just passing from a wretched life into a state of tranquillity and happiness; and therefore they think they cannot act a kinder part than to accelerate their deliverance. Among the vulgar this notion leads to the barbarous practice of stopping the mouth and nose of a dying person, and thumping upon the breast with violence, that he may the sooner pass into a state of felicity.

The Congoese have no written laws; but custom and tradition serve them instead of a code and commentaries, unless favour or bribery interpose. Every province has a chief justice for civil and criminal affairs from whom an appeal may be made to the king; and under him are inferior officers in every town and community. Three offences, *viz.* treason, murder, and sorcery, are deemed capital; and the two first are punished with decollation, and the latter by being burned alive. The punishments of lesser offences are the bastonade, hanging, fines, and imprisonment.

The traffic of the Congoese with the Europeans consists chiefly in slaves, and St. Salvadore is the principal mart of the country. The traders who reside in this place bring thither the products of Brasil, such as grain, fruit, plants, and other provisions, and the manufactures of Europe, which are usually Turkey carpets, English cloth, and other stuffs; copper and brass vessels, blue earthen ware, rings, and ornaments of gold, silver, and base metals, coral, glass beads, bugles, and other trinkets; tobacco, wine, brandy, and other spirituous liquors; light stuffs made of cotton, linen, and woollen, for cloathing; and a great variety of tools and utensils. In return they carry off a number of slaves, amounting annually to 15 or 16,000. Slaves indeed are employed at home in all their laborious occupations, and are reckoned the most valuable commodities, which a man possesses or is able to bequeath to his children or relations. Among the Congoese every kind of manufacture is in a very imperfect state. The roads through different parts indicate the inattention and indolence both of the government and the people, as they are either extremely bad in themselves or infested with banditti, and a variety of pernicious animals.

The houses of the Congoese are low, ill-built huts, thatched with straw or fern, without windows and with doors so low, that the shortest man is obliged to stoop when he enters them. They are so slightly built, as to be liable to be blown away by a gust of wind. Those, however, belonging to the Portuguese are built of brick and mortar, and generally well-furnished and adorned. The furniture of the Congoese houses consists chiefly of some few contrived instruments for agriculture, a hatchet to fell timber, a cutlass for travelling or for war, some few calabashes for containing their provisions, a pot, kettle, and ladle, a few earthen platters, and a hand-mill for grinding their corn. Their bed bedding is a large coarse sackcloth, filled with straw or leaves, with a slight covering, and perhaps a log of wood instead of a pillow. But the Portuguese have introduced

roduced among the superior classes, and particularly in the palaces of the princes and viceroys, various articles of luxury.

Polygamy was universally allowed in Congo before the introduction of Christianity; and since that period, the missionaries have in vain endeavoured to persuade the inhabitants to be contented, each of them, with one wife. Previous to marriage the person is allowed three years trial; and when this term is expired, the priest performs the ceremony, and the stipulated dowry is paid. This ceremony is preceded by a sumptuous banquet, and dancing and drinking are continued till the next morning, when the parties retire.

The musical instruments, new used by the Congoese, are such as the Portuguese have introduced; such as the trumpet, cornet, French-horn, and fife; but the common people are contented with their flutes and tabors at their weddings and other rejoicings. They have also stringed instruments, which by their rude construction seem to be natives of the country; such are their "nambi," resembling the Spanish guitar, and the "mambimba," consisting of fifteen or sixteen small calabashes, of different sizes, fastened to a flat board by strings that pass across their mouths, and which, being touched by small pieces of wood, like the sticks of our dulcimers, yield an agreeable variety of sounds. Their drums are made of a long hollow trunk of a tree, with a single skin stretched over one end of it, the other being left open; they are beat either with the fists, or by sticks of heavy wood, and are used at their festivals as well as in the army; they are called "ngambo" or "ingombo," and give but a dull heavy sound, which is raised either by that of the fife, or the "longa," which consists of two or more small bells. The dancing of the Congoese consists in a promiscuous round of men and women, all striving who shall shew the greatest agility and variety of gambols, contortions, and indecent postures.

The history of the foundation of the monarchy of Congo is uncertain and fabulous. It is ascribed to the son of a neighbouring prince, whose small territory was situate on the banks of the Zair, in the province of Corimba. The name of the young prince was Luqueni, who subdued the whole province of "Npemaassii," since called Congo, and extended his conquests from the mouth of the Zair to the city of St. Salvador. His successors, it is said, have maintained themselves on the throne ever since his time. This country was discovered by the Portuguese in the reign of king John II., who employed Diego Cam, a person of enterprise and a famous navigator, in an expedition for making discoveries on the coasts of Ethiopia. Cam, on his arrival near these coasts in the year 1484, fell insensibly upon the rapid stream of the river Zair, as he was endeavouring to double the cape Catalina; and having cast anchor at its mouth, he explored the country situated on its banks, and was well received by the inhabitants, who conducted four or five of his officers to St. Salvador. Before their return, he determined to set sail for Portugal, and took with him four of the natives. King John was so pleased with the account which he received of the country, that he ordered Cam to return with his companions as speedily as possible, and furnished him with valuable presents for the king and his court. He charged him, moreover, to exhort the monarch of Congo, in his name, to become a convert to the worship of the only true God, and to permit the Christian religion to be propagated through his dominions. Cam, in the year 1485, arrived at Congo, and was very favourably received. No time was lost in establishing an alliance between the two crowns of Portugal and Congo, which has continued to

subsist, though often suspended by intervening wars. This alliance was followed by the conversion of the king to the Christian faith. For a further account of the hereditary sovereigns of Congo, too minute in detail to be introduced into our work, and too uninteresting at this remote period for abridgment, we refer to the "Modern Universal History," vol. xvii.

Congo money, or Guinea money, a name given to a peculiar species of *concha venetis*, or porcelain shell, which passes by way of money among the natives of those places. It is distinguished from the other porcelains by having a dentated mouth, and six gibbous protuberances on its surface.

Congo Tea, in Commerce. See Tea.

CONGORLAN, a town of Persia, in the province of Irak; 75 miles N.N.E. of Amadan.

CONGOU, in Geography, a town of Persia, situated on the eastern side of the Persian Gulf. N. lat. 25°. E. long. 52°.

CONGRATULATION, denotes the immediate expression of our joy, on account of any favourable event that has occurred in any of our connections.

CONGREGATION, an assembly of several ecclesiastics, united so as to constitute a body.

The term is principally used for assemblies of cardinals, appointed by the pope, and distributed into several chambers, for the discharge of certain functions and jurisdictions, after the manner of our offices and courts. The decisions of these societies are generally sanctioned by the approbation of the Roman pontif, who has not a right, without alleging the most weighty and evident reasons, to reverse what they pronounce to be just and expedient. This form of ecclesiastical government is, without doubt, a check to the authority of the pope; and hence it is, that many things are transacted at Rome in a manner that is in direct opposition to the sentiments of its spiritual ruler. This may serve to correct a mistaken notion concerning the nature and limits of the papal hierarchy maintained by those, who pretend, that all the iniquitous proceedings of the court of Rome, the calamities it has occasioned, the contentions, rebellions, and tumults it has excited, are to be wholly laid to the charge of the Roman pontif. Hence also arises that important distinction that has been frequently employed by the French and other nations in their debates with the Roman pontif, that is, the distinction between "the pope of Rome," and "the court of Rome." The one is often loaded with the bitterest reproaches and the heaviest accusations, while the other is spared, and in some measure excused. Nor is this distinction by any means groundless; since the cardinals and congregations, whose rights and privileges are held sacred, undertake and execute many projects without the knowledge, and sometimes against the will and consent, of the Roman pontif.

The principal congregations of cardinals are these: 1. "The congregation of the Pope," instituted first by Sixtus V., to prepare the matters that were to be brought before the consistory, at which the pope is always present. Hence this is called the "consistorial congregation," and in it are treated all affairs relative to the creation of bishops and cathedral churches, the reunion or suppression of episcopal sees, the alienation of church goods, and the taxes and annates that are imposed upon all benefices in the pope's gift. The cardinal-dean presides in this assembly. 2. "The congregation of the Inquisition," or, as it is otherwise called, "of the holy office," instituted by Paul III., or, as others say, by Pius IV., and reformed by Pius VI., which takes cognizance of heresies, apostacy, magic, and profane writings.

ings, assembling thrice in the week, and every Thursday in presence of the pope, who presides in it. This congregation consists of at least 12 cardinals, with several other prelates and divines of different orders, who were called confulators of the holy office. The office of grand inquisitor, which encroached upon the prerogatives of the pontif, has been long suppressed, or rather distributed among the cardinals who belong to this congregation, and whose decisions come under the supreme cognizance of his holiness. See *INQUISITION*. 3. "The congregation for the propagation of the Roman Catholic faith," founded under the pontificate of Gregory XV., and composed, (says the translator of Moheim's *Ecl. Hist.*), of 18 cardinals, one of the secretaries of state, a protonotary, a secretary of the inquisition, and other inferior members. (See *COLLEGE de propaganda fide*).

In this congregation are carried on the deliberations which relate to the extirpation of heresy, the appointment of missionaries, &c.; this congregation has built a most beautiful and magnificent palace in one of the most agreeable situations that could be chosen at Rome, where profelytes to popery from foreign countries are lodged and maintained gratis in a manner suitable to their rank and condition, and instructed in those branches of knowledge to which their genius inclines. The prelates, vicars, and curates, who are obliged, without any fault on their own part, to abandon the places of their residence, are entertained charitably in this noble edifice, in a manner corresponding to their rank in the church. 4. "The congregation designed to explain the decisions of the council of Trent." 5. "The congregation of the Index," whose principal business is to examine MSS. and books that are designed for publication, to decide whether the people may be permitted to read them, to correct those books whose errors are not numerous, and which contain useful and salutary truths, to condemn those whose principles are heretical and pernicious, and to grant the peculiar privilege of perusing heretical books to certain persons. This congregation, which is sometimes held in the presence of the pope, but generally in the palace of the cardinal-president, has a more extensive jurisdiction than that of the inquisition, as it not only takes cognizance of those books that contain doctrines contrary to the Roman Catholic faith, but of those also that concern the duties of morality, the discipline of the church, and the interests of society. Its name is derived from the alphabetical tables, or indexes, of heretical books and authors, which have been composed by its appointment. 6. "The congregation for maintaining the rights and immunities of the clergy, and of the knights of Malta." This congregation was formed by Urban VIII., to decide the disputes and remove the difficulties and inconveniences that arose from the trials of ecclesiastics before princes, or other lay judges. 7. "The congregation relating to the Bishops and regular Clergy," instituted by Sixtus V., to decide the debates which arise between the bishops and their diocessans, and to compose the differences that happened so frequently among the Monastic orders. 8. "The congregation," appointed by Gregory XIV., for examining into the capacity and learning of the bishops. 9. "Another," for inquiring into their lives and morals. 10. "A third," for obliging them to reside in their dioceses, or to dispense with that obligation. 11. "The congregation for suppressing monasteries," i. e. such whose revenues are exhausted, and which thereby become a charge upon the public. 12. "The congregation of the Apostolic Visitation," which names the visitors who perform the duties and visitations of the churches and convents within the district of Rome, to which the pope is obliged, as archbishop of that city. 13. "The congregation of Relics,"

designed to examine the marks, and to augment the number of these instruments of superstition. 14. "The congregation of Indulgences," designed to examine the case of those who have recourse to this method of quieting the conscience. 15. "The congregation of Rites," appointed by Sixtus V., to regulate and invent the religious ceremonies that are to be observed in the worship of each new saint that is added to the kalendar. Such are the congregations of cardinals, set apart for administering the spiritual affairs of the church; and they are undoubtedly, in some respects, a check upon the power of the pontif, enormous as it may be. There are six more, which relate to the temporal government of the papal territories. In these congregations, where the pope is never present, all things are transacted which relate to the execution of public justice in civil or criminal matters, the levying of taxes, the providing of good governors for the cities and provinces, the relief of those who are unjustly oppressed by subordinate magistrates, the coinage, the care of the rivers, aqueducts, bridges, roads, churches, and public edifices.

CONGREGATION is also used for a company or society of religious cantoned out of this or that order; and making, as it were, an inferior order, or a subdivision of the order itself. Such are the congregations of the Oratory, and those of Cluny, &c. among the Benedictines.

The word is also used for assemblies of pious persons, in manner of fraternities; frequent among the Jesuits in honour of the Virgin, &c.

CONGREGATION of *Aids*, or *de Auxiliis*, was established in consequence of a dispute between the Dominicans and Jesuits. The former had long cherished a deep rooted and invincible hatred against the latter; and having a favourable opportunity of venting their indignation, exhorted their furious zeal against the doctrine of Molina, notwithstanding the pacific orders of the papal edict, issued by Clement VIII., in the year 1594. They incessantly wearied the Spanish monarch, Philip II., and the Roman pontif, Clement VIII., with their importunate clamours, till at length the latter found himself under a necessity of assembling at Rome a sort of council for the decision of this controversy. Thus commenced, about the year 1598, those famous deliberations concerning the contest of the Jesuits and Dominicans, which were held in the congregation of aids. This congregation was so denominated on account of the principal point in debate, which was the efficacy of the aids and succours of divine grace; and its consultations were directed by Lewis Madruzi, bishop of Trent, and one of the college of cardinals, who sat as president in this assembly, which was composed besides of three bishops and seven divines, chosen out of so many different orders. The history and transactions of this congregation are related and illustrated by several writers of different complexions, by Jesuits, Dominicans, and Jansenists. After all it is still a matter of doubt, which party was most favoured by the court of Rome on this occasion, the Jesuits or the Dominicans, and which of these two parties defended their cause with the greatest dexterity and success.

CONGREGATION of the *Immaculate Conception*. See *IMMACULATE*.

CONGREGATION of the *Lateran*. See *LATERAN*.

CONGREGATION of the *Lord*, in *Ecclesiastical History*, an association of reformers in Scotland, formed in the year 1557 by the earl of Argyle, his son Lord Lorne, the earl of Morton and Glencarne, Erskine of Dun, and others, who, observing the danger to which they were exposed, and desirous of propagating their principles, entered privately into a bond or association; and assumed this appellation

Iation; in contradistinction to the established church, which they denominated the congregation of Satan. Supported by the authority, which, they thought, belonged to them under the denomination they assumed, they ordained that prayer in the vulgar tongue should be used in all the parish-churches of the kingdom; and that preaching, and the interpretation of the Scriptures, should be practised in private houses, till God should move the prince to grant public preaching by faithful and true ministers. This congregation, encouraged by some favourable appearances which occurred, proceeded with alacrity in openly soliciting subscriptions to their league; and the death of Mary of England, with the accession of Elizabeth, which happened about this time, contributed to increase their hopes of ultimate success in their undertaking. They ventured to present a petition to the regent, craving a reformation in the church, and of the wicked, scandalous, and detestable lives of the prelates and ecclesiastics. They also framed a petition, which they intended to present to parliament, in which, after premising that they should not communicate with the damnable idolatry, and intolerable abuses of the papistical church, they desired that the laws against heretics should be executed by the civil magistrate alone, and that the Scripture should be the sole rule in judging of heresy. They even petitioned the convocation, and insisted, that prayers should be said in the vulgar tongue, and that bishops should be chosen with the consent of the gentry of the diocese, and priests with the consent of the parishioners. The regent prudently temporized between these parties; but after some time, she proceeded with greater rigour against the reformers, and the dispute terminated in a civil war. At length the covenant was subscribed by the reformers, who committed themselves to the guidance of John Knox. The consequence was, that the Catholic religion was suppressed, and the presbyterian discipline established. See REFORMATION.

CONGREGATION of *Mission*. See MISSION.

CONGREGATION of *Penitence*. See PENITENCE.

CONGREGATION of *Holy Sacrament*. See SACRAMENT.

CONGREGATION of *Holy Trinity*. See TRINITY.

CONGREGATION, in *Physics*, is used by Dr. Grew for the least and lowest degree of mixture; or that wherein the parts of the mixt do not conflux with, or adhere to, each other, but only touch in one point. That author declares himself of opinion, that the particles of all fluids only touch in this manner; or that their cohesion only amounts to a congregation. See FLUID.

CONGREGATION also denotes an assembly of persons in social and public worship.

CONGREGATIONALISTS. See INDEPENDENTS.

CONGRESS, CONGRESSUS, is used for an assembly of commissioners, deputies, envoys, &c. from several courts or provinces, meeting to settle terms for a general pacification or to concert measures for their common good.

The congress at the Hague, while held during the course of the war, terminated in 1697, by the treaty of Ryfwick, was composed of the envoys of all the princes in the confederacy against France.

CONGRESS, in *Modern History*, denotes that body, in which, by the constitution of the United States of America, all legislative powers are vested. It consists of a senate and house of representatives. The house of representatives is composed of members chosen every second year by the people of the several states; and the electors in each state shall have the qualifications requisite for electors of the

most numerous branch of the state legislature. No person shall be a representative under the age of 25 years, who has not been seven years a citizen of the United States, and who shall not, when elected, be an inhabitant of the state in which he shall be chosen. The number of representatives, apportioned among the several states, which may be included within this union, according to their respective numbers, to be ascertained by actual enumeration within three years after the first meeting of congress, and within every subsequent term of ten years, shall not exceed one for every thirty thousand; but each state shall have at least one representative. In case of vacancy in the representation of any state, writs shall be issued by the executive authority for filling such vacancies. The house of representatives chuse their speaker, and other officers, and have the sole power of impeachment.

The senate of the United States is composed of two senators from each state, chosen by its legislature for six years; and each senator has one vote. The senators are divided into three classes; the seats of those of the first class being vacated at the expiration of the second year; of the second class at the expiration of the fourth year; and of the third class at the expiration of the sixth year; so that one-third may be chosen every second year.

No person shall be a senator, under the age of 30 years; after being nine years a citizen of the United States, and who is not, when elected, an inhabitant of the state for which he is chosen. The vice-president of the United States is president of the Senate, but has no vote, unless the votes be equally divided. The senate chuses its other officers, and also a president pro tempore, in the absence of the vice-president, or when he shall exercise the office of president of the United States. The senate has the sole power to try all impeachments; and no person shall be convicted without the concurrence of two-thirds of the members present.

The congress shall assemble at least once in every year, and such meeting shall be on the first Monday in December, unless they shall, by law, appoint a different day. Each house has its peculiar powers; but neither house, during the session of congress, shall, without the consent of the other, adjourn for more than three days, nor to any other place than that in which the two houses shall be sitting. The senators and representatives shall receive a compensation for their services, ascertainable by law, and payable out of the treasury of the United States. They are, in all cases, except treason, felony, and breach of the peace, privileged from arrest during their attendance at the session of their respective houses, and in going to, and returning from, them; and for any speech or debate in either house, they are not to be questioned in any other place. No senator or representative shall, during the time for which he was elected, be appointed to any civil office under the authority of the United States, which shall have been created, or the emoluments of which shall have been increased, during such time; and no person holding any office under the United States shall be a member of either house, during his continuance in office.

All bills for raising revenue shall originate in the house of representatives; but the senate may propose or concur with amendments, as on other bills. Every bill, which shall have passed the house of representatives, and the senate, shall, before it become a law, be presented to the president of the United States; if he approve, he shall sign it; but if not, he shall return it, with his objections, to that house in which it has originated, who, having entered the objections on their journal, shall proceed to reconsider it. If, after reconsideration, two-thirds of that house shall agree to pass

the bill, it shall be sent, together with the objections, to the other house, by which it shall likewise be reconsidered, and, if approved by two-thirds of that house, it shall become a law. In such case the votes of both houses shall be determined by yeas and nays, and the names of the persons voting for and against the bill shall be entered on the journal of each house, respectively. If any bill shall not be returned by the president within ten days (Sundays excepted) after it has been presented to him, the same shall be a law, as if he had signed it, unless the congress, by their adjournment, prevent its return, in which case it shall not be a law. Every order, resolution, or vote, to which the concurrence of the senate and house of representatives may be necessary, shall be subject to the same rules and limitations as are prescribed in the case of a bill.

By the constitution the congress shall have power—to lay and collect taxes, duties, imposts, and excises—to pay the debts and provide for the common defence and general welfare of the United States—to borrow money on the credit of the United States—to regulate commerce with foreign nations, among the several states, and with the Indian tribes—to establish a uniform rule of naturalization, and uniform laws on the subject of bankruptcies, throughout the United States—to coin money, regulate its value, and that of foreign coin, and to fix the standard of weights and measures—to provide for the punishment of counterfeiting the securities and current coin of the United States—to establish post offices and post-roads—to promote the progress of science and useful arts, by securing for limited times, to authors, and inventors, the exclusive right to their respective writings and discoveries—to constitute tribunals inferior to the supreme court—to define and punish piracies and felonies committed on the high seas, and offences against the law of nations—to declare war, grant letters of marque and reprisal, and make rules concerning captures on land and water—to raise and support armies, but without appropriating money to that use for a longer term than two years—to provide and maintain a navy—to make rules for the government and regulation of the land and naval forces—to provide for calling forth the militia to execute the laws of the Union, suppress insurrections, and repel invasions—to provide for organizing, arming, and disciplining the militia, &c. reserving to the states, respectively, the appointment of the officers, and the authority of training the militia, according to the discipline prescribed by congress—to exercise exclusive legislation, in all cases whatsoever over such district, (not exceeding ten miles square) as may, by cession of particular states, and the acceptance of congress, become the seat of the government of the United States, and to exercise like authority over all places, purchased by consent of the legislature of the state in which the same shall be, for the erection of forts, magazines, arsenals, dock yards, and other needful buildings—and to make all laws which shall be necessary and proper for carrying into execution the foregoing powers, and all other powers vested by this constitution in the government of the United States, or in any department or officer thereof.

The powers of congress, however, are subject to certain limitations; e. g. the privilege of the writ of habeas corpus shall not be suspended, unless the public safety requires it in cases of rebellion or invasion. No bill of attainder, or ex post facto law, shall be passed. No capitation, or other direct tax, shall be levied, unless in proportion to the census, or enumeration, herein before directed to be taken.—No tax or duty shall be laid on articles exported from any state—no preference shall be given by any regulation of commerce or revenue, to the ports of one state over those of another—

nor shall vessels bound to or from one state be obliged to enter, clear, or pay duties, in another—no money shall be drawn from the treasury, but in consequence of appropriations made by law; and a regular statement and account of the receipts and expenditures of all public money shall be published from time to time. No title of nobility shall be granted by the United States; and no person holding any office of profit or trust under them shall, without the consent of the congress, accept of any present, emolument, office, or title, of any kind whatever, from any king, prince, or foreign state. With regard to individual states it is provided, that no state shall enter into any treaty, alliance, or confederation; grant letters of marque and reprisal; coin money; emit bills of credit; make any thing but gold and silver coin a tender in payment of debts; pass any bill of attainder, ex post facto law, or law impairing the obligation of contracts; or grant any title of nobility. Moreover, no state shall, without the consent of the congress, lay any imposts or duties on imports or exports, except what may be absolutely necessary for executing its inspection laws; and the net produce of all duties and imposts, laid by any state on imports or exports, shall be for the use of the treasury of the United States; and all such laws shall be subject to the revision and control of the congress. No state shall, without the consent of congress, lay any duty of tonnage, keep troops or ships of war in time of peace, enter into any agreement or compact with another state, or with a foreign power, or engage in war, unless actually invaded, or in such imminent danger as will not admit of delay. The congress, under certain limitations, whenever two-thirds of both houses shall deem it necessary, may propose amendments to the constitution, established Sept. 17, 1787; or, on the application of the legislature of two-thirds of the several states, shall call a convention for proposing amendments, which, in either case, shall be valid, to all intents and purposes, as part of the constitution, when ratified by the legislatures of three-fourths of the several states, or by conventions in three-fourths thereof, as the one or the other mode of ratification may be proposed by the congress. The senators and representatives before-mentioned, and the members of the several state legislatures, and all executive and judicial officers, both of the United States, and of the several states, shall be bound by oath or affirmation, to support the constitution; but no religious test shall ever be required as a qualification to any office, or public trust, under the United States. The executive power is vested by the constitution in a president of the United States of America. See PRESIDENT.

CONGRESS, in *Law*, is also used for an essay, or trial, made by appointment of a lay, or spiritual judge, in the presence of sergeants and matrons, to prove, whether or no a man be or be not impotent; in order to the dissolution of a marriage. See IMPOTENCY.

Neither the civil nor canon law make any mention of this trial of virility by congress; it had its origin in France, from the boldness of a young fellow, who, in open court, being hard pressed by his wife, demanded the congress. The judge, surprised by the novelty of the demand, found it could not be denied; as being the surest evidence the case could admit of.

In time it became a branch in the French jurisprudence, and was authorized by decrees and arrests: it obtained for about the space of one hundred and twenty years, and was annulled by an arrest of parliament in 1677, as being found precarious; some having failed under the experiment out of mere modesty and shame, which is found to have the same effect with actual impotency.

CONGREVE, WILLIAM, in *Biography*, a celebrated English dramatic writer, descended from an ancient family in Staffordshire, which traces its lineage beyond the Norman conquest. Neither the time nor the place of his birth can be ascertained with any degree of precision; according to the inscription on his monument, it was in the year 1672, and he himself declares that he owed his nativity to England; though by many of his biographers it has been asserted that he was born in Ireland. Wherever he was born, it is known that he was educated, first at Kilkenny, and afterwards at Dublin, his father having found military employment that stationed him in Ireland. After he had passed the usual preparatory studies, he was sent, at the age of sixteen, to study the law in the Middle Temple. For this genius does not appear to have been adapted; he looked, at a very early period of life, to polite literature as that by which he might be distinguished. By a feigned name he published the "Incognita, or Love and Duty reconciled," a novel, which has been characterized as sprightly in dialogue, intricate in plot, and unnatural; and Dr. Johnson says "he would rather praise than read it." As a dramatic writer, Congreve's first piece was the "Old Bachelor," written at the age of twenty, and, according to the author's own account, to amuse himself in a slow recovery from a fit of sickness; but which was regarded by Dryden, and others who were his contemporaries, as a very wonderful performance. Its success was very great; few plays have been so beneficial to the writer, for it procured him the patronage of the earl of Halifax, who was the Mæcenas of the day, and who deserves the praise of having bestowed more public patronage on the muses than they have ever received before, or perhaps since, in this country. Upon Congreve the noble lord bestowed the office of commissioner for licensing coaches; and soon after gave him a place in the pipe-office, and another in the customs of 600*l.* per annum.

If the *Old Bachelor* be nearly examined, says Dr. Johnson, "it will be found to be one of those comedies which may be made by a mind vigorous and acute, and furnished with comic characters by the perusal of other poets, without much actual commerce with mankind. The dialogue is one constant reciprocation of conceits, or clash of wit, in which nothing flows necessarily from the occasion, or is dictated by nature. The characters both of men and women are either fictitious or artificial; and the catastrophe arises from a mistake not very probably produced, by marrying a woman in a mask. Yet this gay comedy, when all these deductions are made, will still remain the work of very powerful and fertile faculties; the dialogue is quick and sparkling, the incidents such as seize the attention, and the wit so exuberant that, it 'o'er-informs its tenement."

Congreve's next play was "The Double Dealer," which was not received with equal kindness by the public, but which was honoured with the patronage of the queen, on whose death he wrote a poetical tribute to her memory; in which, says his biographer, "all is unnatural, and yet nothing is new." In the year 1695, his prolific pen produced "Love for Love," a comedy of nearer alliance to life, and exhibiting more real manners, than either of the former. This proved a very popular and profitable piece: and in the same year he published an irregular ode to king William, on the taking of Namur; which exhibited less of the powers of poetry, than of the spirit of loyalty. With the comedy of *Love for Love*, the new theatre was opened, under the direction of Betterton the tragedian; where, in 1697, was exhibited "The Mourning Bride," a tragedy, so written, as to shew that the author was sufficiently qualified for either kind of dramatic poetry.

About this time began a long and bitter controversy between Jeremy Collier and the poets. In the reign of Charles I., the puritans had raised a violent clamour against the drama, which they regarded as unfit for the encouragement of Christians. This had in a great measure subsided, when, in 1698, Collier published "A Short View of the Immorality and Profaneness of the English Stage;" in which he attacked with great justice, though perhaps with some degree of aggravation, the licentiousness of the dramatic writers, among whom Congreve was included. The poet replied, and endeavoured to palliate the alleged enormity of particular passages, though it was impossible to vindicate the general character and tendency of his pieces. Collier replied, and Congreve retired from the contest; and shortly after published his last comedy of "The Way of the World." This was reckoned the most perfect of his dramatic pieces; but it was received with so little favour on the stage, that, being in a high degree offended and disgusted, he resolved to commit his quiet and his fame no more to the caprices of an audience. From this time his life ceased to the public; he lived for himself and for his friends; and among his friends he was able to name every man of his time whom wit and elegance had raised to reputation.

Congreve continued to write copies of verse upon particular occasions, and in the year 1710, he published a collection of his plays and miscellaneous poems, dedicated to his patron lord Halifax, to whose person and party he remained attached in all fortunes. Such was the respect which Congreve inspired, as well by his private character as his genius, that in the great political change which brought the Tories into power, his places were untouched, and he was allowed to maintain a dignified neutrality, praised and complimented on both sides. On the return of his own friends to power, his emoluments were increased by the secure place of secretary to the island of Jamaica, which raised his public income to full 1200*l.* a year: yet, says Dr. Johnson, his honours were far greater than his profits. Every writer mentioned him with respect; and, among other testimonies to his merit, Steele made him the patron of his "Miscellany," and Pope inscribed to him his translation of the *Iliad*.

Indolence was the result of Congreve's affluence. He not only ceased to make any literary exertions, but seems, with a considerable degree of affectation, to have declined the character of a man of letters; and when he received a visit from Voltaire, the topic of his writings being introduced, Congreve spoke of them as trifles beneath him, and hinted that he expected to be visited only as a gentleman. Voltaire replied, that had Mr. Congreve been so unfortunate as to be a mere gentleman, he should never have been desirous of seeing him.

The latter years of his life were clouded with a considerable portion of sickness and infirmity. Cataracts in his eyes at length terminated in total blindness. The melancholy state was aggravated by the gout, for which he sought relief by a journey to Bath, but, being overturned in his chariot, he returned to his house in London, where he died, Jan. 20, 1728-9, in the sixtieth year of his age. Having lain in state in the Jerusalem chamber, he was buried in Westminster Abbey, where a monument is erected to his memory by the duchess of Marlborough; to whom, for reasons either not known, or not mentioned, he bequeathed a legacy of ten thousand pounds, in preference to the claims of kindred, at that time reduced to difficulties and distress.

It does not appear that any peculiar moral excellencies, or any remarkable talents for social intercourse, obtained for Congreve those marks of attachment and regard which

we have seen that he enjoyed. He lived in an easy independence, and, by the exercise of a polished good nature, pleased and flattered those who associated with him, and never offended any one. He stands first among the English writers of comedy: a distinction for which he is indebted, not to such a lively and humorous delineation of natural characters as delights and instructs in the scenes of Moliere, but to a continuation of wit and repartee in the dialogue, joined with originality of plot. His personages are always strongly marked and well supported. One or two of his comedies are still exhibited, and beheld with pleasure, though so little resembling the productions of the present age. His "Mourning Bride" is interesting, and its principal characters well contrasted; it maintains its place in our theatres, and has, during the present season, been represented with the highest applause. Biogr. Britan. Johnson's Lives of the English Poets.

CONGRIER *en Pouvance*, in *Geography*, a town of France, in the department of the Mayenne; $6\frac{1}{2}$ leagues S.W. of Laval.

CONGRUITY, or CONGRUENCY, in the *Schools*, a suitability or relation of agreement between things; where-by we come at the knowledge of what may be expected from them.

The system of congruity in matters of grace consists in this; that God, who knows perfectly the nature of grace, and the dispositions of the will in all the circumstances that shall befall a man, gives graces, wherewith, by virtue of their congruity with the will of a man, considered in those circumstances, man will always infallibly, but not necessarily, do what God would have him do; because the will, in the language of the congruists, does always infallibly, though voluntarily, choose what appears best.

CONGRUITY, *merit of*. See MERIT.

CONGRUITY, in *Geometry*, is applied to figures, lines, &c. which exactly correspond when laid over one another; as having the same terms, or bounds.

Those things between which there is a congruity are equal and similar.

Euclid, and by his example, most other geometricians, demonstrate all their elements from the sole principle of congruity: M. Leibnitz, and after him Wolfius, substitute the notion of similitude in lieu of that of congruity.

CONGRUITY, in a lax sense, is used to express an aptitude, in some bodies, to unite, or incorporate; by reason of some similitude or fitness of their figures: as incongruity denotes an unfitness of their surfaces for joining together. Thus, quicksilver will unite with gold, and many other metals, but will roll off from wood, stone, glass, &c.; and water, which will wet salt, and dissolve it, will slip off from tallow without adhering to it; as also from a dusty surface, and from the feathers of water fowl.

Two drops of water or of mercury, will, on contact, immediately join and coalesce; but oil of tartar, poured upon quicksilver, and spirit of wine and oil of turpentine on that, and air over all, will remain in the same vessel without any manner of union, or mixture with each other. And the cause of this phenomenon is, that the figures of some bodies will not admit other bodies near enough to be within their spheres of attraction, whence they cannot join and cohere; but where their fitness of figure will let them approach near enough to feel each others' attractive power, then they close and hold together. See COHESION.

CONG-TCHIN, in *Geography*, a town of China, of the third rank, in the province of Quang-si; 20 miles N.E. of Ping-lo.

CONGUSTUS, in *Ancient Geography*, a town of Asia, in Galatia. Ptolemy.

CONHOCTON CREEK, in *Geography*, a creek of America, in the western parts of the state of New York, in the Genesee country, which runs over a bed of gravel at the foot of the hills that surround the newly established post-town, called Bath, and, about 20 miles below this town, falls into Tyoga river. In this creek there is a considerable fall, just above the town, which affords a very fine seat for mills. Extensive saw and flour mills have already been erected upon it; the principal saw in the former of which, gave, when Mr. Weld visited the mill, 120 strokes in a minute, sufficient to cut, in the same interval of time, 7 square feet, superficial measure, of oak timber; and yet capable, when the water is high, of producing effect much more expeditiously. During floods, light bateaux may pass along the creek, Tyoga and Susquehannah rivers, from Bath to Chesapeake bay, without interruption.

CONI, a large fortified town of France, in the department of Stura, which was formerly a part of Piedmont in Italy, belonging to the king of Sardinia. It is situated on the confluence of the Gese and the Stura, 42 miles S. from Turin, 54 N.E. from Nice, and 615, or 820 kilometres, from Paris. As chief place of the department, it has a prefect, a court of justice, and several tax offices, and is the residence of the brigade-general commanding the department. The fertility of the soil of its district, equally abundant in corn and pastures, and the advantage of a canal which goes from the river Stura to the Po, and facilitates its communication with the interior parts of France, render Coni the centre of a considerable commerce. Its inhabitants amount to 16500. The population of the canton, including 16 communes, is 17,275. The whole district comprises 85 communes with 121,433 inhabitants, upon a territorial extent of 2530 kilometres.

Coni is said to have been first founded in 1520, during the pontificate of Calixtus II.; and the following account is given of its origin. The inhabitants of some villages having been grievously oppressed by their lords, who, among other enormities, pretended a privilege granted by the emperor to despoil the brides before the husbands touched them, the people, at length, attacked their lords, expelled them the country, and destroyed their castles, which had served as their protection, and left their oppressors should return with foreign aid, they left their home and founded Coni. Their number daily increasing, they formed an alliance with the city of Asti, and Luchin, duke of Milan, and became a flourishing republic, which form of government continued for some years. At length they submitted to Charles of Anjou, comte of Provence. Some time after his death, they came under Jane, queen of Naples, who was incapable of supporting the weight of government; and therefore the town of Coni, in order to ensure protection, voluntarily submitted to Amadeus VI., comte of Savoy, to whom it afterwards continued faithful. After valiantly defending itself against many successive sieges, for near three centuries, the rapid successes of the French in Piedmont, during the months of April and May in 1796, obliged the king of Sardinia to make overtures for peace, and to surrender Coni, with Alexandria, Sufa, and Tortona, into the hands of the French, as hostages of his good faith; and it afterwards became the principal place of a district, as we have already stated, in one of the six Piedmontese departments, called Stura.

CONIA, in *Botany*, the name of a genus formed by Ventenat, for the powdery byss of Linnæus and other authors.

CONIC SECTIONS.

CONIACI, in *Ancient Geography*, a people of Spain, placed by Strabo near the sources of the Ebrus, in the vicinity of the Cantabri.

CONIC SECTIONS, as the name imports, are such curves as are produced by the mutual intersection of a plane and the surface of a solid cone. The nature and properties of these figures were the subject of an extensive branch of the *Ancient Geometry*, and formed a speculation well suited to the subtle genius of the Greeks. In modern times, the conic geometry is intimately connected with every part of the higher mathematics and natural philosophy. A knowledge of those discoveries, that do the greatest honour to the last and the present centuries, cannot be attained without a familiar acquaintance with the figures that are now to engage our attention.

In this article we shall treat of the cone, and the more general properties of those figures called the conic sections; and we shall conclude with a short historical account of this branch of mathematical learning. The more particular properties of each figure will be delivered under the proper heads in the progress of our work.

We begin with premising a few lemmas, on which the theory of conic sections, we are to deliver, is founded.

LEMMAS.

Definition. If a right line, A B (*Plate II. Conic. fig. 1.*), be fo divided in the points D and E, that AD is to DB as AE is to EB; then that right line is said to be harmonically divided.

Cor. If a right line, A B, be divided in E, then it cannot be cut in D and *d*, so as to be harmonically divided both in E and D, and in E and *d*.

For, if it were possible, it is plain that AD would be to DB as A *d* to *d*B, 11. 5. E: which is absurd, 14. 5. E.

LEMMA I. *Fig. 1.*

If a right line, A B, be bisected in C, and cut in E and D, so that CA or CB is a mean proportional between CE and CD: then A B is harmonically divided in D and E.

For, because CD : CA :: CA : CE
therefore, CD + CA : CD - CA :: CA + CE : CA - CE
that is, A D : D B :: A E : E B.

Cor. If A B be bisected in C, and harmonically divided in D and E, then A C or C B is a mean proportional between C D and C E. *Cor. Def. 1.*

LEMMA II. *Fig. 2.*

If two tangents of a circle be drawn from the same point, A, then any chord of the circle, as E D, which, being produced, passes through A, and cuts the line, B C, that joins the two points of contact, in F, is harmonically divided in the points F and A.

Let O be the centre of the circle, and draw O H perpendicular to E D, and draw O B and O C to the points of contact. Because the angles at B, H, and C, are all right angles, 18. 3. E, the circle described on the diameter A O will pass through A, B, H, O, and C, 31. 3. E: therefore $A F \times F H = B F \times F C = E F \times F D$, 35. 3. E: therefore $A F \times F H + F H^2$, or $A H \times F H = E F \times F D + F H^2 =$ (because E D is bisected in H) $H D^2$, 5. 2. E. Therefore E D is harmonically divided in F and A, *LEM. 1.*

Cor. And if a chord, as E D, which, when produced, passes through A, be harmonically divided in A and F, then F is a point in the chord B C.

For, if not, then the chord, D E, could be harmonically divided at A and F, and also at A, and another point, different from F, which is absurd. *Cor. Def.*

LEMMA III. *Fig. 3 and 4.*

Let C be the centre of a circle, and let D and E be two points in a diameter, A B, and both on the same side of the centre; and let the radius of the circle be a mean proportional between C D and C E: draw M N perpendicular to A B through E; then any chord, as H K, which, being produced if necessary, passes through D, and cuts M N in F, is harmonically divided in D and F.

Draw C L perpendicular to H K from the centre C. Because $C A^2 = C D \times D E$, therefore $C A^2 - C D^2$ (or $C D^2 - C A^2$), or $A D \times D B = E C \times C D - C D^2$ (or $C D^2 - E C \times C D$), or $C D \times D E$. And because the angles at E and L are right angles, therefore $L D \times D F = C D \times D E = A D \times D B = H D \times D K$, 35. 3. E. = (because H K is bisected in L), $L K^2 - D L^2$ (or $D L^2 - L K^2$). Therefore, $L K^2 = D L^2 + L D \times D F$ (or $D L^2 - L D \times D F$) = $D L \times L F$: therefore H K is harmonically divided in D and F. *LEM. 1.*

LEMMA IV. *Fig. 5 and 6.*

The same construction being made as in the last lemma, if H K be a chord, which, when produced if necessary, passes through D; then tangents of the circle drawn from the extremities of H K will meet one another in the line M N. And if tangents of the circle be drawn from a point assumed in M N, the chord drawn through the two points of contact, being produced if necessary, will pass through the point D.

Let H K be a chord passing through D, and let tangents drawn from H and K meet in F: draw C F (cutting H K in L) to the centre of the circle, and join C E and F E. It is manifest that $F C \times C L = C K^2$, 8. 6. E. = $C D \times C E$, hyp. Therefore a circle described through D, F, and L, will pass through E, 36. 3. E; therefore the angle F E D = the angle F L D, 21. 1. E. Therefore F E is perpendicular to A B, and F is a point in M N drawn from E perpendicular to A B.

Next, let F be in M N, and let H K and A B, both produced if necessary, intersect in *d*. Because the angles F L *d* and F E *d* are right angles; therefore $F C \times C L = d C \times C E$, 36. 3. E. But $F C \times C L = C K^2 = C D \times D E$; therefore $d C \times C E = D C \times C E$; therefore the point *d*, in which H K and A B intersect, is the same as the point D.

LEMMA V. *Fig. 7.*

If the base of a triangle, A B, be bisected in D, and C G be drawn parallel to A B through the vertex; then any line, as E F, parallel to C D, and terminated by C B and C A, produced if necessary, is bisected by C G.

Draw B H K parallel to C D. Because A D = D B; therefore A C = C K, 2. 6. E. Therefore B H = H K. And, it is plain that E F, parallel to B K, is likewise bisected.

LEMMA VI. *Fig. 8 and 9.*

If A B, the base of a triangle, be harmonically divided in D and E, and the lines C D and C E be drawn; then any line, as H F, parallel to C E, and terminated by B C and C A, produced if necessary, is bisected by C D.

Draw L K parallel to C E through D.
Because A D : D B :: A E : E B.
Alternando, A D : A E :: D B : E B.
But, on account of equiangular triangles,
A D : A E :: D L : C E, 4. 6. E.
and D B : B E :: D K : C E;
therefore D L : C E :: D K : C E.

Therefore

CONIC SECTIONS.

Therefore $DL = DK$, 9. 5. E. Therefore any line parallel to LK , as FH , is bisected by CD .

Cor. If $H F$ be bisected by CD , and CE be parallel to HF , then $A B$ is harmonically divided in D and E .

For, if not, then $H F$ could be bisected by two lines drawn through C ; which is absurd.

Of the Cone and its Sections.

DEFINITIONS.

Fig. 10. I. Let $A D B$ be a circle, and V a fixed point without the plane of the circle; then, if a right line, passing continually through the point V , be carried round the whole periphery of the circle $A D B$, that right line, being extended indefinitely on the same side of V as the circle, will describe a conic surface; and, if it be likewise extended indefinitely on the other side of V , it will describe two opposite conic surfaces.

Cor. A straight line drawn from the vertex to any point in a conic surface, being produced indefinitely, is wholly in the opposite surfaces.

For a line, so drawn, will coincide with the line that generates the conic surfaces, when this line, by being carried round the circumference of the base, comes to the proposed point.

II. The solid figure, contained by the conic surface and the circle $A D B$, is called a cone. The point V is named the vertex of the cone; the line $V C$, drawn to the centre of the circle, the axis of the cone; and the circle $A D B$, the base of the cone.

III. A right cone is when the axis is perpendicular to the plane of the base; otherwise, it is a scalene, or oblique cone.

IV. A right line that meets a conic surface in one point only, and is every where else without that surface, is called a tangent.

PROP. I. *Fig. 10.*

The common intersection of a conic surface and a plane $V D E$, that passes through the vertex, and cuts the base of the cone, is a rectilinear triangle.

For the common section of the plane of the base, and the plane drawn through the vertex, (which is a right line, 3. 11. E.), will cut the periphery of the base in two points, D and E , and in these two points only; then, having drawn $D V$ and $E V$ to the vertex of the cone, these lines will be both in the conic surface (*Cor. Def. 1.*), and also in the plane surface; and there are no points, excepting in these lines indefinitely produced, which are common to both the surfaces. Therefore the figure $D V E$, which is the common intersection of the cone and a plane through the vertex, is a rectilinear triangle.

PROP. II. *Fig. 11 and 12.*

If two points, D and E , (not in the same right line with the vertex) be assumed in a conic surface, the right line that joins them falls wholly within the conic surface, and when produced both ways it falls wholly without the surface; but if the assumed points be in opposite surfaces, the right line that joins them falls without the conic surfaces, and, when produced, it falls within one conic surface on one side, and within the other conic surface on the other side.

From V , the vertex of the cone, draw the lines $V D$ and $V E$, cutting the periphery of the base in the points B and C ; then, a plane being drawn through the vertex and the points D and E , that plane will cut the base in the chord $B C$, and the common sections of the plane and the conic

surfaces are the two right lines $V B$ and $V C$ indefinitely produced, *Pr. 1.* Now the right line $D E$, which is wholly contained in this plane, can meet the lines $V B$ and $V C$ only in the points D and E . When the points D and E are in the same conic surface, then the line $D E$ is contained in the angle $B V C$ within the conic surface, and, produced both ways, it is contained in the adjacent angles $B V M$ and $C V N$ without the conic surface. On the other hand, when D and E are in opposite surfaces, $D E$ is contained in the angle $B V M$, or $C V N$, without the conic surfaces, and, being produced both ways, it is contained either in the angle $B V C$, or in the angle $M V N$, within the conic surfaces.

Cor. A right line cannot meet a conic surface in more than two points.

PROP. III. *Fig. 11.*

If a point, E , be assumed in a conic surface, and a line, $P Q$, be drawn through it, so as to be parallel to a right line, $V B$, passing through the vertex, and contained in the conic surfaces; then the right line, $P Q$, will not meet either of the opposite surfaces in another point, but it will fall within the surface, in which the assumed point E is, on the one side, and it will be wholly without both surfaces on the other side.

For if a plane be conceived to be drawn through the line $V B$ and the point E , the line $P Q$, parallel to $V B$, will be wholly in that plane, 7. 11. E.; and the common sections of the plane and the conic surfaces will be the line $V B$ and the line $V E C$ drawn through the vertex and the point E , *Pr. 1.* Now the line, $Q P$, does not meet either of the lines $V B$ or $V C$ in another point different from E . Also $Q E$, the part of the line that is contained in the angle $B V C$, is within the cone; and $P E$, the part of it that is contained in the angle $C V N$, is without both the opposite surfaces.

PROP. IV. *Fig. 12.*

If a plane be drawn through the vertex of a cone and a tangent of the conic surface $G H$, it will meet the conic surface only in the line, $V D$, drawn through the vertex of the cone and the point of contact of the tangent.

For, because the point D and the vertex V are common both to the plane surface and to the conic surface, therefore the line $V D$, indefinitely produced, is likewise common to both surfaces. And because $G H$ meets the conic surface only in the point D , and is every where else without the surface, therefore any line (different from $V D$), as $V F$, drawn in one of the conic surfaces, is contained on one side of the plane; and the same line continued in the opposite conic surface, as $V K$, is contained on the other side of the plane.

Cor. 1. Any straight line, drawn in the plane, $V G H$, so as to meet the line $V D$, is a tangent of the conic surfaces.

Cor. 2. No other plane, besides the plane $V G H$, can be drawn so as to touch the conic surfaces in the line $V D$ without cutting them.

For, $R S$ the common section of the plane $V G H$, and the plane of the base, is a tangent to the periphery of the base, *Cor. 1.* And, if there were two such planes, there would likewise be two tangents of a circle drawn through the same point of the periphery, which is absurd.

PROP. V. *Fig. 13.*

If either of two opposite conic surfaces be cut by a plane parallel to the base of the cone, the section is a circle, having its centre in the axis of the cone.

Through

Through V C, the axis of the cone, let two planes be drawn cutting the base in the lines C D and C E, and the plane parallel to the base, in the lines G H and G L, and the conic surfaces in the lines V H D and V L E; then, because the base is parallel to the cutting plane, therefore C D is parallel to G H and C E to G L, 16. 11. E. Therefore, on account of equiangular triangles, 4. 6. E.

$$DC : CV :: HG : GV$$

$$CV : CE :: GV : GL$$

$$\text{Ex æquo } DC : CE :: HG : GL$$

But $DC = CE$, therefore $HG = GL$. And in like manner it may be shewn that any right line, drawn from G to a point in the intersection of the plane, and the conic surface, is equal to G H; therefore the section is a circle.

Cor. If, through a point situated within or without a conic surface, two straight lines, both parallel to the plane of the base of the cone (that is, parallel to straight lines in that plane), be drawn to cut, or touch the conic surface: then the rectangle contained by the two segments (between the point and the conic surface), of one of the lines when it cuts, or the square of its segment when it touches the conic surface, is equal to the rectangle contained by the two segments of the other line when it cuts, or to the square of its segment when it touches the conic surface.

For a plane drawn through the two lines will be parallel to the plane of the base, 15. 16. E; and it will intersect the conic surface in the periphery of a circle: whence the corollary is manifest, 35 and 36. 3. E.

PROP. VI. Fig. 14.

If two diameters of the base of a cone, as A B and C D, intersect one another at right angles, a plane drawn through the vertex of the cone, and one of the diameters, C D, will bisect any straight line, as E F, terminated both ways by one of the conic surfaces, and parallel to the other diameter A B.

Through V and E F draw a plane cutting the conic surface in the lines V G and V K, and the plane of the base in the line G H K; because E F is parallel to A B: therefore G K is parallel both to A B and E F, 16. 11. E; and it is perpendicular to C D; therefore G K is bisected by the diameter C D, 3. 3. E. And, because G K is bisected in H, therefore E F, parallel to G K, is bisected by V H, that is, by the plane drawn through V and C D.

PROP. VII. Fig. 15. Plate III.

If a point, as B, be assumed in the plane of the base of a cone, but without the periphery of the base, and, from that point, two tangents, B P and B Q, be drawn to the base, and likewise a straight line, B V, to the vertex of the cone: then any straight line, as E F, parallel to B V, and terminated both ways by one of the conic surfaces, is bisected by a plane drawn through V, the vertex of the cone, and cutting the plane of the base in the chord P Q.

Because B V and E F are parallel to one another, therefore they are in one plane, 7. 11. E: let the plane, drawn through B V and E F, cut the conic surface in the lines V E G, and V F K; and let the same plane cut the plane of the base in the line B G K, and the plane passing through V, and the chord P Q in the line V D H. Because G K is harmonically divided in H and B, Lem. 2. therefore E F, parallel to B V, is bisected by the line V H, Lem. 6. But D, the point where V H cuts E F, is the point where the plane drawn through V and the chord P Q cuts E F: therefore E F, parallel to B V, is bisected by that plane.

PROP. VIII. Fig. 16.

Let a plane, passing through the vertex of a cone, cut the plane of the base in a diameter of the base C D: and let A B, a diameter of the base, be perpendicular to C D; and let M N be drawn through the vertex of the cone parallel to A B: then if a right line G K, in the plane C V D, and terminated by one of the conic surfaces, be bisected by a plane passing through M N, this plane will bisect all right lines terminated by one of the conic surfaces and parallel to G K.

Let the plane which bisects G K cut the plane of the base in the line P Q, and the plane C V D in the line V H O: through V draw V L parallel to G K, and let it meet C D produced in L. Because M N is parallel to A B; therefore P Q (the common section of two planes drawn through M N and A B) is parallel to M N and to A B, 16. 11. E: therefore P Q is perpendicular to C D. Because G K is bisected by V O, and is parallel to V L; therefore C D, the base of the triangle C V D, is harmonically divided in L, and O, Cor. Lem. 6. consequently, if two tangents of the base be drawn from L, the chord that joins the points of contact of these tangents will pass through O, Cor. Lem. 2; and it will be perpendicular to the diameter C D: therefore that chord will coincide with the line P Q, which is the only line that can be drawn through O perpendicular to C D. Therefore all right lines, terminated by one of the conic surfaces, and parallel to V L or G K, are bisected by the plane V P Q drawn through M N to bisect G K, Pr. 7.

If G K be parallel to C D, then C D will be bisected in O, and P Q will coincide with A B; so that this proposition, in this case of it, is the same as Prop. 6.

Cor. If a plane be drawn through M N to bisect any one right line terminated by one of the conic surfaces, and parallel to a line G K in the plane V C D, the same plane will bisect all right lines terminated by one of the conic surfaces and parallel to G K.

For, if not, then the same straight line could be bisected by two planes both passing through M N, which is absurd.

PROP. IX. Fig. 17.

Let a plane, passing through the vertex of a cone, cut the plane of the base in a line C D, not passing through E the centre of the base: draw the diameter, A F B, perpendicular to C D, and produce it to M; so that E M may be a third proportional to E F and E B the radius of the base of the cone, and draw M V N through the vertex: then if a right line G K, in the plane C V D, and terminated by one of the conic surfaces, be bisected by a plane passing through M N, this plane will bisect all right lines terminated by one of the conic surfaces and parallel to G K.

Let the plane which bisects G K cut the plane of the base in the line P Q M, and the plane C V D in the line V H O: through V draw V I, parallel to G K, and let it cut C D produced in L. Because V O bisects G K, and V I is parallel to G K, therefore C D, the base of the triangle C V D, is harmonically divided in O and L, Cor. Lem. 6; therefore if two tangents of the base be drawn from L, the chord that joins the points of contact of these tangents will pass through the point O, Cor. Lem. 2; but the same chord, being produced, likewise passes through the point M, Lem. 4: therefore that chord will coincide with P Q, which is the only right line that can pass through both the points O and M, therefore all right lines terminated by one of the conic surfaces and parallel to V I, or G K, are bisected by the plane V P Q drawn through M N to bisect G K, Pr. 7.

Cor.

Cor. If a plane be drawn through MN to bisect any one right line, terminated by a conic surface, and parallel to a line GK, in the plane VCD, or parallel to the plane VCD, that plane will bisect all right lines terminated by a conic surface, and parallel to GK.

For, if not, then the same right line could be bisected by two planes, both passing through MN; which is absurd.

PROP. X. *Fig.* 18.

Let a plane, passing through the vertex of a cone, cut the plane of the base in a line CD, which neither cuts nor touches the periphery of the base: draw ABF, through E, the centre of the base, perpendicular to CD, and take EM, a third proportional to EF, and the radius of the base of the cone; and draw MV through the vertex: then if a right line GK, parallel to the plane CVD, and terminated by one of the conic surfaces, be bisected by a plane passing through MV, this plane will bisect all right lines terminated by one of the conic surfaces, and parallel to GK. But the point H, in which the plane, that bisects GK, cuts GK, must not be in the same right line with the point M, and the vertex of the cone.

Let the plane which bisects GK, cut the plane of the base in the line PQ, draw VL parallel to GK; and because GK is parallel to the plane CVD, therefore VL parallel to GK, is in the plane CVD, and it will cut the plane of the base in L, a point of the line CD. And, because GK is parallel to VL, therefore they are contained in one plane, 7. 11. E. Let this plane be drawn, and let it cut the conic surface in VR and VS, the plane of the base in LRS, and the plane VPO, in VO. Because GK is parallel to VL, and it is bisected by VO, therefore SR, the base of the triangle SVR, is harmonically divided in O and L, *Cor. Lem.* 6.; therefore, if two tangents of the base be drawn from L, the chord that joins the points of these tangents will pass through the point O, *Cor. Lem.* 2.; but, because L is a point in CD, the same chord will pass through M, *Lem.* 4.; and, because the point O does not fall upon M, therefore the chord will coincide with PQ, which is the only line that can pass both through O and M. Therefore, all right lines, terminated both ways by one of the conic surfaces, and parallel to VL, or GK, are bisected by the plane, VPQ, *Pr.* 7.

PROP. XI. *Fig.* 19.

Let a plane touching a conic surface cut the plane of the base in a line, CD, which touches the periphery of the base in P; then, if a right line, GK, terminated by one of the conic surfaces, and parallel to the touching plane, VCD, be bisected by a plane drawn through V; this plane will bisect all right lines parallel to GK, and terminated by one of the conic surfaces.

Through V draw VL parallel to GK: because GK is parallel to the plane VCD, therefore, VL, parallel to GK, is in the plane VCD, and it will cut the plane of the base in L, a point in CD. And, because VL is parallel to GK, therefore they are contained in one plane, 7. 11. E.; let this plane be drawn, and let it cut the conic surface in the lines VM and VN, the plane of the base in the line LMN, and the plane VQP, in the line VO. Because GK is parallel to VL, and it is bisected by VO, therefore, MN, the base of the triangle VMN, is harmonically divided in O and L, *Cor. Lem.* 6. Therefore, if two tangents of the base be drawn from L, the chord that joins the two points of contact of these tangents will pass through the point O, *Cor. Lem.* 2.; but the same chord likewise passes through Q, which is one of the points of

contact of tangents drawn from L; therefore, the chord coincides with the line QP. Therefore the plane VQP, bisects all right lines terminated by one of the conic surfaces, and parallel to VL, or GK, *Pr.* 7.

Fig. 20. 1st. 22, 23. If a cone be cut by a plane PQ, which neither passes through the vertex, nor is parallel to the base, then, a plane, as VMN, being drawn through the vertex parallel to the cutting plane, it will necessarily meet the plane of the base of the cone. The line of common section of the parallel plane, and the base of the cone MN, may have one or other of three different positions; viz.

Fig. 20. 1st. It may be without the base of the cone.

Fig. 21. 2dly. It may touch the periphery of the base of the cone.

Fig. 22. and 23. 3dly. It may cut the periphery of the base of the cone.

These three different cases offer three sections for our consideration that are very different from one another, and possess many properties that are peculiar to each, while they have many that are common to all the three.

Def. V. If the line of common section, MN, (*fig.* 20.), be without the base of the cone, then the plane VMN, drawn through the vertex, will be entirely between the two conic surfaces, not meeting either of them. In this case, the cutting plane PQ, will meet every line drawn from the vertex in one of the conic surfaces, and the curve line of common section will surround that conic surface, and will completely enclose a space. In this position of the cutting plane, the conic section is called an ellipse.

Def. VI. If the line of common section MN, (*fig.* 21.) touch the periphery of the base, then the plane drawn through the vertex will touch the conic surfaces, *Pr.* 4. And the opposite surfaces will be on different sides of it. In this case also the cutting plane will meet every line drawn from the vertex in one of the conic surfaces, excepting only the line of contact, VB, in which the touching plane meets that conic surface: and as the cutting plane is indefinitely extended along the touching plane without meeting it, it is obvious that the curve line formed by the common section of the cutting plane and the conic surface does not return into itself so as to enclose a space, but it is open on the side opposite to the vertex of the cone. In this position of the cutting plane, the conic section is called a parabola.

Def. VII. If the line of common section MN (*fig.* 22 & 23.) cut the periphery of the base, then the plane drawn through the vertex will divide each of the opposite conic surfaces into two parts lying on opposite sides of it. In this case the cutting plane being indefinitely extended will meet every line drawn from the vertex in those parts of the two conic surfaces that lie on the same side of the plane, through the vertex, as the cutting plane itself; and thus two curve lines will be formed by the common intersection, of the cutting plane, and the two opposite conic surfaces. It is obvious that these curve lines may be indefinitely extended, and that they do not return into themselves so as to enclose a space. In this position of the cutting plane the conic section, formed by its intersection with one of the conic surfaces is called a hyperbola; and the two conic sections formed by its intersections with the two opposite conic surfaces, are called opposite hyperbolas, or opposite sections.

Def. VIII. The nature of the several conic sections defined in the three last definitions depends entirely, as we have seen, on the relative position that the line of common section of the plane of the base and the plane drawn through the vertex parallel to the cutting plane, has in respect to the cir-

CONIC SECTIONS.

cle that forms the base of the cone. As there will be frequent occasion to refer to this line, in the following theory of the conic sections, it will be requisite, for the sake of abridging language, to distinguish it by a peculiar name. For this purpose we shall call it the *determining line*.

Def. IX. Let a plane, as PQ , (*fig. 20* and *22*.) cut a conic surface, or opposite surfaces; and let MN be the *determining line*, or the common section, of the plane of the base and the plane drawn through the vertex parallel to the plane PQ ; from C , the centre of the base of the cone, draw CD perpendicular to MN , and take CE a third proportional to CD and CA or CB , the radius of the base: then, a line being drawn from the vertex V to the point E , it will meet the plane PQ in a point G , which is called the centre of the conic section, or opposite sections, formed by the common intersection of the plane PQ , and the conic surface, or opposite surfaces.

But, if the *determining line* MN (*fig. 23*.) cut the base of the cone, and pass through its centre, then, the diameter AB being perpendicular to MN , and VG being drawn through the vertex parallel to AB ; VG will meet the plane PQ in a point G , which, in this case, is the centre of the opposite sections.

Fig. 20, 22, 23. Cor. 1. The centre of an ellipse is a point within the figure; but the centre of two opposite hyperbolas is a point without both hyperbolas, and situated between them.

For, when the line MN is without the base of the cone, the point E and the line VE are within the conic surface; but, when MN cuts the base, then E and VE are without both of the two conic surfaces and between them.

Cor. 2. A parabola has no centre.

Fig. 21. For, in this case, the points E and D coincide with the point B , where MN touches the periphery of the base; and the line VE coincides with the line VB which does not meet the cutting plane PQ .

Cor. 3. The centre of a conic section is never in the axis of the cone, unless when the cutting plane is parallel to the base of the cone.

Def. X. A right line drawn in the plane of a conic section so as to meet the curve of the section in one point only, and which, being produced both ways, is contained on one and the same side of the section, is called a tangent of the section.

Cor. 1. A tangent of a conic section is a tangent of the conic surface.

For it can meet the conic surface only in the point in which it meets the section.

Cor. 2. There cannot be more than one tangent of a conic section at the same point of the curve.

For if there were two tangents, then two planes drawn through them and the vertex of the cone would meet the conic surface in the same right line without cutting the conic surface, which is absurd. *Cor. 2. Pr. 4*

PROP. XII.

A right line, drawn in the plane of a conic section, cannot meet the curve in more than two points.

For such a line does not meet the conic surface in more than two points. *Cor. 2.*

PROP. XIII.

A right line drawn through a point in a conic section, in the same plane with it, and parallel to a line drawn from the vertex in the conic surface, does not meet the curve of the conic section again in another point.

For it does not meet the conic surface in another point, Vol. IX.

Pr. 3. Thus, in the parabola, if PQ be drawn parallel to VB , (*fig. 21*.), then PQ meets the curve only in the point P .

PROP. XIV. *Fig. 24, 25, and 26. Plate IV.*

Every straight line, as FH , drawn through G , the centre of an ellipse, or opposite hyperbolas, and terminated both ways by the curve, or opposite curves, is bisected in the centre.

I. When the *determining line* MN , (*fig. 24* and *25*), does not pass through the centre of the base. Through V , the vertex of the cone, and the line FH , draw a plane cutting the conic surface in the lines VHL and VFK , and the plane of the base in the line LKM , and the plane VMN in the line VM . Because the point G is in the line VE ; therefore, the line LKM will pass through the point E . And because FH and VM are the common sections of the plane VKL , and two parallel planes (*viz.* the plane of the section and the plane VMN), therefore FH is parallel to VM , *16. 11. E.* And, because CB or CA , the radius of the base of the cone, is a mean proportional between CD and CE , and MN is perpendicular to AB ; therefore, the chord KL is harmonically divided in E and M , *LEM. 3.* And because LK is the base of the triangle KVL , and FH is parallel to VM , therefore, FH is bisected by VE , *LEM. 6.*: that is, $FG = GH$.

In the ellipse, when FH (*fig. 20*.) is parallel to MN , it will be perpendicular to a diameter of the base drawn perpendicular to the diameter AB ; therefore, it is bisected by the plane VAB , which cuts it in G , *Pr. 6.*

II. When the *determining line*, (*fig. 26*.) pass through the centre of the base. In this case, VG is parallel to the diameter AB . *Def. IX.* And LK , the common section of the plane of the base, and the plane VQK (drawn through V , and the line FGH), is parallel both to AB and to VG , *7. 11. E.* But the diameter MN is perpendicular to the diameter AB ; therefore, it is also perpendicular to LK , and it bisects LK , *3. 3. E.* And because FH and VM are the common sections of two parallel planes (*viz.* the plane of the conic section, and the plane VMN), therefore FH is parallel to VM . And because VM bisects the base of the triangle KVL , and VG is parallel to that base, therefore VG bisects FH parallel to VM . *LEM. 5.*

DEFINITIONS.

XI. A straight line drawn through the centre of an ellipse, or opposite hyperbolas, and terminated both ways by the curve or opposite curves, is called a diameter of the ellipse, and a transverse diameter of the opposite hyperbolas.

XII. A straight line in the plane of a parabola, as PQ , (*fig. 21*.) drawn parallel to the right line VB , in the conic surface (which passes through the vertex of the cone, and the point in which the *determining line* touches the periphery of the base), is called a diameter of the parabola.

Cor. All the diameters of a parabola are parallel to one another.

XIII. A vertex of a diameter is a point where the diameter meets the curve of the conic section.

Cor. A diameter of a parabola has only one vertex, Pr. 13.

XIV. A straight line (which is not a diameter of an ellipse), terminated both ways by the curve of a conic section, and bisected by a diameter of the section, is said to be ordinately applied to that diameter; or it is called a double ordinate;

CONIC SECTIONS.

ordinate; and the half of it, an ordinate of the diameter.

PROP. XV. *Fig.* 24, 25, and 26.

If a straight line be ordinately applied to a diameter of an ellipse, or a parabola, or to a transverse diameter of a hyperbola, then all right lines parallel to it and terminated both ways by the same curve, or by the opposite curve, are ordinately applied to the same diameter.

Let RST (*fig.* 24 and 25.) be ordinately applied to FH, a diameter of an ellipse or a parabola, or a transverse diameter of a hyperbola or opposite hyperbolas: then all other right lines, as PQ, parallel to RT, and terminated by the same curve, or the opposite curve, are ordinately applied to the same diameter FH. Draw a plane through V, the vertex of the cone, and the diameter FH. Then, in the case of the ellipse and hyperbola, when the *determining line* does not pass through the centre of the base, this plane will necessarily pass through the line VE. And, because the plane of the conic section is parallel to the plane VMN, therefore RT, in the former plane, is parallel to the latter plane. And because the plane drawn through V, and the diameter FH, passes through VE, and bisects RT, which it cuts in S, a point not in the same right line with V and E; therefore, the same plane will bisect all right lines in either of the opposite cones that are parallel to RT. *Pr.* 10. and *Cor.* 9. Therefore, the diameter FH in that plane will bisect all the right lines which it meets, that are parallel to RT, and terminated by the section, or either of the opposite sections.

And, when the *determining line* passes through the centre of the base (*fig.* 26), then, as before, RT is parallel to the plane VMN. And the diameter AB is perpendicular to the diameter MN, and GV is parallel to AB, *Def.* IX; therefore, the plane drawn through VG and FH, which bisects RT, will bisect all right lines in either of the opposite cones that are parallel to RT, *Pr.* 8. Therefore, FH in that plane will bisect all the right lines which it meets that are parallel to RT, and terminated by either of the opposite hyperbolas.

In the parabola, because the plane of the section is parallel to the plane VMN; therefore, RT, (*fig.* 27.) in the former plane, is parallel to the latter plane. And because VB is parallel to FH, therefore a plane may be drawn through them both; let this plane be drawn, and it will bisect all right lines in either of the opposite cones that are parallel to RT, *Pr.* 11. Therefore, FH, in that plane, will bisect all the right lines which it meets, that are parallel to RT, and terminated by the curve of the parabola.

PROP. XVI. *Fig.* 28.

A right line, drawn from a vertex of a diameter of an ellipse, or a parabola, or from the vertex of a transverse diameter of a hyperbola, so as to be parallel to a line ordinately applied to that diameter, is a tangent of the curve.

Fig. 28. Let FH be a diameter of an ellipse or a parabola, or a transverse diameter of a hyperbola, and RST, a line ordinately applied to that diameter; then FM, drawn from a vertex of the diameter, so as to be parallel to RT, is a tangent of the curve. For, if FM be not a tangent, it will cut the section again in another point (*Cor.* 2. *Def.* X), let it cut the section again in K, and bisect FK in I. Then, if a diameter of the section be drawn through I, FK will be ordinately applied to that diameter, *Def.* XIV; therefore that diameter would bisect RT parallel to FK, *Pr.* 15. Therefore RT would be bisected by two different diameters; *viz.* by the diameter FH, and by that

drawn through I. But, in the ellipse and hyperbola, all the diameters pass through the centre; and, in the parabola, they are all parallel to one another; therefore two diameters of a conic section will cut every straight line (which does not pass through the centre of the ellipse and hyperbola) in two different points. Therefore RT cannot be bisected by two different diameters. Therefore FM, parallel to RT, does not cut the curve again; that is, FM is a tangent of the conic section.

Cor. 1. If RT be ordinately applied to the diameter FH, it is parallel to a tangent, FM, at a vertex of that diameter.

For there cannot be two tangents of a conic section at the same point of the curve.

Cor. 2. All right lines ordinately applied to the same diameter of a conic section are parallel to one another.

For they are all parallel to a tangent at a vertex of that diameter.

PROP. XVII. *Fig.* 24 and 27.

A diameter of a conic section being given, to draw a right line that shall be ordinately applied to that diameter.

Fig. 24. Let FH be a diameter of an ellipse; draw a plane through the vertex V, and the diameter FH, cutting the plane of the base in the chord KL, which necessarily passes through the point E; draw tangents of the base from K and L, and let them intersect in O. Then O is a point in the *determining line* MN; *LEM.* 4; and VO being drawn to the vertex of the cone, it is in the plane VMN, and parallel to the plane of the ellipse. Now, all straight lines, as PQ and RT, in the plane of the ellipse, drawn parallel to VO, are ordinately applied to the diameter FH; for these lines are all bisected by the plane VKL, that is, by FH in that plane, *Pr.* 7.

The construction is exactly the same for the hyperbola.

Fig. 27. In the parabola the plane drawn through the diameter FH, passes through VB, parallel to FH, and it cuts the plane of the base in a chord BK, drawn from the point where the *determining line* MN, touches the periphery of the base; in this case draw KO, a tangent of the base, intersecting MN in O; then, as before, VO, drawn to the vertex, is parallel to the plane of the parabola; and all right lines, as RT, PQ, in that plane, parallel to VO, are ordinately applied to the diameter FH, *Pr.* 7.

Fig. 20, 21, 22, and 23. In all the conic sections, when the plane drawn through the vertex of the cone, and a diameter PQ, cuts the plane of the base in a diameter of the base AB; then all right lines, as RT, in the plane of the section, drawn parallel to the *determining line* MN, are ordinately applied to the diameter PQ. For, if a diameter of the base be drawn parallel to MN, that diameter will be parallel to RT, and perpendicular to the diameter AB; therefore RT is bisected by the plane VAB, that is, by PQ, the diameter of the section in that plane, *Pr.* 6.

PROP. XVIII.

Tangents drawn from the vertices, of a diameter of an ellipse, or of a transverse diameter of a hyperbola, are parallel to one another; but tangents of a conic section, drawn from the vertices of two different diameters, are not parallel.

Let a right line be ordinately applied, to a diameter of an ellipse, or to a transverse diameter of a hyperbola, *Pr.* 17; then the tangent of the curve at either vertex of the diameter is parallel to that right line; consequently, the two tangents at the extremities of the diameter are parallel to one another.

CONIC SECTIONS.

And because a right line ordinarily applied to one diameter of a conic section is not ordinarily applied to another diameter; therefore a tangent at a vertex of one diameter is not parallel to a tangent at a vertex of another diameter.

Cor. If there be two parallel tangents of an ellipse, or of opposite hyperbolas; these tangents are drawn from the extremities of a diameter of the ellipse, or of a transverse diameter of the hyperbolas.

PROP. XIX. Fig. 28.

A straight line terminated both ways by the curve of a conic section, and parallel to a tangent, is ordinarily applied to the diameter drawn through the point of contact.

Let RT , terminated by the curve of a conic section, be parallel to a tangent of the curve FM ; then RT is ordinarily applied to the diameter FH , drawn through the point of contact. Draw PQ ordinarily applied to FH , *Pr.* 17. Then PQ is parallel to the tangent FM , *Cor.* 1, *Pr.* 16; therefore PQ is also parallel to RT . Consequently, RT is ordinarily applied to FH , *Pr.* 15.

PROP. XX. Fig. 29.

A straight line GT , drawn from the centre of opposite hyperbolas so as to be parallel to FO and HI lines touching the curves at the vertices of a transverse diameter FH , bisects all lines, as RS , terminated by the opposite hyperbolas and parallel to the transverse diameter: and if a transverse diameter, FH , be drawn parallel to a straight line, as RS , terminated by opposite hyperbolas, and bisected by a line GT drawn through the centre, this line is parallel to FO and HI the tangents at the vertices of the transverse diameter.

Draw the diameter RP , join S , P , and produce FH to cut SP in Q . Because RS is parallel to FH , and $RG = GP$; therefore $SQ = QP$: therefore SP is parallel to HI or FO , *Cor.* 1, *Pr.* 16. But GT is parallel to FO or HI : therefore GT is parallel to SP . Therefore it is manifest that GT bisects RS , 2. 6. E.

Again, if GT bisect RS , then is GT parallel to HI or FO ; for, because $RT = TS$, and $RG = GP$, therefore GT is parallel to SP , 2. 6. E. And because FH is parallel to RS , therefore $SQ = QP$, 2. 6. E.: therefore SP is parallel to HI , *Cor.* 1, *Pr.* 16. Therefore GT is parallel to HI or FO .

Def. XV. Let the determining line MN (*fig.* 30.) of two opposite hyperbolas cut the periphery of the base of the cone in M and N , and let tangents of the base be drawn from these points (which tangents will pass through the point E when MN does not pass through the centre of the base of the cone, *LEM.* 4; but they will both be parallel to the diameter AB and to the line VG , when MN does pass through the centre): through the line VG , and the two tangents PM and QN , let two planes be drawn cutting the plane of the hyperbolas in the lines GP and GQ , intersecting in the centre of the hyperbolas: then these lines are called asymptotes of the hyperbolas.

Cor. 1. The asymptotes do not meet the hyperbolas.

For the planes VPM and VQN meet the conic surfaces only in the lines VM and VN produced, *Pr.* 4.: therefore the lines GP and GQ , in those planes, are without the conic surfaces in which the hyperbolas are.

Cor. 2. The asymptotes GP and GQ are parallel to VM and VN , the lines in which the planes VMP and VNQ touch the conic surfaces.

For the plane VMP cuts the plane of the hyperbolas and the plane VMN (which are parallel planes) in the

lines GP and VM ; and the plane VNQ cuts the same planes in the lines GQ and VN .

Cor. 3. If a line be drawn parallel to one of the asymptotes through a point in one of the hyperbolas, that line does not meet the same hyperbola, nor the opposite one, again in another point.

For a line parallel to one of the asymptotes is parallel to one of the lines VM and VN in the conic surface; therefore it does not meet either of the conic surfaces again in another point, *Pr.* 3.

Cor. 4. A straight line in the plane of the hyperbolas, as FH , drawn through the centre of the hyperbolas within the angle contained by the asymptotes, will meet both the hyperbolas.

Because the asymptotes are parallel to VM and VN , therefore, if VO be drawn parallel to FH , it will be within the angle MVN ; and it is plain that FH , parallel to VO , meets both the conic surfaces.

LEMMA VII. Fig. 31.

Let AB and AC be two right lines that meet one another: then if BC , drawn through D , and terminated by AB and AC , be bisected in D , no other straight line, terminated by AB and AC , and drawn through D , will be bisected in that point.

Draw GH through D , and DE parallel to AC ; because $BD = DC$, therefore $AE = EB$, 2. 6. E. Therefore AE and EG are not equal to one another: and, consequently, GD and DH are not equal.

PROP. XXI. Fig. 30.

If a straight line, terminated by the asymptotes, as KL or ST , touch either of the hyperbolas, it is bisected in the point of contact: and if the middle point of a straight line, as KL or ST , terminated by the asymptotes be in either of the hyperbolas, that line is a tangent of the curve. Draw the diameter FH and let ab be ordinarily applied to it, *Pr.* 17: also draw de , between MV and VN , parallel to ab . Conceive a plane to be drawn through VG and FH , and let this plane cut the plane MVN in the line VO . It is manifest that VO is parallel to the diameter FH , 16. 11. E. And because a plane drawn through VG bisects ab , the same plane will bisect all right lines in either of the opposite cones that are parallel to ab , *Cor.* 9; therefore it will bisect de ; that is, $do = oe$. Because KL is a tangent, it is parallel to ab , *Cor.* 1, *Pr.* 16, and, consequently, to de . And because the asymptotes are parallel to VM and VN , *Cor.* 2. *Def.* XV., and FH is parallel to VO , and de to KL , it is plain that KL and de are similarly divided in H and O : therefore $KH = HL$.

Again, if KL meets the hyperbola in H , and is bisected there, it is a tangent. For, if not, then, a line being drawn between the asymptotes to touch the hyperbola in H , it would likewise be bisected in H as has already been shewn: which is absurd. *LEM.* 7. Therefore KL is a tangent.

PROP. XXII. Fig. 32. Plate V.

If a right line, that cuts an hyperbola or opposite hyperbolas, likewise cuts both the asymptotes; the segments between the hyperbola, or hyperbolas, and the asymptotes, will be equal.

Let the right line DE cut an hyperbola in S and P , and the asymptotes in D and E : draw the transverse diameter FH to bisect SP , and let KL be drawn to touch the hyperbola in H : because FH bisects SP , therefore SP is parallel to the tangent KL , *Cor.* 1, *Pr.* 16, but KL is bisected

in H, *Pr.* 21.; therefore D E, parallel to K L, is bisected in Q; and because D E and S P are both bisected in Q, therefore D S and S E are respectively equal to S P and P D.

Next let S R cut the two opposite hyperbolas in S and R; and the asymptotes in N and I: draw G T through the centre to bisect S R; and draw the transverse diameter F H parallel to S R; and let K L touch one of the hyperbolas at H, and draw K M parallel to S R: because G T bisects S R parallel to F H, therefore G T is parallel to K L, *Pr.* 20: because K M and F H are both parallel to S R, therefore they are parallel to one another: but K L is bisected at H, *Pr.* 21, therefore L M is bisected at G, and K M is bisected at O, 2. 6. E; therefore N I, parallel to K M, is bisected at T. And, because S R and N I are both bisected at T, therefore the segments S N and N R are respectively equal to the segments R I and I S.

PROP. XXIII. *Fig.* 32.

The curve of an hyperbola approaches the nearer to the asymptote the farther it is continued; and, if continued far enough, the distance of the curve from the asymptote will become less than any assigned distance how small soever.

Assume any point, as A in the hyperbola, and draw A X parallel to the asymptote G C; then A X does not meet the hyperbola again, *Cor.* 3. *Def.* XV: through A draw any line B C to a point, as Z, in the curve, and let B C meet the asymptotes in B and C, and draw B X perpendicular to A X, and Z Y perpendicular to the asymptote G C: because A B = Z C, *Pr.* 21, it is plain that B X = Z Y: now the more distant the point Z is, the nearer is the line A B to the line A X, and the less is B X, or Z Y the distance of the curve from the asymptote. And because A B may be drawn so as to make B X less than any assigned line, therefore a point of the curve may be found that shall be nearer to the asymptote than any assigned distance.

DEFINITIONS.

Fig. 30. *Plate* IV. XVI. If a straight line be drawn through the centre of opposite hyperbolas parallel to the tangents S T and K L at the vertices of a transverse diameter F H, and a part of that line bisected in the centre, as I R, be taken equal to the segments S T and K L (it is plain that S T = K L) of the tangents terminated by the asymptotes; then I R is called a second diameter of the hyperbolas, and the extremities of it are called the vertices of the second diameter.

But the word diameter is often used to signify a straight line drawn through the centre of an ellipse or opposite hyperbolas, without regard to the magnitude of such line.

XVII. A straight line, terminated by two opposite hyperbolas and bisected by a second diameter, is said to be ordinately applied to that diameter; or it is called a double ordinate, and the half of it, an ordinate.

XVIII. Two diameters of an ellipse, or of opposite hyperbolas, that are mutually parallel to the ordinates of one another, are called conjugate diameters, or they are said to be conjugate to one another.

PROP. XXIV.

If a diameter of an ellipse, or of opposite hyperbolas, be parallel to the ordinates of another diameter, these two are conjugate diameters.

The demonstration of this proposition, in the case of the hyperbola, is manifest from *Prop.* 20th; for the ordinates

of a transverse diameter of a hyperbola are parallel to a tangent at a vertex of the diameter, *Cor.* 1. *Pr.* 16.

Fig. 33. *Plate* V. In the ellipse, let the diameter E D be parallel to P Q S an ordinate of the diameter F H; draw the diameter P R and join S R cutting E D in T. Because P Q = Q S, and P G = G R; therefore S R is parallel to F H. And because E D is parallel to P Q S, and P G = G R; therefore R T = T S. Therefore R S is an ordinate of the diameter E D. *Def.* XIV, and it is parallel to F H; therefore E D and F H are conjugate diameters, *Def.* XVIII.

Cor. If a diameter of an ellipse, as E D, be parallel to F O, a tangent at a vertex of another diameter F H; then F H is parallel to D I, a tangent at a vertex of E D.

For a tangent at a vertex of a diameter is parallel to the ordinates of that diameter.

Def. XIX. When a straight line drawn through a point, situated within or without a cone, meets one, or both, of the conic surfaces in two points, it is called a secant; and the two parts of such a line, between the point through which it is drawn and the conic surface or surfaces, are called the segments of the secant. And when a line, drawn from a point without a cone, touches one of the conic surfaces; that part of it between the point from which it is drawn and the conic surface is denoted by the word tangent in the following propositions.

PROP. XXV. *Fig.* 34, 35, and 36.

If a straight line be drawn from the vertex of a cone to a point, as B, in the plane of the base, but not in the periphery of the base; and, through any point, as P, situated without or within the cone, another straight line, parallel to the former, be drawn to cut or touch the conic surface, or opposite surfaces; then the square of the line drawn from the vertex of the cone to the point B is to the rectangle under the segments of the secant, or to the square of the tangent, drawn from the point P, as the rectangle under the segments of any line drawn from B to cut the base of the cone, is to the rectangle under the segments of any line, parallel to the base of the cone, drawn through the point P, to cut the conic surface.

Fig. 34. Let the point B be without the base of the cone, and let Q R, drawn through P without or within the conic surface, be parallel to V B, and let it cut the conic surface in Q and R: through P and the line V B draw a plane cutting the conic surface in the lines V G and V H, and the plane of the base in the line B G H; and through P draw L K parallel to G H. Because V B and P Q R are parallel, therefore the line P Q R is contained in the plane B V P, 7. 17. E; and the points Q and R are in the lines V H and V G, the common sections of the plane and the conic surface. Because Q P is parallel to V B and L K to G H, therefore the triangle Q P L is equiangular to the triangle V B H, and the triangle P K R to the triangle V G B: therefore 4. 6. E.

$$V B : P R :: B G : P K$$

$$V B : P Q :: B H : P L$$

Consequently, $V B^2 : P R \times P Q :: B G \times B H : P K \times P L$, 23. 6. E. But the rectangle $B G \times B H$ is equal to the rectangle under the segments of any other line drawn from B to cut the base of the cone, 35 and 36. 3. E; and the rectangle $P K \times P L$ is equal to the rectangle under the segments of any other line, parallel to the plane of the base, drawn from P to cut the conic surface, *Cor.* *Pr.* 5; and hence the proportion is manifest in this case.

Fig. 35. And if the point B be within the base of the cone, and a straight line (as P Q R), parallel to the line

V B

CONIC SECTIONS.

VB that joins the point B and the vertex of the cone, be drawn to cut the opposite surfaces through a point P situated without or within the cone: the proposition may be demonstrated in this case, in the very same words as in the former case.

Fig. 36. And if the point P be without the cone as well as the line VB, and PS, parallel to VB, be drawn to touch the conic surface, instead of cutting it; then the plane PV B will meet the conic surface in a line VSM; and BM will touch the base of the cone, and PN, parallel to BM, will touch the conic surface. And because the two triangles SPN and VBM are equiangular, therefore,

$$VB : PS :: BM : PN$$

$$\text{And } VB^2 : PS^2 :: BM^2 : PN^2$$

But BM^2 is equal to the rectangle under the segments of any line drawn from B to cut the base of the cone; and PN^2 is equal to the rectangle under the segments of any line, parallel to the base of the cone, drawn from P to cut the conic surface; and hence the proposition is manifest in this case also.

PROP. XXVI. *Fig. 37.*

If a point be assumed without or within a cone, and two lines be drawn through it to meet a conic surface, or opposite surfaces, and so as to be parallel to two straight lines given by position; then the rectangle under the segments of the secant, or the square of the tangent, parallel to one of the lines given by position, has to the rectangle under the segments of the secant, or to the square of the tangent, parallel to the other line given by position, a ratio that is constantly the same, wherever the point (from which the lines are drawn) is assumed without or within the cone.

Fig. 37. Let VB and VC be two straight lines, drawn from the vertex of a cone to the plane of the base, and given by position (or parallel to lines given by position); and let PQ and MN be two straight lines drawn through any assumed point, as R, to cut the conic surface, and so as to be respectively parallel to CV and VB: and as CV^2 is to the rectangle $CK \times CL$ (contained by the segments of any line drawn from C to cut the base of the cone), so let D, any assumed line, or magnitude, be to E; and as VB^2 is to $BG \times BH$ (the rectangle contained by the segments of any line drawn from B to cut the base of the cone), so let F be to E; and draw ST parallel to the base of the cone through the point R; then, *Pr. 24.*

$$(CV^2 : CK \times KL, \text{ or } D : E :: PR \times RQ : SR \times RT, \text{ and } VB^2 : BG \times GH, \text{ or } F : E :: MR \times RN : SR \times RT. \text{ Therefore inverting and ex æquo,}$$

$$D : F :: PR \times RQ : MR \times RN.$$

And, as the same reasoning applies wherever the point R is assumed, therefore the ratio of the rectangles $PR \times RQ$, and $MR \times RN$ is the same with, or equal to, the constant ratio of D to F, wherever the point R is assumed.

And, in like manner, may the proposition be demonstrated in all other cases, or in all positions of the lines PQ, and MN, whether they cut, or touch, the same or opposite surfaces.

PROP. XXVII. *Fig. 38.*

If a point be assumed in the curve of an hyperbola, and a straight line be drawn through it to cut both the asymptotes; the rectangle, contained by the segments intercepted between the point in the curve and the asymptotes, will be equal to the square of the semidiameter to which the straight line is parallel.

First, let the straight line EMN, drawn through E in

the curve of a hyperbola and cutting the asymptotes in M and N, be parallel to the transverse diameter, GH; join HE, and produce it to meet the asymptotes in R and S: it is obvious that the triangle RGH is equiangular to the triangle REN, and the triangle GHS to the triangle SEM; therefore, 4. 6. E.

$$NE : ER :: GH : HR$$

$$SH : GH :: SE : EM$$

And, because $SH = ER$, and $SE = HR$, *Pr. 22.* therefore,

$$\text{ex æquo } NE : GH :: GH : EM$$

consequently, $ME \times EN = GH^2$, 17. 6. E.

Next, when the line is parallel to a second diameter. And if it touch the curve at the point H through which it is drawn, as KL; then the two segments, KH, and HL, are equal to one another, *Pr. 13.* and to the semidiameter GP, to which KL is parallel, *Def. XVI.*; whence the proposition is manifest. But if a line, as DF, drawn through the point of the curve, E, parallel to the second diameter GP, do not touch the hyperbola, let KL, parallel to GP, touch the hyperbola in H, and join HE, cutting the asymptotes in R and S. Because KL and DF are parallel (being, both, parallel to GP), therefore the triangles, RHL, and KHS, are respectively equiangular to the triangles REF and DES; therefore,

$$FE : ER :: HL : HR$$

$$SH : HR :: SE : ED$$

And, because $SH = ER$ and $SE = HR$, therefore,

$$\text{ex æquo } FE : HK :: HL : ED$$

consequently, $FE \times ED = HK \times HL = GP^2$.

Cor. If any number of straight lines, all parallel to one another, meet the two asymptotes and the hyperbola or opposite hyperbolas; the rectangles contained by the segments of the parallels, intercepted between the asymptotes and the curve, will be all equal to one another.

For each of the rectangles is equal to the square of the semidiameter drawn parallel to the lines.

PROP. XXVIII. *Fig. 38.*

If a point be assumed without or within a conic section, and two straight lines be drawn through it to cut or touch the section or opposite sections, and so as to be parallel to two lines given by position; then the rectangle under the segments of the secant, or the square of the tangent, parallel to one of the lines given by position, will have to the rectangle under the segments of the secant, or to the square of the tangents parallel to the other line given by position, a ratio that is always the same, wherever the point (through which the lines are drawn), is assumed without or within the section. And in the ellipse and hyperbola, or opposite hyperbolas, the constant ratio is equal to that of the squares of the diameters drawn parallel to the lines given by position.

For secants and tangents of a conic section are secants and tangents of a conic surface, and thus the first part of this proposition is included in proposition 25.

And because the diameters of an ellipse intersect in the centre, and are bisected there, *Pr. 14.*; therefore the ratio of the rectangles under the segments of the secants, is, in this case, the same with the ratio of the squares of the semidiameters, or the same with the ratio of the squares of the diameters themselves; and thus the second part of the proposition, in as much as it regards the ellipse, is manifest from the first part.

It remains to demonstrate the second part of the proposition in the case of the hyperbola. Assume any point, as F, (*fig. 38.*), in one of the asymptotes, and through F draw

B I and C E (terminated by the hyperbola, or opposite hyperbolas), parallel to two semidiameters G P and G H; and let B I, and C E, or these lines produced, cut the other asymptote in D and A. Because $BA = FI$, *Pr.* 22; therefore $BF \times FI = BF \times BA = GH^2$; and, in like manner, $EF \times FC = DC \times CF = GP^2$, *Pr.* 27. Therefore the ratio of the squares of the semidiameters G H and G P, or the ratio of the squares of the diameters themselves, is equal to the ratio of the rectangles $BF \times FI$ and $EF \times FC$. And because the ratio of the rectangle $BF \times FI$ to the rectangle $EF \times FC$ is equal to the ratio of the rectangles under the segments of any lines terminated by the curve or curves that intersect one another, and are parallel to B I and F D (the squares of the tangents being taken when the lines touch the curve instead of cutting it), therefore, in the case of the hyperbola also, the second part of the proposition is manifest from the first part.

Cor. 1. If two tangents be drawn to an ellipse, or a hyperbola, or opposite hyperbolas, from the same point, then these tangents are proportional to the diameters, or semidiameters, drawn parallel to the tangents.

For the squares of the tangents are proportional to the squares of the diameters.

Cor. 2. If a right line be ordinately applied to a diameter of an ellipse, or to a transverse diameter of a hyperbola; then as the square of the diameter is to the square of the conjugate diameter, so is the rectangle contained by the abscissæ of the diameter, between the vertices and ordinate, to the square of the ordinate.

For the double-ordinate is bisected by the diameter, and it is parallel to the conjugate diameter.

PROP. XXIX. *Fig.* 39.

If an ordinate be drawn to a second diameter of opposite hyperbolas; the square of this second diameter is to the square of the conjugate diameter, as the sum of the squares of the second diameter, and of the part of it between the centre and the ordinate, is to the square of the ordinate.

Let P Q (*fig.* 39.) be a second diameter of two opposite hyperbolas, and F H the diameter conjugate to it, and let M O be an ordinate to P Q; draw M N parallel to P Q; then M N will be an ordinate of the diameter F H; *Def.* XX.

Therefore, $GH^2 : GP^2 :: FN \times NH$, or $GN^2 - GP^2 : MN^2$, *Cor. 2. Pr.* 27;

therefore $GH^2 : GP^2 :: GN^2$, or $MO^2 : GP^2 + MN^2$ 12. 5. E. and invertendo, $GP^2 : GH^2 :: GP^2 + MN^2 : MO^2$.

PROP. XXX. *Fig.* 40.

If a right line, as P T, drawn through a point P in the surface of a cone so as to be parallel to a right line V B contained in the conic surface, meet two parallel lines (in the points R and S) that cut or touch the conic surface or opposite surfaces: then P R is to P S as the rectangle under the segments of the secant, or the square of the tangent, drawn through the point R, is to the rectangle under the segments of the secant or to the square of the tangent, drawn through the point S.

Through the two parallels P T and V B (*fig.* 40.) draw a plane cutting the conic surface again in the line V A, and the plane of the base in the line B A; and, through R and S, draw M N and H G parallel to A B. Because P T is parallel to V B and R N to S G, therefore R N G S is a parallelogram; and R N is = G S. It is obvious that the triangles P M R and P H S are equiangular: therefore P R is to P S as M R is to H S, 4. 6. E, or as $MR \times RN$

is to $HS \times SG$, 1. 6. E. But $MR \times RN$ and $HS \times SG$ are respectively equal to the rectangles contained by the segments of any two lines, parallel to the base of the cone, drawn through R and S to cut the conic surface, *Cor. Pr.* 5, and hence the proposition is manifest, when P T meets two lines parallel to the plane of the base.

And if P T meet two parallel lines D E and I K, not parallel to the plane of the base; then, let the same construction be made as before; and because D E is parallel to I K, and M N to G H; therefore, $DR \times RE : MR \times RN :: IS \times SK : HS \times SG$;

Alternando, $DR \times RE : IS \times SK :: MR \times RN : HS \times SG$. Therefore, as is obvious from what has already been shown,

$$PR : PS :: DR \times RE : IS \times SK.$$

And if S be without the cone and the line drawn through it touch the conic surface instead of cutting it, the reasoning is still the same, when the square of the tangent is taken in place of the rectangle under the segments of the secant.

PROP. XXXI.

If two points be assumed in the diameter of a parabola, or in a right line drawn through a point in the curve of an hyperbola parallel to one of the asymptotes, and two parallel lines be drawn from these points to cut, or touch, the curve or opposite curves; then, as the rectangle under the segments of the secant or the square of the tangent, drawn from one of the assumed points, is to the rectangle under the segments of the secant, or to the square of the tangent, drawn from the other assumed point, so is the segment of the diameter of the parabola, or of the line parallel to the asymptote, between the first assumed point and the curve, to the segment of the same line between the second assumed point and the curve.

Because all the diameters of a parabola, *Def.* XIII. and all the straight lines drawn parallel to an asymptote of a hyperbola, *Cor. 2. Def.* XV. are parallel to a right line contained in the conic surface; and because secants, and tangents of a parabola, or a hyperbola, are secants and tangents of a conic surface: therefore it is manifest that this proposition is included in the last proposition.

Cor. The squares of the ordinates drawn to a diameter of a parabola are proportional to the abscissæ of the diameter between the ordinates and the vertex.

Fig. 43. For the double ordinates of a diameter of a parabola, as G F D and L K E are parallel to one another; *Cor. Def.* XVII. therefore, by this proposition, $GF \times FD$, or $GF^2 : LK \times KE$, or $LK^2 :: AF : AK$.

PROP. XXXII. *Fig.* 41, 42, and 43.

If an ordinate be drawn to a diameter of a conic section, which is not a second diameter of a hyperbola: then, in the ellipse, the square of the ordinate is equal to a rectangle contained by an abscissæ of the diameter and a constant line, deficient by a rectangle similar to that contained by the constant line and the diameter; and, in the hyperbola, the square of the ordinate is equal to a rectangle contained by an abscissæ of the diameter, and a constant line, exceeding by a rectangle similar to that contained by the constant line and the diameter: and in the parabola, the square of the ordinate is equal to a rectangle contained by the abscissæ of the diameter and a constant line.

Let A B (*fig.* 41 and 42.) be a diameter of an ellipse, or a transverse diameter of a hyperbola, F G an ordinate of it, and D E the conjugate diameter; draw A H perpendicular to A B and equal to a third, proportional to A B and D E, and

CONIC SECTIONS.

and join BH; draw FL parallel to AH, and complete the parallelograms AK, FN and AM. It is obvious that BA is to AH as BF is to FL, 4. 6. E. or as BF × FA is to FL × FA or the rectangle FN, 1. 6. E. And because AH is a third proportional to BA and ED, therefore,

$$BA : AH :: BA^2 : DE^2, \text{ Cor. 2, 20. 6. E.} :: AF \times FB : FG^2. \text{ Cor. 2. Pr. 28.}$$

Therefore,

$$AF \times FB : FG^2 :: AF \times FB : \text{rect. FN, 14. 5. E.}$$

Therefore $GF^2 = \text{rectangle FN}$. Now, in the ellipse, the rectangle FN is deficient from the rectangle AM, contained by the absciss AF and the line AH (which is the same for all the ordinates) by the rectangle NM, similar to the rectangle AK, contained by AH and AB; and, in the hyperbola, the rectangle FN exceeds the rectangle AM by the rectangle NM, similar to the rectangle AK.

In the parabola (fig. 43.) let one ordinate of a diameter be pitched upon, as LK, and take AH, a third proportional to the absciss AK and the ordinate LK; then, if FG be any other ordinate,

$$LK^2 : FG^2 :: AK : AF, (\text{Cor. Pr. 31}) :: AK \times AH : AF \times AH.$$

And because $LK^2 = AK \times AH$, therefore $FG^2 = AF \times AH$, the rectangle contained by the absciss AF and the line AH, which is the same for all the ordinates of the diameter.

Def. XX. The constant line AH is called the parameter of the diameter AB; and, in the ellipse and hyperbola, it is a third proportional to the diameter AB, and the conjugate diameter DE; but, in the parabola, it is a third proportional to the absciss of any one ordinate of a diameter, and the ordinate itself.

SCHOLIUM.

The phrases "deficient" and "exceeding by a rectangle similar to another rectangle," occur in Euclid's Elements, 27 and 28. 6. E. although they are now generally disused by geometers; and, it must be confessed, they are far from expressing the meaning they are intended to convey, in a simple and perspicuous manner. These expressions have been used in enunciating this proposition, with the view of drawing the attention to the distinguishing circumstances from which the several conic sections derived their names. For Apollonius gave the name of the ellipse to one of these curves, on account of the defect of the square of the ordinate from the rectangle contained by the absciss and the parameter: and he called another of them an hyperbola, from the excess of the same square above the same rectangle; and the third a parabola, on account of the exact equality of the same two spaces.

PROP. XXXIII. Fig. 44. Plate VI.

Let a scalene cone be cut by a plane drawn through the axis perpendicular to the plane of the base, making the triangular section VAB; and let VD, cutting AB produced, in D, be drawn so as to make the angle BVD equal to the angle VAB; and let IE be drawn in the plane of the base perpendicular to AD: then, if a point be assumed in the plane of the base of the cone, but without the base, the square of the line drawn from that point to the vertex of the cone is greater than, or equal to, or less than, a rectangle contained by the segments of any line drawn from the same point to cut the base of the cone, according as the assumed point is on the same side of the line IE as the base of the cone, or in the line IE, or on the opposite side of the line IE.

For, let I be any point in the line IE, and draw IV to the vertex, and IK to cut the base of the cone through the

centre C. Because the angle BVD is equal to the angle BAV, therefore VD is a tangent of a circle described about the triangle AVB, 32. 3. E.; therefore $VD^2 = AD \times DB$ (36. 3. E.) $= DC^2 - CB^2$, 6. 2. E.: to these equals add DI^2 ; and $VD^2 + DI^2 = DC^2 + DI^2 - CB^2$. But it is evident that DI is perpendicular to the plane AVD; therefore, $VD^2 + DI^2 = VI^2$, 47. 1. E.; and $DC^2 + DI^2 - CB^2 = IC^2 - CL^2 = KI \times IL$, 6. 2. E. Therefore, $KI \times IL = VI^2$.

Secondly, let M be a point, without the base of the cone, and on the same side of the line IE, as the base; and, let a plane drawn through MV, and the centre of the base, cut the cone in the triangle KVL, and the plane of the base in the line KLM: produce KM to meet IE in I, and draw IV. It has been shewn that $IV^2 = IK \times IL$; therefore, if a circle be described about the triangle KVL, VI will be a tangent of that circle (32. 3. E.) and the line VM, will cut its periphery in a point *m*, situated between V and M; and because V, *m*, L, and K are points in the same circle, therefore $VM \times Mm = KM \times ML$, 36. 3. E. But VM^2 is greater than $VM \times Mm$; therefore it is also greater than $KM \times ML$.

Thirdly, let N be a point in the plane of the base of the cone on the opposite side of the line IE; and, the same construction being made as before, it is manifest that VN will be entirely without the circle described about the triangle KVL (of which VI is a tangent); and that VN, when produced, will cut the periphery as at *n*; then $nN \times NV = NK \times NL$. But NV^2 is less than $nN \times NV$; therefore it is less than $NK \times NL$.

Cor. If I be a point in the plane of the base of the cone, such that $IV^2 = IK \times IL$: then I is a point in the line found in the manner described in the enunciation of this proposition.

PROP. XXXIV. Fig. 45.

If a scalene cone be cut by a plane perpendicular to the plane of the base, making the triangular section VAB; and let IE be the line found in the last proposition; also, let the cone be cut by a plane, making an elliptical section, PQH, the determining line of which, MN, is parallel to the line IE; and let FH be the diameter of the section that is parallel to MN. Then, if MN fall between the base of the cone and IE, FH is the least diameter of the section; and, if MN fall upon IE, all the diameters of the section are equal to FH and to one another; and if FH fall on the opposite side of IE to the base of the cone, FH is the greatest diameter of the section.

Let RS be any diameter of the section different from FH, and draw V K (meeting MN in K) parallel to RS; and let KLT cut the base of the cone. Because RS and HF are bisected in the centre G, therefore,

$$RG^2 : HG^2 :: VK^2 : KL \times KT, \text{ Pr. 25.}$$

Now, if MN fall between the base of the cone and IE, then VK^2 is greater than $KT \times KQ$, Pr. 33; therefore RG is greater than HG; and, in this case, FH is the least diameter of the section.

And, if MN fall upon IE, then $VK^2 = KT \times KL$; therefore $KG = HG$; and, in this case, the section is a circle.

And, lastly, if MN be on the other side of IE to the base, then VK^2 is less than $KT \times KL$; therefore RG is less than HG; and, in this case, FH is the greatest diameter of the section.

Cor. 1. If a section of a cone, not parallel to the plane of the base, be a circle, then IE, the line found in Prop. 32, is the determining line of that section.

$$\text{For } RG^2 : HG^2 :: KV^2 : KT \times KL.$$

And,

And, because the section is a circle, therefore $RG = HG$; therefore $KV^2 = KT \times KL$; therefore K is a point in the line IE , *Cor. Pr. 25*. And, in like manner, it may be shewn that every point of the determining line of the section is in the line IE .

Cor. 2. Let PQ be the common section of the plane VAB , and the plane of the ellipse; then PQ is a diameter of the ellipse. It is manifest that MN is perpendicular to the plane VAB ; therefore FH , parallel to MN , is perpendicular to the same plane and to PQ . Also PQ and FH are conjugate diameters, *Pr. 17*. Therefore, when the plane VAB is perpendicular to the plane of the cone, FH , the diameter of the ellipse, parallel to the base of the cone, cuts its conjugate diameter, PQ , at right angles.

SCHOLIUM.

If $FPQH$ be a section of the cone, of which IE is the determining line, it is plain that PQ is parallel to VD ; therefore, the angle $VQP = \text{angle } BVD = \text{angle } VAB$. Therefore, the triangle PVQ is similar to the triangle BAV ; but the angles at the base of the one triangle have a sub-contrary position to the equal angles at the base of the other triangle. For this reason a section of a cone that has the line IE (found as in *Prop. 32*) for its determining line, is called a sub-contrary section.

The word ellipse has hitherto been used to denote, generally, those sections of a cone which have their determining lines without the base of the cone; but, as it has been shewn that the conic section is a circle in one particular case (*viz.* the sub-contrary section) included in this general definition, precision requires that the term ellipse be hereafter restricted in its signification, so as to exclude that particular case.

PROP. XXXV. *Fig. 46.*

An ellipse being given, it is required to draw a diameter of it that shall be equal to FH , the diameter which is parallel to the base of the cone; but the plane VAB , drawn through the vertex of the cone, and that diameter of the base which is perpendicular to the determining line of the ellipse, must not be perpendicular to the plane of the base of the cone.

Draw the line IE , as in proposition 32. And because IE and MN are perpendicular to two different diameters of the base of the cone, they are not parallel: let them meet in K , and draw VK , and the diameter RS , parallel to VK ; then $FH = RS$. For, because RS and FH are bisected in the centre G , therefore,

$$VK^2 = KT \times KL :: FG^2 = RG^2, \text{ Pr. 24.}$$

But $VK^2 = KT \times KL$; therefore, $FG = RG$.

Cor. Only one diameter can be drawn that shall be equal to FH .

For, if $FH = RS$, then $VK^2 = KT \times KL$; therefore, K is in the line IE ; and IE can meet MN only in one point.

Def. XXI. A diameter of a conic section, that cuts its ordinates at right angles, is called an axis.

Cor. Because two conjugate diameters of an ellipse, and opposite hyperbolas, cut their ordinates in the same angles, *Pr. 24*; therefore, if these become axes of these curves, there will necessarily be two; and these will be conjugate diameters, and they will cut one another at right angles.

PROP. XXXVI. *Fig. 47 and 48.*

An ellipse has only two axes.

Let FH (*fig. 47*) be the diameter of the ellipse drawn parallel to the base of the cone; and, first, let FH be the greatest or

the least diameter of the ellipse, *Pr. 34*; then, it has already been shewn, that FH cuts its conjugate PQ , at right angles, *Cor. 2 Pr. 34*; and, therefore, FH and PQ are axes of the ellipse, *Cor. Df. XXI*. Also they are the only axes of the ellipse. For, let XY be any other diameter, then XY is not perpendicular to FH ; draw FZO , (cutting the ellipse again in O) perpendicular to FY , and draw GO . Because FH is the greatest or least diameter of the ellipse; therefore, FG is not equal to GO ; therefore, FZ is not equal to ZO , *47. 1. E*. Therefore FO , perpendicular to XY , is not an ordinate of XY ; therefore, XY is not an axis.

Secondly, when FH is not the greatest or least diameter of the ellipse, draw the diameter RS equal to FH , *Pr. 35*; and draw the diameter LK and DE to bisect the angles contained by FH and RS ; join FS . And, because LK bisects the angle at the vertex of the isosceles triangle FGS , it will bisect the base FS , and will cut it at right angles. And because LK cuts FS , one of its ordinates at right angles, therefore LK is an axis; and, it is plain, that DE , parallel to FS , is another axis and the conjugate of LK . Also, LK and DE are the only axes of the ellipse. For, let XY be any other diameter; then XY is not perpendicular both to FH and to RS ; let it be not perpendicular to FH , and draw FZO (cutting the ellipse again in O) perpendicular to FY , and join GO . Because RS is the only diameter of the ellipse that is equal to FH , *Cor. Pr. 35*; therefore FG is not equal to GO ; therefore FZ is not equal to ZO . And because FO , perpendicular to XY , is not an ordinate of XY , therefore XY is not an axis.

PROP. XXXVII. *Fig. 49.*

A hyperbola has only two axes.

Let G and GK be the asymptotes of the hyperbola, and draw the transverse diameter GA to bisect the angle of the asymptotes, and the second diameter DE to bisect the adjacent angle; let FK , drawn between the asymptotes, be perpendicular to GA , and meet the hyperbola in M and N . Because FK is perpendicular to GL , and the angle $FGL = \text{the angle } KGL$, therefore $FL = LN$, *26. 1. E*. But $FM = NK$, *Pr. 22*; therefore $ML = LN$. Therefore, MN perpendicular to GA , is an ordinate of GA ; therefore, GA is an axis; and DE , parallel to MN , is the conjugate of GA , and another axis, *Pr. 24*.

And if GA do not bisect the angle FGK , then FK , perpendicular to GA , will not be bisected in L ; therefore ML will not be equal to LN ; therefore in this case, MN , perpendicular to GA , is not an ordinate of GA . Therefore, the hyperbola has no axes besides GA and DE .

PROP. XXXVIII. *Fig. 50.*

A parabola has only one axis.

Let OS , terminated by the curve, be perpendicular to any diameter, and draw the diameter PQ to bisect OS ; and, because all the diameters of the curve are parallel, therefore, PQ is perpendicular to OS , and an axis of the curve, *Def. XXI*. And because OS can be an ordinate of only one diameter, therefore there is only one axis.

PROP. XXXIX. *Fig. 51 and 52.*

The two axes of an ellipse are always unequal; and the greater axis is the greatest diameter, and the less the least diameter of the curve. And that axis of a hyperbola, which is a transverse diameter, is the least of all the transverse diameters.

CONIC SECTIONS.

Let AB and DE (*fig. 51.*) be the two axes of an ellipse, C the centre, and CH any semidiameter; draw HP perpendicular to AB, and HQ perpendicular to DE. Because AB and DE are conjugate diameters; and HP an ordinate to AB, and HQ an ordinate to DE; therefore,

$$AB^2 : DE^2 :: AP \times PB : HP^2, \text{ Cor. 2 Pr. 28.}$$

Now, if AB be supposed to be equal to DE, it will follow that $AP \times PB = HP^2$; therefore, $AP \times PB + CP^2 = HP^2 + CP^2$, or $AC^2 = CH^2$. Therefore, $AC = CH$; and the ellipse will be a circle, which is not the case, *Cor. 1. Pr. 33.* Therefore, AB and DE are unequal; let AB be supposed to be greater than DE.

Because AB^2 is greater than DE^2 , therefore $AP \times PB$ is greater than HP^2 , and $AP \times PB + CP^2$, or AC^2 , is greater than $HP^2 + CP^2$, or CH^2 . Therefore the semi-axis AC is greater than any other semi-diameter HC.

In like manner,

$$DE^2 : AB^2 :: DQ \times QE : HQ^2.$$

Therefore $DQ \times QE$ is less than HQ^2 ; and $DQ \times QE + CQ^2$, or CD^2 , is less than $HQ^2 + CQ^2$, or CH^2 . Therefore the semi-axis DC is less than any other semi-diameter CH.

Fig. 52. In the hyperbola, a tangent of the curve drawn from the extremity of the axis CA, as AT, falls between the centre and the curve; and because CA, the semi-axis, is less than any other line drawn from C to AT, much more is it less than a semi-diameter CH drawn from C to the curve on the other side of AT.

DEFINITION XXII.

The greater axis of an ellipse is called the transverse axis; and the less, the conjugate axis; and, in the hyperbola, that one is the transverse axis which is a transverse diameter, and the other is the conjugate axis.

PROP. XL. *Fig. 51 and 52.*

A diameter of an ellipse nearer the transverse axis is greater than one more remote; and a transverse diameter of the hyperbola nearer the transverse axis is less than one more remote.

Fig. 51. Let CK and CH be two semi-diameters of an ellipse; join HK, and draw AG parallel to HK; join CG and draw CL to bisect HK. Because CL bisects HK, it will likewise bisect AG, *Pr. 15.* And because AM = MG, and AC is greater than CG, therefore the angle AMC is greater than the angle GMC, *25. 1. E.*; that is, the angle KLC is greater than the angle HLC. And because HL = LK, therefore KC, nearer to CA, is greater than HC more remote from CA, *24. 1. E.*

In the hyperbola, the same construction being made, because AC is less than CG, therefore the angle AMC, or KLC, is less than the angle GMC, or HLC. Therefore CK is less than CH.

DEFINITIONS. *Fig. 53, 54, and 55.*

XXIII. Let AB (*fig. 53 and 54.*) be the transverse axis, DE the conjugate axis, and C the centre of an ellipse, or hyperbola, or opposite hyperbolas; and let CF and C*f* be taken in the transverse axis, such that CF^2 and Cf^2 are each equal to $CA^2 - CD^2$ in the ellipse, and to $CA^2 + CD^2$ in the hyperbola; then the two points F and *f* are called the foci of the ellipse, hyperbola, or opposite hyperbolas.

Vol. IX.

Fig. 55. But the focus of a parabola is a point F in the axis, within the curve, and distant from the vertex by a line equal to one fourth part of the parameter of the axis.

Cor. The distance of each of the foci of an ellipse from either extremity of the conjugate axis is equal to half the transverse axis; and the distance of either of the foci of a hyperbola from the centre is equal to the distance between the extremities of the transverse and conjugate axes.

XXIV. If F (*fig. 53 and 54.*) be a focus of an ellipse, or hyperbola, or opposite hyperbolas, and AG be taken in the transverse axis (on the opposite side of the vertex to the focus F), such that AF is to AG as CF is to CA; then a line, as HK, drawn through G perpendicular to the transverse axis, is called a directrix of the ellipse, or hyperbola, or opposite hyperbolas.

Fig. 55. But the directrix of a parabola is a line, as HK, perpendicular to the axis, drawn through a point G as far distant from the vertex of the axis on the one side as the focus is on the other side.

Cor. An ellipse, hyperbola, or opposite hyperbolas, have two directrices; one corresponding to each focus. For the same construction that is made for one focus, may be made for the other focus.

PROP. XLI. *Fig. 53 and 54.*

Let AB be the transverse, and DE the conjugate, axis of an ellipse, or hyperbola, or opposite hyperbolas; from any point in the curve, or opposite curves, as M, let MC be drawn to the centre, and MP perpendicular to the transverse axis, and take CO, in the same axis, such that CO^2 may be equal to $MC^2 - CD^2$ in the ellipse, and to $MC^2 + CD^2$ in the hyperbola; then as AC is to CF so is PC to CO.

For, because AB and DE are conjugate diameters, therefore,

$AC^2 : CD^2 :: AP \times PB : MP^2, \text{ Cor. 2. Pr. 28,}$ therefore, $AC^3 : AC^2 \mp CD^2 :: AP \times PB : AP \times PB \mp MP^2$. But in the ellipse $AC^2 - CD^2 = CF^2$; and $AP \times PB - MP^2 = AC^2 - CP^2 - MP^2 = AC^2 - MC^2 = AC^2 - AC^2 - CD^2 - CO^2 = CF^2 - CO^2$; and, in the hyperbola, $AC^2 + CD^2 = CF^2$; and $AP \times PB + MP^2 = -PC^2 - AC^2 + MP^2 = MC^2 - AC^2 = CO^2 - CD^2 = CA^2 - CO^2 - CF^2$. Therefore, the last analogy becomes,

$$AC^2 : CF^2 :: AC^2 \mp CP^2 : CF^2 \mp CO^2$$

Consequently $AC^2 : CF^2 :: CP^2 : CO^2$ *19. 5. E.*

$$\text{And } AC : CF :: CP : CO.$$

PROP. XLII. *Fig. 53 and 54.*

If M be a point in an ellipse or hyperbola, and MF and M*f* be drawn to the foci; then, in the ellipse, the sum of MF and M*f* is equal to the transverse axis; and, in the hyperbola, the difference of MF and M*f* is equal to the transverse axis.

Draw MP perpendicular to the transverse axis, and take CO as in the last proposition. And, because

$$AC : CF :: CP : CO, \text{ Pr. 41.}$$

Therefore $AC \times CO = FC \times CP$; and $4 AC \times CO = 4 CF \times FO$. But, because AB and F*f* are bisected in C, therefore $4 AC \times CO = BO^2 - AO^2$, *8. 2. E.*, and $4 FC \times CP = PF^2 - PF^2 = fM^2 - MF^2$, *47. 1. E.*; therefore $BO^2 - AO^2 = fM^2 - MF^2$.

Again, $MF^2 + Mf^2 = fP^2 + FP^2 + 2 MP^2 = 2 FC^2 + 2 CF^2 + 2 MP^2 = 2 FC^2 \pm 2 CD^2 + 2 CO^2 = 2 AC^2 + 2 CO^2 = BO^2 + AO^2$.

3 H

And,

CONIC SECTIONS.

And, because $BO^2 + AO^2 = fM^2 + MF^2$, and $BO^2 - AO^2 = fM^2 - MF^2$; therefore, by adding the equals, $2BO^2 = 2fM^2$; and, by subtracting the equals, $2MF^2 = 2AO^2$. Therefore $fM = BO$, and $FM = AO$; whence the proposition is manifest.

PROP. XLIII. *Fig. 53, 54, and 55.*

A straight line drawn from any point in a conic section to a focus has to a perpendicular drawn to the corresponding directrix, a ratio that is constantly the same wherever the point is assumed in the curve; and, in the ellipse, the constant ratio is a ratio of minority (or of a less magnitude to a greater); in the hyperbola, the constant ratio is a ratio of majority (or of a greater magnitude to a less); and, in the parabola, the constant ratio is a ratio of equality.

Fig. 53 and 54. Let M be a point in an ellipse or hyperbola, and draw MF to a focus and MK perpendicular to the directrix HG , which corresponds to that focus; draw MP perpendicular to the transverse axis and take CO as in *Prop. 41.* Then

$$AC : CF :: CP : CO, Pr. 41.$$

Invertendo, $CF : CA :: CO : CP$

Therefore $CF : CA :: FO : AP, 10. 5. E$

But $CF : CA :: AF : AG, Def. XXIV.$

Therefore $CF : CA :: AO : GP, 12. 5. E$

But, as has been shewn in the demonstration of the last proposition, $AO = MF$, and $GP = MK$; therefore

$$CF : CA :: MF : MK.$$

But the ratio of CF to CA is a constant ratio; and it is a ratio of minority in the ellipse, and a ratio of majority in the hyperbola.

Fig. 55. In the parabola, $GA = AF$, and $4AF \times AP = 5P^2, Def. XXIII.$; but $4AF \times AP = GP^2 - P^2, S. 2. E$; therefore $MP^2 = GP^2 - P^2$; and $MP^2 + P^2 = GP^2$, or $MF^2 = GP^2$, or MK^2 . Therefore $MF = MK$.

Most branches of human learning take their origin from a few detached truths, viewed at first without connexion, and which, in the progress of knowledge, are at length joined together in one body of science. But when a science has risen, by accumulated discoveries, to such a degree of importance as to interest the curiosity of mankind, it is often too late to retrace its history, and to delineate its rise and progress in an accurate and satisfactory manner. It generally happens that the authors of many of the subordinat discoveries have already fallen into oblivion; and that some important improvements are disputed, and ascribed to different inventors by different writers. In reviewing the history of the conic sections, we must add, to the causes which commonly obscure the origin of all the sciences; the very high antiquity of this branch of the mathematics, and the loss of the early geometers who have written on it. No work of antiquity that professedly treats of the history of the conic sections has reached our time; and there is little to satisfy curiosity in this inquiry, excepting a few incidental notices collected from different authors.

The discovery of the curves, denominated the conic sections, is attributed to the philosophers of the school of Plato; and it is even ascribed, by some authors, to the founder, himself, of that celebrated sect. Other authors, grounding their opinion on a few words in an epigram of Eratosthenes, have given the honour of this discovery to Menechmus, who lived a little posterior to the time of Plato. But the information derived from ancient writers is too scanty to enable us to decide concerning the original disco-

verer of the conic sections, or to form a well-founded judgment of the respective inventions of the early mathematicians whose works have not come down to our time. We know nothing of Aristotle, or Conon the friend of Archimedes, excepting that they treated of the conic sections; and that they deserved the commendations of succeeding geometers by improving and extending the branch of science which they cultivated.

It is probable that the theory of the conic sections, like other parts of science, grew up gradually from a small beginning, increasing in magnitude and importance by the successive improvements of many geometers. New and difficult problems would naturally lead to new artifices and inventions for their solution; and they would thus contribute to the extension of knowledge. The history of the mathematics mentions two problems, famous in ancient times, much agitated by the geometers of the Platonic school, and both of them so difficult as to transcend the limits of the ordinary, or plane, geometry. We allude to the problems of the duplication of the cube, and the trisection of an angle; and there is no doubt but that the theory of the conic sections received great additions, and was enriched with many new properties, by the researches that were undertaken for resolving these problems. Two solutions of the former problem, derived from the conic sections, are preserved by Eutocius, in his commentary on the works of Archimedes, which are attributed by him to Menechmus. Some solutions of the latter problem, by means of the conic sections, are likewise extant in ancient authors, for which science is probably indebted to the ingenuity of the followers of Plato.

The testimony of ancient authors, as well as the solutions of the problems which we have just mentioned, lead us to infer that great progress had been made in investigating the properties of the conic sections before the time of Archimedes. This conclusion is confirmed by the writings of that celebrated mathematician. Many principal propositions are there expressly said to have been demonstrated by preceding writers, and are spoken of as truths commonly divulged and known to mathematicians. Archimedes himself, perhaps the greatest genius of antiquity, and deserving to be ranked with Galileo and Newton, enriched the theory of the conic sections with many noble discoveries. After a lapse of two thousand years, the quadrature of the parabola is still the most remarkable instance, within the precincts of geometry, of the exact equality of a curvilinear to a rectilinear space. To this beautiful discovery there must be added, the determining of the proportions of the elliptic spaces to one another, and to the circle; and likewise the mensuration of the solids generated by the revolution of the conic sections about their axes.

But we are chiefly indebted to the preservation of the writings of Apollonius for a more perfect knowledge of the theories of the ancient geometers concerning the conic sections. Apollonius was born at Perga, a town of Pamphylia, and he is said to have lived under Ptolemy Philopater, about forty years posterior to Archimedes. He was instructed in geometry in the school of Alexandria; and, under the successors of Euclid, he there acquired that superior skill in the science which distinguishes his writings. Besides his great work on the conic sections, he published many smaller treatises, relating chiefly to the geometrical analysis, which have all perished, and are known to us only by the account given of them in the seventh book of the mathematical collections of Pappus.

The treatise of Apollonius on the conic sections is written

ten in eight books, and it was esteemed a work of so much merit by his contemporaries as to procure for its author the title of the great geometrician. The purpose of the four first books, as we are informed in the prefatory epistle to Eudæmus, is to deliver the elements of the science; and, in this part of his work, Apollonius professes only to have collected and methodized what had already been published by former writers. One improvement introduced by him deserves to be particularly mentioned; as it is a curious instance of the progress of the mind in generalizing its first conceptions. The conic sections, according to the definitions now given of them, are such curves as are produced by the common section of a plane and a cone of whatever kind. But the first mathematicians who noticed these curves, did not define them in a way so general. They confined their attention to the right cone only; and, even in this kind of cone, they always supposed the cutting plane to be perpendicular to the slant side. In this view of the matter it is manifest, that the species of the curve would depend on the sort of cone by which it was produced. If the vertical angle of the cone were supposed to be an acute-angle, then the cutting plane, perpendicular to the slant side, would meet one of the conic surfaces only, and the line of common section would surround the whole, and would be an ellipse. If the vertical angle of the cone were supposed to be a right-angle, then the cutting plane would still meet only one of the conic surfaces, but the line of common section, not embracing the whole contour of the solid, would, in this case, be a parabola; and, lastly, if the vertical angle of the cone were supposed to be obtuse, then the cutting plane would intersect both the opposite conic surfaces, and the curve produced would be a hyperbola. It is true that the curves, thus defined, were rightly denominated conic sections, considering them as parts of a class; but it did by no means follow that they comprehended all the species of the class. Even retaining the right cone, yet curves of a different nature might possibly be produced merely by varying the inclination of the cutting plane: and much more so, if the species of the cone, and the position of the cutting plane, were both changed. To Apollonius belongs the honour of having generalized the ancient definitions of the conic sections, and of presenting the subject in the more perfect form in which it still continues to be taught: and the improvement is equivalent to the discovery that all the possible sections of any cone, are reducible to three distinct species and no more.

Before the time of Apollonius, the names of the several conic sections were likewise different from those that they now bear. In conformity to the ancient definitions of the curves, the ellipse was called the section of an acute-angled cone by the more early geometricians: and, in like manner, the parabola, and hyperbola, were denominated the sections of a right-angled, and obtuse-angled, cone. The present names are commonly supposed to have been invented by Apollonius; and, in compliance with the generality of writers, we have noticed the properties from which he derived them. But the received opinion on this point is probably not well founded: for both the terms, parabola and ellipse, occur in the writings of Archimedes, which were prior to the time of Apollonius.

The four first books of the conics of Apollonius is the only part of that work that has come down to us in the original Greek. On the revival of learning, the lovers of the mathematics had long to regret the loss of the original of the latter part of this important treatise. In the year 1658, Borelli, passing through Florence, found an Arabic manuscript in the library of the Medici family, which he

judged to be a translation of all the eight books of the conics of Apollonius. Transported with joy, he had interest enough to prevail on the duke of Tuscany to entrust him with the manuscript, which he carried to Rome: and, having procured the assistance of Abraham Ecchelenfius, a person skilled in the Arabic tongue, he published a Latin translation of it in 1661. The manuscript, discovered by Borelli, was entitled, "Apollonii Pergæi Libri Octo," and was supposed to be a complete translation of the work of the ancient geometrician: but, on examination, it was found to contain the first seven books only. Two other Arabic translations of the conics of Apollonius have been discovered by the industry of learned men: but both of them have the same defect as that found at Florence. From the circumstance of all the three manuscripts agreeing in the want of the eighth book, it is reasonable to suppose that this part of the treatise had already perished when the translations were written: and there is now no room to hope that the loss will ever be recovered. It is not easy to ascertain in what age the original of Apollonius's work disappeared; but we know that the whole of it was extant in the time of Pappus Alexandrinus. In the "Collectiones Mathematicæ" this author has given a succinct account of the contents of all the eight books, and has added the lemmas required for the demonstrations of the propositions they contain: and this circumstance enabled Dr. Hailey to annex, to the complete edition of the conics of Apollonius, which he published in 1710, a restoration of the eighth book executed with so much ability as to leave little room to regret the want of the original.

In the four last books of his treatise, Apollonius, as he informs us in the prefatory epistle, delivers the higher and more abstruse parts of the theory of the conic sections. He here claims the merit of originality, and professes to develop the results of his own researches. And it must be confessed that the genius, invention, and geometrical skill, displayed in this part of his work, are such as fully to justify the honourable appellation bestowed on him by his contemporaries. This treatise must be allowed, even in the present times, to contain a very extensive, if not a complete, theory of the conic sections. This branch of the mathematics has, perhaps, been more cultivated than any other, since the revival of learning; but the industry of modern mathematicians has discovered few properties of their curves, of which some traces are not to be found in the work of the great geometrician. Montucla thus delivers his opinion of the treatise of Apollonius: "Pour donner enfin de l'ouvrage d'Apollonius l'idée qu'il mérite, je remarquerai que nous avons dans notre langue, et en style algèbre, un traité des sections coniques dont on fait cas avec justice; je veux parler de celui de M. le marquis de l'Hôpital: cependant je ne craindrai point de dire qu'il y a dans le géomètre ancien un théorie bien plus étendue et plus complète de les courbes que dans le géomètre moderne."

The mathematicians, who followed Apollonius, seem to have been content with the humble task of commenting on his treatise. It would be uninteresting to enumerate the crowd of commentators who, at different times, have written on his work, and have endeavoured to render it of more easy access to the general class of mathematicians. Among the number we find the name of the learned Hypatia, the daughter of Theon: and we still possess the lemmas of Pappus Alexandrinus for all the eight books, and the commentary of Eutocius on the four first books. Since the revival of learning, the theory of the conic sections has been much cultivated, and is the subject of a great variety of ingenious works.

There is a relation subsisting between all the parts of human knowledge, which frequently connects speculations the most abstract, and seems 'g'y the most barren, with inquiries that are highly interesting to us, and most fertile in useful consequences. In studying the properties of the conic sections, the followers of Plato sought merely to gratify a contemplative turn of mind. Their researches were chiefly undertaken with the view of resolving speculative problems; they were directed to no immediate object of practical utility. It excites some degree of admiration, when we reflect that enquiries, purely intellectual, and apparently so little connected with external things, have, in modern times, been employed to explain many of the most remarkable phenomena of the material world. The doctrine of the conic sections is equally useful in the science of optics, and in determining the path of a projectile body. Above all, this branch of the mathematics derives its chief importance from the applications that are made of it in modern astronomy.

The uses of the conic sections in physical science have, as it is natural to conjecture, led modern mathematicians to consider these curves under particular points of view suited to their purposes. It is for this reason that the properties of those remarkable points, called foci, have been investigated with so much care in latter times. In optics, these points are almost exclusively the subjects of consideration when the conic sections are concerned; and, in astronomy, the sun invariably occupies one of the foci of the elliptical orbits which the planets and comets describe round him. These points did not entirely escape the penetration of the ancient geometricians. Apollonius has anticipated the moderns here, as well as in other parts of this science. He has unfolded many of the most curious properties of the foci, in the ellipse and hyperbola. He treats of them under the appellation of "Puncta ex applicatione facta;" which signifies that they are points formed by cutting the transverse axis in the ellipse, and the transverse axis produced in the hyperbola, into two segments containing a rect. angle equal to the square of half the less axis; and the phrase is thus equivalent to the modern definitions of the same points. The focus of the parabola is not noticed by Apollonius, nor by any other ancient author; unless, indeed (as has been pointed out to the writer of this article by a friend,) we except a proposition (Theor. 22, Prop. 238.) in the seventh book of the "Collectiones Mathematicæ," where Pappus delivers, in the form of a Locus, that beautiful property of the focus, and the corresponding directrix of any conic section, which some modern writers, considering it as characteristic, have made the basis of a definition of the curves in plano. Mydorgius, contemporary with Des Cartes, is the first who treated generally of the foci, of all the conic sections. Since his time the properties of these points have been gradually and fully developed.

Before Dr. Wallis, all the writers on conic sections followed the ancient geometricians in making the cone the common origin and foundation of their theories. That mathematician first entertained the idea of using the cone as little as possible in delivering the elements of the conic geometry; and this plan is pursued in his treatise, published at Oxford in 1655. In support of this innovation, Dr. Wallis urges the prolixity of Apollonius's work, and the difficulty and perplexed nature of the demonstrations. On the old plan, many propositions respecting the generating of the cone, and the properties of that solid, are to be previously gone through; and the diagrams are rendered confused by many lines drawn in different planes. On these accounts, he asserts, that the study of the conic sections was generally neglected: "unde

et nimis neglecta fuit (conicorum doctrina), tanquam infuperabilis difficultatis plena." It must be allowed that the objections of Dr. Wallis are not without foundation. On the other hand, it has been the opinion of some later mathematicians, that the defects of the treatise of Apollonius arise, not from his having made too much use of the cone, but from his having availed himself too little of the assistance to be derived from that solid. They contend that the most general and characteristic properties are first to be sought for in the cone itself; whence they are to be transferred to its sections, as particular cases of more general propositions. The latest, and most approved writers, who have adopted this opinion, are Dr. Hamilton and professor Robertson of Oxford. Although Dr. Wallis proposed to introduce the cone as little as possible in delivering the elements of the conic geometry; yet it is to be remarked that he still imitated his predecessors in deriving, from that solid, the fundamental property which he afterwards made the basis of all his reasoning. But the idea, which he introduced, was soon carried farther; and treatises on the conic sections were written, in which the cone was entirely laid aside, and the curves were defined from descriptions in plano. De la Hire, in his "Nouveaux Elements des Sections Coniques," published at Paris in 1679, is the first author who successfully treated on the conic sections in this new view of the subject. He derives the description of the parabola from the equality that subsists between two lines meeting in any point of the curve, one of which is drawn to the focus, and the other is perpendicular to the directrix; and he describes the ellipse and hyperbola from the analogous properties, that, in the one, the sum of two lines drawn from any point in the curve to the two foci, and, in the other, the difference of two such lines, are equal to the transverse axes. In these fundamental points De la Hire is followed by most of the later writers, who have treated of the conic sections independently of the cone; and, in particular, by Dr. Simson of Glasgow, who has published an extensive and accurate treatise on this subject. Besides the method of De la Hire, another way of defining the curves in plano has been proposed. It is founded on that general property of the directrix first given by Pappus Alexanderinus, as we have already noticed above. The learned abbé Bossovich, an excellent Italian mathematician, has drawn his definitions of the curves from this fundamental property in the ingenious treatise on conic sections, published in his "Elementa Mathematicæ Universæ;" and we have two works in our own language, which are founded on the same primary definitions; that of Mr. Newton of Cambridge, and that of Mr. Walker of Nottingham.

The doctrine of the conic sections is of great use in physical and geometrical astronomy, and the physico-mathematical sciences. This doctrine has been much cultivated by geometers ancient and modern: and we have many good treatises on the subject; but that published by Mr. Simson, professor of mathematics at Glasgow, deserves to be particularly mentioned, not only for its elegance, but for its geometrical accuracy, which, as he justly remarks in his preface, has not always been so well observed in treatises of this kind, as it ought to be. See also Gregorii a St. Vincenti Opus de Quadratura Circuli, & Sectionum Coni; Mydorgius de Sectionibus Conicis; De la Hire de Sectionibus Conicis; Trevisar Elem. Section. Con.; Hamilton's Tract. Geom. de Section. Con.; De l'Hopital's Anal. Treat. of Conic Sections; Muller's Treatise, &c.; Hutton's; and Halley's edition of Apollonius, &c. Oxon. 1710. fol.

To the properties of the conic sections, mentioned

above, it may be proper to add the properties of their osculatory circles, or circles of curvature. See CURVATURE.

Conic sections, similar. See SIMILAR.

Conic Form of Mountains and Hills. Too many naturalists have fallen into the mistake, of denominating mountains or hills which have a conical top, to be of volcanic origin; because, granite sometimes, as Aelterman mountain in the Hartz, assumes a conic form, Lafius 17; and porphyry frequently takes this shape. In some rare instances, the rupture of the strata has produced conical hills. See ELEVATION of Strata and VOLCANO.

CONICA, in *Ancient Geography*, a town of Asia, in Paphlagonia. Ptolemy.

CONICS, that part of the higher geometry, or geometry of curves, which considers the cone, and the several curve lines arising from the sections thereof.

CONICHYDONTES, or *Plesronites*, in *Natural History*, one of the three names by which the fossil teeth of fish are known; so called, from their supposed resemblance to the spur of a fighting cock.

Though authors assure us that these are the teeth of a fish, the jaws having been found with these bodies in them; yet they do not pretend to know to what fish they belong. They are generally of an oblong conic figure, broad at the base, and narrow at the point, where they are usually a little crooked: they are hollowed at the root, and are from the tenth of an inch to two inches long, commonly of a chestnut colour, and are found in the strata of clay, but most usually in those of stone; and are seen more frequently in England than in any other part of the world. Hill's *Fossils*, p. 645.

CONJECTURE, in the *Philosophy of the Mind*, expresses a degree of belief founded upon slight evidence. In some cases, a disposition to conjecture, indiscreetly indulged, may be productive of many extravagancies. It may prompt us to build favourite hypotheses on very weak foundations, and to ascribe the conduct of others to wrong motives, according to our prejudices for or against them. When indulged with discretion, a conjecture affords some relief to the mind from the inquietude of ignorance and uncertainty. It provides a temporary substitute for knowledge; and it frequently suggests ideas which lead to the discovery of truth.

Conjectural criticism, and consequent emendations of ancient authors, classical and scriptural, should be exercised with great caution; otherwise, the imagination will be apt to mislead persons most eminent for their genius and learning.

It is one of the most important, and at the same time one of the most disputed points in sound criticism, says Michaelis, whether what is called "conjectura critica," may be applied to the New Testament; or, in other words, whether in certain cases, and under certain restrictions, provided we use all due care and caution, we may reject the readings of all the MSS., versions, and fathers, and merely on a probable supposition, admit a reading that is supported by no written authority; and whether, if we proceed on these principles, we have any reason to expect, that we shall ever arrive at the truth. Many learned men, deservedly esteemed critics, are of opinion, that conjectures are as allowable at present in the New Testament, as in the classic authors. Nevertheless, the majority of divines formerly considered them as presumptuous, if not impious; but those persons who are so strenuously attached to the printed text, are not aware, as Wetstein observes, in his *Prolegomena*, that a very great number of readings, which they so zealously support, are merely critical conjectures, advanced either by the ancient fathers,

or by the modern editors of the Greek Testament, in the 16th and 17th centuries. These readings must therefore be immediately rejected, if critical conjecture is wholly inadmissible. As this question is purely critical, it should be argued, not on theological, but on critical grounds. The argument which is drawn from the hypothesis, that Divine Providence would not permit the true reading in any text of the New Testament to be lost, seems to be very extraordinary, when it is urged by persons who tacitly acknowledge that the same providence has not guarded against the necessity of conjecture in the Old Testament. Besides, no man can assert, that, because the true reading of any passage is no longer to be found, it is therefore totally lost, since the number of MSS. of the Greek Testament (together with other original documents) which have been actually collated, are trifling in comparison with the whole number that have been written; and a reading, which is now supported only by probable conjecture, may, in process of time, be confirmed by good authority. Moreover, if by no means diminishes the certainty of our faith, that some few passages of the New Testament have certain internal marks, which discover them to be not genuine, and which render it necessary to restore the true reading by critical conjecture. Our faith would only be in danger, if the number of these passages was so very great, as to render the whole New Testament suspicious; or, if the principal and distinguishing doctrines of Christianity must be either added to, or taken from, the sacred text, on no other authority than that of mere conjecture. But if, without assuming to ourselves the power of altering articles of religion, and confining our emendations to mere matters of criticism, we alter some words or sentences, the grounds of our faith are by no means affected, nor need we apprehend any evil consequences. In ancient writings, of which only one copy is extant, critical conjecture is indispensable. The necessity remains the same, even where there are several MSS. if those MSS. are only copies of one and the same more ancient MS. If we have more than a single copy of any work, and those copies are transcripts of different and distinct MSS., the necessity of critical conjecture decreases in proportion to the number of copies; but it does not entirely vanish, unless the number of the MSS. is very considerable. We have, therefore, no reason for censuring the critics of the 16th century, if, in their editions of the Greek Testament, they have sometimes, departed from the reading of their MSS., and substituted such as were agreeable to probable conjecture. The probability, however, that critical conjecture alone can restore the true reading, decreases in the same proportion, as our materials of criticism, or collections of various readings increase. And since so many MSS., works of the fathers, and ancient versions made in distant countries, and in different periods, have been carefully collated; and since also those very ancient Latin versions that vary so considerably from each other, and were translated from very different Greek MSS. have been made known to the public, we might even doubt whether critical conjecture ought not at present to be entirely rejected. It has, however, its learned and zealous advocates. It deserves to be considered, in reply to the plausible objection above suggested, that we have not a single MS. now extant, that was written in the four first centuries, and that the ancient versions have not descended to us without alterations. It is likewise evident, from the writings of the fathers, that many readings were in those times in the Greek MSS., which are not now found in any, or only in a very few; having been altered either by accident, or because they appeared to the transcribers to be obscure, or exceptionable.

ceptionable. It is therefore not impossible, that other readings, which have not been preferred in the works of the fathers, or in the Greek MSS., may have been equally left; and among them, perhaps, some that were genuine. Besides, it is not impossible that there are many important MSS. of which we have no knowledge; and that a collation of those MSS. might confirm the critical conjectures of the 18th century, in the same manner as many conjectures of the 16th century have been confirmed in the 18th, by the authority of MSS., and ancient versions. It might further be added, and it deserves consideration, that all our MSS., and versions of the New Testament, were probably taken, not from the single copies of the Gospels and Epistles, which proceeded from the hands of the Apostles themselves, but from the collection that was formed of the several parts of the New Testament. If, instead of 292 MSS. enumerated by Michaelis, we had above 1000, they would still be transcripts of one and the same copy; and if this copy had any errors, which it would be the highest presumption to deny, these errors must have been transmitted into every MS. of the Greek Testament, whatsoever; and these errors can be remedied only by the aid of critical conjecture. Upon the whole, it appears, that a collection of critical conjectures may be of great use in establishing the genuine text of the Greek Testament; and it is likewise attended with this particular advantage, that we are led by it to examine MSS., and other original documents, with greater accuracy, in order to see whether those readings, which had no other support than conjecture, may not be established by written authority. Such a collection has been published by Bowyer, a learned bookseller in London, the third edition of which, with improvements, was published in London in 1782. Of several hundred conjectures, which Bowyer has produced, there is hardly one, says Michaelis, which, after impartial examination, will be found probable. On the other hand, it cannot be denied, that there are some few, which bear on them the marks of probability. Several of these are examined by Michaelis, and he has added a variety of his own conjectures, for which we must refer to his work, cited at the close of this article. Besides the critical conjectures already mentioned, there is another kind of conjecture, denominated by Michaelis "theological conjecture," which consists in altering the text of the sacred writings, according to the maxims adopted by any particular party, whether it be the ruling, or the persecuted party, in the church. Although it is allowable to venture a conjecture in matters relating to history, to dates, or to names, as in these cases the Bible is not our only "principium cognoscendi," yet whoever alters the text in subjects which relate to points of divinity, evidently presupposes a "principium cognoscendi," that is prior to the Bible itself; and this is frequently nothing more than a set of principles, which this or that particular person has thought proper to adopt. It has been urged by those who defend theological conjecture, that we ought never to lose sight of the "auro in fidei," or analogy of faith. Thus, if two passages in the Bible contradict each other in matters of faith, the one must be altered. But the question recurs, how shall we determine which of the two is to be altered? "In my opinion," says Michaelis, "we should alter neither, but reject the whole, as not coming from the Deity, if it be true that there are real contradictions, for it is upon this ground, that we condemn the Koran." But every apparent contradiction is not a contradiction in reality; and passages that are seemingly at variance may, with skill and patience, be reconciled. Such is the case with respect to Rom. iii. 28. and James, ii. 24. the whole contradiction vanishing, as soon as we reflect that St. Paul understands

faith in Christ, St. James faith in the unity of the Godhead. For other observations on this subject, we refer to the author. Michaelis's Introduction to the New Testament by Murh, vol. ii. part. 1. See CARRICISM.

CONIFERÆ in *Botany*, the fifteenth natural order in the Philoſophia Botanica of Linnaeus, and the fifty-first of the Prælections. In the Philoſophia Botanica the genera included in it are abies, pinus, cupressus, thuja, juniperus, taxus, cædria. These are all retained in the Prælections, pinus and abies being united, and equisetum added with a mark of doubt, and an observation that it has the pollen of flax. The order derives its name from the cones or strobiles in which the seeds are contained. The fruit of juniperus, indeed, seems to be a berry, but it is properly a strobile, with pulpy scales, which do not open; for it has six fleshy connate scales, each containing a single seed. Taxus also apparently bears a berry; but this fleshy berry is only the fleshy receptacle almost covering the seed. All the coniferæ yield a resin, which renders most of them evergreen. The fruit in all is biennial, produced in the spring, but not ripening and dropping its seeds until the spring after.

The coniferæ compose also one of the natural orders of Jussieu, the fifth of his fifteenth class, with the following character: *Flowers* monoicous or dioicous. *Males* most frequently in a catkin, or heaped together upon a catkin, each furnished with a scale, with or without a calyx: the stamens attached either to the calyx, or to the scale. *Stamens* definite or indefinite in number: filaments sometimes distinct, sometimes united into a simple or branched stipe. *Females* either solitary, or capitate, or disposed in a strobile or cone, densely imbricated with scales that separate the flowers; furnished either with a calyx or with a scale discharging the office of a calyx. *Germ* superior, cortical, either double or manifold, with as many styles and stigmas, and either as many seeds, or as many one-seeded capsules. *Coraculum* cylindrical, central, in a fleshy perisperm, two-lobed; the lobes sometimes, but rarely, divided or palmate, thence appearing many-lobed. *Stem* a tree or shrub. It contains the following genera: I. With a stamiferous calyx; cædria, castanea, taxus. II. With only a stamiferous scale, the true coniferæ: Juniperus, cupressus, thuja, araucaria (Dom. beya: Lam.), pinus, abies.

Ventana has the same division and genera, except that he omits araucaria.

CONIGLIANO, in *Geography*, a small, but populous, town, in the district of Treviso, in the territory of Venice, which now forms part of the kingdom of Italy.

CONIL, a small town of Spain, in the kingdom of Seville, in Andalusia, on a bay to which it gives name; 15 miles S. E. from Cadiz, with a strong castle. Its inhabitants subsist chiefly by fishing. N. lat. 36° 16'. W. long. 6° 8'.

CONIMBRIGA, or COMBRICIA, in *Ancient Geography*, Coimbra, a town of Spain, in Lusitania, on the Munda.

CONIN, or KONIN, in *Geography*, a town of Poland, in the palatinate of Kalisz; 18 miles S. E. of Gnesen.

CONJOINED, or CONJUNCT, in *Heraldry*, a term used for charges in arms when linked together.

CONJOINT, or CONJUNCT, is applied in *Ancient Music*, in the same sense as *consonant*, to two or more sounds heard at the same time. See CONSONANCE.

CONJOINT *degrees*, two notes which immediately follow each other in the order of the scale; as *ut* and *re*.

CONJOINT *tetrachords*, are two tetrachords, where the same *chord* is the highest of the one, and the lowest of the other.

CONIQUE,

CONIQUE, *Fr.* This term is applied to a piece of artillery, of which the bore is wider towards the muzzle than it is towards the breech.

CONIRA, in *Botany*, a name used by some authors for the *myrrhis*. *G-r. Emac. Ind. 2.*

CONISALUS, in *Mythology*, a god of the Athenians mentioned by Strabo, and supposed to be the same with Priapus.

CONISBERG, in *Geography*. See **KONIGSBERG**.

CONISCI, in *Ancient Geography*, a people of Spain, who formed a part of the Cantabri, and in their dress resembled the Gauls, according to Strabo.

CONISIUM, a town of Asia, in Mysia, according to Pliny. Hercules calls it *Ciniosine*, and makes it an episcopal city in the province of the Hellespont.

CONISOR. See **COGNISOR**.

CONISSALÆ, in *Natural History*, the name of a class of fossil bodies; the word is derived from *κωνισσάλος*, powder; all the species of bodies of this class being found like common sand, in form of powder, have been usually considered together, under the common name of *fanula*. The conissalæ are defined to be stones of a differently defaced, crystalline, or sparry matter, but always found in form of small and disunited particles, great numbers of which, being amassed together, form a kind of powder.

Of this class of bodies there are two distinct and large genera. 1. The fanula properly so called, which are composed of particles all appearing to have a tendency to the same regular figures, transparent, vitrifiable by a strong fire, and not soluble in, or effervescing with acids. 2. The *faburra*, or *grit*, of stone found loose; these are found in form of powder, the particles of which, in general, have no tendency to any particular figure, but appear to be rudely broken fragments of larger masses. Hill's *Hist. of Foss. p. 543.*

CONISTERIUM, a room in the ancient *Gymnasia* or *Palaestra*, in which was kept the sand for the use of the wrestlers, who were accustomed, after anointing their bodies with oil, to sprinkle themselves with sand to afford a firmer grasp in their encounters.

CONISTON, in *Geography*, a village in the northern part of Lancashire, in the hundred of Loynfdale. Latitude about $54^{\circ} 29'$, and longitude $2^{\circ} 44'$ W. It is situate on the steep ascent of a mountain of blue argillaceous schistus, near the northern end of a romantic lake, of six miles in length, and one in breadth, called after its name; near this town some copper-mines are worked, but to no considerable extent, and some veins of lead-ore: slate quarries are also to be found near this place. There is a torrent or mountain stream of water which precipitates itself into the lake near this place.

CONISTORSIS, in *Ancient Geography*, a town of Spain in Celtiberia. Strabo mentions it as a very famous town.

CONITZ, or **CHOINITZ**, in *Geography*, a town of Prussia, in Pomerania; 40 miles S. of Dantzick.

CONJUGAL RIGHTS, in *Law*. The suit for "restitution of conjugal rights" is one species of matrimonial causes; which is brought whenever the husband or wife is guilty of "subtraction;" or lives separate from the other without any sufficient reason: in which case the ecclesiastical jurisdiction will compel them to come together again, if either party be weak enough to desire it, contrary to the inclination of the other.

CONJUGATE Asia, &c. in Conics. See **CONIC Sections**.

CONJUGATE Point, in *Geometry*. See **POINT**.
CONJUGATES, in *Rhetoric*, denote words deduced from the same origin with that of the subject: e. g. *He who does justly, is just*.

CONJUGATION, in *Anatomy*, a term applied by the older anatomists to the nerves coming from the brain, in the same sense that we employ the expression, pair of nerves.

CONJUGATION, in *Grammar*, an orderly distribution of the several parts or inflexions of verbs, in their different moods and tenses, to distinguish them from each other: or, the manner in which the personal terminations of verbs are changed to express the several moods and tenses.

The Latins have four conjugations distinguished by the terminations of the infinitive, *are, ere, ire, ire*; and most of the French grammarians reduce the conjugations of their language to the same number, ending in *er, re, ir, and oir*. Some have added a fifth Latin conjugation called the *mixt*, because it is composed of the third and fourth, as *accipere, accipio*.

The Greeks have three kinds of verbs; the first called *barytons*, because the last syllable is pronounced with a grave accent; (see **PARYTONUM**); such are *τινω, τεινω*, and *πρωτω, προτω*; the second are circumflex verbs, which admit a contraction in their termination, and are then marked with a circumflex accent; such is *αγαπαω, αγαπαω*, the third kind comprehends the verbs in *μι, αμι, σμι*. Of the first sort there are six conjugations; divided according to their characteristic, i. e. the letter preceding the termination. Accordingly verbs having the labials π, β, φ, or πτ, form the first conjugation of barytons; those having the gutturals κ, γ, χ, or κτ, the second; those having the dentals τ, θ, θ form the third; verbs in ζα, σσα, or τσα, comprehend the fourth conjugation; the liquids λ, μ, ν, ς, mark the fifth; while those in α pure, such as *τινω, λνω*, distinguish the sixth conjugation. Of the second there are three, viz. those in *αω, εω, οω*: but all these and the barytonous verbs are conjugated, that is, are varied in the same way to express mood, time, number, and person. Of the third, there are four. But Messrs. de Port Royal reduce these 13 conjugations to two: viz. one in α, comprehending the barytons and circumflex verbs; and the other those in μι.

Mr. I. Jones, in his "Grammar of the Greek Tongue, on a new and improved Plan," has judiciously rejected the fore-mentioned distinctions as unnecessary, because they are useless and unmeaning; and distributed the Greek conjugations into four; viz. the active α, its passive εαα, the active μι, and its passive μαι.

In the Hebrew language there are four conjugations, viz. *kal* with its passive *niphal*, *piel* with its passive *pyhal*, to which also may be referred *poel*, *hiphil* with its passive *hophal*, and *hitpael*. The third person singular masculine of the first conjugation is the preterite of the theme; the second conjugation has a *dagesh forte* in the second radical; the third has the prefix letter ה; and the fourth, the syllable הן.

In English, where the verbs have scarce any natural inflexions, but derive all their variations from additional particles, pronouns, &c. we have hardly any such thing as strict conjugations.

Some grammarians, however, distribute English verbs into three conjugations, or classes, distinguished from one another by a peculiar formation in some principal part belonging to each: and they observe that the three different terminations of the participles, viz. *ed*, or its contraction *t*, *ght*, and *en*, may be considered as the characteristics of the conjugations.

conjugations. But as the verbs of the first conjugation would far greatly exceed in number those of both the others; and as those of the third conjugation are so various in their form, and incapable of being reduced to one plain rule; it seems better in practice, as bishop Lowth justly observes, to consider the first in *ed* as the only regular form, and the others as deviations from it: after the example of the Saxon and German grammarians. Lowth's *Introd. to English Grammar*, p. 104, 1772. Murray's *Eng. Gram.* p. 96. ed. 8. Others again distinguish them by the different inflexion of the first tense in each root, and thus make four conjugations in the active voice: the first has three radicals alike: as *I do read; I read; i. e. yesterday; I have read, i. e. just now.* The second has the first and third radical alike: as *I run, I ran, I have run.* The third conjugation has the second and third radical alike: as *I grieve, I grieved, I have grieved.* The fourth has the three radicals different; as *I write, I wrote, I have written or writ.* The passive voice, being made up of the third radical and the auxiliary verb *am*, admits of no difference of conjugations. Ward's *Essays on the English Language*, p. 87.

CONIUM, in *Botany*, (*Conium*), Theophrast. Dioscorid. derived by Henry Stephens from *κονίον*, the cone of the mathematicians, a name given also, on account of its form, to that well-known children's toy, a top. From this latter sense came the verb *κονίζω*, which Hesychius explains by *περὶ δυνάμει* implying a capacity to produce a whirling motion; and thence the poisonous herb employed by the Greeks as the means of inflicting a capital punishment, was called *κονίον*, because it occasioned a sensation of giddiness in the sufferer. Linnæus unaccountably derives the word from *κονίον*, (*diff.*) Linn. Gen. 336. Schreb. 469. Willd. 53. (Cicut. *Tourn.* 160. Hall. 766. Gert. 117. Lam. III. 503. Juss. 223. Vent. 3. 28. Cicut. Lam. Enc.) Class and order, *pentandria digynia*. Nat. Ord. *Umbellatæ*; Linn. *Umbellifera*; Juss. Vent.

Gen. Ch. *Umbel* partial, and universal with many spreading rays. *Involucere universal*, three or many-leaved, short, unequal, membranous towards the base: *partial* with about three leaves, only half enclosing the pedicels. *Cal.* scarcely perceptible. *Cor.* Petals five, inflexed, heart-shaped, unequal. *Stam.* Filaments five, about the length of the petals; anthers roundish. *Pist.* Germ inferior; styles two, short, reflexed; stigmas obtuse. *Peric.* none. *Fruit* nearly globular, with five crenulate ridges; composed of two seeds, which are convex, almost hemispherical, striated on one side, flat on the other, separating as they become ripe.

Eff. Ch. *Partial involucre* only on one side, about three-leaved. *Fruit* nearly globular, with five crenulate ridges.

Sp. 1. *C. maculatum*. Common hemlock. Linn. Sp. Pl. 1. Mart. 1. Willd. 1. Jacq. Aust. 2. tab. 156. Curt. Flor. Lond. 1. tab. 17. Eng. Bot. 1191. Woodv. Med. Bot. tab. 22. (Cicut. major; Lam. II. tab. 195. fig. 1. Bauh. Pin. 160. Rai. Syn. Cicut. domestica. Morif. Umb. 18 c. l. § 9. tab. 6. fig. 1. Coriandrum. Roth Cranz.) "Seeds striated." Linn. "Stem spotted at the base; furrows of the seeds crenate." Lam. "Seeds without prickles; stem much branched, shining, striated." Dr. Smith. *Root* biennial, spindle-shaped, often branched, white, fleshy. *Stem* three or four feet high, erect, cylindrical, hollow, furrowed, smooth, shining, marked with purple spots, much branched, especially towards the top, leafy. *Leaves* supra decomposed, or several times pinnated; bottom ones very large, sometimes two feet long; leaflets oblong, acutely notched, dark green above, paler underneath. *Rays* of the *umbel* from ten to twelve; of the *umbellule* fifteen or

sixteen. General involucre commonly many-leaved, reflexed. *Petals* white, heart-shaped, inflexed, nearly equal. The whole plant is narcotic, with a disagreeable smell and nauseous taste. Very different opinions have been entertained with respect to its active qualities, but it may be doubted whether authors have always intended the same plant. Haller was inclined to think, that the plant which was fatal to Socrates and Phocion, was not that now before us, but the *cicut. virosa* of Linnæus, which the French writers have called *cicutaria*. La Marck, on the other hand, asserts that the *conium maculatum* of Linnæus, his *cicut. magna*, is the *cicut.* of ancient authors, the very plant by which Socrates was poisoned; and severely censures Linnæus for changing its name to *conium*. But if this great botanist had looked into the Greek authors, he would have found that Linnæus only restored the most ancient name, and that the word *cicut.* is entirely of Latin origin, unknown to the Greek language. Whether Linnæus would not have done better, if he had retained the term *cicut.*, which had been adopted by all the modern botanists before him, is a question to which an affirmative answer may perhaps be given. His *cicut. virosa* might then, in concurrence with Haller's opinion, have been called *conium*. But when the change was made and had, through the extensive circulation of the works of Linnæus, obtained general currency, a revival of the ancient name, instead of removing, has, in fact, increased the confusion. Whatever may have been the plant by which Socrates was judicially murdered, our *conium maculatum* unquestionably possesses deleterious qualities; but, as Dr. Smith observes, it is happily too nauseous to be incautiously swallowed in any dangerous quantity. See *CICUTA* in the *Materia Medica*, where it should have been observed that Plato does not call the plant, by which Socrates perished, *cicut.*, a word which he had never heard; nor does he give it any Greek name peculiar to it; but constantly uses the very general term *φάρμακον*, which denotes a strong poison either poisonous or medicinal. 2. *C. rugosum*. Willd. 2. Thunb. prod. 50. (C. *sulfuricosum*; Berg. cap. 77.) "Seeds wrinkled." *Stem* somewhat shrubby. A native of the Cape of Good Hope. 3. *C. rigens*. Linn. Mant. 56. Mart. 2. Lam. 2. Willd. 3. Thunb. prod. 50. "Seeds somewhat muricated; peduncles furrowed; leaflets channelled, obtuse." *Root* perennial. *Stem* purplish, rigid, striated, erect, diffuse, branched. *Leaves* twice-winged, somewhat fleshy, divided, obtuse, crenulate, hard, the colour of rue; petioles longitudinally channelled. *Florets* all fertile, white; leaflets of the general involucre five, shorter than the rays of the umbel; one or two divided; those of the little umbels seven; a few of them crenate; petals equal, lanceolate, rolled inwards. *Seeds* reddish, striated and somewhat muricated. A native of the Cape of Good Hope, on the coast, introduced into England in 1787, by Masson. 4. *C. africana*. Linn. Sp. Pl. 2. Mart. 3. Willd. 4. Jacq. hort. tab. 194. (Cicut. africana; Lam. 3. Ill. tab. 195. fig. 2. *Caucalis africana*; Boerh. Lugd. b. 1. tab. 63. *Cappophyllum*; Gert. 2. tab. 85. fig. 6.) "Seeds prickly." Linn. "Seeds muricated; petioles and peduncles even-furrowed." Willd. "Leaves twice winged, glaucous; petioles and peduncles even, furrowed; seeds tooth-muricated." Lam. *Root* annual, *Stems* three or four inches long, herbaceous, cylindrical, smooth, glaucous; with a few leaves, and one or two short axillary branches. *Root-leaves* almost as long as the stem; leaflets flat, not channelled, small, gashed. *Flowers* white, almost regular, in small terminal umbels; leaflets of the general involucre from three to five, membranous towards the base;

bare; several of the florets barren. *Fruit* in the centre, sessile. Linn. *Fruit* elliptical, lenticularly compressed, solitary in the centre of the partial umbels, nearly sessile. *Seeds* slightly convex on one side, with three, sometimes only two, tubercled or tooth-muricated ribs; flat or a little concave on the other; marked with a longitudinal middle line, and two curved, nearly obsolete, lateral ones. Gært. A native of the Cape of Good Hope; cultivated in 1759 by Miller, who received the seeds from Boerhaave. 5. *C. tenuifolium*. Mart. 5. Vahl. Symb. 3. 49. "Root and stem-leaves simple, linear." *Stem* a foot high, herbaceous, upright, scarcely branched, slender, cylindrical, smooth, slightly striated. *Leaves* very narrow, a little broader at the base, somewhat sheathing, very smooth; lower ones about four inches long. *Peduncles* lateral and terminal, few, remote. *General involucre* five-leaved; leaflets awl-shaped, somewhat rigid, shorter than the umbel; *partial ones* the length of the little umbels. *General umbel* small, five-rayed; partial ones eight or ten-flowered. *Seeds* oblong, striated, small, smooth. A native of the Cape of Good Hope.

CONIUM Royenii. Linn. See *CAUCALIS arvensis*.

CONIUM dichotomum. Desfont. See *TORDYLIUM peregrinum*.

CONIUM, in *Ancient Geography*, a town of Asia Minor, in Pacatian Phrygia. It appears to have been founded by Cineas, king of Thessaly; and according to the notitia of Hierocles, it had been episcopal.

CONJUNCT. See **CONJOINT PAIR.**

CONJUNCT of an arch. See **SUPPLEMENT.**

CONJUNCT sentence. See **SENTENCE.**

CONJUNCTION, in *Astronomy*, the meeting of the stars or planets, in the same point or place of the heavens, and it is either *true* or *apparent*.

If the two bodies meet both in the same degree of longitude and latitude, a right line drawn from the centre of the earth through the centre of one of them, passes through that of the other; then the conjunction is said to be true and central: and if the lower hides the upper, the conjunction is said to be corporal.

If the line pass wide of the centre of the earth, the conjunction is said to be partite.

If the bodies do not meet precisely in the same degree, but are joined with some latitude, the conjunction is said to be apparent. Thus, when a right line, supposed to be drawn through the centres of two planets, does not pass through the centre of the earth, but through the eye of the spectator; it is said to be an apparent conjunction.

Some have also divided conjunctions into *great* and *great-est*: the former denoting those which occur at comparatively a shorter interval, such as the conjunctions of Jupiter and Saturn, and the latter happening after a longer interval, such as those of the three superior planets, Mars, Jupiter, and Saturn. But this division has little place in astronomy; being founded on the notion of the particular influences, &c. of the heavenly bodies in such and such aspects.

Astrologers maintain, that the deluge was owing to a conjunction of all the planets in Capricorn; and that the conflagration will be occasioned by their conjunction in Cancer: whence they pretend to foretel the end of the world.

The conjunction is the first, or the principal, of all the aspects; and that whence the other aspects commence; as opposition is the last, where they terminate. See **CHARACTER.**

The moon is in conjunction with the sun every month. Her conjunctions and oppositions are called by a general name, *syzygies*.

VOL. IX.

Eclipses of the sun never happen, but when there is a conjunction of the sun and moon in or near the nodes of the ecliptic.

CONJUNCTION, in *Grammar*, a particle which expresses a relation or dependance between words and phrases; thus called, because it serves to join or connect the parts or members of a discourse, which is its common use, and also to connect words; so as to shew the relations which those words so united have to other parts of the sentence.

Conjunctions, however, often unite sentences, when they appear to unite only words: e.g. "Duty and interest forbid vicious indulgences;" which form of expression contains in reality two sentences. See Murray's Eng. Gram. p. 105, ed. 8.

Mr. Harris defines a conjunction to be a part of speech, void of signification itself, but so formed as to help signification, by making two or more significant sentences to be one significant sentence; and he distributes them into such as connect sentences and their meaning, and such as conjoin the sentences whilst they disjoin the sense. The former are *conjunctive*, and are either copulative or continuative, the former joining all sentences, however incongruous in signification, and the latter joining only those which have a natural connection; and the latter *disjunctive* some of which are simple, as, *either* it is day or it is night, and *adversative*, as, it is not day *but* it is night. Hermes, p. 240, &c. See **ADVERSATIVE** and **CONTINUATIVE.**

Mr. Horne Tooke, in his "Diversions of Purley," has made some remarks, in his usual manner, on the definition of a conjunction given by Mr. Harris, charging the author not only with self-contradiction, but with great want of perspicuity. Accordingly he thus states Mr. Harris's definition: "A sound significant devoid of signification, (referring to Mr. Harris's definition of a word), having at the same time a kind of *obscure* signification; and yet having neither signification nor no signification; but a *middle something* between signification and no signification, sharing the attributes both of signification and no signification; and linking signification and no signification together." This acute and ingenious writer denies conjunctions to be a separate sort of words or parts of speech by themselves. For they have not a separate manner of signification; although they are not devoid of signification. And the particular signification of each must be sought for from amongst the other parts of speech, by the help of the particular etymology of each respective language. By such means alone can we clear away the obscurity and errors in which grammarians and philosophers have been involved by the corruption of some common words, and the useful abbreviations of construction. (See **ABBREVIATION.**) And, at the same time, we shall get rid of that farago of useless distinctions into conjunctive, adjunctive, disjunctive, subdisjunctive, copulative, negative copulative, continuative, &c. &c. &c., which explain nothing; and (as most other technical terms are abused) serve only to throw a veil over the ignorance of those who employ them. In dismissing conjunctions from the rank which they have long held as distinct parts of speech, Mr. Tooke cites several authorities; and among others, bishop Wilkins, who, in his "Essay towards a real Character and a philosophical Language," (part iii. c. 4. p. 312.) says, "According to the true philology of speech, I cannot conceive this kind of words" (speaking of adverbs and conjunctions) "to be properly a distinct part of speech, as they are commonly called. But until they can be distributed into their proper places, I have so far complied with the grammars of initiated languages as to place them here together." Mr. Locke, who was much indebted to Wilkins, expresses his dissatisfaction

these are but medicines and ceremonial forms of words (commonly called *charms*) without apparition. Cowel.

Hawkins, in his "Pleas of the Crown," (l. i. c. 3.) says, that *conjurers* are those, who, by force of certain magic words, endeavour to raise the devil, and oblige him to execute their commands. *Witches* are such who, by way of conference, bargain with an evil spirit, to do what they desire of him; and *sovereigns* are those who, by the use of certain superstitious words, or by the means of images, &c. are said to produce strange effects, above the ordinary course of nature. All these were anciently punished in the same manner as *heretics*, by the writ "de heretico comburendo," after a sentence in the ecclesiastical court; and they might be condemned to the pillory, &c. upon an indictment at common law. 3 Inst. 44. H. P. C. 38. The president Montefquieu also (Sp. Laws, b. xii. c. 5.) ranks sorcery and heresy together; laying it down, at the same time, as an important maxim, that we ought to be very circumspect in the prosecution of magic and heresy; because the most unexceptionable conduct, the purest morals, and the constant practice of every duty in life, are not a sufficient security against the suspicion of crimes like these. See *Witchcraft*.

Our fore-fathers were stronger believers in the ridiculous stories that have been generally told concerning witchcraft and sorcery than any who live in these more enlightened times, when they enacted by stat. 33 Hen. VIII. c. 8. all witchcraft and sorcery to be felony without benefit of clergy; and again by stat. 1 Jac. I. c. 12. that all persons invoking any evil spirit, or consulting, covenanting with, entertaining, employing, feeding, or rewarding any evil spirit; or taking up dead bodies from their graves to be used in any witchcraft, sorcery, charm, or enchantment; or killing or otherwise hurting any person by such infernal acts; should be guilty of felony without benefit of clergy, and suffer death. And if any person should attempt by sorcery to discover hidden treasure, or to restore stolen goods, or to provoke unlawful love, or to hurt any man or beast, though the same were not effected, he or she should suffer imprisonment and pillory for the first offence, and death for the second. These acts continued in force till lately, to the terror of all ancient females in the kingdom; and many poor wretches were thus sacrificed to the prejudice of their neighbours, and their own illusions: not a few having, by some means or other, confessed the fact at the gallows. But though some of the tales that led to these penal statutes still exist among the uninformed vulgar, as the triumph of imposture over credulity, and as bugbears to children, inexcusably employed for this purpose; all executions for this dubious crime are now at an end:—our legislature having at length followed the wise example of Louis XIV. in France, who thought proper by an edict to restrain the tribunals of justice from receiving informations of witchcraft. (See Voltaire's Age of Lewis XIV. c. 29. Mod. Un. Hist. vol. xxv. p. 215.) Yet Voughlans (De Droit Criminel, 353. 459.) still reckons up sorcery and witchcraft among the crimes punishable in France. With us the above recited statutes against conjuration and witchcraft are repealed; and no prosecution shall be carried on for the future against any person for conjuration, witchcraft, sorcery, or enchantment: but where persons pretend to exercise any kind of witchcraft or conjuration, &c. or undertake to tell fortunes, or, from their skill in any occult science, to discover where goods stolen or lost may be found; they shall upon conviction be imprisoned a year, and stand in the pillory once in every quarter, in some market-

town, and may be ordered to give security for their good behaviour, by stat. 9 Geo. II. c. 5.

CONKAIR, in *Geography*, a town of Hindoostan, in the province of Berar, situated between a high rocky hill and the south bank of the Mahanuddoe river, which rises at a place called Sehawah, about 7 cois S. of Conkair. The rajah of Conkair has built a fortress on the summit of the hill, and mounted it with two guns.

CONKERE, a post of Chinese Tartary. N. lat. 44° 56'. E. long. 101° 49'.

CONLIE, a small town of France, in the department of the Sarthe, and chief place of a canton, in the district of Le Mans, 12 miles N.W. from Le Mans. It has 1405 inhabitants. The canton reckons 16 communes, with 13,055 inhabitants upon a territorial extent of 220 kilometers.

CONLIEGE, a small town of France, in the department of Jura, and chief place of a canton in the district of Lons le Saulnier, with 1201 inhabitants. The canton itself reckons 20 communes and 9089 inhabitants upon an extent of 142½ kilometers.

CONLOBONGI, a town of the island of Borneo; 120 miles N. of *Banjer-Massing*.

CONN, in *Sea Language*. See *COND*.

CONN, *Lough*, in *Geography*, a lake of the county of Mayo, Ireland, which is at the foot of mount Neptune, and extends 9 miles in length, but not more than two in breadth. There is a great number of islands in this lake, some of which are well planted, and being very fertile in fine grass, serve for pastures to sheep and other cattle. That kind of trout called *Gillaroo*, is also found here in abundance. Dr. Shaw observes of these, that they do not appear to be specifically different from the common trout, but by living much on shell-fish, and swallowing small stones at the same time, their romachs acquire a much greater degree of thickness, and a kind of muscular appearance, so as to resemble a sort of gizzard. Lough Conn stretches from N.W. to S.E. between the Killalla and Castlebar.

CONNA, in *Botany*, Rheed. See *CASSIA Fistula*.

CONNA, in *Ancient Geography*, a town of Asia Minor, in the Greater Phrygia. Ptolemy. The 6th council of Constantinople places it in Pamphylia.

CONNAC, denotes in Arabia, Palestine, Barbary, &c. the place, whether covered or not, where travellers or caravans halt or break off their journey for a time, in order to rest and refresh themselves and their beasts of burthen. Similar to this was the "malon," or inn (Gen. xlii. 27. xliiii. 21, &c.) where the sons of Jacob opened their flocks to give their asses provender. The appellation Connac in the East corresponds with the *πανδοχειον* and *καταφυγια* in the Old or New Testament, which are rendered inns or hospitia. But excepting the caravanaries which may in some measure answer to the *πανδοχεια* and *καταφυγια*, there are, properly speaking, no houses of entertainment in Barbary; at least, in the sense usually applied to inns or hospitia, *i. e.* where travellers can be provided with lodgings, provisions, and other necessaries for their money.

CONNAMARA, the name of a district, in the county of Galway, Ireland, noted for the woollen stockings knit there, and for the wild state of the country. It is in the barony of Ballinahinch, and an account of it will be found under that name. See *BALLINAHINCH*.

CONNARUS, in *Botany*, (*Κωνάρος*, the name of a tree described by Athenæus), Linn. Gen. 830. Schreb. 1116. Willd. 1268. Juss. 399. 452. 453. Clals and order, *monadelphica decandria*. Nat. Ord. *Dumoseæ*, Linn. *Terr. Indivææ*, Juss.

Gen. Ch. *Cal.* one-leaved, with five segments; or five-leaved. *Cor.* petals five, lanceolate, erect, equal. *Stam.* filaments ten, awl-shaped, connected at the base, (in pairs, Lam.), alternately larger and smaller; anthers roundish. *Pist.* germ single (except in one species), oblong, villous; style cylindrical; stigma obtuse. *Peric.* capsules gibbous, one-celled, either two-valved or dehiscent on one side. *Seed* single, large.

Eff. Ch. *Cal.* five-cleft or five-leaved. *Cor.* five-petalled. *Capf.* one-celled. *Seed* single.

Species, 1. *C. asiaticus*. Ceylon Sumach. Willd. 2. (*C. monocarpus*. Linn. Mart. 1. Rhas zeylanica trifoliata phaeocol facie, floribus copiosis spicatis; Burm. Zeyl. 199, tab. 89. Phaeocolus arborifcens zeylanica monocarpus; Rai. Supp. 438.) "Leaves ternate; leaflets roundish, egg-shaped, one-nerved, veined." A tree. *Leaves* alternate, petioled; leaflets acuminate, quite entire, smooth, equal, petioled. *Racemes* erect, terminal. A native of the East Indies. 2. *C. pentagynus*. Lam. 1. Willd. 3. (Cavan. Diff. 7. 376, tab. 223.) "Leaves ternate; leaflets roundish, egg-shaped, three-nerved; flowers pentagynous." A tree. *Branches* cylindrical, smooth, leafy. *Leaves* alternate, acute, entire, smooth, somewhat coriaceous, finely veined underneath. *Flowers* small, numerous, in axillary and terminal spikes, forming a kind of panicle; calyx villous on the outside; pistils from three to five, villous, short, appearing united at the base; styles shorter than the filaments; stigmas flat or truncated. Described by La Marek from dried specimens without fruit, communicated by Sonnerat. A native of Madagascar and Guinea. 3. *C. africanus*. Mart. 2. Lam. 3. Willd. 1. Vahl. Symb. 3. 86. Cavan. Diff. 7. 375, tab. 221. (Omphalobium indicum; Gaert. vol. i. 253, tab. 46, fig. 3, and vol. ii. præf. p. 33.) "Leaves ternate; leaflets oblong, veined, acuminate." Willd. "Leaves ternate, leaflets egg-shaped, acute at both ends, nerved underneath; flowers paniced, monogynous." Lam. A shrub. *Branches* cylindrical, smooth. *Leaves* alternate, petioled; leaflets four or five inches long, smooth, even-surfaced above, nerved and veined underneath. *Flowers* small, numerous; panicle compound, oblong, terminal. *Capsules* oblong, almost cylindrical, gibbous on one side, pointed at both ends, pedicelled, two-valved. Lam. *Capsule* valveless, dehiscent on the gibbous or outer side. *Seed* large, somewhat kidney-shaped, smooth, shining, dark chestnut-coloured, with an oblong pit on each side; aril incomplete, fleshy-glandular, variously lobed, so as to appear curled, its whole length closely adhering to the lower and exterior part of the seed. Gaert. 4. *C. pinnatus*. Lam. 2. Willd. tab. 572. Willd. 5. Cavan. Diff. 7. 375, tab. 222. (Perimeurigi; Rheed. Mal. 6. 43, tab. 24.) "Leaves ternate and pinnated; leaflets oblong, veined; petals with two bristles at the base." Willd. A tree. *Root* perennial. *Leaflets* of the same consistence, and similarly veined with those of *C. pentagynus*. *Flowers* white, in terminal and axillary panicles; calyx villous on the outside; petals lanceolate, with two remarkable bristles a little above the base, one on each side, pointing downwards, acute and somewhat divaricating; germ single, villous. *Capsules* oblong, gibbous one side, suddenly narrowed at the base, ending rather abruptly in a point, one-celled. *Seed* one. A native of the East Indies; described from specimens communicated to La Marek by Sonnerat. 5. *C. Santaloides*. Mart. 3. Willd. 4. Vahl. Symb. 3. 87. (Santaloides; Flor. Zeyl. 408.) "Leaves pinnated; leaflets egg-shaped, acuminate; peduncles axillary, aggregate; flowers in racemes." A tree. *Branches* cylindrical, smooth. *Leaves* unequally pinnated, scattered, remote, petioled; leaflets sometimes an inch and half long, quite entire, perfectly smooth, shining above, re-

ticularly veined underneath, on very short channelled petioles. *Peduncles* from four to six together, half the length of the leaf, smooth; partial ones scattered, with three or four pedicelled flowers towards the top. A native of the East Indies. 6. *C. mimifolius*. Mart. 4. Willd. 7. Vahl. Symb. 387. "Leaves pinnated; leaflets about twenty-one, oval-oblong, emarginate; racemes axillary." A tree. *Branches* cylindrical, villous towards the top. *Leaves* growing near the ends of the branches, alternate, approximate, on slightly villous petioles; leaflets opposite or alternate, on very short petioles, inner ones smaller, obtuse, smooth, finely veined on the upper surface, paler underneath. *Peduncles* axillary, usually three together, the length of the leaves, slightly hoary; pedicels scattered, filiform, the lowest commonly two-flowered. *Flowers* small, with a minute bracte at the base of each pedicel. A native of the islands of Nicobar.

CONNARUS decumbens; Willd. Vahl. See HERMANNIA triphylla.

Propagation and Culture. *C. asiaticus* is usually propagated in this country by laying down the young branches, which, if tongued in the manner practised for carnations, and duly watered, will put out roots in twelve months. They may then be cut off from the old plants, and planted in separate small pots, which should be filled with light fresh earth and plunged into a moderate hot-bed. They should afterwards be placed in a dry stove; but for about three months in summer they will bear the open air in a sheltered situation. The cuttings of this plant will sometimes take root, but without great care seldom succeed.

CONNATA FOLIA. See LEAF.

CONNAUGHT, in *Geography*, the name of the western province of Ireland, which contains the counties of Galway, Mayo, Sligo, Leitrim, and Roscommon. At the time of Strongbow's invasion, it was a distinct kingdom, and its king was monarch of Ireland. This dignity continued until the reign of Henry III.; after which time, the province was divided amongst petty chieftains, some of whom were of English extraction, until the reign of queen Elizabeth, when the earl of Sussex, lord deputy, divided it into counties, A. D. 1562; and sir H. Sidney, lord deputy, established a lord president of Connaught, A. D. 1567. In 1604, sir Arthur Chichester, lord deputy, established a circuit for judges of assize in Connaught. At present, the distinction of provinces is not attended to in any public acts; and indeed, as calculated to keep up a provincial spirit, which has often led to bitter animosities, it ought to be as much as possible discountenanced.

CONNAUGHT Worms. See WORM.

CONNAUX, in *Geography*, a town of France, in the department of the Gard, and district of Uzès; three leagues N.E. of Uzès.

CONNE, CONE, or COYNE LOUGH, in the county of Down, Ireland. See STRANGFORD.

CONNEAUT, and also ASHTABULA, are small rivers of America, in the state of Ohio, which form good harbours for boats and small craft on the borders of lake Erie.

CONNECTICUT, one of the United States of America, called by the ancient nations *Quinnibicut*, lying between 41° and 42° 2' N lat., and between 71° 20' and 73° 15' W. long.; extending in its greatest length 100 miles, and greatest breadth 72 miles; and comprehending about 4674 miles, or about 2,640,000 acres. It is bounded on the north by Massachusetts; on the east by Rhode island; on the south by the Sound, which separates it from Long island; and on the west by the state of New York. Connecticut is divided into eight counties, viz. Fairfield, the chief towns of which are

CONNECTICUT.

are Fairfield and Danbury; New Haven, with a capital of the same name; Middletown, the chief towns of which are Middletown and Haddam; and New London, the chief towns of which are New London and Norwich; which four counties extend along the Sound from W. to E.: Litchfield, Hartford, Tolland, and Windham, each having a capital of the same name respectively, which four counties extend in the same direction with the former on the border of the state of Massachusetts. These counties contain about 100 townships, which are subdivided into parishes, each of which has one or more places of public worship, school-houses at convenient distances, and a college at New Haven. See COLLEGE. Each township is a corporation, invested with sufficient powers for its own regulation. The number of representatives is sometimes 180; but more commonly about 160. The principal rivers in this state are Connecticut, Housatonic, and the Thames, with their branches; which see respectively. The whole sea-coast is indented with harbours, which are safe and commodious; but the principal are those of New Haven and New London. This state sends seven representatives to Congress. The inhabitants are almost wholly of English descent, besides whom they have no Dutch, French, or Germans, and few Scots or Irish. The original rock, from which have sprung all the present occupiers of Connecticut, and the numerous emigrants from hence to every part of the United States, consisted of 3000 persons, who settled in the towns of Hartford, New Haven, Windsor, Guilford, Milford, and Weathersfield, about the years 1635 and 1636. In 1756 the population amounted to 130,611 persons; in 1774 to 197,356; in 1782 to 202,877 whites, and 6273 Indians and negroes; in 1790 to 237,946, of whom 2764 were slaves; and by the census in 1800, to 251,002, of whom 121,113 were free white males, 123,528 free white females, 5300 free persons, except Indians, not taxed, and 951 slaves.

Connecticut, notwithstanding the changes of temperature to which it is subject, is very healthful. The surface of the country exhibits mountains, hills, and vallies; and though it is very well watered, some small parts of it are barren. Its chief productions are Indian corn, rye, wheat, oats, barley, and buck-wheat; flax in abundance, some hemp, potatoes of several kinds, pumpkins, turnips, peas, beans, &c., together with fruits of all kinds which are common to the climate. The soil is well adapted for pasturage and mowing, so that the farmers are enabled to feed a great number of neat cattle and horses. This state carries on its chief trade with the West India islands, in vessels from 60 to 140 tons. Its exports consist of horses, mules, oxen, oak-slaves, hoops, pine-boards, oak-planks, beans, Indian corn, fish, beef, pork, &c.; and a large number of coasting vessels is employed in carrying the produce of Connecticut to the other states; from which they receive in return, rice, indigo, and money. But as New York is nearer, much of its produce, particularly that of the western parts, is carried thither; such as pot and pearl-ashes, flax-seed, beef, pork, cheese, and butter, in large quantities. The value of the whole exported produce and commodities from this state, before the year 1774, was then estimated at about 200,000*l.* lawful money, annually. In the year ending September 30, 1791, the amount of foreign exports was 710,340 dollars, besides articles carried to different parts of the United States to a great amount; in 1792 it was 749,025 dollars; in 1793, 770,239 dollars; in 1794, 806,746 dollars; and in 1804, 1,516,110 dollars, comprehending 1,486,862 domestic and 29,228 foreign. This state owns and employs in the foreign and coasting trade more than 32,897 tons of shipping. The farmers in Connecticut are generally clothed

in plain, decent, homespun cloth; and both their linens and woollens are domestic manufactures, strong though coarse; and many of their cloths are fine and handsome. This state has large orchards of mulberry trees, and silkworms have been reared with such success, that they promise a supply of silk, not only to the inhabitants, but also for exportation. New Haven has linen and button manufactories; they have established a woollen manufactory at Hartford, besides glass works, a snuff and powder mill, iron works, and a slitting mill. Iron works are also established at Salisbury and Norwich, and in other parts of the state. Stafford has a furnace, at which are made large quantities of hollow ware, and other ironmongery, sufficient for the supply of the whole state. Paper is manufactured at Norwich, Hartford, New Haven, and in Litchfield county. Ironmongery, hats, candles, leather, shoes and boots are manufactured in this state.

Connecticut is laid out in small farms, from 50 to 300 and 400 acres each, which are held by the farmers in fee-simple, and are generally well cultivated. The state is chequered with innumerable roads or highways, crossing each other in every direction; nor can a traveller pass more than two or three miles, even in the most unsettled parts, without finding a house, or cottage, and a farm in such a condition of improvement as to afford necessaries for the support of a family. The whole state, it is said, resembles a well-cultivated garden, which by industry produces the necessaries and conveniences of life in great plenty, without its luxuries. To the agricultural mode of life prevailing in this state, which is favourable to temperance and health, and to the ease with which a comfortable subsistence may be obtained, so encouraging to early marriage, and also to the religious liberty that is maintained, we may ascribe the rapid advance of this state in population. Luxury has not yet found its way into this state, nor contaminated the manners of the people. The common mode of travelling, both for men and women, is on horseback; in this state there are few coaches, but many chaises and whistkeys. In the winter is used the sleigh, which is a vehicle drawn by two horses, and carrying six persons in its box, which hangs on four posts standing on two steel sliders, or large skates. Dancing, fishing, hunting, skating, and riding in sleighs on the ice, are the chief amusements in this state. The men, in general, throughout this province, are tall, stout, and robust; the women are fair, handsome, and genteel; strictly virtuous, and well-informed. We may observe, in general, that there is no part of the world in which the education of all ranks of people is more an object of attention than in this state. Almost every town is divided into districts, each of which has a public school kept in it during a great part of the year. Somewhat more than one-third of the money arising from a tax on the polls and rateable estate of the inhabitants, is appropriated to the support of schools in the several towns, for the education of children and youth. The law enjoins that a grammar-school shall be kept in every county-town throughout the state. A certain gravity and seriousness of deportment, accompanied with a degree of shyness and reserve, appear in the first intercourse of the inhabitants with strangers; but after a short acquaintance, they become very familiar and inquisitive. Their hospitality is exemplary and laudable. In their character there is a certain trait, which renders them less amiable; and that is their fondness for settling even their trivial disputes "according to law;" and the prevalence of this litigious spirit affords employment for a numerous body of lawyers. This party spirit is, however, subsiding; their public proceedings are conducted with calmness and candour; and as they are well informed

with

with regard to their rights, and judicious in the methods they adopt for securing them, the state enjoys a great share of political tranquillity. Another circumstance, favourable to internal peace and harmony, is the abatement of that rage for theological disputation which formerly prevailed. The religion, or at least the church government and discipline, of this state, is such as seems to be peculiarly adapted to a republican government. Each church has a separate jurisdiction, and claims authority to chuse its own minister, to exercise judgment, and to enjoy religious institutions, within itself. The churches, however, amounting, says Morse, to about 200, of the congregational denomination, in which are about 20,000 communicants and 170 pastors, are not strictly independent of each other; they associate for mutual convenience and benefit. The associations have power to licence candidates for the ministry, to consult for the general welfare, and to recommend the adoption of measures by the churches, but have no authority to enforce them. Of these associations there are eleven in the state, and they meet twice in a year. All these are combined in one general association formed in 1709, consisting of delegates from the several associations which meet annually. All forms of religion that are consistent with the peace of society are tolerated in Connecticut; and a spirit of liberality and catholicism is said to be increasing. In this state there are few religious sects; the majority of the people consist of congregationalists. Besides these there are episcopalians and baptists; the episcopal churches are respectable, and are under the superintendance of a bishop.

The constitution of Connecticut is founded on its charter, which was granted by Charles II. in 1662, and on a law of the state. Agreeably to this charter, the supreme legislative authority of the state is vested in a governor, deputy-governor, 12 assistants or counsellors, and the representatives of the people, styled the General Assembly. The governor, deputy-governor, and assistants, are annually chosen by the freemen in the month of May. The representatives (whose number is not to exceed two from each town) are chosen by the freemen twice a year, to attend the two annual sessions, on the second Tuesday of May and October. The general assembly is divided into two branches, called the upper and lower houses: the former is composed of the governor, deputy-governor, and assistants; and the latter consists of the representatives of the people. No law can pass without the concurrence of both houses. They have several law courts, of which the superior consists of five judges. The general assembly only have power to grant pardons and reprieves; to issue commissions of bankruptcy; or to protect the persons and estates of unfortunate debtors. The feudal system of descents was never adopted in this state: the whole real estate of intestates is divided equally among the children, males and females; and all estates given in tail must be given to some person then in being, or to their immediate issue, and shall become fee-simple estates to the issue of the first donee in tail. The widow of an intestate is entitled to a third part of the personal estate for ever, and to her dower, or third part of the houses and lands belonging to the intestate at the time of his death, during her life. Attornies are admitted and qualified by the county courts. Before their admission to the bar, they must study two years with a practising attorney in the state, if they have had a college education, and three years if they have not: their morals must be unblemished, and they must be examined by the attorneys of the court of the county where they are admitted, and be by them recommended to the court. There are, upon an average, about 15 attornies to each county, and 120 in the whole state.

The American revolution, which so essentially affected the government of most of the colonies, produced no very perceptible alteration in the government of Connecticut. While under the jurisdiction of Great Britain, they elected their own governors, and all subordinate civil officers, and made their own laws, in the same manner, and with as little controul, as they now do.

The present territory of Connecticut, at the time of the first arrival of the English, was possessed by the Pequot, the Mohegan, Podunk, and many other smaller tribes of Indians. The Pequots were numerous and warlike; and their country extended along the sea-coast from Pautucket to Connecticut river: and about the year 1630, this powerful tribe extended its conquests over a considerable part of Connecticut, Long Island, and a part of Narraganset, the ancient Indian name of New London; the seat of the sovereignty of the whole nation was Pequot. The Mohegans were numerous, and their territory extensive; it comprehended most of New London county, almost the whole county of Windham, and a part of the counties of Tolland and Hartford. The Pedunks inhabited East Hartford, and the circumjacent country. In 1774, there remained of the descendants of the ancient nations only 1363 persons; most of whom lived at Mohegan, between Norwich and New London. From the rapid decrease of the Indians, it is concluded that their number in this state does not now exceed 400.

The first grant of Connecticut was made by the Plymouth council to the earl of Warwick in 1630; and, in the following year, he assigned this grant to lord Say or Seal, lord Brook, and others. In 1632, an attempt was made on the English settlements by a number of Indian traders, who settled at Windsor. In the same year, a little before the arrival of the English, some Dutch traders settled at Hartford, the remains of whose settlements are still visible on the banks of Connecticut river. In 1634, lord Say and Seal, &c. sent over a small number of persons, who built a fort at Saybrook, and made a treaty with the Pequot Indians for the lands on Connecticut river. A number of adventurers afterwards settled in this province; and in 1644, they purchased of the agent of lord Say and Seal, and lord Brook, their right in the colony of Connecticut for 1600 l. Connecticut and New Haven continued two distinct governments for many years; they extended their territories and rapidly increased. At length, John Winthrop, esq., who had been chosen governor of Connecticut, was employed to solicit a charter, which was obtained from Charles II. in 1662. Some jealousy subsisted for a little while between this colony and that of New Haven; but in 1695 these two colonies formed an union, which has ever since amicably subsisted; and the charter of king Charles continues to be the basis of their government. At the close of the revolution, Connecticut ceded all her charter claims west of Pennsylvania to Congress, reserving only a tract of land as wide as the state of Connecticut, and 120 miles in length; bounded east on the western line of Pennsylvania, and north by lake Erie, containing nearly four millions of acres. The cession was accepted by Congress, which establishes to Connecticut her title to these lands. Morse's Geog.

CONNECTICUT, the most considerable river in the eastern part of the United States, which rises in the highlands which separate the states of Vermont and New Hampshire from Lower Canada. This river has been surveyed about 25 miles beyond the 45th degree of latitude to the head spring of its northern branch; from which to its mouth it is upwards of 300 miles, pursuing its course through a settled country, and having on its banks a great number of the most flourishing and pleasant towns in the United States.

It is from 80 to 100 rods wide, at the distance of 130 miles from its mouth. Its course between Vermont and New Hampshire is generally S.S.W., and also through Massachusetts, and part of Connecticut, until it reaches the city of Middleton; after which it runs in a S.E. direction to its mouth, fertilizing the lands through which it flows, though its navigation is much obstructed by a great variety of falls. At its mouth also is a bar of sand, which very much impedes its navigation; however this river is navigable to Hartford city, upwards of 50 miles from its mouth; and the produce of the country for 200 miles above it, is brought thither in boats, which are flat-bottomed, long and narrow, and so light as to be portable in carts. Before the construction of locks and canals on this river, they were taken out at three different carrying places, all of which made 15 miles; but these obstructions will, probably, be soon wholly removed. Sturgeon, salmon, and shad, are caught in plenty in their season, from the mouth of the river upwards, excepting sturgeon, which do not ascend the upper falls; besides a variety of small fish, such as pike, carp, perch, &c.

CONNECTICUT is also the name of a stream in Long Island, in the state of New York, which falls into a bay at the S. side of the island.

CONNECTING *Oil*. See OIL.

CONNECTION, or CONNEXION, a relation whereby one thing adheres to, or depends on another.

Euclid's propositions have such a connection among themselves, that the latter cannot subsist without the former.

CONNECTION, or continuity, in the *Drama*, consists in the joining of the several scenes together.

When the scenes of an act succeed one another immediately, and are so joined as that the stage is never left empty, the connection is said to be observed.

CONNECTIVES, in *Grammar*, one of the four species under which, according to Mr. Harris, all words may be included. They are of two kinds, and as they connect sentences or words, are called by the different names of CONJUNCTIONS and PREPOSITIONS. *Hermes*, p. 31, and 237.

CONNELLSVILLE, in *Geography*, a town of America, in the county of Washington and state of Pennsylvania, pleasantly situated on the Yohiogany, settled about ten years, and containing about 80 houses and 400 inhabitants.

CONNER, ALE. See ALE-*Conner*.

CONNERE', in *Geography*, a town of France, in the department of the Sarthe; 4 leagues E.N.E. of Le Mans.

CONNETABLE, or Connétable de France, countable of France. In the origin of this title, the connetable, who succeeded the grand sénéchal of France, was considered as one of the first domestics of the French kings, in short as master of the horse. Afterwards he became the first officer of the crown, chief and conductor of the armies, first sergeant of the king for executing his orders and commands; for laying hands on the grandees, imprisoning them, and representing them in justice. This employment became by degrees so eminent, that the marshals of France were only lieutenants. This office was abolished in the reign of Louis XIII. Anne de Montmorency, who lost his head on a scaffold, was the last who filled it.

CONNETABIE de France. This was a particular corps under the orders of the feigniors marshals of France, and consisted of 48 guards on horseback.

CONNIE, in *Geography*, a small river of France, in the department of Eure and Loir, remarkable for being so completely dried up in winter, that the fish are obliged to hide themselves in the cavities where there is a little water re-

maining; in summer, on the contrary, its stream is always copious.

CONNIVENTES VALVULÆ, in *Anatomy*, are folds of the internal, or villous coat, of the small intestine. See INTESTINE.

CONNOIE BAY, in *Geography*, a bay on the S. coast of Newfoundland; 50 miles E. of Cape Ray.

CONNOISSEUR, a French term, of late use in English: it literally denotes a person well versed in any thing; being formed of the verb *connoître*, to know, understand. Hence it comes to be used in our language for a critic, or person who is a thorough judge, or master in any way; particularly in matters of painting and sculpture.

CONNON, in *Geography*, a river of France, called also *Aa*, which runs into the Beuvron, six miles S.E. of Beuvron.

CONNOR, BERNARD, in *Biography*, a native of Dublin, in Ireland, where he was born in 1666, received his education at an academy in France, and at a proper age was sent to Montpellier, where he was made doctor in medicine in the year 1690. He was soon after engaged to superintend the education of two young Polish noblemen, with whom, after residing some time at Paris, he travelled over Italy, and the island of Sicily, and then went to Poland, where he was appointed physician to the king. This did not, however, detain him long in Poland, as we find him practising in London, and made fellow of the College of Physicians, and of the Royal Society, in the year 1696. He had published, the preceding year, "Dissertationes Medico-Physicæ de Antris lethiferis, de Montis Vesuvii incendio, de lupendo ossium coactis. Oxoni, 8vo." He had seen, while in Italy, an eruption of Mount Vesuvius, and had visited the Grotto del Cano, of both which he gives descriptions, and of a skeleton, in which the vertebrae, ribs, and ossa innominata, were all firmly united. "Tentamen Epistolare de Secretione Animali," in which he attempts to account for the difference in the colour, taste, and other sensible qualities of the humours, secreted from the blood. "Evangeliæ Medici, seu Medicinæ Mysticæ de suspensis Naturæ legibus, Lond. 1697, 8vo.," and in 1698, in the latter part of which year he died, "A compendious Plan of the Body of Phisic," apparently a text-book, from which he had given, or had proposed giving, a course of lectures. To this work he added, a short, but entertaining, account of Poland. *Heller. Bib. Med. Eloy. Dict. Hist.*

CONNOR, in *Geography*, a village in the county of Antrim, Ireland, that gives name to a bishopric which was united to that of Down in 1454, and which extends over most of the county of Antrim. It contains 395,000 Irish acres, which are divided into 76 parishes; but from unions, there are only 40 benefices and 43 churches. The church of Lisburn was, by letters patent of James I., made the cathedral, that of Connor is in ruins. Connor is 97 Irish miles N. from Dublin, and 17 N. from Belfast. *Beaufort*.

CONNOR, a river of the island of Jamaica, which runs into the sea, between Rocky point, and port Morant.

CONNTHAL. See CAVERIUM.

CONO, in *Commerce*, a Florence wine measure of 10 barrels, each barrel being about 12 gallons.

CONOBEA, in *Botany*, Aubl. See PROPEA.

CONOCARPODENDRON. See CONOPEA and PINUS.

CONOCARPUS, (from *κωνος*, a cone, and *καρπος*, fruit) *Linn. Gen.* 236. *Schreb.* 321. *Willd.* 366. *Lam. Ill.* 353. *Gart.* 1052. *Juss.* 75. *Conocarpe. Enc. Clafs and order, pentandria*

pentandria monogynia, Nat. Ord. *Aggregate*, Linn. *Elemi*. Juss.

Gen. Ch. *Cal.* one-leaved, superior, very small, five-cleft; segments acute, erect. *Cor.* none (or five-petalled?) *Stam.* Filaments five or ten, awl-shaped, erect; anthers globular. *Pist.* Germ inferior, compressed, obtuse; style simple, short; stigma obtuse. *Peric.* none; Linn. Schreb. Samara; Gaert. Capsule very small; rounded, compressed, convex and gibbous on the outside, concave within, with a membranous margin on each side, not deliquescent, one-celled. *Seed* solitary, inversely egg-shaped. Lam.

Eff. Ch. Corolla five-petalled or none. Seeds naked, solitary, inferior. Flowers aggregate. Willd.

Flowers aggregate. Calyx superior, five-cleft. Corolla none. Capsules many, one-seeded, affixed to a common axis, imbricated into a cone. Lam.

Sp. 1. *C. cresta*. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Jacq. Amer. 78. tab. 22. fig. 1. Lam. Ill. tab. 126. fig. 1. Gaert. tab. 177. (*C. mangharica*; Cates. Car. 2. tab. 33. *C. foliis oblongis, floribus in caput conicum*. Brown. Jam. 159. *Alnus*; Pluk. Alm. 18. tab. 240. fig. 3. *Alni fructu laurifolia* aibor; Sloan. Jam. 135. hilt. 2. tab. 161. fig. 2. *Rudbeckia laurifolia maritima*; Amm. herb. 5St. Innominata; Plum. MSS. Burm. Amer. tab. 144. fig. 2.) "Erect; leaves lanceolate." Linn. "Erect; leaves lanceolate; cones panicled, pedicelled." Lam. A tree, about thirty feet high. Younger branches angular. Leaves alternate from two inches and a half, to three inches long, one inch broad, acute, quite entire, smooth, greasy to the touch, on short petioles, which have frequently two lateral glands near the base. Flowers greenish yellow, small, in globular heads, on shortish pedicels; common peduncles longer, axillary and terminal, branching into racemes which altogether form a kind of panicle. Capsules umbilicated, pubescent at their summit, closely imbricated into roundish cones, about the size of a pea. Jacquin attributes to his plant ten stamens, twice as long as the calyx; but other specimens have only five, about the length of the calyx. They are probably different species. A native of the West Indies, and the tropical coasts of America; where it is called button wood or button tree, by the English, and mangle saragoza by the Spaniards. It is used for fire wood, but is of little value for any other purpose. 2. *C. procumbens*. Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Willd. 2. Jacq. Amer. 79. tab. 52. fig. 2. Piet. 42. tab. 260. fig. 22. (*Rudbeckia lupina*; Amm. herb. 5St.) "Procumbent; leaves inversely egg-shaped." Linn. "Procumbent; leaves inversely egg-shaped; cones somewhat racemoid, sessile." Lam. A much branched shrub, almost entirely procumbent, following the irregularities of the rocks among which it grows. Leaves alternate, an inch or an inch and a half long, entire, shining, on short petioles; petioles with an oblong gland on the edge near the base, on each side. Flowers pentandrous and hexandrous, resembling those of the preceding species, but smaller, and producing cones of a looser texture. A native of the island of Cuba. 3. *C. racemosa*. Linn. Syst. Nat. 3. Mart. 3. Willd. 3. Jacq. Amer. 80. tab. 53. Piet. 42. tab. 79. Brown. Jam. 159. n. 1. "Leaves lanceolate; egg-shaped, somewhat obtuse; fruit not aggregate." A lofty branching tree, sometimes dividing into three or four trunks close to the ground. Younger branches opposite, red, shining. Leaves opposite, about three inches long, petioled, coriaceous, thickish, shining, greasy to the touch, deep green; petiole with two glands at the top. Flowers small, sessile, remote, in terminal panicles, composed generally of three simple, or somewhat branched, loose racemes, many of them

abortive; petals five; stamens ten, alternately shorter. Fruit separate; pericarp a coriaceous capsule, containing one or two seeds. Seeds composed of two greenish lamellæ, wrapped up into a round body, and involved in a very thin membrane. The lamellæ in the base of the pericarp become a round obtuse shining body, forming the axis of the seed, destined to put forth the roots; for when the capsule falls to the ground, it penetrates the crowned apex, and when the fibres take possession of the soil, it constitutes the rudiment of the future trunk; then the lamellæ increasing in bulk, burst the capsule, and become the radical leaves. A native of the Caribbee islands, and the neighbouring continent, on sandy and muddy shores; called by the English white mangrove, and by the Spaniards mangle bobo, or foolish mangle.

Obf. Jussieu, in his *Genera Plantarum*, questions whether this species be really a conocarpus. Gaertner observes, that Jussieu's doubt is well founded. La Marck, accordingly, in the *Encyclopedie Methodique*, excludes it from the genus, promising to describe it under manglier, one of the French names for the rhizophora of Linnæus. But Desfontaines, who, on the occasion of La Marck, afterwards wrote that article, instead of attending to his predecessor's reference, and misled by an ambiguity in the popular use of the French word, considers it as synonymous with conocarpus, and actually gives over again the character of that genus, with the description of La Marck's two acknowledged species; entirely omitting the conocarpus racemosa of Linnæus, and not making any further reference concerning it. This plant seems to be sui generis; for, although the account of the manner in which its seed germinates, which we have copied from professor Martyn's Miller, is obscurely expressed; it evidently belongs to Savigny's new natural order paleotierii, published in the *Encyclopedie Methodique*, but cannot be referred either to bruguiera or to rhizophora, the only two genera of that order, and both included in the rhizophora of Linnæus. See PALETURIER, BRUGUIERA, and RHIZOPHORA. La Marck's essential character of conocarpus is drawn up with a view to the exclusion of this species, and Willdenow's its admission; the latter, however, has very imperfectly succeeded, for his description of *C. racemosa*, which says expressly *flores remoti*, is obviously at variance with *flores aggregati* in his essential character.

CONOID, CONOIDES, in *Geometry*, a solid body, resembling a cone, except in this, that the slant sides from the base to the vertex are not straight lines, as in the cone, but curved.

The conoid is produced by the entire circumvolution of a conic section around its axis; and according to the denomination of the section from which it is generated, it is differently denominated; if, *et. gr.* the solid be produced by the motion of a parabola, it is called a *parabolic conoid*, or *paraboloid*; if by that of an hyperbola, an *hyperbolic conoid*, or *hyperboloid*; and an *elliptic conoid*, or a *spheroid*, when produced by the rotation of an ellipsis round one of its axes. See each of these articles; and for determining their superficies and solidity; see SUPERFICIES and SOLIDITY.

If a conchoid, *i. e.* any solid formed by the revolution of a conic section about its axis, such as a spheroid, paraboloid, or hyperboloid, be cut by a plane in any position; the section will be some conic section, and all the parallel sections will be like and similar figures.

Let ABC (*Plate I. Conics, fig. 10.*) be the generating section, or a section of the given solid through its axis ED, and perpendicular to the proposed section AFC,

their common intersection being AC; let GH be any other line meeting the generating section in G and H, and intersecting AC in E; and erect EF perpendicular to the plane ABC, and meeting the proposed plane in F. Then, if AC and GH be conceived to move continually parallel to themselves, will the rectangle $AE \times EC$ be to the rectangle $GE \times EH$, always in a constant ratio; but if GH be perpendicular to BD, the points G, F, H will be in the circumference of a circle whose diameter is GH, so that $GE \times EH$ will be $= EF^2$; consequently, $AE \times EC$ will be to EF^2 , always in a constant ratio; and therefore AFC is a conic section, and every section parallel to AFC will be of the same kind with, and similar to it. Hence.

1. The above constant ratio, which $AE \times EC$ has to EF^2 , is that of KI^2 to IN^2 , the squares of the diameters of the generating section respectively parallel to AC, GH; that is, the ratio of the square of the diameter parallel to the section to the square of the revolving axis of the generating plane. This will appear, by conceiving AC and GH to be moved into the positions KL, MN, intersecting in I, the centre of the generating section.

2. It appears also that the axis AC and 2 EF of the section, supposing E now to be the middle of AC, will be to each other, as the diameter KL is to the diameter MN of the generating section.

3. If the section of the solid return into itself, it will evidently be an ellipse. This always happens in the spheroid, except when it is perpendicular to the axis; which position is also to be excepted in the other solids, the section being then always a circle; in the paraboloid, the section is always an ellipse, excepting when it is parallel to the axis; and in the hyperboloid, the section is always an ellipse, when its axis makes with the axis of the solid an angle greater than that which the said axis of the solid makes with the asymptote of the generating hyperbola: the section being an hyperbola in all other cases, except when those angles are equal, and then it is a parabola.

4. If the section be parallel to the fixed axis BD, it will be of the same kind with, and similar to, the generating plane ABC; that is, the section parallel to the axis, in a spheroid, is an ellipse similar to the generating ellipse; in the paraboloid, the section is a parabola similar to the generating parabola; and in an hyperboloid, it is an hyperbola similar to the generating hyperbola of the solid.

5. In the spheroid, the section through the axis is the greatest of the parallel sections; in the hyperboloid, it is the least; and in the paraboloid, all the sections parallel to the axis are equal to one another. For the axis is the greatest parallel chord line in the ellipse, but the least in the opposite hyperbolas, and all the diameters are equal in a parabola.

6. If the extremities of the diameters, KL, MN, be joined by the line KN, and AO be drawn parallel to KN, and meeting GEH in O, E being the middle of AC, or AE the semi-axis, and GH parallel to MN: then will EO be equal to EF, the other semi-axis of the section. For, by similar triangles, $KI : IN :: AE : EO$. Or, upon GH as a diameter describe a circle meeting EQ, perpendicular to GH, in Q; and EQ is evidently equal to the semi-diameter EF.

7. If AP be drawn parallel to the axis BD of the solid, and meet the perpendicular GH in P, it will be evident that, in the spheroid, the semi-axis $EF = EO$ will be greater than EP; but in the hyperboloid, the semi-axis $EF = EO$, of the elliptic section, will be less than EP,

and in the paraboloid, $EF = EO$ is always equal to EP.

Scholium. The analogy of the sections of an hyperboloid to those of the cone, is very remarkable; all the three conic sections being formed by cutting an hyperboloid in the same positions as the cone is cut. Thus, let an hyperbola and its asymptote be revolved together about the transverse axis, the former describing an hyperboloid, and the latter a cone circumscribing it; then let them be supposed to be both cut by a plane in any position, and the two sections will be like, similar, and concentric figures: that is, if the plane cut both the sides of each, the sections will be concentric, similar ellipses; if the cutting plane be parallel to the asymptote, or to the side of the cone, the sections will be parabolas; and in all other positions the sections will be similar and concentric hyperbolas. That the sections are like figures appears from the foregoing corollaries. That they are concentric will be evident, when we consider that Cc is = Aa, producing AC both ways to meet the asymptotes in a and c. And that they are similar or have their transverse and conjugate axes proportional to each other, will appear thus:—Produce GH both ways to meet the asymptotes in g and h; and on the diameters GH, g h, describe the semi-circles GQH, g h b, meeting EQR, drawn perpendicular to GH, in Q and R; EQ and ER being then evidently the semi-conjugate axes, and EC, Ec, the semi-transverse axes of the sections. Now, if GH and AC be conceived to move parallel to themselves, $AE \times EC$ or CE^2 will be to $GE \times EH$ or EQ^2 in a constant ratio, or CE to EQ will be a constant ratio; and since cE is as Eg, and aE as Eh, $aE \times Ec$ or cE^2 will be to $gE \times Eh$ or ER^2 , in a constant ratio; but at an infinite distance from the vertex, C and c coincide, or $EC = Ec$, as also $EG = Eg$; consequently $EQ = ER$, and then CE to EQ will be = cE to ER ; but as these ratios are constant, it they be equal to each other in one place, they must be always so; and consequently $CE : cE :: QE : ER$. This analogy of the sections will not seem strange, when we consider that a cone is a species of the hyperboloid; or a triangle a species of the hyperbola, whose axes are infinitely little. See Hutton's Mensuration, part iii. § 4.

The famous solid of the least resistance, sir Isaac Newton, M. Fatio, and the Marquis De l'Hopital, have demonstrated to be a conoid.

CONON, in *Biography*, the son of Timotheus, and a celebrated general of Athens. He was one of those who succeeded Alcibiades, after that celebrated commander had fallen into disgrace with his countrymen, and distinguished himself in the Peloponnesian war. See PELOPONNESUS. In an engagement with Callicratidas, the Spartan general, he was defeated; but he afterwards obtained a complete victory, when his antagonist lost his life. About four hundred years before the Christian era, Conon and Philocles with their fleets were attacked and defeated by Lyfander, the leader of the Spartans. So complete was this victory that Conon barely escaped with his life, and sought refuge in the isle of Cyprus, while Athens itself was reduced to a state of servitude, and its constitution destroyed. In Cyprus, Conon used every means in his power to rescue his country from the state into which he had fallen; he applied to ARTAXERXES, the Persian monarch, for aid against the Spartans; obtained his desire, and was appointed admiral of a large Persian fleet, which Artaxerxes sent to succour the Athenians and other Greek states. He had not long been raised to this honourable situation, when the sailors mutinied for want of

pay: the general hatred to the court of Persia, but was not suffered to approach the sovereign, unless he submitted to a species of adoration very unworthy of a noble and dignified mind; this he refused, and though denied an audience with his majesty, his remonstrances produced the desired effect, and he was allowed to nominate his own treasurers to the fleet. Conon refused his command, attacked the Spartan admiral Pisander, whom he killed with his own hand; the Spartans were defeated with the loss of fifty ships, and the rest were glad to seek shelter in one of their own ports. Conon, having thus obtained the dominion of the seas, returned to Attica with plans for restoring his country to its former honours. Scarcely had he begun his operations when he was accused of a misapplication of the royal money, and was apprehended for that and other crimes, for which there appears to have been little or no foundation. He did not, however, survive the accusation; but the manner and particular time of his death are not known, though it was suspected that he was basely murdered in prison. Plutarch. Univer. Hist.

CONON, a mathematician of considerable celebrity at Samos, flourished about three centuries, and died about the year 223, B.C. He was a contemporary and friend of Archimedes, to whom he communicated his writings, and sent some problems, which Archimedes received with approbation, wishing them to be published during the lifetime of their author, in order that from him they might receive a just demonstration. Conon made many observations on the eclipses of the sun and moon, and gave the name to the constellation called Coma-Berenices. His death happened during the period when Archimedes flourished, whose eulogium for his friend has come down to the present times: speaking of his great genius, he asks: "How many theorems in geometry, which to others seemed impossible, would, had Conon lived, have been brought to perfection?" Conon invented a spiral, the properties of which having been demonstrated by Archimedes, it has obtained the name of Archimedes's spiral. He is referred to with respect in the writings of Propertius and Virgil. Hutton. Moreri. See CONIC SECTIONS.

CONON, POPE, was by birth a Thracian, and educated in Sicily; from this island he went to Rome, where he was ordained presbyter. Upon the death of pope John V., the disputes respecting a successor ran so high, that for three months the papacy was vacant: the clergy espousing the interests of one candidate, and the army declaring for another. At length Conon was fixed upon, who proved acceptable to all those in whom the appointment was vested. He ascended the pontifical throne in the year 686, and died in about a year, but left behind him a character rarely attained by those who have filled that high station. His pious, learning, integrity, and suavity of manners, were exemplary, and justly celebrated. There was also a cardinal of this name, a native of Germany, and advanced to his high rank in the church by pope Pascal II. He was the avowed and intrepid defender of the high claims of the Roman see, and, on this account, selected as a proper person to preside at the council of Jerusalem, in which Henry V., emperor of Germany, was excommunicated, for not submitting to the pope's assumed right to the investiture of bishops and abbots. He was afterwards legate at the council of Soissons, in the year 1121, when the treatise of the celebrated Adelard, on the Unity of God, was condemned to be burnt. Conon, it is believed, might have been elected to the popedom on the death of Gelasius, an honour which he declined for motives not now known. His own vote and

interest he gave to Guy, archbishop of Vienne, who was elected pope, and assumed the name Calixtus II. Moreri.

CONONIS ARAB, in *Ancient Geography*, a place of Ethiopia, upon the Arabic gulf, according to Strabo; near port Malin.

CONONITES, in *Ecclesiastical History*, the followers of Conon of Alexandria in the sixth century, resembling in their opinions the SEVERIANS, THEODOSIANS, and TRITHEISTS.

CONOPA, in *Ancient Geography*, a lake of Greece, in Etolia, afterwards called *Cygnæa*—Also, a town of Greece, in Acarnania, according to Steph. Byz. and Polybius. Strabo says, that the town of Arinoe, which he places in Etolia, had in former times been called *Conopa*.

CONOPEA, in *Botany*, (κωνοπέα, a veil or net to keep off gnats), Mart. (Conocæa; Willd. Juss. 97. Anbl. Guian. 2. 639. tab. 257.) Class and order, *didynamia angiospermia*. Nat. Ord. *Lythæacis*, Juss.

Gen. Ch. Cal. perianth one-leafed, five-angled, permanent, five-cleft; segments somewhat egg-shaped, acuminate, erect. Cor. one-petalled, ringent; tube oblong, gradually widening; border two-lipped; upper lip erect, emarginate; lower lip triid, the middle segment larger, concave. Stam. filaments four, attached, at the bottom, to the tube of the corolla; anthers arrow-shaped. Pisl. Germ. roundish; style filiform, hairy; stigma two-lobed. Peric. Capsule roundish, one-celled, four-valved. Seeds numerous, small, fixed to a roundish receptacle.

Ess. Ch. Calyx five-cleft. Corolla two-lipped. Capsule one-celled, four-valved, with many seeds.

Species. *C. aquaticæ*, a creeping plant, growing naturally near water, spreading over its surface, and the grass near the banks, throwing out small fibrous roots from the joints. Stems and branches square, each angle bordered by a very sharp ring. Leaves at each joint, opposite, embracing the stem, kidney-shaped, plaited at the nerves, undulated at the edge. Flowers blue, axillary, either solitary or in pairs; peduncle an inch long, slender; calyx with two long, narrow, pointed leaflets at the base. Capsule with four grooves, partly enclosed by the calyx. A native of Guiana.

CONOPEUM, in *Antiquity*, a sort of canopy of network, which hung about beds, and was designed to keep away gnats or flies; it comes from κωνοπέ, a fly. A piece of furniture of this kind is now used in the East; and Mr. Harmer (Obl. on Scripture, vol. iv. p. 405.) suggests, that if it obtained there at so early a period as the time of Saul, it may serve to illustrate a passage of Scripture, viz. 1 Sam. xix. 12—17. This writer supposes that the word translated "a pillow of goats-hair," meant a conopeum or guard against gnats. It is in one place translated a "thick cloth," and in another a "sieve;" and Harmer observes, that a cloth of a nature fit to be used as a sieve, is just such a thing as a conopeum, or fine network or gauze-like cloth. It appeared to be something "relating to the head;" but a conopeum relates to the head as well as a pillow, being a canopy suspended over the whole bed, or at least so far as to surround the head, and such upper part of the body as might be uncovered. That this kind of defence against gnats is now used in the East, Mr. Harmer has shewn, from the testimony of Maillet (Description de l'Egypte, lett. ix. p. 37.) The word occurs probably in the same sense in 2 Kings. viii. 15.

CONOPEUM, in *Ancient Geography*, a marsh of Asia, near the mouth of the river Halys, according to Arrian.—Also, a particular part of the Palus Mæotis. Steph. Byz. CONOPHORUS,

CONOPHORUS, in *Botany*, Petiv. Rai. See PROTEA Nana.

CONOPOLI, in *Geography*, a town of European Turkey, in the province of Livadia, 10 miles N.E. of Lepanto.

CONOPS, in *Entomology*, a genus of dipterous insects, the mouth of which is furnished with a projecting geniculate proboscis, and the antennæ clavated and pointed at the end.

The insects of this genus are remarkably active, and are found in gardens, where they subsist on the nectareous juices of flowers; their larvæ are unknown. In the true conops, the head is large and nearly hemispherical; the eyes large, and almost oval, and the antennæ formed of three articulations, the middle one of which is long and cylindrical, the last joint terminating in a little point.

The genus conops is divided in the Linnæan system into two families; the first of which includes those species which have the sheath of the sucker single-valved, abbreviated, and inclosing a single bristle; the other those with the sheath consisting of two equal valves, and which is geniculated both at the base and in the middle. The latter are the myzopæ Fabricius. In the Fabrician Suppl. Ent. Syst. the Linnæan conops subcoleoptriatus is described under the new genus, thereva.

Species.

* *First Section.*

VESICULARIS. Blackish; hind head vesicular, abdomen yellow with a black base. Fabr. Geoffr. Inhabits woods in Europe.

MACROCEPHALA. Black; four of the abdominal segments edged with yellow; antennæ and legs rufous. Linn. Like the last inhabits Europe, and is found in woods.

RUFIPES. Deep-black; abdomen at the base ferruginous; segments edged with white; legs ferruginous. Fabr.

This species is a native of Germany. The rib of the wing, and the antennæ are fuscous, front and poisers yellow.

ACULEATA. Deep-black; incisions of the abdomen yellow; thorax with two yellow dots on the anterior part. Linn. Fn. Succ. A native of the northern parts of Europe.

FLAVIPES. Glossy-black; abdomen cylindrical; three of the segments edged with yellow. Linn. Fn. Succ. This inhabits Europe, and has the legs fasciated with yellow, whence its name.

PICTA. Ferruginous; thorax black, varied with yellow, rib of the wing ferruginous. Fabr.

A native of the American islands, described from the cabinet of Smidt.

VITTATA. Abdomen cylindrical, hooked, and varied with ferruginous; an abbreviated sub-marginal black fillet on the wings. Fabr. Inhabits Kiel.

** *Second Section.*

FERRUGINEA. Ferruginous; abdomen cylindrical and incurved; front yellowish. Linn. *Sicus ferrugineus*, Scop. Inhabits woods of Europe.

PETIOLATA. Antennæ black, the club red; head yellow; abdomen petiolate. Fabr. A native of Siberia.

ATOMARIA. Grey; abdomen ovate; wings fuscous, with crowded dots of white. Gmel. An European species.

TESTACEA. Ferruginous; thorax black on the back. Fabr. *Stenomoxides*, Schæffer. Found in Germany.

ATEA. Abdomen cylindrical and incurved; body black. Fabr. Inhabits woods of Denmark.

CINCTA. Testaceous; abdomen hooked and fasciated with white. Fabr. A native of the East Indies. Koenig.

BUCCATA. Ferruginous; abdomen hooked, grey; face vesicular and white; wings clouded. Linn. Fn. Succ. *Sicus buccatus*, Scopoli. Inhabits woods of Europe.

ANNULATA. Thorax black; abdomen cylindrical, varied with yellow and black; base of the wings ferruginous; legs ferruginous and annulated with brown. Linn. A native of Europe.

FLAVA. Thorax black; base of the abdomen black on the back, with a black mark each side, and the two next segments with an oblique black spot in the middle and at the sides. Lesc. An European species.

CINEREA. Cinereous; mouth vesicular and white; tail black. Fabr. Described from a specimen in the cabinet of Dr. Alioni. It is a native of Italy.

DORSALIS. Ferruginous; thorax fuscous on the back; abdomen cylindrical and hooked; margin of the segments white. Fabr. *Myzopa testacea*, Mant. Inf. Inhabits Germany. Smidt.

CONOPONDIABASSIS, in *Ancient Geography*, a name given by Pliny to an island at the mouth of the Danube, which the ancients called *Pseudostoma*.

CONORIA, in *Botany*, Juss. 287. (Conori; Lam. Encyc. Conohoria; Aubl. Guian. its name in its native country). Class and order, *pentandria monogynia*. Nat. Ord. *Berberides*, Juss.

Gen. Ch. *Cal.* one-leaved, deeply five-cleft; segments lanceolate, acute. *Cor.* Petals five, ovate-oblong, erect, doubled, forming a tube, acute, expanding or reflexed at their summit, attached to the receptacle of the pistil; accompanied by five interior, smaller, erect, lanceolate, concave, petal-like bodies placed opposite to them. (Nectaries?) *Stam.* Filaments five, very short, attached to the base of the petal-like bodies; anthers erect, oblong. *Pist.* Germ superior, roundish; style slender, zig-zag; stigma capitate. *Peric.* unknown.

Sp. C. *flavescens*. Aubl. Guian. tab. 95. A shrub, three or four feet high, with numerous, scattered, knotty, compound branches near the top. *Leaves* opposite, on short petioles, egg-shaped, acute, entire, smooth, green above, reddish underneath, the largest of them six inches long, and near three inches broad. *Flowers* yellowish, alternate, in spikes terminating the branches, and surrounded with scales at the base; peduncles with two, small, opposite scales about the middle. A native of woods in Guiana.

CONOSPERMUM, in *Botany* (*κωνος*, a cone, and *σπέρμα*, seed, from the conical or top-shaped figure of the seed). Smith Tr. of Linn. Soc. v. 4. 213. Class and order, *tetrandria monogynia*. Nat. Ord. *Protea*; Juss. *Shuttkook* seed.

Gen. Char. *Cal.* none. *Cor.* monopetalous, ringent, four-cleft; tube swelling; upper tip vaulted, undivided; lower, in three equal, spreading segments. *Stam.* four. Anthers sessile, single-celled, two in the hollow of the upper lip; two, which often seem abortive, at the base of the lower, remote from each other. *Pist.* Germen superior, inversely conical, bearded at the summit. Style filiform, bent, shorter than the corolla. Stigma obtuse, curved. *Seed* solitary, naked, inversely conical, its upper edge fringed with numerous, spreading, shining bristles, about its own length.

Ess. Char. Calyx none. *Cor.* of one petal, ringent, bearing the stamens; its upper lip vaulted; under three-cleft. Stigma obtuse. Seed one, naked, crowned with bristles.

Observ. Considering the irregularity of the flower, and the inequality of position of the anthers, perhaps this genus might be placed in *dilyndia gymnospermia*, in which order

it would add one to the very few genera that have less than four seeds; but it has no affinity to any already classed there, being nearly allied to that tribe of *protea* whose flowers are simple, not aggregate: and as the anthers are all really fecile, it could not literally accord with the definition of the 14th class.

Sp. 1. *C. longifolium*. Smith Exot. Bot. v. 2. 45 t. 83. "Leaves linear, inclining to obovate, entire, smooth, with a marginal nerve, and numerous transverse veins." Sm. Stem shrubby, rigid, branched, about three feet high, with round leafy branches, which are silky when young. Leaves alternate, several inches long, entire, smooth, varying in breadth from a linear to a narrow obovate figure, tipped with a small point, and tapering at the base, into a longish slender foot-stalk. Their margin is marked with a fine nerve, connected by transverse veins with the midrib. Stipules none. Flower-stalks about the tops of the branches, axillary, much exceeding the leaves in length, each bearing a large bracteated downy corymbus, of white or bluish-coloured, sessile, clustered flowers. Bractees membranous, wedge-shaped, pointed, fringed. Corolla about a quarter of an inch long, externally downy. Seed inversely conical, or top-shaped, brown, downy, crowned with a marginal row of spreading reddish bristles, and altogether resembling a shuttlecock. A native of New South Wales, and other parts of New Holland; not yet brought to Europe. The flowers are ornamental, and the aspect of the whole shrub not inelegant. 2. *C. ellipticum*. "Leaves elliptical, rough, edged." Sm. MSS. A more humble and divaricated shrub than the former. Branches hairy when young, thickly clothed with leaves, which are about three quarters of an inch long, crowded, nearly sessile, elliptical, obtuse, entire, thick, and apparently succulent when fresh, concave when dry, single-ribbed, veinless, roughish underneath, especially at the edges, tipped with a minute point. Flower-stalks situated as in the foregoing, but shorter, and more crowded; very downy, as is likewise the outside of the corolla. Seed rather smaller than the last. Sent from New South Wales by John White, M.D. 3. *C. taxifolium*. "Leaves linear-lanceolate, oblique, somewhat downy." Sm. MSS. Branches long and wand-like, very leafy, silky. Leaves imbricated, scattered, sessile, nearly an inch long, linear-lanceolate, inclining to obovate, oblique, narrow, rigid, pointed, single-ribbed, veinless, thick-edged, entire, for the most part clothed with short silky hairs, rarely smooth. Flowers situated as in the two species just described, forming a dense leafy corymbus at the end of each branch, but their stalks are less compound. In general aspect and structure they seem, as well as the seeds, to agree precisely with those of *C. ellipticum*. Gathered also at New South Wales by Dr. White. 4. *C. ericifolium*. "Leaves awl-shaped, keeled, smooth." Sm. MSS. This has very much the habit of the last, and their flowers and seeds exactly accord. Both seem to be rather herbaceous than shrubby, though they have the hard rigid texture so frequent in New Holland plants. This is the smaller of the two. Its leaves are scarcely more than half an inch long, imbricated, awl-shaped, obtuse, keeled, and somewhat triangular, tipped as in the last with a small point, roughish occasionally to the touch, but, as far as we can discover, always destitute of pubescence, though the branches are silky. Gathered at New South Wales by Dr. White. 5. *C. reticulatum*. "Leaves wedge-shaped, jagged, reticulated on both sides." Sm. MSS. The stems appear to be herbaceous and procumbent, leafy, hairy, a few inches in length. Leaves about three inches long, alternate, erect, wedge-shaped, entire at the sides, dilated and jagged at the extremity, veiny, beautifully reticulated on both sides, tapering down at the base

into rigid, furrowed, hairy footstalks, about their own length, whose bases are dilated, and bordered with a membranous sheathing stipula. Flower-stalks terminal, two or three together, hairy, erect, scarcely so tall as the leaves, each bearing a loose, bracteated, simple spike of downy, apparently white, flowers, whose segments are more obtuse than in the other species. The most remarkable character of *C. reticulatum* consists in the exquisitely reticulated veins, prominent on both sides of the leaf, branching off from the main ribs and veins, and forming a fine regular uniform net-work over the whole surface, whose interstices are commonly pentagonal, and not more in diameter than grains of common sand. The veins themselves are finely hairy. For dried specimens of this most beautiful species we are indebted to Mr. A. Menzies, who discovered it at King George's Sound, on the west coast of New Holland, lat. 35. Its fruit we have not seen, but there can be no doubt of its genus.

CONOSTEIN—*Engers*, or *Engers*, in *Geography*, a town of Germany, in the circle of the Lower Rhine, and electorate of Treves; 4 miles N. of Coblenz.

CONOTHATON, in *Ancient Geography*, an episcopal see of Asia, under the metropolis of Boitra.

CONOU, in *Geography*, a town of Persia, in the province of Laristan, on the coast of the Persian gulf; 66 miles E. S. E. of Lar.

CONOVUIM, in *Ancient Geography*, a town of the Isle of Albion, on the route from Segontium or Caernarvon to Deva or Chester, according to Antonine's Itinerary. It was distant 24 miles from Caernarvon, and is now called Caer-Rhyn.

CONQUASSATION, in *Pharmacy*, a species of comminution, or a particular operation, by which moist concreted substances, such as recent vegetables, their fruits, lactescent seeds, and the softer parts of animals, are contused and agitated in a mortar, until partly by their proper succulence, or the assuasion of some liquor, they are reduced to a soft pulp. Metalline instruments are not to be used for this purpose, because not only the manifest, but also the latent salts of the substances, subjected to this operation, acting on the instruments, may derive an adventitious virulent quality from them, which will not only render such substances unfit for the intended purposes, but also nauseous and hurtful when exhibited as medicines. James.

CONQUEROR, in French *Conquerant*. A captain or commander who has subdued several cities or entire countries by force of arms. Alexander the Great, Julius Cæsar, Tamerlane, Mahomet II., &c. were conquerors.

CONQUES, in *Geography*, a small town of France, in the department of Aude, and chief place of a canton in the district of Carcassonne, with a population of 1591 inhabitants. That of the canton amounts to 5635, in 10 communes, upon an extent of one hundred kilometres.—Also, a small town of France, in the department of Aveyron, in the district of Rhodéz, with 806 inhabitants, 15 miles N. from Rhodéz. The canton, of which it is the chief place, has 12 communes, with 6597 inhabitants, and measures 187 kilometres and a half.

CONQUEST, in French *Conquete*, the acquisition of a place, province, or entire country, by a superiority of arms, which compels the conquered to submit to the conqueror.

CONQUEST, in *Civil Jurisprudence*, is the acquisition of property in common by a number of persons.

In some countries, the most general acquisition with conquest; but, according to the best legal acceptation, acquisition is the gaining of unappropriated goods before the establishment

blishment of a community; whereas, by the term *conquest*, is ordinarily intended whatever is acquired by a number of persons in community; or by some one for all the others.

As it is more especially in the union of persons by marriage, that a community of property takes place; it is in reference to them that we frequently use the word *conquest*. There are, nevertheless, conquests also among other persons who are in a tacit community or society; such as obtain by particular local customs.

According to this sense of the word, it has been contended by several, that William I. claimed this kingdom; that is, not by right of arms, but by right of conquest or acquit; under promise of succession made by Edward the Confessor, and a contract entered into by Harold, to support his pretensions to that succession; and by old writers, conquests, acquisition, and perquisition, are frequently used as synonymous terms.

In consequence of the prodigious slaughter of the English nobility at the battle of Hastings, and the fruitless insurrections of those who survived, such numerous forfeitures had accrued, that king William was able to reward his Norman followers with very large and extensive possessions; which circumstance led the monkish historians, and such as have implicitly followed them, to represent him as having, by right of the sword, seized on all the lands of England, and distributed them among his own favourites. This supposition is grounded upon a mistaken sense of the word "conquell," which, in its feudal acceptation, signifies no more than "acquisition;" and hence many party writers have been led into a strange historical mistake, and one, says judge Blackstone, which upon the slightest examination, will be found to be most untrue. See *FEO DAL Tenure*.

What we call "purchase," *perquisitio*, the feudists called "conquell;" *conquisitio*, or *conquisitio*; both denoting any means of acquiring an estate out of the common course of inheritance. This is still the proper phrase in the law of Scotland; as it was among the Norman jurists, who styled the first purchaser (that is, the person who brought the estate into the family, which at present owns it) the conqueror or *conquereur*. This is all that seems to have been meant by the appellation that was given to William the Norman, when his manner of ascending the throne of England was in his own charter, and in those of his successors, and also by the historians of the times, entitled *conquestus*, and himself *conquestor* or *conquisitor*; signifying that he was the first of his family who acquired the crown of England, and from whom, therefore, all future claims by descent must be derived; though now, from our distaste of the feudal sense of the word, together with the reflection on his forcible method of acquisition, we are apt to annex the idea of "victory" to this name of "conquell," or "conquisitum," a title which, however just with regard to the crown, the conqueror never pretended with regard to the realm of England; nor, in fact, ever had. See *PURCHASE*.

William the Norman, as we have already observed, and as some have maintained, claimed the crown by virtue of a pretended grant from king Edward the Confessor; a grant which, if real, was in itself utterly invalid; because it was made, as Harold well observed, in his reply to William's demand, *absque generali senatus, et populi conventu et edicto*; and this also very plainly implies, that it was then generally understood, that the king, with consent of the general council, might dispose of the crown and change the line of succession. William's title, however, was altogether as good as Harold's,

who was a mere private subject, and an utter stranger to the royal blood. The conquest, then, by William of Normandy, was, like that of Canute before, a forcible transfer of the crown of England into a new family; but, the crown being so transferred, all the inherent properties of the crown were also transferred with it. For, the victory obtained at Hastings not being a victory over the nation collectively, but only over the person of Harold, the only right which the conqueror could pretend to acquire thereby, was the right to possess the crown of England, not to alter the nature of the government. And, therefore, as the English laws still remained in force, he must necessarily take the crown subject to those laws, and with all its inherent properties; the fit and principal of which was its descendibility. See *Right of Crown*.

Some writers have represented William's conquest as more extensive and complete than it has been above stated. Scarcely any of those revolutions, it is said, which, both in history and in common language, have been always denominated conquests, appear equally violent, or were attended with so sudden an alteration of power and property. The Roman state, which spread its dominion over Europe, left the rights of individuals in a great measure untouched; and those civilized conquerors, while they made their own country the seat of empire, found that they could derive the greatest advantage from the subjected provinces, by securing to the natives the free enjoyment of their own laws, and of their private possessions. The barbarians who subdued the Roman empire, though they settled in the conquered countries, yet being accustomed to a rude uncultivated life, found a part only of the land sufficient to supply all their wants; and they were not tempted to seize extensive possessions, which they knew how neither to cultivate nor to enjoy. But the Normans and other foreigners, who followed the standard of William, were so far advanced in the arts as to know the value of a large property; and therefore having made the vanquished kingdom the seat of government, and having totally subdued the natives, they pushed the rights of conquest, for the gratification both of their avarice and ambition, to the utmost extremity. Except the former conquest of England by the Saxons themselves, who were induced, by peculiar circumstances, to proceed even to the extermination of the natives, it would be difficult to find, in all history, a revolution more destructive, or attended with a more complete subjection of the ancient inhabitants. In the conduct of their conquerors, contumely was blended with oppression; and the natives were universally reduced to such a state of meanness and poverty, that the English name became a term of reproach, and several generations elapsed before one family of Saxon pedigree was raised to any considerable honours, or could so much as attain the rank of baron of the realm. "These facts," says Mr. Hume (*Hist.* vol. i. p. 283, 8vo.) "are so apparent from the whole tenor of the English history, that none would have been tempted to deny or elude them, were they not heated by the controversies of faction; while one party was absurdly afraid of those absurd consequences, which they saw the other party inclined to draw from this event. But it is evident that the present rights and privileges of the people, who are a mixture of English and Normans, can never be affected by a transaction which passed 700 years ago; and as all ancient authors, who lived nearest the time, and best knew the state of the country, unanimously speak of the Norman dominion as a conquest by war and arms, no reasonable man, from the fear of imaginary consequences, will even be tempted to reject their concurring and united testimony."

The Norman invasion, and conquest, as it has been usually denominated, were important events in the history of this country; and produced as great an alteration in our laws, as it did in our ancient line of kings—and though the alteration of the former was effected rather by the consent of the people, than by any right of conquest, yet that consent seems to have been partly extorted by fear, and partly given without any apprehension of the consequences which afterwards ensued. The alterations in our laws which then took place are enumerated by judge Blackstone; and we shall here subjoin a summary of them. The *first* of these was the separation of the ecclesiastical courts from the civil, which was effected in order to ingratiate the new king with the popish clergy, who had been for some time endeavouring, in every part of Europe, to exempt themselves from the secular power. This was the more easily accomplished, because, the disposal of all the episcopal sees being then in the breast of the king, he had taken care to fill them with Italian and Norman prelates. The *second* alteration of the English constitution was more violent, and consisted in the depopulation of whole countries, for the purposes of the king's royal diversion; and subjecting both them, and all the ancient forests of the kingdom, to the unreasonable severities of forell laws imposed from the continent, by which the slaughter of a beast was made almost as penal as the death of a man. (See FOREST and GAME.) A *third* alteration in the English law was effected by narrowing the remedial influence of the county courts, the great seats of Saxon justice, and extending the *original* jurisdiction of all the king's judicials to all kinds of causes arising in all parts of the kingdom. (See *AVLA regia*.) Hence all proceedings in the king's courts were ordained to be carried on in the Norman, instead of the English language; a badge of slavery as evident and signal as ever was imposed upon a conquered people, which lasted till king Edward III. obtained a double victory, over the armies of France in their own country, and their language in our courts here at home. A *fourth* innovation was the introduction of the trial by combat, for the decision of all civil and criminal questions of fact in the last resort. (See COMBAT.) The *last* and most important alteration, both in our civil and military polity, was the engraving on all landed estates, a few only excepted, the fiction of feudal tenure; which drew after it a numerous and oppressive train of servile fruits and appendages; aids, reliefs, primer feifins, wardships, marriages, escheats, and fines for alienation; the genuine consequences of the maxim then adopted, that all the lands in England were derived from, and holden, mediately or immediately, of, the crown. See each article respectively, and FEUDAL Tenure.

"The nation at this period," says judge Blackstone, "seems to have groaned under as absolute a slavery as was in the power of a warlike, an ambitious, and a politic prince to create. The consciences of men were enslaved by four ecclesiastics, devoted to a foreign power, and unconnected with the civil state under which they lived:—who now imported from Rome for the first time the whole *farrago* of superstitious novelties, which had been engendered by the blindness and corruption of the times, between the first mission of Augustin the monk, and the Norman conquest; such as transubstantiation, purgatory, communion in one kind, and the worship of saints and images; not forgetting the universal supremacy and dogmatical infallibility of the holy see. The laws too, as well as the prayers, were administered in an unknown tongue. The ancient trial by jury gave way to the impious decision by battle. The forest laws totally restrained all rural pleasures and manly recrea-

tions. And in cities and towns the safe was no better; all company being obliged to disperse, and fire and candle to be extinguished by eight at night, at the found of the melancholy *curfew*. The ultimate property of all lands, and a considerable share of the present profits, were vested in the king, or by him granted to his Norman favourites; who, by a gradual progression of slavery, were absolute vassals to the crown, and as absolute tyrants to the commons. Unheard of forfeitures, talliages, aids, and fines, were arbitrarily exacted from the pillaged landholders, in pursuance of the new system of tenure. And to crown all, as a consequence of the tenure by knight-service, the king had always ready at his command an army of 60,000 knights, or *milites*; who were bound, upon pain of confiscating their estates, to attend him in time of invasion, or to quell any domestic insurrection. Trade, or foreign merchandize, such as it then was, was carried on by the Jews and Lombards; and the very name of an English fleet, which king Edgar had rendered so formidable, was utterly unknown to Europe; the nation consisting wholly of the clergy, who were also the lawyers; the barons, or great lords of the land; the knights, or soldiery, who were the subordinate land-holders; and the burghers, or inferior tradesmen, who from their insignificance happily retained, in their usage and burgate tenure, some points of their ancient freedom. All the rest were vassals or bondmen."

"From so complete and well-concerted a scheme of servility, it has been the work of generations for our ancestors, to redeem themselves and their posterity into that state of liberty, which we now enjoy:—and which therefore is not to be looked upon as consisting of mere encroachments on the crown, and infringements on the prerogative, as some slavish and narrow-minded writers in the last century endeavoured to maintain:—but as, in general, a gradual restoration of that ancient constitution, whereof our Saxon forefathers had been unjustly deprived, partly by the policy, and partly by the force, of the Norman." Blackst. Com. Book iv. See CONSTITUTION.

CONQUEST, in the *Law of Nations*, is the acquisition of sovereignty by force of arms, by some foreign prince; who reduces the vanquished under his empire. The right of conquest is derived from the laws of war; and when a people is subjected, the conduct of the conqueror is regulated by four kinds of law. First, the law of nature, which dictates whatever tends to self-preservation; secondly, our reason, which teaches us to use others, as we would be treated ourselves; thirdly, the laws of political society, to which nature has not assigned any precise boundary; lastly, the law which is derived from the particular circumstances attending the conquest. Thus, a state conquered by another will be treated in one of the four methods following: Either the conqueror will continue it under its own laws, and will only claim the exercise of civil and ecclesiastical sovereignty; or he will impose a new form of government; or he will destroy the frame of their society, and incorporate the inhabitants with others; or he will exterminate them. Ancient and modern history will supply numerous instances of these different modes of treatment. See COLONY and PLANTATION.

The right of conquest is allowed by the law of nations, if not by that of nature; but in reason and civil policy it can mean nothing more than that, in order to terminate hostilities, a compact is either expressly or tacitly made between the conqueror and the conquered, that if they will acknowledge the victor for their master, he will treat them for the future as subjects, and not as enemies. *Puffend. Ls. of Nat. viii. b. 24.*

CONQUET, *LE*, in *Geography*, a pretty, rich, small town of France, in the department of Finistere, with a good harbour, and excellent roads; 15 miles west from Brest. It is one of the 84 maritime quarters into which modern France is divided, and the residence of a maritime syndic who superintends this place, besides Argenton, Lospoder, and Onefant.

CONQUISITORES. Among the Romans, these were commissaries or commissioners, charged by their functions with the raising of troops in the towns, and throughout the country; and obliged, at the same time, to make search for those who wished or attempted to withdraw themselves from the levy.

CONRAD, or CONRADS, ABRAHAM, in *Biography*, an engraver and designer of Holland, who was born about 1620. The works of this artist, for the greater part, consist of portraits, many of which are from his own drawings, and prove him to have possessed very considerable talents. His style of engraving is much varied in his different works: some of his prints very much resemble those of L. Voller-mans. Amongst his best works the following may be enumerated: "Christopher Love," *A. Conrad fecit*, in fol.; "Jacob Triglande, Professor of Theology to the University of Leyden," *Ab. Conradus fecit*, in fol.; "The Flagellation and the Crucifixion of Christ," two plates in folio, from Ab. Van Diepenbeck. Huber, Manuel des Arts.

CONRAD I., emperor of Germany, was, previously to his attaining that high honour, duke of Franconia and Hesse. On the death of Louis IV. king of Germany, A. D. 912, the nobility of the realm assembled at Worms, for the purpose of choosing a successor. They offered the crown to Otho, duke of Saxony, by whom, on account of his great age, it was not accepted. He requested them to turn their thoughts to the duke of Franconia, who was highly esteemed for his great talents and excellent character. Upon this recommendation he was called to the vacant throne, though not with that unanimity which is calculated to secure general homage. The people of Lorrain were attached to Charles the Simple, whom they wished to proclaim as their sovereign: Conrad marched thither with great expedition, and by his presence conciliated those who were disposed to resist his authority. While he was thus engaged, Henry, duke of Saxony, son of Otho, joined by the dukes of Suabia and Bavaria, excited a rebellion. This, after surmounting several difficulties, he crushed, and gained a complete victory over his enemies. The Hungarians now made a dreadful irruption into his dominions, and, after marking their progress with fire and sword, compelled him to purchase a peace on very disgraceful terms: but, notwithstanding all the exertions of his enemies, he retained the sceptre, and conducted the affairs of the empire with considerable prudence till the time of his death. His constitution being broken by the fatigues to which he had been exposed, and his health being much injured in consequence of a wound which he had received in battle, he assembled the princes and states of the empire, and seriously exhorted them to raise Henry, duke of Saxony, who had been his enemy, to the imperial throne. This is a rare instance, on the records of history, of a prince sacrificing his private resentment to the public good. He felt the crown, sceptre, and other regalia to his intended successor; and after an active and respectable reign of seven years, he died, A. D. 918, in peace, with the consciousness of quitting life under the influence of Christian principles.

CONRAD II., emperor of Germany, was likewise duke of Franconia: he was surnamed THE SALIC, on account

of his having been born on the banks of the river Sala, and was unanimously invested with supreme authority. He succeeded Henry II., and was crowned, according to ancient usage, at Thonza. During the first two years of his reign, Conrad was chiefly employed in regulating the police, and other affairs of administration; but in the third, receiving intelligence that the Lombards had shaken off their allegiance, he was obliged to march into Italy. The rebels were soon reduced to obedience, and the king proceeded to Rome, where he was solemnly crowned by pope John, in presence of Canute, king of England and Denmark, and Rodolphus, king of Burgundy. He was recalled to Germany, on account of an insurrection, raised by the dukes of Suabia, Carinthia, and Worms, which he readily suppressed, and brought the offenders to the lowest state of subjection. By a decree of the empire, they were deprived of their dominions. The seven succeeding years were occupied by wars between the emperor, Poland, Bohemia, and Hungary: the detail of these would be uninteresting to our readers. The imperial arms were in general successful; and on the demise of Rodolphus, Conrad acquired the peaceable possession of the sovereignty of Burgundy. A general revolt against the German dominions was planned in Italy, and fomented by many leading persons: the emperor passed suddenly into that country, and seizing some of the principal malcontents, sent them prisoners to Germany. He besieged Milan, but without success; and severely chastised Parma. Being urged by the monks of Cassino to protect them against the violence and oppression of Pandolph, prince of Capua, he marched to that place, expelled the prince, and seized his country. Returning to Germany, he was seized with the gout in his legs, and died suddenly at Utrecht, in 1039, in the fifteenth year of his reign. He was universally revered as a just and magnanimous prince; and all those who distinguished themselves in his service had no reason to be dissatisfied with the remunerations which they obtained. Among many instances of his munificence, it is said that one of his attendants, who had lost his leg in battle, received his boot-full of gold, which the emperor observed might defray the expence of his cure. He was interred in the cathedral church of Spire, which he had formerly founded and endowed.

CONRAD III., another duke of Franconia and emperor of Germany, was nephew of the emperor Henry V., and elected to the imperial throne at Coblenz in 1138-9, as successor to Lothaire II. This measure was warmly contested by Henry, duke of Bavaria, who positively refused to surrender the regalia, which had been deposited in his hands by Lotharius. He was, however, at length compelled to submit, with the loss of his own dominions; and the disappointment and chagrine which he suffered on the occasion brought him to an early grave. Upon the death of this prince, his brother Guelph, with the assistance of the king of Sicily, made vigorous exertions for the recovery of the confiscated duchies: a war ensued, and, after several indecisive engagements, the duke was closely besieged by the emperor in the castle of Weinsberg, celebrated for the conjugal fidelity and affection of the ladies; who, being permitted to leave the place with whatever they could carry, marched out, each with her husband on her back. This instance of kindness and regard so much affected the emperor, that he readily came into terms with Guelph and his partizans. In this war we must look for the origin of the designations of the Guelphs and Ghibellines, which are so often referred to on the page of history. The troubles in Germany were immediately succeeded by a revolt of several of

the town of Italy, which threw off the sovereignty of the empire, and formed themselves into independent republics. Conrad was now prevailed on to join a crusade against the Saracens, and took the cross from the hands of Bernard. He accordingly set out for Palestine, at the head of sixty thousand men. Under his banners a troop of females rode in the attitude and armour of men; and the chief of these Amazons, from her gut spurs and buskins, obtained the epithet of the "golden-footed dame." This expedition proved unfortunate: one half of his troops perished by sickness. occasioned, it is believed, through unwholesome provisions, furnished by the treachery of the Greek emperor, Manuel Comnenus. Conrad, with the remainder, joined Louis VII. king of France, in the siege of Damascus, exhibiting great prowess, but without any success. The siege was raised, and the emperor returned to Germany, where he was overwhelmed with public calamity and private affliction, by another revolt of Guelph, and by the death of his eldest son. This last event preyed on his mind, and evidently affected his health. Aware of his approaching end, he was anxious to provide for the succession, and recommended his nephew, Frederic Barbarossa, to the states of the empire, as a prince of known courage and tried talents. His recommendation was approved, and Conrad died in a short time after, at Bamberg, in the 14th year of his reign. He left one son by his empress Gertrude, whose tender age precluded him from taking any share in the government.

CONRAD IV., the last emperor of Germany of this name, was duke of Suabia, and son of the emperor Frederic II. He was declared successor to his father in 1250, but pope Innocent IV. refused to confirm the election. Conrad, notwithstanding the denunciations of the pontiff, marched into Italy, in order to take possession of the kingdom of the two Sicilies, which had been bequeathed to him by his father. He took the city of Naples after an eight months' siege: afterwards Capua and Aquino opened their gates to him. He did not long enjoy his success: in 1254, he fell sick, and died in the flower of youth, leaving one son, named Conradin, who, at the early age of fourteen, was beleagued by the orders of Charles of Anjou; and in him ended the line of Suabia. Moreri. Univer. Hist. Gibbon's Rom. Empire.

CONRAD is a name distinguished in literary history, as well as among the princes of the earth; but as none of that appellation have become very illustrious by their works, we shall briefly notice them and their writings in a single paragraph. The first was a German abbot of the Benedictine order, about the commencement of the tenth century: he wrote "A Continuation of the History of France;" and on that account has, by some biographical writers, been supposed a Frenchman; by others, he has been confounded with Conrad of Cologne, who was author of the life of S. Wolphemius. Towards the conclusion of the eleventh century, Conrad, bishop of Utrecht, flourished, to which office he had been raised by his pupil, the emperor Henry. He is chiefly known by a work, entitled, "Apologia de Unitate Ecclesie conservanda, et Schismate inter Henricum IV. Imp. ac Greg. VIII. Pont. Max." He wrote also a spirited defence of the imperial right on the subject of investitures. The bishop was assassinated in his palace, A. D. 1099, by a Friesland architect, in revenge for having instructed him in the method of erecting massy buildings on a swampy soil, and afterwards employing a rival in constructing the collegiate church of which the bishop was founder.—Conrad of Slein, a German monk, lived in the thirteenth

century, and was author of "A Chronicle," and of more than fifty volumes on different subjects, chiefly lost, of which John of Aventine made much use in compiling part of his annals. By his various writings, this monk obtained the honourable epithet of "philosopher."—Conrad of Lichtenau, abbot of Ursberg, in the thirteenth century, was author of "A Chronological History," extending from Belus, king of Assyria, to the year 1449, which was afterwards continued, by an anonymous writer, to the reign of Charles V. It was originally printed at Strasburg, in 1537, and afterwards, with the continuation, in 1569, at Basil. It created enemies, by some reflections on the wars carried on between the German emperors and the popes. The same author is said to have written the lives of the saints, in 12 books; but they have not come down to us, and probably were never published.—Conrad of Mentz flourished in the thirteenth century, and is known by a work, entitled, "Chronicum Rerum Moguntiarum," from the year 1140 to 1250, which was first published in 1535, and has undergone several different impressions.—About the same period lived Conrad of Marburg, who was the first prelate of Germany that received the infamous commission of inquisitor from the papal see; an office which he executed with so much cruelty, that at length he fell a sacrifice to the indignation of popular clamour. He wrote "The Life of the Princess Elizabeth of Thuringia," who has obtained a place among the saints.—Conrad is the name of two Dominican monks, natives of Saxony, in the fourteenth century. One was a member of the chapter of his order in that province, and the other appointed by the pope vicar-general of Saxony, in the year 1350. The former published, among many other things, "A Commentary on the Book of Job;" "A Concordance to the Bible;" "The Student's Dream;" and "A common-place Book for the Use of Preachers."—Conrad of Asti, a Piedmontese Dominican monk, was author of "Commentaria in Jus Canonium," and other pieces. He died in the year 1470.—In the sixteenth century appeared Conrad Leontinus, a learned German Cistercian monk, who appears to have been well acquainted with the best writers in profane and sacred literature, and to have maintained an intimate correspondence with the most learned men of his time. He published, in the year 1507, at Basil, "Nicholas de Lyra's Commentary on the Bible, with marginal Notes."—There were several others of this name, but it is needless to mention them all. Conrad of Mur, canon of the church of Zurich, lived in the thirteenth century, and is known for his treatise on the sacraments, and the lives of the popes: and Conrad of Saxony wrote "A Chronicle," and some historical works, to which no date is assigned. Moreri.

CONRI, FLORENCE, a Franciscan friar, was born in the province of Connaught, about the year 1560, and was sent at an early age into Spain, as a student in theology and the philosophy of the times. When he had finished his studies, he travelled into the Low Countries, where he acquired great reputation among the Catholics, by his assiduity and zeal in illustrating and defending the doctrines of St. Augustine. He was author of several tracts on theological subjects, among which were "The Mirror of the Christian Life;" an "Irish Catechism," printed at Louvain, in 1626; and "Tractatus de Statu parvulorum sine Baptismo decedentium ex hac Vita," Lovanii, 1624. As a politician, he was fixed on to conciliate his countrymen to the measures of the court of Spain, when Philip III. attempted the conquest of Ireland, during the reign of Elizabeth. On the failure of that enterprise he escaped from the

the country, and spent the remainder of his life in the Low Countries, and at Madrid, supported by a pension from Spain, in recompence for the services which he intended, but which proved ineffectual. He died at Madrid, in the year 1629. Moreri.

CONRINGIUS, HERMAN, a philosopher of great talents, and almost universal learning, born at Norden in East Friesland in November, 1606, received his education at Helmstadt, where he was made doctor in medicine in 1636, and soon after advanced to the chair of professor in that science. He was also, in succession, appointed professor in physics, law, and politics. For his profound knowledge in the laws of nations and politics, he was consulted, and made physician and aulic counsellor to Christina, queen of Sweden, to the king of Denmark, and to several of the German princes and electors. Of his capacity for these employments abundant proof may be found in his numerous works in philosophy, medicine, and history, which were long held in great repute, though now referred to rather from curiosity than for their utility. In all of them, however, there is a wonderful display of learning. In his philosophy he was a follower of the school of Aristotle, as he proclaims in the first of his publications, viz. "De Calido inuato, de Morte, et Vita, et de Origine Formarum, libri, omnia ad Aristotelis Sententiam elaborata," Lug. Bat. 1631, 8vo., republished with additions in 1640, 43, and 46; "De Germanicorum Corporum Habitus antiqui et novi Causis, Dissertatio," Helmst. 1645, 4to. This has been frequently reprinted. The author has some ingenious conjectures on the causes of the diminished stature, and altered complexion, and habit of body, of the Germans, which he shews from indisputable documents had taken place among these people. The ancient Germans were fair, with blue eyes, and abundant yellow hair, "robustis nato parentibus, sero veneri se dedisse, inque conjugio castis vixisse, et suas vires conservasse integritates, et plenioris silis impretuisse, &c. &c. An entire change in their mode of living, the use of fumes, of tobacco, &c. he conceives to have gradually undermined their constitutions, and to have produced the changes he states to have taken place. An edition of this work was printed at Francfort, with notes, by Philip Burgshaw, 8vo. 1727. "De Hermetica Ægyptiorum veteris, et Paracelsica nova Medicina," Helmst. 1648, 4to.; reprinted, with additions, 1669: a work abounding with ingenious and learned speculations, but little now attended to. "Introductio in universam Artem Medicam, ejuque singulas Partes," 1654; re-edited by Schelhammer, 1687; and again by Hoffman, 1726, 4to.; containing an history and bib. medica, with observations on the principal facts and writers in medicine, besides numerous dissertations on particular diseases, as dropsy, pleurisy, &c. Conringius is said to have been remarkably diminutive in stature, but of great vivacity, and enjoying a strong memory. He retained the situation of senior of the university of Helmstadt to the time of his death, which happened on the 12th of December, 1681. His character is contained in the following epitaph:

Hoc tumulo

Clauditor regum principumque consiliarius,
Juris naturalis gentium publici doctor,
Philosophicæ omnis peritissimus, practicæ et theoreticæ,
Philologus insignis, orator, poeta, historicus, medicus,
Theologus,

Multas putas lus conditas,

Unus est Hermannus Conringius, facili miraculum,
Posuit Henricus Meibomius.

Haller Bib. Eloy Dict. Hist.

VOL. IX.

CONSABURUS, in *Ancient Geography*, a town of Spain, towards the south-west of Althæa Oicadam.

CONSANGUINEO, WRIT DE, in *Law*. See ASSISE de Mort d'Anceſtor.

CONSANGUINEUS FRATER. See CONSANGUINITY.

CONSANGUINITY, the relation of kinship, between persons of the same blood, or sprung from the same root; or, as it is defined by writers on these subjects, "*Vinculum personarum ab eadem stirpe descendendum*;" i. e. the connection or relation of persons descended from the same stock or common ancestor. This consanguinity is either *lineal*, when it subsists between persons, of whom one is descended in a direct line from the other; as between A. B. and his father, grandfather, great grandfather, and so upwards in the direct ascending line; or between A. B. and his son, grandson, great grandson, and so downwards in the direct descending line. Every generation, in this lineal direct consanguinity, constitutes a different degree, reckoning either upwards or downwards: thus, the father of A. B. is related to him in the first degree, and so likewise is his son; his grandfire and grandson in the second; his great grandfire and great grandson in the third. This is the only natural way of reckoning the degrees in the direct line, and therefore universally obtains, as well in the civil and canon, as in the common, law. Consanguinity is *collateral*, when relations descend from the same stock or ancestor, but do not descend one from the other. See COLLATERAL.

It is easy to compute, by the rules of progression, how many lineal ancestors any man has within a certain number of degrees. Thus, it would appear that a person, at the 20th degree, or the distance of 20 generations, hath above a million of ancestors: and if a similar calculation be made of collateral kindred at the distance of 20 degrees forward, on the supposition that each couple of ancestors leave, one with another, two children, the number will be 274877906944: as in the following tables:

TABLE I.

Lineal Degrees.	Number of Ancestors.
1	2
2	4
3	8
4	16
5	32
6	64
7	128
8	256
9	512
10	1024
11	2048
12	4096
13	8192
14	16384
15	32768
16	65536
17	131072
18	262144
19	524288
20	1048576

In forming this table, it is evident that each person has two ancestors in the first degree, and that the number is doubled at every remove, because each of his ancestors has also two immediate ancestors of his own. In order to find the number of ancestors at any particular degree, we need

only to find a power of 2, the index of which is the number of degrees; *e. g.* 2^1 , 2^{10} , 2^{15} , &c. will give the corresponding number respectively. Or, the number of ancestors at any even degree may be had by squaring the number of ancestors at half that number of degrees: thus 16, the number of ancestors at 4 degrees, is the square of 4; the number of ancestors at two; 256 is the square of 16; 65536 of 256; and the number of ancestors at 40 degrees would be the square of 1048576, or upwards of a million of millions. These powers are easily found by means of logarithms. See PROGRESSION.

TABLE II.

Collateral Degrees.	Number of Kindred.
1	1
2	4
3	16
4	64
5	256
6	1024
7	4096
8	16384
9	65536
10	262144
11	1048576
12	4194304
13	16772176
14	67108864
15	268435456
16	1073741824
17	4294667926
18	17179869184
19	68719476736
20	274877969444

It is obvious that in this table the numbers in the progression increase much more rapidly than those of the former table; for though the first born is 1, the ratio of the progression is 4; that is, there is one kinsman (a brother) in the first degree, who makes, together with A. B., the *propogitus*, as he is called, the two descendants from the first couple of ancestors; and in every other degree, the number of kindred must be *quadruple* of those in the degree which immediately precedes it. For, since each couple of ancestors has two descendants, who increase in a duplicate ratio, it will follow that the ratio in which all the descendants increase downwards, must be double that in which the ancestors increase upwards; but the ancestors increase upwards in a duplicate ratio; therefore the descendants must increase downwards in a double duplicate; that is, in a quadruple ratio. This calculation may be formed by a more expeditious process, *viz.* by squaring the couples, or half the number of ancestors at any given degree, which will furnish the number of kindred we have in the same degree, at equal distance with ourselves from the common stock, besides those at unequal distances. Thus, in the 10th lineal degree, the number of ancestors is 1024; its half, or the couples, amount to 512; the number of kindred in the 10th collateral degree amounts, therefore, to 262144, or the square of 512. Or, it will be seen in the table that $2^3 = 8$, the number of kindred in the 3d collateral degree; $2^4 = 16$, the number in the 4th collateral degree; $2^5 = 32$, the number in the 5th degree; $2^{10} = 1024$, the number in the 6th degree, &c. and therefore if the number of degrees be denoted by *n*, 2^{n-1} , will be the number of kindred in the degree expressed by *n*; which is easily obtained by the aid of logarithms in any degree, however re-

note. If any one will be at the trouble of recollecting the state of the several families within his own knowledge, and of observing how far they agree with this account; that is, whether, on an average, every man has not one brother or sister, four first cousins, sixteen second cousins, and so on; he will find that the present calculation is very far from being overcharged.

From the records of scripture we learn, that there is one couple of ancestors belonging in common to us all, from whence the whole race of mankind is descended; and hence wedded, as an obvious and undeniable consequence, that all men are in some degree, however remote, related to each other. For, indeed, if we only suppose each couple of our ancestors to have left, one with another, two children; and each of those children on an average to have left two more; (and, without such a supposition, the human species must be daily diminishing) we shall find that all of us have now subsisting nearly 270 millions of kindred in the 15th degree, at the same distance from the several common ancestors as we ourselves are; besides those that are one or two descents nearer to or farther from the common stock, who may amount to as many more. And, if this calculation should appear incompatible with the number of inhabitants on the earth, it is because, by intermarriages among the several descendants from the same ancestor, a hundred or a thousand modes of consanguinity may be consolidated in one person, or he may be related to us a hundred or a thousand different ways.

The method of computing these degrees in the canon law (Decretal. 4. 14. 3 & 9.) which our law has adopted (Co. Litt. 23.) is as follows: We begin at the common ancestor, and reckon downwards; and in whatsoever degree the two persons, or the most remote of them, is distant from the common ancestor, that is the degree in which they are related to each other. Thus, Titius and his brother are related in the first degree; for, from the father to each of them is counted only one; Titius and his nephew are related in the second degree; for the nephew is two degrees removed from the common ancestor; *viz.* his own grandfather, the father of Titius. See Blackt. Comm. vol. ii.

Marriage is prohibited by the church to the fourth degree of consanguinity inclusive; but, by the law of nature, consanguinity is no obstacle to marriage, except it be in the direct line. See MARRIAGE.

Consanguinity terminates in the sixth and seventh degree, excepting in the succession to the crown; in which case, consanguinity is continued to infinity.

The civilians call *fratres consanguinei*, those born of the same father; in opposition to *fratres uterini*, who are only born of the same mother. See DESCENT.

According to the common opinion, those were not allowed to complain of an inefficient testament, *i. e.* of being disinherited without cause; excepting from the turpitude of the person appointed heir in their place. But Van Water endeavours to shew the contrary; and urges, that the *consanguinei* might plead inefficiency, even where the testament was not made in favour of a person incapable. See KINDRED.

CONSAIR, in *Geography*, a town of Persia, in the province of Irak; 52 miles N.W. of Ispahan.

CONSAIRBRUCK, or CONZ, a town of Germany, in the electorate of Treves, situated at the conflux of the Saar and the Moselle; 2 miles S. of Treves.

CONSBACH, a town of Sweden, in South Gothland; 32 miles N. of Wardberg.

CONSCIENCE, in *Ethics*, a secret testimony or judgment of the soul, or as some have defined it, a distinct faculty or power of the mind, by which it gives its approbation

tion to things it does that are naturally good; and reproaches itself for those that are evil. Or, conscience is a dictate of the understanding power, concerning moral actions; considered as it has the knowledge of laws; and consequently as conscious of what is to be done, or not done, with regard to the legislator.

In the more popular sense of the word, conscience is a judgment, either true or false, whereby we pronounce a thing good or evil. This makes what we call the inner forum, or tribunal. Accordingly, it should be considered, not as a mere intellectual light, or informing faculty, a dictate of the practical understanding (as the schools call it), which directs, admonishes, and influences us, in what we are to do; but as it acts back upon the soul by a reflection on what we have done; and is, by that means, the source and cause of all that joy, or dejection of mind, of those internal sensations of pleasure or pain, which attend the practice of great virtues or great vices.

Some divines maintain, that conscience is infallible; and hold it to be that immutable law whereby God will judge men: they deny that the understanding can be the source of errors, and lay them all at the door of the will. A man, say they, may secure himself from error, by forbearing to judge of things till he have a clear and distinct perception of them.

Some of the schoolmen distinguish between the conscience antecedent to an action, and that consequent to it: the first, called antecedent conscience, determines what is good, and what evil; and consequently prescribes what is to be done, and what avoided. Consequent conscience is a kind of secondary or reflex judgment, with regard to the goodness, &c. of things, already done or committed.

The rule of conscience is the will of God, so far as it is made known to us, either by the light of nature, or by that of revelation. With respect to the knowledge of this rule, conscience is said to be rightly informed, or mistaken; firm, or wavering, or scrupulous, &c. With respect to the conformity of our actions to this rule when known, conscience is said to be good, or evil, &c.

In a moral view, it is of the greatest importance that the understanding be well informed, in order to render the judgment or verdict of conscience a safe directory of conduct, and a proper source of satisfaction. Otherwise, the judgment of conscience may be pleaded, and it has actually been pleaded, as an apology for very unwarrantable conduct. Many atrocious acts of persecution have been perpetrated, and afterwards justified, under the sanction of an erroneous conscience. It is also of no small importance, that the sensibility of conscience be duly maintained and cherished; for want of which men have often been betrayed into criminal conduct without self-reproach, and have deluded themselves with false notions of their character and state.

Dr. Reid (See his "Essays on the active Powers of Man," p. 252, &c.) has made the following observations on that power of the mind, which we call conscience. 1. Like all our other powers, it comes to maturity by insensible degrees, and may be much aided in its strength and vigour by proper culture. 2. Conscience is peculiar to man. We see no vestige of it in brute animals; and it is therefore one of those prerogatives by which we are raised above them. Conscience is evidently intended by nature to be the immediate guide and director of our conduct, after we arrive at the years of understanding. Other principles may urge and impel; but this only authorises. Other principles ought to be controlled by this: this may be, but never ought to be controlled by any other, and never can be with innocence. From these observations it evidently follows, that the moral

faculty of conscience is both an active and an intellectual power of the mind. As an active principle, it sometimes concurs with other active principles, sometimes opposes them, and sometimes is the sole principle of action. As an intellectual principle, we have by it, and by it alone, the original conceptions of right and wrong in human conduct, in their different degrees and different species.

Philosophers in lieu of the word *conscience*, which seems appropriated to theological matters, frequently use that of *conscientiousness*; which see.

The power of conscience has been remarked in all ages of the world, and under all dispensations of religion; and history, both sacred and profane, furnishes innumerable examples, that are eminently instructive. One remarkable instance of this kind occurs in the history of Joseph and his brethren (See Gen. chap. xlii. and particularly v. 21.) Another is presented to us in the account which the evangelist Matthew has given us of the feelings and reflections of Herod the tetrarch, when he heard of the fame of Jesus, after he had occasioned the death of John the Baptist. (See Matth. xiv. 1, 2, 3.) Bishop Atterbury has admirably portrayed the state of Herod's mind, in his excellent sermon on this subject. (Sermons, vol. iv. Sermon 4.) Many instances of a similar kind occur in profane history. We shall content ourselves with selecting one, and shall give it in the words of the elegant preacher already cited. "Tiberius, that complete pattern of wickedness and tyranny, had taken as much pains to conquer these fears (referring to the fears of futurity before described) as any man, and had as many helps and advantages towards it, from great splendour and power, and a perpetual succession of new business, and new pleasures: and yet, as great a master of dissimulation as he was, he could not dissemble the inward sense of his guilt, nor prevent the open eruptions of it upon very improper occasions. Witness that letter which he wrote to the senate from his impure retreat at Capræ. Tacitus has preserved the first lines of it; and there cannot be a livelier image of a mind filled with distraction and despair than they afford us: *Quid, scribam vobis, P. C. aut quomodo scribam, aut quid omnino non scribam hoc tempore, Dei me Deaque pejus perdant, quam perire quotidie sentio, si scio!* that is, "What, or how, at this time, I shall write to you, fathers of the senate, or what indeed I shall not write to you, may all the powers of heaven confound me yet worse than they have already done, if I know or can imagine!" And his observation upon it is well worthy of ours, and very apposite to our present purpose: "In this manner (says he) was this emperor punished by a reflexion on his own infamous life and guilt; nor was it in vain that the greatest master of wisdom (he means Plato) affirmed, that were the hearts of tyrants once laid open to our view, we should see there nothing but ghastly wounds and bruises; the consciousness of their own cruelty, lewdness, and ill conduct, leaving as deep and bloody prints on their minds, as the strokes of the scourge do on the back of a slave. Tiberius (adds he) confessed as much, when he uttered these words; nor could his high station, or even privacy and retirement itself, hinder him from discovering to all the world the inward agonies and torments under which he laboured." Thus that excellent historian. We cannot forbear subjoining the following fact, related by Mr. Fordyce in his "Dialogues on Education" (vol. ii. p. 401), as a real occurrence which happened in a neighbouring state not many years ago. A jeweller, a man of good character and considerable wealth, having occasion, in the way of his business, to travel at some distance from the place of his abode, took along with him a servant, in order to take care of his portmanteau. He had with him some of his

best jewels, and a large sum of money, to which his servant was likewise privy. When the master had occasion to dismount on the road, the servant, watching his opportunity, took a pistol from his master's saddle and shot him dead on the spot; he then rifled him of his jewels and money, and hanging a large stone to his neck, threw him into the nearest canal. With this booty he made off to a distant part of the country, where he had reason to believe that neither he nor his master were known. There he began to trade in a low way at first, that his obscurity might screen him from observation, and in the course of several years seemed to rise, by the natural progress of business, into wealth and consideration; so that his good fortune appeared at once the effect and reward of industry and virtue. Of this he counterfeited the appearance so well, that he grew into great credit, married into a good family, and by laying out his hidden stores discreetly, as he saw occasion, and joining to all an universal affability, he was admitted to a share in the government of the town, and rose from one post to another, till at length he was chosen chief magistrate. In this office he maintained a fair character, and continued to fill it with no small applause, both as a governor and a judge; till one day as he sat on the bench with some of his brethren, a criminal was brought before him who was accused of murdering his master. The evidence came out full, the jury brought in their verdict that the prisoner was guilty, and the whole assembly waited the sentence of the president of the court (an office which that day belonged to him), with great suspense. In the mean while he manifested an unusual disorder and agitation of mind, and his colour often changed; at length he arose from his seat, and coming down from the bench, paced himself just by the unfortunate man at the bar. "You see before you (said he, addressing himself to those who had sat on the bench with him) a striking instance of the just retaliation of heaven, which this day, after 30 years' concealment, presents to you a greater criminal than the man just now found guilty." He then proceeded to make an ample confession of his guilt, and of all its aggravations. "Nor can I feel (continued he) any relief from the agencies of an awakened conscience, but by requiring that justice be forthwith done against me in the most public and solemn manner." We may easily suppose the amazement of the whole assembly, and especially of his fellow-judges. However, they proceeded, upon this confession, to pass sentence upon him, and he died with all the symptoms of a penitent mind.

CONSCIENCE, *Court of*. See COURT.

CONSCIOUSNESS, in *Logic* and *Metaphysics*, is the mind's perception of its own existence, faculties, and operations; and, in this view of it, it is one of the sources of judgment, and one species of evidence. Consciousness, says Dr. Reid, (*Essays on the Intellectual Powers of Man*, p. 578), is an operation of the understanding of its own kind, and cannot be logically defined. The objects of it are our present pains, our pleasures, our hopes, our fears, our desires, our doubts, our thoughts of every kind; in a word, all the passions, and all the actions and operations of our own minds, while they are present. We may remember them when they are past: we are conscious of them only while they are present. It is, therefore, a *first* principle that every thing exists of which we are conscious. When a man is conscious of pain, he is certain of its existence; when he is conscious that he doubts, or believes, he is certain of the existence of these operations. And his conviction of the reality of these operations is not the effect of reasoning: it is immediate and intuitive. The existence, therefore, of the passions and operations of our minds, of

which we are conscious, is a first principle, which nature requires us to believe upon her authority. Indeed, this is the only principle of common sense, which has never been directly called in question, and which retains its authority with the greatest sceptics. Mr. Hume, after annihilating body and mind, time and space, action and causation, and even his own mind, acknowledges the reality of the thoughts, sensations, and passions of which he is conscious. From this source of consciousness we derive all that we know, and indeed all that we can know, of the structure, and of the powers of our own minds; from which we may conclude, that no branch of knowledge stands upon a firmer foundation; for surely no kind of evidence can go beyond that of consciousness. Some have confounded consciousness and reflection, though they are essentially distinct. The former is common to men at all times, but is insufficient to give us clear and distinct notions of the operations of which we are conscious, and of their mutual relations, and minute distinctions. The second, or attentive reflection upon these operations, making them objects of thought, surveying them attentively, and examining them on all sides, is so far from being common to all men, that it pertains to very few.

Another first principle, in relation to the subject of this article is, that the thoughts of which any one is conscious are the thoughts of a being which he calls *himself*, his *mind*, his *person*. "If any man asks a proof of this," says Dr. Reid, "I confess I can give none; there is an evidence in the proposition itself, which I am unable to resist. Shall I think, that thought can stand by itself without a thinking being? or that ideas can feel pleasure or pain? My nature dictates to me that it is impossible. And that nature has dictated the same to all men, appears from the structure of all languages; for in all languages men have expressed thinking, reasoning, willing, loving, hating, by personal verbs, which from their nature require a person who thinks, reasons, wills, loves, or hates. From which it appears, that men have been taught by nature to believe that thought requires a thinker, and reason a reasoner, and love a lover."

"Here," continues Dr. Reid, "we must leave Mr. Hume, who conceives it to be a vulgar error, that besides the thoughts we are conscious of, there is a mind which is the subject of those thoughts." If the mind be any thing else than impressions and ideas, it must be a word without a meaning. The mind, therefore, according to this philosopher, is a word which signifies a bundle of perceptions; or when he defines it more accurately, "It is that succession of related ideas and impressions, of which we have an intimate memory and consciousness." Whence it follows that "I am; says our author, "that succession of related ideas and impressions, of which I have the intimate memory and consciousness. But who is the I that has this memory and consciousness of a succession of ideas and impressions? Why, it is nothing but that succession itself."

Identity of consciousness, according to Mr. Locke, constitutes identity of person. For a farther discussion of this subject, see IDENTITY.

CONSCRIPT, CONSCRIPTUS, a popular term in the Roman history, used in speaking of senators, who were called *conscript* fathers, *patres conscripti*; because their names were written in the register, or catalogue of the senate.

Livy, lib. i. cap. 1. tells us, that when Brutus filled up the places of the senators cut off by Tarquin, with others chosen out of the equestrian order, those new senators only had the appellation given them of *patres conscripti*.

CONSCRIPTS also denote men raised to recruit the Imperial and French armies. All men capable of bearing arms in Hungary and Bohemia, have been usually enregistered and obliged to march wherever their services were called for. The conscripts in France, during the last and present war, have been raised on similar principles.

The militia of Great Britain comes likewise in some measure under this denomination or description, with this difference, that the men have been raised by ballot, and do not leave their native country, unless they voluntarily offer their services for that purpose.

CONSECRATION, the act of converting or setting apart, any profane, or common thing, to a pious purpose; with certain ceremonies, prayers, benedictions, &c. appropriate to it.

Consecration is the reverse of sacrilege and profanation, which consist in perverting a thing set apart for a pious purpose, to a profane and popular one.

The bishop consecrates a church, or a chalice; the pope consecrates medals, agnus dei's, &c. and grants indulgences to those who bear such about them with devotion. The consecration, or dedication, of a church is an episcopal ceremony, consisting in a great number of benedictions, with aspersions and unctions of chrism, &c. on the walls, both within and without. The form for consecrating churches, chapels, and church-yards, or places of burials, in England, may be seen in Wilkins's *Concilia Magnæ Britanniæ*, &c. vol. iv. p. 668. It directs that the bishop and clergy, of whom there are to be at least two, shall enter the church or chapel in their several habits, and, as they walk up from the west to the east end, repeat alternately the 24th Psalm; the bishop beginning, "The earth is the Lord's," &c. with the "Gloria patri." When they are come to the Lord's table, the bishop sitting in his chair shall have the instrument of dedication, donation, and endowment of the church or chapel, church-yard, or burial-place, presented to him by the founder, or some proper person, which he shall cause to be read by his register, or other officer; and then the instrument shall be laid on the table, and he shall stand on the north side of it, and turning to the congregation, deliver an address to them, which is followed by suitable prayers. One of the priests then reads the service of the day, introducing proper psalms and lessons: after which, the bishop proceeds to the communion service, and instead of the collect of the day, uses one proper to the occasion. When the Epistle and Gospel are read, they are succeeded by the Nicene creed and the sermon; and then the bishop is to proceed with the service of the communion. When the service in the church is finished, the bishop and clergy with the people shall go into the church-yard, and make use of a prayer for the occasion. See *ubi supra*.

The custom of consecrating persons, temples, altars, vestments, utensils, &c. is very ancient; and all the ceremonies thereof are prescribed under the old law. When those consecrations relate to men, they are properly called *ordinations*; excepting those performed to bishops and kings, which still retain the name of *consecration*. Those which only consist in a ceremony instituted by the church, are more properly called *benedictions*. When they regard churches, altars, vessels, &c. they are properly called *dedications*.

In the trial of archbishop Laud, A. D. 1644, it was one of the charges alleged against him by the commons, that he had traitorously endeavoured and practised "to alter and subvert God's true religion by law established in this realm, and withed them to set up popish superstition and

idolatry, and to reconcile us to the church of Rome." One branch of this charge was his introducing and practising certain popish innovations, and superstitious ceremonies, not warranted by law, nor agreeable to the practice of the church of England since the reformation. In proof of this charge, the managers, on the part of the commons, insisted on his countenancing the setting up of images in churches, church-windows, and other places of religious worship. See *IMAGE*.

Another popish innovation charged on the archbishop was, his superstitious manner of consecrating chapels, churches, and church-yards, such as had been practised in Creed-church, and in the church of St. Giles's in the Fields. The managers objected further, his consecrating altars with all their furniture, as pattens, chalices, altar cloths, &c. even to the knife that was used for cutting the sacramental bread; and his dedicating the churches to certain saints, together with his promoting annual revels, or feasts of dedication, on the Lord's day, in several parts of the country, by which that holy day was profaned, and the people encouraged in superstition and ignorance. With respect to the consecration of churches, the archbishop replied, that the practice was as ancient as Moses, who consecrated the tabernacle, with all its vessels and ornaments; that the temple was afterwards consecrated by Solomon; that as soon as Christian churches began to be built, in the reign of Constantine the Great, they were consecrated, as Eusebius testifies concerning the church of Tyre, (E. H. l. x. c. 3.), and so it has continued to the present time. Besides, if churches were not consecrated, they would not be holy, &c. &c. As to the manner of consecrating Creed-church, St. Giles's, &c. his grace confessed that, when he came to the church-door, that passage in the Psalms was read, "Lift up your heads, O ye gates, even lift them up, ye everlasting doors, that the king of glory may come in;" that he kneeled and bowed at his entrance into the church, as Moses and Aaron did at the door of the tabernacle; that he declared the place holy, and made use of a prayer like one in the Roman pontifical; that afterwards he pronounced divers curses on such as should profane it, but denied his throwing dust into the air, in which he said, the witnesses had forsworn themselves; for the Roman pontifical does not prescribe throwing dust into the air, but ashes; and he conceived there was no harm, much less treason in it. As to the consecrating of churches, and also dedicating them to God, has been of ancient usage, so has the consecration of altars and their furniture; and such consecrations are necessary, for else the Lord's table could not be called holy, nor the vessels belonging to it, as they usually are; yea, there is an holiness in the altar, which sanctifies the gift, which it could not do, unless itself was holy; if there be no dedication of these things to God, no separation of them from common use, then there can be no such thing as sacrilege, or difference between our holy table and a common one. And as to the form of consecrating these things, the archbishop alleged, that he had it not from the Roman pontifical, but from bishop Andrews.

The managers for the commons replied, that if the temple was consecrated, it was by the king himself, and not by the high-priest; and if the tabernacle was consecrated, it was by Moses, the civil magistrate, and not by Aaron the high-priest; but we read, they said, of no other consecrating the tabernacle and its utensils, but anointing them with oil, for which Moses had an express command; nor of any other consecrating the temple, but of Solomon's making an excellent prayer in the outward court, not in the temple itself, and of his hallowing the middle court by offerings and peace-offerings; and it is observable, that the cloud and
glory

CONSECRATION.

glory of the Lord filled the temple, so that the priests could not stand to minister before Solomon made his prayer, which some call his consecration. But if it should be allowed that the temple was consecrated in an extraordinary manner, we have no mention either in Scripture, or in Jewish writers, of the consecration of their synagogues, to which our churches properly succeed. And, after all, it is no conclusive way of arguing, to derive a Christian institution from the practice of the Jewish church, because many of their ordinances were temporary, and abolished by the coming of Christ. Moreover, it is said, that from the beginning of Christianity, we have no credible authority for consecrating churches for 300 years. Eusebius, in his life of Constantine the Great, does indeed mention his consecrating a temple which he built over our Saviour's sepulchre at Jerusalem; but how?—with prayers, disputations, preaching, and exposition of scripture, as he expressly desires it (cap. 45.) Here were no processions, no knocking at the doors by the bishop, crying, "Open ye everlasting doors;" no casting dust or ashes into the air, and pronouncing the ground holy; no reverencing towards the altars, nor a great many other inventions of later ages. These were not known in the Christian church, till the very darkest times of popery; nay, in those very dark times, we are told by Otho, the pope's legate, in his Ecclesiastical Constitutions, that in the reign of King Henry III., there were not only divers parish churches, but some cathedrals in England, which had been used for many years, and yet never consecrated by a bishop. But the archbishop's method of consecrating churches, it is said, evidently appears to be a modern popish invention; for it is agreed by Gratian, Patina, the Centuriators, and others, that the popes Hyginus, Gelasius, Silvester, Felix and Gregory, were the first inventors and promoters of it; and it is no where to be found but in the Roman pontifical, published by command of pope Clement VIII. (*De Ecclesiæ dedicatione*, p. 209, 250.) for which reason it was exploded and condemned by our first reformers, and particularly by bishop Pilkington, in his comment upon Haggar (ch. i. v. 7, 8.) and archbishop Parker, who (in his *Antiq. Brit.* p. 85, 87.) expressly condemns the archbishop's method of consecration, as popish and superstitious. (See ALTAR.)

The archbishop, however, says, that if churches are not consecrated, they cannot be holy; whereas many places that were never consecrated are styled holy, as the most holy place, and the holy city Jerusalem; and our homilies say, that the church is called holy, not of itself, but because God's people resorting thither are holy, and exercise themselves in holy things; and it is evident that sanctification, when applied to places, is nothing else but a separation of them from common use to a religious and sacred purpose, which may be done without the superstitious method above-mentioned; and though the archbishop avers, that he had not his form of consecration from the Roman pontifical, he acknowledges that he had it from bishop Andrews, who could have had it no where else.

As for the consecration of altars, pattens, chalices, altarcloths, and other altar-furniture, its original is no higher than the Roman missal and pontifical, in both which there are particular chapters and set forms of prayer for this purpose: but to imagine that these vessels may not be reputed holy, though separated to an holy use, unless they are thus consecrated, is destitute of foundation in reason or scripture, and contrary to the practice of the church of England, and the opinion of our first reformers. As to the practice of *dedication*, &c. see DEDICATION. Neal's Hist. of the Puritans, vol. ii. ch. 5. 4to.

CONSECRATION of the Pope, a ceremony which is parti-

cularly described by cardinal Rasponi, in his book concerning the church of the Lat-ran; and which is also related by father Bonanni, in his medallic history of the popes; and by Lenfant, in his history of the council of Constance. "Before the usage of the conclave was introduced by Gregory the tenth," says cardinal Rasponi, "the cardinals, three days after the obsequies of the former pope, convened in the Lateran church, where, after the invocation of the Holy Spirit, and the celebration of mass, they proceed to the election of a pope. The election being made, the first cardinal deacon invested the pope elect in his pontifical habits, and announced the name which he chose to take;" for it has been the custom now, for several centuries, that the pope should assume a new name on being elected. "Afterwards, two cardinals, the most eminent in dignity, one on his right hand, the other on his left, conducted him to the altar, where he prostrated himself in adoration of God, whilst they sang the *Te Deum*. After the *Te Deum*, the cardinals seated the pope in a marble chair, which was behind the altar, under a sort of dome, or vault, where the pope, being set, admitted the cardinals, the bishops, and some others, to kiss his feet, and to receive the *keys of peace*. Then the pope rising, the cardinals conducted him through the portico to another chair, bored like what is called in French, *siège percé*. This chair was thence very properly named *stercoraria*, the stercorary. It was formerly placed before the portico of the patriarchal basilic, and is now to be seen in the cloister of that basilic." The use of these chairs, however, was afterwards abolished by Leo the tenth, probably for this, amongst other reasons, because the perforated chair was become connected with the fabulous story of the female pope. That, however, is not a protestant fable, as some persons ignorantly pretend, for it was current long before the days of Luther. But the continuance of the use of that chair preserved the memory of the story, and might appear to the credulous an evidence of its truth. Whilst the pope sat on the stercorary, the choir sang these words of scripture: *Suscitavit pulvere genibus, et de stercore erigit pauperem, ut sedent cum principibus, et solum gloriæ teneat*. Psalm, cxlii. 7. The last clause is not in the psalm. *He raiseth the poor out of the dust, and lifteth the needy off the dung-hill, that he may set him with the princes of his people, and that he may possess the throne of glory*. The intention of this ceremony, it was said, was to insinuate to the pope the need there is of the virtue of humility, which ought to be the first step of his greatness. After remaining some time in this chair, the pope received from the hands of the chamberlain three deniers, which he threw to the people, pronouncing these words: *Silver and gold I have none for my pleasure, but what I have I give you*. Afterwards, the prior of the Lateran basilic, and one of the cardinals, or one of the canons of that basilic, took the pope between them, and whilst they walked in the portico, shouts of acclamation were raised near the basilic, and the election was declared, with the name which the pope had taken. In this manner they conducted the pope to the basilic of St. Sylvester, where, being placed before this basilic in a chair of porphyry, the prior of the basilic put into his hands a *ferula*, in sign of correction and government, and the keys, to denote the power which God gave to St. Peter, prince of the apostles, of opening and shutting, of binding and loosing, and which passes (according to our historian) successively to all the Roman pontiffs. Thence the pope, carrying the *ferula*, and the keys, went to place himself in another chair, resembling the former; and after remaining there some time, restored the *ferula* and the keys to the prior, who girt him with a girdle of red silk, giving him a

purse

purse of the same colour and stuff, wherein there were twelve precious stones, and a small bit of musk. Onuphris, in his treatise on the basilic of the Lateran, says, that it was the prior of this basilic who gave these things to the pope. His sitting in the two chairs denoted the primacy which St. Peter conferred on him, and the power of preaching the gospel conferred by St. Paul. The girdle signified continence and chastity, the purse denoted the treasure, out of which the poor were to be nourished, the twelve precious stones represented the power of the twelve apostles, which resides totally in the pontiff; in fine, the musk denoted the fragrancy of good works, according to that saying, *We are to God a sweet savour of Christ*. In this chair the pope elect admitted the ministers of the palace to kiss his feet, and to receive the kiss of peace. There, too, several pieces of silver were delivered to him by the chamberlain, to the value of ten pence. These he threw to the people at three different times, pronouncing these words, *He hath scattered; he hath given to the poor; his righteousness remaineth for ever*. All this being done, the pope elect went next Sunday, attended by all the orders of the sacred palace, and the principal people of the city, to the basilic of the Vatican, and there, before the confession of St. Peter, he was solemnly consecrated by the bishop of Ostia, to whom this office specially belongs. After this function, the archdeacon and the second deacon gave the pall to the pope, the archdeacon pronouncing these words, *Receive the pall, which is the plenitude of the pontifical office, to the honour of Almighty God, of the most happy virgin his mother, of the blessed apostles St. Peter and St. Paul, and of the holy Roman church*.

After this description, cardinal Rasponi adds these words: "This is what was done when the pontiff was announced or proclaimed in the church of the Lateran; but when the election was made in the Vatican, the pope, immediately after being conducted to the altar by two cardinals, or after having performed his adoration, and offered a secret prayer, kneeling, was placed in a chair behind the altar, where he admitted the cardinal bishops, and the others, during the singing of the *Te Deum*, to kiss his feet, and to receive the kiss of peace. The following Sunday they assembled in the same church, and the pope, crowned according to the custom of his ancestors, went to the Lateran palace; but before entering it, he feasted himself in the *stercorary*, where, sitting down thrice, according to custom, he was introduced by the cardinals into the basilic, distributing money to the populace." There he ascended a throne behind the altar, where he admitted the canons of the basilic to kiss his feet, and to receive the kiss of peace: which being done, he went to place himself in the chairs that were before the oratory of St. Sylvester, where all was performed that has been recited above. But if it happened that the pope was created out of Rome, all the clergy, when he made his entry into that city, and before entering the gate of the Lateran, went to meet him without the gate, in pontifical habits, with the standard of the cross and censers; and, entering thus into the Lateran church, they observed, though in an order somewhat different, all the ceremonies mentioned above. And if the pope, coming to Rome after his consecration, went to the church of St. Peter, the same rites were used there as in the Lateran church, except only that he did not receive the canons of St. Peter to kiss his feet in the portico, and that he did not sit down on the *stercorary*, which is not in that church. For this reason, the next day after mass, he went without the tiara to the Lateran palace, and before entering the basilic, he placed himself on the *stercorary*, with the accustomed ceremonies."

CONSECRATION, or, as it is more usually called, BENE-

DICTION of the waters, denotes a ceremony annually practised in the Greek church, on the 6th of January, or, as we denominate it, Twelfth-day. For this ceremony at St. Petersburg, a sort of wooden chapel or tabernacle, painted green, and steeled round with boughs of firs, is constructed on the ice of the Neva, between the Admiralty and the Imperial palace. This little building is covered with a dome, resting on eight small columns, on which stands the figure of John the Baptist, with the cross in his hand, amidst bulrushes; the inside of the edifice being decorated with paintings, representing the baptism of Jesus, his transfiguration, and other transactions of his life. From the centre of the dome is suspended, by a chain, a monstrous large holy-ghost of wood, over the aperture in the ice, round which are spread rich carpets. This little temple is entirely surrounded with palisadoes, which are also ornamented with fir-branches; the space within being likewise covered with carpets. A sort of gallery round the building communicates with a window of the palace, from which the imperial family come forth to attend the ceremony; though for several years past (says Mr. Tooke) the empress and her grandchildren only saw the solemnity from the windows of the palace. The ceremony begins immediately when the regiments of guards have taken their station on the river. Then the archbishop appears amid the sound of church-bells and the firing of the cannon of the fortrefs, and proceeds along the carpets, attended by his train of bishops and other ecclesiastics, into this little church, where, standing at the hole in the ice, he dips his crucifix three times in the water, at the same time repeating prayers, and concludes with a particular one to the great saint Nicholas; which done, the water is accounted blessed. The prelate then sprinkles with it the whole surrounding multitude, and the banners of all the regiments which are at that time in Petersburg. When the consecration is ended, he retires: and now the people press in crowds to the hole in the ice, where they drink it with pious avidity; mothers, notwithstanding the cold, dip their naked babes in the stream, and men and women pour it on their heads; every one holds it a duty to take home a vessel of the water, in order to purify their houses, and for the cure of certain diseases, for which it is affirmed to be a powerful specific: during which four popes, one at each corner of the aperture, chant a sort of litany for the occasion. Tooke's Life of Cath. II. vol. i. p. 130.

CONSECRATION, in *Ecclesiastical Law*, is one of the ways by which a benefice may be vacated; the others being by death, by cession, by resignation, and by deprivation. Thus, when a clerk is promoted to a bishopric, all his other preferments are void the instant he is consecrated; but there is a method, by the favour of the crown, of holding such livings in *commendam*; which see.

CONSECRATION is particularly used for the benediction of the elements in the eucharist.

The Romanists define it, the conversion of the bread and wine into the real body and blood of Jesus Christ: and that this is the sentiment of their church, is evident from the priest's elevating the host immediately after consecration, for the people to adore it. See ELEVATION, HOST, &c.

There is a great controversy between the Latin and Greek churches, touching the words of consecration; the common opinion among the Romanists, agreeable to St. Thomas and the Schoolmen, is, that the consecration of the bread and wine consists in these words, *This is my body; this is my blood*. The Greeks, on the contrary, attribute the change of the elements to a certain prayer, which they call the *invocation of the Holy Ghost*, rehearsed after the words, *This is*

my body; this is my blood; which the Greeks maintain are only necessary in the process of the consecration, as they contain the history of the institution; not as they contribute any thing to the change.

CONSECRATION of various animals, was common among the ancient Greeks and Romans. Suetorius mentions the consecration of a great number of horses by Julius Cæsar, when he passed the Rubicon; and Eustathius observes, that it was common among the Greeks to consecrate whole herds of cattle, and several sorts of fowls, especially geese and peacocks, to their gods; giving such animals their liberty, and forbidding all persons to touch or molest them. Athenæus remarks, that they paid the same respect to fishes, particularly those best adapted to the palate; and Pliny takes notice, that the dolphin of Octavius Anicius had this favour conferred upon him. Ælian likewise relates, that they sometimes put necklaces about the necks of their fishes, and then turned them loose to their proper element. The Romans also had their magical consecrations: it being customary for their emperors to offer sacrifices, repeat charms, and dispose statues in certain places, imagining that such magical operations would hinder barbarians from entering their dominions. Thus Marcus Antoninus endeavoured to fortify himself against the invasion of the Marcomanni; and some have thought that the palladium of Troy, and the vocal statue of Memnon, were of this kind. Macrobius has given us a particular description of the consecration of the Roman pontiffs, to the following purport: they dug a pit in the earth, into which the person to be consecrated was let down, dressed in priestly vestments, and the pit was covered with a plank bored almost full of holes; a bull, crowned with garlands of flowers, was placed on this plank, and his throat being cut, the blood poured through the plank on the priest, who received it on his head and face. On ascending from the pit, covered with blood, he received the salutation of *Pontifex*.

CONSECRATION, among Medallists, is the ceremony of the apotheosis of an emperor; or his translation into heaven, and reception among the gods. See APOTHEOSIS.

On medals, the consecration is thus represented: on one side is the emperor's head, crowned with laurel, sometimes veiled; and the inscription gives him the title of *divus*: on the reverse is a temple, a bustum, an altar, or an eagle taking its flight towards heaven, either from off the altar, or from a cippus: at other times the emperor is seen in the air, borne up by the eagle; the inscription always, CONSEC-RATIO.

These are the usual symbols: yet on the reverse of that of Antoninus, is the Antonine column. In the apothecis of empresses, instead of an eagle there is a peacock. As to the honours rendered these princes after death, they were explained by the words *consecratio, pater, divus, and deus*. Sometimes after the temple or altar are put, *memoria felix, or memoria æterna*: for princesses, *æternitas, and sœderibus recepta*: on the side of the head, *dea, or Diva*. See MEDAL.

CONJECTARY, a proposition that follows, or is deduced, from some preceding definition, lemmata, axioms, conclusions, or the like. Some rather choose to call it a *consequence*: and others a *corollary*, &c.

CONSECUTIVE CHORDS, in Music, are such as immediately succeed each other in composition or performance. See MUSIC, Plate IV. Holder truly observes, when speaking of the rule in composition, which allows a succession of octaves or fifths, except by contrary motion, that in strictness the same applies to all consecutive intervals whatever; but that the intermixture of major and minor thirds,

and major and minor-sixths in the scale, renders the occurrence of consecutive major-thirds, major-sixths, minor-thirds or minor-sixths, very rare and inoffensive in their cloying effect upon the ear, compared with those of fourths, fifths, or octaves, if care is not taken by the composer to prevent the succession of the latter, except in contrary motions.

CONSECUTIVELY, CONSECUTIVÉ, in the School Philosophy, is sometimes used in opposition to *antecedently*, and sometimes to *effectively, or causally*.

Thus, say the schoolmen, the corruption of one thing is the generation of another, not *effectively*, but *consecutively*: that is, since matter cannot be without form, it is necessary, that the generation of one thing follow upon the corruption of another.

CONSEDIA, in *Ancient Geography*, a place of Gallia Lyonnensis, situated, according to the Itinerary of Antonine, between *Condate* and *Fanum Martii*.

CONSEIL DE GUERRE, Fr. *Council of War*. This is composed of the general in chief, and the general officers of the army, which he commands, whether it be held for the purpose of deliberating among themselves on the measures they ought to pursue in a difficult conjuncture, of an offensive or defensive nature or otherwise; or for some act of military justice; or for accepting, regulating, stipulating, or refusing articles of a proposed capitulation; or for establishing rules and regulations for the police and discipline of the troops; or, in fine, for judging of any military crime or offence.

CONSEIL de Guerre secret, Fr. A secret council of war. A secret council held by the king and his ministers for deliberating on a defensive, offensive, or federative war.

CONSENT of PARTS, in the *Animal Economy*. See SYMPATHY.

CONSENTES, in *Mythology*, derived from the old Latin *consens, to consensel*, denote twelve superior deities among the Romans, or the "dii majorem gentium," who were apprehended to belong to the council of Jupiter. They were comprehended by Ennius in the following districts:

"Juno, Vesta, Minerva, Ceres, Diana, Venus, Mars, Mercurius, Jovis, Neptunus, Vulcanus, Apollo."

Those which were esteemed the superior deities, and were the principal objects of the Pagan worship, had been men, according to Cicero (*Talcul. Disput. lib. i. c. 12, 13.*); and this was taught even in the mysteries. Varro mentions twelve deities under the same denomination, who superintended agriculture. Lib. i. De Re Rustica.

These consentes had a temple at Pisa in Italy; and they had their common altar at Athens, as Plutarch (in *Nicia*) informs us. Aristophanes says, it was usual to swear by them. In ancient inscriptions they are thus marked; J. O. M. i. e. *Jovi optimo maximo, CÆTERISQ. DIS CONSENTIBUS*. They were also called "Dii magni," "cælestes," or "nobles;" and are represented as occupying a different part of heaven from the inferior gods, who are called "Plebs."

CONSENTIA were feasts instituted in honour of these deities.

CONSENTIA, in *Ancient Geography*, *Cosenza*. a town of Italy and capital of the country of the Brutii by whom it was built. It was situated on the small river Crathis. Alexander, king of Epirus, surprised it in his expedition into Italy. See COSENZA.

CONSEQUENCE, in *Logic*, the conclusion of a reasoning, or argument.

The two premises of a syllogism being granted, the consequence must also be granted.

In a more restrained signification, consequence is used for the relation or connexion between two propositions, wherof one follows, or is inferred, from the other.—Thus: *It is an animal, and therefore feels.*

CONSEQUENT, the last proposition of an argument; being something deduced or gathered from a preceding argumentation. An enthymeme only contains two propositions, the antecedent and consequent: if the antecedent be absurd, the consequent must be too.

CONSEQUENT, in a more precise sense, is used for the proposition which contains the conclusion, considered in itself, and without any regard to the antecedent: in which sense, the consequent may be true, though the consequence be false.

CONSEQUENT of a ratio, in *Arithmetic*, the latter of the two terms of a ratio; or that to which the antecedent is referred. See PROPORTION.

Thus, in $a : b$, or a to b , b is the consequent, a the antecedent.

CONSEQUENTS, in *Rhetoric*, are also used to signify such things, as being allowed, necessarily, or very probably, infer their antecedents. Thus with respect to a substance, it is corruptible, and therefore material.

CONSEQUENTE, in the *Italian Music*, is used to signify concords, or those intervals which afford pleasure, be they either perfect, as the fifth and eighth, or imperfect, as the third, sixth, &c. See OCTAVE.

CONSEQUENTIA, in *Astronomy*, is opposed to antecedentia; and a motion in consequentia is a motion in the order of the signs of the zodiac.

CONSEQUENTIAL DAMAGES, in *Law*. See DAMAGE.

CONSEQUENZA, *Ital.* a term in *Music*, used by Zarlino and other old authors, instead of *Fuga*; but P. Martini makes it synonymous with *Riposta*, or reply to a subject given.

CONSERANS, or CONFERANS, in *Geography*, the name, before the revolution, of a country in France, in Gascony, and the diocese of a bishop, who resided at St. Leger, the capital; it was bounded on the east by Foix, on the south by Catalonia, and on the north and west by Comminges.

CONSERVATION, in *Ontology*, denotes giving duration, or continuance in existence to all creatures, in contradistinction to creation, which gives existence to all created substances. Some of the ancient schoolmen have represented conservation as a continued creation; to which it has been objected that as God, whenever he creates a substance, must create it with all the properties, modes, and accidents which belong to it, it will follow, that he must at the same time create or give being to, all their sinful thoughts and inclinations, and even their most criminal and abominable actions; or, in the most complete sense of the term, be the author of sin. Warts's *Philos. Ess. Ess. xi § 4.*

CONSERVATIVE SUTURE. See SUTURE.

CONSERVATOR, an officer established for the security and preservation of the privileges granted to some cities and communities; or, a person who has a commission to judge of, and decide, the differences arising among them. In most catholic universities, there are two conservators; the conservator of royal privileges, or those granted by kings; and the conservator of apostolical privileges, or those granted by the pope. The first takes cognizance of personal and mixed causes between the regents, students, &c. and the latter of spiritual matters between ecclesiastics.

VOL. IX.

Anciently there were appointed conservators of treaties of peace between princes; and these conservators became judges of the infractions made on a treaty, and were charged with procuring satisfaction to be made. They were usually the feudatories of the several powers. In lieu of conservators, princes now have recourse to other indifferent princes to guarantee their treaties. See GUARANTEE.

CONSERVATOR of the peace, in our *Ancient Customs*, was a person who had an especial charge, by virtue of his office, to see the king's peace kept.

Till the erection of justices of the peace by king Edward III. there were several persons who by common law were interested in keeping the same: some having that charge as incident to other offices; and others simply, or of itself, called *custodes*, or conservators of the peace. Those that were so by virtue of their office still continue; but the latter are superseded by the modern justices.

The chamberlain of Chester is still a conservator in that county; by virtue of his office. 4 Inst. 212.

Sheriffs of counties at common law are conservators of the peace; and constables, by the common law, were conservators, but some say they were only subordinate to the conservators of the peace, as they now are to the justices.

The king's majesty is, by his office and dignity royal, the principal conservator of the peace within all his dominions; and may give authority to any other to see the peace kept, and to punish such as break it: hence it is usually called "the king's peace." The lord chancellor, or keeper, the lord treasurer, the lord high steward of England, the lord marshal, the lord high constable of England, (when any such officers are in being,) and all the justices of the court of King's Bench (by virtue of their offices,) and the master of the rolls (by prescription) are general conservators of the peace throughout the whole kingdom, and may commit all the breakers of it, or bind them in recognizances to keep it. The other judges are only so in their own courts. The coroner is also a conservator of the peace within his own county; as is also the sheriff; and both of them may take a recognizance or security for the peace. Constables, tithing-men, and such like, are also conservators of the peace within their own jurisdiction; and may apprehend all breakers of the peace, and commit them till they find sureties for their keeping it.

Those that were, without any office, simply and merely conservators of the peace, either claimed that power by prescription, or were bound to exercise it by the tenure of their lands; or, lastly, were chosen by the freeholders in full county court before the sheriff; the writ for their election directing them to be chosen "de probioribus et potentioribus comitatus sui in custodes pacis." But when queen Isabel, the wife of Edward II., had contrived to depose her husband by a forced resignation of the crown, and had set up his son Edward III. in his place, this being an unprecedented measure, caused an alarm; and, therefore, in order to prevent any insurrections, and disturbance of the peace, the new king sent writs to all the sheriffs of England, vindicating the manner of his obtaining the crown, and commanding each sheriff to keep the peace throughout his bailiwick, on pain and peril of disheritance and loss of life and limb. Soon after it was ordained in parliament, that for the better maintaining and keeping of the peace in every county, good men and lawful, who were no maintainers of evil, or barretors in the country, should be assigned to keep the peace. Thus, and at this time, the election of conservators of the peace was taken from the people, and given to the king; such assignment being construed to

be by the king's commission. Nevertheless, they were still called only conservators, wardens, or keepers of the peace, till the statute 34 Edw. III. c. 1. gave them the power of trying felonies; and then they acquired the more honourable appellation of justices. Blackst. Comm. vol. i. See JUSTICE.

CONSERVATOR of the truce and safe conducts; *conservator induciarum & salvoorum regis conductuum*, was an officer appointed in every sea-port, under the king's letters patent. His charge was to enquire of all offences committed against the king's truce and safe conducts, upon the main sea, out of the franchises of the cinque-ports, as the admirals were wont to do, and such other things as are declared in statute 2 Hen. V. ft. 1. cap. 6.

Two men learned in the law of the land were joined to such conservators, for hearing and determining according to that law the same treasons, when committed within the body of any county. The above-cited statute, so far as it made these offences amount to treason, was suspended by 14 Hen. VI. c. 8., and repealed by 20 Hen. VI. c. 11., but revived by 29 Hen. VI. c. 2., which gave the same powers to the lord chancellor, associated with either of the chief justices, as belonged to the conservators of truce and their assessors; and enacted that, notwithstanding the party be convicted of treason, the injured stranger should have restitution of his effects, prior to any claim of the crown. See *SAFE CONDUCT*.

CONSERVATORIO, *Ital.* a title given in Italy to almost all charity-schools; but chiefly to those where children are taught music, and are otherwise educated with a view to that profession. The *conservatorios* of the city of Venice have been much celebrated by all travellers previous to the revolution: it had four of these schools: the *Ospedale della Pietà*, the *Mendicanti*, the *Incucabile*, and the *Ospedaleto a S. Giovanni a Paulo*, at each of which there was a performance every Saturday and Sunday evening, as well as on great festivals. At these, the performers, both vocal and instrumental, were all girls; the organ, violins, flutes, violoncellos, bassoons, and even double-basses, kettle drums, and French-horns, were supplied by females. Each of these establishments was a kind of foundling hospital for natural children and orphans, under the protection of several nobles, citizens, and merchants, who, though the revenue is very great, yet contribute annually to its support. These girls are maintained here till they are married, and all those who have talents for music are taught by the best masters of Italy.

There were three conservatorios in the city of Naples, for the education of boys who were intended for the profession of music, of the same kind with those of Venice, for girls. As the scholars in the Venetian conservatorios have been justly celebrated for their taste and neatness of execution, so those of Naples have long enjoyed the reputation of being the first *contra-puntists*, or composers in Europe. It is from these seminaries that Italy, and all Europe, have been delighted with the genius and talents of the two Scarlattis, Vinci, Leo, Pergolese, Porpora, Farinelli, Cafarelli, Gizziello, Durante, Jomelli, Perez, Piccini, Trueta, Anfossi, Sacchini, Pacifello, and innumerable others of the first eminence among composers and performers both vocal and instrument 1.

CONSERVATORY, in *Gardening*, a place constructed somewhat in the manner of the green-house, but more spacious and elevated, and finished in a neater and more perfect manner; being designed for containing and preserving the more rare and curious sorts of exotic plants, as well as for affording amusement by being provided with walks laid with some sort of neat material, according to the taste of

the proprietor, in a serpentine or other irregular manner between the plants.

Houses of this nature should have dry and rather elevated situations, at a small distance from the residence, and be ranged in such a manner as to have the benefit of the sun as much as possible during the day. They must likewise be provided with flues for the purpose of communicating fire heat when it may be necessary, and also valves and other contrivances for the introduction of fresh air when wanted, and to afford due ventilation.

The sides, ends, and roofs, must be formed with glass, as in the green-house, in order to admit light freely; and at the same time protect the plants.

It has been generally considered as synonymous with green-house, but its principle or essential difference consists in this, that in the latter the trees and plants are either in tubs or pots; and placed on stands or stages through the winter till they are removed into some sheltered situation abroad for the summer; while in the former the ground plan is laid out in beds and borders made up of the finest compositions of soils or of earthy materials that can be procured, three or four feet in depth; in which the trees and plants, taken out of their tubs or pots, are regularly planted, in the same manner as hardy plants in the open air. And instead of taking out the plants in the summer, as in the green-house, the whole of the glass roof is taken off, and the plants exposed to the open air; when on the approach of autumn-frosts the lights are again put on, and remain so till the state of the season is such as that they can be removed again without danger from cold.

In cases of necessity, it is evident however that these buildings may also be used as green houses by introducing stages instead of beds, in which case the glass roof should be fixed. Other conveniences may be attached to them, such as retiring rooms, seed rooms, aviaries, &c. Some buildings of this sort are, according to the editor of Miller's dictionary, formed so as to have one of the wings facing the south-east, and the other the south-west, so that from the time of the sun's first appearance upon any part of the building, until it goes off at night, it may be constantly reflected from one part to the other, and the cold winds be also kept off from the front of the centre building. In the area of the adjoining rooms or wings, many of the more tender exotic plants may be placed in the summer season and in the spring before the plants can be set out. The beds and borders of this area may be full of anemones, ranunculuses, early tulips, &c. which will be past flowering, and the roots fit to take out of the ground, by the time the plants are taken out of the house. In the centre of this area may be a small basin of water, which will be very convenient for watering the plants, not only on account of its nearness, but because the water will be softened and warmed by the reflection from the glasses. And the wing facing the south-east should always be preferred for the warmest, or bark-floves, because the sun, at its first appearance in the morning, shines directly upon the glasses, and warming the air of the house, gives new life to the plants, after the long nights of the winter season.

It is also farther observed, that in these buildings, if there are not sheds running behind them their whole length, the walls should not be less than three bricks thick, and if they are even more it will be better, because where the walls are thin and exposed to the open air, the cold will penetrate; and when the fires are made the heat comes out through the walls, so that it will require a larger quantity of fuel to maintain a proper temperature of warmth in the houses; and in general, the clearer and better these houses are built, the less fuel will be required to warm them, so that the

first expence in building them properly will be the cheapest, where the after expence of fires is taken into the account.

The ground plan and elevation of an elegant and very convenient improved house of this sort may be seen in the appropriate plate.

CONSERVATORY is sometimes used for a place to preserve snow and ice. See Phil. Trans. N^o 8. p. 140. See *Ice-House*.

CONSERVE, in *Pharmacy*, &c. a dry confection, or form of medicine, or food, contrived to preserve the flowers, leaves, roots, peels, or fruits of several simples, as near as possible to what they were when fresh-gathered; and to give them an agreeable taste.

Conserve are compositions of recent vegetable matters and sugar beaten together into an uniform mass. Vegetables whose virtues are soon lost by drying, may be preserved in this manner for a considerable time unimpaired, the sugar preventing the natural decomposition and moulding which would otherwise take place.

The preparation of the conserve is as simple as possible. The sugar is first ground to fine powder, and then mixed by long beating (not by solution) with the vegetable pulp or other material. No heat or other mode of preparation is employed, so that the vegetable matter remains as nearly as possible in the state in which it existed in the plant at the moment of gathering. The conserve directed by the London college are those of hips, roses, sloes, arum and squills. Of these the two last alone can be considered as active medicines; and the arum is exhibited with peculiar efficacy in this form, as its pungency to the palate is a little sheathed, whilst its internal stimulating powers remain unaltered.

The *conserve of arum*, or cuckow-pint, is a composition of arum bruised, half a pound, and double refined sugar, $1\frac{1}{2}$ pound, beaten together in a mortar. Those who hold in veneration the integrity and experience of Sydenham, will have no doubt of the effects of this medicine in rheumatic cases. This conserve may be given to adults in doses of a dram.

The *conserve of the hip*, or "conserva cynosbati," is formed by mixing one pound of hips with 20 ounces, by weight, of double refined sugar, powdered. This pulp should be separated with great care from the rough prickly matter inclosing the seeds; a small quantity of which, retained in the conserve, is apt to occasion an uneasiness at the stomach, a pruritus about the anus, and sometimes vomiting.

The *conserve of the sloe*, "conserva pruni sylvestris," is prepared by putting the sloes in water upon the fire, that they may soften, taking care that they do not burst; then taking them out of the water, pressing out the pulp, and mixing it with three times its weight of double refined sugar.

The *conserve of squills*, "conserva scillaz," is made by beating together in a mortar one ounce by weight of fresh squill with five ounces by weight of double refined sugar. This conserve is directed to be prepared in a small quantity, in order to guard against its variation in strength. It may be given to adults, from half a dram to two scruples, or more; especially when fresh.

For the *conserve of sea-worm-wood*, the outer rind of the *Seville orange*, *wood sorrel*, and of the *red rose*; pluck the leaves from the foot-stalks, and the unblown petals from the calyx, cutting off the heels: take off the outer rind of the oranges with a grater: when you have thus prepared them, bruise them with a wooden pestle in a marble mortar; and then beat them up with three times their weight of double-refined sugar, until they are mixed. The sugar should be powdered by itself, and passed through a sieve, before it is

mixed with the vegetable mass; otherwise it cannot be properly incorporated. Rose buds, and some other vegetables, are usually prepared for mixing with sugar by a small wooden mill, contrived for that purpose. All the conserve are to be kept in close vessels, especially those of arum and squill.

With regard to fruits, as currants, &c. they set them on the fire to make them yield their juice, then drain and strain them, and thicken what comes from them over the fire, and add to it the sugar. This last sort of conserve is particularly called a *jelly*; which see.

CONSERVES, Fr. in *Military Language*. See COURTER-GUARD, or *contre-garde*, the names by which this work is usually and best known.

CONSET'S BAY, in *Geography*, a bay on the N.E. coast of the island of Barbadoes, N. of Conset's point, which is a cape, 10 miles N.E. of Bridge-town.

CONSETTI, ANTONIO, in *Biography*, an historical painter, native of Modena, where he enjoyed considerable reputation, in the last century. He was born in the year 1636, and is said to have been successively the disciple of his countrymen Francesco Stringa, and Donato Creti of Bologna, from whose precepts and example he acquired a correct style of drawing, and facility of composing. Unfortunately, however, his colouring is destitute of those charms of union and softness, which captivate the eye at first sight. The principal part of the life of this artist was spent in the state of Modena, where his pictures are by no means uncommon, and where he died in 1766. Lanzi. Storia Pittorica.

CONSIDERATIO CURIE, in *Law*, terms often occurring in law proceedings, and where matters are determined by the court. "Ideo consideratum est per curiam," i. e. therefore it is considered and adjudged by the court. *Consideratio curie*, &c. denotes the judgment of the court.

CONSIDERATION, the material cause, or *quid pro quo*, of any contract, and without which no contract is obligatory or binding.

This consideration is either *expressed*; as if a man bargain to give ten guineas for a horse, or to sell his land for a certain sum, or to grant it in exchange for other lands, &c.; or when a person agrees for a stipulated sum to do a thing; or *implied*, when the law itself enforces a consideration; as if a man coming into an inn, take meat, drink, and lodging for himself and horse, the law presumes he intends to pay for them, though there be no express contract between him and his host: and if he discharge not the house, the host may stop his horse.

Considerations may be regarded either as pertaining to *contracts* generally, or to *deeds* in particular. As to *contracts*, consideration may be defined to be the reason which moves the contracting party to enter into the contract. The civilians hold, that in all contracts, either express or implied, there must be something given in exchange, or something that is mutual or reciprocal. This thing, which is the price or motive of the contract, is called the consideration; and it must be a thing lawful in itself, or else the contract is void. A good consideration is that of blood or natural affection between near relations; the satisfaction accruing from which the law esteems an equivalent for whatever benefit may move from one relation to another. (3 Rep. 83. 1 Inst. 271. 1 Rep. 176.) This consideration may sometimes, however, be set aside, and the contract become void, when it tends in its consequences to defraud creditors or other third persons of their just rights. But a contract for any *valuable* consideration, as for marriage, for money for work done, or for other reciprocal considerations, can never be un-

peached at law; and, if it be of a sufficient adequate value, is never set aside in equity: for the person contracted with has then given an equivalent in recompence, and is therefore as much an owner, or a creditor, as any other person. These valuable considerations are divided by the civilians into four species. 1. *Do, ut des*; as when I give money or goods on a contract to receive in return money or goods: of this kind are all loans of money upon bond, or promise of repayment, and all sales of goods, in which there is an express contract to pay so much for them, or else the law implies a contract to pay as much as they are worth. 2. *Facio, ut facias*; as when I agree with a man to do his work for him, provided that he will do mine for me; or if two persons agree to intermarry; or to do any other positive acts on both sides: or, to forbear on one side on consideration of something done on the other, as that in consideration A, the tenant, will repair his house, B, the landlord, will not sue him for waste; or, for mutual forbearance on both sides. 3. *Facio, ut des*; as, when a man agrees to perform any thing for a price, either specifically mentioned, or left to the determination of the law to let a value on it. Thus, when a servant hires himself to his master for agreed wages, he contracts to serve his master for that specific sum; or, otherwise, if he be hired generally, he is under an implied contract to perform this service for its reasonable worth. 4. *Do, ut facias*; as, when I agree with a servant to give him such wages upon his performing such work, which is the last species inverted; for *servus facit, ut herus det*, and *herus dat, ut servus faciat*.

A consideration of some sort or other is so absolutely necessary to the forming of a contract, that a *nudum pactum*, or agreement to do or pay any thing on one side, without any compensation on the other, is totally void in law; and a man cannot be compelled to perform it. (Dr. and Stud. l. 2. c. 24.) Thus, if one man promises to give another 100*l.*, nothing is contracted for or given on the one side, and therefore nothing is binding on the other. And, however a man may or may not be bound to perform it, in honour or conscience, which the municipal laws do not decide; those laws will certainly not compel the execution of what he had no visible inducement to engage for; and, therefore, our law has adopted the maxim of the civil law, that “*ex nudo pacto non oritur actio*.” But any degree of reciprocity will prevent the pact from being nude; nay, if even the thing be founded on a prior moral obligation (as a promise to pay a just debt, though barred by the statute of limitations), it is no longer *nudum pactum*. And as this rule was principally established to avoid the inconvenience that would arise from setting up mere verbal promises, for which no good reason could be assigned, it therefore does not hold in some cases, where such promise is authentically proved by written documents. For if a man enters into a voluntary bond, or gives a promissory note, he shall not be allowed to aver the want of a consideration in order to evade the payment; for every bond from the solemnity of the instrument, and every note from the subscription of the drawer, carries with it an internal evidence of a good consideration. Courts of justice will therefore support them both, as against the contractor himself; but not to the prejudice of creditors or strangers to the contract. Plowd. 308, 309. Hard. 4. 1 Ch. Rep. 157. Ld. Raym. 760. Fonblanque, Treat. Eq. 334. n.). See CONTRACT.

With regard to *deeds*, it may be observed, that they must be founded upon good and sufficient consideration; not upon an usurious contract (stat. 13 Eliz. c. 8.); nor upon fraud or collusion, either to deceive purchasers *bona fide* (stat. 27

Eliz. c. 4.), or just and lawful creditors (stat. 13 Eliz. c. 5.); any of which bad considerations will vacate the deeds, and subject such persons as put the same in use, to forfeitures, and often to imprisonment. A deed also, or other grant made without any consideration, is, as it were, of no effect; for it is construed to enure or to be effectual, only to the use of the grantor himself. (Park. § 533.). The consideration may be either a *good* or a *valuable* one. A good consideration is such as that of blood, or of natural love and affection, when a man grants an estate to a near relation; being founded on motives of generosity, prudence, and natural duty. A valuable consideration is such as money, marriage, or the like, which the law esteems an equivalent given for the grant (3 Rep. 83.); and is therefore founded in motives of justice. Deeds made upon good consideration only, are considered as merely voluntary, and are frequently set aside in favour of creditors, and *bona fide* purchasers. See DEED.

A mere voluntary censure will not be a good consideration of a promise; but the value and proportion of the consideration is not material for maintaining an action, whether it be a penny or 100*l.*; but a jury will give damages proportionable to the loss. (Hob. 5. 10 Rep. 76.) A consideration that is void in part, is void in the whole; and if two considerations be alleged, and one of them is found false by the jury, the action fails. (Hob. 126. Cro. Eliz. 848.) But if there be a double consideration for the grounding of a promise, for the breach of which an action is brought; though one of the considerations be not good, yet if the other be good, and the promise broken, the action will lie upon that breach; for one consideration is sufficient to support the promise. (1 Lill. 297.) A consideration must be lawful, to ground an *assumpsit*. (2 Lev. 161.) Where considerations are valuable, and consist of two or more parts, there the performance of every part ought to be shewn. (Cro. Eliz. 579.) In case a deed of feoffment be made of lands, or a fine and recovery be passed, and no consideration is expressed in the deed, &c. for the doing thereof, it shall be intended by the law, that it was made in trust for the use of the feoffer or confour; for it shall be presumed he would not part with his land without a consideration; and yet the deed shall be construed to operate something, and that which is most reasonable. (4 Lill. Abr. 299.) Blackst. Com. vol. ii. Jacob's Law Dict. by Tomlins.

CONSIGLIONE, in *Geography*, a town of the island of Sicily, in the valley of Mazar; 19 miles S. of Palermo.

CONSIGNE, Fr. parole or counter-sign. When used in the masculine gender, it also means a person formerly paid by the French government for residing constantly in a garrisoned town in order to take cognizance of all persons that entered by the gates or went out of them. He had a place allotted to him, and regularly delivered a report to the governor or commandant of the place.

CONSIGNÉ. A person who could not pass the post, or quit the house, to which the order of his superior had consigned him.

CONSIGNMENT, or CONSIGNATION, the depositing any sum of money, bills, papers or commodities, in sure hands; either by order of a court of justice, in order to their being delivered to the persons to whom they are adjudged; or voluntarily, in order to their being remitted to the persons they belong to, or sent to the places they are destined for.

CONSIGNMENT *of goods*, is the delivering or making them over to another. Thus goods are said to be consigned to a factor,

factor, when they are sent to him to be sold, &c. or when a factor sends back goods to his principal, they are said to be consigned to him.

CONSILINUM, in *Ancient Geography*, a town of Italy, in a gulf between Brutium and Zephyrium, according to P. Mela. Frontinus says, that it was a Roman colony, and places it in Lucania.

CONSILIUM, *dies consilii*, in *Law*, was a time allowed for the accused to make his defence, and to answer the charge of the accuser. It is now used for a speedy day appointed to argue a demurrer; which the court grants after a demurrer joined, on reading the record of the cause. See IMPARLANCE.

CONSIMILICASU. See CASU.

CONSISTENCE, a state of rest, wherein things capable of growth or decrease, continue for some time at a stand, without either.

This term is particularly used with regard to trees, for the time, or age, beyond which they do not grow, and yet at which they do not decline.

Thus we distinguish three states or stages of a tree; its growth, consistence, and return: and these are common to all trees, even fruit trees.

The consistence of an oak is from fifty to a hundred and sixty years: some, however, hold, that their consistence only commences from a hundred years; asserting that they grow till that time, and that they continue in that state of perfection to two hundred years of age.

CONSISTENCE, in *Physics*, is that state of a body wherein its component particles are so connected, or entangled among themselves, as not to separate or recede from each other.

Consistence only differs from continuity in this, that consistence implies a regard to motion or rest, which continuity does not; it being sufficient to denominate a thing continuous, that its parts are contiguous to each other.

When used relative to a disease, it imports the crisis or acme thereof: when applied to the humours, excrements, or excretions, it imports their state as to thickness or thinness.

CONSISTENCE is particularly used with regard to bodies considered as they are more soft, or more hard, more liquid, or more dry.

Forms of medicines, as electuaries, lambatives, boluses, syrups, unguents, &c. differ chiefly in consistence.

Not only the gratefulness, but also the operation, of medicines, depend in some measure on their consistence; for medicines of a thick consistence are taken into the stomach, and penetrate into the body with greater difficulty than such as are thin and liquid; and it requires more trouble to swallow a thick than a thin medicine: for this reason thick medicines are generally nauseous and ungrateful; and this is the reason why cathartic boluses are often dissolved in some agreeable liquor, since in this form they are more grateful than in any other: for this reason also apozems are generally clarified by whites of eggs, or a strainer.

On the contrary, a thick consistence is on some occasions more to be desired; in ulcers of the aspera arteria, and esophagus, for instance, where we must give medicines made up with gum tragacanth, or other substances of a like nature, which by their viscosity fix the medicines, as it were, longer to the part affected.

CONSISTENT *Bodies*, is a term used by Mr. Boyle,

for such as we ordinarily call *firm*, or *fixed bodies*; in opposition to *fluid* ones.

That author has a particular essay on the *atmosphere of consistent bodies*; wherein he shews, that all, even solid, hard, ponderous and fixed bodies, do exhale or emit effluvia to a certain space all around them.

CONSISTENTES, in *Church History*, a kind of penitents who were allowed to assist at prayers, but could not be admitted to receive the sacrament.

CONSISTORIAL *Advocate*. See ADVOCATE.

CONSISTORY, or *Roman Consistory*, denotes the college of cardinals: or the pope's senate, and council, before whom judiciary causes are pleaded.

De-Cange derives the word from *consistorium*; i. e. *locus ubi consistitur*; used chiefly for a vestibule, gallery, or antechamber, where the courtiers wait for admission; and called a *consistente multitudo*.

The consistory is the first court, or tribunal of Rome; it never meets but when the pope pleases to convoke it: the pope presides in it in person, mounted on a magnificent throne, and habited in his *pontificalia*; on the right are the cardinal bishops and priests, and on the left the cardinal deacons.

The place where it is held, is a large hall in the apostolical palace, where princes and ambassadors of kings are received. The other prelates, protonotaries, auditors of the rota, and other officers, are seated on the steps of the throne: the courtiers sit on the ground; ambassadors on the right, and consistorial and fiscal advocates behind the cardinals.

Besides the public consistory, there is also a private one, held in a retired chamber, called the chamber of *papegay*; the pope's throne here being only raised two steps high.

Nobody is here admitted but the cardinals, whose opinions are collected, and called *sentences*. Here are first proposed and passed all bulls for bishoprics, abbeyes, &c. Hence bishoprics, and abbeyes, are said to be consistorial benefices; in regard, they must be proposed in the consistory, the annats be paid to the pope, and his bulls taken.

Anciently they were elective; but by the concordat, which abolishes elections, they are appointed to be colated by the pope alone, on the nomination of the prince.

CONSISTORY was also the name of a court under Constantine, where he sat in person, and heard causes: the members of this court were called *comites*.

CONSISTORY is also used among the reformed, for a council or assembly of ministers and elders, to regulate their affairs, discipline, &c.

CONSISTORY, or *Court Christian*, in the *English Laws*, is a council of ecclesiastical persons, or the place of justice in an ecclesiastical or spiritual court.

Every archbishop and bishop has a consistory-court, held, before his chancellor or commissary, who is the judge, and supposed to be skilled in the civil and canon law, either in his cathedral, or in some other convenient place of his diocese, for ecclesiastical causes, arising within their respective dioceses. In places of the diocese, far distant from the bishop's consistory, the bishop appoints a commissary, *commissarius foraneus*, to judge in all causes within a certain district, and register to enter his decrees, &c. (2 Rol. Abr. 286. Seld. Hist. Tithes, 413, 414.) The spiritual court was anciently, in the time of the Saxons, joined with the county or hundred court; and the original of the consistory court,

court, as divided from those courts, is found in a law of the Conqueror, quoted by lord Coke.

From this court there lies an appeal to the archbishop of each province respectively, by virtue of stat. 24 Hen. VIII. c. 12.

CONSOLATION, one of the places in *Rhetoric*, wherein the orator endeavours to abate and moderate the grief or concern of another.

In consolation, a principal regard is to be had to the circumstances and relations of the parties. Scaliger considers this exceeding well, *De Arte Poetica*. "The consolator, says he, is either a superior, an inferior, or an equal; with regard, either to preferment, honour, wealth, wisdom, or age. Livia is therefore to comfort Ovid, in a manner very different from that wherein Ovid comforts Livia. Thus, as to authority, a father and son, Cæsar and Pompey, are to conduct their consolations very differently: so in wealth; as if a client should undertake to comfort Crassus: in wisdom; as when Seneca comforts Polybius and his mother: as to age, there need no examples."

"A superior may interpose his authority, and may even chide; a wife man may even dispute; sentences will become him. An inferior is to show respect and affection, and own he had this from some wife or learned person: an equal to appeal to their common friendship."

CONSOLE, in *Architecture*, a bracket or projecting body commonly in the shape of the letter S, which is used to support a cornice, vase, bust, statue, or even a column, as in the barbarous architecture of the Diocletian palace at Spalatro. Corbel is essentially the same thing as console, but is generally confined to the description of Gothic building.

CONSOLIDA, in *Botany*, Major; Bauh. Pin. See *SPHYNTHUM officinale*.

CONSOLIDA *media*; Bauh. Pin. See *AJUGA*.

CONSOLIDA *palystris*; Taber. See *SENECIO palystris*.

CONSOLIDA *regalis*; Bauh. Pin. Taber. Mons. See *DELPHINIUM*.

CONSOLIDATION, in *Law*, the combining and uniting of two benches into one; stat. 37 Hen. VIII. cap. 21. which union is to be by the assent of the ordinary, patron, incumbent, &c. and to be of small churches lying near together.

The term is borrowed from the civil law; where it properly signifies an union of the possession, or occupation, with the property. Thus, if a man hath by legacy *usufructum fundi*, and afterwards buys the property, or fee-simple of the heir; this is called a consolidation.

CONSOLIDATION, in *Surgery*, is the process of nature, by which a solution of continuity is united, either in a soft or hard part of the body; and, as this process was formerly supposed to be within the controul of surgeons, the remedial applications employed for that purpose were denominated *consolidating medicines*, or *jarotics*. Of this kind were the different balsamic and resinous unguents, with all the stimulating compositions containing turpentine. The surgeon may certainly vary the ingredients of his dressings in such a manner as to change the surface of a sore, and, in many cases, so as to occasion a healing process; but, after all, he acts only as the hand-maid of nature, and is unable to advance one step towards the consolidation of a wound, unless there be a previous tendency in the part to heal.

Warm stimulating applications will indeed cause a flow of blood to the part whereon they are applied; and by exciting the healthy action of blood-vessels, as well as by increasing the sensibility of the skin or adjacent ulcerated surface, they may promote suppuration, and even contribute to

effect a cure, where it seemed unlikely before. In this sense of the term, therefore, we may admit the existence of consolidating remedies.

CONSONANCE, in *Grammar*, denotes a like cadence, or close of words, periods, &c.

Consonances are ordinarily faults in discourse, especially in English prose: though the ancients make a figure of them, which they call *ἁρμονία*. Too great a consonancy in the rhymes has always an ill-effect.

CONSONANCE, in *Music*, signifies the union or agreement of two sounds produced at the same time, and in this sense, it includes all sorts of musical intervals, which naturally divide themselves into three kinds, *viz.* 1st. *Concords*, or such as produce an agreeable and pleasing effect upon the ear; see that article. 2^d. *Imperfect or tempered concords*, which are intervals nearly related to concords in respect to their position in the scale, as explained when we were treating of perfect concords, and also in partaking somewhat of the pleasing effect of the concords to which they belong, when not too much tempered; these are also further distinguished by the phenomena of *BEATS*, see that article; and *IMPERFECT Concords*; and 3^d. *Discords*, which are intervals that have a grating or disagreeable jarring effect upon the ear, or sometime a fluttering roughness when nearly equal to an imperfect concord, or to certain intervals in the scale, as the tones major and minor, the tritone, semidiapente, and others, as mentioned in relating Dr. Robison's experiments upon the concords. See *DISCORD* and *FLUTTER*. Consonance, considered as signifying a sound arising from several others sounding together, whether agreeable or disagreeable to the ear, may be divided into *concord* and *discord*. On this principle, Dr. Holder defines *consonancy*, "A passage of several tunable sounds through the medium, frequently mixing and uniting in their undulated motions, caused by the well proportioned commensurate vibrations of the sonorous bodies, and consequently arriving smooth and sweet, and pleasant to the ear; as, on the contrary, *dissonancy*, he maintains to arise from disproportionate motions of sounds, not mixing, but jarring and clashing as they pass, and arriving in the ear grating and offensive."

This notion of a consonance exactly quadrates with that we have already laid down for a *concord*. Accordingly, most authors confound the two together; though some of the more accurate distinguish them; making consonance to be what the word implies, a mere *sounding of two or more notes together, or in the same time*; in contradistinction to the motion of those sounds in *succession*, or one after the other.

In effect, the two notions coincide; for two notes, thus played in consonance, constitute a concord; and two notes that please the ear in consonance, will likewise please it in succession. Notes in consonance constitute harmony, as notes in succession constitute melody.

In the popular sense, consonances are either *simple* or *compound*, &c. The most perfect consonance is union; though many, both among the ancients and moderns, discard it from the number of consonances; as conceiving consonance an agreeable mixture of different sounds, grave and acute; not a repetition of the same sound.

The second consonance is the octave; then the fifth, the fourth, the thirds, and the sixths: the rest are multiples, or repetitions of these.

Consonance is sometimes used by writers in the same sense with *concord*; and thus, such are said to be variable, and the term imperfect is prefix'd when applied to intervals which have a major and a minor of *the same name*, as thirds and

and sixth, and perfect when applied to conords which never change their name, as the fifth, fourth, and octave; the absurdity of this use of the words perfect and imperfect is so apparent, that we wish to see them disused, and discountenanced in elementary books on music, in order that these terms may exclusively apply to intervals correctly tuned or perfect in respect of their accordance, or the reverse: there was an impropriety in originally assigning one name to the thirds and to the sixth, which naturally have no nearer relation to each other, than the fourth and fifth, or octave and unison, or even so much; but these being established in use, may safely remain, without our continuing to confound and reverse all ideas of perfection and imperfection, in consequence only of this defect in the musical nomenclature.

Consonances are said, by Dr. Smith, (*Harmonics*, p. 19.) to be *pure*, where none of the equal times between the pulses of the acuter found are subdivided by any intermediate pulse of the graver; and *interrupted* when any of those equal times are interrupted by one or more pulses of the graver found. See *CYCLES*.

* **CONSONANT**, in *Grammar*, a letter which cannot be perfectly sounded by itself; but joined with a vowel, forms an articulate found, by a particular motion or contact of the parts of the mouth: and hence the name *con-sonant*, q. d. *que sonant cum alia*.

A consonant, considering it philosophically, is nothing else but the modification of a found, produced by means of the organs of the voice, not a production of found itself: thus, v. gr. the founds signified by the characters, *a, e, i, o, u*, &c. are differently modified when we say *ah*, than when we say *ae* or *ea*, *ad* or *da*; and those modifications are called *consonants*.

Accordingly, Dr. Wilkins (*Essay towards a real Character*, p. 366.) defines consonants to be those letters, in the pronouncing of which the breath is intercepted, by some collision or closure, among the instruments of speech: and for this reason, he says, they are styled "*clausæ literæ*," in contradistinction to vowels, which are "*apertæ*." See **VOWEL**.

Consonants are divided into *single*, as *b, m, q*, &c. and *double*, as *x* in *axillary*, corresponding to the ξ of the Greeks.

Consonants have been also divided into *mutes* and *semi-vowels*. The mutes are such as cannot be sounded at all without a vowel, and all of which begin their found with a consonant; as *b, d, g, k, p, q, t*, and *c* hard, being expressed *be, de, te*, &c. The semi-vowels have of themselves an imperfect found, and all begin with a vowel; as *l, m, n, r, s, f, z*, &c. being founded *ef, el, em*, &c. Four of these, viz. *l, m, n, r*, are distinguished by the name of *liquids*, from their readily uniting with other consonants, and flowing, as it were, into their founds. The mutes, as some writers have described them, are those consonants whose founds cannot be protracted; and the semi-vowels are those whose founds can be continued at pleasure, partaking of the nature of vowels, from which they derive their name. The mutes may again be subdivided into *pure*, being those whose founds cannot be at all prolonged, as *k, p, t*; and *impure*, whose founds may be continued for a short time, as *b, d, g*. The semi-vowels may be subdivided into *vocal* and *aspirated*: the former being formed by the voice, and the latter by the breath. The vocal, which are eleven, are *l, m, n, r, v, w, y, z, ih flat, zb*, and the aspirated, five in number, are *f, b, s, th sharp, sb*. The vocal semi-vowels may be subdivided into *pure*, which are formed entirely by the voice, and *impure*, which are such as have a mixture of breath with the voice. Of the pure there are seven, viz. *l, m, n, r, v, w, y*,

az; and four of the impure, viz. *w, z, ih flat, zb*. The popular writer, whose "*Grammar*" we are now citing, has given the following list, exhibiting the founds of the consonants, which are twenty-two in number.

<i>b</i>	as heard in	bay, tub.
<i>d</i>	_____	day, sad.
<i>f</i>	_____	off, for.
<i>v</i>	_____	van, love.
<i>g</i>	_____	egg, go.
<i>h</i>	_____	hot.
<i>k</i>	_____	kill, oak.
<i>l</i>	_____	lap, all.
<i>m</i>	_____	my, mum.
<i>n</i>	_____	no, on.
<i>p</i>	_____	pit, map.
<i>r</i>	_____	rat, far.
<i>s</i>	_____	so, less.
<i>z</i>	_____	zed, buzz.
<i>t</i>	_____	to, mat.
<i>w</i>	_____	wo.
<i>y</i>	_____	ye.
<i>ng</i>	_____	ing.
<i>sh</i>	_____	shy, ash.
<i>th</i>	_____	thin.
<i>th</i>	_____	then.
<i>zh</i>	_____	zition.

Mr. Murray adds, that several letters marked in the English alphabet, as consonants, are either superfluous, or represent, not simple, but complex founds. *C, c, g*, is superfluous in both its founds; the one being expressed by *k*, and the other by *s*. *G*, in the soft pronunciation, is not a simple but a complex found; as *age* is pronounced *adje*. *J* is unnecessary, because its found, and that of the soft *g*, are in our language the same. *Q*, with its attendant *u*, is either complex, and resolvable into *kw*, as in *quality*; or unnecessary, because its found is the same with *k*, as in *opaque*. *X* is compounded of *gs*, as in *example*, or of *ks*, as in *expect*. See Murray's English Grammar, p. 4, &c. ed. 8.

Dr. Wilkins (*ubi supra*) disapproves of the common division of consonants into *semi-vowels* and *mutes*; and prefers the distribution of them into three kinds, viz. *spiritous* or *breathed*, *semi-spiritous* or *half-breathed*, and *non-spiritous* or *breathless*. By the former he means such consonants as require to the framing of them a more strong emission of the breath, either through the nose or mouth; and he distinguishes those that are formed by expiration through the nose into *sonorous*, as *m, n, ng*, and *mute*, as *bm, hv*, and *hng*: the sonorous being such as require some vocal found for framing them, and the mutes being other letters of the same configuration, pronounced by a strong emission of the breath, without any vocal found. The spiritous consonants that are formed by breathing through the mouth are also of two kinds, viz. *sonorous*, as *v, db, l, r, z, zb*; and *mute*, as *f, th, h, hr, s*, and *sh*.

Semi-spiritous or half-breathed consonants are such as are accompanied with some kind of vocal murmur, as *b, d, g*; whereas those are denominated non-spiritous or breathless which are wholly mute, as *p, t, c*. Thus, *b* and *p* are framed when the breath is intercepted by the closure of the lips; the first of them being more soft, with some kind of murmur; the other more hard, and wholly mute. Again, *d* and *t* are commonly framed by an appulse or collision of the top of the tongue against the teeth or upper gums; the first being more soft and gentle, with some kind of murmur; the other wholly mute. Moreover, *g* and *e* are framed more inwardly, by an interception of the breath towards the throat by the middle or root of the tongue, with

such.

such a kind of difference between them as subsists in the two former cases. The consonants already enumerated belong to the class of those that are simple: but those that are called compound are usually distinguished into such as are aspirated, and such as are double: the former seem to be blended with *h*, and are usually so written; and the latter are compounded of some of the other letters, but for the sake of dispatch and brevity in writing, they are in several languages expressed by single characters, and reckoned in the alphabet as if they were distinct species of simple letters: such in the Latin alphabet are *g* and *x*, and the double letter *z*, whose power is the same as *ds* or *ts*. The consonant *q* is allowed to be a compound of *c* and *u*; but what is the true original of *j* consonant, and that power attributed to *ch* in the words *charity*, *chaise*, &c. have not been so well ascertained. It is plain that neither of them is a single letter, because in the prolation of them we do not end with the same found with which we began: it seems, however, to be plain that *j* consonant is a compound of *d* and *z*, and *ch* of *t* and *h*. As for the other three consonants that are reckoned in the common alphabet, *k*, *w*, *y*. Dr. Wilkins thinks them unnecessary. If *c*, he says, be used always according to its proper power, *k* must be superfluous; and therefore the Welsh, who use *c* for only one kind or found, have no *k*. And as for the letters *w* and *y*, their power is the same with that of the vowels *u* and *i*, as will evidently appear when they are rapidly pronounced before any other vowel by way of diphthong, so as to make but one syllable, *war* or *war*, *swim* or *swim*, *ies* or *yes*, *ioke* or *ioke*. Upon the whole, Dr. Wilkins enumerates 34 simple letters, 3 of which are vowels, and 26 consonants, besides 24 diphthongs. See LETTER.

According to some writers, the most natural division of consonants is that of the Hebrew grammarians; who have been imitated in this respect by the grammarians of other oriental languages: these divide the consonants into five classes, with regard to the five principal orders of the voice; which all contribute, it is true, but one more notably than the rest, to certain modifications, which make five general kinds of consonants. Each kind, or class, comprehends several consonants, which result from the different degrees of the same modification, or from the different motions of the same organs.

These organs are the *throat*, *palate*, *tongue*, *teeth*, and *lips*; whence the five classes of consonants are denominated *guttural*, *palatal*, *lingual*, *dental*, and *labial*.

We account sixteen consonants in the English alphabet, viz. *b*, *c*, *d*, *f*, *g*, *k*, *l*, *m*, *n*, *p*, *q*, *r*, *s*, *t*, *x*, *z*; to which there are three others to be added, viz. the *h*, and *j* consonants, and *v* consonant, which make the whole number of consonants nineteen: one whereof is guttural, viz. the aspirate *h*; five palatal, viz. *c*, as when pronounced before *a*, *o*, and *u*, as in *cavern*, *corn*, *curiosity*; *g*, as in *Geneva*; *j* consonant in *julep*; *k* in *kernel*; and *q* in *query*. To these some have added *w* and *y*, which are really consonants when they begin a word or syllable; although in every other situation they are called vowels. That they are consonants when used as initials seems to be evident, from their not admitting the article *an* before them, and from their following a vowel without any hiatus or dissimilarity of utterance; that in other situations they are vowels appears from their regularly taking the found of other vowels.

The four lingual consonants are *d*, *l*, *n*, *t*; the four dental are *r*, *s*, *x*, *z*, the three last whereof are *hissers*; and five labial, *b*, *f*, *m*, *p*, and *v* consonant.

With regard to which division it may be observed, that though the *g* be modified in three different manners, as it

comes before an *a*, an *o*, or an *u*; yet it is still a consonant of the palate; that the *j* consonant differs in nothing but its figure from the *g* before *e* or *i*; that *k* has the same pronunciation with the *c*; that *x* comprehends the found of two letters in its found, viz. *c* or *k*, and *f* or another *c*, as in *Alexander*, and *Alexis*, which we pronounce as if wrote *Alexander* and *Aleaxis*, or *Alefsis*; and that the *c* before an *e* or *i*, is no consonant of the palate, because in that case it loses its proper found, and assumes the hissing found of the *f*.

The abbot Dangean thinks the nature of the division of the Hebrew grammarians to be very reasonable; but he does not acquiesce in the distribution they have made of them: to find a natural and just division of the consonants, he observes, no regard must be had to the characters that represent them; nor any thing be considered but their found, or the modification they give the found.

On this principle, the same author finds in the French five labial consonants, *b*, *p*, *v*, *f*, and *m*; five palatal ones, *d*, *f*, *g*, *k*, *n*; four *hissers*, *s*, *z*, *j*, *ch*; two liquids, *l* and *r*; two that run into and mix with each other, as *ll*, and *gn*; which last, however, is peculiar to the French language; and the *h* aspirate.

He adds, 1. That *m* and *n* are properly two nasal consonants; the *m* a *b* passed through the nose, and the *n* a *d*, in like manner, pronounced through the nose; and, in effect; people with a cold pronounce *barket* for *market*, *deed* for *need*, &c.

2. That among the consonants, some are weak, others strong; their difference consisting in this, that the former are preceded with a small emission of the voice, which softens them, which the latter have not. The weak are *b*, *c*, *d*, *g*, *z*, *j*; the strong, *p*, *f*, *t*, *k*, *s*, *ch*.

It may be here observed, that when we speak of a person's talking through the nose, it must be understood in a sense quite different from what the words seem naturally to import: since the nose in this case concurs less to the pronunciation than when we do not speak through the nose; in regard the air, not being able to make its way through the nose, is returned into the mouth, where it forms a dull obtuse found, called *nasal*.

From the whole we may conclude, that the excess of consonants in one language above another only consists in this, that there are more modifications of found received and established in the one than in the other: for all men, having the same organs, may form the same modifications; so that it is entirely owing to custom, nothing to nature, that the English have not the *z* of the Greeks, the *ain* and *hah* of the Hebrews, the *ch* of the Germans, the *gn* of the French, the *gl* of the Italians, the *ll* of the Welsh, &c.

Also, that the Chinese have no *r*, the Iroquois no labial consonants, the Hurons have abundance of aspirates, and the Arabs and Georgians abundance of double consonants: which last is owing to this, that they make several organs concur strongly and equally to the modification of a found; whereas, in the rest, only one organ is moved very strongly and sensibly, and the rest weakly.

It is hence also visible, that in all languages the aspirates, or guttural letters, are real consonants; since the throat modifies the found as much as the palate, tongue, or lips.

Lastly, to find all the consonants that may be formed in any language, there needs nothing but to observe all the modifications that the founds of speech will admit of, by which we shall have all the consonants practicable.

Dr. Hunter (Edinb. Transf. vol. ii.) in his investigation of the manner in which consonants are formed, distinguishes them in two different respects, viz. by the operation of the

the breath which is employed to make them audible. There are *five* positions, he says, by which the vocal found is to be articulated: the *first* is formed by the close junction of the lips, so that no breath is suffered to transpire, and the just modification of this position is that called *oral*, when the passage of the breath or sound by the nose is stopped, and thus are formed the letters *p* and *b*; and the second modification, termed the *nasal*, is formed by opening the communication, or exit, by the nose, and suffering the found or breath to pass that way; in which case the letter *m* is founded. The *second* position is formed by the application of the under lip to the fore-teeth of the upper jaw, which do not form an absolute interruption to the breath, but suffer it to pass in an audible manner, by means of the restraint with which it is made to pass: and then are produced the letters *f* and *v*. The *third* position is formed by a similar application of the tongue to the fore-teeth, and a similar expression of the breath; these producing the two consonants *h* and *th*. The *fourth* position is formed by the application of the point or fore part of the tongue to the root of the same teeth, or fore part of the palate, which position may be variously modified; as by applying the tongue closely to the palate, so as to form an absolute interruption of the breath, in a manner similar to that of the first position, which may be called the *mute* modification, and which seems to form the consonants *t* and *d*. 2. The tongue is not kept closely fixed to the palate, but suffers the breath to be expressed in an audible manner, similar to those of the second and third positions: this may be termed the *filabating* modification, and is that by which are expressed *f* and *z*. 3. The passage of the breath between the point of the tongue and the palate is opened alternately in a quick and tremulous vibration: this may be denominated the *vibratory* modification, and serves to form the letter *r*. 4. The passage of the breath or sound is not interrupted in any degree, but it is made to pass in a very peculiar manner through the mouth; for this purpose the tongue is closely applied to the fore part of the palate, but it is retracted on each side so as to leave an open space, and then a passage is preferred for the breath, which goes under the tongue and out of the mouth: this may be termed the *liquid* modification, and serves to form the sonorous letter *l*. 5. The lateral passages opened for the breath in the last modification are shut, and the found at the same time is suffered to escape by the nasal passage, as in the second modification of the *first* position: this may be denominated the *nasal* modification, and produces the letter *n*. The *fifth* position is formed in all respects like the *fourth*, but only by a different part of the tongue and palate, and has the same number of modifications, which correspond in their nature, and may be denominated in the same manner. Thus, the letters *k* and *g* are formed in the *mute* modifications; *ph* and *j* in the *filabating*; the guttural or Northumbrian *r* in the *vibratory*; the Spanish *ll*, or the French *l moullé*, in the *liquid*; and the guttural *n* or the English *ng* in the *nasal* modification. Having thus explained the several positions of the organ, with their different modifications, Dr. Hutton proceeds to illustrate the formation of the consonants, and articulations of voice, by the action of the breath and found. In all the positions of the articulating organ, he says, there is either employed the simple aspiration of the breath, or a found produced in the wind-pipe, and modified in the articulating organ. Thus, in all the positions, and in several of their modifications, there are produced two distinct articulators, according either as found is emitted along with the articulation, or only the breath employed without any other found. Hence proceeds the

distinction of mutes and consonants among the articulators of voice.

But in each of these distinctions of mutes and consonants, it is necessary to make a sub-distinction, according as the articulator is either perfect or imperfect, whether as a mute or as a consonant. Each of these, the author explains in the following manner: The perfect mute can only take place in those positions in which the breath is absolutely interrupted by the close or impervious organ; which does not happen in the second and third positions, and only in some of the modifications of the fourth and fifth. This mute articulator is formed, either by interrupting the vocal found with the close position, in which case it is a final articulator; or by beginning to express the vocal found in this close position, when it forms, upon opening the passage, an initial articulator. Of this kind there are just three articulators, corresponding to the three positions in which the organ may be absolutely closed, in relation to the exit of the breath: these are *p* in the *first* position, *t* in the *fourth*; and *k* in the *fifth* position. The imperfect mute is formed by emitting a guttural found, or that of the wind-pipe, in these three positions of the mute articulator. The found here is extremely limited; for it is necessarily restricted to that quantity of breath which may be expelled through the sounding wind-pipe in compressing the air, or distending the cavity of the close organ. These short founded articulators may therefore be termed imperfect mutes. The *b*, *d*, and *g*, are the three imperfect mutes, corresponding to the three absolute mutes, *p*, *t*, and *k*, of the *first*, *fourth* and *fifth* positions. In the filabating articulators of the *second* and *third* positions, and of the second modification of the *fourth* and *fifth* positions, the breath may be continually emitted, either with the simple expiration, or attended with the guttural found. This, then, forms two cases of articulation, differing from each other, and also from the other two cases of mute articulation; seeing that in the present case, whether the consonant be formed with a guttural found, or only an audible aspiration, it is a continued thing, and is not necessarily terminated, as in the mutes, by the close position of the organ. Now, as in the case of mutes, we have the distinction of perfect and imperfect, with regard to that species of letter, so, in the case of consonants, we have a species which is perfect, and one which is imperfect. The imperfect species of consonant-articulators is formed in the four filabating positions and modifications just now mentioned, viz. the *f* in the *second* position, the *h* in the *third* position, the *z* in the filabating modification of the *fourth*, and the *ph* in that of the *fifth* position. To perfect those four consonants, we have merely to add the guttural found to the continued expiration, and we then produce of the *f* the *v*, of the *h* the *th*, of the *z*, and of the *ph* the *j*. We have now only remaining the *nasal* modification of the *first* position, which gives the consonant *m*; the *vibratory* modification of the *fourth* and *fifth* positions, which give two species of the letter *r*; the *liquid* modifications, which give two species of the letter *l*; and the *nasal* modifications of those two last positions, which give two species of the letter *n*. In none of all these is formed a distinct articulator, by means of the simple aspiration; consequently all these are perfect consonants. Our author observes, that the letter *h* is a general articulator, which is formed in many different positions of the vocal organ. Diphthongs and consonant-vowels, or rather articulating vowels, are formed in the following manner: the diphthong, by sounding both vowels equally in the time of one; the consonant-vowel again, by an unequal division of this time, or by sliding quickly from the

sition of the two extreme vowels *i* and *u*, to the vocal sound which is to be thus articulated. See VOWEL.

CONSONANT, is a term in *Music*, which Dr. Callcott in his *Musical Grammar* applies to the conords, octave, fifth, fau th, thirds major and minor, and sixths major and minor. The consonant triads, or common chords, according to the same author are,

in the major mode  and in the mi-

nor mode . See TRIAD.

CONSORT. *Queen*. See QUEEN.

CONSOUD, in *Botany*. See SYMPHYTUM and SOLIDAGO.

CONSOW, in *Geography*, a town of Poland, in the palatinate of Sandomirz; 28 miles S.E. of Radom.

CONSPIRACY, in *Law*, is taken for a combination or confederacy to do something evil, or illegal: though in the original sense of the word, and in its use in other languages, it signifies merely an agreement, whether for good, bad, or matters indifferent.

In our statutes and law books, *conspiracy*, in a general sense, is frequently confounded with *maintenance*, and *champarty*.

CONSPIRACY, in its special signification, is used for a confederacy of two, at least, falsely to indict one, or procure him to be indicted of felony; who, after acquittal, shall have writ of conspiracy. See 3 Edw. I. stat. 2. 7 Hen. V. 18 Hen. VI. c. 12. "The term is now commonly used for the unlawful combination of journeymen to raise their wages, or to refuse working, except on certain stipulated conditions; an offence particularly provided for by stat. 2 & 3 Ed. VI. c. 15. revised, continued, and confirmed by stat. 22 & 23 Car. II. c. 19 (now expired); which enacts, among other things, that "if any artificers do conspire, that they shall not do their work but at a certain price, or shall not take upon them to finish what another hath begun, or shall do but a certain work in a day, or shall not work but at certain times, every person so conspiring shall forfeit for the first offence, 10*l.* or be imprisoned 20 days; for the second, 2*l.* or be pilloried; and for the third, 4*0l.* or be pilloried, lose an ear, and become infamous." This statute appears to be yet in force, though it is not frequently resorted to for remedy in this case; the proceeding being usually by indictment for conspiracy.

By the common law all conspirators wrongfully to prejudice a third person are highly criminal. 1 Hawk. P. C. c. 72. § 2. stat. 5 Eliz. c. 4. Journeymen confederating and refusing to work unless for certain wages, may be indicted for a conspiracy, although the statutes which regulate their work and wages do not direct this mode of prosecution; for the offence consists in the conspiring, and not in the refusal; and all conspiracies are illegal, though the subject-matter of them may be lawful. Thus also, a bare conspiracy to do a lawful act to an unlawful end is a crime, though no act be done in consequence of it. 8 Mod. 321. The fact of conspiring need not be proved on the trial, but may be collected by the jury from collateral circumstances. 1 Black. Rep. 392. Stra. 144. And if the parties concur in doing the act, although they were not previously acquainted with each other, it is conspiracy. 1 Hawk. P. C. c. 72. § 2. Writ of conspiracy lies for him that is indicted of a trespass,

and acquitted, though it was not felony; also upon an indictment for a riot. 2 Mod. 306. 5 Mod. 405. Writ of conspiracy lies where a man is falsely indicted of any crime which may prejudice his fame or reputation; and though it doth not import slander, if it endanger his liberty, or the indictment be injurious to his property, &c. 3 Salk. 97.

But though a conspiracy to charge falsely be indictable, yet the party ought to shew himself to be innocent; for the writ of conspiracy doth not lie without an acquittal. Mod. Caf. 127. 185. 186. Not only writ of conspiracy, which is a civil action at the suit of the party, but also action on the case in the nature of a writ of conspiracy, doth lie for a false and malicious accusation of any crime, whether capital or not capital, even of high treason; and this, though the bill of indictment be found *ignoramus*, or it does not go so far as an indictment. And the same damages may be recovered in such action as in a writ of conspiracy, where the party is lawfully acquitted by verdict. 1 Rol. Abr. 111, 112. 9 Rep. 56. Gilb. Ca. 185. 10 Mod. 148. 214. Salk. 15. An action on the case is preferable, as it is more in use, and the proceedings more easy and not attended with such niceties as the writ of conspiracy.

If one falsely and maliciously procure another to be arrested, and brought before a justice of peace to be examined concerning a felony, &c. on purpose to vex and disgrace him, and put him to charges and trouble, although he is not indicted for the same, yet he may have an "action on the case;" in which he need not aver that he was lawfully acquitted, as he ought to do in a writ of conspiracy; but he must aver that the accusation was *false et malitiose*, which words are necessary in the declaration; and it must appear that there was no ground for it. And as an "action on the case" may be prosecuted against one person, where the writ of conspiracy or indictment doth not lie but against two, this action is most commonly brought. 1 Dauv. Abr. 208. 213. 2 Inst. 562. 638.

Conspirators may be indicted at the suit of the king, and at the common law, one may prefer an indictment against conspirators, though nothing be executed: however, the conspiracy ought to be declared by some act, or promise to stand by one another, &c. But a bare conspiracy will not maintain a writ of conspiracy, at the suit of the party, because he is not damaged by it; though it is a ground for an indictment. 9 Rep. 56. 2 Roll. Abr. 77. If the defendants can shew any foundation or probable cause of suspicion, they shall be discharged: and if a man hath good cause of suspicion, that a person is guilty of felony, and causes him to be indicted, in prosecution of justice, action of conspiracy will not lie; but it is otherwise if the prosecutor imposes the crime of felony, where no crime of felony was committed. 1 Roll. Abr. 115. 4 Rep. 438. Conspiracies ought to be out of court; for if a protection be ordered in a course of justice, and witnesses appear against a party, &c. there shall be no punishment; and if persons acted only as jurors in a criminal matter, or judges in open court, there is no ground for prosecution. S. P. c. 173. 12 Rep. 24. If all the defendants but one are acquitted on indictment for conspiracy, this one must be also acquitted; because one person alone cannot be indicted for this crime: and husband and wife, being but one person, may not be indicted alone for a conspiracy. 2 Rol. Abr. 708. The acquittal of one person is the acquittal of another upon indictment of conspiracy (3 Mod. 220.) *i. e.* where only two are indicted, and it is not laid or proved that they conspired with others, unknown. However, where one is found guilty, according to the opinion of lord chief justice Hale, if the other doth not come in upon process, or if he

dies pending the suit, judgment shall be had against the other. 1 Vent. 234. It hath been resolved, that if an "action on the case" be brought against several persons, and all but one be acquitted, yet judgment may be given against that one only. 1 Hawk. 192. Judgment may be also given against one only before the trial of the others; and it has been held, that a conspiracy may be laid without any overt act. 1 Str. 195. Persons acting separately may be also guilty of a conspiracy; as particularly in the case where they are all of a family, e. g. husband, wife, and servants. 1 Str. 144.

If the parties are found guilty of conspiracy, upon an indictment of felony, at the king's suit, the judgment anciently was, that they should lose their "frank law," (which disabled them to be put upon any jury, to be sworn as witnesses, or to appear in person in any of the king's courts,) and that their lands, goods, and chattels should be forfeited into the king's hands, their houses and lands stripped and wasted, their trees rooted up, and their bodies imprisoned. This is commonly called "villainous" judgment, and is given by the common law, and not by any statute, and in some books it is said generally to be the proper judgment upon every conviction of conspiracy at the suit of the king, without any restriction to such as endangered the life of the party; but this point doth not seem to be any where settled. 1 Hawk. 193. 2 Inst. 143. 222. This judgment, however, hath been but seldom given; there being no instance of it since the reign of Edw. III. The usual mode of punishment at present is by pillory, fine, imprisonment, and surety for good behaviour. Burr. 696. 1027. Str. 196. The quarter sessions have jurisdiction over this offence. Finch. 80. 8 Mod. 321. And on motion in arrest of judgment, the defendant must be personally present in court. Stra. 1227. Burr. 931.

In cases where villainous judgment is imposed, the matter of the conspiracy ought to touch a man's life. As fine and imprisonment are at this day the usual punishment for conspiracy, so on writ of conspiracy, &c. the party shall be fined, and render damages. 1 Hawk. P. C. 72.

CONSPIRATION, Fr. See CONSPIRACY.

CONSPIRATION, *contre le service du Roi*, conspiracy against the king's service. Under the old government of France every conspiracy, collusive, or unlawful combination or understanding against the king, his governors, commanders, or other officers, was regarded as a capital military offence; and by an order of the 1st July 1727, it was enacted that every person convicted of such a crime should be broken on the wheel.

CONSPIRATIONE, in *Lawo*, a writ that lies against conspirators. Reg. Orig. 134. F. N. B. 114.

CONSPIRATORS, according to the statute, are those that do confederate, or bind themselves by oath, covenant, or other alliance, that every one of them shall aid, and bear the other, falsely and maliciously, to indict, or cause to indict, or falsely to move, or maintain pleas; and such as retain men in the country, with liveries or fees, to maintain their malicious enterprizes: and this extendeth as well to the takers, as the givers; and stewards, and bailiffs, of great lords, which, by their office, or power, undertake to bear, or maintain quarrels, pleas, or debates, that concern other parties than such as touch the estate of their lords, or themselves. 33 Edw. I. stat. 2. 2 Inst. fol. 384. 562.

Moreover, against conspirators, false informers and imbracers of inquest, the king hath provided a writ in the chancery; and the justices of either bench and justices of

assize, shall, on every plaint, award inquest thereupon. Stat. 28 Ed. I. st. 3. c. 10. There are also conspirators in treason, by plotting against the government, &c. See TREASON.

CONSPIRING POWERS, in *Mechanics*, are all such as act in directions not opposite to one another. See POWER, and MOTION.

CONSTABLE. This appellation hath afforded ample matter of disquisition to learned antiquarians. History has traced it backwards from its introduction to England, through France, Germany, and Greece, to the imperial seat at Constantinople, in the days of Constantine the Great; and if we ascend farther towards the East, we shall find the term *cône* or *clône* in Palestine, which signified in the times of the Old Testament, a stability, strength, or stay. Some trace of this word has been discovered in the appellation of Laocoon at Troy, and particularly in that of Constantine, who was himself of oriental extraction, having sprung from Dardania, a country of Upper Macedonia, and said by flatterers to have been descended from Dardanus and the Trojans. It is not improbable that this appellation of the emperor might have occasioned the adoption of the word into the Roman language about the same time. For it was at that period that the word *count*, obviously deduced from *cône* or *cune*, first became a name of dignity; and from thence was transmitted westwards, with some variation, according to the different genius of languages throughout the provinces. Amongst the Saxons the word was *kening* or *kyninge*, from which, without doubt, we derive our word king. Moreover, the word *stole*, *stalls*, *steele*, or *stable*, by an easy transmutation of the several letters frequent in almost all languages, which seems to be the other constituent of the appellation *constable*, is likewise common to the languages of the middle ages, and signifies a standing place, division, or department, called by the Romans *statio*. According to this etymology, the word *constable* signifies the stability or stay of the place, or the strong man of the division. Those who derive it from the Saxon, discover *constable* in *konings-pretzel*, denoting the support of the king. But others, as Sir Henry Spelman, and Dr. Cowel, considering that we borrow the name, as well as the office, from the French, deduce it, with greater probability, from that language; in which it is plainly derived from *comes stabuli*, the master of the stables, or perhaps of the horse, an officer well known in the empire; so called, because, like the great constable of France, as well as the lord high constable of England, he was to regulate all matters of chivalry, tilts, tournaments, and feats of arms, which were performed on horseback. Accordingly, they suppose, that the dignity, which at first was civil, in time became military, and the master of the stables was made general of the army.

CONSTABLE of England, *Lord High*, is an ancient officer of the crown, now disused in England, except on solemn occasions, as the king's coronation, and the like. The first constable of England is said to have been created by the conqueror, who appointed Ralph de Mortimer, one of the principal commanders of his army; and the office continued till the reign of Henry VIII. A. D. 1521: when it became extinct, as the powers annexed to it rendered it troublesome to the king, by the attainder of the third duke of Buckingham, who derived it from the Bohuns, earls of Hereford, and in whom it was hereditary. Since this time there hath not been any permanent high constable; but the office has been kept vacant, except on particular occasions. About a century after, *viz.* in 1607, it was also suppressed.

in France, by an edict of Lou's XIII.; though the office has been exercised in the command of the marshals, by the first officer in the army. See *CONNETABLE*.

What authority and jurisdiction belonged to the constable, we may partly learn from a statute of the 13th of Richard II., in which it is said "that he ought to have cognizance of contracts touching feats of arms and of war out of the realm, and also of such things relating to arms or war within the realm, as could not be determined or discussed by the common law, with other usages and customs appertaining to the same matters, which other constables before that time had duly and reasonably used." Madox (*Hist. Excheq. c. 11.*) says, that he was a high officer, both in war and peace. As the duties enjoined on the constable and marshal or marshal, as well in war as in peace, in camp and in court, were multifarious, honourable, and confidential; so the powers, privileges, authority, and pre-eminence of those officers, were extensive, judicial, executive, and respectable. The powers and functions of each of these two high officers, when acting in their military capacities, were, in some instances, concurrent; in others, separate and independent. In the discharge of some official duties, they were upon an equal footing, and the marshal acted as coadjutor to the constable, but in others, the former was subordinate and subservient to the latter. The functions of the constable, in his civil capacity, were few, and in a great measure restricted to certain personal attendances on the king in his court, on high festivals, and on occasions when such affairs were transacted as required pomp and solemnity. In his military capacity, the constable examined the number and qualifications of those who were sent by the military tenants, either into the field or garrison, and also the stipendiaries retained by the king, and gave them either their admittance or discharge. When the army took the field, and was commanded by the king in person, the constable acted as his lieutenant, and was next to him in authority; but whenever the king was absent, the constable had the supreme and sole command of the forces. In both cases, the marshal was the substitute or vice-general of the constable. See *COURT OF Chivalry*, and *MARSHAL*.

From those mighty magistrates, the constables of England, are derived the inferior ones, since called the *constables of hundreds and franchises*: these were first ordained in the thirteenth year of Edward I. by the statute of Winchester (13 Ed. I. stat. 2. c. 6.); which, for the conservation of the peace, and view of armour, and for preventing defaults of armour, and of the suits of towns and of highways, &c. appointed, that two constables should be chosen in every hundred and franchise.

These are what we now call *constabularii capitales*, or *high constables*: because continuance of time, and increase of people, &c. have occasioned others of like nature, but inferior authority, in every town and parish, called *petty constables*, or *sub-constabularii*, first instituted (as some say) about the reign of Edward III.

Although it has been a prevalent opinion, maintained by Coke, Hale, and others, that high constables are not more ancient than the statute of Winchester above cited; yet Hawkins concurs with others in maintaining, that both constables of hundreds, commonly called high constables, and also constables of tythings, now denominated petty constables or tything-men, existed by the common law, and were not first ordained by the statute of Winton or Winchester; for that statute doth not say, that such officers shall be constituted, but evidently seems to suppose that there were such before the making of it. 2 Hawk. 61. That the high con-

stable was instituted long before the statute of Winton is a fact ascertained by a writ or mandate of Henry III., preserved in the *Adversaria* to Watts's edition of *Matt. Paris*, and from which chapters 4 and 6 of the statute of Winton are evidently taken. By this writ it is provided, "that in every hundred there shall be constituted a CHIEF CONSTABLE, at whose mandate all those of his hundred, sworn to arms, should assemble and be observant to him, for the doing of those things which belong to the conservation of the king's peace." No mention of this officer, it is believed, can be any where found prior to the date of this instrument; which perhaps may no more determine the question as to his original creation than the statute of Winton. As for the "constable of the vill," or petty constable, as he is frequently called by way of distinction from the chief constable, this officer has been repeatedly acknowledged to be one of the most ancient officers in the realm, for the conservation of the peace (*Poph. 13. 4 Inst. 265.*). It must be confessed, however, that no mention of him by this identical name is any where found to occur anterior to the writ or mandate of king Henry III. already mentioned; by which it is also provided, that in every village or township there should be constituted a constable or two, according to the number of the inhabitants. But it is partly certain that lord Coke's idea is well founded, and that "this officer is actually owing to the institution of the frank-pledge, usually attributed to king Alfred," and was in fact originally the senior or chief pledge of the tything or *decima*. Hence it appears, that the ordinance of Henry III., far from instituting the office, merely enlarged the number of officers, placing them in towns and villages, instead of franchises; hence it might frequently happen, that a manor of great extent had only a single constable for several townships; a case exactly similar sometimes occurring at this day, in which a township, comprehending several hamlets, equally populous perhaps with itself, has only one constable for the whole. Upon the whole, it seems highly probable, that, at the common law, and before the mandate of Henry III., the constable of the hundred and the constable of the manor, were officers of the same nature and authority, originating at the same time and differing only as to the extent of their several districts; in short, that they bore to each other the same analogy as subsisted between the bailiff of the hundred and the bailiff of the manor. Hence it follows, that the constable of the hundred neither possessed nor could have exercised any more authority within the precinct of the latter, than the constable of one manor possessed or could have exercised in another; the manor being to all intents and purposes exempt from, and excluded out of the hundred.

High constables are chosen at the court leets of the franchise or hundred over which they preside, or, in default of that, by the justices at their quarter sessions, or by the greater number of the justices of the division: and they are sworn on the sessions, or by warrant from the sessions; which course hath often been allowed and commended by the justices of assize. *Dalt. c. 28. Salk. 150.* And by stat. 29 Geo. II. c. 25, § 8, 9, in Westminster a high constable is to be elected annually by the dean or high steward or his deputy at a court leet. But by 1 Geo. stat. 2. c. 13, high constables are required to take the oaths of allegiance, supremacy, and abjuration, as other persons who qualify for offices; but they are not within the statute of the 25 C. II. c. 2. as to receiving the sacrament and subscribing the declaration against transubstantiation; and petty constables are exempted both from the one and from the other. The petty constables have two offices united in them; the one ancient, the other modern. Their ancient office is that of *Head-borough* (which see), tything-man,

or borough, who are as ancient as the time of Alfred; and their more modern office is that of constable merely, which was appointed (as it has been said) so lately as the reign of Edward III., in order to assist the high constable. And, in general, the ancient head boroughs, tything-men, and borough-keepers, were made use of to serve as petty constables; though not so generally, but that in many places they still continue distinct officers from the constable.

The common law requires, that every constable should be *idoneus homo*, i. e. apt and fit to execute the said office; and in law he is said to be *idoneus* when he possesses three qualifications, *viz.* honesty, knowledge, and ability, (8 Rep. 41. b.) And if one be elected constable, who is not *idoneus*, he by the law may be discharged of his office, and another who is *idoneus* appointed in his place. He must also be an inhabitant of the place for which he is chosen, (12 Mod. 256.) nor should he be the keeper of a public-house, (6 Mod. 42.) which is made an express disqualification in Westminster, by stat. 29 Geo. II. c. 25. Persons exempt from serving the office of constable are aged persons, and in Westminster those 63 years old are expressly exempted by stat. 31 Geo. II. c. 17. § 13;—aldermen of London;—the president, commons and fellows of the college of physicians in London, by 32 Hen. VIII. c. 40; but no other physicians, nor they elsewhere:—apothecaries, practising in, or within seven miles of London, free of the company, or in the country having served seven years, stat. 6 and 7 W. III. c. 4;—surgeons, free of the company of surgeons in London, examined, approved, and exercising the science, by stats. 5 Hen. VIII. c. 6: 32 Hen. VIII. c. 42: 18 Geo. II. c. 15; and by custom all surgeons (Com. Rep. 312.), and it seems by the same stats. barbers free of that company in London;—attornies of the courts of K. B. and C. P.;—practising barristers;—dissenters, being teachers and preachers in a congregation, tolerated by law, taking the oaths and making the required declaration, but not others, by 1 W. c. 18. § 11;—foreigners naturalized, who may rather be said to be incapacitated;—militia-men, during the time of their service, by 20 Geo. III. c. 107. § 130;—servants to members of parliament, but doubtful;—professors of felons to conviction; the original proprietors, or first assignees of a certificate (commonly called a tyburn-ticket), if a parish or ward office; within the parish or ward where the felony happened; to be only once used, by 10 and 11 W. c. 23. § 23; but this is no exemption from serving the office for a manor, nor, as it should seem, for a vill or township; nor where the office is to be executed out of the privileged district;—but masters of arts, justices of peace in another county, officers of the guards, officers or watchmen at the Custom-house, tenants in ancient demesne, and younger brothers of the trinity-house, cannot plead exemption. If, however, a gentleman of quality, or a physician, officer, &c. be chosen constable, where there are sufficient persons besides, and no special custom exists; such persons, it is said, may be relieved in B. R. 2 Hawk. P. C. 100. c. 10. § 41. A constable, whose office is ministerial, and not judicial, may appoint a deputy; but the constable is answerable, and his deputy ought to be sworn, though this is not in all cases necessary; but if the deputy is allowed and sworn, the principal is not responsible. Dissenters chosen to the office of constable, &c. scrupling to take the oaths, may execute the office by deputy, who shall comply with the law in this behalf, stat. 1 W. & M. c. 18. § 7. And by 31 Geo. III. c. 32. the like privileges are given to Roman Catholics on their taking and subscribing the oath and declaration therein specified. Constables may appoint a deputy to execute a warrant, when by reason of sickness, &c. they cannot do it themselves. A woman made constable, by virtue of a cus-

tom, that the inhabitants of a town shall serve by turns, on account of their estates or houses, may procure another to serve for her, and the custom is good.

Constables are chosen by the common law at the leet, or, where there is no leet, at the tourn; sometimes by the suitors, and sometimes by the steward; and now, in many towns and parishes, by the parishioners: all according to ancient and particular usage. But by whomsoever they shall be chosen and appointed, they are to be sworn and placed in their office by the lord, or his steward, or by the sheriff respectively, as being judge of the court. 2 Hawk. 62. If the constable be present when chosen, he is to take the oath in court; if absent, he may be sworn before a (single) justice of the peace: but in the latter case, he ought to have special notice of his election, and a time and place should be appointed for his taking the oath (well and truly to serve the office). Every petty constable being a principal peace officer, and it being necessary for the preservation of the peace, that every vill should be furnished with one, the justices of the peace have, ever since the institution of their office, taken upon them, as conservators of the peace, not only to swear the petty constables, who have been chosen at a tourn or leet, but also to nominate and swear those who have not been chosen at any such court, on the neglect of the sheriffs or lords to hold their courts, or to take care that such officers are appointed in them. And this power of justices of the peace, having been confirmed by the uninterrupted usage of many ages, shall not now be disputed, but shall be presumed to have been grounded on sufficient authority. Some have carried this point so far, as to allow the justices, at their sessions, to swear one who was chosen at the leet, and unduly rejected by the steward, who had sworn another in his place. 2 Hawk. 65. A constable has been sworn by a single justice of the peace; and upon motion for an information as not being duly sworn, the court held this to be a good swearing. 2 Strad. 1149. It is certain that justices of the peace had power to nominate and swear constables, on the default of the tourn or leet, before the statute of 13 & 14 C. II. c. 12.; and therefore that they have such authority in some cases not mentioned in that statute, which enacts, that if a constable shall die, or go out of the parish, any two justices may make and swear a new one, until the lord shall hold a leet, or till the next quarter sessions, who shall approve of the officer so made and sworn, or appoint another; and if any officer shall continue above a year in his office, the justices in their quarter sessions may discharge him, and put in another, till the lord shall hold a court as aforesaid. 2 Hawk. 65. 13 & 14 C. II. c. 12. § 15. It seems to be clear at this day, that the King's Bench hath power by mandamus to compel the court or judge to swear a constable duly chosen. 2 Hawk. 65. And constables lawfully chosen, if they shall refuse to be sworn, may be bound over by a justice of the peace to the assizes or sessions, there to be indicted. Dalt. c. 28. 2 Str. 920. But it seems that a justice hath no power to commit any person for such refusal and no more, the proper mode being to indict him upon his refusal; and if found against him, to assess a good fine upon him. Cro. Car. 567.

Constables of London, which city is divided into 26 wards, and every ward into precincts, in each of which is a constable, are nominated by the inhabitants of each precinct on St. Thomas's day, and confirmed, or otherwise, at the court of wardmote; and after they are confirmed, they are sworn in to their office, at a court of aldermen, on the next Monday after Twelfth-day. The oath of these constables is long and particular, and comprehends a variety of duties, now seldom performed, but regulated by articles of the Wardmote in-
quest,

quest, which directs the conduct of the constable; who is a kind of superintendent of the morals of the inhabitants, and who ought to notice all new-comers, that those whose character is bad may be required to give security for their good behaviour, or be imprisoned. Cath. 129, 138. Every constable may execute warrants through the whole city. Such as are chosen into the office are obliged to place the king's arms, and the arms of the city, over their doors; and if they reside in alleys, at the ends of such alleys, towards the streets, to signify that a constable lives there, and that they may be more easily found when wanted.

The general duty of all constables, both high and petty, is to keep the king's peace in their several districts; and for this purpose they are armed with very large powers, of arresting, and imprisoning, and of breaking open houses, and the like. One of their principal duties, arising from the statute of Winchester, which appoints them, is to keep watch and ward in their respective jurisdictions. See **WARD** and **WATCH**.

If any one shall make an affray or assault upon another, in the presence of the constable, or shall threaten to kill, beat, or hurt another, or in a fury be ready to break the peace; the constable may commit him to the stocks, or other safe custody, and afterwards take him before a justice, or to a gaol, until he shall find surety for the peace; and if the party will not find surety to the constable, he may imprison the party till he shall do it, provided the offence be in his own view. Dalt. c. 1. Cro. Eliz. 375, 376. The duties of constables are so numerous and minute, in consequence of a variety of statutes, that the mere recital of them would extend this article beyond its due bounds. They will be found under several different heads or titles, that occur in this work.

If a constable neglect any duty incumbent on him either by common law or by statute, he may be indicted and fined by the justices of peace, to whom he is subordinate. If he will not return his warrant, or certify what he has done under it, he may be fined. If he wilfully lets a felon escape out of the stocks, and go at large, it is felony; and it seems generally agreed, that all voluntary escapes in the officer amount to the same crime as the offender was guilty of, whether treason or felony. 2 Hawk. P. C. c. 19. § 22, &c. It is a misdemeanour in him to discharge an offender, brought to the watch-house by a watchman in the night. In short, he is liable to various pecuniary, and sometimes personal, punishments, on neglecting the duty imposed on him by various statutes. As by his office he is subordinate to a justice of the peace, he is bound to execute his warrants; and therefore it hath been resolved, that where a statute authorises a justice of the peace to commit a man of a crime, and to levy the penalty by warrant of distress, without saying to whom such warrant shall be directed, or by whom it shall be executed, the constable is the proper officer to serve such warrant, and indictable for disobeying it. 2 Hawk. 262. By 33 Geo. III. c. 55. two justices, at any special or petty sessions, upon complaint upon oath, of any neglect of duty, or disobedience of any lawful warrant or order of any justice, by any constable, or other peace or parish officer, (such person being duly summoned to appear and answer to such charge,) may impose, upon conviction, any reasonable fine, not exceeding 40s., upon such constable, &c.; and if not paid, levy the same by distress and sale of the goods of such offender, to be applied to the poor of the parish or place where he resides; or for want of such distress, the offender shall be committed to the house of correction for any time not exceeding ten days. The officer executing such warrant, if required, shall shew the same to the person, whose

goods and chattels are distrained, and suffer a copy of it to be taken. 27 Geo. III. c. 26.

On the other hand, the constable is protected by law, in the execution of his duty. By stat. 7 Jac. I. c. 5. 21 Jac. II. c. 12. if any action is brought against a constable for any thing done by virtue of his office, he, and all who aid him, may plead the *general issue*, give the special matter in evidence, and if he recovers, shall have double costs; but this must be certified on the record by the judge: and stat. 19 Geo. II. c. 21. against profane swearing, gives treble costs. By stat. 24 Geo. II. c. 44. no action shall be brought against any constable or others assisting him for any thing done in obedience to any warrant of a justice of peace, until demand of the perusal and copy of such warrant, and the same hath been refused or neglected for the space of six days, &c. &c. No action shall be brought against any constable but within six months after the act committed. For the charges of conveying malefactors to gaol, see **COMMITMENT**. By 27 Geo. II. c. 20. the constable executing a justice's warrant, for levying a penalty or other sum of money directed by an act of parliament by distress, may deduct his own reasonable charges; and if any person shall be appointed to execute any warrant for felony, two justices may order by warrant under their hands a reasonable allowance to such special constable for his expences and loss of time, to be paid by the treasurer out of the county rate. 41 Geo. III. c. 78. Two justices may in like manner order an allowance to be made to any high constable for extraordinary expences incurred in the execution of his office, to be defrayed in the same manner. And by 18 Geo. III. c. 19. every constable, headborough, and tything-man, shall every three months, and within fourteen days after he goes out of office, deliver to the overseers of the poor a written account, entered into a book kept for that purpose, and signed by him, of all sums expended in consequence of his office, which the overseers within the next fourteen days shall lay before the inhabitants; and if approved, the money shall be paid out of the poor rate: but if disallowed, they are to return the book to the constable, who may produce it before a justice of peace, giving reasonable notice to the overseers; and the justice shall examine the account, settle the sum due, sign the account, and order payment out of the poor rate; the overseers, however, may appeal to the quarter sessions.

If a constable commits a person in charge, he is not liable to an action for false imprisonment, though the charge be ill-founded; and if the constable is assaulted in the execution of his office, and the constable kill the assailant in a contest, it is no felony; but if the constable is killed, it shall be construed premeditated murder. A justice of peace's warrant is a sufficient justification of a constable in a matter within the jurisdiction of such justice.

High constables shall account, if required, at the general or quarter sessions, for the general county-rate by them received, on pain of being committed to gaol until they account; and they shall pay the money in their hands, according to the order of the court, under the like penalty. 12 Geo. II. c. 29.

Constables may be removed in the same manner and by the same authority by which they were chosen. The sheriff, or steward of the leet, having power to place a constable in his office, has also a power of removing him. Justices of the peace have also displaced such constables as have been chosen and sworn by them. Dalt. c. 28. 2 Hawk. 63. 65. And by 13 & 14 Geo. II. c. 12. if a constable shall continue above a year in his office, the sessions may discharge him, and put another in his place, till the court shall hold a leet. And if the court, or other judge, shall refuse

to discharge a constable, the King's Bench may compel them by mandamus. 2 Hawk. 65. If a constable be discharged without just cause, the court of King's Bench will by rule of court order him to be restored to his place. Bult. 174.

CONSTABLES of the *Castles*, in *Antiquity*, were keepers or governors of the castles of the king, or of great barons, who were frequently hereditary, or by feudal tenure: such were the constable of the Tower, the constable of London, or Baynard's castle, the constables of the castles of Dover, Windsor, Chester, Caernarvon, and other castles in Wales; some of which offices, though not now hereditary, are remaining to this day. Their office seems to have been the same with that of the *castellani*, or governors of castles. These constables are those to whom Magna Charta (c. 17. 20.) refers; and who in the stat. of Westm. 1. (3 Ed. 1.) c. 15. are called constables of fees, and there considered as keepers of prisons; a constituent part indeed of all ancient castles. 2 Inst. 31. The statute of 5 Hen. IV. c. 10. reciting the oppressions of these constables, and enacting that none be imprisoned but in the common gaol, seems to have put an end to a race of tyrants, who, by their misconduct, had rendered themselves odious to the people.

CONSTABLE of France. See CONNETABLE.

CONSTABLE, *Provost of the*. See PROVOST.

CONSTABLE, in *Biography*, general of the Dominican order about the end of the sixteenth century, was born at Ferrara, to which city he was constituted inquisitor, and afterwards nominated master of the holy palace by pope Gregory XIII. In literary history he is known by a work entitled, "De causis in sancto officio cognoscendis," which related to the history of the dreadful tribunal invented by the founder of his order. His own zeal in the duties of the office to which he had been chosen was exemplary; and to excessive fatigue and over exertions occasioned in visiting on foot the monasteries under his government, is to be ascribed an illness that terminated in his death, at Venice on 17th of Sept. 1582. Moreri.

CONSTADT, or KUNSTADT, in *Geography*, a small town of Prussia, situated in Lower Silesia, in the principality of Oels.

CONSTANCE, COSTANTZ, or COSTNITZ, a considerable town of Wirtemberg, in the circle of Swabia, formerly a free imperial city, under the protection of Austria, delightfully situated at the north-western extremity of the lake of Constance, where the Rhine issues out of it again; or between the two lakes; 45 miles N.E. from Zurich. N. lat. 47° 40'. E. long. 9° 12'. The fort of Peterhausen defends it on the left side of the Rhine. "I was much afflicted," says Mr. Coxe, who visited this place in 1776 (see Travels in Switzerland, vol. i. p. 16.) "with the solitary appearance of a town once so flourishing in commerce, and so celebrated in the annals of history. A dead stillness reigns throughout; grass grows in the principal streets; in a word, it wears the melancholy aspect of being almost totally deserted, and scarcely contains 3000 inhabitants. This city has endured a sad reverse of fortune; it was formerly in alliance with Zurich and Basse; and, supported by their assistance, expelled the bishop, and embraced the reformation. But the Protestant cantons being worked in 1351; and the league of Smalcalde, of which Constance was a member, being defeated by Charles V., the town was obliged to submit to the emperor;" (having been placed under the ban of the empire in the year 1548, for deserting the Roman Catholic religion), "and readmit the Catholic religion. From this period it lost its independence." In 1549 it was placed under the

power of the house of Austria by Ferdinand I.; and though the estates of Swabia refused their assent, the subjection was ratified by the diet at Augsburg. Being neglected by the house of Austria, the town fell to decay. Constance somewhat revived, and afforded the prospect of becoming a commercial town, through the permission granted by the emperor Joseph, to the emigrants from Geneva, of settling and carrying on their trade and manufactures, with very considerable privileges; the principal of which were the following: *viz.* the right of purchasing or building houses; the free exercise of religion, entirely independent of the Catholic clergy; the power of erecting a tribunal for the purpose of deciding all affairs relative to their manufactures and commerce; exemption from serving in the militia and quartering soldiers, from all contributions during the space of 20 years, from duties on their tools and utensils; and the invariable establishment of the standard of the gold and silver employed in their manufactures. "These favourable terms (says Mr. Coxe) signed on the 30th of June 1785, attracted so many settlers to Constance, that in my second visit to this place, on the 25th of October 1787, the new colony of Genevans consisted of 70 families, comprising 350 persons: among these were 54 watch-makers, who had introduced the different branches of manufacture which belong to their trade. Four hundred watches were already finished, and above 1400 more were preparing. The emperor also has granted to Mr. Macaire the convent of Dominicans lately secularized, towards establishing a manufacture of printed linens and cottons. The refectory is appropriated for the chapel of the new colony." "This convent, which was once the asylum of monkish superstition, is now the seat of trade and industry; and it must suggest a pleasing reflection to a philosophic mind, that a successor of Sigismund, who violated his word," (as in the case of Hufs) "should have assigned to a reformed establishment that very convent in which the Bohemian divine was imprisoned, and from which he was led to the stake; and that the most enlarged principles of toleration should be manifested in the same spot where persecution was inculcated by precept and example. It is the triumph of reason and religion over bigotry and intolerance." Since the period to which we have now referred, France has extended its revolutionary spirit and operations to the states of Switzerland; and time must develop the effects on the liberty and commerce, and consequent prosperity of the country. See HELVETIC CONFEDERACY and SWITZERLAND. At present the manufactures and commerce of Constance are inconsiderable. Its celebrity is chiefly owing to a council held here from 1414 to 1418, which deposed three popes, *viz.* John XXIII., Gregory XII., and Benedict XIII., who had set up against each other; appointed Martin V. in their room, condemned the doctrine of Wickliff, and committed his works to the flames, in 1415; and caused John Hufs and Jerome of Prague to be burnt, the former July 6, 1415, and the latter May 30, in 1416. At this council the assembled fathers on the 14th of June in 1415, passed the famous decree which took the cup from the laity in the celebration of the eucharist, ordered that the Lord's supper should be received by them only in one kind, *i. e.* the bread, and rigorously prohibited the communion in both kinds. The history of this council by L'Enfant is composed with great accuracy and elegance. A second edition of this work appeared at Amsterdam in the year 1728, in 2 vols. 4to.: the first was published in 1714. For an account of the treaty at Constance, A. D. 1183; see the article CITY.

CONSTANCE, *Lake of*, separates Switzerland from that

that part of Germany hitherto called the circle of Swabia.

It is divided into three parts: the upper part, which is the broadest, is called *Boden-See*, the middle part *Bodmer-See*, and the lower part *Zeller See*.

The superior lake is about 15 leagues in length, and 6 in its greatest breadth. The borders consist of gently rising hills; on the left hand Swabia, and on the right Thurgau, with a variety of scattered towns, villages, and monasteries, and delightful villas, which afford several views to those who navigate the lake, that are truly enchanting. The form of the lake inclines to an oval, and the water is of a greenish hue. This lake, like all the other lakes of Switzerland, is considerably deeper in summer than in winter; a circumstance which is owing to the first melting of the snow from the neighbouring mountains. It abounds with all sorts of fish, and more particularly with the species of trout, called in its vicinity "Illankin," and by Linnaeus *Salmo lacustris*. A little above Stein, which is an independent town, under the protection of Zurigo; the Rhine widens considerably, and forms the inferior lake of Constance, or the *Zeller-see*, which is divided into two branches; from Stein to Constance is about 16 miles, and from the latter to Zell, its greatest breadth, about 10.

Near Meribourg the lake of Constance is said to be 350 fathoms deep. This great depth is extremely advantageous to commerce, the lake being navigated by vessels of 100 tons and upwards. There are two islands in its middle, on one of which is the town of Lindau, formerly a free imperial city, but belonging now to the king of Bavaria, who, by the treaty of the confederation of the Rhine, has engaged to have it fortified and provided with artillery establishments. On the other island, about a mile in circumference, is the town of Meinau, which belonged to the knights of the Teutonic order, and whose situation is delightful.

The Rhine enters the lake of Constance at its south-eastern extremity, and issues out of it again at the north-west, not far from Stein. There is an ancient, and generally accredited tradition, that the Rhine, in crossing the lake in all its length, does not mix with its water. The same is said of the Rhone, which runs through the lake of Geneva. Pliny the Elder, and Ammianus Marcellinus, are the authors of these fables. It is true that the two rivers are distinctly seen some time after their entrance into the lakes, but the difference of colour vanishes as soon as they have deposited the sand which they carry. Mr. Coxe, seated on board a vessel on the lake, in vain attempted to distinguish the waters of the Rhine from those of the lake. The river, in its course from the superior lake, being exactly of the same beautiful greenish colour as the inferior lake into which it flows; it is evident that the one can never be distinguished from the other. Probably, upon its first entrance into the superior lake it is troubled, and, consequently, for some distance, its current may be easily traced; but it purifies itself by degrees, and becomes an indistinct part of the great body of water.

Of no better foundation is the report that the lake of Constance never freezes. Wagner assures that it was frozen in 1572 and 1596, when two inhabitants of Constance walked over the lake on the ice, measured it, and found it to be 7265 fathoms long, from Romizhorn to Bouchon, which is not its whole length.

CONSTANCY, in a general sense, denotes immutability; but in ethics, or the philosophy of the human mind, the term implies resolution or steadiness, particularly under

adverse trials and suffering. It was the saying of a heathen philosopher, that there cannot be imagined upon earth a spectacle more worthy of the regard of the creator, intent on his works, than a brave man superior to his sufferings. Nothing, indeed, can be more noble or honourable, than to possess courage sufficient for executing the injunctions of reason and conscience; for maintaining the dignity of our nature, and the station assigned us; and for being to much unaffected by poverty, pain, and even death itself, as not to do any thing that is reproachful or sinful in order to avoid them. To possess this temper, is to be great above title and fortune; and manifests a mind of heavenly extraction, and worthy of the offspring of the deity. Of this kind, many illustrious instances occur in history, and particularly in the history of the Christian church, and of the last moments of confessors and martyrs.

CONSTANS I., FLAVIUS JULIUS, in *Biography*, third son of Constantine the Great, by Fausta, was born A. D. 320, and was created Cæsar at six years of age. Upon the death of his father in 337, Constans succeeded to the sovereignty of Italy, Africa, and the western Illyricum, as his share of the empire. He had enjoyed his power but three years, when he was attacked by his brother Constantine, whom he defeated and slew.

Constans, by this victory, became possessor of Gaul, Spain, and Britain; and in his turn, attacked the Franks, whom he humbled, and the Scots, which probably did not end much to his credit, as no notice is taken of the fact by his early biographers. Nevertheless, the prince was elated by the success of his arms, and assumed a degree of pride on the occasion, which would have ill become any man, and in him was rendered quite contemptible, owing to his want of talents and application. He was, moreover, a slave to his passions, and allowed himself in acts of voluptuousness, that drew down upon him the indignation of the people. Magnentius, an ambitious soldier, encouraged by popular discontent, was resolved to assert the honour of the Roman name. A conspiracy was formed, and Marcellinus, count of the sacred largesse, who had already supplied, with a liberal hand, the means of seduction, under pretence of celebrating his son's birth-day, gave a splendid entertainment: the intemperance of the feast was artfully protracted till a late hour, and the unsuspecting guests were tempted to indulge themselves in a dangerous freedom of conversation. On a sudden, the doors were thrown open, and Magnentius, who had retired for a few moments, returned into the apartment invested with the diadem and purple. The conspirators instantly hailed him with the titles of Augustus and emperor. The guards immediately took the oath of fidelity, and ere the dawning of the day, Magnentius became master of the troops and treasure of the palace and city of Autun. Constans, who was pursuing his pleasure in an adjacent forest, being informed of the fact, threw off the imperial robes, and fled towards Spain; but before he could reach the seaport, where he intended to embark, he was overtaken by a party of cavalry near Helena, at the foot of the Pyrenæes, and put to death. Gibbon. Univer. Hist.

CONSTANS II. grandson of Heraclius, emperor of the East, was raised to the throne in 641, after the senate had deposed the usurper Heraclionas, and his mother Martina. He was then only in his twelfth year, yet before the Byzantine senate, he delivered an oration that did him great credit. Having returned thanks for the just punishment of the assassins, who had intercepted the fairest hopes of his father's reign, he added "By the divine providence, and by your righteous decree, Martina and her incestuous progeny have
been

been cast headlong from the throne. Your majesty and wisdom have prevented the Roman state from degenerating into lawless tyranny. I therefore exhort and beseech you to stand forth as the counsellors and judges of the common safety." The senators were gratified by the respectful addresses of their sovereign; but Constantius was anxious to secure the crown that had suddenly devolved on him. He obliged his elder brother Theodosius to take hasty orders, which rendered him incapable of civil government. The young emperor was not satisfied with this act, which was regarded as a profanation of the sacraments, but he caused Theodosius to be put to death. The act was scarcely perpetrated before the execrations of his subjects, joined to the agonies of remorse, rendered life a burden. He could no longer bear to reside in the capital that had been the witness of a base and infamous fratricide. He became a voluntary and perpetual exile; and embarking for Greece, displayed the hatred which he felt, and was conscious that he inspired, by spitting against the walls of Constantinople as he left them. After passing the winter at Athens, he visited various parts of Italy, and concluded a pilgrimage of disgrace, by fixing his residence at Syracuse. Constantius easily fled from the imprecations of an injured people, but he could not forget what he had done. The remorse of his conscience created a phantom that pursued him wherever he went: the image of his murdered brother was ever before his eyes, presenting to his lips a cup of blood, and saying, or seeming to say, "Drink, brother, drink,"—"a sure emblem," says the historian, "of the aggravation of his guilt, since he had received from the hands of the deacon, the mystic cup of the blood of Christ." Constantius, however, did not resign the cares of government. He took part in some wars carried on in Italy, and having been successful, entered the capital with great pomp, and was met by the pope and clergy at a distance from the city. In return for this mark of respect, he plundered Rome, and sent its wealth and ornaments to Constantinople. He then departed for Syracuse, where he resided five years, oppressing the people, and hated by those about him. Domestic treason put an end to his life; he was assassinated while he was in the bath, in the year 668, after a miserable reign of 27 years. Gibbon. Univer. Hist.

CONSTANT, DAVID, was born at Lausanne, in Switzerland, in the year 1638, and became distinguished as a protestant divine, and professor of theology. He was indebted to his own country for the rudiments of useful knowledge, and was afterwards a student at Herborn in Germany, from which place he went to Groningen, Leyden, and Paris, for farther improvement. At Paris, he became acquainted with many very celebrated members of the reformed church, and having laid the foundation of solid learning, and formed a connection with several worthy characters, he returned to Switzerland in the year 1658, was ordained minister according to the calvinistic form, and undertook the charge of a church at Copet. Here he cultivated a literary intimacy with Turretin, Tronchin, and other professors in the university of Geneva, and with Bayle, the celebrated historian, but who at that time was tutor in the family of count de Donha, baron of Copet, the patron of David Constant. On a vacancy at the college of Lausanne, Constant was appointed tutor to the first class, by the magistrates of Berne, and was afterwards elected professor of moral philosophy and the Greek language. The important duties of these stations he discharged with high honour to himself, and to the advantage of those placed under his instructions; his vacant hours were employed in editing some of the classics,

or on original works. By his contemporaries he was much respected; they regarded him as a man of considerable literary acquirements, possessed of a solid judgment and a correct taste. In the year 1700, he was chosen professor of theology, a situation which he retained until he was eighty-nine years of age, when he resigned in favour of a successor, reserving to himself, even then, the right of giving his assistance and advice at the public meetings of the college. He died in 1733, having attained the venerable age of ninety-five. He published new editions of Forus; of Cicero's smaller pieces, and of various other pieces adapted to the use of schools. His original writings were respectable; they were dissertations on curious theological subjects. We have also "Systema Ethico-theologicum," printed at Lausanne, 1695; a work "De Juramentis;" and another "On Providence."—Moreri.

CONSTANT quantity, in *Geometry*, that which remains the same, while others increase or decrease. Thus the semi-diameter of a circle is a *constant quantity*; for while the absciss and semi-ordinates increase, it remains the same.

CONSTANT winds. See WIND.

CONSTANTIA in *Ancient Geography*, a town of Valeria, in the vicinity of the Danube.—Also, a town of Thrace, in the territory of mount Rhodope.—Also, a town of Asia, in Mesopotamia; said by Ammianus Marcellinus to have been *Amida*, which was enlarged by the emperor Constantine, and assumed his name.—Also, a name given to Majumas, the port of Gaza, after Constantine raised it to the rank of a town and gave it the name of his son.—Also, a name given to the town of Salamine.—Also, a name assigned by Constantine to the town of Arclata (*Arles*), according to Ausonius, cited by Scaliger.

CONSTANTIA *Castris*, a town of Gaul, in the second *Lyonensis*; now *Coutances*.

CONSTANTIA, in *Geography*, a district of the Cape of Good Hope, a mile and a half from Alphen, close under the mountains, about midway between Table bay and False bay, consisting of two farms which produce the far-famed Cape or Constantia wine, so remarkable for its peculiar rich flavour and sweetness. One of the farms where the white wine is made is called *Little Constantia*; the other produces red. There are only from fifty to one hundred casks, of 154 gallons each, made annually of the genuine Constantia wine. The grape is the muscadell, and the rich quality of the wine is owing partly to the situation and soil of the vineyards, and partly to the care taken in manufacturing the wine. No stalks, and no fruit but such as is full ripe, are suffered to go under the press; precautions rarely taken by the other farmers of the Cape, who make annually about six hundred 154-gallon casks of the common Cape wine, which, however, is frequently brought into the European markets, under the name of Constantia wine. The muscadell grape grows at every farm: and at some farms in Drakenstein, the wine pressed from it is equally good, if not superior, to the Constantia, though sold, on account of the name of the latter, at one sixth part of the price. This wine sells at the Cape for 70 or 80 six-dollars for the half-um, which ought to contain 20 gallons; but the avaricious disposition of the proprietors, has led them to fabricate false casks, few of which that come to England being found to measure more than 17 or 18 gallons, and many not above 16. When they find that the wine is to be sent abroad, they adulterate it with some other wine. For, according to their own returns, the quantity exported and consumed in Cape Town, as in the case of Madeira wine, greatly exceeds the quantity manufactured.

The following table shews the quantity of Constantia wine exported in four successive years.

Years.	Half Anns.	Value.
1799	157	11,752
1800	188	14,070
1801	173	13,007
1802	210	15,745
In 4 years.	728	54,574 R. D.

Barrow's Travels in S. Africa, vol. ii. p. 290.

CONSTANTINA, or CONSTANTINE, the eastern province of the kingdom of Algiers, which see. This province, which is the largest and richest of the four provinces into which Algiers is commonly divided, (the three others being Mascara, the territory of the city of Algiers, and Titeri,) lies betwixt the meridians of the rivers Booberak and Zaine, which separates it from Tunis, and is bounded on the north by the Mediterranean, on the east by the kingdom of Tunis, on the south by Biledulgerid, and on the west, in its greatest extent, by the river Malva, or by the territory of Algiers, &c. It is nearly equal in extent to the two western and southern provinces, being, by Dr. Shaw's statement, 250 miles in length, and more than 100 in breadth; and far surpassing them in wealth and strength, as well as in the number and goodness of its cities. The tribute collected by the vicery of this province, according to Dr. Shaw, is proportionably greater. For whilst the Titeri bey brings every year into the treasury of Algiers little more than 12,000 dollars, each dollar being 3s. and 4d. or 6d., and the Tlemian bey from 40 to 50 thousand; the vicery of Constantina never pays in less than 80, and sometimes 100 thousand. The sea-coast of this province, from the Booberak to Boujciab, and from thence almost entirely to Bona, is rocky and mountainous; and the whole tract which lies between the meridians of the rivers Booberak and Zhorre, from the sea-coast to the parallels of Seteef and Constantina, is, for the most part, a continued chain of exceedingly high mountains; few of whose inhabitants, from the ruggedness of their situation, pay any tribute to the Algerines. Near the parallels of Seteef and Constantina it is diversified with a beautiful interchange of hills and plains, which afterwards become less fit for tillage, till it terminates, upon the Sahara, in a long range of mountains, supposed by Dr. Shaw to be the *Buzara* of the ancients. The district of *Zaab* (which see) lies immediately under these mountains; and beyond *Zaab*, at a great distance in the Sahara, is *Wadraag*, another collection of villages. This part of the eastern province, including the parallel of *Zaab*, answers to the *Mauritania Sitifensis*, or the first Mauritania, as it was called in the middle age. The mountains are inhabited by free Arabian and Moorish tribes, which from time to time have proved formidable enemies to the power of Algiers. The most remarkable places are *Boujciab* or *BUGIA*, *CULLU*, *BONA*, *LA CALLE*, the island of *TABARCA*, and *CONSTANTINA*; which see respectively.

CONSTANTINA, *Constantine*, formerly *Cirta*, is one of the most considerable cities of ancient Numidia, the capital of the above-described province, and the residence of the bey. Next to Algiers, it is the most populous city in the Algerine dominions. For a particular account of it, see *CIRTA*.

CONSTANTINA, a town of Spain, in Andalusia; 50 miles S.W. of Cordova, and 42 N.N.E. of Seville.

CONSTANTINA, in *Ancient Geography*, a town of Phœnicia.—A town of Asia, in Melopotamia.

CONSTANTINE I., FLAVIUS VALERIUS CONSTANTINUS, in *Biography*, the first Christian emperor, and surnamed the GREAT, was son of Constantius Chlorus by Helena. The celebrity to which this prince attained, has rendered posterity attentive to the most minute circumstances of his life and actions. The place of his birth, and the condition of his mother, have been subjects of warm, not to say violent, disputes. According to Mr. Gibbon, Helena was the daughter of an inn-keeper, and Naiffus in Dacia was the birth place of her son, the subject of this article, about the year 274. In his youth he discovered little inclination to improve his mind by the acquisition of knowledge; but the comeliness of his figure, the dexterity which he exhibited in all manly exercises, and his known courage and affability, rendered him a favourite with the army and the people. He was about eighteen years of age when his father was promoted to the rank of Cæsar: this event was attended with his mother's divorce, in order to make way for the second wife of Constantius, who could boast of an alliance with the imperial race. By this act the noble-minded Constantine was reduced to a state of disgrace and humiliation. Indignant, probably, at the base conduct of his father, he remained in the service of Dioclesian, and signaling himself in the wars of Egypt and Persia, he was raised to the rank of tribune of the first order. The popularity of this young man rendered him an object of jealousy to Galerius, through whose interest he had already been denied the rank of Cæsar. Endangered by the power and wiles of his opponent, and being sent for by Constantius, his father, whose health was daily declining, he secretly left Nicomedia, where he then was, and travelled with all expedition to Boulogne, and embarked with Constantius for Britain. The expedition was prosperous, and they easily obtained a victory over the Caledonians; but it was the last exploit of Constantius. He died at York, in the year 306, within little more than a year after he had received the title of Augustus. His death was immediately succeeded by the elevation of Constantine, who was proclaimed emperor by the army. The throne was the object of his ambition; and he knew too well the character of Galerius, the colleague of his late father, to hesitate as to the part he must take in this crisis. He was satisfied that if he wished to live, he must resolve to reign. At first he affected to resist the choice of his people, and wrote a respectful letter to the emperor of the East, acquainting him with the event. The earliest emotions of Galerius were those of surprise, disappointment, and rage: he threatened to commit to the flames the letter, and him that brought it. Upon farther deliberation, he resolved not to contest his succession to the sovereignty of the provinces beyond the Alps, but conferred on him the title of Cæsar, reserving that of Augustus to his favourite Severus. Constantine, who already possessed the substance, expected without impatience an opportunity of obtaining the honours, of supreme power; and accordingly employed himself some years in governing and securing the dominions fallen to his share. In defending his own rights, he was often betrayed into acts of cruelty, unworthy of a great mind. Contending with the Franks, he took two of their kings, whom he barbarously exposed to wild beasts in the amphitheatre of Trèves: in some instances where he was victorious, he spared neither sex nor age; exhibiting a ferocity that seems ill to accord with the general tenor of his character, to which he was probably

probably prompted by the supposition, that upon a barbarous foe all kinds of barbarity were allowable. In 307 he married Fausta, daughter of Maximian, who had resumed the purple; but he took no part in the fortunes of his father-in-law, who was ever engaged in warfare, till he became himself Constantine's open enemy, and endeavoured to dispossess him of his rightful authority. Under these circumstances he was delivered into the hands of his son-in-law, who slewed him no other favour than that of allowing him the choice of the manner in which he would die: Maximian strangled himself in the year 310.

Shortly after this event, which was little creditable to the feelings of Constantine, or to the filial piety of Fausta, who took no means to soften the resentment of her husband, a civil war broke out. Maxentius, who had reigned in conjunction with Constantine, now laid claim to the monarchy of the whole West, and made preparations for an invasion of Gaul. Constantine relying as well on his own talents, as on the hatred borne to his rival, resolved to anticipate the attack, and to carry the war into the heart of Italy. The armies of Maxentius, amounted to one hundred and seventy thousand foot, and eighteen thousand horse. The wealth of Italy supplied the expenses of the war, and the adjacent provinces were exhausted to form magazines of corn and other kinds of provisions. The whole force of Constantine consisted of ninety thousand foot, and eight thousand horse; a large part of which was necessary to the defence of his other dominions. At the head of forty thousand soldiers, he marched to encounter an enemy, whose numbers were at least four times superior to his own. Constantine had been trained from his earliest youth to war, to action, and to military command, and his troops were in the highest state of discipline: these he disposed with consummate skill, and for himself he chose the post of honour and danger. Distinguished by the splendor of his arms, he charged, in person, the cavalry of his rival, and his irresistible attack determined the fortune of the day. The victory was complete, and the dismayed followers of Maxentius rushed by thousands into the Tyber. The emperor himself attempted to escape back into the city over the Miltivan bridge, but the crowds which pressed together through that narrow passage, forced him into the river, where he was immediately drowned by the weight of his armour. His body which had sunk deep into the mud, was found the next day; and the sight of his head, when it was exposed to the eyes of the people, convinced them of their deliverance, and led them to acknowledge as their sovereign Constantine, who thus attested by his valour and high talents the most splendid enterprize of his life. It was previous to this battle, A. D. 312., that historians assign the date of Constantine's conversion to Christianity, who had never before discovered religious principles of any kind. A splendid miracle is mentioned as the immediate instrument of this change. Dr. Lardner, indeed, offers some reasons why Constantine could not well have remained through life without some religious impressions; he is however willing to follow the account of Eusebius, who says, that about the period of the war with Maxentius, the emperor was led to consider that he stood in need of more powerful assistance than military forces; he therefore fought for a God that should be his helper. The historian goes on to say, that in part of his march, as the day was declining, there appeared to the sight of Constantine, and to that of all his army, a luminous cross above the sun, with the inscription *crux vinca*, by this conquer; that the monarch not comprehending the meaning of this sign was farther instructed, in the following night by a vision of Christ himself, bearing his cross, and directing him to take a similar standard, under which he should march to victory. In the morning Con-

stantine communicated this wonderful circumstance to his friends; and sending for ingenious workmen, he gave them a description of the sign, and saw them make one like it in gold and precious stones; which, says Eusebius, "we have seen." Much has been said respecting this surprising phenomenon. By some the whole is regarded as a fiction, a stratagem and political device of Constantine, yet it is related by Eusebius a grave historian, who declares that he had it from the emperor, who confirmed the narration by an oath. By Fabricius, we are told, that the appearance in the heavens was generally looked upon as a reality, and a miracle: but for his own part, he is inclined to consider it as the result of a natural phenomenon in a solar halo; he accordingly admits of the reality of the phenomenon, but does not suppose it to be properly miraculous. Upon a full and candid review of the evidence, Dr. Lardner, whom we have before quoted, and than whom no one was a better judge of human testimony, seems inclined to doubt the relation given by the emperor, upon whose sole credit the story is recorded, though it was twenty years after the event, when Eusebius wrote his account, during which period he must have heard it frequently from eye-witnesses, if the emperor's relation were accurate that the appearance was visible to his whole army as well as to himself. The oath of Constantine, on the occasion, with Dr. Lardner, brings the fact into suspicion, and another striking circumstance is that Eusebius does not mention the place where this wonderful sight appeared. Without, however, entering, at present, farther into the discussion, which we shall refer to the article Cross; we may observe, that Eusebius has led us to the period, when the sign of the cross began to be made use of by Constantine, among his armies, and at his battles; this was probably the day before the last battle with Maxentius, fought on the 27th of October, 312. About this period, it is admitted, that Constantine became a Christian, and continued to the remainder of his life, taking care also to have his children educated in the same principles. His conversion seems to have been partly owing to his own reflections on the state of things, partly to conversation and discourse with Christians, with whom, the son of Constantine, their friend and favourer, must have been some time acquainted, but perhaps, chiefly to the serious impressions of his early years, which being once made can never be wholly obliterated. Constantine was however a politician as well as a Christian, and he probably hit upon this method to reconcile the minds of his army, to the important change in their religious profession and habits, as well as making use of it as a mean of success in his designs against his enemies, for which purpose he rightly judged, that the standard of the cross, and the mark of it as a device on his soldier's shields, would be of no small service.

We must now return to Constantine in the character of a victorious general. After the battle, he entered the capital in triumph, wholly destroyed the family of his rival, but refused to include among the victims, many whom the Romans would gladly have sacrificed to their abhorrence of the late tyranny. He disbanded and dispersed the pretorian guards which had so often made and murdered emperors: he recalled many who had been banished, and resorted to them their estates: he discouraged informers, and promoted the welfare of the city. The senate immediately passed a decree, conferring on him the first rank among the three Augusti, who then were masters of the world: Licinius and Maximin were the other two. Africa readily followed Italy in recognizing the sovereignty of the conqueror. To Licinius, with whom he had an interview, he gave his sister Constantia in marriage, in order to strengthen his own hands. From Milan, where the two emperors issued an

edict under their joint authority, allowing a general toleration in religious matters within their dominions, Constantine was called by an attempt of the Franks to cross the Rhine. Over these he gained a complete victory, and made many prisoners, whom, as in former instances, he exposed to wild beasts. In the mean time a civil war arose between Maximin and Licinius, which terminated in the destruction of the former, and the extirpation of his whole family.

Constantine and Licinius were now masters of the world, but they did not long continue united. A war broke out between them in the year 314, but the result of several battles was decidedly in favour of Constantine. Licinius sued for peace, which he obtained, and which continued eight years. In 323 another war was excited between the emperors. Licinius had long been hostile to the Christians, whose affections he had alienated, and who looked up to Constantine as their patron, and the head of their religion. Aware of this circumstance, and relying on his own superiority, as a military commander, Constantine began the quarrel. Under the banner of the cross, and accompanied by bishops and other ministers of their holy religion, he went out with 130,000 well-disciplined and well-accounted soldiers to meet his rival, who waited his arrival in the vicinity of Adrianople. Constantine was again victorious: Licinius fled to Byzantium, and when he found that place no longer tenable against the power of his enemy, he withdrew to Chaledon, and from thence, after hazarding another battle, in which he was also unsuccessful, to Nicomedia; where, by the intercession of his wife, he obtained a solemn promise of having his life spared, on the condition of his renouncing all claims to sovereignty. To the disgrace of Constantine imprisonment and death soon followed the humiliation of his rival. This deed has been justified on the plea that the fallen emperor had engaged in a treasonable correspondence against the reigning sovereign, but sufficient evidence of the fact was not adduced. The son of Licinius was also sacrificed to the jealousy of Constantine, who, by these atrocious means, delivered himself from all dread of opposition. An arbitrary prince seldom finds any difficulty in freeing himself from his enemies, but Constantine with all his powers, could neither foresee, nor prevent, those domestic calamities to which he shortly became the prey. Crispus, his son, by a former wife, was viewed, by his mother-in-law Fausta, as the chief obstacle to the future greatness of her own children. She insinuated into the breast of Constantine suspicions of his son's loyalty, and is said also to have brought a charge against him of having attempted her own chastity. Crispus was examined, imprisoned, and put to death in the year 326. His grandmother Helena, convinced of his innocence, resolved to be revenged for his hard fate, and found means of convicting the empress of an adulterous connection with a slave of the palace, for which she was suffocated in the steam of a hot bath. From these circumstances, and from the contempt which he shewed for the pagan rites, the emperor became unpopular with the people and the senate. On his part there was no personal attachment to the ancient metropolis, and he was resolved to perpetuate his name by the foundation of a new city. After much deliberation he fixed on Byzantium, which he had once besieged, as the imperial city that should, with future ages, give him celebrity and renown. See CONSTANTINOPLE.

In the year 331 Constantine was involved in a war with the Goths, who at first were successful against his power, but were, at length, defeated and compelled to agree to such terms as the victor thought proper to propose. Constantine, by chastising the pride of the Goths, and by accepting the

homage of a suppliant nation, vindicated the majesty of the Roman empire; and ambassadors from Ethiopia, Persia, and the most remote countries of India, came to congratulate him on the peace and prosperity of his government; and he seems to have enjoyed as uninterrupted a share of felicity, as a man situated as he was could reasonably expect. He attained to the thirtieth year of his reign, a period which none of his predecessors, since Augustus, had been permitted to celebrate. Constantine survived that solemn festival about ten months, and, at the age of sixty-four, after a short illness, he ended his memorable life at a palace in the suburbs of Nicomedia, whither he had retired for the benefit of the air, and with the hope of recruiting his exhausted strength by the use of the warm bath. The demonstrations of grief, or at least of mourning, surpassed whatever had been practised on any former occasion. The body of the deceased emperor was transported to the city which was destined to preserve the name and memory of its founder: there it was adorned with the symbols of greatness, and deposited on a golden bed in one of the apartments of the palace, which was splendidly illuminated and furnished for the purpose. Every day, at the appointed hours, the officers of state, approaching the person of their sovereign, offered the same respectful homage to his dead body as they had been accustomed to present to him during his life, so that it has been said Constantine alone, by the peculiar indulgence of heaven, reigned after his death.

It remains now to give a general estimate of the character of this great man, who was unquestionably the most splendid among the Roman emperors. It is no wonder that a prince who removed the seat of empire, and introduced such important changes into the civil and religious constitution of his country, should have fixed the attention, and divided the opinions of mankind. By certain classes of Christians he has been regarded as the deliverer and defender of the church, and has been decorated with every attribute of a hero, and even of a saint: by others he has been considered as the real, though without any ill intentions on his part, enemy to the cause of true Christianity, by incorporating it with the civil government of the world: by contemporary historians who did not embrace the religion of Christ, Constantine was compared to the most abhorred of those tyrants, who, by their vices and weakness, dishonoured the imperial purple.

Constantine was, in person, remarkably tall, of a comely and majestic presence, and great bodily strength. The general tenor of his life proves that he was a person of no mean capacity: the achievements and success of Constantine do not belong to men of weak and irresolute minds. His mind indeed was equal to his fortune, great as it was: his valour was tried and approved frequently in his youth, and was conspicuous on all proper occasions throughout his whole life: his chivalry, justice, and prudence, are commended by those of his biographers, who, on account of a difference in religion, were not disposed to flatter him: his many acts of bounty to the poor, and his just edicts are arguments of a merciful disposition, and a love of justice. According to Eusebius the palace of Constantine was converted into a church; and the emperor himself cheerfully led the way to those that assembled there with him. Taking the sacred books into his own hands, he attentively read and meditated upon the divine oracles; and then recited the usual prayers with those who were met together. Constantine besides prayed daily in private in his closet. In time of war he had a chapel at a small distance from his camp for the performance of religious duties, especially before battle, seeking thereby the divine protection and blessing. He
taught

taught even his heathen soldiers a form of prayer, in which they worshipped the one true God. These and many other instances of the Christian temper are ascribed to the emperor by Eusebius. By our own historian, the early part of his life is highly pauperized: "He delighted," says Mr. Gibbon, "in the social intercourse of familiar conversation; and though he might sometimes indulge his disposition to rally with less reserve than was required by the severe dignity of his station, the courtesy and liberality of his manners gained the hearts of all who approached him. The disadvantage of an illiterate education had not prevented him from forming a just estimate of the value of learning; and the arts and sciences derived some encouragement from the munificent protection of Constantine. In the dispatch of business, his diligence was indefatigable; and the active powers of his mind were almost continually exercised in reading, writing, or meditating: in giving audience to ambassadors, and in examining the complaints of his subjects. Even those who censured the propriety of his measures were compelled to acknowledge, that he possessed magnanimity to conceive, and patience to execute, the most arduous designs, without being checked either by the prejudices of education, or by the clamours of the multitude. In the field, he infused his own intrepid spirit into the troops, whom he conducted with the talents of a consummate general; and to his abilities, rather than to his fortune, we may ascribe the signal victories which he obtained over the foreign and domestic foes of the republic. He loved glory, as the reward, perhaps as the motive, of his labours. The boundless ambition, which, from the moment of his accepting the purple at York, appears as the ruling passion of his soul, may be justified by the dangers of his own situation, by the character of his rivals, by the consciousness of superior merit, and by the prospect that his success would enable him to restore peace and order to the distracted empire." As he advanced in life, his character was less respectable, his actions less honourable. The ostentatious grandeur of his court, and his magnificent buildings, were supported by taxes which bore very heavily on the people, and in his old age he was charged with prodigality and rapacity. Eutropius says, that Constantine, "in the early parts of his reign, might be compared to the best princes, in its conclusion to the indifferent ones." And Dr. Lardner, who took great pains to understand and appreciate the worth of this emperor, observes, with his usual candour, that "we should be willing to make allowances in favour of princes, and especially of long reigns. It is next to impossible for human wisdom and discretion, in the course of many years filled with action, not to be surprised into some injustice, through the bias of affection, or the specious suggestions of artful and designing people. Though, therefore, there may have been some transactions in this reign which cannot be easily justified, and others that must be condemned, yet we are not to consider Constantine as a cruel prince or a bad man." Gibbon, Lardner, Jortin, Univer. Hist.

CONSTANTINE II., the eldest of the three sons of Constantine the Great, was born in the year 316, and, by the indulgence of his father, was admitted at a very tender age to share the administration of the empire. He and his brothers may be said to have studied the art of reigning at the expence of the people entrusted to their care. During his father's life-time, the younger Constantine was appointed to hold his court in Gaul; and upon his death in 337, he succeeded to the government of Gaul, Spain, and Britain; to him also was assigned the city of Constantinople, with a certain superiority of rank above his brothers. During his short

reign, he did little that has been deemed worthy of historical record. Dissatisfied with the share of empire allotted to him, he was desirous of possessing the provinces of Africa, which had been given to Constantine. His intentions were in vain: determining, therefore, to wield by force, what he could not obtain by argument, at the head of a tumultuary band, he invaded the dominions of Constantine, and laid waste many parts of the country. The measures of his brother were directed with more prudence; and Constantine, by too great eagerness, was betrayed into an ambushade, which had been concealed in a wood, where he and his attendants were surrounded and slain, A. D. 340. His body was afterwards found in the obscure stream of Alfa, and obtained a place in the imperial sepulchre; but his provinces transferred their allegiance to the conqueror. Contemporary historians speak of Constantine as a prince of great accomplishments; but his conduct towards his brother met with a punishment which neither merited nor obtained the pity of survivors.

CONSTANTINE III., the next emperor of this name, was the son of Heraclius by Eudoxia, and succeeded his father in 641. Of him more cannot be well said than that he reigned three months, and died in his 30th year, either by disease, or by poison, supposed to have been administered by his mother-in-law.

CONSTANTINE IV. succeeded his father, Constantine II., in the year 668. Very soon after he came to the throne, he went to Sicily, with a view of punishing his father's murderers, and to depose the usurper whom they had established. His enterprize was successful: but upon his return to Constantinople, he was scarcely recognized, on account of the alteration in his beard; hence he obtained the appellation of the *bearded*. In this reign the Saracens invaded Africa, Sicily, and Cilicia, and at length laid siege to Constantinople. Their attempts were completely baffled, and their loss in men was very considerable. The emperor, however, became tributary to the Bulgarians, who successfully invaded some of his territories. This prince, who died in the year 685, appears to have possessed a small share of talent, intermixed with cunning and cruelty. On his two brothers he had bestowed the empty title of Augustus, unconnected with trust or power. At their secret instigation, the troops of the Anatolian province approached the city on the Asiatic side, demanding for their royal brothers the partition or exercise of sovereignty, and supported their claims by a theological argument. "We are Christians," they said, "the sincere votaries of the holy and undivided Trinity: since there are three equal persons in heaven, there should be three equal persons on earth." The emperor invited them to a friendly conference, in which they might propose their arguments to the senate: they obeyed the summons; but the view of their bodies, hanging on the gibbet in the suburb of Galatea, reconciled their companions to the unity of the reign of Constantine. He pardoned his brothers; but on the repetition or suspicion of a similar offence, the obnoxious princes were deprived of their titles and noses, that the deformity might disqualify them from the empire. In the close of life, Constantine was anxious to establish the right of primogeniture; and the eldest son was exalted to the rank of Augustus, and the assurance of the empire.

CONSTANTINE V., son of the emperor Leo, was born in 719, and crowned in his infancy. He was surnamed *Copronymus*, from having polluted the baptismal font. During a long reign of 34 years, he ever exhibited an abhorrence of image-worship, which rendered him an object of hatred to the catholics, who have used every means in their power to transmit his name to posterity in the most disgusting light.

light. Although he did not merit all the opprobria affixed to his character by ecclesiastical bigots, yet he undoubtedly exercised much cruelty towards the party which resisted his attempts for reform in the church. Some were put to death, others mutilated, and not a few underwent less severe punishments. As a general, he exhibited much prudence and courage. Soon after his accession he marched against the Saracens, who had made an irruption into Asia; and his brother-in-law, taking advantage of his absence, placed himself at the head of the orthodox faction, and was declared emperor. A civil war ensued, in which Constantine was victorious: the metropolis surrendered to its lawful sovereign, and the usurper and his son were deprived of their ill-gotten power, and of their eyes. When every thing at home was settled to his satisfaction, he made war again upon the Saracens, took their strong places, and destroyed their fleet. In the midst of his successes, an earthquake, and a pestilence among his own people, were calamities which excited in him the greatest consternation. After this he was attacked by the Bulgarians, by whom he was so completely defeated, that he was obliged to seek refuge in his capital: but in another attack, victory determined for Constantine, who cut off the invaders, with scarcely any loss. As he was proceeding on a new expedition against the same people, he was seized with a fever, which terminated his life in 775. To the praise of this prince, his enemies admit that he restored the ancient aqueduct, a work of great importance to the inhabitants of Constantinople. He redeemed nearly three thousand captives: and under his reign, plenty was the characteristic of the times. Moreri. Gibbon. Univer. Hist.

CONSTANTINE VI., grandson of the preceding, was born in 770; and when only five years of age, he was associated with his father, Leo IV., in the government: but neither then, nor in 780, when he succeeded entirely to the throne, was he capable of efficient business. His mother Irene was appointed guardian to the young emperor: she, naturally ambitious, and impatient of control, was unwilling to resign the power out of her own hands. The contents between the mother and her son were the most prominent features of this reign. During the childish years of the emperor, nothing could be better administered than the government under Irene: but when he had attained the years of maturity, by the advice of his adherents, he would fain have rewarded his mother's services by perpetual banishment to the isle of Sicily. Irene was too politic to be thus served: she retaliated upon her enemies, and obtained for herself almost an unlimited obedience. Her abuse of victory proved detrimental to her interests: Constantine ascended the throne sole sovereign, and his mother was dismissed to a life of solitude, to the enjoyment of which her mind was by no means adapted. She was recalled to court, and soon obtained a certain degree of authority. The emperor was attacked and defeated by the Bulgarians; and suspecting an insurrection in favour of Nicephorus, son of Constantine V. by a second marriage, he had him seized and his eyes put out, and the tongues of his four brothers were amputated. After this cruel punishment, they were doomed to perpetual imprisonment. For five years they submitted to their fate: an opportunity then offered, and they made their escape to the church of St. Sophia, displaying a pathetic spectacle to the people. "Countrymen and Christians," exclaimed Nicephorus for himself and mute brethren, "behold the sons of your emperor, if you can recognize our features in this miserable state. A life, an imperfect life, is all that is spared: this is now threatened, and we appeal to your compassion." Their wretchedness affected the people, but the minister of

Constantine contrived to soothe their miseries, and draw them from public view. They were speedily embarked for Greece, and Athens allotted to them as a place of exile. Once more they escaped from the hands of their keepers, and appeared in purple at the gates of Constantinople. This was their last effort: in attempting to gain a crown, they lost their lives. Irene soon found an opportunity of exciting discontents, with a view of deposing her son. Suspecting his danger, he attempted to escape to the provinces, but was seized on the Asiatic shores, and carried prisoner to his own palace, where, in the very chamber in which he was born, the emissaries of his unnatural and infamous mother assaulted him in his sleep, and plunged their daggers in his eyes. In this state he survived many years, to reflect on his own cruelty, and to learn the usurpations of Irene.

CONSTANTINE VII. was son of the emperor Leo VI., and nephew to Alexander, whom he succeeded in 912, being but seven years of age. During his minority, Romanus Lecapenus, a successful general, got possession of the emperor's person, and persuaded him to marry his daughter. He then assumed the royal purple himself, and associated his own three sons in the imperial authority, degrading the lawful emperor to the fifth rank among the titular princes. Much, however, to the honour of Romanus, he permitted him to live unmolested; and the time of Constantine was spent in the study and practice of the fine arts. The fall of Romanus was occasioned by the ambition of his own children, who effected the banishment of their father, and, contrary to their own expectations, elevated Constantine to his rightful throne. To prevent their future intrigues, the emperor's first act was to seize the conspirators, and banish them to the same island and monastery in which they had so lately confined their father. Romanus met them on the beach with a sarcastic smile, and, after a just reproach of their folly, ingratitude, and weakness, presented his imperial colleagues with an equal share of his water and vegetable diet. Constantine was now in possession of the eastern world, which he governed, or appeared to govern, fifteen years. He was, however, devoid of that energy of character which became the sovereign of so mighty an empire. The studies which had amused his life of comparative solitude, were not easily exchanged for the serious and important duties of a monarch. The reins of government he entrusted to his wife Helena, while he employed much of his time in the instruction of his son Romanus, and in drawing up a treatise for his immediate benefit, but of which he made no ill use, that he is suspected of having administered poison to his father, in order to succeed him in the empire. The death of Constantine was regretted by his subjects, who paid every demonstration of respect to his deceased corpse, which, according to usual custom, lay in state at the palace. Before the procession moved to the sepulchre, an herald proclaimed the awful admonition: "Arise, O King of the world, and obey the summons of the King of kings."—One of the deposed sons of Romanus had, during his short-lived authority, assumed the title of CONSTANTINE VIII.: of him therefore enough has been said;—and we proceed to the reign of CONSTANTINE IX., who, in conjunction with his brother, Basil II., succeeded to the throne, on the death of John Zimisces, in the year 976. During the long life of Basil, Constantine had only the name of emperor: all emanated from his brother. After his decease, Constantine enjoyed, about three years, the power, or rather the pleasures, of royalty; and his chief care was the settlement of the succession. He had possessed, sixty-six years, the title of Augustus; and the reign of the two brothers is the

longest and most obscure of the Byzantine history. He ended his inglorious life in 1028, at the age of seventy.

CONSTANTINE X. was surnamed *Monomachus*, the single combatant, which was probably expressive of his valour and victory in some public or private quarrel. He was a Greek of noble extraction, and recalled from exile in Lesbos to succeed Michael V. He was at that time married to Zoe, the daughter of Constantine IX. With her, who had already been wife to two emperors, he was dissatisfied, and took, as concubine, a widow, to whom he gave the title of Augusta. This reign was disturbed by various revolts, in which the emperor was usually victorious. He was successful also against his foreign enemies; but his indolence or avarice gave the Turks an opportunity of gaining a footing in Asia Minor. He died in 1054. The health of this emperor had, during the greater part of his life, been broken by the tortures of the gout, and his reign was spent in the alternatives of sickness and pleasure.

CONSTANTINE XI. surnamed *Ducas*, was chosen by the emperor Isaac Comnenus, as the fittest person to succeed him, when he voluntarily laid down the crown in 1059. The beginning of his reign was affected by a conspiracy of his own people against him. Having quelled this, he began to turn his attention to government, for which he seems to have been very unequal. By the principles of avarice, he neglected the maintenance of his garrisons on the frontiers, and the Uxiens, a people of Scythia, taking advantage of this circumstance, passed the Danube, and laid waste the country. They penetrated into Greece, and defeated the imperial generals, who had been sent against them. Constantine would have gladly purchased peace, on any terms; they, however, disdain to treat, and were finally stopped in their victorious career, by pestilence, and the arms of the Bulgarians, circumstances which destroyed the greater part of the number, that in the outset amounted to nearly half a million of souls. During this reign an earthquake did much damage to the empire. Constantine died at the age of 60 years, having previously secured the succession of his three sons. Of these one assumed the title of CONSTANTINE XII.; but his glory was merely nominal, and lost in that of his elder brother Michael. Of the eleventh CONSTANTINE, historians say he was an orthodox and just prince, but the slave of avarice. The XIIIth prince of this name was son of the emperor Manuel Palaeologus, and succeeded his brother John in 1448, at a period when the whole empire scarcely extended beyond the limits of the capital. This sovereign having squandered the small remaining resources of his dominion in imperial ostentation, found himself threatened with the hostility of his potent neighbour, sultan Mahomet II., who erected a fortress on the Bosphorus, found occasion for a quarrel, and laid siege to the capital. Constantine determined to resist to the last, and to share the fate of his people. He sought for succour among the Christian princes of the West, but the aid he obtained was tardy, and insufficient to the greatness of the occasion. Constantinople was encompassed by Turkish arms, and the emperor, in this extremity, fulfilled the part of a hero. When the final assault was prepared, he took leave of his people in a moving harangue, received the sacrament in the church of St. Sophia, and then went to the walls. The numbers of the Turks without, exceeded those of the Christians within, the city, more than a hundred fold. Every hope of successful resistance was vanished; breaches had been made in the walls, and at length they and the towers were covered with swarms of the assailants. Amidst these multitudes, the emperor, who nobly accomplished all the duties of a general, and soldier, was long seen, and finally lost; his mournful exclamation

was heard, "Cannot there be found a Christian to cut off my head?" His last fear was that of falling alive into the hands of the infidels. He had thrown off the purple, and falling by an unknown hand, was buried under a mountain of slain. The final catastrophe of the Greek empire, and emperor, happened May 29th, 1453, Constantinople having sustained a siege of 58 days. See CONSTANTINOPLE. Moreri. Gibbon. Univer. Hist.

CONSTANTINE, FLAVIUS JULIUS, from a private soldier, in the legions of Britain, was raised to imperial honours, on account of his name, and in respect for the great Constantine. He had no sooner attained the high honour, than he passed over to Gaul with his troops, and made himself master of that country. With the assistance of his son Constantus, he reduced Spain; and upon Constantus he conferred the title of Augustus. Constantine fixed his throne at Aries, and when the Goths under Alaric had taken possession of Italy, he marched as far as the Po, on the pretence of effecting its deliverance, but probably with a view of sharing in the spoil. After passing through various scenes, in which he experienced by turns success and disaster, Constantine was besieged in his capital by Constantius, to whom he surrendered, on the promise of security for himself and his son. The terms were granted, but the engagement was not fulfilled. The fallen prince was sent to Italy, where he and his son Julian, in violation of a solemn promise, suffered death by the emperor's orders, Sept. the 18th, 411. Moreri. Gibbon.

CONSTANTINE: there were two popes of this name: the one a native of Syria, raised to the Roman see in 708, characterized for his charity to the poor; and for his ambition, in engaging Justinian to subjugate the independent see of Ravenna to the yoke of Rome; the other, from a layman, was raised to the highest office in the church by the influence of his brother; an honour, however, that he did not long retain. An insurrection being excited against him, in about a year after his elevation, he was deposed, and, under the reign of the new pope, was subject to the insults and most cruel treatment of the people, deprived of his sight, and condemned to perpetual imprisonment. Moreri.

CONSTANTINE is the name likewise of an abbot who flourished at Metz in the eleventh century, and who was author of "The Life of Adalberon II." bishop of that city; and of a monk distinguished for his writings in the thirteenth century, against Veccus, patriarch of Constantinople. Another of the same name was born at Florence, and became bishop of Orvieto. He acquired celebrity by his preaching talents, and after his elevation to the bishopric, he was appointed legate from pope Alexander IV. to Theodore Lascaris, the Grecian emperor, hoping, by his persuasion, to induce the emperor and his clergy to submit to the Roman see. He was author of the life of St. Dominic, and other works. He died in the year 1257.

CONSTANTINE, surnamed the *African*, was born at Carthage, about the middle of the eleventh century. He resided many years in Babylon, where he became celebrated for his knowledge in the Arabian, Chaldean, Persian, and Egyptian languages. Among the sciences, medicine seems to have received the greatest share of his attention, as appears by two of his works, which were thought deserving of being printed several centuries after his death. In the first, which was published at Bale, in the year 1536. in folio, "De morborum cognitione, et curatione," libri septem, he treats of affections of the stomach, hypochondriasis, on the diseases of women, &c. In the second, which was also published at Bale, three years after the former, he treats of fevers, of the elephantiasis, of incantations, and of remedies taken

taken from parts of animals. The whole are however supposed to have been principally translated from Arabian writers. After a residence of thirty nine years at Babylon, he returned to Carthage, but soon fell into such disgrace with his countrymen, whom he suspected of intending to destroy him, that he went to Salerno. Though he was there introduced to duke Robert, who wished to retain him about his person, preferring a life of ease and retirement, he entered into a monastery of the Benedictines, St. Agatha, in Aversa, where he died in 1087. Haller Bib. Med. Eloy Dict. Hist.

CONSTANTINE, ROBERT, a native of Caen in Normandy, was born, as it is said, about the year 1502. He was profoundly versed in Greek, Latin, and oriental literature. This procured him the intimacy of J. Cæsar Scaliger (with whom he resided several years), and of other great scholars, but did not defend him against the sarcasms of Joseph Scaliger, who attacked him with great ferocity. He took his degree of doctor in medicine, but from the many learned works he published, does not seem to have dedicated much of his time to the practice of that art. His editions, with annotations, of the works of Theophrastus, Dioscorides, Celsus, and Quintus Serenus, gained him much credit. They were published between the years 1554 and 1566, as was also his "Nomenclator insignium Scriptorum, quorum libri extant vel manuscripti, vel impressi," Svo. But the work which established his name as a scholar, was his "Lexicon Græco-Latinum," first published at Geneva, in 1562, in two volumes folio; reprinted, much improved, in 1592. He is said by De Thou to have lived to the great age of 103 years, preserving his faculties entire to the last. Other writers say he died of a pleurisy at the age of 75 years. Haller. Bib. Bot. Eloy Dict. Hist.

CONSTANTINE, ANTONY, an eminent physician at Lyons, published in 1597, in Svo. "Brief traité de la Pharmacie Provençale, et familière," in which he attempts to shew his countrymen, that they may find in their fields remedies for their diseases, without having recourse to drugs imported from foreign countries. Also "Opus Medicæ prognosæ, in quo omnium symptomatum, causæ et eventus exponuntur." Svo. 1613. He died, far advanced in years, in 1616. Eloy Dict. Hist.

CONSTANTINE, *Order of, in Heraldry*, otherwise the order of the Golden Angel and St. George. Constantine the Great is by some considered as the founder of this order, after his memorable victory over the tyrant Maxentius, A. C. 312. This is at present the second order of the kingdom of Naples. Others affirm that the emperor Isaac Angelus Comnenus was the founder of it. The badge of the order is a red cross, somewhat in the form of four fleurs-de-lis joined at the extremities, surrounded with a border of gold, thereon embroidered the four letters I. H. S. V.; meaning, "In hoc signo vinces," being the words displayed on the celestial meteor, or luminous cross, which is said to have appeared to Constantine, and encouraged him to attack Maxentius. In the centre of the badge is a monogram, or cypher of our Saviour's name, expressed by the letters X and P, and on each side are placed one of the letters A and Ω (alpha and omega, or the first and the last letters of the Greek alphabet.)

The great collar of this order, worn over the mantle, consists of fifteen enamelled golden shields of an oval form, and on each the letters X and P appear in the form of a cypher. The middle shield is somewhat larger than the others, and is surrounded with oak and laurel leaves entwined; and from the lower part of it is suspended the effigy of St.

George, in complete armour, on horseback, and in the act of striking the dragon.

The council of this order is composed of 50 ferators, who are grand crosses. When the grand master assists in state therein, his dress is as follows: the vest and small cloaths are of imperial scarlet, as also the stockings and shoes; above the vest is worn a cassock of silver, richly embroidered, with wide sleeves, and reaching to the knees, fastened round the waist with a girdle of scarlet velvet, embroidered with silver, and about the neck with two rich cords of gold and scarlet silk mixed, with tassels reaching to the ground. On the left side of the mantle, the crests of the order is richly embroidered in gold. The cap is of crimson velvet, and is one span high, lined with white satin, and adorned with a black ostrich feather. The four sides are turned up, and on each the cypher of our Saviour, as above described.

The grand crosses (in number 50) wear a blue vest and small cloaths, and over the same a white vest, which reaches to the knees; their stockings and shoes are white; their girdle red, and their mantle of blue damask is lined with white; they wear the great collar of the order, and their cap, which is of blue satin, is turned up at the four sides, and on each the cypher as before: the cap is also adorned with a white ostrich feather.

The popes had conferred the grand mastership on the house of Comnenus for ever; but in 1699 Angelus Flavius Comnenus, the last of this house, resigned it to Francis Farnese, the then duke of Parma, to him and his successors for ever; which was confirmed by a brief of pope Innocent XII. dated 20th October, 1699. In 1735 the ducal house of Farnese becoming extinct in the male line by the death of Anthony the last duke, Don Carlos, the eldest son of Philip V. king of Spain, and of Elizabeth Farnese, the sole heirs of the family, succeeded to the duchies of Parma and Placentia, and to the grand mastership of this order. This prince was successively grand duke of Tuscany, and king of Naples: upon his succession to the latter he declared this order royal, and annexed it to the crown of Naples.

CONSTANTINOPLE, in *Geography*, the metropolis of the Turkish empire, was built on the site and ruins of the ancient *Byzantium* in Thrace, by the Roman emperor Constantine the Great, who, in the year of our Lord 330, removed the seat of the empire from Rome to this new capital. The reasons which induced Constantine to fix his residence here, are not exactly known. The imperial court had in fact been removed from Rome about thirty years before. Of the associate emperors Diocletian and Maximian, the former resided at Nicomedia, and the latter mostly at Milan. Galerius had his court at Nicomedia; Constantius Chlorus at York. It is supposed that Diocletian and Maximian, having concerted a plan of administration more systematically despotic than that of any of the preceding emperors, and being desirous of setting entirely aside the nominal authority which the senate still possessed, had fixed their residence at a distance from the ancient metropolis of the empire, in order to avoid the republican remonstrances of that august body. Constantine was probably actuated by the same motive, for his administration was still more despotic; and after he had removed the seat of empire to Constantinople, the senate could scarcely be reckoned a constituted order in the state. Others attribute Constantine's choice of a new capital to a dislike which he had conceived against Rome, on account of the enthusiastic attachment of that city to paganism. But whatever may have been Constantine's motive, it cannot be denied that the situation of Constantinople actually was preferable to that of Rome, both as
a check

a check to the Persians, and as a barrier against the Goths, those terrible enemies of Rome, who, having once tasted the rich plunder of Greece and Asia Minor, seized every opportunity of making predatory incursions into all parts of the empire. Besides, the beautiful and picturesque arrangement of the land and water in the environs of Constantinople decidedly entitled it to be preferred to Rome. It is situated on an elevated ground, consisting of gently swelling eminences, rising like terraces, one above another, without any of those deep valleys which separate the seven hills on which Rome is seated, and which, together with the marshes adjoining the Tyber, render the air unwholesome. It fills a triangle formed by the harbour, the Bosphorus and the Propontis, or sea of MARMORA. Situated in the 41st degree of latitude, the imperial city commanded, from her seven hills, the opposite shores of Europe and Asia; the climate was healthy and temperate, and the soil fertile, and the approach on the side of the continent was small in extent, and easy of defence. The harbour on the north side is secure and capacious; it is five hundred yards wide at its entrance from the Bosphorus, and runs seven miles into the land. The Bosphorus and the Hellespont may be considered as the two gates of Constantinople; and the prince who possessed those important passages could always shut them against a naval enemy, and open them to the fleets of commerce when those gates were shut. The capital still enjoyed within their spacious enclosure every production which could supply the wants, or gratify the luxury, of its numerous inhabitants. In sailing up the Propontis towards Constantinople the most enchanting prospects charm the eye of the navigator; from every part of that sea he may discover the high lands of either Thrace or Bithynia, and never loses sight of mount Olympus, till at last the city itself, rising from the Strand, attracts his view, and exhibits the most magnificent appearance. Constantinople also commands the commerce of the vast regions of the north, by means of the Euxine sea, and of the rivers Don and Dnieper, which discharge themselves into it. By the strait of the Hellespont, which forms the communication between the Propontis and the Mediterranean sea, it is equally well situated for the trade of the south and west; and when Egypt is under its dominion its position is extremely advantageous with respect to the trade to India, and the eastern coasts of Africa.

Whatever rude commodities were collected in the forests of Germany and Scythia, as far as the sources of the Tanais and Borythenes; whatsoever was manufactured by the skill of Europe or Asia; the corn of Egypt, and the gems and spices of the farthest India, were brought by the varying winds into the ports of Constantinople, which for many ages attracted the commerce of the ancient world.

The prospect of beauty, of safety, and of wealth, united in a single spot, was sufficient to justify the choice of Constantine. However, as prodigy and fable have, in every age, been supposed to reflect a becoming majesty on the origin of great cities, the emperor thought proper to avail himself of this circumstance; and in one of his laws he has taken care to inform posterity, that in obedience to the commands of God, he laid the everlasting foundation of Constantinople. The ingenuity of succeeding writers has led them to describe the nocturnal vision which appeared to the fancy of Constantine as he slept within the walls of Byzantium. The tutelary genius of the city, a venerable matron, sinking under the weight of years and infirmities, was suddenly transformed into a blooming maid, whom his own hands adorned with all the symbols of imperial great-

ness. The monarch awoke, interpreted the auspicious omen, and, without hesitation, obeyed the will of heaven. In order deeply to impress the minds of the spectators, the emperor himself, on foot, with a lance in his hand, led a solemn procession, and directed the line, which was traced as the boundary of the destined capital, till the growing circumference was observed with astonishment by the assistants, who, at length, ventured to observe that he had already exceeded the most ample measure of a great city. "I shall still advance," replied Constantine. "till He, the invisible guide who marches before me, thinks proper to stop." In surveying the actual state of the city, the palace and garden of the seraglio; occupy the eastern promontory, the first of the seven hills, and cover about 150 acres of our measure. The new walls of Constantine stretched from the port to the Propontis across the enlarged breadth of the triangle, at the distance of fifteen stadia from the ancient fortification; and with the city of Byzantium they enclosed five of the seven hills, which, to the eyes of those who approach Constantinople, appear to rise above each other in beautiful order. About a century after the death of the founder, the new buildings, extending on one side up the harbour, and on the other along the Propontis, already covered the narrow ridge of the sixth, and the broad summit of the seventh hill. The incessant inroads of the Barbarians rendered it necessary for Theodosius the younger to surround his capital with an adequate and permanent enclosure of walls. The new wall of Theodosius was constructed in the year 413; and after having been thrown down by an earthquake in 447, it was rebuilt in three months by the diligence of the prefect Cyrus. The suburb of the Blachernæ was first taken into the city in the reign of Heraclius. From the eastern promontory to the golden gate, the extreme length of Constantinople was about three Roman miles; the circumference measured between ten and eleven; and the surface might be computed as equal to about 2000 English acres. The suburbs of Pera and Galata, though situate beyond the harbour, may deserve to be considered as a part of the city; and this addition may perhaps authorize the measure of a Byzantine historian, who assigns sixteen Greek (about fourteen Roman) miles for the circumference of his native city. After all, Constantinople must yield to Babylon and Thebes, which filled the great but not incredible circumference of about 25 or 30 miles, to ancient Rome, to London, and even to Paris.

As to the expence incurred by the progress of the work, some estimate may be formed of it by the allowance of about two millions five hundred thousand pounds for the construction of the walls, the porticoes, and the aqueducts. The forests that overshadowed the shores of the Euxine, and the celebrated quarries of white marble, in the little island of Proconessus, supplied an inexhaustible stock of materials ready to be conveyed, by the convenience of a short water-carriage, to the harbour of Byzantium. A multitude of labourers and artificers urged the termination of the work with incessant toil; but the impatience of Constantine soon discovered that, in the decline of the arts, the skill, as well as the number of his architects, bore a very unequal proportion to the greatness of his design. However, the buildings of the new city were decorated by the hands of the most celebrated masters of the age of Pericles and Alexander. By the commands of the emperor, the cities of Greece and Asia were despoiled of their most valuable ornaments. The trophies of memorable wars, the objects of religious veneration, the most finished statues of the gods and heroes, of the sages and poets of ancient times, contributed to the splendid triumph of Constantinople; whence the historian Cedrenus took

occasion to observe, that nothing seemed wanting except the souls of the illustrious men, whom those admirable monuments were intended to represent. For an account of the principal buildings with which this imperial city was decorated, we must refer to the articles *FORUM*, *HIPPODROME*, &c. and the sequel of this article.

The baths of this city, which still retained the name of Zeuxippus, were enriched by the munificence of Constantine with lofty columns, various marbles, and above three-score statues of bronze. In short, whatever could adorn the dignity of a great capital, or contribute to the benefit or pleasure of its numerous inhabitants, was contained within the walls of Constantinople. A particular description, composed about a century after its foundation, enumerates a capitol or school of learning, a circus, two theatres, eight public, and 153 private baths, 52 porticoes, five granaries, eight aqueducts or reservoirs of water, four spacious halls for the meetings of the senate or courts of justice, 14 churches, 14 palaces, and 4388 houses, which, for their size and beauty, deserved to be distinguished from the multitude of Plebeian habitations. In order to furnish this favoured city with a population, corresponding to its extent and magnificence, Constantine invited many opulent senators of Rome, and of the eastern provinces, to fix upon his chosen residence for their own habitation; and he bestowed on his favourites the palaces which he had built in several quarters of the city, assigned them lands and pensions for the support of their dignity, and alienated the demesnes of Pontus and Asia, for the purpose of granting hereditary estates by the easy tenure of maintaining a house in the capital. By degrees, however, a variety of concurring circumstances contributed to fill the city with inhabitants. In less than a century, Constantinople disputed with Rome itself the pre-eminence of riches and numbers; and it became necessary to enlarge its extent by additional edifices, the foundations of which, on either side, were advanced into the sea, and which, of themselves, might have composed a very considerable city. The emperor also conferred, by way of additional allurements or encouragement to his plan of population, several privileges on the settlers at Constantinople. He divided the city into fourteen regions or quarters, dignified the public council with the appellation of senate, communicated to the citizens the privileges of Italy, and bestowed on the rising city the title of colony, the first and most favoured daughter of ancient Rome. The walls, porticoes, and principal edifices of this city, were completed, as some say, in a few years, or, according to others, in a few months; and the founder soon prepared to celebrate the dedication of his city, a ceremony which was attended with pompous games, and munificent largesses. As often as the birth day of the city returned, the statue of Constantine, framed by his order, of gilt wood, and bearing in its right hand a small image of the genius of the place, was enriched on a triumphal car. The guards, carrying white tapers, and clothed in their richest apparel, accompanied the solemn procession as it moved through the Hippodrome. When it was opposite to the throne of the reigning emperor, he rose from his seat, and with grateful reverence adored the memory of his predecessor. At the festival of dedication, an edict, engraved on a column of marble, bestowed the title of *SECOND*, or *NEW ROMAN*, on the city of Constantine. But the name of Constantinople has prevailed over that honourable epithet, and, after the revolution of fourteen centuries, still perpetuates the fame of its author.

It has been conjectured, that the removal of the imperial residence from Rome, contributed to hasten the downfall of the empire: but it is certain, that the fixing of it at Constan-

tinople, put a final period to the passage of the Barbarians, through the Bosphorus. They could never after force that insurmountable barrier, and Greece, as well as Asia Minor, felt secure from their ravages, until Valens unadvisedly suffered the Goths to pass the Danube, and received their armed bands into the heart of the empire.

Constantine the Great did not long enjoy his new residence. He died the 22d May, 337, and by his will divided his vast empire among his three sons, Constantius, Constant, and Constantine. Within three years after their father's death, Constant invaded the dominions of his brother Constantine, who, being drawn into an ambush and slain, left Constant in possession of two-thirds of the Roman empire. But Magnentius revolting soon after against Constant, surprised him hunting, and pursuing him in his flight, put him to death. Magnentius being in the next place defeated by Constantius, terminated his life by suicide; and thus, by the disastrous fate of his brothers, Constantius became sole emperor in 353; three and twenty years after the seat of the empire had been removed to Constantinople.

At the death of Constantius, which happened in the year 361, Julian, commonly called the Apostate, son of Julius Constantius, and nephew to Constantine the Great, assumed the imperial purple. He marched soon after against the Persians, and was so infatuated by his expectations of conquest, as to destroy the fleet of boats which he had upon the Tigris. Allured by spies who pretended to be deserters, he advanced far into an unknown country. His army found itself at last in the midst of sandy deserts, and felt the dreadful effects of famine. The guides suddenly disappeared, and the Persian monarch approaching, with the whole military force of his kingdom, want of provisions rendered a retreat necessary, in which the troops were continually harassed by the Persians, who carefully avoided any close engagement. In spite of the incessant attacks of the Persian cavalry, the Romans succeeded in gaining the banks of the Tigris, but for want of their boats they could not pass the river. Exhausted with fatigue, and perishing with hunger, they still repulsed the attack which the Persian king made on their camp. In the confusion of the battle, Julian received a mortal wound, of which he died in a few hours, on the 26th of June, 363.

This emperor had conceived the project of extirpating the Christian religion; and if he had appointed, or if the army had elected an emperor equally averse to Christianity, his death would not have dispelled the storm that was gathering over Christendom. Fortunately, Jovian, a Christian officer, was chosen emperor. Forced to conclude a disadvantageous peace with Persia, he purchased a safe retreat by the cession of Mesopotamia, and the strong cities of Nisibis and Singara.

Jovian dying in 364, soon after the conclusion of the peace with Persia, Valentinian, another Christian commander, was decorated with the imperial purple. He named his brother Valens his colleague in the empire, assigning him the eastern part, whilst he himself ruled the west. It was in this reign that the first step towards the subversion of the western empire took place. The Huns, a Tartar nation, being driven out of their own country, rushed like a torrent upon the Goths, on the north side of the Danube, who, seeing their possessions invaded, presented themselves in immense crowds on the banks of the river, and requested an asylum in the Roman dominions. They delivered up their children, at least those of rank, as hostages; but were unfortunately suffered to retain their arms. The number of Goths who passed the Danube on the occasion, was computed at about 200,000 armed men, with their wives and children

CONSTANTINOPLE.

children along with them. A second army of Goths, coming to the banks of the Danube with the same request, was refused: but they passed without leave, and being ill supplied with provisions, they joined their countrymen, and commenced a war against the empire. After various skirmishes, Valens, without writing for his nephew Gratian, who was on his march to join him, gave battle to the Goths, in the plains of Adrianople, A. D. 378, and was totally defeated. The loss on the side of the Romans was so great, that this defeat was considered as the most severe since the battle of Cannæ. Valens was never more seen. It is supposed that he was consumed in the flames of a cottage where he had taken refuge.

By the death of Valens, the empire fell into the hands of his nephew Gratian, who had some time before succeeded to Valentinian in the west. But at the end of the year 378, he declared Theodosius his partner in the empire, and committed the East to his care.

Theodosius was a native of Spain. In four years and a half he terminated the Gothic war. The Goths had lands assigned to them in the Roman provinces, and submitted to the Roman sceptre on condition of being governed by their own laws.

Theodosius was in every respect a second Constantine the Great. Like him he rendered the empire triumphant over all its enemies, extinguished intestine commotions, established Christianity upon a solid basis, and divided the empire between his two sons Arcadius and Honorius, assigning to the former the eastern, and to the latter the western part. From that period, the two monarchies, forming two separate and independent states, gradually became strangers to each other, and even regarded each other's prosperity with a jealous eye. Rome fell a prey to the Goths, whilst Constantinople appeared totally unconcerned at the event. Theodosius died at Milan, the 17th of January 395, in the sixteenth year of his reign, and the sixtieth of his age.

After the death of Theodosius, the history of Constantinople affords nothing remarkable, until the total destruction of the Roman empire in the west by the Goths. Towards that time Basiliscus usurped the Eastern empire. Assisted in his conspiracy by the empress Verina, his sister, he drove out Zeno, the lawful emperor, who fled into Isauria, whither he was pursued by Ius and Trecondes, two of the usurper's generals, and forced to shut himself up in a castle. But Basiliscus having lost his popularity by his cruelty, his generals joined Zeno and restored him to the throne. Basiliscus perished in a dungeon in the year 467. He had reigned about twenty months. During his usurpation, a dreadful fire happened at Constantinople; together with a considerable part of the city, it consumed the imperial library which is supposed to have contained 120,000 volumes.

Zeno had the good fortune to escape other conspiracies that were formed against him: but he was unsuccessful in the wars which he waged against the Ostrogoths, and purchased a short peace at the expence of the provinces of Lower Dacia and Mæsia. Theodoric, king of the Ostrogoths, soon renewed his irruptions into Thrace, and advanced within fifteen miles of Constantinople, which he was expected to besiege, when he suddenly turned his arms against Odoacer, king of Italy, whom he subdued. Theodoric himself was proclaimed king of Italy in his room, two years after the death of Zeno, which happened in 491.

The administration of Athanasius, Zeno's successor, was equally weak. Theodoric, however, reigned in Italy under the sanction of the imperial court of Constantinople, and still acknowledged himself a vassal of the eastern emperor.

But on his death the kingdom of Italy devolved upon his beautiful and accomplished daughter, Amalontha; and at her demise, which happened in the year 535, the Goths of Italy refused to acknowledge the paramount authority of the imperial court, and renounced all dependence on the empire. Justinian was then reigning at Constantinople. His uncle Justin, who ascended the throne in 518, after Athanasius, had named him his colleague in the year 527, and dying soon after, had left him sole master of the empire. He first turned his whole force against Chosroes, king of Persia, dispatched his general Belisarius against him, and after a severe defeat, forced him to sue for peace.

About this time, a great tumult happened at Constantinople. It began among the different factions in the circus. Hypatius, nephew to Athanasius, was proclaimed emperor. To crush this sedition, Justinian sacrificed two of his ministers who were most obnoxious to the people; but the multitude grew the more outrageous, and several senators having joined the rebels, the emperor felt so much alarmed that he thought of abandoning the city, and making his escape by sea. Encouraged, however, by his empress Theodora, he resolved to defend himself to the last with the few senators who had not yet abandoned him. In the mean time, Hypatius was carried in triumph to the circus, where he was beholding the sports from the imperial throne, among the acclamations of the populace, when Belisarius on his return from Persia entered the city with a considerable body of troops. He immediately marched to the circus, fell sword in hand upon the disarmed multitude, and took Hypatius the usurper, and Pompey, another of the nephews of Athanasius, prisoners. They were both beheaded, and their estates, as well as those of the senators who had joined them, confiscated.

Justinian now turned his arms against the Vandals in Africa, and the Goths in Italy. Belisarius entered Rome A. D. 536, where he was besieged by the Goths. His gallant defence, with only five thousand veterans, against a numerous army of Goths, commanded by Vitiges their king, during the space of a whole year, is deemed one of the most signal military exploits recorded in history. He made many successful sallies. In one single assault the Goths are reported to have lost 30,000 men. They were obliged to raise the siege on the arrival of fresh troops from Constantinople. At length the Gothic kingdom of Italy was completely subdued. Vitiges the king was sent to Constantinople. Justinian assigned him for maintenance a rich estate in Asia Minor, and on his conforming to the Athanasian creed, conferred upon him the rank of Patrician and Senator, which still continued as an honorary title in the empire. Gelimer, king of the Vandals, over whom Justinian also triumphed, had likewise an ample estate assigned to him, but could not enjoy any honorary title on account of his professing Arianism.

In the year 546, the Goths again revolted under the command of Totila, whom they had elected king. Belisarius a second time entered Italy, and retook Rome in 547, but at his recall it was again captured by the Goths. The command of the army of Italy was then conferred on Narses, an eunuch of great military skill and the most daring courage. This general defeated and slew Totila the Gothic king, and made himself master of Rome in 552. He likewise defeated and slew Teias, who had succeeded Totila as king of the Goths, and made a prodigious slaughter of the Franks and Allemanni, who invaded Italy soon after. Italy was then made a province of the eastern or Byzantine empire, and a government established under the denomination of the Exarchate, of which Narses was the first exarch.

By the conquest of Italy and Africa, Justinian gave to the eastern empire an aggrandizement which it had never before possessed. He displayed consummate political abilities, during a reign of thirty-eight years, and exhibited, during a life of eighty-three, a singular instance of long continued personal prosperity. He has left a noble monument of his legislative talents in his code of laws, and a no less noble one of his skill in architecture, in the magnificent cathedral of St. Sophia at Constantinople, now a Mahometan mosque. His reign is also the important era of the transplantation of the silk-worm from China to Constantinople. The brilliancy of Justinian's reign was however in some degree clouded by great calamities of a physical nature. Tremendous earthquakes happened almost every year throughout the whole extent of the empire. A dreadful pestilence spread from Pelusium in Egypt, over the greatest part of Asia, Africa, and Europe. During the space of three months, from five to ten thousand individuals died daily in Constantinople. Many cities in the East were almost depopulated, and in some parts of Italy, the harvest rotted on the ground. This contagion, which began in the fifteenth year of Justinian's reign, was not extinguished in less than fifty-two years.

Justinian died in the year 527. Soon after his death the Eastern empire began to decline. After the successive reigns of Justin II. and of Tiberius, which filled up the interval, from the death of Justinian to the accession of Maurice in 582, a spirit of revolt manifested itself in Constantinople, and terminated in the assassination of Maurice, and election of Phocas the centurion in 602. Phocas was in his turn deposed and put to death by Heraclius, A. D. 610, whose reign is remarkable for a most obstinate contest with Persia, to which country it proved finally fatal.

During a period of twelve years, from 610 to 622, the Eastern empire exhibited a scene of almost unexampled distress. From the Adriatic to the suburbs of Constantinople, the provinces were ravaged by the Chan of the Avars, who had subdued the Huns and resided in the royal village of Attila, in the great plain of Hungary; and a Persian army was encamped at Chalcodon, now Scutari, on the brink of the Bosphorus, directly opposite to Constantinople. The general consternation was so great that the emperor was about to leave the city, and transport himself with the treasures of the imperial palace to Carthage, when the patriarch of Constantinople led him to the altar of the church of St. Sophia, and made him take a solemn oath that he would live and die with his people. Heraclius having thus solemnly bound himself to the defence of his country, carried devastation to the very centre of the Persian dominions. He every where defeated the numerous forces of Chofroes, whose continual disasters excited a general revolt of the Persians. Chofroes was deposed A. D. 628, and Siroes his son proclaimed king. The latter put to death his father and eighteen brothers, and then concluded with Heraclius a treaty of peace, in consequence of which, the former boundaries of the Byzantine and Persian empires were restored.

The northern nations, which had overthrown the Roman empire in the West, were yet in an unsettled state, and Europe exhibited the most disgusting scene of barbarism and anarchy, whilst Constantinople was triumphing in the successful termination of a war, which had threatened the extinction of its empire. It was, however, soon to witness horrors similar to those with which the West had been familiarized for the space of two centuries.

About the year 609, Mahomet, an Arabian, assumed the character of a prophet, and assembling together a determined and daring band, in whom he excited military enthusiasm by means of religious tenets, calculated to flatter their passions,

he subdued one after another, all the Arabian tribes, and attacked the Eastern empire three years before his death. His successor, Abubeker, preferred, however, turning his arms towards Persia, which had not yet recovered from the confusion into which it had been thrown, by the dreadful contest between Heraclius and Chofroes. But after the death of Abubeker, which happened in 634, Omar, who succeeded him, assailed the Byzantine empire, with renovated ardour. In the course of a very few years, both Syria and Egypt acknowledged the sway of the conqueror. The loss of Egypt was severely felt by the people of Constantinople; that country having always been esteemed the granary of the city, and Syria, being in possession of an enemy, laid all the Asiatic provinces open to invasion.

In the year 644, this new Saracen empire devolved to the Caliph Othman, who completed the conquest of Persia, and subdued all that part of Africa, which had successively been under the dominion of the western and eastern empire, and which extended from Egypt to the Atlantic, and from the Mediterranean to the Great Desert.

But during the whole period of the existence of the Saracen empire, Constantinople still resisted all the attacks of these Arabian conquerors. They twice laid siege to the city. In their first attempt their fleet blockaded Constantinople, on the side of the Propontis, from 668 to 675. Their second siege in 716, was rendered memorable by the invention of the Greek fire, which totally destroyed the Saracen fleet, whilst the army which attacked the city on the land side, was compelled to raise the siege with prodigious loss.

If the progress of Mahometanism was hurtful to the interests of Christianity, and to the splendour of the Byzantine empire, the contest between the advocates of the use of images in Christian temples and their opponents, which violently agitated the church, proved equally fatal in its consequences. It occasioned the first schism between the Greek and Latin churches, and was the origin of those differences which in the end produced their total separation, and hastened the fall of Constantinople.

This dispute broke out about the year 720, in the reign of Leo, the Maurian, who is distinguished in history as the first of the Iconoclast emperors. A council was held at Constantinople in 754, by 333 prelates of the eastern empire, who condemned all visible representations of Christ and his apostles, as heretical. This decision immediately caused the secession of Italy. A new Roman republic was established; but not being able to maintain its independence against the Lombards, it was delivered from their oppression by Pepin, king of France, whose son and successor Charlemagne received from the pope Adrian IV. the title of emperor of the Romans, and founded the Holy Roman or German empire.

The decree of the council of Constantinople did not, however, maintain its authority for more than thirty years. Irene, an Athenian female, who for her beauty had been advanced to the imperial bed and throne, began to reign in conjunction with her son Constantine VI. in the year 780. Her ambition incited her to cause the eyes of her son to be put out that she might reign sole empress of the East. She strongly exerted herself in favour of the restoration of images, which the second council of Nice, condemning that of Constantinople, effected in 787. Still the two churches of the East and West, were never more cordially united.

During the four centuries which elapsed between the death of Theodosius the Great and the reign of Charlemagne, Europe was in a state of anarchy and barbarism: the eastern empire alone exhibited marks of civilized society, and for a while flourished in power, till it was curtailed of

CONSTANTINOPLE.

half of its possessions by the conquests of the Mahometan caliphs. Under Charlemagne the whole world was divided into the Eastern, Saracen, and new Western empire. Of these the Saracen empire, under the caliphs, stood the highest in literary attainments; Constantinople, though much declined, still held the second rank; and the rest of Europe was making some advances towards the restoration of learning, when Charlemagne, by dividing his new empire among his sons, repunged it into barbarism.

In the ninth century, the Bulgarians, who had commenced their attacks towards the latter end of the seventh, and renewed their inroads at different periods, continued to be formidable enemies. They were completely subdued by Basilus II. towards the end of the tenth century. It was about the same time that the empire of the Saracens, being, like that of Charlemagne, split into a number of independent states, by the revolt of factious and ambitious chiefs, fell a prey to the Seljukian Turks and other barbarous nations of Asia. This subversion of the caliphate was attended with the complete wreck of Arabian learning; and the Byzantine empire remained the sole depository of all that was worthy of notice in literature, commerce, and the arts and embellishments of civilized society. Thus the tenth century, which, in the western countries, was one of the darkest periods of Gothic ignorance, constituted the most flourishing era of the Byzantine learning, under the reigns of Leo the philosopher and his son Constantine Porphyrogenitus.

About the year 1063 the emperor Constantine XI. Ducas left, at his death, the empire to his three sons, Michael, Andronicus, and Constantine XII., and appointed the empress Eudocia regent during their minority, on condition that she should not marry again. But having been released from her engagement, through a stratagem practised upon the patriarch, who absolved her of the oath she had taken, Eudocia married an officer of great military merit, named Romanus Diogenes, who was proclaimed emperor. After various successes against the Turks, who were continually encroaching upon all sides of the empire, Romanus was wounded in a desperate engagement, and taken a prisoner. Before his return to Constantinople, Eudocia was driven from the throne by John, the brother of Constantine Ducas, and her eldest son, Michael Ducas, proclaimed emperor. Romanus was besieged in a strong castle, whither he had retired, and killed in the year 1067, after a reign of three years and eight months.

Immediately after the death of Romanus, the empire was again invaded by the Turks. In less than ten years they made themselves masters of all Media, Lycaonia, Cappadocia, and Bithynia. At last Alexius Comnenus, having wrested the empire from Nicephorus Botaniates, who had deposed Michael Ducas, prepared for war with so much vigour, that Solyman the Turkish sultan made proposals of peace, to which Alexius acceded, in order to defend himself in the west against the Italians, under Robert Guiscard, duke of Puglia and Calabria, whom he defeated, with the assistance of the Venetian fleet. He also forced the Scythians, who had laid waste great part of Thrace, to submit on his own terms.

The war with the Turks was renewed in 1083, and carried on with various success. But about the year 1095, a romantic scene of religious enthusiasm and military enterprise began to display itself; and though it threatened the utter ruin of the Turkish nation, proved finally fatal to Constantinople.

Under the polished empire of the caliphs, the frequent pilgrimages of Christians to the holy sepulchre at Jerusalem had been encouraged; but the barbarians who had overturned the caliphate oppressed the pilgrims with unreason-

able impositions, and often added insult to injustice. Inspired at these outrages, Peter, a hermit, who had visited the holy sepulchre, preached a crusade for the recovery of the holy land from the infidels. The pope approved the project, and the princes and nobles of Europe readily entered into the measure.

This religious war was carried on, with some intervals, during the space of almost two hundred years, from the setting out of the first crusade in 1095, to the loss of Acre and all Palestine in 1291. Innumerable armed hordes were collected out of England, France, Germany, the Netherlands, and Italy. Yet these tremendous efforts were not attended with effects of such permanency as might have been expected. But one of the most remarkable events which occurred in the course of the crusades, was the capture of the city of Constantinople by the Latins.

The emperor, Isaac Angelus, having been deposed and deprived of sight by his inhuman brother, his son, Alexius, who was only a youth, made his escape into Italy, and met with a number of the barons of France and Flanders, who were come to Venice to contract with the republic for the ships necessary to facilitate one of those crusading enterprises. He concluded with them a treaty, whereby they engaged to restore his father to the imperial throne of the East, and he promised to unite the Greek to the Latin church. The French and Venetians, changing the destination of their armament, sailed up the Hellespont to Constantinople, broke the chain of the harbour, and assaulted the city. When they were almost ready to enter the town, the usurper made his escape. Isaac Angelus and his son, the young Alexius, were proclaimed joint emperors. A cessation of arms took place; but as soon as the clergy understood the terms of the treaty concluded by young Alexius, they reprobated the idea of an union with the see of Rome, and excited the people to fly to arms. The insurrection was also fomented by Alexus Mourzoufle, of the family of Ducas, who assumed the purple, imprisoned the blind emperor Isaac, and put young Alexius to death. The legal succession of the Greek empire being thus overturned, the French and Venetians recommenced the war. After a siege of more than three months, they assaulted the city from the harbour, and carried it by storm, eight hundred and eighty years after its foundation by Constantine. The city being given up to pillage, the plunder was valued at 400,000 marks, nearly equivalent to 800,000 sterling, the greatest sum ever found in any captured city previous to that period; and notwithstanding the penalties of excommunication, and even of death, denounced against any one who should secrete any part of the spoil, the secret plunder is supposed to have exceeded what was produced in public. Baldwin, earl of Flanders, was elected emperor, with one-fourth part of the empire for his share: the rest was divided among the barons and knights, into fiefs, held under the emperor.

The Greeks, after this disaster, established independent states at Nice, Trebisonde, and Epirus. The Latins were not prosperous in their newly-acquired empire. The dissensions which prevailed among the barons, laid their dominions open to the attacks of the Greeks. They continually gained ground. The Bulgarians also revolted, and the emperor, Baldwin of Flanders, being defeated and taken prisoner by them, died in captivity. He was succeeded by his brother Henry, who shewed himself of equal capacity for peace and war.

Henry checked the proceedings of the popish legate, in the persecution of the Greek schismatics. But after his death, which happened in 1216, the Latin empire of Constantinople rapidly declined: and so pressing were the exigencies of the state, that Baldwin II., the last emperor of the

CONSTANTINOPLE.

the Latin dynasty, pledged to the Venetians the crown of thorns pretended to have been worn by Christ.

At last Michael Paleologus, having usurped the Greek empire of Nice, his general, Alexius Strategopulus, with an inconsiderable force, surpris'd and recovered Constantinople in 1261: and thus, after a period of 57 years, that metropolis returned under the dominion of the Greeks. But a considerable part of the city had been destroyed in the three dreadful conflagrations which happened at the time of the siege and capture by the Latins: Constantinople never more regained that splendour which it had all along maintained. The imperial palace, which, during eleven centuries, had been the admiration of all who visited the East, was in ruins. It stood between the Hippodrome and the magnificent church of St. Sophia. Its superb gardens descended, by several rows of terraces, to the shore of the Propontis. The primitive edifice, erected by Constantine, rivalled the palace of the Cæsars on the Palatine Mount. The improvements made by his successors still added to its magnificence; and the emperors of the Comnenian dynasty had taken particular delight in embellishing this imperial residence.

The inveterate enmity of the clergy and people of Constantinople against the Latin church still subsisted. To avert a crusade, which the Latins were meditating against Constantinople, Michael Paleologus negotiated with the pope, and concluded a concordat between the Greek and Latin churches; but at his death, in the year 1282, the union was dissolved. His son Andronicus, who succeeded him, restored the ancient Greek ceremonies, and by this imprudent step threw the empire into a new ferment.

In the mean time Constantine his brother successfully opposed the Turks, who continued their encroachments: but his valour rendered him suspected by the emperor. Constantine was thrown into prison. On his removal from the army, the Turks under the famous Othoman made themselves masters of several places. Philantropenus and Libadarius, two officers of great merit, were sent to oppose them. The former gained some advantages over the enemy: but elated with his success he caused himself to be proclaimed emperor. This rebellion however was soon suppressed. Philantropenus was betrayed by his own men: but the Turks taking advantage of these intestine commotions extended their dominions in Asia, conquered most of the islands in the Mediterranean, and infested the coasts of the empire. Andronicus, not trusting his subjects, hired the Massagetes to assist him: but they being defeated, turned their arms against him. He next applied to the Catalans who behaved in the same manner, and, in 1292, assailed the empire in conjunction with the Turks. This was their first appearance in Europe. Their enterprize this time proved unsuccessful.

New commotions having taken place in the empire, the Turks returned to the charge in 1327. The next year, however, Othoman, who may be styled the founder of the Turkish monarchy, being dead, the emperor recovered Nice and some other places, which were again lost the year following; and, in 1330, a peace was concluded, which left the Turks in possession of their conquests.

This peace the Turks broke in 1357. Having reduced all Asia, they passed the Hellespont, and took a strong castle on the European side. Soon after sultan Amurath, advancing still farther, made Adrianople the seat of his empire. He was slain by treachery, and succeeded by his son Bajazet, who levied a yearly tribute on the emperor of Constantinople, and commanded him to send him his son Manuel to attend him in his military expeditions. This

demand was complied with. But the emperor dying in 1392, Manuel hastened to Constantinople without taking leave of the sultan. This incensed Bajazet so highly, that he passed with great expedition into Thrace, ravaged the country adjoining Constantinople, and at last invested the city both by sea and land. In this extremity, Manuel had recourse to the western princes, who sent him an army of 130,000 men, under the command of Sigismund, king of Hungary, and John count of Nevers. After a few successes they were defeated with great slaughter by Bajazet, who resumed the siege of the city, and would infallibly have accomplished the conquest of Constantinople had he not been obliged to turn his forces against Tamerlan the victorious Tartar, by whom he was overcome in battle, and confined in an iron cage against the bars of which he beat out his brains in the year 1399.

But as this relief could not be expected to be of long duration, Manuel Paleologus set sail for Venice, and from thence visited London and Paris in the year 1400. in the reign of Henry IV. of England and Charles VI. of France, with the view of procuring some assistance, which the circumstances of those countries did not permit them to grant. He also endeavoured to negotiate an union with the Latin church; but the negotiation broke off. His son John Paleologus, who succeeded him, was more fortunate. He concluded a treaty at Florence with pope Eugenius IV.; but it was universally reprobated by the whole body of the clergy of Constantinople, and the emperor was obliged to renounce it. He did not long survive these unhappy disturbances, and, in 1448, left the empire now confined almost within the walls of Constantinople to the last Constantine.

Upon the near prospect of being besieged in his capital by the Tatar Turks, Constantine Paleologus renewed the concordat with the Latin church. A cardinal legate from Rome was admitted at Constantinople; but after he had officiated in the cathedral of St. Sophia, the Greek clergy abandoned it as a polluted temple, and the whole city of Constantinople displayed every extreme of fanaticism and aversion against the Latin church. Though reduced to a narrow corner between the Propontis and the Euxine, the Byzantine empire continued the theatre of crimes and political as well as fanatical factions, until the 29th of May, 1453, when, after a siege of 53 days, Constantinople was taken by the Turks under Mahomet II. Whatever may have been the strength of the army which the Turks brought against that celebrated metropolis, the force, which the minister was able to enrol by the emperor's command for its defence, was inconsiderable. There were only 4970 volunteers, and including the Italian auxiliaries, the emperor's troops did not exceed 8000 men.

Constantine Paleologus made a vigorous defence, and rashly refused advantageous terms of capitulation. When the city was at last carried by assault, he nobly fell in the breach by which the enemy entered Constantinople. A shocking scene now followed. The persons and property of the citizens were given up to the disposal of the conquering army. The terrified people fled to the cathedral of St. Sophia and other asylums, from whence they were dragged forth, and without any distinction of sex or rank, chained together, driven through the streets like beasts, and more than sixty thousand of them sold into slavery. Mahomet, at the expiration of the three days allotted for pillage, made his triumphal entry into Constantinople, which has ever since the capital of the Ottoman empire, and which has never since held that station. See *Turks*.

Such was the dreadful catastrophe of Constantinople, once the metropolis and long the sole existing remnant of the

the

the Roman empire. It fell a prey to the Turks 1043 years after Rome was taken by Alaric, and 977 years after the entire subversion of the western empire. Gibbon's Hist. of the Decline and Fall of the Roman Empire, *passim*. Le Beau, Histoire du Bas Empire. Bigland's Letters on Ancient and Modern History.

Constantinople is called by the Turks *Stampol*, *Istampol*, or (according to Thornton's present State of Turkey, p. 79.) *Istambol*, *abounding in faith*. It is situated at the eastern extremity of the province named Romania, or Romelia, on the European side of the Bosphorus, or straits of Constantinople, which separates Europe from Asia; in N. lat. 41° 10'. 830 miles S. E. of Vienna and 500 E. of Rome. It rises gradually from the shore in the form of an amphitheatre; but the streets are narrow, and the houses, in general, mean; the most spacious not exceeding two stories in height. The street called Adrianople is the longest and broadest in the city. The public buildings, such as the palaces, the mosques, bagnios, bazars, and caravanerais or khans, for the entertainment of strangers, are many of them very magnificent. On one point of the triangle, on which the city is built, is the seraglio from whence there is a charming prospect of the delightful coast of Asia Minor. This inclosure of the Ottoman palace is separated from Constantinople by a wall thirty feet high with battlements, embrasures, and towers, in the style of ancient fortifications. Its circumference is above six miles. There are in it nine gates, but only two of them remarkable for their size and beauty. It is from one of these the *Baba Hoama-jun*, or *Sublime Porte*, that the Ottoman court is supposed to have taken the name of the *Porte*, or *Sublime Porte*, in all public transactions and records. But Mr. Thornton, in his present State of Turkey, page 117, contends that the palace of the grand vizir, by a metaphor familiar to most of the Eastern languages, is called the *Porte* or King's gate, in Persian *Der*, being, as it were, the door of communication between the sultan and his subjects, and corresponding with the European appellation of a court which follows the person of the sovereign.

The seraglio is so extensive, that it is supposed to occupy the whole of the ground on which the ancient city of Byzantium stood, and to contain 10,000 inhabitants. That wing of the seraglio which is exclusively appropriated to the ladies of the Grand Signor, is called the *Harem*. Among the ancient monuments preserved in the seraglio, is the tomb of Constantine the Great. Of the mosques, or Turkish churches, the most celebrated is that of St. Sophia, which fronts the great gate of the seraglio, and is thought, in some respects, to exceed in grandeur and architecture St. Peter's at Rome. Round it are several chapels, which serve as burial-places for the imperial family. The other mosques of sultan Achmet, sultan Mahomet, sultan Selim, sultan Solyman, and sultan Bajazet, are also very fine. These imperial mosques are founded chiefly by sultans, who have obtained victories, and devote the spoils of war, gained from the enemies of their religion, to the service of public worship, the instruction of youth, and the relief of the poor. Foundations of this kind are annexed to every mosque. There are in Constantinople 518 seminaries of learning, and 1250 primary schools. The Greeks, besides their patriarchal church, dedicated to St. George, have 22 others. The palace of their patriarch is on a hill, about two hundred paces from the harbour. The Armenians have an archbishop and three churches; the Roman Catholics have six convents, and the Jews several synagogues. There is also a Swedish Lutheran church.

The bazars, or beshikins, answer to our markets. They are squares enclosed within gates, where merchants meet for

traffic, having generally two rows of shops built under piazzas. The market of female slaves, *Avrat Bazar*, is a quadrangle, surrounded by a covered gallery, and ranges of small and separate apartments; but Malometans only are admitted.

The bagnios, or public baths, are elegant and noble structures, built with hewn stones; the inner chambers are capacious, and paved with slabs of the rarest and most beautiful marble.

At the fourth end of the city, is the formidable flate prison of the seven towers, built of fine free-stone, and surrounded by a wall, with several smaller towers.

There are no theatres at Constantinople; the *Ombres Chinoises*, which are sometimes exhibited in the streets, supply the want of dramatic exhibitions. Of other public amusements, the principal are wrestling, and throwing the javelin, on horseback, in the ancient Hippodrome, an oblong square, called by the Turks *Alweidan*.

Constantinople counts 35 public libraries, some of which contain 15,000 volumes. That which was founded under Mustafa III. by the vizir Racub Pacha, is the most modern. A renegade, of the name of Ibrahim, encouraged by the grand vizir, Ibrahim Pasha, and the Mufti Abd'ullah Effendi, introduced the first printing-press at Constantinople, in the year 1727. It was afterwards destroyed by some fanatics, but Abdul Hamid restored it. Only the Koran, and books treating of the law and the doctrines of the prophet, are forbidden to be printed. These circulate in manuscripts, and afford a comfortable subsistence to 20,000 individuals who live by copying them.

The trade of Constantinople is chiefly in the hands of the Jews, Armenians, and Greeks; and its commerce is carried on by foreigners of all nations, who are confounded under the general name of Franks. No restrictions are laid on commerce, except in the articles necessary for the support of human life; the exportation of which is sometimes prohibited, especially from Constantinople, where alone the prohibition is rigorously enforced. Besides silk, cotton, wool, flax, drugs, coffee, sugar, wax, honey, fruits, hides, and tobacco, Constantinople exports its own printed muslins, the fatins, silk stuffs, and velvets, of Brusa and Aleppo, the ferges and camelots of Angora, the crapes and gauzes of Salonica, the sword-blades of Damascus, and the carpets of Smyrna. The harbour is spacious, and supposed capable of holding 1200 ships. Near it is *Galata*, a suburb chiefly inhabited by Greeks, Armenians, Jews, and Franks, who have their warehouses here. Beyond this is *Pera*, which may be considered as the suburb of Galata, where the foreign ambassadors reside. The air is uncommonly healthy, and the prospect delightful. Near Pera is the quarter called *Tophana*, from its canon foundery.

According to Mr. Dallaway, the population of Constantinople, including its suburbs, does not exceed 400,000 souls, of whom 200,000 are Turks, 100,000 Greeks, and the remainder Jews, Armenians, and Franks, or strangers from all the European nations. Mr. W. Eton (in his Survey of the Turkish Empire, second edition, page 287.) brings it down to less than 300,000. But this computation is evidently too low. At the time of its capture by the Latins, Constantinople is supposed by Villehardouin to have contained 400,000 effective men; this, however, must be regarded as an exaggeration. Mr. Le Beau, in his Histoire du Bas Empire, supposes that it contained then about one million of inhabitants, and that its present population amounts to 400,000, which, by all accounts, is the most probable computation.

Constantinople is frequently visited by the plague, which, however, excites but little alarm, and Turkish indifference

counteracts all efforts to subdue this dreadful epidemical disorder. From the year 1783 to 1785, it swept away 100,000 children and young people. The city has also often been exposed to great conflagrations. In 1782 a fire consumed from 7 to 8000 houses, among which were some belonging to the first officers of the state. On the 5th of August, 1784, more than 10,000 buildings were laid in ashes, and towards the end of the same year, 1600 houses and mosques were burnt down. In 1788 there was to be extensive a conflagration as to threaten the entire destruction of the city. They generally originate in the discontents of the Janizaries, or other military bodies. In the last revolution, which they effected on the 28th of May, 1807, when they forced Selim III. to abdicate the throne, and proclaimed Moutapha IV. emperor; they contented themselves with cutting off the heads of a few ministers and military chiefs. But between the fifth and sixth day of August following, three great fires reduced several hundred houses to ashes, and are supposed to have proceeded from the strong dissatisfaction that prevailed in the mutinous army against the new grand signor, for having issued an order to pay the troops only in the camp. In time of peace the Janizaries watch over and secure the public tranquillity, and exercise all the functions of police officers. A foreigner, who would be insulted if seen alone in the streets of Constantinople, may walk any where without the least molestation if accompanied by a Janizary. See JANIZARIES. (D'Ossion Tableau General de l'Empire Ottoman. Eton's Survey of the Turkish Empire. Thornton's present State of Turkey.)

CONSTANTINOPLE, *Patriarch of*. See GREEK CHURCH. CONSTANTIUS, FLAVIUS VALERIUS, in *Biography*, surnamed *Chlorus* from the paleness of his complexion, was son of Eutropius, a Dardanian noble, but his education did not correspond with the style of his birth. Under the emperors Aurelian and Probus, he had learned the military art, and by the emperor Carus, he was appointed governor of Dalmatia in the year 282. Ten years afterwards, in conjunction with Galerius, he was made Cæsar, and associated with the emperors Diocletian and Maximian. To Constantius were assigned the provinces of Gaul, Britain, and Spain. At this time Carausius, an ambitious general, had excited a revolt in Britain, and carried matters so far as to assume the imperial authority; he was also in possession of the port and fleet of Boulogne. To oppose the usurper, Constantius first attacked Boulogne, which surrendered to his arms, together with a great part of the naval strength of the place. After this, Constantius employed three years in preparing a fleet for the conquest of Britain; he scoured the coast of Gaul, invaded the country of the Franks, and deprived the usurper of the assistance of those allies. Before the preparations were finished, Carausius was deposed and murdered by his own servants. Allectus, his prime minister, succeeded to his power and to his danger. But he did not possess equal abilities, either to exercise the one or to repel the other. Constantius, under favour of a thick fog, escaped the British fleet, and landed in safety on the western coast, where an engagement took place, in which Allectus was slain; a single battle decided the fate of this great island, and when Constantius landed afterwards on the shores of Kent, he found them covered with obedient subjects. He now had occasion only to exert his talents in establishing a regular government; to which he appears to have been fully competent; he reigned with mildness, and was anxious not to oppress his subjects by heavy taxes; his court was distinguished by simplicity and great frugality, and he himself was a decided enemy to the persecutions which disgraced the reigns of Diocletian and Maximian; but in which, as their superior, he was obliged occasionally to join. When, how-

ever, he rose to the supreme power of Augustus, he banished persecution entirely from the provinces over which he governed. That event occurred in 305. Finding his health declining, he sent, as we have seen, (see CONSTANTINE the Great,) for his son Constantine to join him at Boulogne, thence they sailed to Britain, where the Picts had made an incursion into the northern part of the Roman province. This expedition, and an easy victory over the barbarians of Caledonia, were the last exploits of the reign of Constantius. He closed his days in the imperial palace of York, fifteen months after he had received the title of Augustus, and near fifteen years after he had been promoted to the rank of Cæsar. His death was immediately succeeded by the elevation of Constantine the Great; besides whom, he left three sons and as many daughters, by a second wife. Moreri. Gibbon.

CONSTANTIUS II, FLAVIUS JULIUS, was the second son of the great Constantine, by Fausta, and born in 317. At a very early period of his life he was declared Cæsar: when even a stripling, the care of the East was committed to him. On the death of his father, being then in his twentieth year, he repaired to Constantinople where he took a solemn oath that his kinsmen, who were already in discredit with the soldiery, should be permitted to remain in safety. He is however accused of an utter disregard to the sanction of the oath, and of having excited the massacre in which his two uncles, and seven of his cousins, were put to death. In a new division of the empire, in the year 338, Asia, Syria, Egypt, and Thrace were allotted to Constantius. From this period he was involved in wars with various nations; of which the most important was that with Magnentius, in Lower Pannonia. In the first campaign Constantius was so far unsuccessful, that he offered terms of accommodation, and a partition of his dominions, which his opponent haughtily refused, proposing as the only ground of solid peace the abdication of Constantius. A very bloody and decisive battle ended in a signal defeat of Magnentius, who with difficulty escaped to Italy. Constantius spent the winter in Sirium, the place of his birth, and in the spring of the following year 352, he passed the Alps, and proceeded to the conquest of Italy, a task of no great difficulty on account of the enmity which the cruelties of Magnentius had excited against him and his cause. He now attempted to treat, but his overtures were not listened to: from Italy he passed to Gaul, and made a stand at Lyons, Africa, Sicily, and Spain, declared for his rival. Another victory over Magnentius, rendered Constantius, in 353, the sole master of the Roman empire; but Magnentius, and his brother Decentius, chose death by their own hands, rather than run the chance of falling into those of their conquerors.

The conduct of Constantius upon this important change, has been variously represented; but there is no doubt that measures of the severest kind were carried on against those who had engaged against him, or had rendered themselves liable to suspicion. Notwithstanding his talents and success as a general, he was by no means equal to the duties attaching to the high office of emperor, and he dread too much a rival, to place the government under the auspices of a vigorous mind. His chief advisers were eunuchs, with whom his court was crowded, and to whom he committed the fortunes and lives of his numerous subjects. Constantius had already declared his nephew Gallus, Cæsar, and to him was given the care of the East, where he displayed the most atrocious acts of tyranny, and exhibited an intention of assuming an independent sovereignty. By the advice of Eusebius, the chamberlain of the eunuchs, Gallus was recalled, imprisoned, and executed. Those who write favourably of Constantius, assert, that he had no sooner signed

the warrant, than he relented, and endeavoured to recal the Bloody mandate; but that the second messenger entrusted with the reprieve, was detained by the eunuchs, who dreaded the unforgiving temper of Gallus, and were likewise desirous of reuniting to their empire the wealthy provinces of the East. Some time after this event, Sylvanus, a Frank, who had been in the confidence of the emperor, and who had been of the utmost importance to him in his contels with Magnentius, was, by false accusations, driven into rebellion. He assembled an army at Cologne, but was assassinated before it could be properly organized. The barbarian tribes of Germany, resolving to be revenged for his death, burst into the province, destroyed many cities, and among the rest Cologne itself, and reduced the empire to the most alarming danger. Julian, the remaining nephew of the emperor, was sent against them, and returned victorious. In 357, Constantius paid a visit to Rome, where he was received with the highest honours. He displayed his regard for the ancient capital, by adding to its ornaments an obelisk of granite in a single piece, brought from Egypt, and set up in the Circus Maximus. After this, he engaged in other wars, and was in general successful. His nephew Julian became now his rival; his high reputation in the army, induced the soldiers to proclaim him Augustus, but the emperor refused to acknowledge him as partner in the empire, and began to make preparations to assert his own rights over those of his aspiring relation. Julian had anticipated him, and had already seized upon Illyricum; in pursuit of him there, Constantius was seized with a fever, which at first threatened no serious consequences, but which terminated his life, and thus delivered the country from the horrors of a civil war. He died in November 361, having reigned twenty-four years. He obtained the character of a zealous Christian, and is applauded for having discouraged Pagan rites and ceremonies. He built many churches, and behaved with great respect towards the clergy; in matters of speculation and theological controversy, he considered himself an adept; was himself a favourer of the Arian party, and the persecutor of Athanasius, and of those who maintained his doctrines. It must be confessed that the genuine principles of Christianity were never understood by any of the Roman emperors; and their support of it, however laudable their motives might be, was highly injurious to its progress in the world. Gibbon. Univer. Hist.

CONSTAT, in *Law*, the name of a certificate, which the clerk of the pipe, and auditors of the exchequer, make at the request of any person, who intends to plead or move in that court for the discharge of any thing; and the effect of it is, the certifying what (appears) *constat* upon record, touching the matter in question. 3 & 4 Edw. VI. cap 4. and 13 Eliz. cap. 6.

A *constat* is held to be superior to an ordinary certificate; because this may err or fail in its contents, that cannot, as certifying nothing but what is evident upon record. Also the exemplification under the great seal of the enrolment of any letters patent, is called a *constat*. Coke on Littl. 225.

CONSTELLATION, in *Astronomy*, an assemblage or system of several stars, expressed and represented under the name and figure of some animal, or other thing: this assemblage is by some called also an *asterism*.

The ancients portioned out the firmament into several parts, or constellations; reducing a certain number of stars under the representation of certain images, in order to aid the imagination, and the memory, to conceive and retain their number, disposition, and even to distinguish the virtues, which astrologers attributed to them: in which sense a man is said to be born *under a happy constellation*, i. e. under a happy configuration of the heavenly bodies. The division

of the heavens into constellations is very ancient, and, probably, as old as astronomy itself; at least, it was known to the most ancient authors extant, whether sacred or profane. In the book of Job, mention is made of the names of some of them: as in chap. ix. 9. "Which maketh Arcturus, Orion, and Pleiades, and the chambers of the south." By the "chambers of the south," some have understood the constellations near the south pole, which are invisible to the inhabitants of the northern hemisphere. From the manner in which Job speaks of commerce, we may infer that he lived in a country frequented by merchants, who imported thither the rarities of the south. To this purpose Sir Isaac Newton suggests, (*Chronology*, p. 157.) that Job, who lived in Arabia Petraea, among the merchants, might have derived from them his knowledge of the constellations. And again, mention of them occurs in that sublime expostulation, chap. xxxviii. 31, 32. "Canst thou restrain the sweet influence of the Pleiades, or loosen the bands of Orion? Canst thou bring forth Mazzarath, (by which some understand the twelve signs, or zodiac,) or canst thou guide Arcturus with his sons?"

The first of the three constellations, mentioned by Job, is *אֵיֶשׁ* *aisch*, or *אֵיֶשׁ* *aisch*, by which some have thought that he meant the constellation, now called the "Great Bear." The root of *aisch* is *אֵשׁ* *ouch*, which, in Hebrew, signifies, "to gather together, or to assemble;" and in Arabic, "to make a circuit, or to describe a circle." These two significations may very well be applied to the Great Bear, which is a group of stars making a remarkable circuit round the pole. "Canst thou guide (or feed) *Aisch* with his sons?" (chap. xxxviii. v. 32.) is an expression which figuratively represents the stars that compose the Great Bear, collected together, like a flock which feeds in a meadow. In the same strain Virgil says, (*Bn* l. 1. v. 611.) "Polus dum sidera pacet." It has been further observed, that *Aisch* is the first star named in Job; and that *אֵשׁ*, or the Great Bear, is the first constellation mentioned by Homer, in his description of the shield of Achilles. The second constellation or group of stars mentioned by Job is *כִּמָּב* *kimab*. From the different passages in which this term occurs, we may reasonably conclude, that it must be understood of some constellation remarkable for its relation to an agreeable season. God says to Job, "Canst thou bind up the sweet influences of *Kimab*? i. e. Canst thou bind up or restrain the fertility of the earth, for producing fruits and flowers, when *Kimab* appears?" The different significations of this word, both in the Hebrew and Arabic, concur in pointing out the same sense of the term. *Kimab* may be derived from *כָּמַח* *kamah*, which, in Hebrew, signifies, "to desire, or to rejoice." Of all the seasons the spring is the most desirable, and the most productive of delight and joy. If we deduce the word *kimab* from the Arabic root *kevuam*, or *kam*, this characterizes the spring as distinctly as the former. *Kam*, in Arabic, signifies, "subigere mulierem," and "to become warm." Accordingly, the earth, at the approach of spring, begins to become warm, and to open its bosom: this is also the time when the females of most kinds of animals become pregnant. It remains only to know, what was the constellation which in the time of Job introduced the spring; and this, as we have sufficient reason for believing, was the Pleiades. *Kam* also signifies a "troop, number, or multitude;" and this etymology agrees perfectly well with the Pleiades, on account of the number of stars included in this collection, or in the constellation of the Bull.

The third constellation mentioned by Job is *כְּפִיל* *kefil*; the root of which word is *כָּפַל* *kafal*, which, in Hebrew, signifies, "to be inconstant or changeable;" and in Arabic,

“to be benumbed, to be idle, to be cold.” By *Kesfil*, therefore, it is supposed that Job means the Scorpion. God says to Job, “Canst thou loosen the bands of *Kesfil*?” i. e. “Canst thou loosen and open the earth, which is shut up and benumbed when *Kesfil* appears? Canst thou then make it produce flowers and fruits?” Adverting to the interpretation already given of *kimab*, we shall perceive, by the contrasted characters which distinguish them, that they are two constellations of the zodiac, pointing out two very opposite seasons. If by *kimab* Job designed the Pleiades, it is not improbable that by *kesfil* he meant the Scorpion, a constellation opposed to Pleiades by almost one-half of the circuit of the heavens, and which then announced the approach of winter. Accordingly, Aben-Ezra understood by *kesfil* that star of the first magnitude, known by the name of the Scorpion’s heart, or Antares. In his commentary on Job he thus explains himself: “*Kimab*,” says he, “is the northern star, and *Kesfil* is a southern star. *Kimab* produces fruits, which are the delight of man; and *Kesfil* does the contrary. *Kimab* is a great star, called the Bull’s eye, that is to say, Hyades; and *Kesfil* is a great star, called the Scorpion’s heart, that is to say, Antares.” Rabbi Levi Ben-Gerson says also, in his commentary on Job, that *Kesfil* is one of the southern constellations; and that when the sun enters into the sign where this star is found, the trees can no longer bring forth fruit, on account of the cold which this star brings with it. *Kesfil* has been supposed, by some learned commentators and critics, to denote the constellation Orion, which, at the time of its rise, portends clouds and tempests; and they derive it from *קסל* *kasal*, denoting inconstancy. See Schultens’s Commentary on Job, vol. i. p. 239, &c. vol. ii. p. 186. Goguet’s Origin of Laws, &c. vol. i. Dissert. 3.

In the prophecy of Amos, who is supposed to have lived 790 years B. C., we have the following animated exhortation (chap. v. 7, 8.): “Ye who turn judgment into wormwood, and leave off righteousness in the earth; seek him that maketh the seven stars and Orion, and turneth the shadow of death into the morning, and maketh the day dark with night; that calleth for the waters of the sea, and poureth them out upon the face of the earth: the Lord is his name.” In this passage, the seven stars and Orion are mentioned as being well known, both by Amos, who was a herdsman of Tekoa, and the common people, to whom this exhortation was addressed; and we may hence infer, that the constellations had been invented for some time before that period. Some of the constellations are also occasionally mentioned by Hesiod and Homer, who flourished above 900 years before Christ; and Aratus of Tarsus, the astronomical poet, who lived about 277 years B. C., in his “Phenomena,” professedly treats of them all, except some few which were invented after his time; shewing how each constellation is situated with regard to those that are near it, the sphere on it bears with respect to the principal circles of the world, and what other constellations rise or set with it. Hipparchus, the Bithynian, has shewn, that Aratus followed the descriptions of Eudoxus, who flourished about 366 years B. C.; and it is very probable that the Greek astronomer who succeeded him continued to use the same figures of the constellations till the time of Ptolemy, though not without some variations and additions. Ptolemy’s Almagest (see ALMAGEST) has been in such esteem among astronomers, that almost all who have written since his time have agreed in drawing the figures of the constellations, or supposing them to be drawn, so as to answer his description, as far as possible; and indeed this is necessary, in order to avoid confusion, when ancient and modern observations are compared.

The division of the ancients only took in the visible firmament, or so much as came under their notice: they distributed into forty eight constellations, those being reckoned ancient constellations which have been received from the Greeks, and particularly from Ptolemy; twelve of these took up the zodiac: the names they gave them are, *Aries*, *Taurus*, *Gemini*, *Cancer*, *Leo*, *Virgo*, *Libra*, *Scorpio*, *Sagittarius*, *Capricornus*, *Aquarius*, *Pisces*: from whence the signs of the ecliptic and zodiac take their names; though they are now no longer contiguous to the constellations which denominate them; e. g. the constellation Aries, about 2020 years ago, occupied the place of the first sign of the ecliptic; but, on account of the precession of the equinox, it is now removed to the second; and so of the others. See SIGN.

The other stars, on the northern side of the zodiac, were disposed into twenty-one constellations; viz. *Ursa major* and *minor*, *Draco*, *Cepheus*, *Bootes*, *Corona Septentrionalis*, *Heracles*, *Lyra*, *Cygnus*, *Cassiopeia*, *Perseus*, *Andromeda*, *Triangulum*, *Auriga*, *Pegasus*, *Equuleus*, *Delphinus*, *Sagitta*, *Aquila*, *Ophiureus* or *Serpentarius*, and *Serpens*: to which have been since added *Antinous*, and *Coma Berenices*, and some others.

The stars on the southern side of the zodiac were distributed into fifteen constellations: their names are, *Cetus*, *Eridanus flavivus*, *Lepus*, *Orion*, *Canis major* and *minor*, *Argo*, *Hydra*, *Crater*, *Corvus*, *Centaurus*, *Lupus*, *Ara*, *Corona Meridionalis*, and *Piscis australis*: to which have been since added several others, viz. *Phoenix*, *Grus*, *Indus*, *Pavo*, *Apus* or *Avis Indica*, *Apis Musca*, *Chamaeleon*, *Triangulum australe*, *Piscis volans*, *Toucan*, *Hydrus*, *Xiphiæ* or *Dorado*, *Columba Noachi*, and *Robur Carolinum*, &c. &c. See each constellation under its proper head, *ARIES*, *TAURUS*, &c.

The other stars, not comprehended under these constellations, yet visible to the naked eye, the ancients called *infirmos*, or *sporades*, some of which the modern astronomers have since reduced into new figures, or constellations.

Thus, Hevelius, v. g. between *Leo* and *Ursa major*, makes *Leo minor*; and between *Ursa minor*, and *Auriga*, over *Gemini*, makes *Lynx*; under the tail of *Ursa major*, *Canes venatici*, *Cerberus*, *Vulpecula*, and *Anser*, *Scutum Sobieski*, *Laerta*, *Camelopardalus*, *Monoceros*, and *Sextans*. See also *ANTINOUS*, *BERENICE*, and *COR CAROL*.

In these constellations, the stars are ordinarily distinguished by that part of the image wherein they are found. Bayer distinguishes them farther by the letters of the Greek alphabet: and many of them, again, have their peculiar names, as *Arcturus*, between the knees of *Bootes*; *Gemina*, or *Lucida*, in the *Corona septentrionalis*; *Pollitium*, or *Aldebaran*, in the Bull’s eye, *Pleiades* in the neck, and *Hyades* in the forehead of the Bull: *Castor* and *Pollux* in the heads of *Gemini*; *Capella*, with the *Hædi*, in the shoulder of *Auriga*; *Regulus*, or *Cor Leonis*; *Spica Virginis* in the hand, and *Vindemiatrix* in the shoulder of *Virgo*; *Antares*, or *Cor Scorpionis*; *Fomabant*, in the mouth of *Pisces-australis*; *Regel*, in the foot of *Orion*; *Sirius*, in the mouth of *Canis major*; *Procyon*, in the back of *Canis minor*; and the *Pole-star*, the last in the tail of *Ursa minor*.

The knowledge of the stars has become more extensive; the number of constellations has increased; and a greater number of stars has been introduced into each constellation; as their positions, by more accurate observations, have been ascertained.

The following tables exhibit the names of the constellations, and the number of stars in each, including all to the sixth magnitude: and also some of the most remarkable stars in each constellation.

CONSTELLATION.

TABLE I. *Constellations in the Zodiac.*

Names of Constellations.	Number of the Stars.					Chief Stars.	
	Ptolemy.	Tycho.	Hevelius.	Flamsteed, &c.		Magn.	
Aries, the Ram - - -	18	21	27	66			
Taurus, the Bull - - -	44	43	51	141	Aldebaran -	1	
Gemini, the Twins - - -	25	25	38	85	Castor and Pollux -	2	
Cancer, the Crab - - -	13	15	29	83			
Leo, the Lion - - -	with Coma } Berenices } 35	30	49	95	Regulus -	1	
Virgo, the Virgin - - -	32	33	50	110	Spica Virginis -	1	
Libra, Chelæ, the Scales - - -	17	10	20	51	Zubenich Meli -	2	
Scorpio, the Scorpion - - -	24	10	20	44	Antares -	1	
Sagittarius, the Archer - - -	31	14	22	69			
Capricornus, the Goat - - -	28	28	29	51			
Aquarius, the Water-bearer - - -	45	41	47	108	Scheat -	3	
Pisces, the Fishes - - -	38	36	39	113			

TABLE II. *Constellations northward of the Zodiac.*

Names of the Constellations.	Number of Stars.					Chief Stars.	
	Ptolemy.	Tycho.	Hevelius.	Flamsteed, &c.		Magn.	
Ursa minor, the Little Bear - - -	8	7	12	24	Polestar -	2	
Ursa major, the Great Bear - - -	35	29	73	87	Dubhe -	1	
Perseus - - -	29	29	46	59	Algenib -	2	
Auriga, the Waggoner - - -	14	9	40	66	Capella -	1

In the Southern Hemisphere 45	9	36	84	190	221	323	863
	20	76	223	510	695	1604	3128

There are several ways of delineating the constellations and stars, so that an observer may be able to distinguish them in the heavens. The most eligible method of all is to construct a hollow globe of such a large size as to admit the observer to stand on a frame near its centre; and then to paint the stars and constellations in its inner surface, in their proper situations with regard to one another. If such a globe, elevated according to the latitude, were made to turn on its poles, the observer near the centre would behold the motions and aspects of the stars as they really are in the heavens, and soon obtain a correct idea of the whole. A machine of this kind, however, could not be constructed without a very considerable expence as well as ingenuity. Large machines on this plan have been made at Gottorp, at the expence of Frederick III. duke of Holstein; and at Paris by the direction of cardinal d'Etrees; but these are far inferior in size to one erected at Pembroke college, in Cambridge, under the direction of Dr. Long. The description of this curious machine is here subjoined in the doctor's own words. "I have, in a room lately built in Pembroke hall, erected a sphere of 18 feet diameter, wherein 30 persons may sit conveniently: the entrance into it is over the south pole by six steps:—the frame of the sphere consists of a number of iron meridians, not complete femicircles, the northern ends of which are screwed to a large round plate of brass with a hole in the centre of it; through this hole, from a beam in the ceiling, comes the north pole, a round iron rod about three inches long, and supports the upper parts of the sphere to its proper elevation for the latitude of Cambridge; the lower part of the sphere, so much of it as is invisible in England, is cut off; and the lower or Southern ends of the meridians, or truncated femicircles, terminate on, and are screwed down to a strong circle of oak, of about thirteen feet diameter, which, when the sphere is put into motion, runs upon large rollers of lignum vitæ, in the manner that the tops of some wind-mills are made to turn round. Upon the iron meridians is fixed a zodiac of tin, painted blue, whereon the ecliptic and heliocentric orbits of the planets are drawn, and the constellations and stars traced:—the great and little bear, and draco, are already painted in their places round the north pole; the rest of the constellations are proposed to follow: the whole is turned round with a small winch, with as little labour as it takes to wind up a jack, though the weight of the iron, tin, and wooden circle, is about a thousand pounds. When it is made use of, a planetarium will be placed in the middle thereof. The whole, with the floor, is well supported by a frame of large timbers." In 1758, the constellations and chief stars visible at Cambridge, were painted in their proper places upon plates of iron joined together, which form one concave surface. We here add with regret, that this curious machine has been much neglected and is so far decayed as to answer none of the purposes which the ingenious contriver proposed. The constellations and stars might also be drawn in two concave

hemispheres, which would contain them all, or segments of spheres might be made of brass or pasteboard, of such dimension that each segment should contain a single constellation upon its concave surface. Sometimes the constellations are drawn upon two planispheres projected upon a great circle, which give us the pictures of the two concave hemispheres in plano. See our *Plates of Constellations*. The constellations and stars may be also depicted on a celestial globe.

The first use of all these concave spheres, planispheres, and globes is, by comparing them with the originals, to know the stars in the heavens; but as the rotation of the earth round its axis causes the heaven and stars, &c. apparently to move the contrary way; and thus the sphere of the fixed stars is made to change its position, with respect to us, every moment of the natural day: it will be necessary, in order to compare the stars upon a concave hemisphere, globe, or planisphere, with the stars in the heaven, to place the globe, hemisphere, &c. in such a position as to correspond with the situation of the heavens at the time of observation. The method of rectifying the celestial globe for any hour of the night, or so to place it that every star on the globe may point at the corresponding star in the heavens, will be shewn under the article *CELESTIAL GLOBE*; and when this is done, the constellation may be known, by comparing the heavens and the globe with one another. *E. G.* If I would find a star called Arcturus in the heavens, the globe being rectified for the hour, I find Arcturus upon it; then if I imagine a line to be drawn from the centre of the globe through that star, that line continued will point at Arcturus in the heavens. Suppose, on the other hand, I see some bright star in the heavens which I want to find upon the globe, I first rectify the globe for the hour of the night, and then if I imagine a line to be drawn from the star to the centre of the globe, it will point at the corresponding star on the surface of the globe. Maps of the concave surface of the heavens, especially such as take in only one constellation, with some parts of those which surround it, are very useful for the purpose of becoming acquainted with the stars. Of this sort are the figures given by Beyer in his "Uranometria," and those of Flamsteed, published after his death by Hodgson. See our *Plates of Constellations*. The manner of using these maps will be seen by the following example. If I would know the stars in the Great Bear, I turn the figure about, till the principal stars of it are in the same situation with regard to upper or under, right or left, as they appear in the heavens, at the time of making my observation: when this is done, it is easy, by looking first on the heavens and then upon the map, to discover to what parts of the figure, whether to the eye, snout, &c. the rest of the stars are to be referred.

It is very probable that the stars, and more especially some of the most remarkable collections of them, such as Charles's Wain, the Pleiades, Orion, &c. were formed into constellations.

lations and had names given them, in the early ages of the world. Some of them, by their different appearances, serve to mark out the different seasons of the year, and on that account they were not only taken notice of as a kind of directory for the commencement of ploughing, sowing, and other operations of husbandry (see Hesiod, *Op. et Dies*, l. ii. v. 1 and 2.), but were also thought to have a great influence on the temperature of the air and the fertility of the earth. Hence, from their being *signs*, pointing out the times of the year when heat or cold, dryness or moisture, are usually predominant, they were also regarded as the causes of those qualities in natural bodies, and imagined to have dominion over minerals, vegetables, and animals, over the complexions, and constitutions, and even the dispositions of mankind. This opinion obtained credit the more easily, because the sun, moon, planets, and stars, were believed to be of a divine nature; inasmuch that some conceived they were inhabited by an inferior kind of deities, which governed their motions and directed their influences; whilst others thought that they were animals, each of which had a living soul, which was guided by an intelligence, and others again suppose that they were animated by a part of the substance of the supreme Being. Each of these notions led mankind to pay them a sort of religious worship. The most ancient idolaters are with great probability thought by some learned men to have received the name of Zabu from their worship of the host of heaven; and this they could hardly do, without dividing the stars into parcels, as we find their aptest scholars in idolatry, the Egyptians, did, who divided the heavens into several regions, which they called the habitations or mansions of their gods. The Egyptians worshipped the heavenly bodies; and more especially the sun and moon, which they called their great gods, denominated the sun Osiris, and the moon Isis. They also found, or imagined that they found, in various animals, some properties or qualities corresponding to the motions, appearances, or influences of the sun, moon, and some of the stars: hence they were induced not only to use those animals in their hieroglyphic representations of their deities, but also to pay them divine honours. Thus by the *ram*, *aries*, a prolific animal, they represented the genial fertilizing warmth of the sun in the spring, as they did his violent scorching heat in the summer, by the hot and furious beast, the *lion*. The *bull* was regarded by them as another emblem of the various powers of the sun in forwarding the operations of agriculture, to which this animal is subservient; and hence were derived their *Apis* or *Mnevis*. The *goat* had divine honours paid him in some parts of Egypt, as a representative of the tendency of universal nature to propagate the several species of beings; whence the Greeks took their image of *Pan*. *Virgo* was a representation of their goddess Isis: the *Scorpion* was an emblem of the destructive power of the malignant genius Typhon; the *triangle* was a picture of the land of Egypt, which is of this shape; the *balance* was the hieroglyphic of justice, and therefore *Libra* was thought to be a proper constellation for that part of the heavens wherein the sun appears at one of the equinoxes, where he distributes equal day and night to the whole earth: or, in its relation to the land of Egypt, it may intimate the equal distribution of the Nile to the several parts of the country, by the genius of the waters; for the figure of this constellation was among the Egyptians a man holding a pair of scales. The Egyptians worshipped *serpents* and *fishes*: and the *altar* is said to have been an hieroglyphic of the land of Egypt. Many other similar instances might be adduced, as most of the animals and other figures that occur among our present constellations were

originally Egyptian. The Greeks, who learned astronomy of the Egyptians, retained several of their figures, as the ram, the bull, the lion, the dog, the triangle, &c.; but accommodated almost all of them to the fabulous history of their gods and heroes, whom they thus placed among the stars. Accordingly the Greek and also the Roman poets, from the ancient theology, have given us wild and romantic fables about the origin of the constellations, probably derived from the hieroglyphics of the Egyptians, and transmitted, with some alterations, from them to the Greeks; which may be seen in Hyginus's Poeticum Astron. and Ricciolus's *Almagest*, lib. vi. cap. 3, 4, 5; and Sherburne's notes upon Manilius.

Sir Isaac Newton observes, (see his *Chronology*, apud *Oper. vol. v. p. 64.*) that Musæus, one of the Argonauts, was the first among the Greeks who made a sphere; and the sphere itself, he says, shews that it was delineated in the time of the Argonautic expedition; for that expedition is delineated in the *Asterisms*. Thus we have the golden *Ram*, the ensign of the vessel in which Phryxus fled to Colchis; the *Bull* with brazen hoofs tamed by Jason; and the twins, *Castor* and *Pollux*, two of the Argonauts, with the *Swan* of Leda their mother. We have also the ship *Argo*, and *Hydrus* the watchful dragon: with Medea's *cup*, and a *Raven* upon its carcass, the symbol of death. We have *Chiron* the master of Jason, with his *altar* and *sacrifice*; the Argonaut *Hercules* with his *club* and *sulture* falling down, and the *Dragon*, *Crab*, and *Lion*, which he slew; and the *Harp* of the Argonaut Orpheus. All these, says Sir Isaac, relate to the Argonauts. We have also *Orion*, the son of Neptune, or, as some say, the grandson of Minos, with his *Dogs*, and *Hare*, and *River*, and *Scorpion*. We have the story of Perseus in the constellations of *Perseus*, *Andromeda*, *Cepheus*, *Cassiopea*, and *Cetus*; that of Callisto, and her son Arcas, in *Ursa major* and *Arctophylax*; that of Icarus and his daughter Erigone in *Bootes*, *Plautium*, and *Virgo*. *Ursa minor* relates to one of the nurses of Jupiter; *Auriga* to Erechthonius; *Ophiuchus* to Phorbias; *Sagittarius* to Crolus the son of the nurse of the Muses; *Capricorn* to Pan; and *Aquarius* to Ganimedee. We have Ariadne's *Crown*, Bellerophon's *Horse*, Neptune's *Dolphin*, Ganimedee's *Eagle*, Jupiter's *Goat*, with her *Kids*; Bacchus's *Asses*, the *Fishes* of Venus and Cupid, and their parent the *South-fish*. These with *Delton* are the old constellations mentioned by Aratus; and they all relate, says Newton, to the Argonauts and their contemporaries, and to persons one or two generations older; and nothing later than that expedition was delineated there originally. Antinous and Coma Berenices are novel. Although it be true, as Sir Isaac Newton affirms, that none of the figures on this sphere bear relation to any transaction of later date than the Argonautic expedition; yet the great disagreement that subsists among mythologists in their accounts of these figures shews them to be of greater antiquity, and that the constellations were received for some time among the Greeks, before their poets, according to their several fancies, applied them to different fables. See Long's *Astronomy*, vol. i. p. 162.

As the stars grouped in our constellations are capable of being reduced to very different figures, those of the Chinese and Japanese are very different from ours; and some superstitious Arabians, though they received their astronomy from the Greeks, have given some of their constellations different figures; because they thought it unlawful to draw any human figure; and therefore they changed all such on the celestial globe into some other form. Some Christian astronomers, displeas'd to see the heavens of the fixed stars occupied by the fabulous heathen deities and heroes have proposed,

proposed, from superstitious zeal but without a due regard to the science of astronomy, to introduce a reformation in this respect; and whilst they retained the ancient figures, to refer them to some scripture history. With this view they would have *Aries*, or the ram, to be a memorial of that which was offered instead of Isaac, *Virgo* to represent the blessed Virgin, &c. Thus, venerable Bede, instead of the profane names and figures of the twelve constellations of the zodiac, substituted those of the twelve apostles; whose example being followed by Julius Schillerius, in 1627, he completed the reformation, and gave scripture names to all the constellations in the heavens. Thus, *Aries*, or the ram, became converted into St. Peter; *Taurus*, or the Bull, into St. Andrew; *Andromeda* into the sepulchre of Christ; *Lyra* into the manger of Christ; *Hercules* into the Magi coming from the East; *Canis major* into David, &c. Weigelius, professor of mathematics in the university of Jena, made a new order of constellations; converting the firmament into a *calum heroidicum*; and introducing the arms of all the princes in Europe, by way of constellations. Thus, *Ursa major*, he transformed into the elephant of the kingdom of Denmark; the *Swan* into the Ruta with swords of the house of Saxony; *Ophiuchus* into the cross of Cologne; the *Triangle* into the compasses, which he calls the *symbol of artificers*; and the *Pleiades* into the *Abacus Pythagoricus*, which he calls that of merchants, &c. However, the more intelligent among astronomers never approved of innovation; as serving no purpose but to introduce confusion into astronomy. The old constellations, therefore, are still retained; both because better could not be substituted, and likewise to keep up the greater correspondence and uniformity between the old astronomy and the new. See CATALOGUE.

CONSTERNATION is defined by ethical writers to be an excess of horror, owing to the ill government of our admiration and fear: or such an immoderate degree of fear as confounds the faculties, and incapacitates a person for consultation and execution. It denotes a strong foreboding of tremendous evils, that are likely to follow misfortunes which have already taken place.

CONSTIPATION, in *Medicine*, is synonymous with *costiveness*, and signifies a retention of the stools beyond the usual period; which likewise implies, in general, a dry and hardened condition of the excrements, and some difficulty in discharging them.

The proximate cause of constipation of the bowels may consist in an unusual slowness of the peristaltic motion, or in an obstruction to the passage of the feces, while the proper peristaltic motion continues to propel them. The natural motion of the bowels is considerably different in individuals of different constitutions, and even in the same individuals at different periods: so that it is not easy to say when the peristaltic motion can be considered as preternaturally slow, while the general health continues good. But it is probable that a stool should occur once in 24 hours, in most habits, although there are many persons who retain the feces much longer without inconvenience. Dr. Cullen affirms, that he is clearly of opinion, that every deviation from a diurnal stool is an approach to an unnatural state. The accumulation and induration of the feces in the great intestines not only often produces many diseases in the lower part of the canal, but even occasions disorders in distant organs, and deranges the system in general.

The occasional causes of an inefficient peristaltic motion are various. A weakness of the muscular coat of the bowels appears to be, in some cases, the origin of costiveness, which is then accompanied with other marks of de-

bility; hence costiveness is not unfrequent in the female sex, who suffer considerable inconveniences from it. A cause of a contrary nature seems likewise to give rise to constipation, namely, a rigour and rigidity of the alimentary canal. In such cases there is necessarily a degree of immobility or torpor, so that the stimulus of the passing feces excites the intestines to less active motions, than in the more irritable habits; at the same time digestion is more perfectly performed, and a smaller proportion of feces therefore is produced: the absorption of the liquid parts too is more complete, and hence the feces are not only smaller, but drier, and pass less easily. In rigid and robust persons therefore habitual constipation is not uncommon. And in those of hypochondriacal or melancholic habits, a similar torpor in the motions of the whole system, and particularly of the intestinal canal, produces a similar disposition to costiveness. Another cause of the slowness of the peristaltic motion may be a deficiency of *Life* in the intestines, which is considered as one of the principal stimuli in maintaining the motion of the canal downwards. It is not indeed always in our power to ascertain the occurrence of this circumstance; but we know that, where the bile is withheld from the intestines, as in jaundice, there is commonly constipation. It is not quite evident in what manner a regular and constant exercise of gestation, as in a carriage or on the water, produces costiveness, rather than any considerable bodily activity, which is accompanied by much perspiration; Dr. Cullen is disposed to attribute it to the abstraction of the other intestinal fluids, secreted from the mucous glands and exhalant arteries. See *Materia Med.* vol. ii. p. 496.

The causes which may obstruct the passage of the fecal matter, occur either in the intestines themselves, or in the neighbouring parts. In the intestines, a mechanical impediment is sometimes occasioned by a thickening of the coats, which straitens the passage, or by scirrhous tumours, especially near the lower extremity of the canal. Sometimes the cavity of the intestine is partly filled by calculous concretions. A temporary diminution of the calibre of the canal is also occasioned by spasmodic contractions in the coats, as occurs in colic, or by the occurrence of inflammation, as in *enteritis*, and *dysentery*; in all of which the fecal matter is retained. Tumours in the neighbouring parts, compressing the intestines, necessarily impede the passage of the contained feces. Hence obstinate constipation has sometimes been occasioned by a scirrhus tumour in the omentum; and a very frequent cause of costiveness is the compression of the distended uterus upon the rectum, or lower gut, in pregnant women.

When, from neglect of evacuation, or other circumstances, an accumulation of feces to a considerable extent takes place in the rectum, or lower intestines, this collection of matter itself becomes a cause of a most painful and distressing constipation, attended with peculiar symptoms, and sometimes terminating fatally. This disorder was first described by an anonymous writer in the *Medical Observations and Inquiries*, vol. iv. p. 123, and other cases have since been recorded by other practitioners. (See *Duncan's Medical Commentaries*, vol. x. p. 255, and vol. xiii. p. 282.) It is the more important to attend to this complaint, because it assumes the appearance of a *diarrhea*, or rather a chronic dysentery, and has been often mistaken for the former, and erroneously treated with astringents and opiates in consequence. The patient complains of severe pain about the lower region of the belly, remitting and again returning after frequent, but short intervals, and accompanied with a perpetual bearing down, and almost continual inclination to evacuate the contents of the intestines; but only a trifling quantity

quantity of thin discharge is expelled, sometimes mixed with small knobs of hardened excrement, or scybala; after which the pain abates. A fresh spasmodic effort succeeds, and with similar success. It may be considered as a kind of spontaneous spasm of all the parts in, or connected with, the pelvis, for the exclusion of this irritating substance. When, from a previous costiveness, from the acuteness of the pain and *teneismus* (or bearing down), and the obstruction of formed and feculent stools, this state of the rectum is to be suspected, the gut should be examined *per anum*, when the feces will be readily detected in general, and must be broken down and removed by the finger, or some other mechanical means. The accumulation, which thus takes place, is sometimes very great. The following account from an apothecary, is given by Dr. Warren of Taunton:—"the evening you left us, I extracted from our patient (a lady, aged 65, who had laboured under this disease for five months,) four large balls of hardened excrementitious matter, about the size of hen's eggs; the next morning she discharged near twenty, and has continued to pass more or less of them every day, until about a week ago, when she took a larger dose than ordinary of castor oil, which evacuated 18 lumps of the same size as formerly; since that her stools have been natural, none of the balls having appeared." See Duncan's Med. Com. vol. x. p. 259. This disorder is peculiar to persons in advanced life, when a degree of atony often exists in the bowels; and it is more frequently observed in the female, than in the male sex. Whatever tends to lessen the peristaltic motion of the bowels, must induce a predisposition to it; and it is said to have been frequently occasioned by a long continued use of bark, opium, and other astringent medicines.

The consequences of a constipated state of the bowels, however, though in a comparatively trivial degree, whether idiopathic, or as a concomitant of other diseases, are frequently extremely injurious to the constitution; producing, when it is idiopathic, a variety of disorders; and aggravating, when symptomatic, the diseases of which it is a symptom.

The stomach and intestines, being a continuation of the same canal, reciprocally affect each other, when disordered. Hence, complaints of the stomach are frequent consequences of costiveness of the bowels; such as flatulence, stomach iclic, or gastrodynia, heart-burn, indigestion, &c. Another affection of the canal is frequently produced by constipation, namely, the appearance of hemorrhoidal tumours, or piles, at the lower extremity of the rectum, about the anus. See HÆMORRHOIS. Sometimes from a sympathy of the head with the stomach, and sometimes probably from the pressure of the loaded intestines on the great vessels, impeding the circulation of the blood downwards, and therefore determining it more copiously towards the head, a pain of the head is excited by a constipated condition of the bowels. This head-ache is various in different instances, but most commonly is confined to the forehead, or to the *occiput*, or nape of the neck: occasionally the hemicrania, or intermitting head-ache, appears to arise from constipation. In those whose habits predispose them to apoplectic, paralytic, or lethargic attacks, a loaded state of the bowels, by obstructing the circulation downwards, increases the predisposition, and occasionally even becomes the exciting cause of these diseases.

There are, besides, many disorders both acute and chronic, which, although they cannot be said to be produced by constipation of the bowels, are nevertheless greatly aggravated by it; and the constipation is frequently a leading symptom of these disorders. Thus in all acute febrile complaints,

and particularly in idiopathic and eruptive fevers, such as the synochus, or summer-fever, typhus, scarlet-fever, small-pox, &c. constipation is liable to occur, and when occurring at any period of the fever, tends to aggravate its symptoms, and to prolong its duration: and if, on the contrary, the bowels are freely opened in the commencement of these disorders, their severity is mitigated, and their duration frequently abridged. This is more especially the case in synochus and typhus, and in the febrile complaints of children. In a certain set of chronic diseases, which have heretofore been considered as unconnected with the condition of the bowels, such as many hysterical affections, chlorosis, and particularly chorea, or St. Vitus's dance, constipation has lately been shewn to be a source of much mischief, if not frequently the exciting cause. (Hamilton on Purgatives.) See CHOREA, and CATHARTICS. In short, a constipated state of the bowels is at all times liable to produce injurious effects on the constitution: in health it is a common exciting cause of various complaints; and in all states of diseases, whether acute or chronic, it tends to aggravate the symptoms, and to prevent the beneficial operation of remedies.

The mode of obviating constipation must be varied, according to the nature of the cause, and the constitution of the patient. Where it is slight and accidental, any of the milder cathartics, such as *magnesia vitriolata*, or Epsom salt, castor oil, (*oleum ricini*), rhubarb, or small doses of calomel, will generally answer the purpose of removing it: if these fail, the more active purgatives must be resorted to, especially in strong habits, such as jalap, aloes, extract of colocynth, calomel in larger doses, and combined with some of the preceding substances. Calomel, or the other mild mercurial preparations, appear to be peculiarly useful, when the constipation is occasioned by a torpor of the hepatic system, and a consequent deficiency, or morbid change in the quality of the bile, as they appear to stimulate more particularly the biliary ducts and vessels. The colour and fætor of the stools should be noticed with care, since the quality and condition of the bile, which is the principal colouring matter of the feces, may be thus most easily ascertained. In acute diseases this observation is more peculiarly important, as the sensible qualities of the feces frequently indicate a loaded and morbid condition of the alimentary canal, and the necessity of laxatives, when the number of motions does not appear to require such evacuation. See Hamilton; also Abernethy, Surgical Observations, vol. ii.

When constipation is habitual, some gently stimulating or cooling laxative, according to circumstances, may be required to be given daily, until the habit be removed. Much may be done for the relief of this by diet; as by eating a large proportion of vegetables, or by the free use of fruits, even those which are dried, or preserved with sugar; and by avoiding such articles as manifestly tend to constringe the body. And the advice of Mr. Locke should be steadily followed; *i. e.* the patient should go regularly to stool at the same hour daily: for such is the periodical regularity of all the functions of the body, that they are more perfectly performed at the accustomed hours than at any other period. Thus sleep, and the appetite for food, often forsake us altogether, if we delay the gratification beyond the usual hour.

In states of extreme constipation it is very common among the vulgar to resort to a medicine which appears to have been first employed from the most absurd and false notions of its powers, namely, crude mercury, or quicksilver. Whether it may have been supposed to open the bowels by some self-

moving power, or by its mechanical weight, the theory is equally absurd: and what is worse, the practice is not only useless, but dangerous. There are cases on record, in which the quicksilver, thus administered, had accumulated in the intestines, formed itself a sac by its weight, and at length produced death, by passing into the cavity of the abdomen, in consequence of the rupture of this sac. It is obvious, indeed, that the medicine could not ever force a passage by its weight, along the course of the bowels, since it must ascend occasionally, if the body is erect; and the whole passage must be nearly horizontal, if the patient be in a recumbent posture.

In the worst degrees of constipation, glysters consisting of an infusion of tobacco, or the smoke of tobacco, have been thrown into the bowels with advantage. And when all other expedients have failed, the affusion of cold water on the lower extremities while the patient is placed with his feet on a cold hearth, has been found to excite the propulsion of the feces. See COLIC. A glyster consisting of Venice turpentine, suspended in water by means of mucilage, or the yolk of an egg, was a favourite remedy with Dr. Cullen for severe constipation; and it is undoubtedly an efficacious expedient, more especially if administered a few hours after an active cathartic has been taken internally.

Where the constipation is occasioned by a mechanical obstruction, it can of course be alleviated only by the removal of the obstruction. If it arises from the presence of tumours or concretions external to the bowels, it may be considered as incurable; and can only be alleviated by keeping the bowels lax, and the feces in as liquid a state as possible. Strictures of the lower intestine have been frequently relieved by the introduction of a bougie, mechanically enlarging the passage. An intelligent writer remarks, that "strictures take place in different situations; but they occur frequently about the sigmoid flexure of the colon, near its termination in the rectum, that this part should be carefully examined in every case of a total obstruction of the bowels." The insertion of an unyielding tallow candle, though often practised, has been generally found painful and inefficient. It is requisite for the purpose to employ a bougie thirteen inches long, and of a proportionate strength; which should also be directed, with a nice hand, by a skilful surgeon. "I lately saw a lady," he adds, "thus relieved, who had been twenty-six days without any evacuation from the bowels, and who seemed nearly exhausted by violence of pain, and distension of the abdomen, hiccough, cold sweat, &c. It is remarkable how long patients subsist under these distressing circumstances. In one instance the time was twenty-nine days; in another patient thirty-three days. As the latter recovered after enduring every torture such a disorder could inflict, practitioners may be encouraged to persevere steadily in their attentions, and to retain some hopes even in the greatest extremity." Willan on Diseases in London, page 185.

CONSTITUENT PARTS, in Chemistry. The constituent parts of bodies are their dissimilar parts, or principles, into which they may be resolved, by the rules of that art. They are thus called in distinction from the integrant parts of bodies, which are parts of the same nature and properties with the bodies themselves. Thus quicksilver, dissolved by aqua fortis, may be separated from the diluted menstruum, by means of a copper plate, in its own form; this therefore was only divided into its integrant parts; but cinnabar resolved by chemistry into sulphur and mercury, is divided into its constituent parts, neither of these, nor any particle of them, being cinnabar, or having its properties. Shaw's Lectures, p. 15.

CONSTITUTION, an establishment, ordinance, decision, regulation, or law, made by authority of a prince, or other superior, ecclesiastical or civil.

The constitutions of the Roman emperors make a part of the civil law. The constitutions of the church make a part of the canon law. Some of the papal constitutions are in form of *bulls*, others of *briefs*. See each article.

CONSTITUTIONS of Clarendon. See CLARENDON.

CONSTITUTIONS, Clementine. See CANON LAW.

CONSTITUTIONS, Legatine, were ecclesiastical laws enacted in national synods, held under the cardinals Otho and Othobon, legates from pope Gregory IX. and pope Clement IV., in the reign of Henry III., about the years 1237 and 1268.

Cardinal Otho arrived in England, as a legate from the pope, in the year 1237, where he continued about three years, receiving many valuable presents from the bishops, monasteries, and clergy. This legate held a council at London, A. D. 1237, in which a great number of canons were framed, which were called "the Constitutions of Otho." These constitutions do not contain many things new or remarkable. By the second canon, the sacraments are declared to be seven in number; the fifteenth is against the clandestine marriages of the clergy; and the sixteenth against their keeping concubines publicly: both which practices were still very frequent in England. This legate convened two other assemblies of the clergy, with no other view but to make exorbitant demands of money. After the restoration of the royal authority, by the victory of Evesham, the pope sent his legate Othobon into England, who held a national council, A. D. 1268, at St. Paul's in London. In this council many canons were made, much the same in substance with those of the former council of London, in 1237, under the legate Otho.

CONSTITUTIONS, Provincial, are principally the decrees of provincial synods, held under several archbishops of Canterbury, from Stephen Langton, in the reign of Henry III. to Henry Chicheley, in the reign of Henry V., and adopted also by the province of York in 1463, under Henry VI.

CONSTITUTIONS of 1603. See CANON LAW.

CONSTITUTIONS, Apostolical, in Ecclesiastical History, denote a collection of regulations attributed to the apostles, and supposed to have been collected by St. Clement, whose name they likewise bear.

These are divided into eight books; consisting of a great number of rules and precepts, relating to the duties of Christians, and particularly to the ceremonies and discipline of the church.

Mr. Robert Turner, in his "Discourse of the pretended Apostolical Constitutions," maintains, that these eight books seem to have been made out of several doctrines, constitutions, canons, travels, and traditions, ascribed to the apostles, and out of some of the ancient liturgies, and the discipline and practice of the Greek church, only blended together, adulterated, and changed, by some ignorant Arian, in the fifth century. Bishop Pearson was of opinion, that the Apostolical Constitutions were formed out of several lesser works, called Doctrines and Constitutions, said to be written by Clement, Ignatius, Hippolytus, and others, but altered and interpolated by the author of this collection; and that the eight books of the Constitutions, as we now have them, were not composed and finished till after the time of Epiphanius.

Authors, however, are divided about the genuineness of these Constitutions: the generality hold them spurious, and endeavour to prove them posterior to the apostolic age; maintaining they were unknown till the fourth century;

which, if this be the fact, shews, that St. Clement had no concern in them. It is certain, that no such book is quoted as Scripture by any Christian writer of the three first centuries. The first who cites a work under this title is Epiphanius, and yet he speaks of it as of doubtful authority; and some modern writers are of opinion, that the Constitutions quoted by Epiphanius were different from the present Constitutions. When he says, that it was "doubted by many," he himself intimates, that some suspected it to be the work of some heretic; in opposition to which he says, it ought not to be rejected, as, from its contents, it appeared to be the work of some honest, orthodox, or Catholic Christian.

It is not easy to say, what respect Epiphanius himself had for this work. He quotes things from it as ordinances of the apostles, and as the divine word or doctrine; but it is not mentioned in any of the passages, where he gives the catalogues of the books of Scripture. Besides, his expressions just taken notice of seem to imply no more, than that the book was an ecclesiastical or orthodox writing; and we may observe farther, either that his Constitutions were not the same as ours, or that he had no great regard for them. For in our Constitutions, several early heretics are named, and they are condemned and confuted; of which passages, nevertheless, Epiphanius has made no use in his history of those heretics, or in his arguments against them: which every one must think he would have done, if the Constitutions which we have had been then in being, and had been esteemed by him as of authority. Whatever might be his opinion concerning this work, we have no good reason for supposing that it was a book of sacred Scripture; because no such book is quoted as Scripture by Irenæus, Clement of Alexandria, Origen, Eusebius, or any other Christian writer of the first three centuries. It is more than probable that the eight books, as we have them, were not composed and finished till after the time of Epiphanius, towards the middle, or before the end, of the fifth century. Cotelerius (Ap. Patr. Apoll. t. i.) says, it is certain, that the work of the Apostolical Constitutions, in eight books, is apocryphal and pseudo-apocryphal, not composed by the apostles, nor by the apostolical Clement. Tillemont concurs in opinion with Cotelerius. Daillé thinks, that the Constitutions were composed after the council of Nice, and before the end of the fifth century; and bishop Pearson supposes, that the eight books of the Constitutions, as we now have them, were not composed and finished till after the time of Epiphanius. Le Clerc mentions some things in the Constitutions exceedingly unsuitable to the character of the apostles of Christ, and says, that they well represent the ecclesiastical discipline of the fourth century, but not of earlier times. He thinks, they were composed by some Arian of the fourth century; and seems to imagine, there may be some probability in the conjecture of another learned man, viz. Thomas Bruno or Brown, that they are the work of Leontius, bishop of Tripoli in Lydia.

Mr. Whiston has ventured to oppose the general opinion: and with some reason, much learning, and more warmth, asserted the Apostolical Constitutions to be one of the sacred writings, dictated by the apostles in their meetings, written down from their mouths by St. Clement, and intended as a supplement to the New Testament; or, rather, as a scheme and system of Christian faith and polity. See his Essay on the "Apostolical Constitutions," and his historical preface; wherein the several steps he made in his fancied discovery are traced.

Dr. Lardner, after citing several opinions of learned men concerning this work, offers his own sentiments in his usual judicious and impartial manner. In his investigation of its

contents and authority, he observes, that the whole of the work, and all the ordinances in it, from beginning to end, are delivered in the name of all Christ's apostles, and as from God himself; and moreover, that they assume not only the names of the apostles, but also their characters and actions. Hence, according to the whole tenor of the work, they are rightly termed "Apostolical." Dr. Lardner next proceeds to inquire, both from external testimony and internal evidence, how far the authority claimed by these constitutions, and by the advocates of their antiquity, is well founded. To this purpose he observes, that Daillé, after having examined all the several ecclesiastical writers of the first three centuries. Barnabas, Clement of Rome, Justin Martyr, Athenagoras, Irenæus, Clement of Alexandria, Tertullian, Origen, Cyprian, Dionysius, Peter of Alexandria, and some others, has shewn, with great probability, that the constitutions were unknown to all these writers. In this opinion Mr. Turner, already cited, concurs. Moreover, the constitutions contain a long history of Simon Magus, and an account of divers other heretics, such as Cleobius, Dositheus, the Ebionites, Cerinthus, Marc, Menander, Basilides, Saturninus, the Nicolaitans, and Hæmorrhoids. The evil of heresies is shewn; the causes of them are ascertained and enumerated; they are condemned and confuted. Nevertheless, no notice is taken of all this by Irenæus, Tertullian, Clement of Alexandria, or Eusebius; nor even by Epiphanius; though it would have been much more to their purpose. In short, says Dr. Lardner, they could not have omitted it in their censures of the ancient heresies, or in their arguments against them, if they had been acquainted with it; for, certainly, the express authority of the apostles would have been of great advantage to them. As to Clement of Alexandria, though he quotes Clement of Rome, Barnabas, and other Christian authors, and had many occasions for quoting the constitutions, if he had been acquainted with them, yet he does not take the least notice of them. Besides, the constitutions absolutely forbid the reading of heathen authors; nevertheless, the fore-mentioned Clement, who was himself a man of extensive reading, and a great master of heathen learning, frequently cites in his works all sorts of authors, and has recommended the reading of heathen authors, and the study of philosophy; which he would not have done, if he had been acquainted with these constitutions, and had acknowledged them to be apostolical. Tertullian, Origen, and many more justify and recommend the reading of heathen compositions, which could not have been the case, if in doing this they would have violated an apostolical constitution. If, indeed, there had been a constitution of the Christian church, which forbade the reading of such books, the emperor Julian would have had no occasion to make the same prohibition. In the third century a dispute occurred about baptism; in which Cyprian and the African bishops maintained against Stephen bishop of Rome, that the baptism of heretics was null and void, and therefore that those who came over from them were to be re-baptized; this controversy is decided in the constitutions agreeably to the judgment of Cyprian and his colleagues; and yet it was not appealed to at that time, because, probably, it was not then extant. Dionysius, who was bishop of Alexandria about the year 248, appears to have been altogether unacquainted with our apostolical constitutions. When a controversy occurred about the time of keeping Easter, which commenced in the second century, and lasted till the sitting of the council of Nice, no appeal was made to the constitutions, which would have served to decide the dispute, if they had actually existed or had been received as apostolical. If an appeal be made to the writers of the fourth and the former part of the fifth century, such as Gregory Nazianzen, Basil, Chryso-

ton, the Cyrils of Jerusalem and Alexandria, Jerom, Augustine, &c.; they give us no intelligence concerning the apostolical constitutions; having neither cited nor mentioned them in any of their writings. The first (Epiphanius excepted) who has mentioned them, as divided into several books, is the author of the imperfect work upon St. Matthew, probably a Latin writer, and plainly an Arian, who wrote some time after the reign of Theodosius the Great; probably not till after the end of the fifth century. Upon the whole, the constitutions are destitute of all external evidence, that should entitle them to the character of apostolical. As to the internal evidence, they evidently bear many marks of a later age than that of the apostles, and unfit to be their character. Their manner of quoting the books of the New Testament does not suit the apostles, of which Dr. Lardner has given several instances; many things occur in these books, that refer to a later period than that of the apostles: e. g. they mention several heretics, as we have already observed, that did not appear before the end of the apostolical age; they also record various circumstances, which seem to shew, that the reign of heathenism in the Roman empire had terminated, and that Christians enjoyed ease and prosperity; and they write in a style, make use of terms and appellations, and refer to practices and observances, and offices of the church, which did not obtain till a much later period than the age of the apostles. Several things in the constitutions appear to be unworthy of the apostles of Christ; of which numerous instances are cited by Dr. Lardner, and also by Dr. Jortin, *ubi infra*. Moreover, this work is not free from inconsistencies, which are a disparagement to any writings, and they use a mode of expression that betrays a later time than is pretended. From a recital and ample illustration of the several particulars, above cursorily mentioned, by the two learned writers already named, and of others which our limits will not allow us to introduce, we may justly conclude, that the constitutions, in eight books, are not a work of the apostles, and since they bear their names without sufficient authority, they must be referred to the class of impostures. Although the exact time when this work was compiled, cannot be determined, and learned men have offered various conjectures, Dr. Lardner inclines to the opinion of those, who think that it was composed in the latter part of the fourth, or the beginning of the fifth century. "The author," probably, says Dr. Lardner, "was a bishop of a proud and haughty spirit, who was fond of church-power, and loved pomp and ceremony in religious worship." To this purpose Dr. Jortin says, that the constitutions repeatedly assert, "that a bishop is a God, a God upon earth, and a king, and infinitely superior to a king, and ruling over rulers and kings. They command Christians to give him tribute as to a king, and to reverence him as a God, and to pay him tithes and first-fruits, according, say they, to God's command; and they strictly forbid Christians to make any inquiry, and to take any notice, whether he dispose of these revenues well or ill." Sentiments these which seem to have been dictated at a time when there were Christian emperors.

Many learned moderns, says Dr. Lardner, "think the author was an Arian; but I do not concern myself about that: the passages, which have been supposed to favour Arianism, make a very small, or no part of the preceding collections; I have no reason, therefore, to bring that point into the conclusion. But I presume, that none ever suspected the author to be a Homotian." The author of this work, whoever he was, bears testimony to the scriptures; and appears to have received all those books of the New Testament, which were all along generally received by Christians. Lard-

ner's works, vol. iv. part 2. ch. 35. p. 320—354. Jortin's Remarks on E. H. vol. i. p. 228—275.

CONSTITUTION, in a *Physical Sense*, is used to denote the general condition of the body, as evinced by the peculiarities in the performance of its functions: such are, the peculiar pre-disposition to certain diseases, or liability of particular organs to disease: the varieties in digestion, in muscular power and motion, in sleep, in the appetites, &c. &c. Some marked peculiarities of constitution are observed to be accompanied with certain external characters, such as a particular colour and texture of the skin, and of the hair, and also with a peculiarity of form and disposition of mind; all of which have been observed from the earliest times, and divided into classes, which have received names, during the prevalence of the humoral pathology, which they still retain, in consequence of the neglect of this important study by modern physicians. See TEMPERAMENT.

CONSTITUTION, in *Political Economy*, is frequently used in common language as synonymous with government; but the constitution and the government of a country have different meanings, and are actually distinguished by accurate writers. "By constitution we mean," says lord Bolingbroke, in his "Dissertation on Parties" (Works, vol. ii. p. 130.), "whenever we speak with propriety and exactness, that assemblage of laws, institutions, and customs, derived from certain fixed principles of reason, directed to certain fixed objects of public good, that compose the general system, according to which the community hath agreed to be governed. Whereas by government we mean, whenever we speak in the same manner, that particular tenor of conduct which a chief magistrate, and inferior magistrates under his direction and influence, hold in the direction of public affairs." (See GOVERNMENT.) Constitution, says the same writer, in reference to our own country, is the rule by which our princes ought to govern at all times: government is that by which they actually do govern at any particular time. One may remain immutable; the other may, and as human nature is constituted, must vary. One is the criterion by which we are to try the other; for surely we have a right to do so, since, if we are to live in subjection to the government of our kings, our kings are to govern in subjection to the constitution; and the conformity or non-conformity of their government to it prescribes the measure of our submission to them, according to the principles of the revolution, and of our present settlement, in both of which, though some remote regard was had to blood, yet the preservation of the constitution manifestly determined the community to the choice then made of the persons who should govern. In order further to evince the difference between the constitution and the government of a country, lord Bolingbroke observes that "kings may have preceded lawgivers, for ought I know, or have possibly been the first lawgivers, and government by will have been established before government by constitution. Theseus might reign at Athens, and Eurytion at Sparta, long before Solon gave laws to one, and Lycurgus to the other of these cities. Kings had governed Rome, we know, and consuls had preceded kings, long before the decemviri compiled a body of law; and the Saxons had their monarchs before Edgar, though the Saxon laws went under his name." These examples plainly prove, "that however men might submit voluntarily in the primitive simplicity of early ages, or be subjected by conquest to a government without a constitution, yet they were never long in discovering, that (as Hooker observes, Eccles. Pol. l. 1. § 10.) "to live by one man's will became the cause of all men's misery;" and therefore "they soon rejected the yoke,

or made it fit easy on their necks." By the *constitution* of a country, says archdeacon Paley (*Princ. of Moral and Political Philos.* vol. ii. chap. 7.), is meant so much of its law, as relates to the designation and form of the legislature; the rights and functions of the several parts of the legislative body; the construction, office, and jurisdiction of courts of justice. Accordingly, the constitution is one principal division, section, or title of the code of public laws; distinguished from the rest only by the superior importance of the subject of which it treats: and therefore the terms *constitutional* and *unconstitutional*, mean legal and illegal. In England the system of public jurisprudence is made up of acts of parliament, of decisions of courts of law, and of immemorial usages: consequently, these are the principles of which the English constitution itself consists; the sources from which all our knowledge of its nature and limitations is to be deduced, and the authorities to which all appeal ought to be made, and by which every constitutional doubt and question can alone be decided. This plain and intelligible definition will serve to discover the error of those writers who absurdly confound what is constitutional with what is expedient, and what is unconstitutional with any measure which they adjudge in any respect to be detrimental or dangerous; and also of others, who ascribe a kind of transcendent authority, or mysterious faculty, to the constitution, as if it were founded in some higher original than that which gives force and obligation to the ordinary laws and statutes of the realm, or were inviolable on any other account than its intrinsic utility. An act of parliament, in England, can never be unconstitutional, in the strict and proper acceptation of the term; but in a lower sense it may, *viz.* when it militates with the spirit, contradicts the analogy, or defeats the provision of other laws, made to regulate the form of government. Most of those, says our author, who treat of the British constitution, consider it as a scheme of government formerly planned and contrived by our ancestors, in some certain era of our national history, and as set up in pursuance of such regular plan and design. This is intimated in the expressions of those who speak of the "principles of the constitution," of bringing back the constitution to its "first principles," of restoring it to its "original purity," or "primitive model." This, in his opinion, is an erroneous conception of the subject. No such plan was ever formed; consequently no such first principles, original model, or standard exist; that is, as he conceives, there never was a date, or point of time in our history, when the government of England was to be set up anew, and when it was referred to any single person, or assembly, or committee, to frame a charter for the future government of the country; or when a constitution, so prepared and digested, was by common consent received and established. The great charter, and the bill of rights, were wise and strenuous efforts to obtain security against certain abuses of regal power, by which the subject had been formerly aggrieved; but these were, either of them, much too partial modifications of the constitution to give it a new original. The constitution of England, like that of most countries in Europe, hath grown out of occasion and emergency; from the fluctuating policy of different ages; from the contentions, successes, interests, and opportunities of different orders and parties of men in the community. It resembles one of those old mansions, which, instead of being built all at once, after a regular plan, and according to the rules of architecture, at present established, has been reared in different ages of the art, has been altered from time to time, and has been continually receiving additions and repairs suited to the taste, fortune, or convenience of its successive proprietors; to such a building

we look in vain for the elegance and proportion, for the just order and correspondence of parts, which we expect in a modern edifice; and which external symmetry, after all, contributes much more perhaps to the amusement of the beholder, than the accommodation of the inhabitant.

Some of our approved historians, and political writers, have discovered, as they conceive, the origin of the British constitution in the government of the Anglo-Saxons, brought hither from Germany and the northern countries. To this purpose, it is alleged, that the government of the northern nations, which established themselves on the ruins of Rome, was always extremely free; and that the free constitutions then introduced, however impaired by the encroachments of preceding princes, still preserve an air of independence and legal administration, which distinguishes the European nations; and in this part of the globe maintains sentiments of liberty, honour, equity, and valour, superior to the rest of mankind, it is said to have owed these advantages chiefly to the seeds implanted by the generous barbarians of the north. The Saxons who subdued Britain in the 5th century, as they enjoyed great liberty in their own country, obstinately retained that invaluable possession in their new settlement; and they imported into this island the same principles of independence, which they had inherited from their ancestors. The chieftains, (for such they were, more properly than kings or princes,) who commanded them in their military expeditions, still possessed a very limited authority; and as the Saxons exterminated, rather than subdued, the ancient inhabitants; they were indeed transplanted into a new territory, but preserved, without alteration, all their civil and military institutions. Their manners and customs were wholly German; and the same picture of a fierce and bold liberty, which is drawn by the master pencil of Tacitus, will suit those founders of the English government. The king, so far from being invested with arbitrary power, was only considered as the first among the citizens; and his authority depended more on his personal qualities, than on his station. The Anglo-Saxons, being an independent people, little restrained by law, and cultivated by science, were not very strict in maintaining a regular succession of their princes. Although they paid great regard to the royal family, and ascribed to it an undisputed superiority, they either had no rule, or none that was steadily observed, in filling the vacant throne; and present convenience, in that emergency, was more attended to than general principles. We are not, however, to suppose, that the crown was considered as altogether elective; and that a regular plan was traced by the constitution for supplying, by the suffrages of the people, every vacancy made by the demise of the first magistrate. All the changes which occurred in the royal succession, and indeed the ordinary administration of government, required the express concurrence, or at least the tacit acquiescence of the people. The Anglo-Saxon monarchies were not, strictly speaking, either elective or hereditary; and though the destination of a prince might often be followed in appointing his successor, they could not be regarded as wholly testamentary. The states by their suffrage might sometimes establish a sovereign; but they more frequently recognized the person whom they found established. Our knowledge of the Anglo-Saxon history is so imperfect, that it is not easy to ascertain all the prerogatives of the crown and privileges of the people, or to give an exact delineation of that government. It is probable, that the constitution might be somewhat different in the different kingdoms of the HEPTARCHY, and that it changed considerably during the course of six centuries, which elapsed from the first invasion of the Saxons, till the Norman conquest. It appears, however, that at all

times, and in all the kingdoms, there was a national council, called a *wittenagemot*, or assembly of the wise men, as the term imports, whose consent was requisite for enacting laws, and for ratifying the chief acts of public administration. The preambles to all the laws of Ethelbert, Ina, Alfred, Edward the Elder, Athelstan, Edmund, Edgar, Ethelred, and Edward the Confessor; even those to the laws of Canute, though a kind of conqueror, supply unquestionable proofs every where of a limited and legal government. But who were the constituent members of this *wittenagemot*, is a question that has not been determined with certainty by antiquarians. (See *WITTENAGEMOT*.) Nevertheless, it is certain, that whatever we may determine concerning the *wittenagemot*, in whom, with the king, the legislature resided, the Anglo-Saxon government, in the period preceding the Norman conquest, was become extremely aristocratical; the royal authority was very limited; and the people, even if admitted to that assembly, were deemed of little or no importance and consideration. Upon the whole, notwithstanding the seeming liberty, or rather licentiousness, of the Anglo-Saxons, the great body even of the free citizens, in those ages, really enjoyed much less true liberty, than where the execution of the laws is the most severe, and where subjects are reduced to the strictest subordination and dependence on the civil magistrate. But though the general strain of the Anglo-Saxon government seems to have become aristocratical, there were still considerable remains of the ancient democracy, which, though insufficient to protect the lowest of the people, without the patronage of some great lord, might nevertheless give security, and some degree of dignity, to the gentry or inferior nobility. The administration of justice, in particular, by the courts of the decenary, the hundred, and the county, was well calculated to defend general liberty, and to restrain the power of the nobles. The county courts, in particular, where all the freeholders were admitted, formed a wide basis for the government, and furnished considerable checks on the aristocracy. However, the great influence of the lords over their slaves and tenants, the clientship of the burghers, the total want of a middle class of men, the extent of the monarchy, the loose execution of the laws, and the continued disorders and convulsions of the state, sufficiently evince, that the Anglo-Saxon government became at last extremely aristocratical; and the events, during the period immediately preceding the conquest, confirm this inference or conjecture. If we direct our views to a period much more ancient than that of the establishment of the Anglo-Saxon government, and prior to the invasion of the Romans, we shall find that the governments of the Britons, who were divided into many small nations or tribes, though monarchical, were free, as well as those of all the Celtic nations; and the common people seem to have enjoyed more liberty among them, than among the nations of Gaul, from whom they were descended.

Other writers have maintained, that the government, established by the Anglo-Saxon princes, had little more affinity with the present constitution, than the general relation common indeed to all the governments founded by the northern nations, that of having a king and a body of nobility; and the ancient Saxon government is said to be "left us in story," (according to the statement of sir William Temple—Int. to the Hist. of England,) but like to many antique, broken, or defaced pictures, which may still represent something of the costume and fashions of those ages, though little of the true lines, proportions, or resemblance." According to these writers, it is at the era of the conquest, that we are to look for the real foundation of the English constitution. From that period, says Spelman, "novus seclorum

nascitur ordo." William of Normandy, it is said, having defeated Harold, and made himself master of the crown, subdued the ancient fabric of the Saxon legislation; he exterminated, or expelled, the former occupiers of lands, in order to distribute their possessions among his followers, and established the feudal system of government, as better adapted to his situation, and indeed the only one of which he possessed a competent idea. A distinction, however, ought to be made between the government of William I., which was very tyrannical, and the constitution established under him in this kingdom, which was no absolute monarchy, but an ingraftment of the feudal tenures and other customs of Normandy upon the ancient Saxon laws of Edward the Confessor. He more than once swore to maintain those laws, and in the 4th year of his reign, confirmed them in parliament; yet not without great alterations, to which the whole legislature agreed, by a more complete introduction of the strict feudal law, as it was practised in Normandy.

But that the liberty of the subject was not destroyed by these alterations to the degree which some writers have supposed, plainly appears, says lord Lyttelton, (Hist. Henry II. vol. i. p. 59.) by the very statutes which William enacted; in one of which we find an express declaration, "that all the freemen in his kingdom should hold and enjoy their lands and possessions free from all unjust exactions and from all tallage; so that nothing should be exacted or taken of them but their free service, which they by right owed to the crown, and were bound to perform." It is further said, "that this was ordained and granted to them as an hereditary right for ever, by the common council of the kingdom; which very remarkable statute is justly styled by a learned author (Nathanael Bacon) *the first Magna Charta of the Normans*; and it extended no less to the English than to the Normans. But it was ill observed by William, who frequently acted as if his will had been the only law to both nations. It must be also allowed, that by the interposition of many *Mesne Lords* between the crown and the people, and by many offices of judicature and military command being rendered hereditary, which under the Saxons had been either elective, or granted for a short time, the constitution became more aristocratical than before, more unequally balanced, and, in some respects, more oppressive to the inferior orders of freemen. Nor was the condition of the nobles themselves to be envied. For there were certain burthens annexed to their system of fiefs, which, as they naturally grew out of that policy, were imposed on the highest vassals as well as on the lowest, and were more grievous than any which the Saxons had borne under their constitution. In process of time the excessive power arrogated and exercised by the king contributed to establish and guard the freedom of the British constitution; because this excess gave rise to the spirit of union and of concerted resistance. Possessed of extensive demesnes, the king found himself independent; and vested with the most formidable prerogatives, he crushed at pleasure the most powerful barons in the realm. It was, therefore, only by close and numerous confederacies that those barons could resist the tyranny of the sovereign; and for this purpose they were constrained to associate the people with themselves, and to render them partakers of public liberty. As acts and instances of tyranny on the part of the conqueror were multiplied, the confederacies of the barons and of their vassals became more general and more vigorous; and the people at large, instructed and inspired by their leaders, stipulated conditions for themselves, and insisted that, for the future, every individual should be intitled to the protection

tion of the laws. Thus did those rights, with which the lords had flung themselves, in order to oppose the tyranny of the crown, become a bulwark, which was, in time, to restrain their own. It was in the reign of Henry I., about forty years after the conquest, that the operation of these causes produced effect. As the nation had resolved to bestow the crown on a prince, who should acquire and hold it under no other claim than a *compact* with his people, the title of the king became thus a kind of security for the liberty of the subject. In order to give that liberty a more solid and lasting establishment, they demanded a charter; which Henry granted soon after his coronation, as he had sworn to do before he was crowned. By this he restored the Saxon laws which were in use under Edward the Confessor, with such alterations, or (as he styled them) *emendations*, as had been made in them by his father with the advice of his parliament; at the same time annulling all evil customs, and illegal sanctions, by which the realm had been unjustly oppressed. Some of those grievances were specified in the charter, and the redress of them was there expressly enacted. It also contained very considerable mitigations of those feudal rights claimed by the king over his tenants, and by them over theirs, which were either the most burthenfome in their own nature, or had been made so by an abusive extension. In short, all the liberty, that could well be consistent with the safety and interest of the lord in his fief, was allowed to the vassal by this charter, and the profits due to the former were settled according to a determined and moderate rule of law. "This," says Sir Henry Spelman, "was the original of king John's Magna Charta, containing most of the articles of it, either particularly expressed or in general, under the confirmation it gives to the laws of Edward the Confessor." These are therefore much mistaken, who have supposed all the privileges granted in *Magna Charta* were innovations extorted by the arms of rebels from king John;—a notion which seems to have been first taken up, not so much out of ignorance, as from a base motive of adulation to some of our princes in later times, who, endeavouring to grasp at absolute power, were desirous of any pretence to consider those laws, which stood in their way, as violent encroachments made by the barons on the ancient rights of the crown; whereas they were in reality restitutions and sanctions of ancient rights enjoyed by the nobility and people of England in former reigns;—or limitations of powers which the king had illegally and arbitrarily stretched beyond their due bounds. In some respects, says Lord Lyttelton, this charter of Henry I. was more advantageous to liberty than *Magna Charta* itself. Henry II. in a parliament held in London, A. D. 1155, granted a charter of liberties confirming that of his grandfather, Henry I., already mentioned. In consequence of the legal rights established by this excellent prince and the mixture of Saxon customs, which mitigated and tempered the Norman institution, the constitution of England was the best feudal system subsisting, at that time, in any part of the world. The honour of establishing in the English constitution itinerant judges belongs to Henry II., by whom this institution was revived and regularly settled in the 22d year of his reign, with the advice and concurrence of his parliament held at Northampton. The extension of trials by juries to civil causes may also be well esteemed a principal glory of this reign. Although some vestiges of that method of trial appear among the Anglo-Saxons; yet Spelman says, that the use of trials by 12 men before the conquest was rare, and did not prevail in any great degree, till the reign of Henry II. (See *JURY* and *Grand Assize*.) The despotic reign of king John excited through the kingdom a general conse-

deracy against him and constrained him, A. D. 1215, to sign the famous deed, commonly called the great charter or *Magna Charta*, which either granted or secured very important liberties and privileges to every order of men in the kingdom; to the clergy, to the barons, and to the people. (See *MAGNA CHARTA*.) By this charter, the rigour of the feudal laws was greatly mitigated in favour of the lords; and conditions were also stipulated in favour of the numerous body of the people, who had concurred to obtain it, and who claimed, with sword in hand, share in that security which it was designed to establish. This charter was confirmed in parliament by king Henry III., A. D. 1217, with the addition of some articles to prevent the oppressions by sheriffs; and also with an additional charter of forests. Accordingly, these famous charters have subsisted nearly in their original form, during many generations, as the peculiar favourites of the English nation; and they have been justly esteemed as the most sacred rampart to national liberty and independence. As they secured the rights of all orders of men, they were anxiously defended by all, and became the basis, in a manner, of the English constitution, and a kind of original contract, which both limited the authority of the king, and ensured the conditional allegiance of his subjects. King Edward I. who made it a rule in his own conduct to observe, except on extraordinary occasions, the privileges secured to the barons by the great charter, acquired a right to insist upon their observance of the same charter towards their vassals and inferiors. By the statute (25 Edw. I.) called *Confirmatio Chartarum*, (the confirmation of which was renewed eleven times in the course of his reign,) he directed the great charter to be allowed as the common law; all judgments contrary to it are declared void; copies of it are ordered to be sent to all cathedral churches, and read twice a year to the people; and sentence of excommunication is directed to be as constantly denounced against all those, who by word, deed, or counsel, act contrary to it, or in any degree infringe it. He also, in the statute *De Tallagio non Concedendo*, (24 Edw. I.) decreed, that no tax should be laid, nor imposed levied, without the joint consent of the lords and commons. This important statute, in conjunction with *Magna Charta*, forms the basis of the English constitution. Under Edward II. the commons, feeling their importance, began to annex petitions to the bills by which they granted subsidies; and this was the dawn of their legislative authority. Under Edward III., they declared they would not, in future, acknowledge any law to which they had not expressly assented. Soon after this, they exercised a privilege, in which consists, at this time, one of the great balances of the constitution: they impeached, and procured to be condemned, some of the first ministers of state. Under Henry IV., they refused to grant subsidies before an answer had been given to their petitions. In a word, the fundamental articles of our free constitution have been asserted and confirmed by a multitude of statutes, (Sir Edward Coke is said to reckon thirty-two,) from Edward I. to Henry IV. Then, after a long interval, they were corroborated by the *petition of right*, which was a parliamentary declaration of the liberties of the people, assented to by king Charles I., in the beginning of his reign. This famous act was soon followed by the still more ample concession made by that unhappy prince to his parliament, before the fatal rupture between them; and by the many salutary laws, particularly the *habeas corpus*, passed under Charles II. To these succeeded the *bill of rights*, or declaration delivered by the lords and commons to the prince and princess of Orange, 13th February, 1688; and afterwards enacted in parli-

ment, when they became king and queen: which declaration terminates with these remarkable words: "And they do claim, demand, and insist upon, all and singular, the premises, as their undoubted right and liberties." And the act of parliament itself (t W. & M. ft. 2. c. 2.) recognises "all and singular the rights and liberties, asserted and claimed in the said declaration, to be the true, ancient, and indubitable rights of the people of this kingdom." The Révolution of 1688 may, therefore, be justly deemed the third grand epoch in the history of the English constitution. The great charter had marked out the limits within which the royal authority ought to be confined; some outworks were raised in the reign of Edward I.; but it was at the Revolution that the circumvallation was completed. "It was at this era," says De Lolme, "that the true principles of civil society were distinctly specified and fully established. By the expulsion of a king, who had violated his oath, the doctrine of Resistance, that ultimate resource of an oppressed people, was confirmed beyond a doubt. By the exclusion of a family, hereditarily despotic, it was finally determined, that nations are not the property of kings. The principles of Passive Obedience, the divine and indefeasible right of kings; in a word, the whole scaffolding of false and superfluous notions, by which the royal authority had till then been supported, fell to the ground: and in the room of it were substituted the more solid and durable foundations of the love of order, and a sense of the necessity of civil government among mankind." The liberty of the press, the bulwark and guardian of a free constitution, was, properly speaking, established four years afterwards, in consequence of the refusal of the parliament to continue any longer the restrictions to which it had before been subject. Finally, the liberties of the British constitution were again asserted at the commencement of the last century, in the *act of settlement*, (12 & 13 W. III. c. 2.) by which the crown was limited to his present majesty's illustrious house; and some new provisions were added, at the same fortunate era, for better securing our law, religion, and liberties, which the statute declares to be "the birth-right of the people of England," according to the ancient doctrine of the common law.

The distinguishing excellence of the British constitution, which has been sometimes called a mixed government, and sometimes a limited monarchy, consists in its being formed by a combination of the three regular species of government, *viz.* the monarchy, residing in the King; the aristocracy, in the House of Lords, and the democracy or republic being represented by the House of Commons. To this purpose Cicero declares himself of opinion, (in his *Fragmenta, de rep.* l. 2.) "esse optimè constitutum rempublicam, quæ ex tribus generibus illis, regali, optimo, et populari, sit modicè confusa." As the executive power of the laws, in the British constitution, is lodged in a single person, they have all the advantages of strength and dispatch, that are to be found in the most absolute monarchy: and as the legislature of the kingdom is entrusted to three distinct powers, entirely independent of each other; and as this aggregate body, actuated by different springs, and attentive to different interests, composes the British parliament, and has the supreme disposal of every thing; no inconvenience can be attempted by either of the three branches, which will not, according to the theory of the constitution, be withstood by one of the other two: each branch being armed with a negative power, sufficient to repel any innovation which it shall think inexpedient or dangerous. Whereas, if the supreme power were lodged in any one of the branches separately, we must be exposed to the inconveniences of

either absolute monarchy, aristocracy, or democracy; and so want two of the three principal ingredients of good polity, either virtue, wisdom, or power. If it were lodged in any two of the branches, *e.g.* in the king and house of lords, our laws might be providently made, and well executed, but they might not have always the good of the people in view: if lodged in the king and commons, we should want that circumspection and mediatory caution, which the wisdom of the peers is to afford: if the supreme rights of legislature were lodged in the two houses only, and the king had no negative on their proceedings, they might be tempted to encroach upon the royal prerogative, or perhaps to abolish the kingly office, and thereby weaken (if not totally destroy) the strength of the executive power. But the constitutional government of this island is so admirably tempered and compounded, that nothing can endanger or hurt it, but destroying the equilibrium of power between one branch of the legislature and the rest. For if events should happen, that the independence of any one of the three should be lost, or that it should become subservient to the views of the other two, there would soon be an end of our constitution. The legislature would be changed from that, which (upon the supposition of an original contract, either actual or implied) is presumed to have been originally set up, by the general consent and fundamental act of the society: and such a change, however effected, is, according to Mr. Locke, (on Government, part ii. § 212.) who, says judge Blackstone, perhaps carries his theory too far, at once into an entire dissolution of the bands of government; and the people thereby reduced to a state of anarchy, with liberty to constitute to themselves a new legislative power.

Archdeacon Paley, in his discussion of this subject, has stated the expedients by which the British constitution provides for the interest of its subjects, and for its own preservation. With a view to the first of these purposes, it promotes the establishment of salutary public laws, by rendering every citizen of the state capable of becoming a member of the senate, and by investing every senator with the right of propounding to the deliberation of the legislature whatever law he pleases. In order to the attainment of this object, it provides such representatives of the people, with respect to their rank, condition, and character, the mode of their election, as well as the publicity and utility of their parliamentary deliberations, as shall be most likely to answer the end of their appointment, and to satisfy their constituents. (See COMMONS and PARLIAMENT.) For preventing destructive contentions for the supreme power, and for securing the advantages of decision, secrecy, and dispatch, which belong to the resolutions of monarchical councils, and other important objects, the constitution has committed the executive government to the administration and limited authority of our hereditary king. (See KING.) The British constitution has also guarded the safety of the people in the two articles of *taxation* and *punishment* by the most studious precautions. With regard to *taxation*, this business is exclusively reserved to the popular part of the constitution, who, it is presumed, will not tax themselves, nor their fellow-subjects, without being first convinced that the aids which they grant are necessary. The application of the public supplies is also watched with the same circumspection as the assessment. The national expenditure is accounted for in the house of commons, and computations of the charge, appropriated to any particular purpose, are previously submitted to the same tribunal. In the infliction of *punishment*, the power of the crown, and of the magistrate appointed by the crown, is confined by the most precise limitations: the offender's guilt, being submitted to the judg-

ment of 12 men, of his own order, and the nature and degree of the punishment being ascertained by fixed laws. In order to prevent arbitrary or clandestine confinement, with all its injurious consequences, the constitution has provided with extreme solicitude. The ancient writ of habeas corpus; the habeas corpus act of Charles II., and the practice and determinations of our sovereign courts of justice founded upon these laws, afford a complete remedy for every conceivable case of illegal imprisonment. (See these articles; and see also TREASON.) The constitution has also provided for its own preservation, by securing each part of the legislature in the exercise of the powers assigned to it, from the encroachment of the other parts. This security is sometimes called the *balance of the constitution*; and the political equilibrium, which this phrase denotes, consists in two contrivances—a balance of power, and a balance of interest. By the former is meant, that one part of the legislature possesses no power, the abuse, or excess of which, is not checked by some antagonistic power residing in another part. Thus, the power of the two houses of parliament to frame laws, is checked by the king's negative; and, on the other hand, the application of this negative is checked by the privilege which parliament possesses, of refusing supplies of money to the exigencies of the king's administration. The constitutional maxim "that the king can do no wrong," is balanced by another maxim, not less constitutional, "that the illegal commands of the king do not justify those who assist, or concur, in carrying them into execution;" and also, "that the acts of the crown acquire not any legal force, until authenticated by the subscription of some of its great officers." In connection with this maxim, we might mention the check which parliament holds over the administration of public affairs, in the practice of addressing the king, for the purpose of knowing by whose advice he resolved upon a particular measure, and of punishing the authors of that advice for their pernicious counsel. Again, the power of the crown to direct the military force of the kingdom, is balanced by the annual necessity of reporting to parliament for the maintenance and government of that force. The prerogative of the king, in declaring war, is checked by the privilege which the house of commons possesses, of granting or withholding supplies for carrying it on. The king's choice of his ministers, is controlled by the obligation he is under of appointing those men to offices in the state, who are found capable of managing the affairs of his government, with the two houses of parliament.

By the *balance of interest*, which accompanies and gives efficacy to the *balance of power*, is meant this, that the respective interests of the three estates of the empire, are so disposed and adjusted; that whichever of the three shall attempt any encroachment, the other two shall unite in resisting it. The exercise of arbitrary power, on the part of the king, would contract the power and privileges of the commons, degrade their dignity, and endanger their independence. It would also be no less formidable to the grandeur of the aristocracy than fatal to the liberty of the republic; as it would reduce the nobility from their hereditary participation in the national councils, which constitutes their true greatness, to the low and servile state of making a part of the empty pageantry of a despotic court. On the other hand, if the commons should trench upon the crown, the house of lords, attached to the monarchy which gives them their distinction, would instantly receive an alarm from every new stretch of popular power. If the nobles themselves should attempt to revive the superiority, which was exercised by their ancestors under the feudal constitution, the king and the people would alike remember how the one had been

insulted, and the other enslaved, by that barbarous tyranny. After all it should be remembered, that there is a wide difference between the constitution, or the theory of government, and the actual exercise of it, nor should those anomalies, or irregularities, which occur in peculiar circumstances, or periods of the public administration, be charged on the constitution itself. It is a well-known, and often cited observation of Montesquieu, in reference to the British constitution, "as all things have an end, the state we are speaking of (viz. England,) will lose its liberty, and perish. Have not Rome, Sparta, and Carthage perished? It will perish when the legislative powers shall be more corrupt than the executive." Spirit of Laws, vol. i. b. xi. chap. 6.

CONSTRUCTION, compounded of *con*, together; and *stringere*, to tie or close up; the act of binding, or drawing the parts of a thing close together.

CONSTRUCTOR CUNNI, in *Myology*, a name applied to the sphincter muscle of the vagina. See GENERATION, organs of.

CONSTRUCTOR IJHNI FAUCIUM, one of the muscles belonging to the soft palate. See DEGLUTITION.

CONSTRUCTOR NASI. See COMPRESSOR.

CONSTRUCTOR ORIS. See ORBICULARIS ORIS.

CONSTRICTORES PHARYNGIS. See DEGLUTITION.

CONSTRUCTION, in *Geometry*, the art or manner of drawing, or describing a figure, scheme, the lines of a problem, or the like. The equality of the lines of such a triangle, &c. is demonstrated from their construction.

CONSTRUCTION OF EQUATIONS, is the method of reducing a known equation into lines and figures; whereby the truth of the rule, canon, or equation, may be demonstrated geometrically. Or, it is the method of finding the roots or unknown quantities of an equation, by the geometrical constructions of right lines or curves, according to the order or rank of the equation. The roots of any equation may be determined; that is, the equation may be constructed, by the intersections of a straight line with another line or curve of the same dimensions with those of the equation to be constructed; for the roots of the equation are the ordinates of the curve at the points of intersection with the right line; and it is well known, that a curve may be cut by a right line in as many points as its dimensions amount to. Thus, a simple equation will be constructed by the intersection of one right line with another: a quadratic equation, or an affected equation of the second rank, by the intersections of a right line with a circle, or any of the conic sections, which are lines of the second order, and which may be cut by the right line in two points, which will give the two roots of the quadratic equation. A cubic equation may be constructed by the intersection of the right line with a line of the third order, &c. &c. But if, instead of the right line, some other line of a higher order be used; then the second line, whose intersections with the former are to determine the roots of the equation, may be taken as many dimensions lower as the former is taken higher. And, in general, an equation of any degree may be constructed by the intersections of two lines whose dimensions, multiplied together, produce the dimension of the given equation. Thus, the intersections of a circle with the conic sections, or of those with each other, will construct the biquadratic equations or those of the fourth power, because $2 \times 2 = 4$; and the intersections of the circle or conic sections with a

line of the third order, will construct the equations of the fifth and sixth powers, &c. &c. Hence it appears, that the method of constructing equations is different, according to the diversity of equations.

To construct a simple equation. The whole mystery consists in this, that the fractions, to which the unknown quantity is equal, be resolved into proportional terms: the method of which will be better shewn by examples than it can be taught by many rules.

1. Suppose $x = \frac{ab}{c}$, or $cx = ab$; then will $c : a :: b : x$, to be determined by the method of finding a fourth proportional.

2. If $x = \frac{b^2}{a}$, or $ax = b^2$; then $a : b :: b : x$, a third proportional to a and b .

3. Suppose $x = \frac{abc}{de}$; let $d : a :: b : \frac{ab}{d}$. This fourth proportional found, being called g ; $x = \frac{g \cdot c}{e}$, which is therefore found as in the first case.

4. Suppose $x = \frac{a^2 - b^2}{c}$, or $cx = a^2 - b^2$. Since $a - b$ is a fourth proportional to c , $a + b$ and $a - b$.

5. Suppose $x = \frac{ab}{c} + \frac{ad}{be}$. Find, as before, $g = \frac{ab}{c}$, and $f = \frac{ad}{be}$. Then will $x = g + f$ be the sum of the lines g and f .

6. Suppose $x = \frac{a^2b + bcd}{af + cg}$. Seek $\frac{cg}{a}$, and let $f + \frac{cg}{a} = b$; then will $af + cg = ab$; consequently, $x = \frac{a^2b + bcd}{ab}$. Thus is the present case brought to the preceding one.

7. Suppose $x = \frac{a^2b - bad}{af + bc}$. Find $\frac{af}{b}$, and make $\frac{af}{b} + c = b$; then will $af + bc = bb$. Hence, $x = \frac{a^2b - bad}{bb} = \frac{a^2 - ad}{b}$. Consequently, $bx = a^2 - ad = a \times a - d$; and $b : a :: a - d : x$.

8. Suppose $x = \frac{a^2 + b^2}{c}$, or $cx = a^2 + b^2$. Construct the triangle ABC (*Plato's Analysis, fig. 8.*) whose side $AB = a$, $BC = b$; then will $AC = \sqrt{a^2 + b^2}$. Let $AC = m$; then will $a^2 + b^2 = m^2$. And therefore $x = \frac{m^2}{c}$; consequently, $c : m :: m : x$, a third proportional to c and m .

9. Suppose $x = \frac{a^2 - b^2}{c}$. On AB (*fig. 9.*) = a , describe a semicircle, and therein set off $AC = b$. Since the triangle ACB is rectangular; $CB = \sqrt{a^2 - b^2}$. Let $CB = m$; then will $x = \frac{m^2}{c}$; consequently, $c : m :: m : x$.

10. Suppose $x = \frac{a^2b + bcd}{af + bc}$. Say, $b : a :: f : \frac{fa}{b}$; and let $\frac{fa}{b} + c = b$; then will $bc + af = bb$. Hence, $x = \frac{a^2b + bcd}{bb} = \frac{a^2 + cd}{b}$. Find betwixt $AC = c$ (*fig. 10.*) and $CB = d$,

a mean proportional $CD = \sqrt{cd}$. Let $CE = a$; then will $DE = \sqrt{a^2 + cd}$. Call this m ; then will $x = \frac{m^2}{b}$; consequently, $b : m :: m : x$.

To construct a quadratic equation geometrically. Since quadratic equations may be reduced to simple ones, those may likewise be constructed from the methods already laid down: for if the equation be pure, $x^2 = ab$; then will $a : x :: x : b$; wherefore we shall find $x = \sqrt{ab}$; and therefore if between $AC = a$, and $BC = b$, we find a mean proportional DC , this will be equal to x .

If the quadratic be affected, *e. g.* $x^2 + 2ax = b^2$, then form the right-angled triangle ACB (*fig. 11.*), whose base AB is a , and perpendicular BC is b ; and on the centre A , with the radius AC , describe the semicircle DCE , then will DB and DE be the two roots, *viz.* the affirmative and the negative, of the given quadratic equation. For by resolving the quadratic, we shall have $x = a \pm \sqrt{b^2 + a^2} = AB \pm \sqrt{BC^2 + AB^2} = AB \pm \sqrt{AC^2} = AB \pm AC$, *i. e.* DB or BE , with their proper signs. If the quadratic be $x^2 - 2ax = b^2$, then the construction will be the same with that of the preceding one, $x^2 + 2ax = b^2$. But if the form be $2ax - x^2 = b^2$; form a right-angled triangle FGH (*fig. 12.*), whose hypotenuse FG is a , and perpendicular GH is b ; then with the radius FG and centre F describe a semicircle IGK ; and IH and HK will be the two roots of the given equation $2ax - x^2 = b^2$, or $x^2 - 2ax = b^2$. *Maclaurin's Algebra, part iii. chap. 2. and Simpson's Algebra, p. 269.*

To construct cubic and biquadratic equations. The roots of a biquadratic equation may be determined by the interfections of two conic sections; for the equation by which the ordinates from the four points in which these conic sections may cut one another can be determined, will arise to four dimensions; and the conic sections may be assumed in such a manner, as to make this equation coincide with any proposed biquadratic: so that the ordinates from these four interfections will be equal to the roots of the proposed biquadratic.

If one of the interfections of the conic section falls upon the axis, then one of the ordinates vanishes, and the equation by which these ordinates are determined, will then be of three dimensions only, or a cubic; to which any proposed cubic equation may be accommodated. So that the three remaining ordinates will be the three roots of that proposed cubic. The conic sections for this purpose should be such as are most easily described. The circle may be one, and the parabola is usually assumed for the other.

Let APE (*fig. 13.*) be the common Apollonian parabola. Take on its axis the line AB = half of its parameter. Let C be any point in the plane of the parabola, and from it as a centre describe, with any radius CP , a circle meeting the parabola in P . Let PM , CD , be perpendiculars on the axis in M and D , and let CN , parallel to the axis, meet PM in N .

Then will always $C P^2 = C N^2 + N P^2$ (47 E. 1.)

Put $C P = a$, the parameter of the parabola = b , $A D = c$, $D C = d$, $A M = x$, $P M = y$.

Then $C N^2 = (x + c)^2$, $N P^2 = (y + d)^2$; and $x + c + y + d = a$. $(x - c)^2 = a^2$. ($x - c$ is the difference of x and c indefinitely, whichever of the two is greatest. That is, $x^2 \pm 2cx + c^2 + y^2 \pm 2dy + d^2 = a^2$. But from the nature

CONSTRUCTION.

ture of the parabola, $y^2 = bx$, and $x^2 = \frac{y^4}{b^2}$; substituting therefore these values for x^2 , and x , it will be $\frac{y^4}{b^2} \pm \frac{2cy^2}{b} + y^2 \pm 2dy + c^2 + d^2 - a^2 = 0$. Or, multiplying by b^2 , $y^4 \pm 2bc + b^2 \times y^2 \pm 2d^2 \times y + c^2 + d^2 - a^2 \times b^2 = 0$. Which may represent any biquadratic equation that wants the second term; since such values may be found for a, b, c , and d , by comparing this with any proposed biquadratic, as to make them coincide. And then the ordinates from the points, P, P, P, P, on the axis will be equal to the roots of that proposed biquadratic. And this may be done, though the parameter of the parabola (*viz.* b) be given: that is, if you have a parabola already made or given, by it alone you may resolve all biquadratic equations, and you will only need to vary the centre of your circle and its radius.

If the circle described from the centre, C, pass through the vertex A, (*fig.* 14.) then $CP^2 = CA^2 = CD^2 + AD^2$, that is, $a^2 = d^2 + c^2$; and the last term of the biquadratic ($c^2 + d^2 - a^2$) will vanish; therefore, dividing the rest by y , there arises the cubic, $y^3 \pm 2bc + b^2 \times y \pm 2d^2 = 0$. Let the cubic equation proposed to be resolved be $y^3 \pm py \pm r = 0$. Compare the terms of these two equations, and you will have $\pm 2bc + b^2 = \pm p$, and $\pm 2d^2 = \pm r$, or, $\mp c = \frac{b}{2} \mp \frac{p}{2b}$, and $d = \pm \frac{r}{2b}$. From which you have this construction of the cubic $y^3 \pm py \pm r = 0$, by means of any given parabola APE.

From the point B take in the axis (*forward, if the equation has -p, but backwards, if p is positive*) the line BD = $\frac{p}{2b}$; then raise the perpendicular DC = $\frac{r}{2b}$, and from C describe a circle passing through the vertex A, meeting the parabola in P, so shall the ordinate PM be one of the roots of the cubic $y^3 \pm py \pm r = 0$.

The ordinates that stand on the same side of the axis with the centre C are negative or affirmative, according as the last term r is negative or affirmative; and those ordinates have always contrary signs that stand on different sides of the axis. The roots are found of the same value, only they have contrary signs, when r is positive as when it is negative; the second term of the equation being wanting.

A cubic equation, that has all its roots equal, may be constructed by a circle. Let the radius OB (*fig.* 15.) = R, the sine EF = s , GH the sine of the arc GB or 3 BE. Then, by trigonometry, $3s - \frac{4s^3}{3R} = GH$. Draw CD parallel to AB, and put SF = c , ES = x , GH = b ; then $c + x = s$, whence $3 \times c + x - \frac{4}{3R} \times (c + x)^3 = b$; and this reduced will give $x^3 + 3cx^2 + 3ccx + c^3 - \frac{3}{4}RR + \frac{1}{4}bRR = 0$.

$$-\frac{3}{4}RR + \frac{1}{4}bRR = 0.$$

$$-\frac{3}{4}RR$$

Suppose this cubic equation to be given; *viz.* $x^3 + px^2 + qx + r = 0$. Comparing this with the former, and equating the coefficients, we shall have $p = 3c$, and $c = \frac{1}{3}p$; also $q = 3cc - \frac{3}{4}RR = \frac{1}{3}p^2 - \frac{3}{4}RR$; whence

$$R = \frac{2}{3} \sqrt{pp - 3q}, \text{ and } r = c^2 + \frac{1}{4}bRR - \frac{3}{4}cRR,$$

and $b = \frac{9r - pq}{pp - 3q} + \frac{2}{3}p$. Hence we obtain the following rule for the solution of the given equation $x^3 + px^2 + qx + r = 0$. With the radius $\frac{2}{3} \sqrt{pp - 3q}$ describe the circle BGA K (*fig.* 16.) Draw the diameter AB, and CD parallel to it at the distance of $\frac{1}{3}p$; above it, if it be $+p$, but below it, if it be $-p$. Draw also ZG parallel to AB, at the distance $\frac{9r - pq}{pp - 3q} + \frac{2}{3}p$, above it, if it be affirmative, or below it, if negative. Let it cut the circle in G.

Take the arc BP = $\frac{1}{3}BG$, and make PQ = QK = KP. From the points P, Q, K, let fall perpendiculars upon the line CD, which will be the roots of the equation; the affirmative above the line, and the negative below it. N. B. If $3q$ be greater than pp , the equation is impossible; for in this case the equation has two impossible roots. Also,

if $p = 0$, then the radius of the circle OB = $\frac{2}{3} \sqrt{-3q}$, and CD coincides with AB; and the distance of ZG from AB is $-\frac{3r}{q}$. And if q be affirmative, the equation is impossible. These constructions are easy: *e.g.* 1. Let $x^3 + 9x^2 - 22x - 120 = 0$. Here the radius OB = $\frac{2}{3}$

$\sqrt{pp - 3q} = \frac{2}{3} \sqrt{81 + 60} = 8.0829$, and $\frac{1}{3}p = 3$, the distance of CD above AB. And $\frac{9r - pq}{pp - 3q} + \frac{2}{3}p = \frac{-1080 + 198}{81 + 66} + \frac{2}{3} \times 6 = -6 + 6 = 0$, the distance of GZ from AB, which therefore coincides with it; and the arc BG, and also its third part is 0, and P falls on B; and making PQ = QK = KP, and letting fall perpendiculars on CD, we shall have PS = -3, QT = +4, and KT = -10, the three roots required.

E. G. 2. Suppose $x^3 - 17x^2 + 82x - 120 = 0$. The radius OB (*fig.* 18.) = $\frac{2}{3} \sqrt{289 - 246} = 4.37$; $\frac{1}{3}p = -5.66$, the distance of CD below AB, and $\frac{9r - pq}{pp - 3q}$

$+\frac{2}{3}p = \frac{-1080 + 1394}{289 - 246} - \frac{34}{3} = 7.302 - 11.333 = -4.031$, the distance of GZ below AB. Take BP the third part of BG, and making PQ = QK = KP; and measuring the perpendiculars upon CD, we have PS = +4, QT = +10, and KV = +3, the roots of the equation.

E. G. 3. Let $y^3 - 13y + 12 = 0$. In this example $p = 0$, and therefore CD (*fig.* 19.) coincides with AB; and the radius OB = $\frac{2}{3} \sqrt{-3q} = \frac{2}{3} \sqrt{39} = 4.18$; and $-\frac{3r}{q} = \frac{-36}{-13} = 2.77$, the distance of ZG above AB. Take the arc BP = $\frac{1}{3}$ arc BG, and make PQ = QK = KP, and let fall perpendiculars on AB; then PS = +1, QT = +3, and KV = -4, will be the roots required. ff

CONSTRUCTION.

If the roots of a cubic equation, $x^3 - qx + r = c$, be possible, they may be found by means of a table of cosines. Let $\triangle DAC$ (fig. 20.) be an angle whose cosine, to the radius m , is x ; in AD take $AB = m$; from B , as a centre, with the radius BA , describe a circle cutting AM in C , and from C , with the same radius, describe a circle cutting AD in D ; join BC , CD , and draw BK , DM , at right angles to AM , and CL at right angles to AD . Then, the triangles BAC and BCD being isosceles, the angles BAC and BCA are equal, as also CBD and CDB ; and the perpendiculars BK , CL , bisect the bases AC , BD . Also, the angle $DBC = BAC + BCA = 2BAC$; and the angle $DCM = CAD + CDA = CAD + CBD = CAD + 2CAD = 3CAD$. Let CM , the cosine of the angle DCM to the radius m , be called c ; thence, from the similar triangles ABK , ACL ,

$$AB : AK :: AC : AL, \text{ or } m : x :: 2x : \frac{2x^2}{m} = AL;$$

$$\text{and } AL - AB = \frac{2x^2}{m} - m = BL; \text{ hence } AD, \text{ or } AL + BL = \frac{4x^2}{m} - m;$$

$$\text{Again, } AB : AK :: AD : AM, \text{ or } m : x :: \frac{4x^2}{m} - m : \frac{4x^3 - m^2x}{m^2} =$$

$$AM, \text{ and } AM - AC = CM = \frac{4x^3}{m^2} - 3x = c; \text{ therefore } 4x^3 - 3m^2x = m^2c, \text{ and } 4x^3 - 3m^2x - m^2c = 0.$$

Let the equation $4x^3 - 3m^2x - m^2c = 0$, or $x^3 - \frac{3m^2}{4}x - \frac{m^2c}{4} = 0$, be made to coincide with the equation

$$x^3 - qx + r = 0; \text{ that is, let } \frac{3m^2}{4} = q, \text{ and } \frac{m^2c}{4} = -r, \text{ or } m = \sqrt{\frac{4q}{3}} \text{ and } c = -\frac{3r}{q}; \text{ then, from a table of}$$

cosines, find the angle whose cosine is $-\frac{3r}{q}$ to the radius

$$\sqrt{\frac{4q}{3}}, \text{ and the cosine of one-third of this angle, to the same radius, is one value of } x. \text{ Hence it follows, 1. That if } A \text{ be the arc whose cosine is } c, \text{ and } P \text{ the whole circumference, } c \text{ is also the cosine of } A + P, \text{ or } A + 2P; \text{ therefore the cosines of } \frac{A + P}{3}, \text{ and } \frac{A + 2P}{3}, \text{ are also values}$$

of x . 2. Since the radius is greater than the cosine,

$$\sqrt{\frac{4q}{3}} \text{ is greater than } -\frac{3r}{q}, \text{ or } \frac{4q}{3}; \text{ is greater than } \frac{9r^2}{q^2}; \text{ that is, } \frac{q^3}{27} \text{ is greater than } \frac{r^2}{4}; \text{ therefore this solution can only be}$$

applied when the roots of the cubic equations are possible.

Vieta's in his "Canonica Rerensioe affectuum geometricarum," and Ghettaldus, in his "Opus posthumum de Resolutione et Compositione Mathematica," and also Des Cartes, in his "Geometria," have shewn how to construct simple and quadratic equations. Des Cartes has also shewn how to construct cubic and biquadratic equations, by the intersection of a circle and parabola, and the same has been done by Baker in his "Clavis Geometrica," or "Geometrical Key." (See the article BAKER.) But the genuine foundation of all their constructions was first laid and explained by Salsus in his "Mesolabium," pars 2. This doctrine is also treated of by De la Hire, in a small treatise, entitled, "La Construction des Equations Analytiques," annexed to his "Conic Sections." Sir Isaac Newton, at

the end of his "Algebra," has given the construction of cubic and biquadratic equations mechanically; and also by the conchoid and cissoid, as well as the conic sections. See also Dr. Halley's construction of cubic and biquadratic equations, and Colson's in the Philosophical Transactions; the Marquis de l'Hospital's "Traité Analytique des Sections Coniques," lib. iv.; and Maclaurin's "Algebra," part iii. chap. 3. However, the intent of these geometrical constructions is more readily answered by the method of extracting roots by converging series and approximation; and therefore this mode of obtaining them is very much less safe.

CONSTRUCTION, or *Syntax*, in *Grammar*, denotes the arranging and connecting of the words of a sentence, according to the rules of the language. See SYNTAX.

The construction is generally more simple, easy, and direct, in the modern tongues than in the ancient: we have very few of those inversions which occasion so much embarrassment and obscurity in the Latin: our thoughts are usually delivered in the same order in which the imagination conceives them: the nominative case, for instance, always precedes the verb, and the verb goes before the oblique cases it governs.

The Greeks and Latins, M. St. Evremont observes, usually end their periods, where, in good sense and reason, they should have begun them; and the elegance of their language consists, in some measure, in this capricious arrangement, or rather in this transposal and disorder of the words.

Construction is either *simple* or *figurative*. *Simple*, is that wherein all the terms, or parts of the discourse, are placed in their natural order.

Figurative construction, is that wherein we recede from this simplicity, and use certain expressions, shorter, and more elegant than nature affords.

The syntax, or construction of words, is distinguished into two parts, *concord* and *government*, or *regimen*.

CONSTRUCTION of *deeds* and *wills*, in *Law*, is regulated by some general rules and maxims, which have been laid down by courts of justice. These are, 1. That the construction be favourable, and as near the minds and apparent intents of the parties, as the rules of law will admit. For the maxims of law are, that "verba intentioni debent inferri;" and "benigne interpretatur chartas propter simplicitatem laicorum." And therefore the construction must also be reasonable, and agreeable to common understanding. 2. That "quoties in verbis nulla est æquivocitas, ibi nulla expositio contra verba fienda est;" but that where the intention is clear, too minute a strictness is not laid on the strict and precise signification of words; "nam qui interpret in litera, hæret in cortice." Therefore, by a grant of a remainder a reversion may well pass, and *in converso*. Another maxim of law is, that "mala grammatica non vitiant chartas;" neither false English nor false Latin will destroy a deed. 3. That the construction be made upon the entire deed, and not merely upon disjointed parts of it. "Nam ex antecedentibus et consequentibus fit optima interpretatio." And therefore that every part of it be (if possible) made to take effect; and no word but what may operate in some shape or other. "Nam verba debent intelligi cum effectu, ut res magis valeat quam pereat." 4. That the deed be taken most strongly against him that is the agent or contractor, and in favour of the other party. "Verba fortius accipiuntur contra proferentem." As, if tenant in fee-simple grants to any one an estate for life, generally, it shall be construed an estate for the life of the grantee. 5. That, if the words will bear two senses, one agreeable to, and another

other against law, that sense be preferred which is most agreeable to it. As, if tenant in tail lets a lease to have and to hold during life generally, it shall be construed to be a lease for his own life only, for that stands with the law; and not for the life of the lessee, which is beyond his power to grant. 6. That, if there be in a deed two clauses to totally repugnant to each other, that they cannot stand together, the first shall be received, and the latter rejected. In this respect it differs from a will: for there, of two such repugnant clauses the latter shall stand. In both cases, however, we should endeavour to reconcile them. 7. That a devise be most favourably expounded, to pursue if possible the will of the donor, who, for want of advice or learning, may have omitted the legal or proper phrases. Hence the law often dispenses with the want of words in devises, that are absolutely requisite in all other instruments. Thus, a fee may be conveyed without words of inheritance; and an estate-tail without words of procreation. By a will also an estate may pass by mere implication, without any express words to direct its course. With regard to a will, in this respect, there is no distinction between the rules of law and of equity; for the will, being considered in both courts in the light of a limitation of uses, is construed in each with equal favour and benignity, and expounded rather on its own particular circumstances, than by any general rules of positive law. Blackit. Comm. b. ii. ch. 23.

CONSTRUCTION of Statutes, comprehends the following rules: 1. In the construction of remedial statutes there are three points which require consideration, *viz.* the old law, the mischief, and the remedy; that is, how the common law stood at the making of the act: what the mischief was, for which the common law did not provide; and what remedy the parliament hath provided to cure this mischief. And it is the business of the judge so to construe the act, as to suppress the mischief and advance the remedy. An instance may be specified in the restraining stat. of 13 Eliz. c. 10. By the common law, ecclesiastical corporations might let as long leases as they thought proper; the mischief was, that they let long and unreasonable leases, to the impoverishment of their successors: the remedy applied by the statute was the making void all leases by ecclesiastical bodies for longer terms than three lives, or 21 years. In the construction of this statute, it is held, that leases, though for a longer term, if made by a bishop, are not void during the bishop's continuance in his see; or, if made by a dean and chapter, they are not void during the continuance of the dean: for the act was made for the benefit and protection of the successor. The mischief is, therefore, sufficiently suppressed, by vacating them after the determination of the interest of the grantors; but the leases, during their continuance, being not within the mischief, are not within the remedy. 2. A statute, which treats of things or persons of an inferior rank, cannot, by any *general words*, be extended to those of a superior. Thus, a statute, treating of "deans, prebendaries, parsons, vicars, and others having spiritual promotion," is held not to extend to bishops, though they have spiritual promotion; deans being the highest persons named, and bishops being of a still higher order. 3. Penal statutes must be construed strictly. Thus, by the statute 14 Geo. II. c. 6. stealing sheep, or other cattle, was made felony, by benefit of clergy: but *other cattle* being considered as too loose an expression for creating a capital offence, the act was held to extend to nothing but mere sheep. In the next sections it was therefore found necessary to make another statute, 15 Geo. II. c. 34. extending the former to bulls, cows, oxen, steers, bullocks, heifers, calves, and lambs, by name. 4. Statutes against frauds are to be

liberally and beneficially expounded. 5. One part of a statute must be so construed by another, that the whole may (if possible) stand: "ut res magis valeat, quam pereat." As if land be vested in the king and his heirs by act of parliament, saving the right of A.; and A. has at that time a lease of it for three years; here A. shall hold it for his term of three years, and afterwards it shall go to the king. 6. A saving, totally repugnant to the body of the act, is void. If, therefore, an act of parliament vests land in the king and his heirs, saving the right of all persons whomsoever; or vests the land of A. in the king, saving the right of A.: in either of these cases the saving is totally repugnant to the body of the statute, and (if good) would render the statute of no effect or operation; and therefore the saving is void, and the land vests absolutely in the king. 7. Where the common law and a statute differ, the common law gives place to the statute; and an old statute gives place to a new one: and this upon a general principle of universal law that "leges posteriores priores contrarias abrogant;" consonant to which it was laid down by a law of the Twelve Tables at Rome, that "quod populus postremum jussit, id jus ratum esto." This is to be understood only when the latter statute is couched in negative terms, or where its matter is too clearly repugnant, that it necessarily implies a negative. But if both acts be merely affirmative, and the substance such that both may stand together, here the latter does not repeal the former, but they shall both have a concurrent efficacy. 8. If a statute, that repeals another, is itself afterwards repealed, the first statute is hereby revived, without any formal words for that purpose. 9. Acts of parliament, derogatory from the power of subsequent parliaments, bind not. 10. Acts of parliament, that are impossible to be performed, are of no validity; and if out of them arise collaterally any absurd consequences, manifestly contradictory to common reason, they are, with regard to those collateral consequences, void. Some have laid down this rule more largely, alleging that acts of parliament, contrary to reason, are void. We may further observe, that equity is frequently called in to assist, to moderate, and to explain positive laws. Nevertheless, our courts of equity are only conversant in matters of property. For the freedom of our constitution will not allow, that in criminal cases a power should be lodged in any judge, to construe the law otherwise than according to the letter. This caution, while it admirably protects the public liberty, can never bear hard upon individuals. A man cannot suffer more punishment than the law assigns, but he may suffer less. The laws cannot be strained by partiality to inflict a penalty beyond what the letter will warrant; but in cases where the letter induces any apparent hardship, the crown has the power to pardon. Blackit. Com. vol. i. Introd. § 3.

CONSTRUCTION MILITARY. This term, in its general and unlimited acceptance, extends to the constructing of every sort of military work. But it is commonly and peculiarly applied to the construction of the different parts of the various systems of fortification that have been delivered by writers on the subject in different nations and languages. And to this application of it we shall chiefly attend.

Fear and necessity must have first given rise to works of defence or fortification, of which the object originally was safety or security. And although there must have been quarrels ever since there have been men, we have every reason to suppose that the erection of works of defence, even of the simplest kind, were subsequent to the sithing and hunting state of society, and even in a great measure to that of the pastoral.

CONSTRUCTION.

The discovery of America, which exhibited men in a much simpler state of society than any that was recorded prior to that event in history, sacred or profane, afforded no specimens or traces of such works among tribes who had not formed some sort of villages, and become partly, at least stationary, by paying some attention to agriculture. The form and structure of works of defence, varied gradually with the means and the modes of attacking them. At first, a simple row of pickets, or a ditch, with that addition, was deemed sufficient. Afterwards, in woody countries (and all countries have been more or less covered with woods) an enceinte or enclosure of solid timber was made use of. Sometimes the walls round towns were raised with beams, earth, and stones. This mode of erecting them appears to have prevailed among the Gauls, in the time of Julius Cæsar, who, in the 23d chapter or section of his seventh book, "De Bello Gallico," expresses himself on the subject in the following words.

"*Maris autem omnibus Gallicis hæc fere forma est. Trabes directæ perpetuæ in longitudinem, paribus intervallis, distantes inter se binos pedes, in solo collocantur. Eæ revincuntur introrsus, et multo aggere vestiuntur. Eæ autem, quæ diximus intervalla grandibus in fronte faxis efficiuntur. Iis collocatis et coagmentatis, alius insuper ordo adijcitur, ut idem illud intervallum fervetur. neque inter se contingant trabes, sed paribus intermissis spatiiis singulæ singulis faxis intersectis arte continentur: sic deinceps omne opus contextitur dum juxta muri altitudinem expleatur. Hoc quum in speciem varietateque opus deforme non est, alternis trabibus aut faxis, quæ rectis lineis suos ordines servant, tum ad utilitatem et defensionem urbium summam habet opportunitatem, quod et ab incendio lapis, et ab ariete matris defendit, quæ perpetuis trabibus pedes quadragenos, per unquam introrsus revincta, neque perrumpi neque dirahi potest.*"

In some parts of Russia, there are even at this day towns defended by wooden walls; and in America there are some works, even with small bastions, composed entirely of wood or timber.

In countries, however, either considerably cleared, or not abundantly supplied with timber, stones come chiefly, and almost solely, to be made use of for erecting walls round their towns and cities. These walls were at first simple stone enclosures, of a sufficient height to prevent surprises, and thickness at top for three or four men to walk a-breast. But having no flanking defences, they occasioned dead or unsafe parts throughout their whole extent; by which means the assailants, as soon as they got near the foot of them, were almost as much screened or covered from the view of those who defended them, as they on the other hand were from theirs. To remedy this inconvenience and defect, openings were made on the top of such a wall, and loopholes. This contrivance, however, did not afford a complete remedy, or entirely remove the defect. For the opposite sides of every adjacent two of these openings and loopholes, which were wider within than without, produced, formed with the front of the wall a triangular space, that could not be seen or commanded from them. To remove this defect, square towers were added to the wall at distances from one another, suited to the missile weapons then in use, with one face of each looking towards the field. This mode, however, of enclosing towns, was still found to be imperfect and defective, as the face of each of those towers that fronted the field, could not be seen from any other part, and of course could not be defended. Round towers were therefore introduced instead of them, as creating fewer dead parts,

and as being better calculated for resisting battering engines. This method was practised a long time, and would, in all human probability, have continued in use had it not been for the invention of gun-powder, which changed the mode of attacking places, and of course rendered alterations in that of defending them necessary. Even after the application of that powerful and inflammable substance to military purposes, bulwarks, or large bastions, of a round form, continued for a long time in use. Most of these have been either taken down, or charged into angular ones. But several still remain, and are to be seen in different parts of Europe.

The intestine wars which harassed Italy for a length of time, taught the Italians experience in war, and the necessity of attending to every thing that contributed to improve the art of defence. They were accordingly the first people in Europe who fixed the idea of modern fortification, and reduced it to a sort of system. Unaccustomed then, however, to the effects of shells, and a numerous artillery, they confined their improvements chiefly to the covering of two guns in each flank, for disputing the passage of the ditch.

The war, which afterwards broke out in the Low Countries, and continued during eighty years with an extraordinary degree of valour and obliquity, and a destruction of the human race, of which there are but few examples, contributed a good deal to the advancement of this science. The Dutch, who alone, and unsupported, had to oppose for a long time the whole preface of a power so formidable as that of Spain then was, made great progress in the attack and defence of places. And it is from that time that we ought to date the epoch of the superiority which the former of these has acquired over the latter.

The following is Errard's method of construction. He fortifies inwards; and his line of defence isasant in all figures. He makes his flank from the square, up to the octagon, inclusive, perpendicular to the face of the bastion. But, in all other polygons, he makes it perpendicular to the curtain.

The flanked angle, or salient angle of the bastion, is, in the square, equal to sixty degrees, in the pentagon, to eighty, and in all other polygons, to ninety degrees.

For instance, let *AB* (*Plate V. Fortification, fig. 1.*) be the side of a hexagon, of which *O* is the centre. Draw the radii *AO*, *BO*, at the extremities *A*, *B*, of the exterior side *AB*, make the angles *OAF*, *OBE*, each equal to forty-five degrees. From the points *A*, *B*, draw right lines *AE*, *BF*, bisecting these angles, and meeting *BE*, *AF*, in the points *E*, *F*. Then these last-mentioned points *E*, *F*, will be the terminations of the curtain *EF*, of the lines of defence *AF*, *BE*, and of the flanks *EC*, *FD*, which in all figures, up to the octagon inclusive, are by this construction perpendicular to *AF*, *BE*, the lines of defence, but in all other polygons to *EF*, the curtain. If the same construction be made on each of the other sides of the hexagon, it will be fortified. And if from *C*, *D*, the angles of the epaules or shoulders, right lines be drawn parallel to theasant lines, or lines of defence *AF*, *BE*, we get the counterescarp of the ditch. On the inside he makes a rampart equal in breadth to the length of one of the flanks.

Since the line *AB*, in the preceding figure, is supposed to represent the side of a regular hexagon inscribed in a circle, the angle *AOB* of the centre is equal to 60 degrees, the angle *ABK* of the polygon is equal to 120 degrees; the flanked angles, or angles of the bastions *LAC*, *DBM*,

CONSTRUCTION.

D B M, are each of them equal to a right one, or 90 degrees. The angles of the epaules or shoulders ACE, B D F, are also each of them equal to a right angle. The angle *diminué* A F G, or B E H, or the angle A B E, or B A F, formed by the exterior side, and either line of defence being equal to the difference between 60 and 45 degrees, is of course equal to 15 degrees. The angle C E F, or D F E of the flank, is equal to 75 degrees, and the flanking angle C N D, is equal to 150 degrees. But since the angle C A E, which is half the flanked angle, or angle of the bastion, is equal to 45 degrees, and is by construction bisected by the right line A E, each of the angles C A E, E A G is equal to 22° 30'. And the angle A E C, the complement of C A E to 90°, is consequently equal to 67° 30'. The angle A E G is therefore equal to 37° 30', the angle A E F to 142° 30'; the angle A G F to 120 degrees, and the angle E A B to 37° 30'. Also the angle A E B is equal to 127° 30'.

Thus then all the necessary angles are known for calculating the different parts of the construction. For the exterior side A B being given, the line of defence A F or B E is easily found by means of the triangle A F B, or the triangle A E B, by the following analogies.

As the sine of the angle A F B
Is to the sine of the angle A B F,
So is the side A B
To the side A F.
As the sine of the angle A E B
Is to the sine of the angle B A E,
So is the exterior side A B
To the line of defence B E.

And the right line A E, or its equal B F, is found by the following analogy.

As the sine of the angle A E B
Is to the sine of the angle A B E,
So is the exterior side A B
To the right line A E or B F.

And as the angle A C E is a right one, we get the face A C of the bastion, and the flank C E, by means of A E, and the following analogies.

As radius
Is to the sine of the angle A E C,
So is the right line A E, or its equal B F,
To A C, the face of the bastion, or its equal B D.

And,

As radius
Is to the sine of the angle C A E,
So is the right line A E, or its equal B F,
To the flank C E, or its equal D F.

The perpendicular to the exterior side A B, or the rectilinear distance from the middle of it, to the point N, the intersection of the rasant lines, or lines of defence, is determined by this analogy.

As radius
Is to the tangent of the angle B A N, or A B N,
So is half the exterior A B
To the perpendicular distance from the middle thereof, to the point N.

By means of the flank, the curtain is found by the following analogy.

As radius
Is to the secant of the angle C E F, or D F E,
So is the flank C E, or D F,
To the curtain E F.

And the capital A G of the bastion is found by this analogy.

As the sine of the angle A C E
Is to the sine of the angle A E G,
So is the right line A E
To the capital A G of the bastion.

In like manner, the demi-gorge E G, or F H, is found by the following analogy.

As the sine of the angle A G E
Is to the sine of the angle E A C,
So is the right line A E, or its equal B F.
To the demi-gorge G E, or its equal F H.

The calculation of these different parts will be similar when the flank is perpendicular to the curtain, instead of the lines of defence as in polygons above an octagon, which is effected by taking the right lines N C, N D, equal, respectively, to the lines N E, N F. The flanks then are longer and better.

This author assigns no reason drawn either from the nature of the polygons, or their capability of being embraced or defended for the length of his perpendicular or the magnitude of the angle formed by an exterior side, and a line of defence. And, as in all polygons, from the hexagon upwards, the flanked angle or salient angle of the bastion, is the same, or equal to 90 degrees; his construction in all polygons, above an octagon, gives this perpendicular or angle much greater than it ought to be. Thus, in a de-

agon, it gives this angle equal to $\frac{180^\circ - \frac{360^\circ}{10} - 90^\circ}{2} = 27^\circ$; whereas, it ought but very little to exceed $22\frac{1}{2}^\circ$.

In a dodecagon is given this angle = $\frac{180^\circ - \frac{360^\circ}{12} - 90^\circ}{2}$

= 30°. whereas it ought only to be about 24°. And this construction on part of a right line, which may be regarded as a polygon of an infinite or rather indefinite number of sides, gives this angle equal to 45 degrees, and the flanking angles formed by the intersections of the lines of defence, equal each to 90 degrees. The lines of defence in this case exactly correspond with Montalambert's construction in his "Fortification Perpendiculaire."

As in this construction the angle *diminué*, or the angle formed by an exterior side and a line of defence increases fast in magnitude, as the number of the sides of the polygon increase, being in the dodecagon twice as great as it is in the hexagon, the lengths of the curtains decrease and the faces of the bastions increase greatly beyond their just proportions, which is a material defect; since the faces, which are the weakest parts, being defended respectively, only on one side by a single flank, are thereby augmented, and the curtains, which are the strongest, being defended each on both sides, or by two flanks, are diminished.

His mode of placing the flanks in figures up to the octagon inclusive at right angles to the lines of defence, and in other polygons perpendicular to the curtains, though it certainly secures them well against the enemies' batteries, and renders them fit for defending the gates and curtains, (which, however, by their narrowness to the flanks, are naturally best figured), does not enable them to discover the enemies' batteries sufficiently to defend the counterscarp, and prevent them from advancing their works to it, a circumstance which affords great advantage to the besiegers. And if orillons be made in flanks, so placed, the covered flanks would be so hid, that they could scarcely see the ditch throughout its whole width, and the merlons from their angles towards the field being very acute, would easily be ruined by the enemies' batteries and rendered useless. Flanks ought to be placed per-

CONSTRUCTION.

pendicularly, or at least very nearly so to the lines of defence. For when an enemy once makes a lodgment on the counter-scarp, he will discover them whether they be so placed or not. And if flanks be discovered, they also discover, and being either reveted or demi-reveted and formed of earth that is well settled, they are by no means so easily ruined as the batteries of the besiegers, which are formed of gabions and newly raised earth.

Count Pagan's method of construction on a polygon, (fig. 2.) is widely different from that of Errard, and also much preferable. For instead of making the angle of the flank acute in the octagon and figures of a smaller number of sides, and only equal to a right one in any polygon of a greater number of sides, as Errard does, he makes it obtuse and places his flanks perpendicularly to the lines of defence, in order that they may discover more ground, and the better raise and defend the faces of the bastions, which are the most salient and weakest parts of the body of the place and are first attacked, breaches being commonly made in them. This ingenious author makes his lines of defence like Errard's, always rasant, but does not like him make 90 degrees the maximum of his flanked angle, or angle of his bastion.

He delivers constructions for three sorts of fortifications, namely, the great, the mean, and the little. He fortifies or constructs inwards, and in the great fortification makes the exterior side equal to 200 toises, in the mean equal to 180 toises, and in the little equal to 160 toises. He allows 60 toises to each face of a bastion in the great, 55 in the mean, and 50 in the little, in all figures above a square. He makes the perpendicular to the exterior side in the great fortification in all figures, except the square where it is 27 toises, equal to 30 toises; in the mean equal to 24 toises; and in the little equal to 21.

The dimensions of these principal lines in these three kinds of fortification, are contained in the following Table.

	Great Fortification.		Mean.		Little.	
	square.	In all other Polygons.	square.	In all other Polygons.	square.	In all other Polygons.
Exterior Sides.	200	200	180	180	160	160
Perpendiculars.	27	30	24	30	21	30
Faces of bastions	60	60	55	55	45	50

Supposing then the exterior side A B, (see the figure,) equal to 200 toises in the great, to 180 in the mean, and to 160 in the little, bisect it in the point C. In C O, which is perpendicular to A B, take C D equal to 30 toises, in all regular figures of a greater number of sides than four. Through the point D, draw the lines of defence A D H, B D G, on which take A E and B F, each equal to 60 toises in the great fortification, to 55 in the mean, and to 50 in the little. Then draw the flanks E G, F H, perpendicularly to the rasant lines or lines of defence B G, A H, and form the curtain by joining the points G, H. This is Count Pagan's construction, without orillons and retired flanks.

The figure is a regular hexagon, supposed to have each of its sides equal to 180 toises, as in his mean fortification. The angle A O B of the centre is therefore equal to 60 degrees, and the angle of the polygon to 120. A C, or B C, is equal to 90 toises, the perpendicular C D is equal to 30, and the face A E, or B F, to 55 by construction.

Now by means of these lines and angles, the others are ea-

sily found. And in the first place, the angle *diminué* C A D, or the angle formed by the exterior side A B, and the line of defence A H, is formed by the following analogy.

As A C, equal to 90 toises,
Is to C D, equal to 30 toises,
So is radius

To the tangent of the angle C A D = $18^{\circ} 26' 0''$ very nearly. If this angle be taken from 60 degrees, half the angle of the polygon, we get the angle O A H, or M A E, equal to $41^{\circ} 33' 54''$. But this is equal to half the salient angle of the bastion, wherefore the whole flanked angle or angle of the bastion is equal to $83^{\circ} 7' 48''$. And the flanking angle A D B, being equal to the excess of 180 degrees above twice the angle *diminué*, is evidently equal to $143^{\circ} 7' 48''$.

The tenaille A D, being equal to $\sqrt{AC^2 + CD^2}$, is = $\sqrt{90000} = 10\sqrt{90} = 94.868329825$ nearly. Or it is found by this analogy.

As radius
Is to the secant of the angle *diminué* C A D,
So is A C, half the exterior side A B,
To the tenaille A D.

If from this there be taken the face A E, which is equal by construction to 55 toises, we get the right line D E, and the following analogy for the flank E G.

As radius
Is to the sine of double the angle *diminué* C A D,
So is the right line D E
To the flank E G.

And as the angle A E G of the epaule or shoulder is always, in regular construction, equal to twice the angle *diminué* C A D, and the angle E G B formed by the flank and line of defence, the angle D E G is known, and D G is ascertained by the following analogy.

As radius
Is to the sine of the angle D E G,
So is the right line D E
To the right line D G.

The angle E G H of the flank, is in this construction equal to 90 degrees, together with the angle *diminué*, or the angle formed by the exterior side, and one of the lines of defence.

The complement, D G, or D H, being thus found, the curtain G H is ascertained by the following analogy.

As the sine of the angle *diminué* D G H
Is to the sine of double the said angle,
So is the complement D G
To the curtain G H.

The lengthened curtain M H, or G N, is determined by the following analogy.

As the sine of half the angle of the polygon
Is to the sine of half the flanked angle,
So is the rasant line, or line of defence A H,
To the lengthened curtain M H. From which, and the curtain G H, the inward or interior side M N is immediately obtained.

And the capital A M is ascertained by this analogy.

As the sine of half the angle of the polygon
Is to the sine of the angle *diminué*,
So is the rasant line, or line of defence A H,
To the capital A M of the bastion.

It is manifest from the foregoing table, that the perpendicular in this learned and judicious author's great fortification, subtends in the square an angle of about $15^{\circ} 6' 34''$ nearly, and in all other regular figures of about $16^{\circ} 41' 57''$ nearly; that in his mean fortification it subtends in the square an angle of

about

CONSTRUCTION.

about $14^{\circ} 55' 5''$, and in all other regular figures an angle of about $18^{\circ} 29' 6''$; and that in his little fortification, it subtends in the square an angle of about $14^{\circ} 42' 30''$, and in all other regular figures an angle of about $20^{\circ} 33' 22''$.

For his casemates or retired batteries and orillons, he bisects his flanks, leaving one-half of each adjoining the capote or shoulder for its orillon. The first flank or battery on the other half is retired five toises behind the orillon, and is two toises above the level of the ditch; the second is retired seven toises within the first, and is four toises above the level of the ditch; and the third is retired seven toises behind the second, and is six toises above the level of the ditch, being as high as the rampart, which is three toises above the level of the field, or terre-plain of the place, as the bottom of the ditch is three toises below it. These are formed by continuing the lines of defence into the bastions, and drawing lines parallel to these continuations from the points bisecting the flanks.

He makes within each of his bastions a sort of smaller bastion, or a cavalier in the form of one, having its faces parallel to those of the bastion and 12 toises distant from them, which serves as a retrenchment. The great ditch is 16 toises wide, and its counterscarp is parallel to the faces of the bastions or to the lines of defence. The capital of each of the ravelins, which he places on the re-entering angles of the counterscarp in such a manner as to be defended by the faces of the bastions and the counter-guards before them, is equal to 50 toises, and its faces are drawn to the shoulders. The demi-gorges of the redoubt within the ravelin are each equal to 15 toises, and the faces of it are parallel to those of the ravelin itself. The ditch of the ravelin is 12 toises wide, and that of the redoubt 6. The salient angle of each counter-guard is 40 toises distant from that of the bastion which it covers, and this work is from 9 to 10 toises broad at its extremities. The ditch before it is 12 toises wide. The covert-way is 4 toises wide, and the faces of the places of arms are each 8 toises long, and parallel to the opposite counterscarp.

The flanks, curtain, and other lines in this construction found above by means of lines, tangents, and secants, may be ascertained without any logarithmic table, in the following manner.

Since the tenaille AD is $= 10\sqrt{90}$ toises $= 30\sqrt{10}$ toises, and AC is $= 90$ toises by hypothesis, and CD is $= 30$ toises, by construction, or $= \frac{AC}{3}$, we have AD :

AC :: $\sqrt{10} : 3$, and AD : CD :: $\sqrt{10} : 1$. But AD : AC :: AE (55 toises by construction) : the excess of AC above one half of EF, which excess is therefore equal to $\frac{2 \times 55}{\sqrt{20}}$ toises, and its double, which is the excess of AB above EF, is of course equal to $\frac{330}{\sqrt{10}}$ toises, or to $33\sqrt{10}$ toises; consequently EF is equal to $180 - 33\sqrt{10}$ toises; but AD : CD :: EF : FH, and AD : AC :: EF : EH; wherefore the flank FH is equal to $\frac{180 - 33\sqrt{10}}{\sqrt{10}}$ toises $= 18\sqrt{10} - 33$ toises; and EH

is equal to $\frac{540 - 99\sqrt{10}}{\sqrt{10}}$ toises $= 54\sqrt{10} - 99$ toises. And since ED is $= AD - AE = 30\sqrt{10} - 55$ toises; we get DH equal to $24\sqrt{10} - 44$ toises. But AD : AB :: DH : GH, which is therefore equal to $\frac{24\sqrt{10} - 44}{\sqrt{10}}$

$\times 6$ toises $= \frac{144\sqrt{10} - 264}{\sqrt{10}}$ toises; and DI, which is

equal to a sixth part of GH is equal to $\frac{24\sqrt{10} - 44}{\sqrt{10}}$ toises.

Consequently CI is equal to $\frac{54\sqrt{10} - 44}{\sqrt{10}}$ toises. And OC : CI :: OA : the capital AM of the bastion. Count Pagan's flank, in his mean fortification, being to the perpendicular, as $18\sqrt{10} - 33$ to 30, is upwards of 5 toises less than it, which is certainly too great a difference.

This learned and judicious author, whom the principal fortifiers since his time, particularly Vauban, have very much followed, considering that the flanks, ramparts, and ditches, were the works that contributed most powerfully towards the defence of the body of a place, and the retarding of the approaches of an enemy to it, made the demi-gorges of his bastions large, in order to have three flanks or batteries on each of them, sufficiently long for placing four pieces of cannon in, respectively. Three of these, in each of the said three flanks, are, by his construction, so well covered from the counter-batteries of the besiegers, that they cannot easily be damaged by them. And the besiegers, on approaching the breaches, and attempting to make lodgments in the ruins of them, must suffer greatly from the guns so covered in these retired flanks, as they are then fired on by them, de revers, or in the rear.

Though his division of fortification, into great, mean, and little, seems not to be of much use, or moment, he must certainly be allowed to be the first writer on the subject that gave the true position to his flanks, making them perpendicular to the lines of defence. His mean fortification appears to be preferable to the great, as it does not make the lines of defence too long for musquet-shot. The position of the flanks, and great length, he gives to the faces of his bastions, render his demi-gorges long enough to afford a sufficiency of room for his retired flanks.

The two ditches, with the two ramparts, that he makes, are well calculated for obstructing and retarding the enemies' passage of the ditch, for depriving them of the use of fourneaux, and for preventing them from lodging themselves on the ruins of the breaches. For when the besiegers have even passed the main ditch, and taken the first rampart, they will find themselves exposed in the second ditch to the besieger's fire on all sides, and liable to be destroyed by shells, handgrenades, fourneaux, mines, &c.

By giving one-half of his flank to the orillon, he covers his retired batteries extremely well. The ditch is very well defended from the flanks, which being perpendicular to the lines of defence, look fully along the faces of the opposite bastions.

It must be observed, however, that though the position of his flanks be good, they are too small, particularly in polygons of a considerable number of sides, being a good deal shorter than the perpendiculars to the exterior sides; whereas they should be equal, or nearly equal to them, as perpendiculars to the exterior sides of polygons were first introduced into construction for the sole purpose of obtaining flanking defences. This is in a great measure occasioned by his making the faces of his bastions too long, which he was probably led to do from a desire of obtaining three retired batteries in each flank. The face of the bastion is equal to the $\frac{1}{3}$ th part of the exterior side, whereas it may with confidence be asserted, that it ought not to exceed a fourth. For the faces of the bastions are most salient, and consequently the tenderest part of the body of the place. They are always first attacked, and in them the breaches are constantly made. But when they are very long, the besiegers can

can make large breaches in them, which is a great advantage to them, and a no less disadvantage to the besieged.

The retrenched bastion, or redoubt in form of one within the bastion, must increase the expence at least one-third. The ditch before it is but ill defended, as there are no tenailles for that purpose. And as it is hollow or empty, it may be taken as easily as the main bastion, by means of a second mine, and thereby occasion the loss of the place, especially as no retrenchment can be raised within it to enable the besieged to capitulate with more advantage.

His retired flanks, or batteries, appear to be too near to one another, being only seven toises distant from outline to outline.

He makes no traverses. But this cannot be imputed to him as either an oversight or fault, as firing *en ricochet* was not known in his time. By giving the same perpendicular to the exterior sides of all figures of a greater number of sides than four, he makes the flanked angle, or angle of the bastion in a polygon of a considerable number of sides, very obtuse. This angle begins to become obtuse in the hexagon, and by his construction on part of a right line, it is no less an angle than one of 143° or 48° .

He assigns no reason whatsoever for the length of his perpendicular, derived from the properties of different polygons, or their relative degree of importance and capability of defence, nor for his giving the same perpendicular in all regular figures of a greater number of sides than four. His perpendiculars are mere arbitrary assumptions, like those of all other authors, who have written on fortification since his time. The truth however is, that every regular figure has a perpendicular of its own, which is different from that of any other, of a precise and determinate length, and bearing a given ratio to the exterior side.

Mr. Blondel's method of construction is as follows :

Like Count Pagan he fortifies inwards, but instead of the perpendicular he begins with the angle *diminué*, or the angle formed by an exterior side, and a line of defence. This angle he determines by taking a right angle, or 90 degrees from the angle of the polygon, and adding 15 degrees to a third part of the remainder. Thus, if n denote the number of the sides of a regular figure, the angle of the polygon, or the angle contained by two of its sides, will be equal to $180^{\circ} - \frac{360^{\circ}}{n}$, and his angle *diminué* will of course be

equal to $30^{\circ} - \frac{120^{\circ}}{n} + 15^{\circ}$ or $45^{\circ} - \frac{120^{\circ}}{n}$, which gives 15°

for it in the square, 21° in the pentagon, 25° in a hexagon, and in his construction on part of a right line 45° , which then makes the perpendicular equal to half the exterior side. This expression for his angle *diminué*, as is evident by inspection, is always equal to the excess of 45° above 120° divided by the number of the sides of the figure; wherefore it is always found without any reference whatsoever to the angle of the polygon, by dividing 120° by the number of the sides of the figure, and subtracting the quotient from 45° . And since the angle of the centre, or the angle subtended by one of the sides of the figure, is equal to $\frac{360^{\circ}}{n}$, this angle

diminué is had by taking from 45 degrees a third part of the angle of the centre.

His angle *diminué* gives the angle of the bastion, or flanked angle, in a square equal to 60 degrees, in a pentagon equal to 66 degrees, in a hexagon equal to 70 degrees, and in a construction on part of a right line equal to 90 degrees.

The flanking angle, or the angle formed by the lines of

defence, is in the square, equal to 150 degrees, in the pentagon, to 138, in the hexagon, to 130, and in a construction on part of a right line, to 90 degrees.

He supposes two sorts of fortification, *viz.* the great, in which he makes the exterior side equal to 200 toises in all polygons; his line of defence equal to seven tenths of the exterior side, or 140 toises; and the face of his bastion equal to half the tenaille, or line between a flanked angle and the intersection of the lines of defence; and the little, in which he makes the exterior side in every figure equal to 170 toises, the line of defence equal to seven tenths of this, or to 119 or 120 toises, and the face of the bastion equal to half the tenaille, his construction in both being the same.

Thus for instance, let AB (*fig. 3.*) be the side of a hexagon. At its extremities A, B, make the angles *diminué* ABG, BAG, each equal to 25 degrees, the excess of 45 degrees above a third part of AMB the angle of the centre. On A, G, B, G produced take A F, B E for the lines of defence, each equal to seven tenths of AB the exterior side. Biseñ the tenailles A G, B C, in the points C, D, to get the faces A C, B D, draw the flanks C E, D F, and form the curtain by drawing E F.

Mr. Blondel takes on each flank 10 toises for his square orillon, employing the rest of it as a covered flank, which he keeps retired five or six toises inwards, as high as the heptagon; on higher polygons from 10 to 12 toises, in order to lengthen the curtains; and to obtain curtains in constructions, which being made on a straight line, or very high polygons, have none, or very short ones, he retires his flank as much as 20 toises, that he may have a curtain upwards of 20 toises long. For by his construction on a right line, where the angle *diminué* is 45 degrees, the tenaille is upwards of seven tenths of the exterior side. The retraite of the flank is measured on a right line, drawn from the angle of the opposite bastion, to the point terminating the ten toises, set off from the epaule on the flank for the orillon. Like Count Pagan, he makes three retired batteries in each flank within the casemate, allowing three toises for the breadth of the parapet in each, and five for its platform, or eight toises from the outline of one battery to that of another. The lowest of these retired flanks is from nine to twelve feet above the bottom of the ditch, the second from 18 to 24, and the third, or highest, from 27 to 36 feet, being level with the rampart. These three flanks are terminated towards the demi-gorge upon the line of defence produced, and towards the orillon, on the line drawn from the angle of the opposite bastion, through the end of the same orillon. The parapet of the lowest flank is nine or ten feet high, that of the middle one six or seven, and that of the third, or highest one, $3\frac{1}{2}$. Those of the lowest, and middle one, must of course have embrasures in them.

As there is a great deal of space between the two high flanks in each bastion, he makes a cavalier in it, having its faces parallel to the flanks, and each of them capable of holding twelve pieces of cannon at least. These cavaliers and retired flanks must be made with the earth taken from the great ditch, of which the width is equal to the length of one of the flanks. The re-entering angle of the counter-scarp is therefore opposite to and nearly about the middle of the exterior side.

This author places a counter-guard in front of each bastion, with its faces parallel to those of the same composed entirely of masonry without any earth, and every where countermined. Its breadth or thickness is only from 3 to 4 toises, including its parapet, which is from 5 to 10 feet thick. It is erected in the great ditch 10 or 12 toises distant

tant from the counterfearp, which distance therefrom forms its ditch. The principal object in erecting this counter-guard is to conceal from the enemies' view the low flanks opposite to it, whilst its narrowness or small breadth puts it out of his power to place his guns in after he has taken it.

The salient angle of his ravelin is determined by the interfection of two arcs, described from the shoulders of the two adjoining bastions, with a radius equal to the distance between them. Its faces produced meet those of the bastions about 6 toises from the shoulders and are bounded on the lines or faces of the counter-guards produced, which also determine the gorge of the ravelin.

The ditch of the ravelin is from 10 to 12 toises broad, and that it may be the better defended, Mr. Blondel takes, in the face of the bastion, a space equal to this breadth, commencing six toises from the shoulder, in which he makes a low battery of 4 or 5 feet high, and another on the inside of the same height with the parapet of the place, and retired about 7 toises within the face.

The ditch before the counter-guards is 10 toises broad. The ravelin not only covers the shoulders and the oissons of each bastion, but likewise defends the ditch of the counter-guard, as he takes as much of its face as is sufficient for seeing or discovering all that to make two batteries in, *viz.* a low one and a high one in the same manner as he does in the faces of the bastions. He allows no more terre-plain in the ravelin, than what is just enough for the recoiling of his guns, leaving all the rest of its inside empty for the purpose of being able easily to countermine the rampart, and to prevent the enemy from making a lodgment in it, after he may have forced it.

The better to cover the batteries in the face of each bastion, which defend the ditch of the ravelin, he adds in the angles of the counterfearp of the ravelin *lunettes*, in the form of lozenges, allowing 20 toises for the semi-gorge in each. These have their faces parallel to the counterfearps of the ditches before the ravelin and counter-guard, and the ditch before them 8 toises broad.

The author likewise makes a *lunette* in his great ditch from 7 to 8 toises broad, which he carries quite round the work to prevent the low flanks, which would be otherwise easily accessible, from being got at. A smaller or narrower *lunette* might also be made in the ditches of the outworks, particularly when there are batteries in the demi-lunes or ravelins.

The calculations for the angles and lines of a construction

on the sides of a polygon, according to Mr. Blondel's method, are made in the following manner.

Since the figure referred to is a hexagon, the angle of the centre is equal to 60 degrees, the angle of the polygon to 120, and the angle *diminué*, B A F or A B E, to 25 degrees. The flanking-angle, A G B, is 130 degrees, and the flanked angle, N A G, or D B S, is equal to 70 degrees. Wherefore half the flanked angle, E B O, or F A P, is equal to 35 degrees.

The tenaille A G, and of course the face A C of the bastion, is found by the following analogy.

As the sine of the angle A G B

Is to the sine of the angle A B G,

So is the exterior side A B

To the tenaille A G, of which the face A C is one-half.

From the sine of defence A F, which is seven-tenths of the exterior side A B, we get the complement G F or G E, and the curtain E F of course by this analogy.

As the sine of the angle E F G

Is to the sin. of the angle E G F,

So is the complement E G

To the curtain E F.

And as the sum of the angles C E F, E C F, is equal to 180°—the angle *diminué* C F E (25°) = 155°, and C F, E F, are known, we have this analogy.

As the sum of the sides C F, E F

Is to their difference,

So is the tangent of $\frac{77}{77} 30'$, half the sum of the angles,

To the tangent of half their difference.

Half this difference added to half the sum, gives C E F the angle of the flank, and taken from half the sum gives E C F the supplement of A C E the angle of the *epaule* or shoulder.

And for the flank C E we have the following analogy.

As the sine of C E F, the angle of the flank,

Is to the sine of the angle *diminué* C F E,

So is C F

To the flank C E.

The demi-gorge E P is determined by first finding the lengthened curtain F P by this analogy.

As the sine of the angle A P F, which is known,

Is to the sine of the angle F A P which is also known,

So is the line of defence A F = $\frac{7}{5}$ of A B

To the lengthened curtain F P.

Then from F P so found take the curtain E F, and there will remain the demi-gorge E P.

TABLE of the Angles of the different Parts of the Construction, according to Mr. BLONDEL's Method.

tant from the counter-scarp, which distance therefrom forms its ditch. The principal object in erecting this counter-guard is to conceal from the enemies' view the low flanks opposite to it, whilst its narrowness or small breadth puts it out of his power to place his guns in after he has taken it.

The salient angle of his ravelin is determined by the intersection of two arcs, described from the shoulders of the two adjoining bastions, with a radius equal to the distance between them. Its faces produced meet those of the bastions about 6 toises from the shoulders and are bounded on the lines or faces of the counter-guards produced, which also determine the gorge of the ravelin.

The ditch of the ravelin is from 10 to 12 toises broad, and that it may be the better defended, Mr. Blondel takes, in the face of the bastion, a space equal to this breadth, commencing six toises from the shoulder, in which he makes a low battery of 4 or 5 feet high, and another on the inside of the same height with the parapet of the place, and retired about 7 toises within the face.

The ditch before the counter-guards is 10 toises broad. The ravelin not only covers the shoulders and the orillons of each bastion, as he likewise defends the ditch of the counter-guard, as he takes as much of its face as is sufficient for seeing or discovering all that to make two batteries in, viz. a low one and a high one in the same manner as he does in the faces of the bastions. He allows no more terre-plain in the ravelin, than what is just enough for the recoiling of his guns, leaving all the rest of its inside empty for the purpose of being able easily to countermine the rampart, and to prevent the enemy from making a lodgment in it, after he may have forced it.

The better to cover the batteries in the face of each bastion, which defend the ditch of the ravelin, he adds in the angles of the counter-scarp of the ravelin *lanettes*, in the form of lozenges, allowing 20 toises for the semi-gorge in each. These have their faces parallel to the counter-scarps of the ditches before the ravelin and counter-guard, and the ditch before them 8 toises broad.

The author likewise makes a *lanette* in his great ditch from 7 to 8 toises broad, which he carries quite round the work to prevent the low flanks, which would be otherwise easily accessible, from being got at. A smaller or narrower *lanette* might also be made in the ditches of the outworks, particularly when there are batteries in the demi-lunes or ravelins.

The calculations for the angles and lines of a construction

on the sides of a polygon, according to Mr. Biondel's method, are made in the following manner.

Since the figure referred to is a hexagon, the angle of the centre is equal to 60 degrees, the angle of the polygon to 120, and the angle *diminué*, $\angle B A F$ or $\angle A B E$, to 25 degrees. The flanking-angle, $\angle A G B$, is 130 degrees, and the flanked angle, $\angle N A G$, or $\angle D B S$, is equal to 70 degrees. Wherefore half the flanked angle, $\angle E B O$, or $\angle F A P$, is equal to 35 degrees.

The tenaille $A G$, and of course the face $A C$ of the bastion, is found by the following analogy.

As the sine of the angle $A G B$
Is to the sine of the angle $A B G$,
So is the exterior side $A B$

To the tenaille $A G$, of which the face $A C$ is one-half.

From the line of defence $A F$, which is seven-tenths of the exterior side $A B$, we get the complement $G F$ or $G E$, and the curtain $E F$ of course by this analogy.

As the sine of the angle $E F G$
Is to the sine of the angle $E G F$,
So is the complement $E G$

To the curtain $E F$.

And as the sum of the angles $C E F$, $F C F$, is equal to 150° —the angle *diminué* $C F E$ (25°) = 155° , and $C F$, $E F$, are known, we have this analogy.

As the sum of the sides $C F$, $E F$

Is to their difference,

So is the tangent of $77^\circ 30'$, half the sum of the angles,

To the tangent of half their difference.

Half this difference added to half the sum, gives $C E F$ the angle of the flank, and taken from half the sum gives $E C F$ the supplement of $A C E$ the angle of the *epaule* or shoulder.

And for the flank $C E$ we have the following analogy.

As the sine of $C E F$, the angle of the flank,

Is to the sine of the angle *diminué* $C F E$,

So is $C F$

To the flank $C E$.

The demi-gorge $E P$ is determined by first finding the lengthened curtain $F P$ by this analogy.

As the sine of the angle $A P F$, which is known,

Is to the sine of the angle $F A P$ which is also known,

So is the line of defence $A F = \frac{1}{2} A B$

To the lengthened curtain $F P$.

Then from $F P$ so found take the curtain $E F$, and there will remain the demi-gorge $E P$.

CONSTRUCTION.

This ingenious author also gives a table of the lengths of the different lines in his construction on the two following suppositions:

1st. That the exterior side of each figure is equal to 200 toises.

And 2^{dy}. That the exterior side of each figure is equal to 170 toises.

Mr. Blondel was undoubtedly a man of considerable talents and eminence, and had travelled over the greatest part of Europe, America, and the West Indies, making sensible and judicious observations on the various modes of fortifying, practised by different nations.

His acuteness however in discovering the mistakes committed by others, and his anxiety to avoid them, did not prevent him from falling into still greater ones himself. He did not attend sufficiently to the great expense that the execution of his method would unavoidably occasion, or to the numerous artillery that would be required for its defence.

Imagining, that places are generally lost for want of sufficient flanks, he makes three, one behind another. They are however so near to each other, that the rubbish of the higher ones must certainly render the lower ones useless: and were shells to fall into the lower ones they must unquestionably destroy the troops for want of room to avoid them. They are moreover too open and liable to be destroyed from the covert-way, as the counter-guards are not broad enough to cover and screen them from the enemies' fire. The low flanks are too narrow and too much confused. Before shells, however, were much used at sieges, they might have afforded a good defence.

He makes no use of traverses. But this is not to be imputed to him as a fault or omission, as rocket-firing was not used in his time.

His great ditch appears to be too wide, being not less than 25 toises before the faces of the bastions.

His angle *diminué* must be allowed to be preposterously great, as he makes it of as many degrees as it ought to be in a construction on a straight line, or on the sides of a polygon of an infinite or indefinite number of sides.

The following is the construction according to Mr. Bombelle's method.

Like Count Pagan he establishes three sorts of fortification. But instead of constructing inwards like him, he constructs outwards. His three sorts he denominates the little royal, the mean, and the great royal. The interior side of the little royal is equal to 60 rods of 12 Paris feet each, or 120 toises, that of the mean is equal to 70 such rods or 140 toises, and that of the great royal is equal to 80 such rods or 160 toises. His manner of fortifying in all the three is the same, and is the following.

Having determined on the side AB, (*fig. 4.*) (which we shall here suppose to be that of a hexagon), for the great, mean, or little royal, allow a fifth part of it for the demi-gorges AC, BD; and a fourth part of it for the flanks CE, DF, each of which must make, with the curtain CD, an angle of 100 degrees. Then the points, G, H, of the bastions are ascertained by the rasant lines CH, DG, and the whole operation or construction is finished.

As the construction in this figure is supposed to be made outwards on three of the sides of a regular hexagon, the angle AOB of the centre is equal to 60 degrees, and the angle GHK of the polygon is equal to 120 degrees. But the angle ECD of the flank is by construction equal to 100 degrees, the demi-gorge AC or BD is equal to a fifth part of the interior side AB, and the flank CE or DF is equal to a fourth part of AB. Consequently the sum of the

angles CDE, CED, is given equal to 80 degrees, and the sides CE, CD, are given; wherefore we have this analogy.

As the sum of the curtain CD and flank CE

Is to their difference,

So is the tangent of 40° half the sum of the angles CDE, CED

To the tangent of half their difference.

Hence the angle *diminué* CDE or CDG, the angle CED the supplement of the angle CEG of the *epaule* or shoulder, and AGD half the flanked angle, or half the angle of the bastion, are given.

And as the lengthened curtain AD or BC is given by the construction equal to four fifths of the interior side AB, we have the following analogies for DG, the line of defence, and AG the capital of the bastion.

As the sine of AGD, half the angle of the bastion,

Is to the sine of the angle GAD,

So is the lengthened curtain AD

To the line of defence DG.

And,

As the sine of AGD, half the angle of the bastion,

Is to the sine of the angle *diminué* ADG

So is the lengthened curtain AD

To AG the capital of the bastion.

In like manner we obtain DE from the triangle CED by means of the following analogy.

As the sine of CDE, the angle *diminué*,

Is to the sine of ECD, the angle of the flank,

So is the flank CE which is given

To the right line DE, which taken from DG, the line of defence, gives EG the face of the bastion.

And as in this figure, which is supposed to be a hexagon, the exterior side GH, or line joining the salient angles of two adjoining bastions, is equal to OG the perpendicular distance of the point I, the intersection of the lines of defence from GH is obtained by the following analogy.

As radius

Is to the tangent of I CZ, the angle *diminué*,

So is GZ, the half of GH or OG, in this figure,

To IZ, the perpendicular distance of I from GH.

And the perpendicular distance of the intersection of the rasant lines, or lines of defence, from the curtain, is found by this analogy.

As GH or OG in this figure

Is to the curtain CD,

So is IZ

To the perpendicular distance IY of I from CD.

And in any other regular figure than a hexagon, GH is found by this analogy.

As OA, the radius of the circumscribing circle,

Is to the interior side AB, which is given,

So is OG = OA + AG

To GH, the side of the exterior polygon.

And as radius

Is to the tangent of IGZ, the angle *diminué*,

So is GZ equal to half GH,

To IZ, the perpendicular distance of I from GH.

And as GH, the side of the exterior polygon,

Is to CD the curtain, which is known,

So is IZ, the perpendicular distance of I from GH,

To IY, the perpendicular distance of I from the curtain.

Mr. Bombelle, in the construction of each of his three sorts of fortification, makes the angle ECD or FDC of the flank, always equal to 100 degrees, and the angle *diminué* GDC or HCD invariably equal to about 20° 56'.

For

CONSTRUCTION.

For CD being always equal to three-fifths of AB, and CE equal to a fourth part of AB, the ratio of CD + CE to CD - CE is a given or constant ratio, being that of 17 to 7, whatever be the length of AB. And the construction of his mean fortification gives the demi-gorge AC or BD, equal to 28 toises, the curtain CD, equal to 87, the lengthened curtain AD or BC, equal to 112, the flank CE or DF, equal to 35, the line of defence DG or CH, equal to about 153½, the capital AG or BH of the bastion, equal to about 63½, the face GE or HF of the bastion, equal to about 61½. And in all the three the ratio of DY half the curtain, to IY the perpendicular distance from it to I, the intersection of the lines of defence, or of GZ, half the side of the exterior polygon, to ZI, the perpendicular distance from it to the said point of intersection, is given or constant, being always that of radius to the tangent of 20° 56'. The construction of his mean fortification on the sides of a hexagon gives ZI, equal to about 38,884 toises, and YI to about 16,066 toises.

This author makes his main ditch, or the ditch of the body of the place, 12 rods of 12 Paris feet each, or 24 toises broad, beyond which and opposite to the curtain he places a ravelin, the salient angle of which is in the intersection of two arcs described with the lengthened curtain AD, or BC, as radius from the extremities A, B, of the interior side AB, and the faces of which produced across the main ditch would terminate on the shoulders *i, i*, of the square orillons, that cover his rounded flanks or casemates, which are described in the following manner.

From the extremities C, D, of the curtain, and perpendicularly thereto, he draws two other flanks, Ci, Di, meeting the lines of defence in the points *i, i*, lengthening the faces GE, HF respectively by Ei, Fi in order to have room enough in each flank of every bastion for two covered ones, which are constructed in the following manner:

Take the two lines Gr, Hr, equal each to a third part of Gi or Hi, (Ci, Di being drawn from the extremities C, D, of the curtain CD perpendicular thereto), and the lines *ik, ik*, also equal each of them to a third part of Ci or Di. From the points *r, r*, draw right lines, *rkl, rkl*, through the points *k, k*, terminated at the points *l, l*, by the right lines Cl, Dl, drawn perpendicularly to the lines of defence G D, H C, which must be produced till they meet the radii of the polygon in some points as *p, p*, in order to take upon the same radii the distances *pg, pg*, for terminating the covered flanks, of which the common centre *x* is found by describing from the extremities D l, Cl, of the right lines Cl, Dl, arcs with a radius equal to three-fourths of Cl or Dl.

The distance between the two covered flanks on each flank of every bastion is equal to 12 rods of 12 Paris feet each, or twenty-four toises, and the parapets every where are 10 such rods or 4 toises thick.

The casemates which Mr. Bombelle adds at the points of the bastions, and which, in cases of necessity, may serve as retrenchments, are described by taking on the capitals of the bastions the right lines Gs, Hs, equal respectively to half the lines Gr, Hr, and describing from the points *s, s*, as centres, arcs, *rr, rr*, for the casemates, each of which has its parapet 4 toises broad. They are somewhat lower towards the points of the bastions than the other parts of the bastions, and the ways to them are through passages as *o, o*, in the bastions.

This author covers his ravelin with a sort of counter-guard or tenaille beyond its ditch, which he makes 8 rods of 12 Paris feet each, or 16 toises broad, or a third part of the breadth of his great ditch, thus rendering his ravelin a tenailleid, or horned half-moon.

Round covered flanks were first invented by the Italians; and Mr. Bombelle uses them in order to render them the more capacious, and the fitter for resisting the shock and effects of the enemies' cannon. They seem, however, to have too much convexity, advancing too far towards the centre of each bastion, and leaving too small a distance between the two high flanks.

As his flanks are great, he makes use of no second flanks on the curtains. But contrary to sound sense and reason, and inconsistently with the genuine principles of construction, he makes them of the same lengths or sizes in all polygons. His angle *diminué* also is invariably of a given magnitude, *viz.* of 20° 56', which by his construction on the sides of a square leaves the flanked angle, or angle of each bastion, equal only to 48° 8' in a pentagon, to 66° 8', in a hexagon, to 78° 8', and so on. His angle *diminué* in a square, is therefore more than double what it ought to be, by upwards of two degrees. And in a pentagon it does not fall quite 7½ degrees short of being twice as great as it should be in reality. He makes it even greater in a square than it ought to be in an octagon.

Mr. Vauban in his method fortifies inwards; and like Count Pagan, from whom he has borrowed his perpendicular for the hexagon and all higher polygons, begins with the perpendicular to the exterior side, and the salient lines or lines of defence. He does not, however, make the faces of his bastions so long, or his flanks quite so short. And he omits second flanks as not of very great moment, as they can be added at any time, without changing either the flanks or curtains.

Bisect, as in Count Pagan's construction, the exterior side AB in the point C. (*fig. 5.*) At the point C erect a perpendicular, CD, equal to an eighth part of AB in the square, to a seventh part of AB in the pentagon, and to a sixth part of AB in the hexagon and all higher polygons. From the extremities A, B, through the point D, draw the lines of defence ADH, BDG. On these take AE, BF for the faces of the bastions, equal each to two seventh parts of AB, and take EH, FG, each equal to EF, the distance between the shoulders E and F. Then join the points G, H, for the curtain GH. And if a similar construction be made on each of the other sides of the figure or polygon, we get the master-line of the curtains and bastions, or the principal or outline of the body of the place. To this must be added a rampart from 10 to 12 toises broad at the base, and elevated more or less above the level of the place, on the outer part of which, at top, there is raised a parapet three toises broad at the base, and elevated above the rampart from six feet to 7½. The ditch of the body of the place, or the great ditch, is 20 toises wide opposite to the flanked angles or salient angles of the bastions, and it is formed by describing from these angles with a radius of 20 toises, circular arcs, and drawing right lines from the *epaules*, or shoulders, to touch these arcs. For the parts of these lines lying between their intersections and the points of contact, together with these arcs, form the outline of the ditch.

The foregoing figure is a regular hexagon, and the exterior side is here supposed to be equal to 180 toises.

To determine the salient angle S (*fig. 6.*) of the half-moon or ravelin, let off 50 toises on the perpendicular DC, produced beyond the exterior side AB; from the point S draw right lines to the counter-scarp of the great ditch, so that if produced across the same, they would, according to some authors, terminate on the *epaules* or shoulders of the bastions, but according to others, about 3 toises from the shoulders on the faces of the bastions. These lines so drawn

CONSTRUCTION.

from the salient angle S, of the ravelin to the counterescarp, form the faces SL, SM, of the half-moon or ravelin. It is generally supposed that when the faces SL, SM of the ravelin terminate when produced across the great ditch on the faces of the bastions a few toises from the *épaules* or shoulders, they cover the flanks much better than they do when they terminate on the shoulders themselves.

The ditch before each ravelin is 12 toises broad; its counterescarp is parallel to the faces, and is made of a circular form, before the salient angle of each like the ditches before the salient angles of all works in general.

When the ravelin is made with flanks, as PN, QO, the faces SP, SQ, when produced across the great ditch, ought to terminate on the faces of the bastions 5 toises at least from the *épaules* or shoulders.

When a ravelin has flanks, they are commonly made by setting off 10 toises from L to P, and M to Q, from the extremities of the faces, and by drawing them from the points P, Q, parallel to the capital rS of the ravelin.

There is sometimes a redoubt made in a ravelin, which is done by setting off from the extremities, L, M, of the faces on the semi-gorges Lr, Mr, and then drawing right lines for its faces parallel to those of the ravelin. The ditch before such a redoubt should be 6 toises broad, and its counterescarp parallel to its faces.

Orillons and retired flanks are described in the following manner.

The front, AEG, HFB, being described as above taken, Ea equal to a third part of the flank EG. From the opposite flanked angle B, draw the right line Ba, on which produced take ab, equal to 5 toises. Take also on the line of defence, BG, produced, Ge equal to 5 toises, and join b, c. On be as a base describe the equilateral triangle bcf, and from the angular point f as a centre, describe the circular retired flank bc with the radius fb or fe.

Again, if Ea be bisected in the point a, and cd be drawn perpendicularly to Ea to meet a perpendicular to the face AE, from the point E in the point d, and if from the point d as a centre a circular arc be described with dE as radius, we shall get the circular orillon Ea.

ab is called the *revers*, or back part of the orillon, and Ge, the *enfacement* or depth of the casemate or concave flank bc.

In like manner are the retired or concave flank bi, and the circular orillon Fg described.

The orillons are useful in covering the retired or concave flanks, which by means of them cannot be seen but directly in front. And as Mr. Vauban makes his orillons round, they cannot be so easily destroyed as they might be were they of any other figure or form.

The calculation of the lines and angles of a construction on a polygon, according to this method of Mr. Vauban, is as follows:

If AB be supposed to be the side of a hexagon, the angle of the centre will be equal to 60°, and the angle of the polygon to 120°. And as the perpendicular CD is by the construction equal to a sixth part of AB, the angle *diminué* ABD or BGH is determined by the following analogy:

As AC or BC, the half of AB, } or, As 3
Is to CD the perpendicular, } Is to 1,
So is radius

To the tangent of the angle CAD or CBD, which is nearly equal to 18° 26' 6". Wherefore the flanked angle or angle of the bastion is equal to 83° 7' 48" nearly. And since the triangle EFG is isosceles by the construction, and the angle EFG, which is equal to the angle ABD, is of

enure equal to 18° 26' 6", we have the angles FEG, FGE, equal each to half the excess of 180° above 18° 26' 6", or to 80° 46' 57" nearly. Wherefore the angle EGH of the flank, which is equal to the angle FGE, together with the angle FGH, or angle *diminué*, is equal to 99° 13' 3". And the angle AEG of the *épaule*, or shoulder, being equal to the angle EGF or EGD, together with the angle EDG, which is equal to the angles ABD, BAD, taken together, or to twice the angle *diminué*, is equal to 117° 39' 6".

Now since AC, half of the exterior side AB, is given, and CD is found by the foregoing analogy, AD is known, its square being (47 E. 1.) equal to the squares of AC and CD; and as AE is equal to two sevenths of AB, the exterior side ED is known. But AD is to ED, as AB is to EF or FG, which are of course known. Or, either of these lines may be found by the following analogy.

As the sine of the angle EFD, which is equal to the angle *diminué*, or to 18° 26' 6",

Is to its opposite side DE,

So is the sine of the angle EDF, which is equal to 180°, twice the angle *diminué*, or to 143° 7' 48",

To the opposite side EF, the distance between the *épaules*.

And if from EF, or its equal EH, there be taken ED, the complement DH, or its equal DG, will be known. Wherefore the curtain GH is determined by either of the two following analogies.

As AD

Is to the exterior side AB,

So is the complement DG or DH

To the curtain GH.

Or, As the sine of the angle *diminué* DGH

Is to the sine of the angle GDH, which is = 143° 7' 48" nearly,

So is the complement DH

To the curtain GH.

The flank EG is easily found by means of either the triangle EFG, or the triangle EDG, as in the following analogies.

As the sine of the angle TGH, which is = 80° 46' 57" nearly,

Is to the sine of the angle EFG, which is = angle *diminué*, or 18° 26' 6" nearly,

So is EF the distance between the two opposite *épaules*

To the flank EG.

Or, As the sine of the angle EGD, which is = 80° 46' 57" nearly,

Is to the sine of the angle EDG, which is = twice the angle *diminué*, or 36° 52' 12" nearly,

So is ED the distance from the *épaule* to the intersection of the lines of defence

To the flank EG.

And as half the flanked angle is equal to 41° 33' 36", and the angle AHG, which is equal to the angle *diminué*, to 18° 26' 6" nearly; the angle formed by the capital of the bastion, and the lengthened curtain, or the curtain HG produced to meet the same, will be equal to 125° 0' 18" nearly. Wherefore the lengthened curtain is found by this analogy.

As the sine of 120° 0' 18"

Is to the sine of 41° 33' 36", half the flanked angle,

So is AH

To the lengthened curtain; from which, if the curtain HG be taken, we get the demi-gorge.

And the capital of the bastion is found by this analogy:

As the sine of 120° 0' 18"

Is to the sine of $13^{\circ} 26' 6''$, the angle *diminué*,

So is AH

To the capital of the bastion.

And the perpendicular distance, DI, of the curtain from the intersection of the lines of defence is found by the analogy, As AB is to CD, so is GH to DI.

Supposing the exterior side AB, as in his mean fortification, to be equal to 180 toises, the principal lines belonging to the construction may easily be found, as in the following manner.

The perpendicular CD being by construction $= \frac{AB}{6}$
is = 30 toises.

The *tenaille* AD or BD being equal to $\sqrt{BC^2 + CD^2}$ is equal to $\sqrt{9000}$ toises = $30\sqrt{10} = 94.8683298$ nearly.

The face BF of the bastion is commonly equal to 50 toises, or two-sevenths of AB nearly.

The distance DF of the *epaule* F from the intersection D of the lines of defence being equal to $BD - BF$, is equal to $10\sqrt{90} - 50 = 44.8683298$ toises nearly.

If from the *epaule* F there be drawn F I perpendicular to the exterior side AB, we shall have $BI = \frac{BC \times BF}{BD} =$

$5\sqrt{90}$ toises = $\frac{3D}{2} = 47.4341649$ toises nearly; and F I

the perpendicular distance of the *epaule* F from the exterior side = $\frac{CD \times BF}{BD} = 5\sqrt{10}$ toises = $\frac{BD}{6} = 15.8113883$ toises nearly.

The distance EF, between the two opposite *epaules*, E, F, or its equal EH or FG, is equal to $AB - 2BI = AB - BD = 180 - 30\sqrt{10}$ toises = 85.13167 toises nearly.

The complement DG or DH being equal to $FG - DF$ is equal to $230 - 10\sqrt{360}$ toises = 40.26334 toises nearly. The perpendicular distance DI of the intersection of the

lines of defence from the curtain GH being = $\frac{CD \times DG}{BD}$

is equal to $23\sqrt{10} - 60$ toises, or 12.7323861846 toises nearly. Consequently the perpendicular distance CI between the exterior side AB and the curtain GH being equal to $CD + DI$, is equal to 42.7323861846 toises nearly.

The curtain GH being equal to six times DI, is equal to $138\sqrt{10} - 360$ toises, or 76.3943171 toises nearly.

If Fm be drawn perpendicularly from the *epaule* F to AH, the line of defence, E_m, being equal to $\frac{EF \times BC}{BD}$

is equal to $54\sqrt{10} - 90$ toises, or 80.76299365 toises nearly.

The perpendicular Fm being to E_m as CD is to BC, is equal to a third part of E_m or $18\sqrt{10} - 30$ toises, or 26.921 toises nearly.

The distance mH of the point m from the extremity H of the line of defence being equal to $EH - E_m$, is equal to $270 - 84\sqrt{10}$ toises, or 4.3686765442 toises nearly.

The distance Dm of the point m from the intersection D of the lines of defence being equal to $E_m - DF$ or $E_m - DE$, is equal to $24\sqrt{10} - 40$ toises, or 35.8946538448 toises nearly. But since FEH is an isosceles triangle, the angle FEH or DBC is equal to twice the angle mFH, which is therefore equal to $9^{\circ} 13' 3''$ nearly.

The flank FH being equal to $\sqrt{Fm^2 + mH^2} = 3\sqrt{16300} - 5100\sqrt{10}$ toises, is equal to 27.27322895 or 27.275 toises nearly. And if from the extremity H of the line of defence AH there be drawn Hn to meet the face FB of the bastion in the point n, we shall have Hn

equal to $\frac{DH \times Fm}{Dm} = \frac{230 - 60\sqrt{10} \times 18\sqrt{10} - 30}{24\sqrt{10} - 40}$

toises, or 30.1976 toises, exceeding the perpendicular CD to the exterior side by 0.1976 of a toise only.

And as Fm is a fourth proportional to Dm, mH, and DF, or is equal to $\frac{mH \times D \times F}{Dm} = \frac{270 - 84\sqrt{10} \times 30\sqrt{10} - 50}{24\sqrt{10} - 40}$

toises, it is equal to 5.161 toises nearly. And Dn is equal to 50.392 toises nearly.

Now in Count Pagan's construction, from whom Mr. Vauban has borrowed the length of his perpendicular, on which the other parts chiefly depend, the flank FH is equal to $18\sqrt{10} - 33$ toises, or to 23.921 toises nearly, which falls short of the perpendicular Fm, drawn from the *epaule* F, in Vauban's construction, to the line of defence AH, by 3 toises, and of the flank FH by 3.35222895 toises. In any polygon, having its exterior side equal to 180 toises, their perpendiculars are equal, as well as the salient angles of their bastions. And we are persuaded, that even the greatest admirers of Vauban can assign no good reason for his not having followed Count Pagan also, with regard to the position of his flank, and placed it at right angles to the line of defence, instead of making them meet in an angle of $80^{\circ} 46' 57''$. There is great reason to suppose, that the Count would have made the face of his bastion considerably shorter than he did, had he not intended to have three flanks instead of one. He makes it 55 toises. But it is naturally to be presumed, that, had he intended to construct with a single flank, he would have bisected the perpendicular distance between his orillon and inner flank, (which is 19 toises,) and drawn his flank at right angles to the line of defence through this point of bisection, thereby forming a more complete construction for the body of the place than Vauban has done. And it is somewhat remarkable, that this line nearly coincides with the perpendicular Hn, to Vauban's line of defence, from its point H of intersection with the flank. Had he therefore, instead of taking 5 toises from the face of Count Pagan's bastion, taken 10, and then placed his flank at right angles to the line of defence, he would, without lengthening this line, have given the face of his bastion its proper length, and, at the same time, made the flank itself about equal to the perpendicular, as it ought to be, since perpendiculars to the exterior sides of polygons were first introduced into construction for the sole purpose of obtaining flanking defences. The lengths, however, with both these authors, as well as the other writers on fortification, are merely arbitrary, and by no means derived from reasoning either on the properties of the figures, or their relative degrees of importance and capability of defence. For there appears no reason for giving the same perpendicular to a hexagon and every other polygon of a greater number of sides, as Vauban has done, or to all regular figures above the square, as Count Pagan has done.

This author retains part of the *fausse-bray*, which used to go round the whole body of the place, at the distance of from 4 to 5 toises from the same, making use of it as *tenailles* opposite to his curtains, which are made differently.

A tenaille is commonly from two to three feet only higher than the level ground of the ravelin. The tenaille *abcd*, *efg*, (Plate VI. fig. 7.) is constructed by first setting off from the epaulés E, F, on the lines of defence Ea, Fg, equal each to three toises, for a passage between it and the flanks of the baillons; then taking *ab, gf*, for its faces, equal each of them to 16 toises, by describing from the shoulders *b* and *f*, as centres arcs with a radius equal to *bf*, and then by intersecting these arcs from the same shoulders as centres, with a radius equal to 10 toises, for its flanks *bc, fe*. Some, however, make the faces *ab, gf*, equal to half the lines *aD, gD* respectively, and place the flanks at right angles to the lines of defence, which is certainly the best position for them.

The tenailles *abcd, efgb*, (fig. 8.) are without flanks, and have their faces on the lines of defence. The passage between them, as well as the passages between them and the flanks, are three toises wide. These are called *simple tenailles*, and the foregoing is called a *reinforced tenaille*. There is also a third sort of tenailles, which have only faces *ab, gf*, and flanks *bc, fe*, without a curtain *ee*.

Simple tenailles, with their faces on the lines of defence, but without flanks, are not so well calculated for scouring and defending the ditch as either the *reinforced tenailles* are, or those with faces, and flanks without curtains. However, as they are not liable to be enfiladed, Mr. Vauban has generally preferred them to the other two, in most of the places which he fortified.

The *reinforced tenailles* defend the ditch much better, and add low flanks to those of the baillons, but are liable to have their own flanks enfiladed, an inconvenience that might be remedied by constructing them in such a manner as to be covered by the extremities of the parapets of the opposite ravelins, or by the adjoining *lunettes*. These are well calculated for scouring not only the ditch, but also the level ground of the ravelin, and the ditch before the *corps de guard, reduit*, or redoubt, commonly made within it, which cannot be so well seen or defended from any other parts.

Those with faces and flanks only, have the same advantages with these as to the defending or scouring of the ditch, but are also, like them, liable to have their flanks enfiladed, which should be guarded against in the same manner.

The better to scour and defend the ditch, and oppose its passage, this fortifier places in it, opposite to the middle of the *tenaille*, or of the curtain, a caponiere, or double way, covered with a parapet raised three feet above the bottom of the ditch. It is about 12 feet broad, is perpendicular to the curtain, and is palisaded on both sides. This work is good, and very useful, as it commands without being commanded, and serves as a passage for the musketeers from the body of the place to the outworks. He thus has four flanks for the defence of his ditch, namely, that of the body of the place, that of the orillon, that of the tenaille, and the caponiere.

Tenailles are reckoned to be necessary, that it is with good reason that there are few places fortified without them. For when the ditch is dry, the spaces behind them serve as places of arms, from which the troops may fall to oppose the enemies' descent of the ditch, to retard his operation, and destroy his works in it, and then retire to them as places of safety. They also render the communication between the body of the place and the ravelins more easy and secure, which is a great advantage, as the ravelins are thereby enabled to make a much better defence than they otherwise could do, being readily supplied at any time with troops and necessaries. And when the ditch is wet, the spaces behind them serve as harbours for boats, which armed men can make use of, both for opposing the passage of the ditch,

and for facilitating the communication between the tenailles and the ravelins.

This fortifier, in order to increase the strength of a place, places frequently works called *lunettes* (which literally signify spectacles) on both sides of his ravelin. He sometimes makes one face of his lunette perpendicular to the middle of the face of the ravelin, and sometimes perpendicular to the face of the ravelin, and so as produced to the same about one-third from the salient angle. In the former case he makes that face of the lunette equal to 30 toises, and determines its other faces by taking for the demi-gorge 25 toises, on the counterescarp of the great ditch from that of the ditch before the ravelin; and in the latter he makes the demi-gorge equal to 20 toises only. The ditch before the *lunettes* is 12 toises broad, the thickness of the parapet is equal to three toises, and that of the rampart to eight, as in the ravelin.

When he makes use of *lunettes*, he sometimes covers the salient angle of the ravelin with a work called *borne*, of which the faces are parallel to those of the ravelin, and when produced bisect those of the *lunettes*. The ditch before it is ten toises wide.

Tenailions. The term *tenailion* is sometimes applied to a reinforced tenaille; but it is generally confined to a work somewhat like a lunette, made on each side of a ravelin, but differing from a lunette in this circumstance, that one of the faces of a *tenailion*, though it is 30 toises long, like that of the lunette, is in the direction of the ravelin produced beyond its ditch, whereas that of the lunette is perpendicular to it. The other face of the *tenailion* is determined by taking 15 toises on the counterescarp of the great ditch from that of the ravelin. There is sometimes in a *tenailion* a battery 15 toises long, and 10 toises retired from the front and parallel thereto.

There are generally retranchments in *tenailions* which have their parapets either parallel to their fronts or perpendicular to their other faces, which, when produced, terminate on the faces of the baillons. The ditch before such a retranchment is about three toises wide; and as these works are commonly made of earth, without any revetement of masonry, there is a banquette, called *berm*, before the parapet, next to the ditch, about eight feet broad, to prevent it from falling into the fame.

As to the construction of counter-guards, horn-works, crown-works, covert-ways and glaces, detached redoubts, second ditches, and covert-ways, and profiles. See the same under these articles respectively.

Mr. Vauban, in his second method with tower-baillons, according to the plans of Landau and Besford, begins with his construction inwards, and fortifies outwards in the following manner.

Supposing A B (fig. 9.), to be the interior side of the hexagon of 120 or 130 toises, draw A C, B D from the centre thereof, through the extremities A, B; set off six toises from A to *b*, and from B to *c*; through the points *b* and *c*, draw right lines at right angles to A B, on which set off six toises from *b* to *f*, and *c* to *b*, and four toises from *b* to *d*, and *c* to *g*; and from the points *f, d*, draw perpendiculars *fr, dn*, to the capital A C, as also from the points *b, g*, perpendiculars to the capital B D. Then, if *rE* be taken equal to *rf*, and *pF* to *pb*, the points E, F, will be the salient angles of the tower-baillons, of which E *f d n* and F *bg g* are the halves.

If on the capitals A C, B D, there be taken E C, F D, equal each to 40 toises, the points C, D, will be the salient angles of the counter-guards before the towers. From the points C, D, draw the lines of defence C *e*, D *b*, to the points *e, b*, where the flanks of the towers intersect the curtain.

CONSTRUCTION.

tain. On these set off 56 toises, from C to G, and D to H, for the faces CG, DH, of the counter-guards. The flanks and tenailles are found or determined as in his first method.

The ditch before the salient angles of the towers is six toises broad, and its counterfearp is drawn to the extremities of the flanks of the counter-guards. The right line, which joins the ends of these flanks, determines the inside of the tenailles.

The ditch before the counter-guards is 12 toises broad at the salient angles, and its counterfearp is drawn towards the opposite shoulders, in the same manner as in his first method.

The capital of the ravelin is 45 toises, and its faces, when produced, terminate on those of the counter-guards, about 10 toises from the shoulders. Ten toises, however, are cut off from the faces of the ravelin, for the flanks which are parallel to its capital.

The ditch before the ravelin is 10 toises broad, the covert-way five, the demi-gorges of the places of arms 12 each, the faces 17 each, and the glacis is 20 toises broad.

The construction of Mr. Vauban's third method, according to the plan of New Briſach, is applied to an octagon, of which the exterior side is equal to 180 toises, and is made inwards. The perpendicular to the exterior side is, as in his first method, equal to 20 toises. The faces of the counter-guards are each of them equal to 60 toises. The flanks are found by setting off 22 toises, in arcs described from the opposite shoulders, as centres, and with the distance between as radius. A right line drawn through the extremities of the flanks, parallel to the exterior side, to meet the capitals of the counter-guards, determines both the inside of the tenailles, and the salient angles of the tower-baillon.

And if another right line be drawn parallel to this, at the distance of nine toises from it, the points, where it meets or intersects the capitals of the counter-guards, will be centres of the towers; from which points, if seven toises be

set off each way for their demi-gorges, the positions of their flanks, which are perpendicular to the said line, will be determined. For each of these flanks, five toises are let off outwards, and four from the said line. And the line joining the inside of the flanks at the end of four toises completes the towers.

The ditch is six toises broad before the salient angles of the towers, and its counterfearp meets the line joining these angles, within ten toises of the extremities of the flanks of the counter-guards.

The great ditch before the counter-guards is 15 toises broad, and its counterfearp is parallel to the faces. The capital of the ravelin is 55 toises in length, and that of the redoubt within it, is equal to 23 toises. The faces of the ravelin are drawn towards those of the counter-guards, within 15 toises from the shoulders, and those of the redoubt are parallel to these. Twelve toises are cut off from each face of the ravelin, and six from each of the redoubts by the flanks, which are parallel to its capital. The ditch before the ravelin is twelve toises wide, and that before the redoubt is six. The covert-way and glacis are the same as in his second method. The profiles also are nearly the same in both. This method, indeed, differs but little from his second, except in two small flanks, of about four toises each, which in this he makes in each curtain, that are not in the other. The parapets of his counter-guards, on both sides of the salient angles for the distance of about twenty feet, are raised four feet higher than the rest, to prevent these works from being annoyed by ricochet-batteries.

In Mr. Vauban's first method of military construction, it may not be amiss to give a table of the principal parts thereof, for drawing the matter-line by, as also an ichnographical one of the principal dimensions of the body of the place, tenailles, ravelin, covert-way, traverses, and places of arms, as published with his approbation (for he never published any thing himself respecting it.)

TABLE for the Construction.

Side of Figure, or Polygon.	Forts.						Little Fortification.				Mean.		Great.	
	90	100	110	120	130	140	150	160	170	180	190	200	260

		The breadth of the ditch	20			Thickness of its parapet at the base	3			

Thickness

CONSTRUCTION.

		Toises.	
Of the Half-moon or Ravelin.	Thickness of its rampart at the base	10	striking against, scatter the stones, and make them fly in different directions.
	Thickness of its parapet at the base	3	
	The breadth of its ditch	12	
Of the Covert-way, Traverſes, and places of Arms.	The breadth of the covert-way	5	He observes, that the bridges of his curtains do not interfere with the fire from his flanks along the faces of the bastions in the ditch, and he prefers that ditch which, by means of sluices, can be filled or emptied at pleasure.
	Length of the demi-gorge of the places of arms at the re-entering angles	10	
	Length of the faces, each of the places of arms	12	
	Length of the traverſes at the re-entering angles	5	
	Length of the traverſes at the salient angles	4½	
	Thickness of each traverſe at the base	3	

The construction of the Chevalier de Ville's method of fortifying is the following.

He begins inwards, and constructs outwards. He makes his flanks equal to the demi-gorges, and each of them equal to a sixth part of the side of the figure or polygon on which he constructs. In the square and pentagon, he determines the flanked angle or salient angle of the bastion by a tangent line; but in all figures and polygons of a greater number of sides than five, he makes it equal to a right angle, by describing a semicircle, as EGN on a right line, (fig. 10.) EN joining the epaules E and N, thereby making a second flank, as DI, CH, which increases with the number of sides in the figure or polygon. The length AG, of the capital of the bastion is, in this case, equal to the gorge line CP, or the distance between the points where the flanks of the bastion meet the adjoining curtains, a circumstance which furnishes an easy method of finding the points of the bastions.

The traverſes on the sides where their banquettes are, or on their insides, are from 5 to 5½ feet high, and from 3 to 4 on the outside, towards the covert-way, which they form at the re-entering angles.

He gives his caponiere a banquette on each side, and the parapet of the place two or three, to suit men of different heights or stature, that they may all of them fire on the same level.

He makes a cut opposite to each traverse in the parapet of the covert-way, 4½ or 5 feet deep, for the soldiers to pass, which he flunts up with a small merlon, except at the salient angles, where such cuts could not be seen by those who defend the place.

When he gives flanks to his ravelin, he makes places of arms in its ditch, perpendicular to its faces, and near the angles of the epaules, to prevent the passage of the same. When the counterſcarp of the ditch is reveted, or faced with masonry, he makes steps at all its angles for the convenience of the troops, and the service of the covert-way. Each detached piece or work should, for a similar reason, have a pair of stairs to lead up to it.

He makes the countermines of a place under the terre-plain of the rampart, on a level with the ditch, and about ten feet distant from the revetement, to which they are parallel, and have a communication with it through small arched heads, or passages. From the countermines of the place men go down into the caponieres, and then up into the countermines of the covert-way, from which heads or passages are carried on under the field to fourneaux or small mines, made for blowing up the besieger's works, and retarding their approaches.

He was of opinion, that when an eminence falls gradually from its summit towards the glacis of a place, works ought to be made one before another, with their salient or flanked angles sufficiently raised; that the most distant ought to cover all the rest, and draw its defence from them; and that they ought all of them to be built in such a manner, as to prevent an enemy from making a retrenchment in the first, without being exposed to the fire of the second; or in the second, without being exposed to that of the third, and so on.

The glacis should as often as possible be composed of pebbles, or of stones covered with turf, since the besiegers can work but slowly in it when so made, and the parapets thrown up in it by the pioneers, are apt to occasion their being killed or wounded, as the cannon-shot of the place

In constructing his casemates, or retired flanks and orillons, he sets off from C and D, on the flanks CE, DF, lines equal each to a third part of CE or DF, or of the demi-gorge, as Da, for instance, on DF. He also takes Fb in the face HF produced, equal to Da, and then draws bc parallel to Fa, to meet a right line joining a, and G the point of the opposite bastion. Then bc is the front of the orillon, when it is made square. But when he makes it round, he describes two arcs from b and c, as centres, with a radius equal to bc, and from their intersection as a centre through the points b, c, he describes the arc of his orillon.

The calculation of the lines and angles, according to his construction, may be made in the following manner.

If we suppose AB to be the side of a hexagon, the angle AOB of the centre will be equal to 60 degrees, and the angle BAS, or ABT, of the figure, equal to 120°. And as the flank is by the construction perpendicular to the curtain, the angle ECD of the flank is, of course, equal to 90 degrees. But as the flanked angle EGN is also equal to 90 degrees, the half of it, AGI, is equal to 45 degrees, and consequently the angle diminué AIG, being equal to half the excess of the angle of the polygon above the flanked angle, is equal to 15°. And the angle of the epaule is of course equal to 105°.

Wherefore, if AB be assumed of a given length, whether equal to 120 toises, or otherwise, the capital AG of the bastion, and the gorge-line CP, which is equal to it, is easily found by the following analogy, and the isosceles triangle CAF.

As the sine of the angle ACP, or APC, half the excess of 180° above the angle of the polygon, or half the angle of the centre.

Is to the sine of the angle of the polygon or centre,
So is the flank of the bastion or $\frac{AB}{6}$

To the gorge-line CP, or capital of the bastion AG. And the salient line GI, in the oblique-angled triangle AGI, is found by this analogy.

As the sine of the angle diminué AIG

CONSTRUCTION.

Is to the sine of the angle GAI , or its supplement

OAI , half the angle of the polygon,

So is the capital AG of the bastion

To the radius line GI .

And the line AI is obtained from the same triangle, by this analogy.

As the sine of AIG the angle *diminué*

Is to the sine of AGI , half the flanked angle,

So is the capital AG of the bastion

To the line AI .

From which, if there be taken the flank or demi-gorge, there will remain the complement CI ; which, taken from the curtain CD , leaves the second flank DI . The complement CI is also easily found from the right-angled triangle, ECI , by the following.

As radius

Is to the tangent of the angle $CEI = 90^\circ -$ the angle *diminué*,

So is the flank EC , a sixth part of AB ,

To the complement CI .

The side GH of the exterior polygon is determined by taking a fourth proportional to OA , AB and $OA + AG$.

The foregoing methods of construction have been called the *French manner*, particularly those of Count Pagan and Mr. Vauban, who borrowed from him the length of his perpendicular, which is the principal part of construction, and that on which all the other parts chiefly depend. Vauban's method, however, has been chiefly followed on account of its plainness and simplicity, with a single flank. It is proper, nevertheless, to give the constructions of some of those methods of fortifying that have been made use of in other nations.

The Italians, who have not been anxious about making the flanked angle, or angle of the bastion, either right or obtuse, but prefer having it acute for the purpose of getting a second flank on the curtain, have several methods of fortifying delivered by their authors, amongst which that of Sardi has been esteemed one of the best.

He begins inwards and constructs outwards, supposing AB equal to 800 geometrical paces or feet (*fig. 11.*). Of these he allows 150 for the demi-gorge AC or BD , and the same for the flank CE or DF , which he places perpendicularly to the curtain CD , on which he takes an eighth part DI for the second flank, making I the point in the curtain, from which the radius line drawn through E the extremity of the flank or angle of the epaule, gives the salient point G of the bastion on the lengthened radius OA . And this operation, continued round the figure or polygon, completes the construction.

He makes a casemate in each flank, capable of holding three pieces of cannon, by setting off from the extremity of the curtain on the demi-gorge, a line equal to a third part of the flank, and the same on the flank itself. And he makes his orillons either square or round.

He places square cavaliers on the middle of his curtains, of which the faces are parallel to the parapet of the rampart, and 30 feet distant from the same. In each of these he puts 7 pieces of cannon, three of which look into the field, and the other four towards the two adjoining bastions to flank such breaches as the besiegers may make in the faces of them, and prevent them from giving the assault.

The calculation of the principal lines and angles in Sardi's construction, may be made in the following manner.

Since the interior side AB is by supposition equal to 800 geometrical paces or feet, and the demi-gorge AC , and flank CE , each equal to 150 of these, the curtain CD

is equal to 500, and the second flank DI , which is the eighth part thereof, is equal to $62\frac{1}{2}$. Consequently the complement CI is equal to $437\frac{1}{2}$ fath feet or paces.

But if we suppose AB to be the side of a hexagon, the angle AOB of the centre will be equal to 60° , and the angle SAB or ABT of the polygon will be equal to 120° . And the angle ECD of the flank is by the construction equal to 90 degrees.

The angle *diminué* CIE is therefore found from the right-angled triangle ECI by this analogy.

As the complement CI

Is to the flank CE ,

So is the radius

To the tangent of the angle *diminué* CIE , which is about $18^\circ 55'$. If this be added to the angle of the flank, which is equal to 90° , we get $108^\circ 55'$ for the angle CEG of the *epaule*. And if the said angle *diminué* of $18^\circ 55'$ be taken from the angle OAI , or half the angle of the polygon, which is here equal to 60° , we get $41^\circ 5'$ for the angle AGI half the flanked angle. Consequently the flanked angle is about $82^\circ 10'$.

If to the complement CI we add the demi-gorge AC , we get AI equal to $587\frac{1}{2}$ fath feet or paces, and the radius line GI is therefore found from the oblique-angled triangle AIG by the following analogy.

As the sine of half the flanked angle AGI

Is to the sine of the angle GAI , or of half the angle of the polygon,

So is the line AI

To the radius line GI .

The capital AG of the bastion is also obtained from the same triangle by this analogy.

As the sine of half the flanked angle AGI

Is to the sine of the angle *diminué* AIG ,

So is the line AI

To the capital AG of the bastion.

If to the curtain CD we add the demi-gorge AC , we get the lengthened curtain AD , equal to 650 fath feet or paces, and from thence by means of the oblique-angled triangle GAD the sicient line GD in the following manner.

As the sum of the lengthened curtain and capital AD , AG ,

Is to their difference,

So is the tangent of half the sum of the angles AGD , ADG , or of one quarter of the angle of the polygon,

To the tangent of half their difference, which is found to be about $12^\circ 31'$. This taken from 30° one quarter of the angle of the polygon, or 120° , leaves $17^\circ 29'$ for the angle ADG , and added to the same gives $42^\circ 31'$ for the angle AGD . Wherefore,

As the sine of the angle ADG

Is to the sine of the angle GAD , or of half the angle of the polygon,

So is the capital AG of the bastion,

To the sicient line GD .

The Italian writers on fortification seem fond of having the flanked angles, or angles of the bastions acute, in order that the faces of the bastions, on the same side of the place, may defend one another, and serve as flanks when the casemates and flanks are battered down or ruined. But the second flank on the curtain is by this construction too small to make the flanked angle always acute. To make it answer this purpose, it would be an improvement of it to make the second flank increase in length, as the number of the bastions or of the sides of the figure increases.

It is perhaps worthy of remark, that the angle ADG

by this confitition on a hexagon, exceeds that subtended by the true perpendicular of a hexagon by about 17' only.

The angles of the fquare and pentagon are too fmall for a fecond flank. And the Chevalier de Ville, whose conftruction much refembles Sardi's in feveral refpects, appears to have borrowed from him the idea of making his flanks equal to his demi-gorges. He takes care however to avoid fecond flanks in the fquare and pentagon, and in other figures to make them increafe with the number of the fides of the figure.

The following is the conftruction of the Dutch method of fortifying according to Marolois.

Before he begins his conftruction he afcertains the magnitud of the flanked angle, or angle of the baftion, by adding 15° to half the angle of the polygon, which makes it in the fquare equal to 60° , in the pentagon equal to 69° , in the hexagon equal to 75° , in the heptagon equal to about $79^\circ 17'$, in the decagon equal to 87° , in the dodecagon equal to 90° , which he alfo allows for it in all figures or polygons of a greater number of fides.

He makes the curtain I K (fig. 12) equal to 36 rods of 12 Paris feet each, or 72 toifes, the face of the baftion A F equal to 24 fuch rods or 48 toifes, making the ratio of the curtain to it a fequalteral one, or that of 3 to 2. He makes the flank-forming angle F M I equal to 40° , when he wifhes to have only a fingle flank, in order that the demi-gorge I M may be to the flank in the ratio, nearly of 6 to 5, and equal to 35° only, when he intends to have a covered flank, making then the ratio of the demi-gorge to the flank about that of 7 to 5.

Let A B be an exterior fide. Make the angle B A O equal to half the angle of the polygon. Bifect the fame by the right line A P. Take the angle P A E equal to $7^\circ 30'$. On the rafant line A E fet off from A 48 toifes for the face A F. From the epaule F draw the perpendicular F G, and produce G F indefinitely towards I, making at the point F an angle I F M of 50° . Draw through the point M, where the line F M meets the radius A O, an indefinite right line, M N, parallel to the exterior fide A B, which will be a fide of the inward polygon. Take the curtain I K, equal to 72 toifes, and the line G H equal to it. Join K H, and on it take K L equal to the flank I F. Make the demi-gorge K N equal to the demi-gorge I M, and H B equal to A G. Draw the face B L, and the capital B N, which, being produced, will meet the capital A M alfo produced in the centre O.

The calculation of the principal lines and angles of the conftruction on the fides of a polygon fortified, according to Marolois's method, may be made in the following manner.

If we fuppofe A B to be the fide of a hexagon, we have the angle of the centre equal to 60° , the angle of the polygon equal to 120° , and confequently O A B half the angle of the polygon equal to 60° . Wherefore O A E, half the flanked angle, is equal to $37^\circ 30'$, which taken from O A B, half the angle of the polygon or 60° , leaves $22^\circ 30'$ for the angle *diminué* E A B. But the angle of the flank is a right angle by the conftruction. If to this then there be added the angle *diminué*, we fhall have $112^\circ 30'$ for the angle A F I of the *epaule* or fhoulder, from which if the angle I F M, which is equal to 50° , be taken, there will remain $62^\circ 30'$ for the angle A F M. The angle A M F is $= 80^\circ$.

The capital A M of the baftion is found from the oblique-angled triangle A M F by this analogy.

As the fide of the angle A M F
Is to the fine of the angle A F M,

So is the face A F of the baftion
To the capital A M.

And the line M F is found by this analogy.
As the fine of the angle A M F
Is to the fine of the angle F A M,
So is the face A F of the baftion
To the line F M.

The flank I F is found from the right-angled triangle M I F by this analogy.

As radius
Is to the fine of the flank-forming angle I M F $= 40^\circ$,
So is the line F M

To the flank I F, which is equal to about 19 toifes.

And the demi-gorge M I is found from the fame triangle by this analogy.

As radius
Is to the fine of the angle I F M $= 50^\circ$,
So is the line F M

To the demi-gorge M I, which is equal to about $22\frac{3}{4}$ toifes, the double of which or $45\frac{1}{2}$ toifes added to the curtain I K, which is equal to 72 toifes, gives the interior M N, equal to about $117\frac{1}{2}$ toifes.

The exterior fide A B is determined by means of the line A G, which is found from the right-angled triangle A G F, by this analogy.

As radius
Is to the fine of the angle A F G $= 67^\circ 30'$,
So is the face A F of the baftion, which is equal to 48 toifes,

To the line A G, which is equal to about $44\frac{1}{2}$ toifes, the double of which added to G H, that is, equal to 72 toifes, gives $160\frac{1}{2}$ toifes for the exterior fide A B.

The fecond flank E K is determined by means of the complement E I, which is found from the triangle E I F, by either of the following analogies.

As the fine of the angle *diminué* I E F $= 22^\circ 30'$

Is to the fine of the angle E F I $= 67^\circ 30'$,

So is the flank I F

To the complement I E.

Or, As radius.

Is to the tangent of the angle E F I $= 67^\circ 30'$,

So is the flank I F

To the complement I E, which is equal to about $45\frac{5}{8}$ toifes, and which taken from the curtain, which is equal to 72 toifes, leaves $26\frac{3}{8}$ for the fecond flank E K or I C.

The perpendicular diftance of the interfection of the lines of defence, from the middle of the exterior fide A B, is found by this analogy.

As radius

Is to the tangent of the angle *diminué*, which is $= 22^\circ 30'$,

So is half the exterior fide A B

To the perpendicular from it to the interfection of the lines of defence, which is therefore equal to about $32\frac{1}{2}$ toifes.

This conftruction furnifhes an eafy method of working on the ground, when through interruptions from buildings, hedges, thickets, &c. and from the unevennefs and irregularity of the ground itfelf, a regular polygon cannot eafily be defcribed by finding the centre of the circumfcribing circle. For fuch a polygon may be traced on the ground by means of the mafter-lines of the curtains and baftions, fetting off firft fucceffively the angle of the polygon without any reference to the centre. This author, however, inftead of making his flank equal to his perpendicular, as it ought to be, makes it fall fhort of the fame by not lefs than $13\frac{1}{2}$ toifes.

There are other methods of conftruction delivered by Dutch writers, which, however, are hardly deferving of notice. And

as in all their methods, they make a second flank on the curtain, and for the molt part draw at the same time the counter-scarp of the great ditch parallel to the faces of the baillions, they render the defence very defective. For the branches of the counter-scarp being thus parallel to the sicient lines, will, when produced, frequently meet the curtains, and will of course cover the greatest part of the ditch itself, from the view of the flanks of the baillions. And as the principal part of the ditch is thus fenced by the second flanks only, which are easily ruined, the entrance into it is rendered easy to the besiegers.

The following is the construction of the Spanish method of fortifying.

Take the interior side AB (*fig. 13.*) equal to 120 toises. From A to C , and B to D , set off 20 toises or a sixth part of AB , for each of the demi-gorges A, C, B, D . On perpendiculars to AB at the points C, D , take CE, DF , equal respectively to AC, BD , or to 20 toises each, or a sixth part of AB . Let O be the centre of the circle, which circumscribes the polygon, of which AB is a side. From D through E , and C through F , draw right lines to meet the radii OA, OB , of the said circle, produced in the points G, H . Then EG, FH will be the opposite faces of the baillions $CEGPQ, DFHRS$, and AG, BH their capitals. And the same construction continued on the other sides AM, MT, TV, VN, NB , completes the operation.

The calculation of the principal lines and angles of this construction is made in the following manner.

Since AB is equal to 120 toises, and AC, BD , each equal to 20, the curtain CD is equal to 80 toises. And since CE, DF , are each equal to 20 toises, or the sixth part of AB , and also perpendicular to AB by the construction, CD is to CE as four to one, and as radius to the tangent of the angle CDE , which is therefore equal to about $14^{\circ} 2'$. Wherefore the angle CED is equal to about $75^{\circ} 58'$, and the angle CEG of the epaule or shoulder is equal of course to about $104^{\circ} 2'$. These angles, therefore, are the same in all polygons. But the flanked of consequence, with the angles of the polygons.

Now, if we suppose AB to be the side of a hexagon, we have the angle AOB of the centre equal to 60° , and the angle MAO or ABN of the polygon equal to 120° . Consequently half the flanked angle OGD or AGD , which is equal to the excess of OGH or OAB , half the angle of the polygon, above the angle *diminué* ADG or CDE , is equal to $45^{\circ} 58'$: and the whole flanked angle, or angle PGE of the baillon, is equal to $91^{\circ} 56'$.

The capital AG of the baillon, is found from the oblique-angled triangle AGD , by this analogy.

As the sine of half the flanked angle AGD , which is $=45^{\circ} 58'$

Is to the sine of the angle *diminué* $ADG = 14^{\circ} 2'$,

So is the lengthened curtain AD , which is $=100$ toises,

To the capital AG of the baillon, which is equal to about 33.73 toises.

And the rasant line or line of defence DG , is found from the same triangle by this analogy.

As the sine of half the flanked angle $AGD = 45^{\circ} 58'$

Is to the sine of the angle $DAG = 120^{\circ}$,

So is the lengthened curtain AD , which is $=100$ toises,

To the rasant line or line of defence DG , which is equal to about 120.46 toises, or $120\frac{1}{2}$ toises nearly.

But DE is equal to $\sqrt{CE^2 + CD^2} = \sqrt{20^2 + 80^2} = 4\sqrt{425}$ toises $= 82.86$ toises nearly. Wherefore the face GE of the baillon is equal to 37.6 toises nearly.

The gorge-line CQ is found from the isosceles triangle CAQ , by the following analogy.

As the sine of the angle $ACQ =$ half the angle of the centre

Is to the angle of the polygon CAQ ,

So is the demi-gorge AC , which is $= 20$ toises,

To the gorge-line CQ , which in a hexagon, as this figure is supposed to be, is equal to about 34.64 toises.

The line OG being equal to about 153.73 toises, the exterior side GH , when AB is the side of a hexagon, will also be equal to about 153.73 toises. But GH is always determined by taking a fourth proportional to OA, AB , and OG .

The perpendicular distance KL of the intersection of the lines of defence, from the exterior side GH , is found by this analogy.

As radius

Is to the tangent of the angle *diminué* $L GK = 14^{\circ} 2'$,

So is GL or the half of GH , the exterior side,

To the perpendicular KL , which in the hexagon, as this figure is supposed to be, is equal to about 19.2 toises, falling short of the flank CE by about 0.8 of a toise, or eight-tenths of a toise.

The Spaniards, who are rather partial than otherwise to obtuse flanked angles, have no second flank on the curtain, but always construct their fortifications with a rasant, and never with a sicient line of defence, not minding whether the flanked angle or angle of the baillon be acute, right, or obtuse. Their mode of construct on, except as to the second flanks, and the making of the flanked angle right, is the same with that of the Chevalier de Ville, above described, being compounded of the Italian and Spanish methods, has on that account been called the composed draught, or the composed method of construction.

Let AB (*Plate VII. fig. 14.*) be the side of a regular hexagon inscribed in a circle, and equal to 160 toises. Set off from its extremities A and C on it AC, BD as demi-gorges, and each equal to an eighth part of AB , or to 20 toises. From the points C and D on right lines perpendicular to AB take CE, DF , as flanks equal each to 20 toises, or an eighth part of AB also. Take the curtains CI, DK , from the points C, D , and A, B , each equal to 40 toises, or a fourth part of the interior side AB ; and from the points I, K , on right lines, drawn perpendicularly to AB inwards, take IL, KM , for the retired flanks, each equal to 20 toises, or the eighth part of the interior side. Join the points L, M , by drawing LM for the retired curtain. From the extremities L, M , thereof through the points K, I , draw the right lines LK, MI , which being produced, will pass through the outward extremities E, F , of the flanks CE, DF , and will meet the lengthened radii OA, OB , in the points G, H , which will determine the salient points of two of the baillions. And a similar operation continued quite round on the other sides of the polygon, will complete the construction.

As the foregoing figure is supposed to be a regular hexagon, the angle of the centre is equal to 60° , and that of the polygon to 120° . And as ML is to LI , as 40 to 20 or 2 to 1, the natural tangent of the angle *diminué* $LM I$, or MGH to unity, as radius is equal to $\frac{1}{2}$ or to 0.500000, which is nearly equal to the natural tangent of $26^{\circ} 34'$. If this angle be taken from 60° , half the angle of the polygon, there will remain $33^{\circ} 26'$ for half the flanked angle, or half the angle of the baillon. The flanked angle therefore, or the angle of the baillon, is in a hexagon equal to $66^{\circ} 52'$.

Now the line GI is found from the oblique-angled triangle AGI , by this analogy.

As the sine of $33^{\circ} 26'$, half the flanked angle, or AGI

Is to the sine of the angle $GAI = 120^{\circ}$,

So is the line AI , which is equal to 60 toises

To the line GI , which is equal to 94.31 toises nearly.

And the capital AG of the bastion is found from the same triangle by this analogy.

As the sine of AGI , half the flanked angle $= 33^{\circ} 26'$

Is to the sine of the angle *diminué* $AI G = 26^{\circ} 34'$,

So is the line AI , which is equal to 60 toises,

To the capital AG of the bastion, which is equal to about 48.704 toises.

But the line IM is equal to $\sqrt{IL^2 + LM^2} = \sqrt{25^2 + 40^2} = 4\sqrt{125} = 44.72$ toises nearly.

But EI is equal to IM . Wherefore GE , the face of the bastion, being equal to $GI - EI$, is equal to about 49.59 toises, or 49.6 toises nearly.

The short or little line of defence GM or HL , being equal to $GI + IM$, is equal to $94.31 + 44.72$ toises, or 139.03 toises, or 139 toises nearly.

The lengthened radius OG , and consequently the exterior side GH , when $A B$ is the side of a hexagon, is equal to $160 + 44.72$ toises, or to 204.72 toises.

The perpendicular distance of the intersection I , of the lines of defence, from the exterior $dc GH$, is found by either of the two following analogies.

As radius

Is to the tangent of the angle *diminué* $iGH = 26^{\circ} 34'$,

So is half the exterior side GH , or 102.36 toises,

To the perpendicular distance of i from the same.

Or, As radius

Is to the sine of the angle *diminué* $iGH = 26^{\circ} 34'$,

So is the little line of defence $GM = 139$ toises

To the perpendicular distance of the point i from GH , which is equal to about 62.166 toises.

This method was adopted for the purpose of constructing on a large front, and thereby lessening the number of bastions. And to keep the lines of defence GM, H, L , within musquet-shot, a curtain LM retired inwards, is made equal to a fourth part of the interior side $A B$, and opposite to the middle thereof. This manner of fortifying has been called the *ordre renforce* or re-inforced order, concerning which several Italian and Spanish authors have written large treatises. Like most other writers on fortification, who have delivered different methods of construction, they very absurdly make their angle *diminué* invariably the same in all polygons, without assigning any good reason for doing so, drawn from the natures or properties of the polygons themselves, the facility or difficulty of embracing them respectively, or from their relative degrees of capability of defence. In this method, the perpendicular distance of the intersection i of the lines of defence, from the exterior side GH , is more than three the length of the flank CE or DF .

Of Coehorn or Koehorn's methods.

The famous Minno, baron of Koehorn, who took many of the places, which the celebrated marshal Vauban had fortified, published three methods of construction, the first for a hexagon, the second for a heptagon, and the third for an octagon. The publication of his treatise on fortification however took place before he had acquired that great experience, which justly procured him the reputation of being one of the first engineers, that has ever appeared in Europe; and the methods delivered in it are not reducible to practice. That he afterwards thought so himself is evident from the towns which he fortified. For if, after acquiring experience in the attack of places he had really been of opinion that the methods he had published, were capable of making such a prodigious resistance or defence as he endeavoured in his book on fortification to show, that they were, it is a circumstance difficult to be

accounted for, that he never once thought of using them, when he had frequent opportunities of doing so. It ought also to be remembered, that his system of fortification was published before the method of firing *en ricochet* was either practised or invented.

In his first method the works occupy twice as much ground as they do in Mr. Vauban's, and being entirely of earth, low, and liable to be easily surpris'd, would require thrice as many men, at least, for their defence. His second and third methods are, in fact, impracticable, as the fortification in each of them takes up five times as much ground as the town or place it surrounds.

This being the case, we will just give a general description of them. In all the three he begins inwards and constructs outwards. The first he applies to a hexagon and supposes the surface of the water to be only about four feet lower than the level ground. In this he constructs from an interior side of 150 toises, from the extremities of which he sets off on the same 29 toises for each of the demi-gorges and 80 toises on the lengthened radii of the hexagon for the capital of each of the bastions. He thus leaves 72 toises for the length of his curtain. From the extremities of the interior side he takes, on the lengthened radii respectively, 40 toises for the points of intersection of the higher faces of the bastions, which are also equal each to 40 toises, and parallel to the lower faces that are in the lines of defence. The space between the lower and higher faces of the bastions is a dry ditch, the bottom of which is only about six inches above the level of the water in a wet ditch. Behind the lower parapet there is a banquette of three feet and a rampart of five, and under this rampart is a stone gallery, that runs from one end of it to the other, and is divided into several apartments, which are shut with doors. There is also a gallery, which goes from the salient angle formed by the lower faces to that formed by the higher with loop holes at small distances from one another, looking into the dry ditch. There are likewise rows of palisades placed parallel to the higher face at the distance of four toises from them.

The great ditch is 24 toises broad, and its counterscarp is parallel to the lower faces of the bastions. The demi-gorges of the ravelin are each equal to 29 toises, and the faces each to 45 toises. The dry ditch between the lower and upper faces of it is 16 toises broad. The rampart is 28 feet broad, the banquette three, and the parapet 20 . The lower faces are parallel to the higher ones.

The angle *diminué*, or the angle formed by the exterior side, and either line of defence, is in this method equal to $24^{\circ} 38' 48''$.

His second method he applies to a heptagon, and supposes the level of the ground to be only about three feet above that of the surface of the water. In it he constructs outwards from an interior side of 126 toises in length, from the extremities of which he takes on the same 30 toises for each of the demi-gorges. On the lengthened radii of the heptagon he sets off 72 toises for the capital of each of the bastions, at the extremities of which he draws right lines forming with the said capitals angles each of 40° , and on these lines he sets off 66 toises for the faces of the bastions respectively. From the salient angles of the bastions as centres with radii equal to the distance from the same to the extremities of the demi-gorges 30 toises distant from those of the interior sides he describes arcs, in which he sets off respectively chords equal each to 30 toises, and on these chords describes the mean flanks which are arcs of 60° .

The outline of his higher flank is 13 toises distant from that

that of the mean, and this flank is an arc described from the same centre, that the mean flank is described from, having its chord equal to 40 toises.

The dry ditch round the body of the place is 20 toises broad before the faces of the bastions, to which its counterescarp is parallel. There is a wet ditch before his tenailles 10 toises broad with two bridges at each end near the orillons, the one of which leads directly across it and the other along the face of the bastion.

The salient angle of the ravelin is 125 toises distant from the curtain of the body of the place and is of 70 degrees of magnitude. The faces are each 50 toises long, and the faces of the redoubt in it are 10 toises distant from those of the ravelin, and each 14 toises long. The wet ditch before the lower faces of the ravelin is 24 toises broad, and the work beyond that ditch, which he calls the second counterescarp, is 20, and parallel to the ditch.

The flanked angle or angle of the bastion in this method is equal to 80°, and the angle *diminué* or the angle formed by the exterior side and either line of defence is equal to twenty-four degrees and two sevenths. In his first method the angle of the bastion or flanked angle is equal to 70° 4' 24".

He applies his third method to an octagon, of which the side is equal to 110 toises, and from which he constructs outwards; and at its extremities he sets off 21 toises for each of the demi-gorges. On the lengthened radii, or radii of the octagon produced, he sets off from the said extremities of the interior side 64 toises for the capitals of each of the bastions, the faces of which he supposes to be each equal to 54 toises, and the salient or flanked angle equal to 85°. He thus makes his curtain equal to 68 toises.

In his first and second methods he has three flanks including that of the tenaille. But in this he has only two, the lower of which is determined or found by describing an arc through the extremity of the tenaille from the salient angle of the opposite bastion as centre and setting off from the said extremity in the said arc a chord equal to 20 toises, on which an arc of 60 degrees is described for the flank. The upper flank is described from the same centre, that the lower one is described from through one extremity of the curtain, and its chord is equal to 30 toises.

The wet ditch before the body of the place is 20 toises broad, and its counterescarp is parallel to the faces of the bastions.

The capital of the detached bastion is equal to 100 toises, its faces are directed towards the salient angles of the inner bastions. The dry ditch between the lower and higher faces of the detached bastions is 20 toises broad; and the higher faces are parallel to the lower, and each of them 34 toises long. The ditch before the detached bastions 24 toises broad. It is evident, that in this third method of Coehorn the angle *diminué* or the angle formed by the exterior side and either line of defence is equal to 25 degrees. For since the angle of the centre in an octagon is equal to 45°, that of the octagon is equal to 135°, from which, if the flanked angle, that by the construction is equal to 85°, be taken, we get 50° for the double of the angle *diminué*, which is of course equal to 25°.

Of Mr. Belidor's methods.

This author delivers three methods of construction, the first he applies to an octagon, of which the side is equal to 200 toises. In the three he begins outwards and constructs inwards. In the first he makes the perpendicular to the exterior side equal to 50 toises, the faces of his bastion equal each to 70 toises, and he finds his flanks in the same

way with Mr. Vauban in his first method. He makes his bastion with flanks equal each to about 26 toises. On the line joining the extremities of these flanks he constructs inwards, erecting a perpendicular to the middle thereof equal to 13 toises, through the inner extremity of defence and takes on them the faces equal each to 23 toises. The parts of the lines of defence from their intersection to the points where they terminate the flanks, are each equal to 14 toises. The dry ditch before this front is 10 toises broad at the inner extremities of the bastion, and its counterescarp produced terminates at the opposite shoulders. He connects the flanks of the bastions with the curtains or lines joining the faces of the interior front by means or works in the form of arcs called ram's-horns, which are described from the middle points of the said faces as centres with a radius of 23 toises. The salient angle of the redoubt in his bastion is in the intersection of the two adjoining curtains produced, and the faces of it terminate on those of the inner front within three toises of the *epaules* or shoulders. The ditch before it is 3 toises broad. It has a stone wall in the faces from three to four feet thick with loopholes. Mr. Belidor adds no outworks to this method of construction, which has certainly the advantage of all those with detached bastions. The retracements within are capable of a good defence, but occupy too much ground, particularly the ditches, that might be better disposed of. The flanks of such large bastions as his are too small. The great ditches are too large, being 20 toises broad at the salient angles of the bastions with its counterescarp directed towards their shoulders.

In this method his angle *diminué* or the angle formed by the exterior side and either line of defence is equal to 26° 33' 54", and of course the angle of his bastion or the flanked angle, as the construction is applied to an octagon, is equal to 81° 52' 12".

His second method of construction he also applies to an octagon, of which the exterior side is equal to 200 toises, the perpendicular to which, from the middle point thereof, he makes equal to 55 toises. The faces of his bastions, which are detached, are each equal to 70 toises, as in his first method. And the flanks as well as in the first are found in the same way as Mr. Vauban's.

The right line, that passes through the inner extremities of his bastion, serves as an exterior side for constructing the inward polygon on, the perpendicular to which, at the middle point thereof, is equal to 5 toises, through the inner extremity of which the lines of defence are drawn. On these the faces are set off, each equal to 24 toises; and the flanks are chords of arcs described from the opposite shoulders of the detached bastions as centres.

The inward polygon is in fact nothing else than a strong wall, behind the curtain of which, and at the distance of about 18 feet from it, there is an epaulement or a parapet of earth 3 toises thick. And within the bastions there are cavaliers, of which the fronts are circular arcs, described with a radius of from 23 to 24 toises. Their flanks are each equal to 7 toises, and their gorges to 33 toises each.

The counterescarp of the ditch before this inner polygon is distant from it at the salient angles, and is parallel to the curtain.

His tenailles, called ram's-horns, touch the outer lines of defence within three toises of the *epaules* or shoulders of the detached bastions, and are so described as to meet the said lines of defence inwards, beyond their intersection in the points, where the counterescarp of the inner ditch meets the same.

The outline of the curtain between the ram's-horns is 9 toises beyond or without the inner ditch.

The exterior line, from the retrenchment within his detached bastion is constructed, runs across the face, and meets the faces thereof about 20 toises from the *epaules*, or should-ers, the perpendicular to which line at the middle point thereof is equal to 17 toises. Through the inner extremity of this perpendicular the lines of defence for the retrenchment are drawn. On these lines, from the faces of the bastion, those of the retrenchment are set off equal each to 20 toises. The chord, on which the orillon is described, is equal to 5 toises, as is also that on which the retired flank is described. Both are made according to Mr. Vauban's method. The circular curtain of this retrenchment, and the rounded part of the ditch adjoining it, are described from the salient angle of the inner construction next to it, with a radius of 25 toises. The great ditch before the salient angles of the detached bastions is 20 toises broad, and as it is supposed to be dry, Mr. Belidor made a *caponiere* from the curtain between the ram's-horns to the ravelin of about 18 or 20 feet wide, the parapets of which he made terminate on both sides in a slope or glacis.

The capital of the ravelin he makes equal to 66 toises, and that of the redoubt within it equal to 30 toises. The faces of the ravelins are directed towards those of the retrenchments within the detached bastions, and those of the redoubt within it to the shoulders of the said bastions. The batteries in the ravelin are retired 8 toises back from the faces of it. The ditch in front of the ravelin is 12 toises, and the breadth of that before the redoubt is equal to 7 toises.

The demi-gorges of the *lunettes* are each equal to 25 toises, and their faces are perpendicularly directed towards those of the ravelin and detached bastions. The ditch before them is 8 toises wide, and the batteries in them are retired 8 toises back from their faces, and are each of them 15 toises long. The covert-way is 6 toises broad.

In this method the angle *diminué*, or the angle formed by the exterior side and either line of defence, is equal to $28^{\circ} 48' 39''$; and as the construction is applied to an octagon, the angle of the bastion, or the flanked angle, is of course equal to $77^{\circ} 23' 42''$.

It is manifest that in this construction the perpendicular to the exterior side, or of the great polygon, is much longer than it ought to be, since it exceeds the true perpendicular belonging to a polygon of 30 sides. For the angle *diminué*, which it gives, is greater than the true angle *diminué* belonging to a polygon of 30 sides, by upwards of one degree. And the angle of the bastion, or flanked angle, falls short of the real flanked angle in a polygon of 30 sides, by not less than 33° . The bastions are thereby made by far too large and extensive. The great ditch appears also to be too wide, as the excavation of it will furnish more earth than what is wanted for raising the ramparts. The works indeed, taken altogether, are too expensive to be erected. For it would require almost a whole army to defend them, besides such a prodigious quantity of stores and ammunition, as cannot be allotted for the service or defence of any one place.

Mr. Belidor applies his third method of construction, as he does his first and second, to an octagon, of which the exterior side is equal to 200 toises. But he makes the perpendicular to it at the middle point thereof equal only to 40 toises, which is very nearly indeed equal to the true perpendicular of an enneagon of the same exterior, and therefore comes nearer to the true perpendicular of an octagon

than that which has been described for it by any other writer on fortification. On this account we will give the construction of part of the body of the place on an octagon according to this method.

Let AB (Plate VIII. fig. 15.) be equal to 200 toises infide of an octagon. Bisect AB in the point C, and draw CD perpendicular thereto. From C to D set off to D, equal to 40 toises, and from the extremities A, and B, of the exterior side AB, through the point D, draw the lines of defence. On them take AE and BF for the faces of the bastions, equal each to 55 toises. The parts DA, DR, between the intersection, D, of the lines of defence, and the broken parts of the curtain, take each equal to 30 toises, and the length of each of the broken parts remains equal to 25 toises. The orillon is equal to 9 toises, and is part of a flank found according to Mr. Vauban's method. The flanks are retired 8 toises, and are arcs of 65° each. The outlines of the ram's-horns are 13 toises distant from one another. The passages at their extremities are each 3 toises wide. The outermost or lowest is described with a radius of 30 toises, and the other is described from the same centre. By making the same construction on two other sides of the octagon, the positions of the other faces, AG, BH, of the bastions is determined as well as the magnitude of the salient angle of each. He places cavaliers in the gorges of the bastions.

The capital of his ravelin is 44 toises, the demi-gorges of it are each equal to 31 toises, and its flanks, which are directed towards the shoulders of the bastions, are each of them equal to 9 toises. The ditch before the ravelin is 10 toises wide, and the covert-way is 6 toises broad.

The glacis before the salient angles of the bastions is 15 toises broad. The demi-gorges of the places of arms are each equal to 26 toises, and those of the redoubts or stone walls within them to 20. And the faces are parallel to the opposite demi-gorges. He makes arrows and detached redoubts after the manner of Mr. Vauban, but gives flanks to his arrows, which are parallel to the passages of 10 toises wide, that lead to them.

In this his third method of construction, the angle *diminué*, or the angle BAD, or ABD, formed by the exterior side and either line of defence, is equal to $21^{\circ} 48' 5''$, which differs from the true angle *diminué* of an enneagon by about 3 minutes only. And as it is applied to an octagon, the angle of the bastion, or the flanked angle, is of course equal to $91^{\circ} 23' 50''$.

It must be allowed that this construction for the body of the place is good. The ram's-horns are unquestionably well contrived, and are much preferable to tenailles, as they cannot be enfiladed from any one place, as they resist better by their bending or curvature outwards, the enemies' batteries, and render the flanks much superior to any batteries that the besiegers can erect against them. Like a mesc constructor on paper, however, he makes so many outworks, that they occupy a vast extent of ground, cannot be defended but by a very numerous garrison, and uncommonly large supply of ammunition, artillery, and provisions, and cannot be erected but at an immense expence.

The learned and ingenious Mr. Ozanam has given four methods of construction, in all of which he begins inwards, and fortifies outwards, from an interior side of 120 toises, and at the same time places or takes his flanks on right lines drawn from the centre of the polygon through the extremities of the demi-gorges set off on the interior sides.

In his first method he makes each demi-gorge equal to as many toises more than 20 as the polygon to be fortified

CONSTRUCTION.

has sides. In the square the demi-gorge is therefore equal to 24 toises, in the pentagon to 25, in the hexagon to 26, in the heptagon to 27, and so on to the decagon, in which the demi-gorge being equal by this rule to 30 toises, he makes it continue of this length in all higher polygons. He makes each flank equal to four times as many toises as the number of the sides of the polygon, allowing 16 toises for it in the square, 20 in the pentagon, 24 in the hexagon, 28 in the heptagon, and so on to the decagon, where the flank

being by this rule equal to 40 toises, continues of that length in all higher polygons.

The angle formed by right lines from the salient angle, and either shoulder or *epaule* of his bastion, he calls the *flank-forming angle*.

The following is a table of the lines and angles of a fortified polygon, from the square to the dodecagon, according to his first method of construction, the inward or interior side being equal to 120 toises.

Polygons	Sides.									
	4	5	6	7	8	9	10	11	12	
Angle of the centre	90° 0'	72° 0'	60° 0'	51° 26'	45° 0'	40° 0'	36° 0'	32° 44'	30° 0'	
Angle of the polygon	90° 0'	108° 0'	120° 0'	128° 34'	135° 0'	140° 0'	144° 0'	147° 16'	150° 0'	
Flank-forming angle	14° 2'	13° 1'	11° 53'	10° 36'	10° 2'	9° 21'	8° 44'	7° 50'	7° 22'	
Angle of the flank	120° 53'	112° 59'	108° 7'	105° 7'	102° 28'	100° 39'	99° 16'	98° 32'	97° 38'	
Angle diminuë	9° 42'	13° 19'	16° 49'	20° 14'	23° 46'	27° 16'	30° 43'	30° 49'	31° 16'	
Angle of the epaule	130° 40'	126° 18'	124° 56'	125° 21'	126° 14'	127° 55'	129° 59'	129° 21'	128° 54'

The following is this construction on a hexagon, of which the exterior side is equal to 120 toises.

Let ABCEPD (fig. 16.) be a regular hexagon, inscribed in a circle, of which the radius, A O, is equal to 120 toises. From the extremities A and B, set off A L, B M, for demi-gorges, equal each to 20 + 6 or 26 toises. In like manner set off A P, C Q; B a, D b; C T, E V; E c, F Y; F Z, D X; equal each to 26 toises. From the centre O, through the points, L, M, a, b, P, Q, T, V, c, Y, Z, X, draw the right lines O L, O H, O d, O e, O N, O S, O m, O h, O l, O b, O g, O f, and take I L, K M, a d, b c, Q S, T m, V h, c k, Y b, Z g, X f, equal each to 6 x 4, or 24 toises. From the points L, M, through the points K, I, draw right lines to meet the radii O B, O A, lengthened or produced in the points H, G. From the points a, b, through the points c, d, draw right lines in like manner, and so on round the figure. This operation will determine the salient angles of the bastions, and all the parts of the construction.

The calculation of the different lines and angles in this construction may be made in the following manner.

Since A B is equal to 120 toises, if from it there be taken the demi-gorge A L, or B M, which is equal to 26 toises, there will remain 94 toises for the lengthened curtain, A M, or B L, from which, if 26 toises be taken, we get the curtain L M, equal 68 toises. But as this figure is a hexagon, the angle of the centre is equal to 60°, and the angle of the polygon to 120°. The little radius is also of course equal to 120 toises.

The angle, I L M, of the flank, or its equal, A L O, is found by means of the following analogy.

As the sum of the sides O L + A L = 146 toises,

Is to their difference O L - A L = 94 toises,

So is the tangent of half the sum of the angles A L O, A O L = 60°,

To the tangent of half their difference, which is equal to about 48° 7'. This angle added to 60° gives 108° 7' for the

CONSTRUCTION.

the angle ILM of the flank, and taken from 60° leaves $11^\circ 53'$ for the flank-forming angle AOL, or AOL.

In like manner the angle *diminué*, LMI, or MGH, is found from the oblique-angled triangle ILM, by means of this analogy.

As the sum of the sides LM, LI, which is equal to 92 toises,

Is to their difference, which is equal to 44 toises,

So is the tangent of half the sum of the angles LIM, LMI = $35^\circ 56\frac{1}{2}'$.

To the tangent of half their difference, which is equal to about $19^\circ 77'$. This angle, taken from $35^\circ 56\frac{1}{2}'$, leaves about $1^\circ 49'$ for the angle *diminué* LMI, or MGH, and added to $35^\circ 56\frac{1}{2}'$ gives about $55^\circ 4'$ for the angle LIM; consequently the angle GIL of the epaule is equal to $124^\circ 56'$. And if $33^\circ 38'$, which is equal to twice the angle *diminué*, be taken from 180° we get $146^\circ 24'$, for the flanking angle GiH, or IiK. Double the angle *diminué*, or $33^\circ 38'$, taken from 120° , the angle of the polygon leaves $86^\circ 22'$ for the flanked angle, or angle of the bastion.

The angle *diminué*, $16^\circ 49'$, taken from $108^\circ 7'$ the angle of the flank leaves $91^\circ 18'$ for I L K, or I L H, the inner or inward flanking angle.

The line of defence, GM, is found from the oblique-angled triangle, A G M, by means of the following analogy.

As the sine of A G M, half the flanked angle, or $43^\circ 11'$,

Is to the sine of the angle of the gorge, G A M = 120° ,

So is the lengthened curtain A M = 94 toises,

To the line of defence G M, which is equal to about 119 toises.

And the capital, A G, of the bastion, is found from the same triangle, by means of this analogy.

As the sine of A G M, half the flanked angle, or $43^\circ 11'$,

Is to the sine of the angle *diminué* = $16^\circ 49'$,

So is the lengthened curtain A M = 94 toises,

To the capital A G of the bastion, which is equal to about $59\frac{1}{2}$ toises, to which, if we add the little radius OA, which is equal to 120 toises, we get $159\frac{1}{2}$ toises, for the great radius OG, to which the exterior side, G H, is equal, as the figure is a hexagon. And in every polygon, the exterior side, G H, is a fourth proportional to the little radius OA, the great radius OG, and the interior side A B.

The face, G I, of the bastion, is determined by finding the line I M from the oblique-angled triangle, I L M, by this analogy.

As the sine of the angle *diminué* I M L = $16^\circ 49'$,

Is to the sine of the angle I L M of the flank = $108^\circ 7'$,

So is the flank I L, which is equal to 24 toises.

To the line I M, which is equal to about $79\frac{1}{2}$ toises, and when taken from I M, the line of defence, leaves about $40\frac{1}{2}$ toises for G I, the face of the bastion.

The angle A O B is called the angle of the centre.

The angle B A C is called the angle of the polygon.

The angle N G I is called the flanked angle, or angle of the bastion.

The angle Ii K, or G i H, is called the outward flanking angle.

The angle G I L is called the angle of the epaule or shoulder.

The angle I L M is called the angle of the flank.

The angle I M L, or M G H, is called the angle *diminué*.

The angle AOL is called the flank-forming angle.

P N G I L is called a bastion.

A P, or A L, is called the demi-gorge of the bastion.

The line joining the points P, L, is called the gorge of the bastion.

The angle I L K, or I L H, formed by the flank I L and the line of defence L H' is called the inner flanking angle.

A B is called the inward or interior side.

G H is called the outward or exterior side.

O A is called the little radius.

O G is called the great radius.

I L, or K M, is called a flank.

I M is called the curtain.

A M, or L B, is called the lengthened curtain.

GM, or I H, is called a line of defence.

A G is called the capital line, or capital of the bastion.

A I, or H K, is called the face, or *pan* of the bastion.

The flank I L is called right flank, when it makes a right angle with the curtain; oblique flank when it makes an oblique angle with the same; and acute flank when it makes an acute angle with the curtain; as it does by Errard's method in figures up to the octagon. When the orillon is rounded or formed by the arc of a circle, it is called a round orillon, and when it is rectilinear, or formed by the face of the bastion, produced a few toises beyond the *epaule*, and a right line drawn from the extremity of the said prolongation, either parallel to the flank, or nearly so, it is called a square orillon. It is made for the purpose of covering part of the flank, which for that reason, or in order to be the more effectually covered, is taken a few toises inwards from the flank itself towards the centre of the bastion, and is generally made in an arc of a circle, though it would be better in a right line, or on the chord of an arc. It is on this account called the *retired*, or *covered flank*, and sometimes the *casemate*, and *place-basse*. And its depth, or enforcement, on the line of defence, produced beyond its intersection with the curtain, as well as its distance from the outside of the orillon, is called the *retirade* or *retrenchment of the flank*, or the *platform of the casemate*.

The line Q S is called flank, because it defends the face GN of the opposite bastion. For, in fortification, to flank has the same meaning or signification with the phrase *to defend*. When the line G Q is not composed of the face GN of the bastion, and a prolongation thereof to the angle Q of the flank, it is called *flank-siebert*, because a musketeer, at its extremity Q, can fire, or *sieher*, as the French term it, at or against any part of the face G N. Hence the line Q G, drawn from the said extremity Q of the flank, is called the *siebert-line of defence*, and sometimes only the *siebert-line*. It is also called the *great line of defence*. But when the face, G N, of the bastion produced, meets the curtain Q P, in any point R, between the points Q and P, or in any point R nearer to the said bastion, the line G R is called the *rasant-line of defence*, or simply the *rasant-line*, and also the *little line of defence*, being shorter than the line G Q, because a musketeer cannot from the point R fire at or against any part of G N, the face of the bastion, but can only rase or fire along it. The part Q R of the curtain intercepted between the lines G Q, G R, is called the *second flank*, as also the *fire or curtain*, because from every point in it, except the extremity R, one may shoot or fire against every part of the face G N. Second flanks are not always, nor indeed frequently, made. And when there are none, there are no *siebert lines*, but only *rasant-lines of defence*, in which case the flanks are called *rasant flanks*, because from their extremities, that join the curtains, one can only rase or fire along the faces of the opposite bastions, but from any intermediate points between those extremities and the *epaules*, he can fire at or against the said faces. The flanks form the principal defences, since an enemy cannot, whilst they remain entire, approach the body of the place. And they

CONSTRUCTION.

are, for that very reason, the parts which he first endeavours to destroy, in order to facilitate his passage of the great ditch.

The angle ILM, which the flank IL makes with the curtain LM, is called the *angle of the flank*, and the angle GIL, which the flank IL forms with the face GI of the bastion, is called the *angle of the epaule*, or simply the *epaule*, from which comes the word *epauler*, to cover on one side, or to cover the flank or the shoulder of the besieged in such a manner, that he cannot be seen or discovered on that side from without. The face GI, which thus covers the *epaules* or shoulders of those who assist in defending the place in the flank IL, is therefore called *epaulement*. The point or angle A, of the inward or interior polygon, is called the centre of the bastion.

When the flank, IL, is on a right line, drawn from the epaule I, to the centre O of the polygon, as it is in all his four methods of construction, it forms, when produced to the said centre O, an angle AOL, which is called the *flank-forming angle*. The angle IGN, which the two faces GI, GN, form at the point G of the bastion, is called the *flanked angle*, or *angle of the bastion*, because it is flanked or defended by the two opposite flanks QS, MK. The right line GH, drawn from one flanked angle to another, and which marks the distance between them, is called the *base-line*, and the side of the outward or exterior polygon, which in regular construction is always parallel to AB, the corresponding side of the inward or interior polygon. A re-entering angle is that which retires inwards; and in terms of fortification it is called a *tenaille-angle*, or simply a *tenaille*. And such of them as are formed by the meeting or intersection of two rasant lines, making an obtuse angle, are called *flanking angles*, as for instance the angle GiH; and the lines Gi, Hi, forming it, are also called *tenailles*. The angle GiH is also called the *outward flanking angle*, to distinguish it from the angle ILM, formed by the flank IL, and the rasant line GL, when the flank is rasant, which is called the *inward*, or *inner flanking angle*; or from the angle GRQ, when there is a second flank RQ, which is also called an *inward flanking angle*.

The rasant lines, GM, HL, always make acute angles with the curtain LM, either of which, as IML or GML, is called the *angle diminué*, or *angle diminué*, and is equal to the angle MGH, which GM forms with the base-line, or exterior side GH. The angle GAL, formed by the capital AG and the demi-gorge AL, is called the *gorge angle*, or *angle of the gorge*, and is always equal to the excess of 180° above half the angle of the polygon OAB; which half angle is called the *base-angle*.

In his second method of fortifying or constructing, he supposes the demi-gorges to be the same as in his first method: but instead of making each flank equal, as in it, to four times as many toises as the number of the sides of the figure or polygon, he, in this, makes each flank equal to 10 toises, together with twice as many more as the figure or polygon has sides. He thus allows 18 toises for each flank in the square: 20 for each in the pentagon; 22 in the hexagon; 24 in the heptagon; 26 in the octagon; 28 in the enneagon; and 30 in the decagon, in which the flank and demi-gorge being equal to each other, and to 30 toises respectively, he makes them continue so in all higher polygons.

But as it happens by this method of construction, that in the octagon, and all the higher polygons, the flanked angle or angle of the bastion becomes obtuse, in order to limit it to a right angle, he describes on a right line, joining the epaules or outer extremities of the flanks of each bastion, a

femircircle, which occasions a second flank upon the curtain, and two lines of defence, one rasant and the other schanct.

The calculation of the principal lines and angles in this construction is easily made.

In his third method of construction he makes his demi-gorges, as in the second, of the same length as in the first, and his flanks of the same length as in the second: but instead of limiting the flanked angle or angle of the bastion to a right one, by supposing a femircircle to be described on a right line, joining the two epaules, he supposes it to remain always acute, by making the capital AG equal to the gorge-line PL.

The calculation of the principal lines and angles is easily made on this supposition.

In his fourth method he has no second flanks, but makes all the defences rasant. He considers this method as more general than the three foregoing ones, which it certainly is, since it does not limit the lengths either of the demi-gorges or of the flanks, which, in this as well as in the others, are always on right lines, drawn from the centre of the polygon, through the extremities of the demi-gorges. And although the demi-gorges become greater with the number of the sides of the polygon, they increase so slowly, that in one of 60 sides the demi-gorge is only equal to about $3\frac{1}{2}$ toises. The following is his construction for this method.

From the centre O of the polygon or figure, draw a right line perpendicular to the inward or interior side AB. Divide this perpendicular into such a number of parts, as exceeds the number of the sides of the figure or polygon by unity. Set off two of those parts from each extremity of the inward or interior side, which is always supposed to be equal to 120 toises for each demi-gorge, and take three of them from the said extremities on the little radii produced for the capital of each bastion. Then, from the outer extremities G, H, of these capitals, which are the points of the bastions, draw right lines to the points M, L, where right lines, drawn from the centre through the extremities M, L, of the demi-gorges, intersect the interior side. And these rasant lines, so drawn, will determine both the faces GI, HK, and the flanks IL, KM.

By this construction, which is very simple and easy, the flanked angle or angle of the bastion begins to become obtuse in the enneagon, where it is equal to about $92^{\circ} 6'$, and grows more and more so in the higher polygons. This angle, however, increases but slowly, or at the rate of about one degree in each successive polygon, amounting in the dodecagon to about $96^{\circ} 26'$.

The calculation of the principal lines and angles, in this construction, is easily made in the following manner.

The perpendicular, from the centre O of the polygon to the inward or interior side AB, is found by this analogy.

As radius

Is to the tangent of the angle OAB = 60° ,

So is half the interior side AB, or 60 toises,

To the perpendicular from O to AB, which is equal to about 104 toises. Wherefore the gorge AL being, by this construction, equal to two-sevenths of this perpendicular, is equal to about $29\frac{2}{7}$ toises; and the capital AG, being equal to three-sevenths of it, is equal to about $44\frac{2}{7}$ toises. The lengthened curtain AM is consequently equal to about $90\frac{1}{2}$ toises. Wherefore the angle *diminué* AMG, or IML, is easily found from the oblique-angled triangle AMG, by this analogy.

As the sum of the sides AM, AG, which is equal to $134\frac{1}{2}$ toises,

Is to their difference, which is equal to $45\frac{1}{2}$ toises,

So

CONSTRUCTION.

So is the tangent of half the angle OAM, or 30° ,

To the tangent of half the difference of the angles AGM, AMG, which is equal to about $11^\circ 6'$. Consequently the angle AGM, or half the flanked angle, is equal to about $41^\circ 6'$, and the angle *diminué* LMI to about $18^\circ 54'$. Wherefore the flanked angle, or salient angle of the bastion, is equal to about $82^\circ 12'$, to which adding the angle of the centre, or 60° , we get the flanking angle G i H, equal to about $142^\circ 12'$.

The angle LIM, in this construction, is obtained by means of the following analogy.

As the sum of the perpendicular from O to AB and half LM, or $134\frac{1}{2}$ toises,

Is to their difference, which is equal to $74\frac{1}{2}$ toises, or as 403 to 224 ,

So is the tangent of 45° , which is equal to radius,

To the tangent of $28^\circ 42'$, which added to 45° , gives $73^\circ 42'$ for the angle OLM, and consequently $106^\circ 18'$ for the angle ALO, or its equal ILM, the angle of the flank; to which if the angle *diminué* LMI = $18^\circ 54'$ be added; we get the angle GIL of the epaule, equal to $125^\circ 12'$. And if from the angle OLM there be taken the angle OAB, or half the angle of the hexagon, we get $13^\circ 42'$ for the flank-forming angle AOL.

The flank IL is found from the triangle ILM by this analogy.

As the sine of the angle LIM, which is equal to about $54^\circ 48'$,

Is to the sine of the angle *diminué* LML, which is equal to about $18^\circ 54'$,

So is the curtain LM, which is equal to about $60\frac{1}{2}$ toises,

To the flank IL, which is equal to about 24 toises.

And the perpendicular distance of the intersection *i* of the lines of defence, from the exterior side GH, is found by this analogy.

As radius

Is to the tangent of the angle *diminué* iGH = $18^\circ 54'$,

So is the half of the exterior side GH, which is equal to about 82.25 toises,

To the perpendicular distance of *i* from GH, which is equal to about 28.1605 or 28.16 toises nearly, exceeding the flank by 4.16 toises.

Mr. Muller, in his "Elements of Fortification," has delivered what he is pleased to call a new construction. It differs, however, from Mr. Vauban's first method only in the following particulars.

1st. Instead of supposing, like Vauban, each flank to be the chord of an arc described from the shoulder or epaule of the opposite bastion as centre, he supposes it to be the chord of an arc described from the intersection of the line of defence and counterescarp produced.

2dly. He makes his retired flanks rectilinear, instead of making them in circular arcs.

3dly. Instead of using Vauban's tenailles before the flanks, he places ram's-horns before them.

4thly. He makes his orillon 5 toises long only, instead of 9, like Mr. Vauban.

Lastly. Instead of drawing the right line, which terminates the retired flank from the salient angle of the opposite bastion, like Mr. Vauban, he draws it from a point on the face 5, or rather 10, toises within the said angle.

For, in his construction of this method, he begins, like Vauban, in his first method outwards, and constructs inwards. Like him he also supposes the exterior side of the polygon to be equal to 180 toises; and after observing that the perpendicular may be of any length, as the 6th, 5th,

or 4th part of that side, he, like him, also fixes on 30 toises for its length. Like him also he makes the face of his bastion equal to 50 toises, or to $\frac{5}{7}$ ths of the exterior side.

He determines the salient angle of his ravelin in this manner: he sets off on the face of his bastion from 12 to 15 toises from the shoulder or epaule, and from the opposite angle of the flank as centre, with the distance therefrom on the line of defence to the extremity of the line, set off from the shoulder on the face of the bastion, he intersects the perpendicular to the exterior side, produced beyond it outwards.

He also gives the construction of a place with detached bastions from an inward or interior side of 130 toises, applied to an octagon, in which he substitutes small bastions instead of Vauban's tower-bastions. In this method, he makes the demi gorges of his small bastions each equal to 12 toises, the capitals of his detached bastions each equal to 55 toises, and their faces equal each to 60 toises. He determines the salient angle of his ravelin, by describing from the extremity of the flank, as centre, through a point in the face of the opposite bastion, about 20 toises from the shoulder, an arc to intersect the right line, in which is the capital of the ravelin.

He likewise gives the construction of a place with detached orillon-bastions, beginning outwards, and constructing inwards from an exterior side of 200 toises, and applying it also to an octagon.

He makes his perpendicular, in this construction, equal to 40, or a fifth part of the exterior; the faces of his bastions equal each to 55 toises; the radius of the arc, that serves to determine the position of his flank, equal to 22 toises; the width of the ditch of the salient angles equal to 16 toises; his orillon equal to 5 toises; and he keeps his flank retired 5 toises.

The marquis de Montalembert has published a large treatise on fortification, in which he makes much use of casemates and arches so much condemned by the Chevalier de Ville. His construction is in fact the same with Mr. Blondel's, applied to a right line or polygon, of an infinite or indefinite number of sides. For in this extreme case, which is of all others the most defective, Mr. Blondel's construction leaves no curtain, but gives the perpendicular equal to half the exterior side, and the angle *diminué* equal to 45° . In descending, however, from the right line or polygon of an indefinite number of sides, Mr. Blondel's construction affords a curtain, which gradually increases as the number of the sides of the polygon decreases, whilst the angle *diminué* at the same time gradually decreases, which in a hexagon, by his rule for determining it, *viz.* by taking from 45° , a third part of the angle of the centre of the polygon, is equal to 25° . But the marquis de Montalembert makes his angle *diminué* in every polygon, and on all occasions, invariably equal, to 45° . His construction is formed by the placing of triangles contiguous to one another, or by the juxtaposition of the angles at the bases of triangles in such a manner, as to make the other sides form re-entering angles equal each to a right angle, from which circumstance it is called *la fortification perpendiculaire*. It therefore affords no curtains or bastions, but when the section is of only an ordinary height, it necessarily creates dead parts from the re-entering angles quite to the salient ones, or throughout its whole extent.

It may indeed be alleged, that these dead parts can be removed by casemates in the revetements, counterescarp, caponiers, &c. &c. and no doubt they may. But what good reason can be assigned for adopting a mode of construction, which creates every where those very defects, which in constructing the body of any place, it has hitherto been the first object and principal business of every fortifier to avoid, and

then having recourse to a number of expensive, and otherwise unnecessary, contrivances, merely to get rid of the defects thus created.

As we understand that this system of fortification has been much disapproved of by some of the ablest engineers, on the Continent of Europe; and as the late duke of Richmond, when master-general of the ordnance, was so partial to it that it was with much difficulty and after a great deal of discussion, that the engineers in the Portsmouth division, could persuade him to adopt Vauban's first method in preference to it, for the new pentagonal fort, that has been erected on Portsea island, near Lauceston harbour; a candid and impartial comparison between these two methods of construction may not be useless to professional men, or unacceptable to the public. But we cannot make a comparison between them more ably, correctly, and scientifically, than it is drawn in an anonymous publication of 1794, re-published in 1805, in the following words.

"It is manifest then, that after a work is once adapted to the ground it is to occupy, &c. the first consideration is to construct it in such a manner, as to leave no dead parts; that is, to leave no such parts as cannot be seen, fired on, or flanked from some other parts. That this is a fundamental maxim, and ought to be a primary object of attention in the construction of every work, is manifest from this circumstance: that, were it not with a view to obtain flanking defences for the different parts, a rampart and parapet might as well be raised along the exterior sides of figures themselves, or the curves circumscribing them, as along the several parts of those figures, into which the sides are usually broken for this purpose. The strength of a work, indeed, depends chiefly on its flanks; since an enemy cannot approach the body of the place, whilst the flanking defences remain entire. But if there be dead parts, the moment an enemy gets to them, he finds himself in a state of security, and out of the reach of the besieger's fire. An idea therefore of the necessity of avoiding them has always made such a forcible impression on the minds of able fortifiers, as to induce them to limit the heights of bastions. For even when the side of a polygon is 180 toises long, and is broken into two demi-bastions, and a curtain with flanks, if the section of the work be very high, the guns in these flanks cannot see or scour the ditch but at too great a distance. When it is only of an ordinary height, it is well known that the guns in the flanks do not see the ditch effectually nearer than the intersection of the lines of defence, which in Vauban's construction is 44.8683 toises, or 45 toises nearly from the shoulders of the bastions, and 40.2632, or 40 toises and a quarter nearly from the re-entering angles formed by the curtain and flanks. When the exterior side, therefore, is less than 180 toises, the section ought to be kept proportionally lower, provided only it be not so low as to expose the body of the place to surprise. But if it once be admitted as a maxim, that a fortification ought to be constructed without the least regard to any flanking defence, and that the avoiding of dead or unseen parts is an object not worthy of attention, it is evident that the rectilinear and curvilinear are greatly preferable to the zig-zag or triangular construction formed by constituting triangles on the sides of any right-lined figure or polygon. The fire from a straight line is the best of the direct kind that can be obtained, being equally and uniformly distributed. And the enemy cannot advance against it directly, without a good deal of delay, inconvenience, and trouble, but must carry on his approaches somewhat in the way commonly practised, till he gets to the dead parts in front of it: when, unless contrivances be made use of that have no natural or inseparable connexion with the construction itself, it will cease to be formidable for want of

flanking defences. This observation likewise holds good in a great measure with regard to regular curves, from which the fire is also regularly distributed. The interior area too in each of these comprehended within the same eccentricity, length of enclosure, or extent of rampart, is much greater than in the triangular construction, which naturally, instead of producing any fire that is direct or at right angles to the exterior sides, produces no good flanking one for itself, but causes a continuity of dead parts, when the section is high and the lines of defence but short, to reign throughout its whole extent. An enemy can approach it without annoyance from the besieger in lines bisecting either the salient or re-entering angles, or in short in lines directed to any intermediate points whatever between these angles.

It must therefore be allowed, that the triangular construction, whether the re-entering angles be right ones (as in the "Fortification perpendiculaire" of the marquis de Montalembert), or acute or obtuse ones, is naturally the most defenceless and ill contrived of any, that can possibly be thought of or conceived: for it creates dead parts throughout the whole extent almost of the work, and is equally destitute of flanking fires for itself, and of a good or well distributed direct one against the enemy.

The marquis, fig. 4, planche 15, vol. i. of his performance, gives what he calls his regular construction in a dodecagon, of which the exterior side is 180 toises. The radius of the circumscribing circle is of course equal to 347.733297 or 347.7333 or 348 toises nearly, and the perpendicular distance from its centre to the exterior side 335.884572, or 335.8846, or 336 toises nearly. Consequently the annular area occupied by his construction is equal to that of the inscribed circle, in the circumference of which are his re-entering angles of 90°, or which comes to the same thing, to half the area of the circle circumscribing the dodecagon. But if Vauban's construction be made on the sides of the same figure, the annular area occupied by it will be to that of the inscribed circle, to which the curtains are tangents at the points, where the perpendiculars produced meet them, as 34986.228 to 85938.24, or as 17490 to 42969 nearly, or in small numbers as 20 to 49 nearly.

The exterior area between the construction and the sides of the dodecagon in Montalembert's method is to that in Vauban's as 8100 to 4270.2687, or in small numbers, as 19 to 10 nearly; and as both the salient and re-entering angles in the former are less than in the latter, this difference of lost area will be considerably increased in practice. For in the marquis's construction, each of the salient angles contains 60 degrees, and each of the re-entering ones 90; whereas in Vauban's the salient angle of each bastion is 113° 7' 48", and each of the re-entering ones formed by the flanks and curtains is 99° 13' 3".

Montalembert's construction gives the enceinte or boundary of the body of the place equal to 3054.70128 toises, exceeding Vauban's, which is equal to 2771.2836, by 283.41768 toises.

When he inserts or intercalates triangles having their salient angles right ones and in straight lines, as in figures 3, 5, 7 and 8, planche 15, after the method pointed out in fig. 1, he loses still more area in proportion to the interior space. And the very circumstance of his having recourse to different centres of construction, even on figures that are regular, is sufficient to create a suspicion, that he did not understand even his own method in its full extent.

Although he must certainly be considered as a very shallow and superficial geometer, the reason for his not fixing on any polygon under a dodecagon for illustrating his regular construction, is very obvious; for no regular figure of a smaller number

CONSTRUCTION.

number of sides, will by it give salient angles of sixty degrees, which is the smallest angular magnitude that engineers have generally reckoned admissible in fortification. I can see no good reason, however, (says our author) for his abandoning regular polygons, when he has occasion for more triangles than twelve, and by way of interpolation inserting the additional ones to this number between right lines parallel to the sides of triangles, squares, or rectangles; since a construction on the sides of a regular polygon furnishes much more interior area, with a comparatively but trifling increase of length in the enceinte or enclosure of the body of the place.

The comparison, which he draws, p. 197, (illustrated by fig. 9, planche 15.) between Vauban's method on the sides of a square, of which each is equal to one hundred and eighty toises, and his own on the sides of a dodecagon inscribed in the circle circumscribing this square, is a very improper and unfair one. In this figure, each of those lines, which he calls his lines of defence, is equal to 45.5874 toises, and mult, with a section of an ordinary height, have dead parts in front of it throughout its whole extent. Each of the sides is equal to 65.8846 toises very nearly, and not to 66 toises one foot, as from his scale he erroneously states it to be. The most candid and impartial mode of comparing these two methods of construction together is to suppose both to be made on the sides of one and the same figure. The marquis's construction, however, on the sides of a square, neither leaves interior area nor salient angles. For its re-entering angles meet in the centre of the circumscribing circle. But as in it the lines of defence when equal form angles of 45° with the exterior side, each of the salient angles, which it gives in any polygon, is equal to the excess of the angle of that polygon above 90°; or which comes to the same thing, to the excess of the re-entering angle formed by the lines of defence above the angle at the centre of the figure, since the excess of the angle of any regular polygon above 90° is equal to the excess of 90° above the angle at the centre of the circumscribing circle subtended by one of its sides. Consequently, when the polygon has an indefinite number of sides, or becomes a straight line, the salient angle is equal to ninety degrees. Thus a square with this construction gives no salient angle at all; a pentagon one of 18 degrees; a hexagon one of 30 degrees; a heptagon one of 38 degrees and four sevenths; an octagon one of 45 degrees; an enneagon one of 50 degrees; a decagon one of 54 degrees; an endecagon one of 57 degrees and three elevenths; a dodecagon one of 60 degrees; a polygon of 13 sides one of 70 degrees; a polygon of 36 sides one of 80 degrees; and so on indefinitely. By this construction on a pentagon, of which the side is equal to 180 toises, the re-entering angles come within 34 toises of the centre of the circumscribing circle; and within 19, if the exterior side be only equal to a hundred toises. How little interior area then would have been left, had this construction been made use of for the new pentagonal work on Portsea island, called Fort Cumberland, of which one of the exterior sides is equal to 120 fathoms, and each of the other four to a hundred! Even on a hexagon, of which the side is equal to 180 toises, it brings the re-entering angles within 66 toises of the centre of the circumscribing circle, and gives the annular area occupied by it to the area of the inscribed circle as $2\sqrt{3}$ to $4-2\sqrt{3}$, or as 6.4641 to 1, or in small numbers as thirteen to two nearly. If it be even made on parts of one and the same straight line as exterior sides, of which each is equal to 90 toises only, the perpendicular distance between that line and the right line passing parallel to it through the re-entering angles exceeds that between the parallel right lines, limiting Vauban's construction on parts of one and the same straight line as exterior sides

equal each to 180 toises, or two of the others, by 2.2576 toises, and only becomes equal to it, when the exterior side is reduced to 85.4548 toises.

The angle (105°) of a pentagon exceeds 90° by 15°, which are equal to the excess of 90° above (72°) the angle of the centre. But 15° are equal to $90^\circ \times \frac{1}{6}$ or $360^\circ \times \frac{1}{4 \times 6}$. In

like manner the excess of (120°) the angle of a hexagon above 90° is equal to 15° + 12° (= 30°) the excess of 90° above (60°) the angle of the centre, that is, to 360°

$\times (\frac{1}{4 \cdot 5} + \frac{1}{5 \cdot 6})$. Wherefore we get $360^\circ \times (\frac{1}{4 \cdot 5} \times \frac{1}{5 \cdot 6} + \frac{1}{6 \cdot 7} \times \frac{1}{5 \cdot 6})$, &c. indefinitely or *ad infinitum* = 90°, and of course

$\frac{1}{4 \cdot 5} + \frac{1}{5 \cdot 6} + \frac{1}{6 \cdot 7} + \dots$, &c. *ad infinitum* = $\frac{1}{4}$. Whence it is obvious, that methods of summing an endless variety of

such series, together with such series, as $\frac{n+m}{n \cdot n+1 \cdot n+m+1} + \frac{n+m+1}{n+1 \cdot n+2 \cdot n+m+2} + \dots$, &c. *ad infinitum*, and innumerable

other forms, may easily be derived from common geometry and the angular relations of rectilinear figures. But the summation of infinite series is a subject which it is not my intention to enter into the consideration of at present.

There is a circumstance attending this construction, which, I dare say, never occurred to the marquis. It is this: though on the sides of a square it brings the re-entering angles to the centre of the circumscribing circle, and leaves neither interior area nor salient angles; yet, if it be made on the sides of any given regular polygon, and the re-entering angles be joined by right angles forming a similar polygon, and on them a similar construction be made, and so on indefinitely or *ad infinitum*, it will never bring the re-entering angles to the centre of the circle circumscribing the given polygon, but nearer to it than by any given right line or distance. And if spirals be supposed to pass from the angles of the polygon through the angular points of equal angles in endless or indefinite succession (each equal to 45 degrees, together with the salient angle of the construction and the complement of its half) formed by the lines of defence taken singly from the first in the indefinitely successive constructions, will pass round the centre of the circle circumscribing the given polygon an indefinite number of times without ever reaching it; and the area between any two of these spirals commencing from one of the exterior sides of the polygon will become nearer in point of equality than by any given space or area to such a part of the polygon, as is expressed by the number of its sides, without ever equaling it. The sum or aggregate of these lines of defence, in decreasing geometrical progression and endless succession, can always be expressed by a given definite straight line.

From what has been observed, the following inferences may certainly be very fairly and impartially drawn respecting Montalembert's construction:—1st. When the exterior sides are short, it naturally creates, with a section of an ordinary height, dead parts throughout its whole extent. It may perhaps be alleged, that this capital defect can be removed by casemated defences with artillery near the re-entering angles on a level almost with the ditch. To a certain degree it certainly may: but that method of construction, which by itself naturally removes every such defect without any subsequent or adventitious contrivance, is surely entitled to preference in the opinion of every able or intelligent fortifier.

2dly. His saliant angles are too small, being less in a dodecagon than Vauban's are even in a square; for in a dodecagon his saliant angle is only equal to sixty degrees, whereas in a square Vauban's is equal to $60^{\circ} 55' 39''$, and in the dodecagon $113^{\circ} 7' 48''$. This is unquestionably an essential defect.

3dly. It furnishes no fire that is direct or perpendicular to the exterior sides. That this is a great defect cannot be denied.

4thly. Opposite to each re-entering angle, at the distance only of 90 toises from the exterior side, there is a quadrangular space (which no fire from the place scours, commands, or touches), commencing in an angle of 90 degrees, and terminating in one of 30 degrees, at the same distance from the exterior side with the centre of the dodecagon.

5thly. Opposite to every saliant angle, and at the distance from it only of about 254 toises and a half, there is a space that is not scoured or commanded by the fire of the place, which commences in an angle of 60 degrees, widens till its breadth becomes equal to the radius of the circle circumscribing the dodecagon, and then runs on indefinitely at that width between parallel lines.

6thly. The greatest width of each of the first-mentioned spaces not traversed by the fire of the place is to the corresponding width of each of the spaces traversed by it as 104 to 147, nearly: and the greatest width of each of the last-mentioned spaces not traversed by the fire is to the corresponding width of each of the spaces traversed by it as the radius of the circle circumscribing the dodecagon to 131.769 toises, or as 264 to 100, nearly.

7thly. As the respective breadths of these spaces not covered by the fire of the place bear so great proportions to the corresponding breadths of those covered by it, and, as the distance between every two of them is only equal to one of his lines of defence, or 127.2794 toises, the besiegers may advance almost to the very crest of the glacis without any interruption from the fire of the besieged. But it is an important object in defence to keep the besiegers at a distance from the body of the place as long as possible. For when they once get within the distance of serious musketry from it, they will infallibly silence artillery, whether the embrasures be open or covered at top, or whether the guns be in casemates or not.

8thly. The besiegers may easily destroy his principal covered musketry-defences before they are exposed to his principal casemated defences with artillery, which being low, to take off the dead parts unavoidably occasioned by the very nature and badness of his construction, are chiefly calculated for defending the passage of the ditch, and cannot annoy an enemy till he gets to the very crest of the glacis, after which every thing almost, except battering in breach, is determined without artillery.

Lastly. The great proportion which the annular area, occupied by his construction, bears to that of the inscribed circle, will for ever render it unfit for the purpose of fortifying any considerable town or city.

The marquis de Montalembert's construction has no claim even to originality, if we except the great impropriety (I had almost said folly) of making the lines of defence in it form the same angle in all figures, and on all occasions; for when applied to a straight line (as in fig. 1, planche 15, vol. i.) it is the same with Mr. Blondel's. In this case both give the perpendicular equal to half the exterior side, the angle *diminué* equal to 45° , the saliant angle of the bastion equal to 50° , the same line of defence, the same flanking or re-entering angle, and no curtain. The only difference between them consists in this, that Mr. Blondel, in descending from

the right line or polygon of an indefinite number of sides to interior polygons, makes his angle *diminué* gradually decrease according to the rule he has delivered for ascertaining its magnitude, whereas the marquis keeps his in all figures invariably the same. [Mr. Blondel's rule for ascertaining the angle *diminué* is the following: add fifteen degrees to one-third part of the excess of the angle of the polygon above 90 degrees.] Mr. Blondel's construction on an indefinite right line gives the perpendicular nearly double what it ought to be; and the marquis, by keeping this preposterously large perpendicular in all figures on the same exterior side and his angle *diminué* invariable, finds the saliant angle of his dodecagon equal only to 60° , the smallest that is generally considered by engineers as admissible in fortification. This circumstance, therefore, by the marquis's own acknowledgment, renders his construction inapplicable to any polygon of a smaller number of sides than twelve, and is certainly sufficient of itself to demonstrate not only its impropriety, but, I believe I may venture to say, even absolute absurdity. It in fact furnishes nothing but star-figures with re-entering angles of 90° ; and it is manifest that no regular figure of this sort under a dodecagon will give saliant angles of 60° .

Notwithstanding these observations, which I have certainly made with the strictest attention to truth, and, I flatter myself, also to candour, I am heartily disposed to allow every sort of merit to the marquis's voluminous performance, that either his grace or any other person can point out as really belonging to it. I never can be hostile to any person who even endeavours to enlarge the *potioria* either of abstract science or professional knowledge; for the very attempt is laudable. And I must confess I am inclined to believe, that some of his casemated contrivances might, in certain situations and circumstances, be advantageously united with Vauban's construction. I cannot help considering him however as rather a superficial geometer, and as a very loose and incorrect writer. But to prevent the possibility of charging me with misrepresentation in regard of his inaccuracies, I will briefly quote his own words.

In his "Discours Préliminaire," p. 38, he says, "Le premier système de M. de Cohorn est absolument le même que celui du Comte de Pagan, auquel il a seulement ajouté une tour casematée à chaque orillon, pour défendre les faces hautes des bastions."

That he should have hazarded such an assertion is to me astonishing. For these two methods differ widely and essentially. In Cohorn's first method, which is applied to a hexagon, for instance, the ratio between the perpendicular and exterior side is very different from what it is in Count Pagan's; since in the first the angle formed by the exterior side and line of defence is equal to $24^{\circ} 38' 48''$, whereas in the last it is only equal to $18^{\circ} 26' 6''$. The difference is $6^{\circ} 12' 42''$. The saliant angle of the bastion in a hexagon by Count Pagan's method is equal to $83^{\circ} 7' 48''$, whereas in Cohorn's first method it is only $70^{\circ} 42' 24''$, falling short of the other by $12^{\circ} 25' 24''$. These are capital and essential differences. And every person who chooses to examine them will find them very different in many other respects. Vauban indeed appears to have borrowed more from Pagan than Cohorn has done. For, in any polygon having its exterior side equal to 180 toises, their perpendiculars are equal as well as the saliant angles of their bastions; and I am persuaded that even the greatest admirers of Vauban can assign no good reason for his not having followed Count Pagan also with regard to the position of his flank, and placed it at right angles to the line of defence instead of making them meet in an angle of $80^{\circ} 46' 57''$. There is great reason to suppose that the Count would have made the face of his bastion considerably

siderably shorter than he did, had he not intended to have three flanks instead of one. He makes it 55 toises. But it is naturally to be presumed, that had he intended to construct with a single flank, he would have bisected the perpendicular distance between his orillon and inner flank (which is 10 toises), and drawn his flank at right angles to the line of defence through this point of bisection, thereby forming a more complete construction for the body of the place with single flanks than Vauban has done. And it is somewhat remarkable, that this line nearly coincides with a perpendicular to Vauban's line of defence from its point of intersection with the flank. Had he therefore, instead of taking five toises from the face of Count Pagan's bastion, taken ten, and then placed his flank at right angles to the line of defence, he would, without lengthening this line, have given the face of his bastion its proper length, and at the same time made the flank itself about equal to the perpendicular, as it ought to be, since perpendiculars to the exterior sides of polygons were first introduced into construction for the sole purpose of obtaining flanking defences. Were I at present treating formally of fortification, I would deliver a very simple method of construction for rendering the flanks always equal to the perpendiculars to the sides of the polygons. The lengths however assigned to these perpendiculars are merely arbitrary, and by no means derived from reasoning either on the properties of the figures or their relative degrees of importance and capability of defence. For there appears no reason for giving the same perpendicular to a hexagon and every other polygon of a greater number of sides, as Vauban has done, or to all regular figures above the square, as Count Pagan has done. In like manner Coehorn's perpendiculars are too long, and merely arbitrary: for in his first method, which is applied to a hexagon, the angle formed by the exterior side and line of defence is, as I have already observed, equal to $24^{\circ} 38' 48''$; in the second, which is applied to a heptagon, 24 degrees and two sevenths; and in the third, which is applied to an octagon, 25 degrees. This angle in Belidor's first and second methods applied to an octagon is also too great, being in the former equal to $26^{\circ} 33' 54''$, and in the latter to $28^{\circ} 48' 39''$. In his third method however, which is also applied to an octagon, it is equal to $21^{\circ} 48' 5''$, and is not so much distant from what it really ought to be, as it differs only about three minutes from the angle subtended by the true perpendicular of an enneagon.

The perpendiculars are also a great deal too long in Blondel's method, which, when it is applied to a straight line or polygon of an indefinite number of sides, gives one equal to half the exterior side.

The marquis, vol. i. p. 193, says, "Mais dès que lignes de défense peuvent avoir jusqu'à cent cinquante toises, et les hypothèses environ deux cent dix huit toises, il suit que le rayon de ce polygone régulier inscrit dans le cercle peut être de quatre cent vingt-neuf toises et demie, le rapport du côté du dodécagone à son rayon étant comme quinze est à vingt-neuf environ, et ce rayon est à-peu-près celui d'un polygone à bastions de quinze côtés, par conséquent de quinze bastions."

A right-angled triangle however, having each of the sides containing the right angle equal to 150 toises, does not give the hypothenuse equal to 218 toises, but to 212.132 toises, which, as the side of a dodecagon, gives the radius of the circumscribing circle equal to 409.876 toises very nearly, and not to 421 and a half, as he states it to be.

In page 203 he falls into the same mistake.—Take however his own words:

"Mais l'on a vu, comme il est aisé de le sentir, qu'il est un terme où le rayon d'un cercle ne pourrait plus déterminer le côté de notre manière de fortifier: et ce terme est

celui où la corde de l'angle au centre de trente degrés que le rayon donneroit, passeroit deux cent vingt toises, puisqu'alors cette corde prise pour diagonale auroit deux côtés de plus de cent cinquante toises chacun, qui est une distance plus grande que celle admise pour la portée des armes à feu de but en blanc."

Here he mentions 150 toises as the greatest admissible length for each of the lines of defence, and 220 for the corresponding hypothenuse, or exterior side, which he calls the diagonal. But the fact is, that a hypothenuse of 220 toises, gives either side of an isosceles right-angled triangle constituted on it greater than 155 toises and a half. There are many mistakes of a similar nature in this gentleman's performance, who appears to have used scales much more than calculation. The exposure of error, however, is an unpleasant task, even when the elucidation of truth is the object."

From the whole of what is above delivered, it appears evident, that the magnitude of the angle *diminué*, and of the perpendicular to the exterior side, on which the other parts of the construction chiefly depend, is with all the writers on fortification a mere arbitrary assumption, for which they do not even attempt to assign any reason, and much less any good one, drawn from the nature of the polygons themselves, the relative degrees of difficulty in embracing them, or their respective degrees of capability of defence. The truth is this, that every polygon has a perpendicular belonging to itself, of a precise and determinable length, or bearing a given ratio to the exterior side. And the ascertaining of the true perpendiculars belonging to all different polygons is the great desideratum now wanted for perfecting military construction. We understand, that Mr. Glenie, formerly of his majesty's corps of engineers, has had in his possession a complete investigation of this important problem for upwards of twenty-five years. But as he has not yet chosen to make it known to any person, we could not expect him to communicate it to us. He has, however, been pleased to furnish us with the following rules, which have been made known to several individuals, both for regular and irregular construction, on the latter of which nothing of extensive application or much deserving of notice has as yet been delivered by the writers on fortification.

A short paper on fortification, delivering a method of construction for always making the flanks either equal to the perpendiculars to the exterior sides, or in any given ratio to them, and also a rule alike applicable to regular and irregular construction; and, in its application to the latter of these, infinitely more extensive than all that has been hitherto published on the subject. By James Glenie, esq. A. M., and fellow of the Royal Societies of London and Edinburgh.

"After the invention of gun-powder, the ancient method of securing and fortifying places was gradually departed from. Various and important alterations were by degrees introduced into fortification, as the construction and management of artillery became more and more improved. Many treatises have been written on the subject in different nations and languages. And could we for a moment suppose improvements in the *ars muniendi* to have kept pace with these publications, we must naturally conclude, that military construction has by this time reached almost all the perfection it is capable of. But although war has been a profession in Europe, and the attack and defence of places has been studied as a science for almost these two centuries past, it is a certain and undeniable fact, that no writer on fortification has as yet either discovered or demonstrated the true lengths of those lines, on which the other parts of the construction of a work chiefly depend; viz. the perpendiculars

culars to the sides of a polygon, from which the body of the place is to be constructed. No writers on this subject have assigned any sufficient, good, or even plausible reasons for the lengths they give to these lines. With them all, without a single exception, the perpendiculars to the exterior sides of a work are mere arbitrary assumptions, and not the result either of any scientific or professional investigation. Even Mr. Muller, in the three new constructions which he gives in his "Elements of Fortification," in imitation of others, assumes those lines in a manner altogether arbitrary, without assigning any reason whatsoever for such assumptions. In page 76 of his said elements, in his problem "for determining the several parts of a front of a fortification," he makes use of the following words: "But as to the length of the perpendicular CD, it is no way determined; for some engineers make it twice as long as others; they seem indeed to differ from one another merely out of contradiction; since none of them, that I know of, has given any reason for this practice." This observation sufficiently shews, in what an imperfect state military construction remains even at present. For the true lengths of the perpendiculars form the great desideratum in it, since on them the flanking defences chiefly depend; for the sole purpose of obtaining which, and preventing dead parts, the sides of a polygon are broken, each of them into a curtain with two demi-battions to form the respective fronts of the work. And it must be allowed, that when a work is once adapted to the ground, it is intended to occupy, and its position is fixed on, the first consideration after determining the true lengths of the perpendiculars to the exterior sides, is to construct the whole of it in such a manner, as to have no dead parts; that is, to leave no such parts, as cannot be seen, fired on, or flanked from some other parts. That this is a leading or fundamental maxim, and ought to be a primary object of attention in the construction of every work, is manifest from this circumstance, that were it not with a view to obtain flanking defences for the different parts, a rampart and parapet might as well be erected on the exterior sides themselves of a fortification as on the figures, into which they are usually broken for that purpose. The strength of a work, indeed, it must be confessed, depends chiefly on its flanks, since an enemy cannot approach the body of the place, whilst the flanking defences remain entire. But if there be any dead parts through a deficiency of such defences, the moment an enemy gets to them, he finds himself in a state of security, and out of the reach of the besieged's fire. The absolute necessity of avoiding them, has always made such a forcible impression on the minds of able fortifiers, as to make them limit the height of sections. For even when the side of a polygon is not more than 180 toises, or 360 yards long, and is broken into a curtain with two demi-battions, if the section of the work be very high, the guns in the flanks cannot see or scour the ditch but at too great a distance; and it is well known, that when it is only of an ordinary height, they cannot see or command it effectually, nearer than the intersection of the lines of defence. But were it even to be alleged, which would however be an allegation altogether inadmissible, that a fortification ought to be constructed without the least regard to any flanking defences, and that the avoiding of dead or unseen parts is an object unworthy of attention, it is evident that the rectilinear is preferable to the zig-zag or angular construction formed by the placing of triangles contiguous to one another, or by the juxta-position of angles at the bases of triangles. For the fire from a straight line is the best of the direct kind that can be obtained, being equally and uniformly distributed. And the enemy cannot advance against

it directly, without a good deal of delay, inconvenience, and trouble, but must carry on his approaches somewhat in the way commonly practised, till he gets to the dead parts in front of it, when it will cease to be formidable for want of flanking defences. The angular or zig-zag line, on the other hand, has no good direct fire, and indeed no flanking fire whatever, where it is most wanted, or can be of any utility; but a continuity of dead parts, when the section is of a sufficient height, reigns throughout its whole extent. An enemy can approach it without being exposed to any direct fire from the besieged, that can annoy him, in the lines bisecting either the salient or re-entering angles, or, in short, in lines directed to any other intermediate points whatsoever, between these angles.

And it is no less evident, that the direct fire from the circumference of a circle, or from any other curve, that returns into itself, is much more equal and uniform, and better distributed than that from an angular or zig-zag line.

That able general and fortifier, the celebrated marshal Vauban, whose system has been most generally followed in Europe, in constructing from the sides of a square, made the perpendicular an eighth part of one of them, in a pentagon a seventh part, and in a hexagon, and all polygons of a greater number of sides, a sixth part. For this practice, however, he has not assigned any reasons. It is impossible indeed to assign any good reason for giving to a polygon of twenty or thirty sides, or to a construction on part of a right line, which may be regarded as a polygon of an indefinite or infinite number of sides, and to a hexagon, or a figure of only six sides, the same length of perpendicular. Any person, without even a knowledge of geometry, to enable him to draw deductions from the properties of figures themselves, who reflects but a little on the subject, must naturally conclude, that there can be no found or good reason for doing so. The truth, in fact, is this, that every polygon has a precise and determinate perpendicular of its own, proportional to and connected with its capability of being defended, and of being embraced by a besieging enemy, as, says Mr. Glénie, I shall clearly demonstrate in a subsequent paper, that may ere long be presented to the society, as well as shew, how an indefinite number of infinite series may not only be derived from, but also summed geometrically by means of polygons: and I make no doubt, that had Vauban possessed a sufficient knowledge of mathematics for the purpose of applying them to the improvement of the theoretical part of his profession, he would have discovered the precise or genuine lengths of perpendiculars, which different polygons ought to have, and would have regulated his practice accordingly, in the numerous works he constructed. Unwilling to give into prolixity, I will not, at present, enumerate the different lengths of perpendiculars to the sides of one and the same figure or polygon, which the various writers on fortification have assumed, although the enumeration would prove beyond controversy, that in assuming them they were guided by their own whims and fancies, and not by any just or determinate rule. It must however be regarded as a singular fact, that though perpendiculars to the sides of polygons were first introduced into construction, for the sole purpose of obtaining flanking defences, not one of these writers, in even treating formally of regular fortification, has either offered, or attempted to deliver, a method of construction for rendering the flanks always equal to the perpendiculars as they ought to be. To supply this defect I will now proceed to give such a construction, which, like many other things in science, most pregnant with utility, and most extensive in their consequences, has probably been hitherto overlooked chiefly on account of its simplicity.

Construction.

Let *AB* (fig. 17.) be a side of any given polygon, either regular or irregular. Let it be bisected in the point *C*, and let *CV* be an indefinite perpendicular to *AB* at the point *C*. Through the point *O* let indefinite right lines *AA*, *BT*, be drawn from the points *A*, *B*, and let *CD*, *CE*, be each equal to one-half of *AO* or *BO*. Draw the right lines *DF*, *EG*, parallel to *CV* till they meet *A*, *B*, *T*, in the points *F*, *G*; and from the said points *F*, *G*, draw *FK*, *GL*, perpendicular respectively to *BT*, *AS*. Then I say that *FK*, *GL*, are each equal to *CO*.

Demonstration.

Since by construction *AD* is equal to *BE*, and *AC* to *BC*, and *CO* is perpendicular to *AB*, the angle *CAO*, or *DAF*, is equal to the angle *CBO* or *EBG*, and *DF* is equal to *EG*, being parallel thereto. Wherefore *FG* is parallel to *AB*, and equal to *DE*, which is equal to *AO* or *BO*. Consequently, since *FK* is perpendicular to *BT*, and *GL* to *AS*, by construction, the triangles *ACO*, *GKF*, *FLG*, are equiangular and equal, and *CO*, *FK*, *GL* are equal. *Q. E. D.*

Thus then the flanks *GL*, *FK*, drawn at right angles to the lines of defence *AL*, *BK*, or *AS*, *BT*, are by this very simple construction always equal each of them to the perpendicular *CO*, whether *AB* be the side of a regular or an irregular polygon.

The perpendicular distances *FL*, *GK*, of the flanks *GL*, *FK*, from the shoulders *F*, *G*, of the demi-bastions *AFK*, *BGL*, are each of them equal to half the exterior side *AB*. And each of these perpendicular distances *FL*, *GK*, is to the curtain *KL*, as the sine of the angle formed by either flank, and said curtain, to the sine of the angle at the shoulder of either demi-bastion, that is, as the cosine of the angle formed by the exterior side, and either line of defence, to the cosine of twice this angle.

From the similarity of the triangles *ACO*, *ADF*, *BCO*, *BEG*, we have each of the faces *AF*, *BG*, of the demi-

bastions equal to $\frac{AO \times AD}{AC}$, or to $\frac{AO \times AC - 2}{AC}$, or

to $\frac{AO \times 2AC - AO}{2AC}$. Now if *AB*, or *2AC*, be denoted by *2P* and *AO* - *AC* by *2Q*, each of these faces

will be expressed by $\frac{P + 2Q \times P - 2Q}{2P}$, or by $\frac{P}{2} - \frac{2Q^2}{P}$,

which, when the perpendicular *CO* is but small, is nearly equal to the half of *AC*, or to a fourth part of the exterior side *AB*.

Each of the angles *AFK*, *BGL*, of the shoulders of the demi-bastions is equal to a right angle, together with the angles *BAO*, *ABO*, formed by the exterior side *AB*, and the lines of defence.

Scholium.

In like manner may a construction be delivered, which will make each of the flanks *FK*, *GL*, have any given ratio *m* : *n* whatsoever to the perpendicular *CO*. For if *CD* or *CE* be taken to $\frac{AO}{2}$ as *n* : *m*, we shall have *DE* equal to

$\frac{AO \times m}{n}$, or *n* : *m* :: *AO* : *DE* (*FG*) :: *CO* : *GL* or *FH*. And if *AC* be denoted as above by *P* and *AO* by *P* + *2Q*, each of the faces *AF*, *BG*, of the demi-bastions,

will, in this case, be equal to $\frac{2n - m}{2n} \times P + \frac{n - m}{n} \times 2Q$

$$- \frac{m}{n} \times \frac{2Q^2}{P}$$

Mr. Muller, in the preface to his "Elements of Fortification," expresses himself in the following words:

"Notwithstanding the art. . . . others."

"For the true art consists in weakest."

Mr. Muller certainly treats of irregular fortification in a more direct and particular manner than any other author that wrote on the subject before him. But his constructions on the sides of an irregular polygon are similar to that which he makes use of on the sides of a regular one. His perpendiculars in both are mere arbitrary assumptions, and the flanks, as well as the faces, of his demi-bastions in each front of both are equal. The rules therefore delivered by him, as well as by the other writers on fortification, may justly be regarded as only applicable to regular construction.

For although they treat of irregular fortification, they suppose the perpendiculars to bisect the exterior sides, the lines of defence, drawn from the extremities of any one of these sides, to make equal angles with it, and the correspondent parts, such as the faces and flanks set off from the face, to be equal, alike, and similar. They do not so much as even contemplate or once speak of any case, wherein the lines of defence make different angles with the exterior side, or wherein either the flanks or faces of the same front are of different lengths, or unequal to each other. It frequently happens, however, that an engineer cannot preserve this equality between either the faces or the flanks set off from the same exterior side, without losing the principal advantages arising from the nature and situation of the ground, and deviating from what ought to be the leading maxim in the construction of every work, namely, the proportioning of the fire of each part, as nearly as possible, to that which the enemy can bring against it; or, in other words, the defence in every place to the attack. To remove this difficulty and inconvenience, and to enable engineers to practise with facility and expedition the whole possible variety of irregular construction, I will proceed to deliver a rule, which I have had in my possession for nearly twenty-two years, but have not till now thought proper to communicate to the public. Its simplicity has, I suppose, been the principal cause of its being so long unnoticed or unattended to. It is easily and expeditiously carried into practice. It is alike applicable to regular and irregular construction, and in its application to the latter is infinitely more extensive than all, that has hitherto been published on the subject.

This rule is derived from the following very simple geometrical proposition.

If from the extremities of any given right line, two right lines be drawn in any angles, either equal or unequal, and from any two points in these lines, two other right lines be drawn reciprocally meeting them, produced beyond their intersection in any given angle, the angles formed thereby at these points, will be equal between themselves, and each of them equal to the two first mentioned angles, together with the given angle.

Demonstration.

Let *AB* (fig. 18.) be the given right line, from the extremities *A* and *B*, of which right lines *AF*, *BE* are drawn, making any angles *FAB*, *EBA*, therewith whatever, either equal or unequal; and from any two points, *C* and *D*, in these lines, let other right lines *CE*, *CD* reciprocally meeting them, produced beyond their intersection *I* in angles *CEI*, *DFI*, equal each to the given angle. I say that the angles

ACE, BDF, formed thereby, are equal, and that each of them is equal to the angle CEI or DFI, together with the angles FAB and EBA.

For (by 32 E. 1.) the angle ACE is equal to the angle CEI, together with the angle CIE: and by the same proposition, the angle CIE is equal to the angle IAE, together with the angle IBA. Therefore ACE is equal to CEI or DFI, together with FAB and EBA.

In like manner, BDF is equal to DFI or CEA, together with FAB and EBA, and consequently is equal to ACE, Q. E. D.

From the foregoing very simple proposition is derived the following rule.

Whether the angles, which the lines of defence drawn from the extremities of any exterior side make therewith, be equal or unequal, and the angle made by another flank with its line of defence be equal, or greater, or less than a right angle; in every case, the angle of either shoulder is equal to these three angles taken together; that is, to the angle formed by either flank with its line of defence, together with the two angles formed by the lines of defence with the exterior side.

By means of this rule, an engineer may trace out any work, however irregular, in a tenth part of the time requisite for tracing out even a regular work of the same size and dimensions, by the methods of construction hitherto prescribed and made use of. He is under no necessity of finding the centre, or of erecting perpendiculars to the exterior sides, which, in irregular construction, cannot be fixed and ascertained without calculation, trouble, and inconvenience; but after determining in his own mind on the angles, which the lines of defence are to make with the exterior sides, and laying them down, fixes the positions of the flanks, and sets them off from the shoulders, almost as expeditiously as he can walk over the ground. He may use it in woody places, with nearly as much ease and facility as in those that are clear and open; and in every situation, in short, where he can see to the distance of a few yards on each side of him. By it he can trace out in the field, and even in the face of an enemy, with almost mathematical exactness and accuracy, and much more expeditiously than by the tentative and inaccurate random-methods commonly made use of, and without the aid of a theodolite, plain table, or other bulky or cumbersome mathematical instrument: for a pocket Hadley's sextant, which will be useful on most occasions, is all that is necessary in any situation.

It may not perhaps be improper to mention the circumstance that first led me to think of this rule, and gave rise to the putting of it in practice. In summer, 1783, Colonel Moncrief, Lieutenant Fiddes of the Engineer-corps, and myself, went one forenoon to trace out a large pentagonal work, near Stoke's Bay House and Gomer Pond in the Gosport division, on one of the fronts of which it was thought advisable, from the nature of the ground, to have the flanks of different lengths, and thereby to vary the directions of their fire, and those of the faces of the demi-bastions, from those which the ordinary method of construction would have given. Colonel Moncrief, who, though he was commonly and justly reckoned a good judge of ground and positions, was, from the inapplicability of the customary rules to such a case, totally at a loss for the construction. He had Muller's "Elements of Fortification" in his hands, but could derive no aid or assistance from them. His embarrassment, and the novelty of our situation, which none of us had thought of beforehand, set me a

thinking seriously how we might surmount the difficulty. After a few minutes reflection, I discovered the foregoing rule, which I immediately applied on the spot, and very expeditiously. I might, however, as well as others, have overlooked it even to this moment, had it not been for the incident now mentioned. For the simplest and most useful things are generally least attended to. I gave copies of it in writing to these two gentlemen at their request, and another to his grace of Richmond.

There are various maxims delivered by the writers on fortification, which relate to the construction and defences of the works, independent of the general considerations for or against the erection of the fortifications themselves, in different circumstances and situations. Some of these maxims, however, are very questionable, and, on due examination, would be found to be inadmissible, having been laid down by men who did not understand the true principles of construction.

The following may, perhaps, be justly regarded as the most unexceptionable of the maxims that are commonly delivered.

1. There ought to be no part in the whole circuit, or *en-ciente*, of a fortress or fortification that cannot be seen, flanked, or defended from some other part. That this is not only an admissible but a fundamental maxim, and ought to be a primary object of attention in the construction of every work, is manifest from this circumstance: that, were it not with a view to obtain flanking defences for the different parts, a rampart and parapet might as well be erected on the right lines themselves, which form the exterior sides of polygons, as on the figures, into which they are usually broken for this purpose. The strength of a work indeed depends chiefly on its flanks, since an enemy cannot approach the body of the place whilst the flanking defences remain entire. But if there be *dead* or *unseen* parts, the moment an enemy gets to them he finds himself in a state of security, and out of the reach of the besieged's fire. An idea, therefore, of the absolute necessity of avoiding them, has always made such a forcible impression on the minds of able fortifiers, as to induce them to limit the height of sections. For even when the side of a polygon is equal to 180 toises, or to 360 yards, and is broken into two demi-bastions and a curtain with flanks, if the section of the work be very high, the guns in these flanks cannot see or scour the ditch, but at too great a distance. When it is only of an ordinary height, it is well known, that the guns in the flanks do not see the ditch effectually nearer than the intersection of the lines of defence, the distance of which, in Vauban's construction, from the epaules or shoulders, is equal to 45 toises nearly. Mr. Blondel's construction, therefore, in polygons of a great number of sides, and that of the marquis de Montalembert, which is nothing but Mr. Blondel's on a straight line or a polygon of an infinite or indefinite number of sides, are in this respect radically defective, creating dead or unseen parts throughout their whole extent, which cannot be removed but by casemates and contrivances, that have no natural connexion whatsoever with the constructions themselves.

2. The defence of every part ought to be always within the certain reach of musket-shot, in order to be defended both by great and small fire-arms: for if any parts be at too great a distance from those that flank them, to be within the reach of a serious and efficient fire of musketry, or can be defended by cannon only, the enemy may dismount these cannon by the superiority of his, and thereby destroy the defences of such parts at once. But if they be defended

by both cannon and musketry, should one of these two species of defence be destroyed, the other will still remain.

It has been frequently alleged, that a musket-shot will not kill at a greater distance than 150 toises, or 300 yards, or 900 feet. If this be true, the great line of defence, or the distance from the flanked angle or salient angle of the bastion to the opposite flank, ought not to exceed 150 toises, or even to be equal to so many toises. If, on the other hand, the line of defence were to be about two-thirds of that length only, or equal to about 100 toises, the bastions would be too near to one another, and too small, which would both increase their number in the same circuit or cunete, and lessen their strength or capability of defence. The length of the great line of defence, in order to render the fire more certain and efficient, is therefore commonly supposed to be equal to from 120 to 140 toises only.

3. All the defences should be as nearly direct as possible; for soldiers naturally fire directly before them. The lines of defence, therefore, should be either like Couat Pagan's, perpendicular to the flanks, or nearly so.

4. A fortification ought to be equally strong on all sides: for if it be not, an enemy may attack it on the weakest, and avail himself of its inequality of strength.

To these maxims we will take the liberty to add a few others, that are not to be found in the writers on fortification, but which we, nevertheless, conceive to be entitled to the most serious consideration. They are the following, and we are favoured with them by Mr. Genie.

1. In regular construction, the two flanks in each front ought to be equal each of them to the perpendicular to the exterior side of the polygon, or nearly so, since perpendiculars to the exterior sides of polygons were introduced into construction for the express purpose of obtaining flanking defences. And in regular construction, when it is necessary (as it generally is, in order to make field-works suit the ground they occupy) to make the two flanks in the same front unequal, their sum or lengths taken together should be equal to twice the perpendicular distance from the intersection of the lines of defence to the exterior side, or nearly so.

Mr. Genie, in the foregoing paper, has given a very easy method of making the flanks in regular construction, either equal to the perpendiculars, or in given ratios to them.

2. The face of the bastion, in regular construction, ought never to exceed one-fourth part, or two-eighths of the exterior side. The construction, which gives each of the flanks in the same front equal to the perpendicular, makes the face of the bastion equal to a fourth part of the exterior side very nearly.

3. The flanked angle, or salient angle of the bastion, ought never to be less than an angle of about $71\frac{1}{2}^\circ$, and should never exceed 120° . In Count Pagan's method, however, and that of Mr. Vauban, who has followed him, this angle in a polygon of only 18 sides is equal to about $123^\circ 7' 46''$; in one of 30 sides, to $131^\circ 7' 48''$; and in a construction on a right line, or part of a polygon of an infinite or indefinite number of sides, to $143^\circ 7' 48''$.

4. The angle of the epaule or shoulder should not be less than an angle of about $108\frac{1}{2}^\circ$, and ought never to exceed an angle of 150° .

5. The angle of the flank ought not to be less than an angle of about $99\frac{1}{2}^\circ$, nor greater than one of about 120° .

6. The outward flanking angle, or the angle formed by the lines of defence at their intersection, ought not to be less than 120° , nor ever greater than $161\frac{1}{2}^\circ$.

Lastly, Different polygons have different perpendiculars, which have respectively given ratios to the sides of the polygons. And the perpendicular that truly belongs to any polygon of a given number of sides, is different from that which belongs to any other polygon of a different number of sides; the exterior side in each of the polygons being supposed invariable or the same. A construction on the sides of any polygon of a given number of sides, ought to be made with the perpendicular that peculiarly belongs to it. An investigation, however, of the various perpendiculars that respectively belong to various polygons, from the square up to the right line, which may be regarded as part of a polygon of an indefinite or infinite number of sides, has never as yet been delivered by any writer on fortification; and it now forms the great desideratum in military construction.

CONSTRUCTIVE TREASON, in *Law*, was defined by 25 Edw. III. cap. 2. See TREASON.

CONSUALES LUDI, among the Romans, the same with CIRCENSES *ludi*. See also CIRCUS.

CONSUALIA, in *Antiquity*, feasts which were held among the ancients, in honour of the god Consus, *i. e.* Neptune; different from those other feasts of the same deity called Neptunalia.

They were introduced with a magnificent cavalcade, or procession on horseback; because Neptune was reputed to have first taught men the use of horses; whence his surname of *Ἰππιος*, *Equus*.

Evander is said to have first instituted this feast: it was re-established by Romulus, under the name of *Consus*; because it was some god under the denomination of Consus, that suggested to him the rape of the Sabines. It is said, that it was with a view to this rape, that he formed this institution. This, however, is certain, that it was to this feast all his neighbours were invited; when, taking advantage of the solemnities and sacrifices, he seized the women. To draw the greater concourse of people, he gave out that he had found an altar under ground, which he intended to consecrate, with sacrifices to the god to whom it had been originally erected.

Those who take upon them to explain the mysteries of the heathen theology, say, that the altar hid under ground, is a symbol of the secret design of Romulus to seize his neighbours' wives.

The consualia were of the number of feasts called *sacred*; as being consecrated to a divinity. Originally they were not distinguished from those of the Circus: whence it is, that Valerius Maximus says, that the rape of the Sabines was effected at the games of the Circus.

Plutarch observes, that during the days of this solemnity, horses and asses were left at rest, and were dressed up with crowns, &c. on account of its being the feast of Neptune's Equetris. Fessus says, the cavalcade was performed with mules; it being an opinion, that this was the first animal used to draw the car.

Servius gives us to understand, that the consualia fell on the thirteenth of August; Plutarch, in the life of Romulus, places them on the eighteenth, and the old Roman calendar on the twenty-first of that month.

CONSUBSTANTIAL, in *Theology*, a term of like import with *co-essential*; denoting something of the same substance in kind with another. That this is the meaning of the term *ὁμοουσιος* has been shown by Petavius, Curellæus, Cudworth, Le Clerc, Clarke, &c. &c.

The orthodox believe the Son of God to be consubstantial with the Father.

The term *ὁμοουσιος*, *consubstantial*, was first adopted by the fathers,

fathers of the council of Nice, convened A. D. 325, and consisting of 318 bishops, to express the orthodox doctrine the more precisely, and to serve as a barrier and precaution against the errors and subtleties of the Arians; who owned every thing excepting the *consubstantiality*.

At the Nicene council, Eusebius proposed a creed, in which he avoided the word *ὁμοουσιος*; and anathematized every impious heresy, without specifying any; but his advice was not followed; *ὁμοουσιος* was inserted, and the Arian doctrines were anathematized. Disputes ensued among the bishops concerning the meaning and the consequences of the word *ὁμοουσιος*. Eusebius assented to it, declaring at the same time in what sense he understood it. His sense of *consubstantial* was, that the Son of God was not like created beings, but received his existence and his perfections from the father in a different and in an ineffable manner. Others gave other senses to it; and the debate, says Socrates, the ecclesiastical historian, (i. 23. et Soz. ii. 18.) was like a battle fought in the dark. Sociates however was a consubstantialist, so far as even to believe that miracles were wrought by the Monks in favour of that doctrine; though he intimates, that the bishops of each party disputed about words of which they had no ideas, and charged one another with consequences and inferences, which neither side would own. By the word *ὁμοουσιος* the Nicene fathers meant, not the same numerical or individual substance, but the same general substance or subsistence. As amongst men, a son is *ὁμοουσιος* with his father, that is, of the same human nature; so, in their opinion, the Son of God is *ὁμοουσιος* with the Father, that is, of the same divine nature. By this word, therefore, they intended to express the same kind of nature, and so far a natural equality. But according to them, the natural equality did not exclude a relative inequality; a majority and minority, founded upon the everlasting difference between giving and receiving, causing and being caused. They had no notion of distinguishing between person and being; between an intelligent agent, and an intelligent active substance, subsistence, or entity. When they said, that the Father was God, they meant that he was God of himself, originally, and undivided, *ὁὐτος ἀγεννητος*, and *ὁ ὁὐτος*. When they said that the Son was God, they meant that he was God by generation or derivation, *ὁὐτος-γεννητος*. The unity of God they maintained; and they defended it, first, by considering the father as the first cause, the only undivided and self-existing; secondly, by supposing an intimate, inseparable, and incomprehensible union, connection, indwelling, and co-existence, by which the Father was in the Son and the Son in the Father; and thirdly, by saying, that in the Father and the Son there was an unity of will, design, and consent, and one divine power and dominion, originally in the Father, and derivatively in the Son. In process of time Christians adopted a notion, that the Son was *καὶ ὁμοουσιος*, and *μονοουσιος*, of the same individual substance with the Father and the Holy Spirit; and they seem to have done this with a view of securing the doctrine of the unity.

The Arians declared, that the word was God, as having been made God; but they denied that he was the same God, and of the same substance, with the Father; accordingly, they exerted themselves to the utmost to abolish the use of the word. The emperor Constantine used all his authority with the bishops to have it expunged out of the symbols; but it still maintained itself, and is at this day, as it was then, the distinguishing criterion between an Athanasian and an Arian.

Sandius will have it, that the word *consubstantial* was unknown till the time of the council of Nice; but it is cer-

tain it had been before proposed to the council of Antioch, held A. D. 270, in which Malchion directed and governed, and in which Paul of Samosata had been condemned; though it had there the fortune to be rejected. Curcellæus, on the other hand, maintains, that it was an innovation in doctrine in the council of Nice, to admit an expression, the use whereof had been abolished by the council of Antioch.

According to St. Athanasius, the word *consubstantial* was only condemned in the council of Antioch, inasmuch as it implied the idea of a pre-existent matter, prior to the things formed of it; now, in this sense, it is certain, the Father and the Son are not consubstantial, there having been no pre-existent matter.

In another council, held at Antioch, A. D. 341, consisting of about 100 bishops, the Arians made a creed and left out the term *ὁμοουσιος*; but wanting it to be approved by both parties, they called the Son the unchangeable image of the essence, counsel, and power of the Father, the first born of every creature. The disputes, however, between the consubstantialists and the Arians, and also the Semi-Arians or *ὁμοουσιος*, i. e. the homoiousians, continued to be carried on with great violence, particularly in the Eastern part, for several years. One remarkable difference has been observed between the creeds which were proposed by the contending parties. The consubstantialists drew up their creed with a view to exclude and distress the Arians; whereas the Arians had no design to distress the consubstantialists, but usually proposed creeds to which Athanasius himself might have assented; so that if the compilers were Arians, their creeds were not Arian. The Semi-Arians agreed with the Arians in rejecting the word *ὁμοουσιος*, but differed from them in exalting the perfections and dignity of the Son higher than the Arians did, and in affirming that he was *ὁμοουσιος*, of like substance and like to his father in all things. Dr. Clarke's doctrine, in his "Scripture Doctrine, &c." as stated by Le Clerc, (Bibl. Choix. xxvi. 419.) seems to be the same with that of the Nicene council, excepting that he uses not the word "consubstantial." Before the end of the fourth century the consubstantialists differed and disputed among themselves, whether in the Trinity there were three hypostases, or one hypostasis. See HYPOTASIS and TRINITY.

CONSUBSTANTIATION, a tenet of the Lutheran church, with regard to the doctrine of the real presence of Christ, or the manner of the change made in the bread and wine, in the eucharist; though the term *consubstantiation* was substituted in the room of *transubstantiation*, at the close of the thirteenth century, by John, surnamed Pungens Aflnus, a doctor of the university of Paris.

The divines of that profession maintain, that, after consecration, the body and blood of our Saviour are substantially present, together with the substance of the bread and wine; which is called *consubstantiation*, or *impanation*.

This notion, as the bishop of Meaux justly observes, has all the disadvantages, which the Romanists, and Sacramentarians, charge on one another, without having a single advantage that can be claimed by either. It has all the absurdity which the latter charge upon the former, inasmuch as it represents the same body existing in different places, at the same time; and inasmuch as it represents a substance existing without its accidents, or under the accidents of another substance; but has not the advantage of simplicity which the Romish doctrine has, in interpreting literally the words, "this is my body." On the Lutheran hypothesis the expression ought to have been, not "this is my body," but "in, with, and under this is my body." For the Lu-
therans

therans maintain that the bread remains unchanged, and is that which is seen, touched, and tasted; but that the body of Christ, the same which he had upon the earth and has now in heaven, accompanies the bread. Hence it appears, that the words are to be understood neither according to the letter, nor according to any figure of speech ever heard of before. It is neither literally Christ's body, nor figuratively the sign or symbol of his body; but it is something with which his body is accompanied. The Lutherans, by maintaining this doctrine of consubstantiation, were obliged to adopt another hypothesis not less absurd, *viz.* the ubiquity, or the omnipresence, and consequently the immensity of the body and human nature of Christ; hence they were called *Ubiquitarians*. See also *IMPANATION, TRANSUBSTANTIATION, and LUTHERANISM*.

CONSUEGRA, in *Geography*, a town of Spain in New Castile, containing two parishes and three convents. It belongs to the knights of Malta; 25 miles S.S.E. from Toledo.

CONSUETUDINIBUS ET SERVITIIS, in *Law*, a writ of right, which lies for the lord against the tenant that despotheth his lord of the rent, or service due to him, by custom, or tenure, for his land. This compels a specific payment or performance of the rent or service, and there are also others, whereby the lord shall recover the land itself in lieu of the duty withheld.

CONSUL, the appellation that was given to the first, or chief, magistrate in the Roman government, vulgarly and commonly called the Roman Commonwealth; though it was composed of royalty, aristocracy, and democracy, as much as the government of Great Britain is, and was, perhaps, in several respects, the most energetic and efficient mixture of these three simple forms that has ever existed in the world, particularly for the purposes of conquest and security against subjugation.

After the destruction of royalty at Rome, and the expulsion of Tarquinius Superbus, and his family from thence, in the 244th year of the city, a consular form of government was established in the 245th year in its stead; the people choosing to have some share in the management of public affairs themselves; they accordingly chose two officers, or magistrates, annually, who were invested with sovereign authority, and were originally called *prætores*, *a præcedendo*, according to some writers, but *a præcessu* according to others. These were afterwards called *consules*, *a consulendo*, because it was their duty to consult with the senate, with the people, and with each other. From their acting as judges, they were called *judices*; or from their possessing supreme command they were denominated by the Greeks *ΥΠΑΤΟΥ*. The first consuls were Brutus and Collatinus. The office of the consuls lasted a year; and if either of them died in the course of the year of their consulate, a new one was to be elected. In the beginning of the republic the consuls entered on their office at different times; at first, on the 23d or 24th of February, (vii. or vi. Kal. Mart.) the day on which Tarquin was said to have been expelled, which was held as a festival, and called "regifugium festus;" afterwards on the 1st of August, (Kal. Sext.) which was at that time the beginning of the year, *i. e.* of the consular, not of the civil year, which always began with January:—in the time of the Decemviri, on the 15th of May, (Id. Maii);—about 50 years after, on the 15th of December, (Id. Decemb.);—then on the 1st of July, (Kal. Quint.), which continued till near the beginning of the second Punic war, A. U. 530, when the day came to be the 15th of March, (Id. Mart.):—at last, A. U. 598, or 600,

it was transferred to the 1st of January (in Kal. Jan.), which continued to be the day ever after. After this, the consuls were usually elected about the end of July, or the beginning of August. From their election to the 1st of January, when they entered on their office, they were called "consules designati," and whatever they did in public affairs, they were said to do it by their "authority," not by their "power." This interval was made so long, that they might have time to acquaint themselves with the duties of their office, and that inquiry might be made whether they had gained their election by bribery. If, upon trial, they were convicted of that crime, they were deprived of the consulship, and their competitors, who accused them, were nominated in their place. They were also fined, and declared incapable of bearing any office, or of coming into the senate, by the Calpurnian and other laws. (Cic. pro Sylla, 17 and 32. Cic. pro Cornel. Muren. 23, &c. Sall. Cal. 18.) On the 1st of January, the senate and people waited on the new consuls at their houses; from whence, being conducted to the capitol, they offered up their vows, and sacrificed, each of them, a ox to Jupiter; and then began the exercise of their office, by holding the senate, consulting it about the appointment of the Latin holidays, and about other things relating to religion. Within five days they were obliged to swear to observe the laws, as they had done when elected.

The consuls were at first chosen only from among the Patricians, but afterwards also from the Plebeians. L. Sextius was the first plebeian consul, and the second year after him Licinius Stolo; from whom the law, ordaining one of the consuls to be a plebeian, was called "lex Licinia." Sometimes, but rarely, both consuls were plebeians; the patricians generally engrossed this honour. The first foreigner who obtained the consulship, was Cornelius Balbus, a native of Cadiz; who became so rich, that, at his death, he left to each of the citizens, residing at Rome, 25 drachmæ, or denarii, *i. e.* 16s. 13d.

The legal age for enjoying the consulship (as consularis) was 43; and whoever was made consul at that age, was said to be made in his own year; but we meet with some few exceptions from this rule. (see *AGE*.) Before any person was made consul, it was necessary for him to have gone through the inferior offices of quaestor, ædile, and prætor. No one could be created consul a second time till after an interval of ten years. But these regulations were not strictly observed.

The insignia of the consuls were the same with those of the kings, except the crown; namely, the toga prætexta, sella curulis, the sceptre, or ivory staff, and 12 lictors, with the fasces and securis. He who had the greater number of suffrages was called "Consul prior," and his name was marked first in the calendar; he also had the fasces first, and usually presided at the election of magistrates for the next year. All persons went out of the way, uncovered their heads, dismounted from their horses, and rose up to the consuls as they passed by them. When a prætor happened to meet a consul, his lictors always lowered their fasces. Valerius, called Poplicola, took away the securis from the fasces; *i. e.* he took from the consuls the power of life and death, and only left them the right of scourging, at least within the city; for without the city, when invested with military command, they still retained the securis, *i. e.* the right of punishing capitally. Poplicola likewise made a law, granting every one a liberty of appealing, from the consuls to the people; and that no magistrate should be permitted to punish a citizen, who thus appealed: a privilege which was also enjoyed under the kings. The consuls originally possessed kingly powers, both in civil and military

military matters. But afterwards, when the consuls came to be much employed from home, or abroad in war, and could not be present either to hear or determine civil causes, there was an officer constituted, under the designation of *prator urbanus*, and frequently called by Cicero *prator Romanus*, with power to judge matters of law between citizen and citizen. And for the convenience and accommodation, in this respect, of the great number of strangers that were always at Rome, another officer was appointed to judge causes between them, with the appellation of *prator peregrinus*. And as provinces came to be added to the Roman state, and the number of causes was of course greatly increased, there were eight *prators* appointed, which number continued till the time of Julius Cæsar, who raised it to ten.

The consuls, whilst they remained in Rome, and before they led out Roman armies into the field, were masters of all public affairs. For all the other magistrates, the tribunes of the people alone excepted, were subject to them, and bound to obey their commands. They introduced ambassadors into the senate and gave them audience; and they received all letters from the governors of provinces, and from foreign kings, and states. They also proposed to the senate the subjects of their debates, and directed all the forms that were observed in making their decrees. It was equally a duty likewise, belonging to their office, to attend to those affairs that were transacted by the people; to summon, or call together their general assemblies; to report to them, when assembled, the resolutions of the senate; and to ratify whatever was determined by the greater number. The laws which they proposed, and got passed, were commonly called by their name. The year was named after them, as it used to be at Athens, from one of the archons. The consuls had also command over the provinces, and could, when authorized by the senate, call persons from thence to Rome, and punish them. (See PROVINCE.) Their authority was so great, that kings, and foreign nations, in alliance with the republic, were considered to be under their protection. In dangerous conjunctures, the consuls were armed with absolute power by the senate. In all the preparations that were made for war, as well as in the whole administration, and management of things in the field, they possessed an authority almost absolute. For to them it belonged to impose on the allies whatever services they judged necessary or expedient; to appoint the military tribunes; to enrol the legions, and make the necessary levies; and to inflict punishments in the field on all that were subject to their command. In addition to all this, they had the power to expend whatever sums they might think convenient, or requisite, from the public treasure, and were attended for that express purpose by a *questor*, who was always ready to receive and execute their orders.

When a Roman army encamped, the consular tent was first pitched, and the ground on each side of it marked out for it, and on the breaking up of a camp, it was the first tent that was permitted to be struck; and one entire company of soldiers were always stationed round it.

When an action had taken place, in which any of the soldiers had shewn signal proofs of courage, the consul assembled the troops together, and commanded those to approach who had distinguished themselves by any eminent exploit. And after bestowing on each of them separately, or apart, the commendation that was due to that particular instance of their valour, and after recounting likewise all their former actions that had ever merited applause; he then distributed among them the following rewards:—To him who had wounded an enemy a javelin:—To him who had killed an enemy, and stripped him of his armour, a

goblet, if he were in the infantry; and if in the cavalry, a javelin in ancient times, but afterwards furniture for his horse. These rewards, however, were not bestowed on soldiers, who, in a general engagement, or in the attack of a city, had wounded or spoiled an enemy; but on those only, who in separate skirmishes, and when any occasion offered, in which, though they were not necessarily required to engage in single contest, threw themselves voluntarily into danger, and with design, provoked the combat. In taking a city by storm, those who first mounted the walls, were honoured by the consul with a golden crown. And those who saved the lives of any of the citizens, or of the allies, by covering them from the enemy in the time of battle, received presents from the consul, and were also crowned by the persons whom they had thus preserved.

Although the consuls were the dispensers of military rewards and punishments; although they were entrusted with the absolute direction of the preparations that were made for war, and exercised an uncontrolled authority in the field; although their powers and authorities, when they were present in Rome, made strangers sometimes suppose the government to be a kind of simple royalty; they were in truth, so dependent in different respects, both on the senate and the people, that without their assistance, they were unable to accomplish any design. Armies require a continual supply of necessaries. But neither corn, nor habits, nor even the military expenses, could at any time be transmitted to the legions, without an express order of the senate. It was also the senate that either compelled the consuls to leave their designs imperfect, or enabled them to complete the projects that they had formed, by sending a successor into each of their several provinces on the expiration of the annual term, or by continuing them in their respective commands. The senate also had the power of either aggrandizing and amplifying the victories that were gained, or of depreciating and debasing them. It was also necessary for the consuls, however far they were removed from Rome, to preserve the good affections of the people. For though the consuls might make treaties, the power of annulling, or ratifying, rested entirely with the people. And what was of still greater moment, the consuls, on quitting their office, were bound to submit the whole of their past administration to the judgment of the people. On this occasion they made a speech, and swore that they had done nothing against the laws.

Consuls were even continued under the emperors after the republic was destroyed; but consul was here little more than an honourable title; which, however, the people were fond of keeping up; as esteeming it some remains of their ancient liberty. As long as the emperors condescended to disguise the servitude which they imposed, the consuls were still elected by the real or apparent suffrage of the senate. From the reign of Diocletian, even these vestiges of liberty were abolished, and the successful candidates, who were invested with the annual honours of the consulship, affected to deplore the humiliating condition of their predecessors. In the epistles which the emperor addressed to the two consuls elect, it was declared, that they were created by his sole authority. The title of consul, however, though the real dignity and substantial power that accompanied it were lost, was still the most splendid object of ambition, the noblest reward of virtue and loyalty. The emperors themselves, even after Constantinople became the seat of empire, who disdained the faint shadow of the republic, were conscious that they acquired an additional splendour and majesty as often as they assumed the annual honours of the consular dignity. It dwindled for a long time, and at last the succession of consuls finally ceased, in the 13th year of Justinian, A. D. 541, whole

whose despotic temper might be gratified by the extinction of a title, which admonished the Romans of their ancient freedom: after him, no emperor either created any consul, or assumed the dignity himself. Basil is the last in the consular list, for the year 541. By this time, the dignity was depreciated to that degree, that it was conferred on the meanest persons: indeed, Justinian endeavoured to retrieve it 25 years after, and created himself consul, but without effect. Indeed, the annual consulship long lived in the minds of the people; they applauded the gracious condescension of successive princes, by whom it was assumed in the first year of their reign; accordingly Constantine created two consuls, whose office it was to exercise supreme jurisdictions, the one at Rome, the other at Constantinople; and three centuries elapsed, even after the death of Justinian, before that obsolete dignity, which had been suppressed by custom, could be abolished by a law of Leo the philosopher. Afterwards the title was vitiated, as we learn from the emperor himself.

From the establishment of the republic, and the consulate under L. Jun. Brutus, and L. Tarq. Collatinus, to the consulate of Basil, *i. e.* from the year of Rome 244, or 245, 509 years before Jesus Christ, to the year of Rome 1204, the space of 1049 years, the years were accounted by the consuls; but from the time of Basil, in the year of Christ 541, we find no mention made of consuls, or consulates; but the time was then computed by the years of the emperors' reigns, the indictions, and those of the Christian era.

Indeed, for some time after the consulate of Basil, the years are marked thus; *post consulatum Basilii*, 1, 2, 3, &c. (See the *Facti Consulares* of M. D'Alencouven.) That author reckons 1000 pairs of consuls, besides the substitute consuls, *supplæti*, elected to supply vacancies by death; and yet there were but 1049 years, and consequently only 50 many consulates.

The perpetual consulates of the Eastern emperors, which compose the *Facti Byzantini*, commenced in the year of Christ 507, and ended in 608, in the last year of Constantine.

Constantine Pogonatus would have the consulate inseparable from the empire; which it continued to be till the time of Constantine Porphyrogenetus.

In this form of government the empire and consulate were so closely united, that the empress Irene would needs assume the consulate when she was only regent of the empire.

But the French kings, those of Italy, and the Saracen princes who commanded in Spain, taking on them the title of consuls, as well as emperors of Constantinople; these last despised it, and laid it aside; so that the name was only continued to the magistrates of some cities, and certain other officers, as is shewn by F. Pagi.

Under the emperors there were *ordinary consuls*, *honorary consuls*, and *suffeiti*; which last also subsisted in the time of the republic.

In the middle age, we find the word consul used for *comes*, *count*, and *proconul*, for viscount; as is observed by Spelman, and De Marca.

And thus consul, in our law books, signifies an *earl*. Braët. lib. 1. cap. 8. tells us, that as *comes* is derived from *comitatus*, so *consul* is derived from *consulendo*: and in the laws of Edward the Confessor, mention is made of *vicescomites*, and *vicesconsules*.

CONSUL, at present, is used for an officer established by virtue of a commission from the king, and other princes, in the ports and factories of the Levant, on the coasts of Africa, Barbary, Spain, and other foreign countries of any considerable trade; to facilitate and dispatch business, and protect the merchants of the nation.

These commissions were never granted to persons, as consuls of the French nation, under the age of thirty years. When the consulate is vacant, the most ancient of the deputies of the nation were to discharge the function thereof, till the vacancy should be filled up by the king.

The consuls are to keep up a correspondence with the ministers of England residing in the courts whereon their consulates depend. Their business is, to support the commerce and interest of the nation; to dispose of the sums given, and the presents made, to the lords and principals of places: to obtain their protection, and prevent the insults of the natives on the merchants of the nation. There are also consuls of other nations established in the Levant, especially French and Dutch.

CONSULS also denote judges elected among the merchants and dealers, in ports and trading towns, chiefly in France; to terminate, *gratis*, and on the spot, without any process, such differences and demands as may arise relating to their merchandizes, bills of exchange, and other articles of commerce.

The first jurisdiction of consuls established in France, is that of Tholouse; the edict of whose establishment bears date 1549, under the reign of king Henry II.; that of Paris followed fourteen years afterwards. By degrees, they were established in most of the considerable trading towns in that kingdom.

CONSUL, *Chief*, or *Premier Consul*, the first or chief of the magistrates, who each of them bore the name of consul in the late constitution of France, which has been succeeded by its present military despotism. Napoleon Buonaparte, the present emperor of France, was appointed chief consul, in consequence of the revolution that took place in 1799.

CONSULAR, of or belonging to a consul: as for example, a consular camp, a consular army, the consular dignity, the consular authority, and so on.

CONSULAR comitia, and *medals*. See the substantives.

CONSULATE, or **CONSULSHIP**, the office of consul, which was instituted by the Romans, in the year of Rome 245, after they expelled Tarquin the Proud.

CONSULTATION, in *Law*, a writ whereby a cause, formerly removed by prohibition from the ecclesiastical court to the king's court, is returned thither again.

If the judges of the king's court, upon comparing the libel with the suggestion of the party, find the suggestion false, or not proved; and therefore the cause to be wrongfully called from the court-christian; then, upon such deliberation, or consultation, they decree it to be returned again, and the writ obtained hereon is called a consultation.

And, even in ordinary cases, the writ of prohibition is not absolutely final and conclusive. For, though the ground be a proper one, in point of *law*, for granting the prohibition, yet, if the *fact* that gave rise to it be afterwards falsified, the cause shall be remanded to the prior jurisdiction. If, *e. g.* a cause may be pleaded in the spiritual court, a prohibition ought to go, because that court has no authority to try it; but, if the fact of such a custom be brought to a competent trial, and be there found false, a writ of consultation will be granted. For this purpose the party prohibited may appear to the prohibition, and take a declaration, (which must always pursue the suggestion,) and so plead to issue upon it, denying the contempt, and traversing the custom upon which the prohibition was grounded; and if that issue be found for the defendant, he shall then have a writ of consultation. The writ of consultation may also be, and is frequently, granted by the court without any action brought, when, after a prohibition issued, upon more mature con-

sideration, the court are of opinion that the matter suggested is not a good and sufficient ground to stop the proceedings below. Thus careful has the law been, in compelling the inferior courts to do ample and speedy justice ; in preventing them from transgressing their due bounds ; and in allowing them the undisturbed cognizance of such causes as by right, founded on the usage of the kingdom or act of parliament, do properly belong to their jurisdiction. Blackst. Com. vol. iii.

CONSUMMATE ESTATE. See TENANT *by curtesy*.

CONSUMMATION, the end, period, or completion, of any work.—Thus, we say, the consummation of all things: meaning the end of the world. By the incarnation, all the prophecies are to be consummated.

Consummation of marriage denotes the last act of marriage, which makes its accomplishment.

CONSUMPTION, in *Medicine*, popularly named a *decline*, is a generic term, occasionally applied to different diseases, the most obvious symptoms of which are a gradual decline of the strength and functions of the body, and a diminution of its bulk, in consequence of the decrease or consumption, as it were, of the fat and muscular parts. From whatever cause, therefore, the nutrition of the body is impeded, consumption will be the consequence. The nutrition of the body may be impeded either by some great internal disease, which disturbs the functions, especially that of digestion ; or by deficiency of nutriment ; or by great evacuations or discharges of blood, or fluids secreted from the blood. These considerations have led nosologists to treat of consumption under three divisions or genera, with the titles of *Phthisis*, *Tubes*, and *Atrophia* : the two first being produced by internal organic diseases ; the last by the deficiency, or the abstraction, or corruption, of nutritious matter.

1. *Phthisis*, *Œlvis*, signifying *consumption* in general, is confined to that species which originates from disease of the lungs : this form of consumption being the most frequent and fatal. It is defined “ emaciation, with hectic fever, cough, and commonly with purulent expectoration.” The emaciation is occasioned by the disturbance in the function of digestion, which the daily fever produces ; by the impediment to the function of respiration, which the diseased lungs are unable to carry on ; and by the great discharges by expectoration, sweating, or diarrhoea, which latter frequently alternate with each other.

2. *Tubes*, which, in the Latin language, is synonymous with *phthisis* in the Greek, has been arbitrarily restricted by nosologists to that form of consumption, which is not accompanied by cough. It is defined, “ emaciation, with hectic fever.” Any local disease of long continuance, such as abscesses, ulcers, &c. which excites a hectic fever, may become the origin of a *tubes*. But the most frequent occurrence of *tubes* is observed in scrofulous habit, the scrofula being always slow in its progress : and one of the most common varieties of *tubes* arises, where scrofula attacks the glands of the mesentery. In this case emaciation is produced, not only by the disturbance of functions, and the sweats of the hectic fever, but by the physical impediment to the nutrition of the body, occasioned by the morbid condition of the mesenteric glands, through which the chyle cannot pass, in order to enter the thoracic duct, and thence to be poured into the blood-vessels.

3. *Atrophia*, derived from the primitive particle *a*, and *trophi*, *nutrio*, implying *defect of nourishment*, has been adopted to denote the simple emaciation and loss of strength, which is not accompanied with hectic fever, nor originates from any organic disease ; but depends altogether on the priva-

tion, corruption, or abstraction, of that which would otherwise support the strength of the body. It is defined, “ emaciation, without fever.” Hence atrophia occurs in those who have suffered great evacuations, as from salivation, hæmorrhage, sweat, leucorrhæa, &c. : in those from whom nutriment is abstracted in undue proportion to their strength and digestive powers, as in nurses suckling stout children, or continuing them at the breast too long ; and in those whose nutriment is corrupted, as the salt provisions, which excite fevers.

For a view of the nature and requisite treatment of the different kinds of consumption, see the following articles : *TABES Mesenterica* (or Mesenteric Consumption), and *ATROPHY*. *Savage's Nosol. Method.* Class x. ord. 1. *Cullen's Synopsis Nosol.* Class i. ord. 4. and Class iii. ord. 1.

CONSUMPTION, *Pulmonary*, the *phthisis pulmonalis* of medical writers, from *phthis*, *corruptio*, *consumo*, a distressing and very fatal disease, distinguished by the occurrence of a frequent cough, with expectoration of puriform matter, hectic fever, emaciation, and debility ; to which, in the latter stages, colligative sweats, often alternating with diarrhoea, supervene.

In this disease the number, degree, and progress, of the symptoms are extremely various, in different cases. It usually commences in an insidious manner, with a slight and short cough, which is often little remarked by those affected with it, but soon becomes habitual ; or with an occasional cough, which is more severe. At the same time, the breathing becomes easily hurried by any bodily motion, the patient grows leaner, and becomes languid and indolent. In this state he sometimes continues for a year, or even for two years, without making any complaint, excepting that he is affected by cold more readily than usual, which frequently increases his cough, and produces catarrh. This, however, is sometimes relieved, is supposed to have arisen from cold alone, and therefore gives no alarm either to the patient or to his friends, nor leads them to take any precaution. But upon some occasion of catching cold, as we commonly speak, the cough becomes more considerable ; is particularly troublesome, when the patient lies down at night, and in this state continues longer than is usual in the case of a simple catarrh. This may more particularly attract attention, if the increase and continuance of cough occur during the summer season.

The cough, in many instances, continues for a long time dry, or without any expectoration ; frequently, however, it is accompanied, from the first, with an expectoration of a blackish or bluish mucus, or of tough phlegm ; the expectoration being generally most considerable in the morning, in consequence of the accumulation of the matter during sleep. This matter becomes by degrees more copious, more viscid, and more opaque ; at length of a yellow or greenish colour, and of a purulent appearance, sometimes streaked with blood. As these changes take place, and the cough increases, the breathing at the same time becomes more difficult, and the emaciation and weakness go on also increasing. In the female, as the disease advances, and sometimes early in its progress, the menses cease to flow ; and this circumstance, although doubtless an effect, the sex themselves are generally disposed to believe to be the sole or principal cause of the disease. During this progress some pain is commonly felt in the thorax, at first under the sternum, especially, or almost solely, on the occasion of coughing ; but very often there is a pain in one side, sometimes dull and oppressive, sometimes sharp and shooting, and such as to prevent the person from lying easy upon that side. Even
when

when no pain is felt, it generally happens that phthical persons cannot lie easily on one of their sides, the difficulty of breathing being increased, and the cough excited by the attempt.

These symptoms have seldom continued long, before the pulse becomes frequent, sometimes to a considerable degree, without much of the other symptoms of fever. As it proceeds, the skin becomes dry and hot, especially the palms of the hands and soles of the feet; a circumscribed flush appears on the cheeks; transient chills are often felt by the patient, or he is exceedingly sensible to cold; and commonly a regular morning and evening febrile paroxysm takes place, the evening exacerbation being always the most considerable, and terminating in sweats during the night.

The mind is generally little or not at all impaired during the progress of pulmonary consumption; sometimes it is even more acute than in the previous state of health; and the patient is generally confident of recovery, and his spirits buoyed up by hope to the last extremity. But the gradual loss of flesh and strength, the sharpness of the features, the pearly whiteness of the eyes, the incrustation of the nails, and sometimes the loss of the hair, but too evidently mark the decay of the bodily functions. At length a colliquative diarrhoea, sometimes occurring together, but most commonly alternating, with the night sweats, contributes still farther to reduce the patient's strength; and death is frequently preceded by oedema of the feet and legs, and aphthæ in the mouth and throat, and occasionally by delirium.

Great numbers of people are repeatedly exposed with impunity to the circumstances which excite consumption of the lungs; it is only on a constitution of a peculiar nature, predisposed to the disease, that these exciting causes operate. This predisposition is frequently hereditary, descending from parents whom the disease had attacked, or who had, at some period of their lives, been affected with some form of scrofula. It is marked by a peculiar instability and weakness of the vascular system, more especially of the lungs; inasmuch as the person is subject to frequent catarrh, and spitting of blood. It is also distinguished by external peculiarities of form and appearance. Persons possessing what has been denominated the sanguine temperament, namely, having fine skin, with large veins, soft hair, light eyes, a florid complexion, tall and thin person, long slender neck, narrow chest, and projecting shoulders, may be considered as having the phthical predisposition: and those of the sanguine-melancholic temperament, combining with the fine skin and complexion, and slender form of the former, the dark hair and eyes, and dilated pupils of the melancholic temperament. This combination constitutes in general a temperament of peculiar beauty; but in the eyes of the medical physiognomist, a sense of its delicacy is not the least impression which it excites. Phthisis sometimes occurs also in persons who may be said to possess a sanguineo-phlegmatic temperament, *i. e.* who have the slender form and delicate constitution, with an habitually pale complexion, and without the disposition to acute inflammation, which belongs to the sanguine: it occurs occasionally too in temperaments almost entirely melancholic. See TEMPERAMENT.

In those who have a constitutional predisposition to the phthical state of the lungs, the disease is excited by various causes of irritation in those organs. Thus it is frequently induced by common inflammation of the lungs, or their membranes, by pleurisy, peripneumony, catarrh, whooping-cough, asthma, and the cough connected with measles; by frequent over-exertion of the lungs in speaking, singing, or blowing musical instruments; by inspiring certain kinds of dust or vapour; by hæmoptysis, or spitting of blood; by

sudden variations of the atmospheric temperature; by compressing the chest by tight bandages, &c. Of some of these causes we shall speak more particularly.

A great majority of the cases of pulmonary consumption is referred, by the sufferers, to a common cold or catarrh, as their origin; the expectoration of mucus, which belongs to catarrh, being gradually changed to an expectoration of pus, and a hectic fever supervening. But Dr. Cullen thinks that this supposition is not easily to be admitted; inasmuch as catarrh is properly an affection of the mucous glands of the trachea and bronchiae, analogous to coryza, and less violent kinds of sore-throat, which very seldom terminate in suppuration. He is of opinion, that the apparent catarrh, in such instances, was in fact the beginning of phthisis, for which it may have been mistaken, as the resemblance between the two is so great as commonly to preclude the means of discrimination. This difficulty, however, he admits, presses upon the necessity of paying minute attention to every catarrhal cough, especially in those who bear marks of the temperament which is predisposed to consumption. This observation has been inculcated, indeed, from ancient times. "Quod si mali plus est," says Celsus, "et vera phthisis est, inter initia protinus occurrere necessarium est; neque enim facile hic morbus, cum inveteraverit, vincitur." lib. iii. cap. 22. The attention of friends and parents cannot, indeed, be too strongly urged upon this point; to neglect the slightest catarrhal affection, which continues longer than the usual short period of a few days, is to neglect the only period of suppressing a disease, which almost invariably tends to fatality.

Hæmoptysis, or spitting of blood, is enumerated among the causes of consumption, and certainly very frequently precedes it. But this occurrence may, perhaps, be considered still more than catarrhal symptoms, as a sign of the commencement, and not a cause, of the disease; more especially when it occurs independently of external violence. Numerous instances of hæmoptysis have occurred, from blows and wounds, in which ulceration did not ensue, or at least was of short duration, and did not materially injure the constitution. But when it comes on without any obvious external cause, and especially in persons of one or other of the temperaments already described, ulceration, expectoration of pus, and all the distressing symptoms of phthisis are generally to be apprehended. In such cases, there is either a peculiar tenderness of the vascular system in the lungs; or, what is perhaps more generally the fact, an incipient obstruction, as tubercles, which render the small vessels liable to give way, when the circulation through them is increased by any exertion, or receives an irregular impetus from the action of coughing, occasioned by cold. In this way catarrh may lay the foundation of phthisis. Spitting of blood, however, if not among the first symptoms, very frequently occurs in the course of the disease, especially in the stage of purulent expectoration.

When inflammation of the lungs terminates in extensive suppuration, producing one or more collections of purulent matter, termed *vomice*, the great irritation often produces hectic fever, which, together with the expectoration of pus, continues after the vomice burst, and the patient is cut off with the ordinary train of symptoms belonging to phthisis.

Persons who are occupied in various employments, by which the air they breathe is contaminated with various substances, in the form of a fine powder, are peculiarly liable to be seized with phthisis. Thus hair-dressers, bakers, masons, bricklayers'-labourers, laboratory-men, coal-heavers, and chimney-sweepers, are frequently subject to the most obstinate pulmonary diseases; as are also, in an equal degree, the

dressers of flax and feathers, and the workmen in the warehouses of leather-fellers. Many persons, thus engaged, struggle a long time with a constant, hard, troublesome cough, which at length terminates in consumption. See Willan on Diseases in London, p. 301.

The exanthematous diseases, such as small-pox and measles, the latter of which, more particularly, often lays the foundation of consumption, seem to operate by occasioning some morbid change in the constitution, which may be considered rather as a predisposition than an actual state of disease. Dr. Cullen attributes this change to an acrimony left in the fluids by these exanthemata, which he believes to be the same with the acrimony which prevails in scrofula. But if we would avoid hypothetical language, all that can be said is, simply, that a predisposition to phthisis and to scrofula is occasioned by these diseases. The measles, indeed, may not only induce the predisposition, but, by the irritating cough which it leaves behind, may actually occasion a consumption of the lungs.

The venereal disease, or the irritation of the mercurial medicines necessary for its cure, or both combined, appear also to excite a predisposition, and lay the foundation of consumption.

Dr. Cullen has enumerated, among the exciting causes of phthisis pulmonalis, and as the most frequent of them all, tubercles in the lungs. In the majority of cases these undoubtedly exit; but we must consider them as constituting the essential part of the disease itself, and, if not originally induced by some of the causes above enumerated, excited into a state of activity by some one of them, perhaps most frequently by the common catarrh. Of the pulmonary tubercles, the best morbid anatomist of the times gives the following account.

There is no morbid appearance, he says, so common in the lungs as that of tubercles. These consist of rounded, firm, white bodies, interspersed through their substance. They are, I believe, formed in the cellular structure, which connects the air-cells of the lungs together, and are not a morbid affection of glands, as has been frequently imagined. There is no glandular structure in the cellular connecting membrane of the lungs; and on the inside of the branches of the trachea, where there are follicles, tubercles have never been seen. They are at first very small, being not larger than the heads of very small pins; and in this case are frequently accumulated in very small clusters. The smaller tubercles of a cluster probably grow together, and form one larger tubercle. The most ordinary size of tubercles is about that of a garden pea; but they are subject in this respect to much variety. They adhere pretty closely to the substance of the lungs, and have no peculiar covering or capsule, and have little or no vascularity. When cut into, they are found to consist of a white smooth substance, having great firmness, and often contain in part a thick curdy pus. But when the pus is in considerable quantity, it is thinner, and resembles very much the pus from a common sore. In cutting into the substance of the lungs, a number of abscesses is sometimes found, from pretty large tubercles having advanced to a state of suppuration. In the interstices between these tubercles, the lungs are frequently of a harder, firmer texture, with the cells in a great measure obliterated. The texture of the lungs on many occasions, however, round the boundaries of an abscess, is perfectly natural.

I have sometimes, Dr. Baillie continues, seen a number of small abscesses interspersed through the lungs, each of which was not larger than a pea. The pus in these is rather thicker than what arises from common inflammation, and resembles serofulous pus. It is probable that these abscesses have been

produced by a number of small scattered tubercles taking on the process of suppuration. The lungs immediately surrounding these abscesses are often of a perfectly healthy structure, none of the cells being closed up by adhesions. See Baillie's Morbid Anatomy, p. 66, *et seq.*

This accurate delineation of the condition of the lungs in the last stage of consumption, sufficiently evinces the impossibility of a cure by medicine, and may contribute farther to enforce an attention to its earliest symptoms.

It must not be omitted, however, that although the slightest symptoms of catarrh often prove the commencement of a fatal phthisis; on the other hand, catarrh does occasionally put on the appearance of phthisis, yet terminate well. Dr. Willan observes, in his "Reports on the Diseases in London," "many persons who had catarrhal coughs in March, were farther affected with spitting of blood, thick, viscid expectoration, pains within the chest, hectic fever, and diarrhoea, interchanging with night sweats, but recovered notwithstanding in the month of April." He concludes "that ulcerations in the lungs had not been produced, and that the expectorated fluid, so alarming in its appearance, was perhaps only composed of a puriform secretion, and an increased discharge of mucus, circumstances usual under other membranous inflammation." Reports, p. 4 and 147. But it must be added, that dissection has shewn, that even this condition of lungs has proved fatal, with the usual symptoms of phthisis.

To aid in distinguishing whether the matter expectorated be pus, or mucus only, several tests have been proposed; which, taken together, may afford us the means of an accurate conclusion. 1. The colour; mucus being naturally transparent, and pus always opaque. When mucus becomes opaque, as it sometimes does, it becomes white, yellow, or greenish; but the last mentioned colour is hardly ever so remarkable in mucus as in pus. 2. The consistence; mucus is more viscid and coherent, so as not readily to be diffused in water; pus is more readily friable, being broken into ragged fragments by a little agitation in water. 3. The smell; no odour is in general perceived in mucus, but frequently in pus. 4. The specific gravity; it being usual for the mucus of the lungs to swim on the surface of water, and for pus to sink in it; but in this we may be deceived, as pus which has entangled a great deal of air may swim, and mucus that is free from air may sink. 5. The mixture which is discernible in the matter brought up; for if a yellow or greenish matter appears surrounded with a quantity of transparent or less opaque and less coloured matter, the more strongly coloured may be generally considered as pus. 6. Chemical tests. Mr. Charles Darwin's experiments shewed that the vitriolic acid dissolves both mucus and pus, but most readily the former; that if water be added to such a solution of mucus, this is separated, and either swims on the surface, or, divided into flocculi, is suspended in the liquor; whereas, when water is added to a like solution of pus, this falls to the bottom, or by agitation is diffused so as to exhibit an uniformly turbid liquor. Again he shewed, that a solution of caustic potash, after some time, dissolves mucus, and generally pus; and if water be added to such solutions, the pus is precipitated, but the mucus not.

With respect to the *prognosis* in consumption, its tendency in general must be considered as extremely bad. In constitutions, where all the delicacy of the temperaments before described is observed, and more especially if an hereditary predisposition can be traced, the most trivial symptoms are alarming. The particular degree of danger must be estimated from these circumstances, from the mode in which the disease commenced, from its duration, and the slowness

CONSUMPTION.

or rapidity of its progress, the number and degree of the symptoms present, and the effects which medicine has already produced. The following aphorisms, the result of Dr. Cullen's observation, are worthy of attention.

"A phthisis pulmonalis, from hæmoptysis, is more frequently recovered from, than one from tubercles.

"A phthisis from a suppuration, in consequence of pneumonic inflammation, is that which most rarely occurs in this climate; and a phthisis does not always follow such suppuration, when the abscess formed soon breaks, and discharges a laudable pus: but, if the abscess continue long shut up, and, till after a considerable degree of hætic has been formed, a phthisis is then produced, equally dangerous as that from other causes.

"A phthisis from tubercles has, I think, been recovered: but it is, of all others, the most dangerous; and, when arising from a hereditary taint, is almost certainly fatal.

"The danger of a phthisis, from whatever cause it may have arisen, is most certainly to be judged of by the degree to which the hætic and its consequences have arrived. From a certain degree of emaciation, debility, profuse sweating, and diarrhœa, no person recovers.

"A mania coming on, has been found to remove all the symptoms, and sometimes has entirely cured the disease; but, in other cases, upon the going off of the mania, the phthisis has recurred, and proved fatal.

"The pregnancy of women has often retarded the progress of a phthisis, but commonly it is only till after delivery, when the symptoms of phthisis return with violence, and soon prove fatal." First Lines, parag. 898.

Treatment. It will readily appear, from what has been said above, that the cure of pulmonary consumption must be exceedingly difficult; in the latter stages, perhaps impossible. Many instances, however, have occurred, where the attention of the patient to the incipient symptoms, and his early adoption and steady pursuit of proper measures, have averted the fatality of the disease. When it is deeply rooted, alleviation of the sufferings is all that can be hoped for.

The treatment of a beginning consumption will depend much upon the peculiar constitution of the patient, as well as on the nature of its origin, and of the symptoms which it exhibits; but most particularly upon the prevalence of an inflammatory disposition, or of a general debility of the habit; these opposite states being both accompanied by great irritability; and the principal indications will be to diminish the inflammatory action and irritability; and in the latter state, just mentioned, to avoid debilitating measures, and to support the strength as much as is consistent with the inflammatory irritation that may exist.

Where there is considerable strength, and a complexion still florid, if there is much pain in the chest, or if the pulse be quick and sharp, perhaps small bleedings from the arm may be resorted to, and occasionally repeated; or blood may be drawn from the chest, near the seat of the pain, by means of leeches or cupping. But this discharge should be always effected after a cautious examination of the circumstances; for the debility which is apt but too speedily to ensue, may be thus accelerated, and, with it, the worst symptoms of the disease. It is now well understood, that the appearance of the buffy coat on the blood drawn, is by no means alone an evidence of the necessity of drawing more; for it will appear in phthisis, nearly as long as the arteries have power to propel it. The old doctrines respecting the buffy coat, have doubtless led to much practical error; but no one now considers pregnancy a disease which requires constant blood-letting; or uses the lancet, in the hot stage of an intermittent

fever, although under both these circumstances, the buffy coat is constantly found. In consumption occurring, as it most commonly does, in delicate habits, the practice of repeated venesection decidedly accelerates the fatal course of the disease. Blisters, on different parts of the chest, will better answer the purpose of relieving a local inflammatory disposition. Issues and setons have a similar effect, but the constant discharge tends to debilitate, and the irritation to counteract, in some measure, the good effects of the evacuation.

During the use of blisters, or other local discharge, the internal use of medicines, which have been denominated refrigerant, may be also resorted to with some advantage; such are acids, especially the vegetable, and certain neutral salts, as crystals of tartar, nitre, &c. The last named salt has been strongly recommended by Dr. Dickson, (see Med. Obs. and Inquiries, vol. iv. p. 208.) especially where there is hæmoptysis, administered in small doses frequently; "when given early in an hæmoptœe," he says, "I can almost equally depend upon it, as upon the cortex peruvianus in a genuine intermittent." But general experience does not warrant this encomium to its extent. We believe the digitalis to be the most efficacious medicine, in repressing that inflammatory action of the arterial system at large, and of the pulmonary arteries in particular, which commonly goes on at the commencement of phthisis, whether accompanied by spitting of blood or not. The latter it commonly suppresses, and we have frequently seen a febrile irritation, bordering on hætic, attended with a sharp and quick pulse, a dry ringing cough, and commencing emaciation, speedily subside under its administration. The digitalis may be given in combination with the acids, or with nitre, in a mucilaginous liquid. The cerussa acetata, or acetite of lead, was formerly employed in considerable doses, especially by the continental physicians, with the view of counteracting inflammatory action, and of suppressing hæmoptysis. The medicine, it would appear, is possessed of some efficacy; but the danger of inducing paralysis, and colica pictonum, and other effects, which result from the poison of lead, is sufficient to deter us from its use. Where the inflammatory action is high, we should be cautious in employing opiates, with a view to allay the cough; as, in such cases, opium in any form proves too stimulating; but where there is languor and debility, and less of the sanguine temperament, and the cough extremely harassing, opiates may be employed with benefit; they will save the strength of the patient, by appeasing the incessant irritation of coughing, which tends to wear him down, and deprive him of sleep.

Medicine, however, will not alone secure the patient from the deleterious progress of the disease. He will be required to pay strict attention to his diet, and to every external circumstance that can influence the functions of the body. His meat and drink, his cloathing, his exercise, his sleep, and even his amusements, must be regulated with a rigid correctness, so that the whole may combine, with medicine, to accomplish the same object, that of ridding the constitution of a disease of fatal tendency, and restoring it to its healthy condition. Diet, regimen, and medicine, must become, as it were, the business of the patient. He must regulate his life chiefly upon this principle; that every thing which can heat or irritate the body, or excite any increased or irregular action of the arterial system, must be shunned; and every measure which can support the constitution, without infringing on the last-mentioned precept, zealously adopted.

The diet of the consumptive, in the early stage, of which we now speak, should be light and nourishing, and such as is found to be adapted to his digestive powers. Animal food should

should be avoided; and vegetable matters, in the various forms of preparation, with the ripe saccharine and sub-acid fruits, and milk, be read the exclusive nourishment of the patient. Milk is particularly feasible, as being very nutritious, and easily digestible, without stimulating the system, and should be considered as the basis of the patient's diet. In some habits, however, where the digestive powers are feeble, or where there is a peculiar idiosyncrasy, cow's milk is not readily digested; a load at the stomach, or acidity, or head-ach, ensue after it is taken. In such cases, the whey which is produced by separating the cheesy part, or the butter-milk which is left after the separation of the oily part, or butter, may be substituted with advantage. Or the patient may have recourse to the lighter milk of the goat or the ass, which contains a smaller proportion of those heavy parts. The acidity which milk occasions in the stomach of some people, may be occasionally corrected by the admixture of lime-water. Some of the amygdaceous preparations from vegetables, may be used in conformity with this plan, such as the arrow-root, tapioca, &c.; and it is scarcely necessary to add, that with these, as with all other food, wine, spirits, and fermented liquors, must be most studiously avoided. A mucilaginous vegetable has lately been introduced, which, in feeble habits, seems calculated to assist this plan; namely, the lichen islandicus, which may be taken boiled in milk, and which, with its nutritive qualities, combines a very mild tonic power, which somewhat aids the digestion.

While every thing is done, by means of medicine and diet, to repress inflammatory action, while we moderately support the strength, another measure, still more efficacious, should be adopted, by those who have the power; they should remove to meet the winter in a warm and more equal climate. Cold, but especially sudden vicissitudes of cold and heat, appear to be the most inimical circumstances to a beginning consumption; and there are many living testimonies of the benefits which have been derived from an early visit to a more genial atmosphere. Portugal, the south of France, and Italy, have been resorted to, as well as the more regular and moderate climates of Madeira and St. Helena. Where these countries cannot be visited, some parts of our own island may be tried, as being milder than the rest; as Devonshire, and the neighbourhood of Bristol; which latter place possesses the additional advantage of a wholesome tepid water. Instances of the inefficacy of all these places, are, indeed, but too numerous; but much of this is to be attributed to the patients themselves. They persist in waiting the result of time, or of the less efficacious means of relief, until relief is altogether beyond their reach. "It seems too often to be the fate of consumptive patients," says Dr. Fothergill, "to do that last which they ought to have done first; and, by this profligate conduct, shorten their own lives, and afflict all who have any regard for them." (Med. Obs. and Inq. vol. v. p. 369.) The same intelligent physician affirms, that the Bristol water is, in his opinion, an efficacious medicine, and that he has "often found it of signal benefit to consumptive patients;" but "it is before the approaches to a confirmed phthisis that patients ought to repair to Bristol; otherwise, a journey thither will be, not only without benefit, but will be probably detrimental." Ibid. Those who have visited the pump-room at the hot-wells, must have seen, with pity, the hopeless condition of the poor creatures who are dragged thither, to their personal detriment, and the discredit of an useful medicine.

Exercise, by various modes of gestation, has been frequently employed as a remedy for consumption. Sydenham,

indeed, asserted, that riding on horseback is as effectual in the cure of phthisis pulmonalis, as the bark in agues, or mercury in the venereal disease, provided the journeys be long enough. An example is related in Dr. Darwin's "Zoonomia," vol. ii. (the case of the late ingenious Dr. Currie of Liverpool) in which an hereditary phthisis was removed, by persevering in a daily journey; at first in an easy carriage, and subsequently, as the strength increased, alternately in the carriage and on horseback. Some physicians, however, are of opinion, that exercise on horseback is rather pernicious, than otherwise, in phthisis. (See Dr. Dickson's paper, before quoted.) *Sailing* seems to be considered at present as the most efficacious mode of gestation, especially if a long voyage is taken, which is a double recommendation of the removal to a warmer climate. As a sort of substitute for this kind of gentle motion, *swimming* has been recommended as a remedy for phthisis, and Dr. Carmichael Smith has written a treatise in its favour. In the use of any, or all these modes of gentle exercise, however, the same precept must be pursued; they must be resorted to *early* in the disease.

If the plan, now detailed, has not been adopted in such time and mode, as to have checked the disease; if it has, therefore, advanced to the confirmed state, with purulent expectoration, hectic fever, and profuse night sweats; the principal object of medicine becomes merely palliative, and confined to the alleviation of urgent symptoms. If the cough is exceedingly urgent, opiates may be administered more liberally than in the early stage. At this period, some of the more stimulating expectorants are employed by some practitioners, with a view to facilitate the discharge of the matter which loads the lungs; such as the oxymel, or other preparation of squills, the various balsams, and some of the gum-resins. But the experience of the most observing physicians has decided against the utility of these heating drugs. (See Dr. Fothergill, loc. cit. Dr. Cullen, loc. cit.) There may be occasional circumstances in particular constitutions, where the objections may not exist, as in a cold phlegmatic habit, or where there is considerable debility of circulation, with little inflammatory tendency; but these are not common. The colligative sweats and diarrhoea frequently alternate with each other, and medicines which relieve the one, are liable to increase the other. The diluted sulphuric acid has a considerable influence over the night sweats, and opium is an efficacious medicine against the colligative diarrhoea. But the opium seems to favour the occurrence of the perspirations, and the acid tends to excite the action of the bowels. These medicines, therefore, must be combined, or used singly and alternately, according to the circumstances of the case. Opium may be also given by way of enema, when the diarrhoea is obstinate.

Some practitioners, presuming that the hectic fever, and the whole series of phthisical symptoms, were dependent on debility alone, have recommended the use of tonic medicines, and a generous diet, in the state of confirmed phthisis; and several cases are on record, in which this plan appears to have been attended with success. (See Dr. May's Papers, Lond. Med. Journ. vol. ix. and xi.) But we have already observed, supported by the authority of Dr. Willan, that catarrhal affections occasionally put on the symptoms of phthisis, and recover under the ordinary means. There are also cases of this sort, in which there is, we believe, no ulceration, but only a purulent secretion from the membranes, which nevertheless terminate fatally, with the worst symptoms of phthisis; and perhaps it is in such cases, that a tonic treatment is actually successful. But we have

no means of distinguishing these cases from the more general instances, in which abundant experience has taught us, that all stimulating or corroborant medicines and food tend to augment the cough and expectoration, to increase the hectic fever, and therefore to accelerate the destruction of the constitution, even in the last stages.

Emetics, repeated daily, have also been recommended, as a remedy for phthisis. They afford, we believe, a temporary relief to the respiration and cough, but nothing more. On the contrary, the continued repetition of such an irritation, and such a derangement of the natural action of the stomach, necessarily tends to debilitate and impair the functions of this viscus, and to weaken the constitution at large.

Before we conclude, we cannot omit mentioning an illusion, which was fostered in the minds of some enthusiastic physicians, after the discovery of the composition of atmospheric air by the chemists. It was found that oxygen was the great stimulus of life, and the source of the salutary change of the blood, which is marked by its florid colour. From the general florid colour of the blood of the phthisical, it was supposed that consumption was occasioned by a general hyper-oxygenation of the system; and hence, by an easy inference, the breathing of an air, in which the proportion of oxygen was diminished, by the addition of some azotic air, such as carbonic acid gas, or carbonated hydrogen, was suggested as a probable remedy for consumption. Cases were even published, illustrative of the extraordinary efficacy of this new medicine. But the light of experience has opened the eyes of the visionary, and the phantom has disappeared. It has even been shewn by the experiments of the French chemists, that the absorption of oxygen, or, at least, its disappearance in the lungs, is influenced principally by the state of the body, and not by the proportion existing in the air which is inspired.

CONSUMPTION, *mesenteric.* See **TABES mesenterica.**

CONSUMPTION, in *Barriery*, is also a disease incident to horses, consisting in waste of muscular flesh, attended with a slow fever. In this disorder bleeding in small quantities is recommended: mercurial purges, and a powder of native cinnabar, gum guaiacum and nitre, of each one pound, in the quantity of an ounce twice a day; spring grass, and salt marshes, are also of great service, when there is any prospect of a recovery. See **CONDITION.**

CONSUS. See **CONSUALIA.**

CONTA, in *Geography*, a river of Italy in Genoa, which runs into the sea near Albenga.

CONTACT, (from the Latin *contactus*;) means the meeting, or mutual touching of two things. The word is universally used in the common affairs of life, as well as in scientific subjects.

In geometry a line is said to touch another line, or a surface, or a solid; and a plane figure, or surface, is said to touch another surface or a solid, when the former meets the latter; but, being produced, does not cut it. Thus amongst the definitions of the third book of Euclid's "Elements of Geometry," a right line is said to touch a circle, when meeting with the same, and being produced, it does not cut it. Also two circles are said to be in mutual contact when they meet, but do not cut each other. Thus the mathematical meaning of the word contact is clear and definite, nor can any doubt arise in the speculative mind concerning the nature of it; the abstract ideas of a line, of a surface, or of a solid, being perfect and independent on any physical qualities of a doubtful or uncertain nature.

The contact of two spheric bodies is only in one point; and the same holds of a tangent and the circumference of a

circle. See **TANGENT.** Hence, because very few surfaces are capable of touching in all points, and the cohesion of bodies is in proportion to their contacts; those bodies will stick fastest together, which are capable of the greatest contact. The contact of curve lines or surfaces, with either straight or curved ones, is only in points; and yet these points have different proportions to one another, as Mr. Robartes has shewn in the *Philos. Trans.* vol. xxvii. p. 470, or *Abr.* vol. iv. p. 1.

In mechanics and in philosophy the contact between two bodies is said to take place, when one body, being brought near another body, cannot be approached nearer to it without, in some measure, affecting its state, be it of motion or of rest. Thus a stone, being gradually moved towards another stone, is said to come in contact with it, when its progress is either absolutely, or partially, obstructed by that other stone. Or, if they be both at rest, and contiguous to each other, they are said to be in contact, when one stone cannot be moved towards the other, without either urging the other forward, or being stopped by it, or lastly without making an impression upon its surface. The same thing must be understood of the contact between any two other bodies. But the great question in philosophy is, to determine whether the bodies which thus hinder, or affect, each other's state of rest or motion, do actually come in contact with each other's surface in the strict mathematical sense, or they exert that hindrance, opposition, resistance, &c. in virtue of a repulsive power, which acts at a certain indefinite small distance from their surfaces. This question seems, at first sight, to be easily determined; but, when duly considered, it will be found to involve certain properties of matter in general, and certain effects, which, in the present state of knowledge, are far from being thoroughly understood, or sufficiently examined.—The reasons which suggested the above-mentioned doubts, concerning the contact of bodies, and the answers which may be offered in elucidation of the subject, being fully deserving of notice, we shall now endeavour to state them in a regular and compendious manner.

Sir I. Newton, having placed a glass lens of a figure slightly convex, upon the flat surface of another glass, and having pressed the one against the other, observed certain coloured rings formed between the two glasses, and concentric with the point of contact in the middle of the glasses, which point was marked by a colourless dark spot. He farther observed, that those rings of prismatic colours, and the dark central spot, became larger when the glasses were pressed harder against each other, and became diminished in size when the pressure was diminished.—From the known figure of the glasses employed in this experiment, it is evident that a certain space or a film of air must remain between their contiguous surfaces; that this space, or film of air, became thinner when the glasses were pressed hard against each other, and *vice versa*; lastly, that at the centre, where the glasses may be presumed to have been in real contact, the want of space, or of air, rendered that spot colourless. In this experiment it is supposed, that the colours are owing to the space or film of air between the glasses; hence the central spot exhibits no such colours; and therefore, that when any prismatic colours appear between the contiguous surfaces of two glasses, their contact cannot be perfect. Nearly the same thing is observed when two flat pieces of glass are pressed against each other; prismatic colours being likewise seen between them, though not in rings, but in rows, which assume various directions, according as the pressure may happen to alter the surfaces of the glasses. And these colours cannot be made to disappear without the application

of an enormous degree of pressure; hence it is inferred, that, though of two bodies one may support the other, or push it forward, yet their contact may not be perfect. Professor Robison reckons the force with which two pieces of glass must be pressed against each other, in order to produce a perfect contact, as equivalent to the pressure of 1000 pounds for every square inch of surface; so that if two pieces of glass strike against each other, without exerting a pressure equal to 1000 pounds per square inch of surface, they may affect each other's motion, and yet not come actually in contact. In consequence of the above facts and observations it is supposed, that a repulsive power exists on the surfaces of bodies, and that this power is extended to a very small and inappreciable distance beyond the surface.

Another argument to prove the existence of the above-mentioned resisting power on the surfaces of bodies, is derived from the phenomena exhibited in an electrical experiment.—When an electric jar is discharged through a metallic chain in a darkened room, sparks of electric light are visible between the contiguous surfaces of the links. Dr. Priestley, considering this effect as arising from the want of perfect contact between the links, endeavoured to render it perfect by stretching the chain, until on making the discharge no such sparks should be seen. This he accomplished by making one end of the chain fast on a firm body, and appending weights to the other end. Thus proceeding, he found that a very considerable weight was necessary to be applied, before the sparks could be made to disappear between the links, when the jar was discharged through the chain. This induced Dr. Priestley to conclude, that the links of the chain could not be brought into actual contact without the application of a great force; since the electric sparks are visible only when the electric fluid in passing through a body or a series of contiguous bodies, meets with some obstruction, or interruption of continuity.

Besides the existence of the above-mentioned resisting or repulsive power on the surfaces of such gross bodies as come under the cognizance of our senses; it is farther supposed, that each component particle of such bodies is indued with the same repulsive power; in consequence of which they are not actually in contact with each other, though they form the same firm and impenetrable compound. And the existence of this power has been inferred from the phenomena of contraction and expansion. "Whatever opinion," says Dr. Young, "we may entertain, with respect to the ultimate impenetrability of matter in this sense, it is probable that the particles of matter are absolutely impenetrable to each other. This impenetrability is not however commonly called into effect, in cases of apparent contact. If the particles of matter constituting water, and steam, or any other gas, are of the same nature, those of the gas cannot be in perfect contact; and when water is contracted by the effect of cold, or when two fluids have their joint bulk diminished by mixture, as in the case of alcohol, or sulphuric acid, and water, the particles cannot have been in absolute contact before, although they would have resisted with great force any attempt to compress them. Metals too, of all kinds, which have been melted, become permanently more dense when they are hammered and laminated."

Whoever wishes to form a proper estimate of the merits of the above-mentioned arguments, and of the validity of the proposition which they are intended to establish, must necessarily take into the account all the other properties of matter, which have been discovered and confirmed by repeated and universal experience; for, should it appear impracticable to reconcile the former with the latter, then such other explanation of the phenomena ought to be substituted

as may be attended with less contradiction and greater simplicity.—That there is a mutual and universal attraction amongst all the particles of matter, is now no longer to be doubted; that this attraction is extended to all distances under certain determinate laws, has been sufficiently established by strict mathematical reasoning upon the grandest phenomena of the world; that the surfaces of several bodies, like those of polished glass or metallic bodies, when placed contiguous to each other, manifest a considerable degree of attraction, is well known; and, lastly, that the component parts of solids cannot be separated without a considerable force, is shown by daily and common experience. Yet, notwithstanding all these evidences of attraction between the bodies of the universe at all distances, we are told that a considerable repulsive power exists on the surfaces of bodies, and even that every individual particle of matter is endowed with a similar power; so that in the hardest bodies, such as a diamond, a flint, a piece of metal, &c. which cannot be divided without an immense force, the component particles are not actually in contact with each other. But let us endeavour to explain the phenomena, upon which the above theory is established, in a simpler and more satisfactory manner.

In the experiments with the glasses, it is said that their actual contact is prevented by a power of repulsion on their surfaces, which cannot be overcome without a very extraordinary pressure. Would it not be more natural to suppose, that the contact cannot be easily effected on account of the inequalities of the surfaces, and of the hardness of glass? The surfaces of the plates may be said to be slightly convex or perfectly flat, and such may appear to be for common purposes. But if a person examines how those surfaces are formed and polished; if he considers the alterations of figure which are unavoidably occasioned by the partial dilatations or contractions arising from heat and cold, also from the interposition of the least particle of dust, or even of the air itself; he will be easily persuaded, that those surfaces are by no means really flat or uniformly convex in the strict meaning of those words. It is true that the action of those causes, viz. the inequalities that are produced by them, are exceedingly small; but it is of small effects that we are speaking. Upon the whole, therefore, it seems, that when the flat and convex glasses in the Newtonian experiment, or the two flat glasses, are placed the one upon the other, they do actually touch each other, but in a few points only, viz. with their more prominent parts, and that the other more depressed parts of their surfaces cannot come into actual contact, unless the former are depressed to the level of the latter, by the application of an external force; so that the application of this force is not required by the existence of a repulsive power, but by the necessity of depressing the more elevated parts, in order that the lower or hollow parts may come sufficiently near to each other. This idea seems to derive additional confirmation from the degree of pressure which must be applied, &c. being, at least apparently, proportional to the hardness of the bodies employed. Thus, in glass, which has a great degree of hardness and rigidity, a considerable pressure must be applied for the purpose. Bring two pieces of cold wax close to each other, and the one will push the other forward without adhering to it, because in that state the contact can take place in a very few points only; but if those pieces of wax be softened by heat, it will be found, that one of them cannot be caused to push the other without adhering to it, because in that state their surfaces are easily adapted to each other, and instantly increase the number of points of contact.

The appearance of sparks between the links of a metallic chain, when an electric jar is discharged through it, may be explained

explained in a similar manner, without having recourse to a power of repulsion, &c. for, in consequence of their figure, and of the inequalities of surface, the links cannot touch each other in more than a very few points, through which the electric fluid must pass; and though in those points the contact be perfect, yet the electric fluid either melts them or renders them red-hot, and of course affords the appearance of luminous sparks, in the same manner, and for the same reason, which renders a very fine metallic wire red-hot, or fuses it, when an electric jar is discharged through it; namely, because it is not large enough to afford a free passage to the electric fluid. So that if in the slender wire, where there is no interruption of continuity, the passage of the electric power is rendered manifest to our eyes, it may be evidently presumed that the sparks may appear between the links of the chain, though those links may be in actual contact. That the light disappears when, by stretching the chain, the points of contact are multiplied, needs no farther explanation. But the circumstance which contributes to the production of the sparks, is the adhesion of dirt or dust, or the partial oxydation of the surface of the links; considering that chains for electrical purposes are generally made of brass or iron, which are very liable to a superficial oxydation.

With respect to the last argument, derived from the contraction and dilatation of bodies, we may observe, with professor Prevost, that the diminution of bulk does by no means prove that the component particles of bodies are not in immediate contact; for a person may easily conceive an infinite variety of arrangements or dispositions of the elementary particles, which will admit of contraction and dilatation, without the least interruption of contact. Those particles, for instance, may be disposed in the form of rings, which, by becoming more extended ovals, or more circular, will occasion an enlargement, or a contraction of the aggregate. The particles may be supposed to be arranged in rows, and these rows may be disposed at certain angles with each other; so that the bulk of the aggregate may become expanded or contracted according as those angles are enlarged or diminished; and so forth. That some such arrangement is not only probable, but does actually take place in most bodies (whence it may be inferred to take place in all bodies) is clearly indicated by the crystallization of several bodies; viz. a regular arrangement of their particles; as in zinc, bismuth, frozen water, salts, &c.

CONTACT, *angle of*, is the angle HLM (*Plate III. Geometry, fig. 51.*) formed by the arc of a circle ML, with the tangent HL, at the point of the contact.

Euclid demonstrates, that the right line HL, standing perpendicular on the radius CL, touches the circle only in one point: nor can there be any other right line drawn between the tangent and the circle.

Hence, the angle of contact is less than any rectilinear one; and the angle of the semicircle between the radius CL, and the arc ML, is greater than any rectilinear acute angle.

This seeming paradox of Euclid has exercised the wits of mathematicians: it was the subject of a long controversy between Peletarius and Clavius; the first of whom maintained the angle of contact heterogeneous to a rectilinear one; as a line is heterogeneous to a surface: the latter maintained the contrary.

Dr. Wallis has a formal treatise on the angle of contact, and of the semicircle; where with other great mathematicians, he approves of the opinion of Peletarius. See *ANGLE of Contact*.

CONTAGION, frequently used as synonymous with

infection, the matter or medium by which certain diseases are communicated from one individual to another.

Some writers confine the term *contagion*, in consequence of its derivation from *con* and *tango*, *I touch*, to the communication of those diseases, which can only be transferred by actual contact of the sick, or of the palpable matter from their bodies; and apply the word *infection* to the communication of those other diseases, which spread by means of invisible effluvia, conveyed through the air, or adhering to articles of clothes, &c., constituting what are called *foetites*. The distinction is not important, nor is it philosophically accurate; since there is an actual contact of a morbid matter, in all cases of infection, whether visible or not; and some diseases, as the small pox, are communicated both by palpable matter, and by imperceptible effluvia. Other writers have confined the two terms to more arbitrary significations. We are disposed with Dr. Wilson and others, to consider the word *contagion* as expressing the morbid poison, or the means of transferring a disease; and *infection*, as expressing the operation of the poison, or the act of communication of the disease. Treatise on Febrile Diseases, vol. i. p. 433.

No mention is made of contagion in the writings of Hippocrates, and it is hence maintained by some authors, that the ancients were altogether ignorant of its existence. It cannot be doubted, indeed, that many of the most formidable diseases, which are propagated by contagion, in modern times, were altogether unknown to the ancients: such are the small-pox, measles, and scarlet fever, among the acute; and the venereal disease, among the chronic contagions. Of the existence of contagion, therefore, the evidence which they possessed was comparatively small. From the number of the laws in the Mosaic code, however, forbidding all communication with persons labouring under diseases, which were deemed unclean, and from the caution with which intercourse with foreign nations was precluded, it would appear that a general notion of that species of contagion, which infects by actual contact of bodies, prevailed among the Jewish people, at a very early period. (See Numbers, chap. xxxi.) And whatever might be the knowledge of profane writers on this point, they were certainly well acquainted with epidemic diseases. But this does not imply a knowledge of the existence of contagion, since even with the most confirmed proofs of the existence of febrile contagions before them, physicians have generally disputed, in the worst modern epidemics, whether contagion actually existed or not. Livy, however, in describing the progress of an endemic fever, expressly mentions that contact of the sick excited the disease. "Et primo temporis ac loci vitio, et ægri erant, et moriebantur; postea curatio ipsa et contactus agrorum vulgabat morbos." Lib. xxv. cap. 26. But, although it be admitted that the existence of contagion was occasionally noticed by ancient writers, and was by more modern authors yet more generally known, its nature and mode of propagation were very imperfectly understood, until the latter half of the eighteenth century; when the method of induction was applied to the investigation by some medical philosophers, and more particularly by Dr. Haysarth.

Of that species of contagion by which certain chronic diseases are propagated by actual contact, little need be said. Its existence is obvious in a palpable secretion from the morbid part, and therefore the prevention of it, by avoiding contact with the diseased, is clear and easy. The diseases in which such contagious matter is produced, are the venereal disease, the itch, the tinea capitis, or scald head, the yaws, siveas, &c. The hydrophobia would be incorrectly classed

CONTAGION.

with these diseases, although it agrees with them in being propagated by contact of a poisonous secretion.

In some acute diseases, which may be considered as an intermediate class, being propagated both by contact and effluvia, there is not less evidence of the existence of contagion, as in the small-pox, chicken-pox, and measles; because by the conveyance of a portion of the fluid contained in the pustules of the former, and in the milium vesicles of the last, (See Willan on Cutaneous Dis. p. 219.) the same train of symptoms has been excited in the persons receiving it, as occurred in the persons by whom the contagious matter was produced. But these diseases have been still more frequently observed to attack persons, who have approached within a short distance of the sick, where no contact took place; implying that the contagious matter, in an imperceptible form, was conveyed through the air, from the one body to the other.

The origin of the contagions, which produce these two classes of disease, is a subject of considerable difficulty; and inquiries in regard to it have generally proved fruitless, or led the inquirer into absurdities. By what concurrence of circumstances, or by what particular idiosyncrasy in any individual, a new animal poison can be generated, which shall excite a new and formidable disease, and propagate itself, and spread fatality for centuries through the world, we are altogether unable to discover. Yet in the history of medicine we find new and unknown contagious diseases springing up, and old ones, which had long prevailed, suddenly disappearing. The small-pox, and the measles, were first described by the Arabian physicians, and the scarlet fever first shewed itself in Italy in the fifth century. (See Willan on Cutaneous Dis. Order iii. p. 289.) The venereal disease was alike unknown to the ancients. The Plica Polonica seems to have made its appearance only in the last century. And on the other hand the leprosy of the Jews, and other species of leprosy, which raged in Europe in the 12th and 13th centuries, are scarcely now to be met with: and we have a remarkable instance both of the production and disappearance of a contagious disease in the Ephemera Britannica, Sudor Anglicus, or sweating sickness, as it was termed, described by Celsus and others. In such instances, if it should happen at any time that no person labours under the disease, the contagion might be lost, and the disease for ever disappear, unless the cause, which first gave rise to it, should again concur to reproduce it.

The cause is altogether different in respect to most of the fevers of that class, which are propagated by effluvia only, and in which no palpable poison is generated. Such is the typhus, or fever with debility, which prevails, under different denominations, in the temperate climates. According to the circumstances of its origin, it has been termed jail-fever, camp, hospital, and ship-fever: and from the variety of its appearances, putrid, malignant, petechial fever, &c. and it is occasionally combined with other diseases, along with which it is propagated, as with inflammation of the lungs, constituting the peripneumonia typhodes of authors, and with a dysenteric affection of the bowels, as in the camp-dysentery. In these instances the origin of the contagion has been obviously traced to circumstances of common occurrence; hence pestilential fevers of this class frequently arise spontaneously, that is, independently of the propagation of an existing poison, which has been perpetuated either by fomites or infected persons from its first origin. It is probable that the plague itself belongs to this class, and is the common fever, rendered peculiarly malignant by climate, season, or other circumstances.

The contagion, by which these fevers are propagated, is generated in three ways:—by the confinement of the healthy animal exhalations or effluvia in a crowded, and ill ventilated place;—still more readily by the confinement of morbid effluvia, although the disease be not originally contagious; and 3dly, by the exhalations from putrifying dead animal matter.

1. Many facts have been recorded, which shew that the natural effluvia of the living body, become the source of contagious fevers, when accumulated and concentrated in close apartments. Mr. Howel and others, who escaped, from the black hole of Calcutta, were seized with typhus fever. Dr. Lind informs us, that in a frigate, which sailed from North America, with a healthy crew, a malignant fever broke out before her arrival in England, during very bad weather, which affected a considerable number of the men, and of which the surgeon's mate, boatswain, and some others died. "Thus," he remarks, "a seasoned found crew became infected, as it would appear, from the closeness or damp below, occasioned by the hatchway being kept shut." (On Fevers and Infections, chap. i. § 2.) Sir John Pringle has observed that the hospitals of an army, not only when crowded with sick, but at any time when the air is confined, and especially in hot weather, produce a fever of a particular kind, and often mortal. "I have observed the same sort to arise," he adds, "in full and crowded barracks, and in transport-ships when filled beyond a due number, and detained long by contrary winds; or when the men have been long kept at sea under close hatches in stormy weather. Hospital-ships, for distant expeditions, have for this reason been generally destructive both to the sick and their attendants. (Obs. on the Dis. of the Army, part iii. chap. 7.) But contagious fevers are much more readily produced, under circumstances of confinement, where uncleanliness also conspired: hence such fevers originate most frequently among the poor, and even the most severe pestilence, when not imported, is generally to be traced to some quarter chiefly inhabited by the poor.

2. Where people, labouring under any diseases, are crowded together, more especially if the apartments are imperfectly ventilated, contagion is readily generated. Sir John Pringle remarks, that contagious fever "is incidental to every place, ill aired and kept dirty, that is filled with animal steams from foul and diseased bodies; and on this account, jails and military hospitals are most exposed to this kind of pestilential infection; as the first are in a constant state of impurity, and the latter are so much filled with the poisonous effluvia of sores, mortifications, dysenteric and other putrid excrements: nay, there is reason to apprehend that when a single person is taken ill of any putrid disease, such as the small-pox, dysentery, or the like, and lies in a small close apartment, he may fall into this malignant fever." Loc. Citat. It is very common, indeed, to observe mild febrile attacks among the poor, which, though originating from cold or other causes, become contagious in their course, in consequence of the confined and dirty situations in which the patients lie.

3. Contagion occasionally originates from the putrifying effluvia of animal and vegetable matters. Thus it often happens that typhus fever spreads itself over the adjacent country, when the dead are left unburied on the field of battle. Forellus mentions a contagious fever, which raged at Egmont, in North Holland, occasioned by the putrefaction of a whale, which had been left on the shore. And Senac gives an account of a malignant fever, excited by the offal of a city being accumulated without the walls. It was received

received into a ditch filled with water, and, while it was covered with the water, was not attended with any bad consequence; but when the quantity increased, so that it rose above the surface, a dreadful fever spread through the city, and its neighbourhood; so that, where four hundred used to die yearly, the deaths were increased to two thousand. Wilson on Febrile Diseases, loc. cit.

The most important part of our inquiry respecting contagion, relates to the mode and circumstances of its communication from individual to individual, and of its general spreading, with a view to discover the means of suppressing it, or preventing its extension. This inquiry is, of course, limited to the contagions which are soluble or diffusible in atmospheric air; since it is obvious that the indissoluble contagions may be avoided, by shunning the contact of the diseased. And it must be premised, that all the febrile contagions, whether of a specific origin, as that of small-pox, measles, scarlet fever, or malignant sore throat, or arising from the casual change of the animal effluvia, as that of typhus, jail and hospital fever, and perhaps the plague, have been found, by experiments, to be propagated according to the same laws, and to be suppressed by similar means.

Whenever a contagious epidemic disease prevails, a great general alarm is excited, in consequence of a notion, that the seeds of an evil so generally destructive must be diffused through the atmosphere at large; and that, if we stir abroad, we breathe contagion at every step. This opinion has been promulgated by physicians of high rank and authority; but recent observations have shewn that it is erroneous: thus at once removing all grounds for this unnecessary alarm, and directing our attention to those means of precaution and prevention, which can alone effectually contribute to our security. Dr. Lind long ago affirmed, after an extensive experience in the great naval hospital at Haslar, that the infection of malignant fever, in common with that of the plague, "extends to no great distance from its source."—"In the open free air, this infection does not appear to diffuse itself above fifty or sixty feet from its *nidus*." Chap. iv. sect. 2. With respect to the plague, it has been well ascertained by physicians, that its contagion does not contaminate the atmosphere in general, nor indeed to any great distance from the source of the poison. Dr. Patrick Russell, who was in extensive practice at Aleppo for many years, particularly during the plague of 1760, 1761, and 1762, used to administer medicines to great numbers ill of the plague, every day, out of a street window, about 15 feet above the ground, even in June and July; and, being short-sighted, he examined the sores within four feet: yet neither his family, nor any inhabitant of the square where he lived, were infected by the contagion of such a number of pestilential patients; and he affirms that it never spread in a large house, if communication were prevented. A numerous body of Franks live in Constantinople, and are uniformly preserved from the plague, by observing a few rules of cleanliness and separation, while the Turks die of it in multitudes around them. De Mærtens, author of a history of the plague at Moscow, anno 1771, has shewn that the contagion was disseminated to a very short distance through the air: a fact, which was demonstrated by the successful conduct of the committee of physicians, appointed by the empress to attend the sick on that occasion. The just inference from these observations is, that the plague is principally propagated by actual contact or close communication with the diseased, or their clothes, furniture, &c. "Solo ægrorum et rerum infectarum, contactu communicabatur," says Dr. De Mærtens, "atque atmosphæra contagium non spargebat; sed sanissima

semper fuit. Visitando tam prope adfabamus illis, ut sola pedis distantia inter nos et eos sæpe vix remaneret, et absque alia quacunque cautela, quam quod nec corpus neque vestes aut lectum tangeremus, a peste immunes permanerimus. Linguam propius observando solebam linteum aceto communi imbutum naribus et ori admovere." Hist. Pet. Moscens.

In addition to such facts, which are stated by physicians of high respectability, we have the support of direct experiments, made respecting a contagion not less virulent and fatal than the plague itself, viz. that of the small-pox; by which the short distance, to which the poison is communicated through the air, is demonstrably proved.

Dr. O'Ryan, professor of physic in the college at Lyons, instituted the following experiments, which we shall relate in the words of Dr. Haygarth's translation: "I placed a large doil of cotton, soaked in variolous matter, on the middle of an oval table, whose least diameter was three feet. I seated six children around it, three on each side of the table, in such a manner that all were situated within half a yard of the infectious cotton. This experiment was sometimes made in the open air, sometimes in the house. I took care to renew, every second day, both the variolous matter, and the substance which contained it. I alternately used the poison taken from the inoculated and from the casual small-pox; and I copiously impregnated with it balls of cotton, wool, and silk. This operation, repeated during a whole week, morning, noon, and night, for an hour at each sitting, produced no effect.

"I then sent away the children, desiring the parents to acquaint me, in case any indisposition appeared, and to bring them to me a fortnight afterwards, although no alteration should have taken place in their health. I declare that not only for that term, but for many succeeding months, during which I took care frequently to visit them, they all enjoyed perfect health. It was not till nine months after this time, that four of these children had a mild kind of small-pox.

"Having concluded from these experiments, that the children could not have escaped infection; but because the variolous matter might have lost that spring and that degree of energy, which perhaps it may possess on arising immediately from the human body, I placed a person, in the eruptive fever of the small-pox by inoculation, at the distance of about half a yard from four children properly prepared: each exposure continued one hour, and was repeated daily for a fortnight, reckoning from the commencement of the fever till the pustules were become perfectly dry. Not one of the four received the infection. Two months afterwards, I inoculated three of these children: they had the distemper in a very mild manner, and recovered without difficulty." Diss. sur les Fievres Infectieuses et Contagieuses. See Dr. Haygarth's Sketch of a Plan to exterminate Small Pox, vol. i. p. 79.

Again, proofs that the sphere of activity of febrile contagion is extremely limited in the air, have been greatly multiplied since the institution of fever-wards and houses of recovery, which were suggested by Dr. Haygarth, from the contemplation of such facts as we have just detailed. The fever-wards, in the Chester Infirmary, are situated within thirteen yards of some other wards of the building; yet, during a space of above twelve years, the contagion of fever was never known to extend itself from thence. And Dr. Currie relates, in a letter to Dr. Clark of Newcastle, that contagious fever had not, during ten years, extended itself, in any one instance, from the fever-wards, either in the Liverpool Infirmary or in the workhouse, although the latter of these buildings has sometimes contained 1,400 persons.

CONTAGION.

In like manner, the house of recovery, in Gray's Inn Lane, London, which stands in a row, in contact with dwelling houses on both sides, and which has had a constant succession of contagious fevers in its wards, has now (Dec. 1807) been open nearly six years, and no fever has occurred in its neighbourhood during the whole period. Nay, it has been farther ascertained, in these wards and houses, as well as in the habitations of the rich, that, in a clean well-aired room of a moderate size, the contagious poison is so completely disarmed of its virulence, by dilution with fresh air, as rarely to excite the distemper, even in nurses, exposed to all the putrid miasms of the breath, perspiration, and other discharges. See Dr. Haygarth's Letter to Dr. Percival, on the Prevention of Infectious Fevers, 1801. Dr. Clark's Collection of Papers respecting Fever-wards, Newcastle, 1802. Reports of the Institutions for the Suppression of Contagious Fever, in Dublin, London, Manchester, &c.

A sufficient number of facts, we trust, has been cited, to shew that the popular opinion and apprehension are groundless, and that the most malignant contagions are never conveyed to any great distance through the atmosphere; but that they are, in fact, rendered inert and harmless, by diffusion in the open air, and even in the air of a well ventilated apartment. The necessary inference is, that all pestilence is propagated by *near approach*, to, or *actual contact* of, the diseased, or by the conveyance of the contagious poison in articles impregnated with it.

Dr. Lind remarks, in the essay before quoted, "by a fixed attention to this subject for some years past, I am convinced, that the *body* of the diseased, kept exactly neat and clean, is not so liable to impregnate the *taint*, as his late wearing apparel, dirty linen, and uncleanliness of any sort about him, long retained in that impure state:—I say, these last contain a more certain, a more concentrated, and contagious poison, than the newly emitted *effluvia* or excretions from the sick." There is no doubt that such *fomites* spread and perpetuate many contagious diseases among us. It is ascertained that cotton, hair, and wool, are the substances most readily imbued with contagion, which becomes more virulent, when the air is prevented from having free access to them. If infected clothing, made of these materials, remain for some weeks in a full close room, or locked up in chests, and be then sold out during an unhealthy season, not only the wearers of it, but all who have intercourse with them, are presently affected, and contribute to spread the disease. Thus the Europeans, says Dr. Lind, have carried the small-pox to almost all parts of the world, where their ships have opened a trade; though the seamen in those ships might not have been affected with it in their voyage. This poison has been conveyed, in an old blanket, to nations of Indians, some of whom it has almost extirpated. In the year 1746, while the French Squadron, under the command of the duc D'Anville, passed the summer at Chebueto, now Halifax, an infectious fever prevailed among them, and cut off a great number of their men. On the return of the Squadron to Europe, several blankets and old clothes, which had been used in their tents and hospitals, were unfortunately left behind. These fatal receptacles of disease were soon after eagerly picked up by a party of Mimack Indians, who accidentally came to visit the place, and who clothed themselves with some of them; others they carried home, and distributed among their tribe. The unhappy consequence of which was the almost total extinction of the Mimack nation; scarce any of them survived. The English, upon traversing the country next summer from Annapolis Royal, were surprised with finding the dead bodies and skeletons of whole families lying unburied in their huts, until the neutrals,

who also inhabited that country, and the neighbouring Indians informed them, that the Mimacks had been cut off by the French blankets. In several of their huts, these blankets were found, where not one of the family remained. (Lind. chap. iv. sect. 2.)

Dr. Willan remarks, on the subject of fomites, that the houses of the poor in London are often so little taken care of, that in the apartments where contagious fevers have existed, enough of the contagion remains, to infect all the inmates who successively occupy the same premises; and he mentions some particular houses, in which the fomites of fever were thus preserved for a series of years. (Reports on Dis. of London, p. 256.) The same accurate observer states, that the scarlet fever, which, when epidemic, has often commenced in the eastern extremity of London, and spread westward, though it may have been sometimes imported with infected goods brought from abroad, will be more frequently found to have originated from the large repositories of old clothes, near the Tower, East Smithfield, and Ratchiff Highway. "During the last year of my attendance at the Public Dispensary," Dr. Willan adds, "I had reason to think that a family in Wild-breet, Lincoln's-inn-fields, was infected with *scarlatina maligna* by clothes bought in Monmouth-street. More than fifty persons in the adjoining houses were soon affected with the disease, which afterwards traversed Drury-lane, and spread by Long Acre, and the streets connected with it, through several parishes in Westminster." (On Cutan. Diseases, p. 301.) Thus also, and not by the impregnation of the atmosphere, the small-pox, measles, typhus, whooping-cough, itch, tinea capitis, &c. are perpetuated among us; and the febrile contagions are from time to time widely diffused.

A great number of facts are on record, which serve to shew the extreme virulence of contagious poisons, which have been pent up and accumulated in close places, and have contaminated articles of clothing under such circumstances. In those periods of our history, when a less enlightened humanity was careless of the health of criminals, and prisoners in general, the occurrence of what were called *black affizes* was frequent in different parts of the country. The criminals, brought out of filthy and infected cells, with their clothes fully imbued with *fomites*, often spread a mortal contagion through the court, assembled for the purposes of justice. "The most pernicious infection next to the plague," says lord Bacon, "is the smell of the jail, where the prisoners have been long, and close, and nastily kept, whereof we had in our time experience, twice or thrice, when both the judges, who sat upon the jail, and numbers of those who attended the business, sickened upon it and died." One of the instances, to which lord Bacon alludes, was doubtless at the fatal affizes, held at Oxford, in the year 1577; of which Stow gives the following account in his Chronicle. "On the 4th, 5th, and 6th days of July, were the affizes held at Oxon, where was arraigned and condemned Rowland Jenkins for a seditious tongue; at which time, there arose amidst the people such a damp," (an expression in the language of those days, signifying bad air) "that almost all were smothered, very few escaped that were not taken, here died in Oxen 300 persons, and sickened there, but died in other places, 200 and odd." Similar infections took place at the black affizes at Taunton; and also at those of Exeter, in 1586; at which last some Portuguese sailors spread the contagion, having been confined, without change of clothes, "in a deep pit and stinking dungeon." The last black affizes at the Old Bailey were held so late as the year 1750. On the 11th of May the prisoners, who were brought into court, some of them labouring under jail-fever, had been kept

CONTAGION.

nearly a whole day in small, close, and crowded apartments. All the individuals, who were seated in the course of a draught of air, passing from the prisoners to an open window, were seized with the distemper: the rest escaped. The lord mayor and those of the bench who sat on his left hand were infected; while the lord chief justice, and the recorder, who sat on his right, escaped. Many of the Middlesex jury, on the left side of the court, died of it, while the London jury, who sat opposite to them, received no injury. On the 13th of May died alderman Lambert; on the 14th R. Cox, under-sheriff; on the 17th baron Clark; on the 19th Sir T. Abney, justice of Common Pleas; T. Otway, barrister; W. Baird, ditto; W. Sharplop, and four others; on the 20th, the mayor and eight of the Middlesex jury. See Gentleman's Magazine.

These facts, while they evince the active virulence of contagion, accumulated in fomites in unventilated and crowded rooms, afford, at the same time, evidence, that, except where it is carried at once by a direct draught of air, its tendency to diffuse itself, and its power when diffused, through the atmosphere in general, is very limited. It is only under such circumstances of concentration, that the virulence of contagion is ever so great, as to be infectious at more than a few feet distance. It has already been shewn, that when arising from the body of the sick, either in the open air, or in well ventilated rooms, its influence is confined to a very small distance.

Before we point out the means of prevention from contagious diseases, which these facts and observations suggest, it will be necessary to attend more particularly to the circumstances of individual infection.

All individuals are not equally liable to be infected by contagion; and some, though the number is extremely small, escape altogether. Thus, there are persons who have gone through a long life without taking the small-pox. The constitution, however, appears occasionally to undergo such a change, in the course of life, that those who, in earlier years, had resisted the action of this contagion, have received it on some future exposure to its influence. There is a considerable difference, too, in the infectious degree of different contagions: thus, that of the whooping-cough affects a much smaller proportion of mankind, than that of the measles, or small-pox; and that of the scarlet fever excites the disease in children much more frequently than in adult persons. Again, the contagion, in some instances of pestilence, and, we believe, in the plague in general, is more fatal to the vigorous and middle-aged, than to the old on the one hand, or to children on the other. We were informed by a gentleman, who resided at Malaga, during the late pestilence at that place, that the appearance of the town, after the cessation of the fever, was remarkable, in consequence of the small number of strong, active, and well-looking people, who were to be seen; old people and children constituting almost the whole of the remaining population. In the typhus, or contagious malignant fever of this country, Dr. Haygarth infers, from accurate deduction, that about eight in 188 escape infection, though fully exposed to the contagion; which is less than one in twenty-three. (See Letter to Dr. Percival, p. 31.) It has been calculated that nearly the same number, or one in 20, is naturally exempted from the contagion of the small-pox. Upon this datum it was also calculated, that if two persons together have escaped the disease, the probability, that they were never both exposed to an infectious quantity of the poison, is above 400 to one; if three in a family have escaped, above 8000 to one. (Haygarth's Inquiry how to prevent the

Small-pox, p. 24.) This mode of reasoning is equally applicable to typhous infection.

Now, as great numbers of people, visitors, nurses, &c. breathe the air of the chambers of patients, ill of contagious fever, and yet escape infection, it is obvious that in almost all these cases, (at least in 22 out of 23) a sufficient dose of the poison had not been received. This leads us to an important inquiry, into the dose of typhous contagion requisite to produce infection. The quantity will vary, no doubt, according to different circumstances, but the observations of Dr. Haygarth, and of the physicians of fever-wards, and houses of recovery, have enabled us to judge with some accuracy of the limits of this variation. There appears to be a strict analogy between contagious miasms and other poisons. The larger the dose of a poison or drug, the greater in general is the effect which it produces. Many of the most powerful and salutary medicines, when taken in too large a quantity, are poisons, as opium, antimony, mercury, fox-glove, hemlock, &c. And, on the other hand, even arsenic itself, the most virulent and unmanageable of all poisons, has, by the skill and attention of physicians, been reclaimed from the class of mischievous substances, and by a diminution of the dose is justly held to be a safe and useful remedy. Farther, in different constitutions, and in different maladies, there is a certain degree of variety in the operation of any drug. Thus four or six times the dose, e. g. of antimony or mercury, may be required for one patient more than for another, or for the same person in different diseases. In the same way the mischievous quantity of infectious miasms admits of some variation.

It is clear, from the collected observations of Dr. Haygarth, and of those active and experienced physicians whose correspondence he has published, not to mention the experience which fever-wards have lately afforded, that in a large, airy, and clean apartment, few or none even of the most intimate attendants catch the disease, where the patient labours under infectious fever. The nurses themselves, exposed to the effluvia of the excrements, and perpetually near, and often in contact with the sick, nevertheless hardly ever receive infection. The atmosphere of a room where contagion is generated, if cleanliness and ventilation are employed, may therefore be breathed for a long time with impunity. And it is not less clear, that an atmosphere strongly impregnated with contagion, may be breathed, for a short time, with the same impunity. If we compare the numbers who escape infection after being exposed to breathe a contagious atmosphere, with the small number who are naturally not subject to receive contagion, this proposition must be obvious. But to state facts. "During four years attendance in the hospitals of Edinburgh and London, and afterwards during thirty-one years in private practice in Cheltenham, and fourteen years and a half in the Cheltenham Infirmary, and three years at Bath, I have been," says Dr. Haygarth, "in the habit of breathing air strongly impregnated with the infectious miasms of fever. In many, very many, instances, I have visited patients ill of infectious fevers, in small, close, and dirty rooms: yet never but once, above thirty years ago, had a fever. The physicians of the Manchester Infirmary for many years, and particularly during the late widely-spreading epidemics in that large and populous town, have, with great fortitude and humanity, constantly visited the home patients; that is, they have, in innumerable instances, breathed the most pestilential air, in the most concentrated state. Their and my safety manifestly proceeded from this circumstance; we remained but a short time in the patients' room. We did not receive an infectious dose of the poison." (Lect. to Dr. Percival, p. 40.) We could multiply evidence

CONTAGION.

upon this point: to an indefinite extent, but the general safety of medical men under such circumstances is sufficient to prove, that air strongly impregnated with infectious miasms may be breathed for a short time, and air weakly impregnated for a long time, without any injury. We might hence be almost led to believe, that the poisonous miasms do not generate a fever, till they have been respired without interruption, for several days together: and it is not improbable that, in some persons, such an accumulated quantity of the poison may be required.

There are, however, other facts which prove that this is by no means always the case. Infection is occasioned suddenly, in some instances, and from a very short exposure to a pestilential air. Whether this is owing to peculiar susceptibility of the individual, or to the particular mode of receiving the contagious effluvia, is doubtful. The writer of this article, about six years ago, visited a poor family, of four persons, lying in the same bed, in an exceedingly close and dirty apartment, ill of contagious fever. He always had the precaution to throw open the window on entering the room, to station himself between the window and the bed, whilst he examined the sick, and to remain but a short time with them. He had repeated his daily visits during a week, and with impunity, when he was at length accompanied by another physician, who designed to admit the patients into the House of Recovery, just then opened in Gray's-inn-lane. The latter took no precaution, but examined the skin of the sick minutely and closely, standing on that side of the bed towards which the air from the window impelled the contagious effluvia, and so near as to receive these effluvia and the breath in the most concentrated state. He took the infection, and his fever proved fatal. Here the infection of this excellent physician was attributable only to the full dose of the poison, which his incautious zeal induced him to inhale. In most cases, as in this, where a sudden infection takes place, a disagreeable sensation is excited at the moment of exposure, which different persons have described differently. Some have felt a sharp taste in the mouth, as if blue vitriol were dissolving in it, but which no washing or gargling could remove. Others have compared the first impression to that of an earthy exhalation from a newly-opened grave, the sensation extending down to the stomach, sometimes exciting instantaneous sickness and shivering. Dr. Haygarth mentions that two of his patients, who were physicians, were infected suddenly by a short exposure. One of them thought that he caught the fever by creeping behind, in order to assist his patient; the other by inspecting morbid fæces. In both these cases, the exposure was such as might probably afford a full dose of the contagion. Dr. Lind is of opinion, that, in these diseases, the stools, especially if very fetid, are most communicative of contagion; next to these the breath; and lastly the effluvia from the body.

The activity of contagion is not always proportionate to the appearances of malignancy in the diseased. Sometimes only one man in a ship may be seized with the *peste bubonica* or with the *yellow fever*, says Dr. Lind, while all the rest continue unaffected. And the most malignant case of fever, that we ever witnessed, did not infect any of the family, though in a close and small house. And on the contrary, we have seen fevers, of the mildest description, which spread extensively: so that we fully coincide with Dr. Lind in his observation, that "fevers have often no peculiar characteristic symptom, by which they are known to be infectious:" and again, when he says, "in some this fever will be more severe, in others more mild, and often most of the sick will be able to sit up through great part of the day, which can-

not be urged as an argument against the infection, but only as a proof of its mildness." (Loc. cit. § v.) It is obvious, therefore, that great caution should be used in pronouncing fevers not infectious.

The period at which different fevers begin and cease to generate contagious effluvia is not absolutely ascertained. It seems most probable that in eruptive fevers there is no contagion till the eruption appears; and that contagion remains so long as any scab remains on the skin. This is clearly the case in small-pox.

The latent period of contagion, as Dr. Haygarth terms it, or the period which elapses between the exposure to contagion and the first appearance of the disease which ensues, is ascertained with tolerable accuracy in respect to the small-pox; but in typhous cases it appears to be extremely irregular. The small-pox from inoculation usually commences on the eighth or ninth day after the operation. Thus, of 830 inoculated cases, in 519 fever commenced before the ninth, and 201 on or after the ninth day. But from the testimony of Drs. Woodville, Clark, and Currie, the eruptive fever sometimes commences so early as the fifth day after inoculation; and three cases are related by Dr. Clark where it commenced so late as the 16th, 17th, and 23d day. The latent period in the casual small-pox is somewhat longer than in the inoculated; most commonly from 10 to 16 days. (See Haygarth, Sketch, &c. before quoted.) The latent period of the contagion of measles is from 10 to 14 days. (Willan on Cutan. Dif.) But the latent period of typhous infection is much more irregular, and often much longer. Of a large number of cases related by Dr. Haygarth, more than half commenced between the 17th and 33d day after exposure, a great proportion after the 27th, and almost all between the 20th and 60th. (See Letter to Dr. Percival, p. 20. *et seq.*) The fever occurred in only five instances before the 10th day. So that on the whole, it appears, that the latent period of typhous infection varies from a few days to two months. (Ibid. p. 68.)

This latent infection is probably often allowed to lie long dormant, or is excited into action at an earlier period, according to the occurrence or non-occurrence of circumstances which may render the constitution less capable of resisting its action. Thus persons who had some time previously been exposed to the influence of contagion, have been immediately taken ill upon being wet with rain, or on exposure to a cold and damp air, or after a debauch, or other such debilitating causes. During the prevalence of a pestilence, it has been observed that exposure to the damps of evening, especially in warm countries, is extremely dangerous. And Dr. Chisholm remarks, that those who were addicted to the abuse of intoxicating liquors, were most subject to the fever of Grenada. From the great length of time, indeed, which the contagion of fever often lies dormant, we may infer, with Dr. Lind, that it is probable, that, without the influence of these casual exciting causes, the contagion might never, in such instances, have affected the constitution.

Prevention of infection. The circumstances under which contagion is generated, and the modes in which it is conveyed and propagated, being understood, the means of preventing its production, and of avoiding its pernicious influence, when it exists, will readily suggest themselves. Instead of omitting all attempts at avoiding the contagion of a pestilence, as altogether fruitless, where the very pabulum of life, the common air, is charged with poison; or of adopting the dangerous expedient of closing up every avenue of ventilation in our houses (Willan on Fevers, p. 458. vol. i.), or of employing useless and absurd measures of precaution, we shall

shall proceed upon rational grounds to the use of effectual preventives. All those who contend that the spreading of contagion depends upon some peculiar state of the atmosphere, admit that it is some *occult* quality in the air; that it is neither the heat nor the cold, the moisture nor the dryness, nor any other sensible condition of it, with which pestilence is connected. The great Sydenham, after having noted attentively the state of the atmosphere and the weather, in different years, during which epidemics of different kinds prevailed, was obliged to confess that he could perceive no difference in seasons in which different contagious diseases occurred. He, therefore, had recourse to a supposition equally gratuitous, that some unwholesome exhalations from the earth were the source of pestilential diseases.

But when it is considered, that contagion *originates* in accumulated and confined animal effluvia, and is *communicated* either to those who approach, or come in contact with the sick, or by means of substances impregnated with contagious matter, and in these ways only, the means of prevention are obvious.

With respect to the casual origin of contagion, it is scarcely necessary to say, that cleanliness and ventilation, as they preclude the confinement and accumulation of the animal effluvia and secretions, will infallibly prevent the generation of the poison.

Where contagion exists, its farther communication may be prevented by avoiding contact or approach to the sick, and by confining the patient to a separate room, in which, if it be kept clean, and well ventilated, it has already been shewn, that the contagion will be inert, at a short distance from the sick; and therefore that the necessary attendants, and medical visitors, will receive no injury from respiring the air within it. In this way contagion has been prevented from spreading in large schools, and other places, where a number of people live together, as in work houses and hospitals, of which some examples have been already given. Dr. Haygarth's rules for the prevention of infection, seem to comprise all the requisite means to be adopted in houses where contagious fever exists; they are the following.

Rules to prevent infection.

"1. As safety from danger entirely depends on cleanliness and free air, the chamber-door of a patient, ill of an infectious fever, especially in the habitations of the poor, should never be shut; a window in it ought to be generally open during the day, and frequently in the night. Such regulations would be highly useful both to the patient and nurses; but are particularly important previous to the arrival of any visitor.

"2. The bed curtains should never be drawn close round the patient; but only on the side next the light, so as to shade the face.

"3. Dirty clothes, utensils, &c. should be frequently changed, immediately immersed in cold water, and washed clean when taken out of it.

"4. All discharges from the patient should be instantly removed. The floor near the patient's bed should be rubbed clean every day with a wet mop or cloth.

"5. The air in a sick room has, at the same time, a more infectious quality in some parts of it, than in others. Visitors and attendants should avoid the current of the patient's breath,—the air which ascends from his body, especially if the curtains be close,—and the vapour arising from all evacuations. When medical or other duties require a visitor or nurse to be placed in these situations of danger, infection may be frequently prevented by a temporary suspension of respiration.

"6. Visitors should not go into an infected chamber with

an empty stomach; and, in doubtful circumstances, on coming out, they should blow from the nose, and spit from the mouth, any infectious poison which may have been drawn in by the breath, and may adhere to those passages." (See Letter to Dr. Percival, p. 73. *et seq.*)

By observing these rules, not only numerous visitors, but the medical attendants, and the nurses themselves, who frequently move and otherwise assist the sick, in fever-wards, and the wards of houses of recovery, entirely escape infection. This is proved, with scarcely any exception, in all the institutions of this sort throughout England and Ireland. During the last four years (the writer speaks from personal observation) only one instance of infection seizing a nurse in the London House of Recovery, occurred, and, in that case, she imprudently slept in a bed, just quitted by a convalescent, who had left the house, without changing the linen. By the same rules, Dr. Haygarth arrested the progress of a scarlet fever and fore throat in a school, containing 37 boarders, at a time when Winchester and other great schools were dispersing their scholars on account of this most contagious distemper, which had spread alarmingly among them. Not one was infected after the plan of separation in an unvisited room was adopted, although all the boys remained in the same house. (Let. to Dr. Percival, p. 81.)

Contagion may, however, be extensively circulated by *fomites*, i. e. attached to clothing, furniture, and other articles, which mode of communication is, perhaps, the most to be apprehended, during the prevalence of an epidemic malady. Hence the severe laws of quarantine have been enacted, in order to preserve this country from the contagion of foreign pestilence, which might be imported with the articles of commerce. And it is not less necessary, during times of internal pestilence, to be watchful in regard to this point. It is not, however, by a slight and brief exposure to contagious miasms, that substances are sufficiently imbued with them, to communicate infection. Thus it is, on the whole, well ascertained that the clothes of visitors do not acquire a pestilential quality, so as to infect others. Upon this point, the experience of several observing practitioners coincides. Dr. Clark of Newcastle affirms, that in eighteen years practice, he never communicated the contagion of small-pox, nor of the scarlet fever, with ulcerated fore throat, to any one, even to children in his own family, although he had frequently, on the same day, visited many patients in those diseases, and in the most malignant stages of the latter, and afterwards had intercourse with other children liable to receive them. Mr. Henry adduces his own experience, during nearly forty years, in Manchester, in testimony of the same fact, in regard to the contagion of small-pox. And the testimony of several other practitioners is equally strong, as to the non-conveyance of this contagion by their clothes. Now, whatever is true of the contagion of small-pox, and of scarlet fever, is still more decisive as to typhous infection, which is less powerful than either. (See Haygarth, Sketch of a Plan, &c. pp. 369, 386, 404, &c.) Substances do not become sufficiently impregnated with the poison, in clean and ventilated places, except by being a considerable time in contact with, or very near the sick, as the bed in which the patient lies, or the linen he wears; these *fomites* are chiefly produced in close and dirty places, where the contagion is concentrated by accumulation and confinement, as in the cells of jails, or in the apartments of the poor; in which cases, the utmost virulence of the poison is brought forth.

Where contagion of this degree of activity is produced, and is combined with articles of clothing and furniture, &c. the mere act of ventilation, which effectually prevents

its deleterious action, when arising from the body of the sick, is altogether inadequate to destroy its power in these *fomites*. Hence various means have been devised, in all ages, for annihilating contagion. Among these, fire has been most generally employed, more especially with a view of fumigating, or applying the smoke or vapours from different substances, to the source of the poisonous miasms. Hippocrates and Acron of Agrigentum, believing the air to be the medium of infection, are said to have ordered large piles of wood to be burnt in the streets and infected parts of Athens, by which means they stayed the plague in that city. (Aetii *Tetrab.* Plutarch, de *Isid.* de *Osir.*) But however useful the fumigation of *fomites* may be, it does not appear to be of any utility when employed in the atmosphere in general. In the year 1721, the plague raged at Toulon with such violence, that in the space of ten months it destroyed about two-thirds of its inhabitants. Many having insisted upon fires being made in different parts of the city, the public records were consulted, and it was there found that, on a similar occasion, the same means had been tried without success. The experiment, however, was repeated. Wood was laid before every house, and at the sound of a bell, all the fires were lighted, by which the city was involved in a thick smoke for nearly a whole day. The plague, however, suffered no abatement. The same measure was resorted to both at Marseilles and London, when the plague raged in these cities, with no better success. Nay, after the fires had been kept burning for three days in London, on the night which succeeded, no less than 4000 died, although not more than 12,000 had been destroyed during the preceding three or four weeks. (Wilson on Feb. Dif. vol. i. p. 464.)

There is no doubt, however, that contagion, adhering to clothes and furniture, may be effectually destroyed by the vapours from various combustible and volatile substances. Dr. Lind recommends the fumes of tobacco to be dispersed through the cells and infected apartments, in prisons and ships, as well as for the purification of infected articles; he also advises the exposure of *fomites*, to the fumes of sulphur, from a charcoal fire, as an efficacious mode of purification. But he is perfectly convinced, he says, from long experience, that even the simple heat of a *close confined* fire, or the heat of an oven, is a destroying power which "no infection whatever can resist." The efficacy of gun-powder was ascertained by an accident, and Dr. Lind afterwards used it in wards where fevers were received, every morning. In a ship of war, a contagious fever prevailed, which had destroyed sixty men; when, in an engagement with the French, twenty-five barrels of gun-powder were fired on board of her during the action; and, to the surprise of her officers, none of her men were afterwards attacked with fevers.

Some strong smelling substances, as camphor, the vapours of juniper, and of Cascailla bark, &c. have been occasionally resorted to as preventatives from contagion; but the power of these substances is very questionable, and they may be, perhaps, negatively prejudicial, as their aromatic odour may conceal the smell of bad air in the room of the sick, and thus prevent effectual measures of safety from being employed.

The most efficacious of the means which we possess of destroying contagion in *fomites*, seem to be the fumes of the mineral acids. The vapours of vinegar, and those of the sulphureous acid, have been long used with some degree of success; but those of the muriatic, and still more, perhaps, those of the nitrous acid, appear to be complete antidotes to accumulated contagion. The evidence of the efficacy of the nitrous acid fume, in purifying infected places

and substances, which was a few years ago laid before the House of Commons by Dr. Carmichael Smyth, was such as to induce that house to vote a national donation of five thousand pounds to him for the discovery. This vapour is easily obtained, by mixing with powdered nitre a little of the strong acid of vitriol or sulphuric acid; the latter combines with the potash, the base of the nitre, expelling at the same time the nitrous acid in fumes. (See Dr. C. Smyth's treatise on the subject.) The vapour of the muriatic acid may be obtained in a similar manner, by using common sea or rock-salt, instead of nitre.

Where contagion has been long pent up in close cells or rooms, it is apt even to adhere to the walls. In such cases, white-washing with hot or newly slaked lime, is an efficacious aid of the acid fumigations.

It is a curious fact, and perhaps wholly unaccountable upon any theory of the propagation of contagion, that pestilential diseases, after running an indefinite course, notwithstanding all the measures adopted to restrain their progress, frequently cease spontaneously, at a time when the walls of the houses, furniture, &c. must still be supposed to be highly impregnated with the contagion. The fact is authenticated by Dr. Ruffell, Dr. Lind, and several other physicians of equal respectability. The cessation is not connected with any sensible changes in the atmosphere. Warm weather is perhaps, on the whole, but not without many exceptions, more favourable to the production of contagious diseases, than cold weather. But the worst fevers have often raged in the coldest seasons, as did the plague in London; and there have been instances of the plague suffering a check as the weather grew warmer. (Wilson on Feb. Dif. p. 448.)

During the prevalence of a contagious epidemic, temperance and regularity, and care in avoiding all causes of debility, (such as cold damp air, &c.) the use of the cold bath, and the preservation of an equal state of mind, are great personal preservatives. The general alarm which prevails during those periods of public calamity, is not among the least of the causes which contribute to extend the evil. It would be, therefore, injudicious to condemn the use of camphor, rosemary, and other aromatic substances, or carrying a quill filled with quicksilver, or other amulets, about the person, since whatever tends to inspire confidence in the mind, contributes to the security of the body.

CONTARINI, in *Antiquity*, a kind of horsemen, whose chief armour was the *cutus*, a kind of long spear.

CONTARINI, GASPARD, in *Biography*, a cardinal of the church of Rome, was not more celebrated as a divine than as a politician. He flourished in the Venetian territories, and was nominated from that republic as ambassador to the emperor Charles V, after which he was raised to a considerable station in the government of his country. He was ambassador also to Rome; and when pope Clement VII. surrendered to the imperial army, a commission was given to Contarini to negotiate for the liberty of the pontiff. In 1535, he was created cardinal by pope Paul III.; and in 1541, he was appointed legate to Germany, and with the other legates was appointed to preside at the general council, which was afterwards held at Trent; he was, however, sent legate to Bologna, before that assembly met, where he died at the age of 59, in the year 1542. He was author of many works, and on various topics, in which he displays considerable talent, and a mind superior to the times in which he lived. The principal pieces are "De Immortalitate Animæ," "De Septem Ecclesiæ Sacramentis," "De Potestatè Papæ," "De Predestinatione," "De Libero Arbitrio," and "Confutatio Articulorum Lutheri."

CONTARINI, VINCENT, a considerable scholar in classical literature and antiquities, was born at Venice, in 1577, and attained the professorship of the Greek and Latin languages at Padua, which he held with great reputation till the year 1614, when he retired to Rome. From whence, taking a journey into Ithria, he fell ill, and died at Venice in the prime of life, in 1617. The works by which he is chiefly known are "De Frumentaria Romanorum Largarione," and "De Militari Romanorum Stipendio." Moreri.

CONTARINO, CAV. GIOVANNI, an historical and portrait painter, who was born at Venice in the year 1549, and who steadfastly pursued the solid and pure style of Titian, notwithstanding the pernicious example of almost all his rival compatriots, who, losing the remembrance of those glowing and rich tints which had so long been the boast of the Venetian school, had adopted a manner in which the lights were so extravagantly contrasted by the most obscure and cutting shadows, as to give to their pictures the appearance and gloom of midnight representations. The principal works of Contarino are at Venice, and evince, independent of the beauties of colouring, a very competent knowledge of fore-shortening and the *sfumato*, with an excellent taste of composition. One of his best and greatest performances is the ceiling of the church of St. Francisco di Paola, where, in the centre, he painted the Resurrection of Christ, and on each side the Annunciation and Nativity, together with the Evangelists and the four Doctors of the Church. He executed several considerable works for the court of the emperor Ridofofus II., who conferred on him the honour of knighthood. His portraits bore so strong a resemblance to nature, that one of them, representing Marco Dolce, is said to have deceived his dogs and other domestic animals, who leaped up to the picture, supposing it their master himself. This artist died in the 56th year of his age, 1605. Lanzi, Storia Pittorica.

CONTAY, in *Geography*. See **CONTY**.

CONTCHOUDSONG, a town of Asia, in the country of Thbet; 380 miles E.N.E. of Lassa. N. lat. 30° 20'. E. long. 97° 25'.

CONTE, DEL, JACOPINO, in *Biography*, was born at Florence in 1510, and is said in his youth to have received some instructions in painting, in the school of Andrea del Sarto. Having completed his studies, he soon gave proofs of superior talents, both in historical and portrait painting. Rome, whither he was invited under pope Paul III., was the theatre of his labours, and he was employed to paint the portraits of that pontiff and of his successor Clement VIII., as well as those of the cardinals, the ambassadors, and other nobles of the court. In historical painting, he had no less success; and the frescoes, which he executed in the church of St. Giovanni Decoliate, rank him amongst the least affected or extravagant of the imitators of Michelangelo. An altar-piece in the same church, representing the taking down from the cross, a composition of many figures, is considered his *chef d'oeuvre*. He died at Rome in 1598. Baglione.

CONTE, DEL, OF FASSI, GUIDO, an artist who was born at Carpi, in the state of Modena, in the year 1584, and was the first inventor of the *scagliola*, a species of composition, or paste, with which the finest marbles are with facility imitated, and which acquires sufficient hardness to bear a polish. Some of the works of Guido, particularly two altars, are still existing at Carpi, where he died in the year 1649.

This art has since been brought to such a degree of perfection in several parts of Italy, that not only the finest marbles have been counterfeited, so as occasionally to deceive the best judges; but likewise bas-relieus, vases, medals, and even pictures of great beauty, have been produced; *see* **HIPO-**

much that it is become an article of commerce. (See **SCAGLIOLA**.) Lanzi, Storia Pittorica.

CONTEMPLATION, an act of the mind, whereby it applies itself to consider, reflect on, and admire, the wonderful works of God, nature, &c.

Contemplation is the height of perfection of the mystic divines. See **MYSTIC**.

CONTEMPORARY, or **COTEMPORARY**, a person, or thing, of the same time, or that existed in the same age, with another. Socrates, Plato, and Aristophanes, were contemporaries: the best histories are those of contemporary authors.

CONTEMPT, in the *Doctrine of the Passions*, is a species of hatred, expressing in its general sense disapprobation or aversion, which arises from the mere consideration of a worthless object, especially if it be proposed to us under a pretence of its possessing excellence, or from misconduct in things not of themselves vicious; as, where a person either acts below his station and character, or affects to do that for which he is not qualified. It is opposed to esteem or to emulation. This is one of those passions which in oratory belongs to demonstrative discourses. Thus Cicero (*De Orat. lib. ii. c. 12*) endeavours to expose Cæcilius, and bring him into contempt of the court, for pretending to rival him in the accusation of Verres, for which he was altogether unfit.

CONTEMPT, in *Law*, is disobedience to the rules, orders, or process of a court, which hath power to punish such offence; and a man may be imprisoned for a contempt done in court, but not for a contempt out of court, or for private abuse. But for contempt out of court, an attachment may be granted. Cro. Eliz. 689.

Attachment also lies for contempt to the court, to bring in the offender to answer on interrogatories, &c. and if he cannot acquit himself, he shall be fined. 1 Lill. 305. If a sheriff, being required to return a writ directed to him, doth not return the writ, it is a contempt: and this word is used for a kind of misdemeanor, by doing something that is forbidden, or not doing what is commanded. 12 Rep. 36. As the degrees of this crime vary, the punishment is less or greater; sometimes a mere fine, and sometimes imprisonment.

If a defendant in chancery, on service of a subpoena, does not appear within the time limited, by the rules of the court, and plead, demur, or answer to the bill against him, he is then said to be in contempt; and the respective processes of contempt are in successive order awarded against him: these are attachment; attachment with proclamation; a commission of rebellion; and, finally, a sequestration. It is a contempt to institute a suit fictitiously, though the demand is real, either to hurt any person, or to get the opinion of the court.

The most remarkable instances of contempts may be reduced to the following heads, *viz.* contempts of the king's writs; contempts in the face of a court; contemptuous words or writings concerning the court; contempts of the rules or awards of the court; abuse of the process of the courts; and forgeries of writs and other decrees tending to impose on the court. 2 Hawk. P. C. c. 22. § 3. For an account of the contempts that are punished by attachment; *see* **ATTACHMENT**.

Contempts or misprisions (*see* **MISPRISION**) are offences against the king and government: such is the non-administration of high officers, in public trust and employment, usually punishable by the method of parliamentary impeachment, and subject to the penalties of banishment, imprisonment, fines, or perpetual disability: such is also the offence of embezzling the public money; and such are those con-

tempts of the executive magistrate, which demonstrate themselves by some arrogant and undutiful behaviour towards the king and government. Contempts against the king's prerogative are a refusal to assist him by advice in his councils, and by personal service in his wars, against a rebellion or invasion. To this class may be referred the neglect of joining the "posse comitatus," or power of the county, when required by the sheriff or justices, according to the statute 2 Hen. V. c. 8; which is a duty incumbent upon all that are 15 years of age, under the degree of nobility, and able to travel. Contempts against the prerogative are also a preference of the interests of a foreign potentate to those of our own, and doing or receiving any thing that may create an undue influence in favour of such extrinsic power; as by taking a pension from any foreign prince, without the king's consent; also, a disobedience to the king's lawful commands, issuing by writs out of his courts of justice, or by summons to attend his privy council, or by letters from the king commanding a subject to return from beyond the seas: and likewise disobedience to any act of parliament; all which contempts are punishable by fine and imprisonment, at the discretion of the king's courts of justice. Contempts and misdemeanours against the king's person and government may be by speaking or writing against them, cursing or wishing him ill, giving out scandalous stories concerning him, or doing any thing that may tend to degrade him in the esteem of his subjects, weaken his government, or excite jealousies between him and his people. Contempts against the king's title, not amounting to treason or præmunire, are the denial of his right to the crown, in common and unadvised discourse; punishable by our law with fine and imprisonment. If any person affirm or maintain, that the common laws of this realm, not altered by parliament, ought not to direct the right of the crown of England; this is a misdemeanour, by stat. 13 Eliz. c. 1, and punishable with forfeiture of goods and chattels. A contempt may also arise from refusing or neglecting to take the oaths, appointed by statute for the better securing of the government; and yet acting in a public office, place of trust, or other capacity, requiring the said oaths to be taken, viz. those of allegiance, supremacy, and abjuration; which should be taken within six calendar months after admission. The penalties inflicted by statute 1 Geo. I. stat. 2. c. 13, are little short of those of a præmunire; being an incapacity to hold the said offices, or any other; to prosecute any suit; to be guardian or executor; to take any legacy or deed of gift; and to vote at any election for member of parliament; and after conviction the offender shall also forfeit 500*l.* to those who will sue for it. Contempts against the king's palaces or courts of justice have always been regarded as high misdemeanours; and by the ancient law, before the conquest, fighting in the king's palace, or before the king's judges, was punished with death. And at present with us, by stat. 33 Hen. VIII. c. 12, malicious striking in the king's palace, where he resides, whereby blood is drawn, is punishable by perpetual imprisonment and fine at the king's pleasure; and also with loss of the offender's right hand. But striking in the king's superior courts of justice, in Westminster-hall, or at the assizes, is made still more penal. By the ancient common law, before the conquest, it was a capital felony; and our modern law substitutes for the loss of life that of the offending limb; the crime, and even drawing a weapon, being punishable with the loss of the right hand, imprisonment for life, and forfeiture of goods and chattels, and of the profits of the offender's lands during life. (See ASSAULT, &c.) A rescue of a prisoner from any of the said courts, without a blow, is punished with perpetual imprisonment, and forfeiture of goods, and of

the profits of lands during life. Even in the inferior courts of the king, an assize, or contemptuous behaviour, is punishable with a fine by the judges there sitting; as by the steward in a court-leet, or the like. Those also who are guilty of any injurious treatment to such as are immediately under the protection of a court of justice, are punishable by fine and imprisonment. Lastly, to endeavour to dissuade a witness from giving evidence; to disclose an examination before the privy-council; or to advise a prisoner to stand mute, are high misdemeanours and contempts of the king's courts, and punishable by fine and imprisonment. If one of the grand jury discloses to any person indicted the evidence that appeared against him, he is guilty of a high misdemeanour, and liable to be fined and imprisoned. Blackst. Comm. vol. iv.

CONTENEbra, in *Ancient Geography*, a town of Italy, in Etruria, mentioned by Livy.

CONTENEMENT, a word, in our *Ancient Law-books*, about whose signification authors are not rightly agreed. According to some, it should signify the countenance, credit, or reputation, a person has, from and by reason of his freehold. In which sense it is used in the stat. 1 Edw. III. &c. where it stands as synonymous with *countenance*.

Others will have it signify what is necessary for the support and maintenance of men, according to their several qualities, conditions, or states of life. Thus, Spelman, *Contentementum est estimatio, & conditionis forma, qua quis in republica subsistit*. And in this sense it occurs in Magna Charta, cap. 14.

CONTENSON, VINCENT, in *Biography*, a French Dominican monk, was born at Cordom, in 1640, and celebrated in his time for considerable pulpit talents. He left behind him a work of reputation, entitled, "Theologia mentis et cordis," which has passed through several editions in folio and in octavo.

CONTENT, in *Mathematics*, a term frequently used for the capacity of a vessel, or the area of space; or the quantity of any matter, or space, included in certain bounds. The content of a tun of round timber is 43 solid feet. A load of hewn timber contains 50 cubic feet: in a foot of timber are contained 1728 cubic or square inches, and as often as 1728 inches are contained in a piece of timber, be it round, or square; so many feet of timber are contained in the piece.

In gauging, the gallon for beer and ale is allowed to contain 282 cubic inches, and the wine gallon 231; the gallon of dry measure 272.

Hence, as oft as 282 cubic inches are contained in any vessel, round or square; so many gallons of ale or beer it holds; and the like may be observed of the other measures.

Multiply, therefore, one side of a square, or oblong, into the other; and divide by one of those numbers, according to the quality of the liquor; the quotient gives the area in gallons, upon an inch deep.

Though the work may be considerably shortened by only multiplying the sides of squares, or the diameters of rounds, into themselves; the product is the number of gallons, and parts, the vessel contains, upon an inch in depth: and when that receives an augmentation, by being two, three, or four inches deep, it then commences a solid body, and contains as many gallons, and parts, as it is inches and parts deep.

A cubic foot contains six gallons and almost a pint of ale and beer; and seven gallons two quarts of wine. A cubic foot of dry measure contains six gallons and a half, and

Something more. A bushel of salt contains 56 pounds avoirdupois. See **GAGING**.

CONTENTIOUS JURISDICTION, in *Law*, denotes a court, or assembly, which has a power to judge and determine differences between contending parties.

The lords chief justices, judges, &c. have a *contentious jurisdiction*; but the lords of the treasury, the commissioners of customs, &c. have none; being merely judges of accounts and transactions.

CONTENTMENT, in *Pathology and Ethics*, expresses the acquiescence of the mind in the possession of the good that is assigned to us. It implies a perception that our lot might have been better, or that it is inferior to what others enjoy, or that it does not fully answer the expectations we had formed. An effort of reason, or of prudence, or of religious principles, is necessary to produce it. We compare our present with our former situation, or with the inferior lot of others; and thus learn to acquiesce in the degree of advantage which we have obtained. A regard to the dispensals of Providence, wise, righteous, and benevolent, will very much contribute to the acquisition and exercise of the virtue of contentment.

CONTESSA, in *Geography*, a small town of European Turkey, in the province of Macedonia, situated in the bay of the same name, with a good harbour, on the coasts of the Archipelago; 54 miles N.E. of Salonica. Long. 41° 35'. At the entrance of the gulf of Contessa is situated the island of *Taffo*. The French navigators also call this bight "Golfe de Rhondine," from the corrupted name of the ancient town of *Rhedine*; but the Greeks designate it under the name of *Orfano*. It is the *Sinus Strymonicus* of the ancients.

CONTESTANI, in *Ancient Geography*, a people of Hispania Citerior, to the south of the Edetani. Their territory extended southwards as far as Beticæ, or at least to the extremity of the Tarragonensis, where are found some places dependent on the Ballitani, who inhabited part of the eastern Beticæ.

CONTESTANIA, a country of Spain, in the Tarragonensis, mentioned both by Pliny and Ptolemy. The former says, that this country was first called "Mavitanica," afterwards "Deitania," and then *Contestania*. Here these authors place the river Tader, the colony of Illici, Lacentum, Dianium, the river Sacro, &c.

CONTESTATIO LITIS, among *Civilians*, denotes a general assertion that the plaintiff hath no ground of action, which assertion is afterwards extended and maintained in his plea.

CONTEXT, among *Divines and Critics*, that part of Scripture, or other writing, which lies about the text, before or after it, or both. To take the full and genuine sense of the text, the context should be regarded.

CONTEXTURE, a word frequently used in speaking both of the works of nature and art; and denoting the disposition and union of the constituent parts with respect to one another.

CONTHIL, in *Geography*, a town of France, in the department of the Meurthe, and district of Chateau-Salius; 2 leagues N.N.W. of Dieuze.

CONTHILA, in *Ancient Geography*, a borough of Greece, in Attica; placed by some in the Ptolemaide tribe, and by others in the Pandionide.

CONTI, GIUSTO DE, in *Biography*, an Italian poet and lawyer. His verses are chiefly amatory; and they appeared under the title of "Bella Manè," on account of the beautiful hand of his mistress, which is the subject of frequent

adulation. He died in 1409, and his poems have been published at Venice, Paris, Verona, and Florence. He has been compared to Petrarch; but the best judges have regarded him as much inferior to that writer. *Moreri*.

CONTI, CESARE and **VINCENZIO**, two brothers, the former, a native of Alcona, was celebrated as an expeditionary painter of grotesques; the latter, born at Rome, was a painter of history.

Baglione enumerates many considerable works, in which both these artists were employed at Rome, under the pontificate of Sixtus V. and Gregory XIII. Vincenzio ultimately settled in Turin, where he was taken into the service of the duke of Savoy. They both died during the pontificate of Paul V. Baglione.

CONTI, DOMENICO, of Florence, was the beloved disciple of Andrea del Sarto, and heir to his designs and studies. In gratitude and veneration to the memory of his great master, Conti, at his own expence, erected the monument still remaining in the cloister of the Nunziata, where the bust of Andrea is finely sculptured by the hand of Raffaello di Monte Lupo. Of Domenico's works in painting little is now known. *Orlandi*.

CONTI, CARLO, an engraver, native of Lorraine, in 1742. He established himself at Vienna, where he was reputed a good artist. He was living in 1790. *Heinecken*.

CONTI, FRANCESCO, an historical painter, born at Florence, in the year 1681. He travelled to Rome, where he became the disciple of Carlo Maratti. On his return, he acquired sufficient reputation to merit a place in the celebrated collection of portraits in the Florentine gallery. He died in the year 1760. *Lanzi, Storia Pitt.*

CONTI, LUCA, an engraver and architect, who was born in 1749, and became the disciple of Clerisseau. He established himself at Paris, where he continued to follow his profession in 1790. *Heinecken*.

CONTI, GIOACHINO. See **GIZZIELLO**.

CONTIGLIANO, in *Geography*, a town of Italy, in the duchy of Spoleto, near a lake to which it gives name; 3 leagues W. from Rieti.

CONTIGNE, a town of France, in the department of the Maine and Loire, and district of Segré; 3 miles N. of Chateaufeuil.

CONTIGUITY, the relation of bodies touching one another. See **CONTINUITY**.

CONTIGUOUS, a relative term, understood of things disposed so near each other, that they join their surfaces, or touch.

The houses in ancient Rome were not contiguous as ours are, but all insulated.

CONTIGUOUS angles, in *Geometry*, are such as have one leg common to each angle; otherwise called *adjoining angles*, in contradistinction to those produced by continuing their legs through the point of contact, which are called *opposite* or *vertical angles*.

CONTINENCE, in *Ethics*, a moral virtue, by which we resist concupiscence. It should seem that there is this distinction between *chastity* and *continence*, in that it requires no effort to be chaste, which results from constitution; whereas *continence* appears to be the consequence of victory gained over ourselves. The verb *continere*, in Latin, signifies *to restrain*.

CONTINENT, in *Geography*, a terra firma, main land, or a large extent of country, not interrupted by seas: so called, in opposition to *island, peninsula, &c.* See **EARTH, OCEAN, &c.**

Sicily is said to have been anciently torn from the conti-

ment of Italy; and it is an old tradition, which some of our antiquaries have still a regard to, that Britain was formerly a part of the continent of France.

Mr. Kirwan supposes (see Irish Tranf. vol. vi. p. 298.) that, when by the rupture of the Thracian Bosphorus, or isthmus which connected the Caspian, the lake of Aral, and the Black Sea, on the one side, and of the African isthmus, which joined Ceuta with Gibraltar on the other, the waters of the Ocean and of the Euxine were forced in upon the Mediterranean, an immense pressure took place upon its bed, under which it sunk or fell into the interior cavity of the globe; during this tremendous tumult the islands of Sicily, Sardinia, Corsica, and those of the Archipelago, were torn off from the Continent, and Italy was lengthened to its present shape. The separation of Sicily from Italy is vouched by ancient traditions, as may be seen in Pliny, Ovid, and Claudian.

“Zancla quoque juncta fuiffe

Dicitur Italia, donec confinia pontus
Abtulit, et media tellurem repulit unda.”

Ovid. Met. l. xv. v. 290.

“Trinacria quondam

Italiz pars una fuit, sed pontus et cæstus
Mutavere situm, rupit confinia Nereus,
Victor, et abscisso inclruit æquore montes.”

Claud. de Rep. Prof. l. i.

The entire separation of Great Britain from the Continent must have happened long after the deluge, and that of Ireland from Great Britain at a still later period; for wolves and bears were anciently found in both, and these must have passed from the Continent into Britain, and hence into Ireland, as it cannot reasonably be supposed that they were imported thither. The divisive force, says Kirwan (*ubi supra*), that separated Britain from Germany, seems to have been directed from North to South, but gradually weakened in its progress. Hence that island is sharpened northwards; but the impression must have been considerably weakened by the opposition of the granitic mountains that form the Shetland and Orkney isles. The rupture of the isthmus that joined Calais and Dover was probably effected by an earthquake at a later period, and gradually widened by tides and currents. Ireland was protected by Scotland from the violence of the northern shock; and therefore its separation from Scotland appears to have been late and gradual. That from England was probably diluvial, and effected by a southern shock. All these changes happened 3600 years ago; and there is no reason for thinking that the general level of the ocean has been since altered; but that of the continents seems to have varied considerably, being in some places higher and in some lower than it was in ancient times.

The world is ordinarily divided into two grand continents; the Old and the New; the Old comprehends Europe, Asia, and Africa; the New the two Americas, North and South.

The separation of the two continents Kirwan (*ubi supra*) supposes to have probably been the effect of excavation by volcanos; at least, he says, this cause is adequate to such an effect, and it still exists in the most northern parts; the superior fertility of the western coast of America may arise from the lavas ejected on that coast. But however this separation was effected, we have no traditional account of it, and the period in which it happened is no less difficult to be ascertained than the causes which produced it.

M. Buffon affirms, that they were not separated when the elephants lived equally in the north of Europe, Asia,

and America, the bones of which have been found in Russia, Siberia, and Canada. Hence he concludes, that the separation of the two Continents must have happened after the abode of these animals in the northern regions. But it has been doubted whether the remains of elephants and of the rhinoceros that have been lately found in Siberia, even allowing that the temperature of this country was ever so suited to the constitution of these animals as to admit of their living in it, belonged to animals which ever lived in it. As to the mode of their formation, we have different conjectures and theories, of which an account will be given under the articles DELUGE and EARTH.

M. Buffon observes (see Smellie's Translation, vol. i.) that the surface of the earth is divided, from one pole to the other, into two belts of land, and two of sea. The first and principal belt is the ancient Continent, the greatest length of which is a line commencing at the most eastern point of the north of Tartary, and extending from thence to the neighbourhood of the gulf of Linchidolin, where the Russians fish for whales, from thence to Tobolski; from Tobolski to the Caspian sea; from the Caspian sea to Mecca: from Mecca to the western part of the country inhabited by the Galli in Africa; from thence to Monocmuci, or Monomotapa; and, lastly, to the Cape of Good Hope. This line is about 3600 leagues in length (each league being about 2000 or 2100 fathoms long, and about 27 of them making a degree), and is never interrupted but by the Caspian and the Red Seas, which are of inconsiderable breadth. This greatest length of the Old Continent forms a diagonal line; for, if measured by a meridian, it will appear, that from the northernmost point of Lapland to the Cape of Good Hope, exceeds not 2500 leagues; and that this line, though shorter, meets with greater interruption from the Baltic and Mediterranean. With regard to all other lines which could be drawn under the same meridians in the Old Continent, they must still be shorter than those above-mentioned. *E. G.* From the most southern point of the island of Ceylon to the northernmost coast of Nova Zembla, the distance is 1800 leagues. Thus also, if the Continent be measured by lines parallel to the equator, its greatest length, without much interruption by seas, will stretch from Trefana, on the west coast of Africa, to Ninpo, on the east coast of China, which is about 2800 leagues. Another line may begin near Brest, and extend to the coast of Chinese Tartary, which will be nearly 2300 leagues. From Bergen in Norway to the coast of Kamtschatka the distance is only 1800 leagues. All these lines are much shorter than the first. Hence the greatest length of the Old Continent extends from the eastern point of Tartary to the Cape of Good Hope, and is about 3600 leagues. This line may be considered as the middle of the ancient Continent; for in measuring the surface on each side of it, M. Buffon found, that, on the left there are 2,471,092 $\frac{3}{4}$ square leagues; and on the right, 2,469,687, which two lines differ only by 1405 $\frac{1}{2}$ leagues, or barely 1 $\frac{1}{2}$ degree square. Hence the Old Continent contains about 4,940,780 square leagues, which is not one fifth part of the earth's surface, and may be regarded as a large belt of earth, with an inclination to the equator somewhat more than 30 degrees.

The New Continent is another belt of earth, the greatest length of which may be taken from the mouth of the river Plata to the lake of the Assinibois. This line passes from the mouth of the river Plata to lake Caracas; from thence to Mataguays, Pocona, Zongo, Mariana, Morua, St. Fé, and Cathagena; then it passes through the gulf of Mexico

Mexico to Jamaica and Cuba; from thence along the peninsula of Florida, through Apalache, Chicachas; and from thence to St. Louis, Fort le Sueur; and terminates in the country bordering on lake Assiniboils, the extent of which is unknown. This line is interrupted only by the gulf of Mexico, is about 2500 leagues in length, and divides the New Continent nearly into two equal parts; that on the left containing $1,069,286\frac{1}{2}$ square leagues, and that on the right $1,070,926\frac{1}{2}$; the difference of which is $1639\frac{1}{2}$, or scarcely $1\frac{1}{2}$ degree square. This line is the middle of a belt of land, called the New Continent, and is inclined to the equator somewhat less than 30° , but in an opposite direction to the former; for that of the Old Continent extends from the N. E. to the S. W.; but that of the New Continent from N. W. to S. E. The superficial contents of the Old and New Continents are about $7,080,993$ square leagues, *i. e.* not near a third part of the surface of the globe, which contains $25,000,000$ square leagues. Of these lines which divide the Continents into equal parts, it may be remarked, that they both terminate at the same degrees of N. and S. latitude; and that the two Continents make mutual advances, or projections, exactly opposite to each other; *viz.* those on the African coast, from the Canary isles to Guinea; and those of America, from Guiana to the mouth of the Rio Janeiro. It appears, therefore, that the most ancient lands on the globe are those which extend from 200 to 250 leagues on each side of the two lines above described.

Agreeably to this idea, it is found that, in the Old Continent, the most ancient countries of Africa are those which stretch from the Cape of Good Hope to the Red Sea and Upper Egypt, and are about 500 leagues broad; and, consequently, that the whole western coast of Africa, from Guinea to the straits of Gibraltar, are new lands. In the same manner, if we trace this line through Asia, and include an equal breadth, we shall find, that the most ancient countries are, the two Arabias, Persia, Georgia, Turcomania, a part of independent Tartary, Circassia, part of Muscovy, &c.; and, of course, that Europe, and perhaps also China, and the eastern part of Tartary, are comparatively new countries.

In the New Continent, we shall likewise find, that Terra Magellanica, the eastern part of Brazil, the country of the Amazons, of Guiana, and of Canada, are new lands, when compared with Tucuman, Peru, Terra Firma, the islands in the gulf of Mexico, Florida, the Mississippi, and Mexico. Moreover it may be observed, that the Old and New Continents are nearly opposite to one another. The Old Continent extends farther north of the equator than south; but the New, farther south than north. The centre of the Old Continent lies in the 16th or 18th degree of N. latitude; and the centre of the New Continent lies in the 16th or 18th degree of S. latitude; so as if they were intended to counterbalance each other. Besides, both continents resemble one another in this respect that they might be divided into two portions, which would be surrounded on all sides by the sea, except the two small isthmuses of Suez and Panama.

It is observable that the prodigious chains of mountains in these two continents run from W. to E. in the Old Continent, and from N. to S. in the New. In the Old Continent there are about 430 rivers which directly fall either into the Ocean, or into the Mediterranean and Black seas. But in the New Continent we know only of 135 rivers which fall immediately into the sea. Both the Old and New Continents appear to have been encroached upon by the Ocean in the same latitudes: both are furnished with a great Mediterranean and a vast number of islands, which likewise lie nearly in the same latitudes. The only difference is, that

the Old Continent, being much larger than the New, has a Mediterranean on its west coast, to which the New Continent has nothing analogous. But both seem to have undergone similar revolutions: These revolutions are greatest near their middle parts, or between the tropics, where the motion of the sea is most violent. For other particulars relating to these Continents, we refer to the description of their respective countries.

It has been remarked, that a considerable portion of the elevated and solid matters or strata which form our Continents, are opposite to a large or deep ocean at the anti-podes or opposite side of the earth: and this circumstance affords matter for important reflections, when we take into our account that these parts, now so considerably elevated above the level of the Ocean, once formed part of its bottom, as appears from the nature and disposition of the strata themselves, but more especially from the shells and other aquatic remains found lodged in them, in a perfect and unbroken state, lying in the same manner and positions, as the shells, &c. of living animals are found to be distributed, on the bottom of the sea, in places where divers have had opportunities of examining them. The following questions here naturally present themselves; has the quantity of water on the surface of the earth been so much diminished, as to lay the continents thus bare; or, has the centre of gravity of the earth been so deranged, as to occasion the waters to accumulate in particular places and leave others uncovered? For a long time there seemed little difficulty in solving the mystery, by answering the first question in the affirmative, on the principles of those who maintained, that the earth was only a hollow crust or shell of matter, and that great part of the waters of the universal ocean had retreated into the internal cavities of the globe. But since the labours of British philosophers have concurred in proving, that the specific gravity of the entire or compound mass of the terraqueous globe is 5 times that of water, while all the water existing in or upon the earth, (of sp. grav. 1, or little more) and all the earths and stones (whose specific gravities do not exceed $2\frac{1}{2}$ or $2\frac{3}{4}$ on the average) are included; we are forced to conclude, not only that the central parts of the globe are solid, but composed also of much heavier materials, than those which constitute the superficial strata. Another circumstance also concurs to shew the improbability, of any large caverns now existing, filled with water in the interior parts of the earth, *viz.* the fissures, which so universally are found, breaking and dividing even the hardest rocks and strata, into comparatively small and irregular fragments, so as to render them incapable of arching or supporting themselves over water without an actual contact or bearing upon each other: and accordingly caverns or grottos of any considerable size are rarely met with in mining, and these principally, if not entirely, in very hard lime-stone strata, near the surface, and carrying but a comparatively small load of superincumbent strata.

This ruptured and broken state of the solid matters of the globe, has probably fitted them for obeying the action of the centrifugal force generated by its diurnal revolution, and for assuming nearly the form of an *ellipsoid* (as the late measurements of degrees upon the earth's surface in various parts of the world have shewn;) otherwise, most probably, the equatorial parts of the earth must have been occupied by a zone of water instead of possessing islands and parts of Continents in common with other parts of the world, as they now do. Let the reader but consider the immense weight of solid matter which exists above the level of the sea, or general ellipsoidal lines of equilibrium, in one of our Continents; and suppose a cylindrical perforation to be made under such Continent, quite through the earth to the opposite ocean, so

as to separate, for the sake of argument, this cylindrical column of the earth and water from the rest of the earth, (as the broken state of the strata and the actual hardness of their fragments entitles us to suppose possible) and it will appear, as a necessary consequence of equilibrium, that the continent and strata under it to the centre of the earth must be equal in weight to the same space of Ocean at the antipodes, and the strata under its bottom extending to the same centre; for if these were different, and we suppose the Continent to preponderate, it is plain from the waters of the Ocean covering the other end of the cylinder being at liberty to recede, that they would do so, and the Continent would sink and the bottom of the opposite Ocean would rise, until the equilibrium was restored: and in like manner if the strata under the ocean be supposed the heaviest, a further protrusion and consequent elevation of the Continent, compared with its surrounding seas, would ensue. This view of the subject leads, in the opinion of the writer of this part of our article, to the conclusion, that a very large mass, or perhaps several masses of matter of a high specific gravity, now occupy the bottom of the Ocean opposite to the Continents and large islands, which were not there at the time that these Continents occupied a lower place in respect to the centre of the earth, and were covered by the universal Ocean: and he thinks, that he has discovered the source whence these very heavy and disturbing masses of matter were derived, in the disappearance of some immense satellite body which apparently for a long period revolved round this earth, very near to its surface, and occasioned tides so rapid and enormous, as to leave up the land and break the strata into innumerable fragments, permanently denuding some parts, when elevated above the point of equilibrium between the earth and satellite's attraction, and pouring down upon other parts of the surface, such torrents of the ruins of abraded strata, as entirely to hide the strata of these districts under alluvial coverings; forming, in numerous instances, hills of great height and extent, containing large and irregular fragments of rocks, and different known strata, thrown together throughout their whole thickness and extent, in the greatest apparent confusion. For other observations and conjectures, relating to this subject; see EARTH.

The discovery of a southern Continent has been an object of curious and diligent investigation; but hitherto without success. Captain Cook's second voyage commenced in the year 1772, was undertaken with a particular view to the decision of the question, concerning the existence of a southern Continent. In the prosecution of this voyage, and while he was proceeding southward in quest of a Continent, he fell in with ice islands, in S. lat. $50^{\circ} 40'$ and 2° of longitude from the Cape of Good Hope; in his farther progress, he was stopped by other fields of ice, which led him to imagine, from a notion that these are formed in bays and rivers, that he could not be at a great distance from land. But having failed in S. lat. $55^{\circ} 40'$ for more than 30 leagues along the edge of the ice without finding any opening, he found that this ice did not join the land; and therefore he thus discovered the fallacy of the general opinion, that ice is always formed in the vicinity of land. The observations of captain Cook confirmed those of other navigators, that the ead of the southern seas is much more intense than that of equal latitudes in the northern hemisphere; and he also ascertained that this cold was not owing to the vicinity of a Continent, as had formerly been imagined. On the contrary, it was now determined beyond dispute, that if any such Continent existed in the eastern part of the southern Ocean, it must be confined within the latitude of 60° . Having advanced as far as S. lat. $62^{\circ} 10'$ and W. long. 172° , he found

the farther he proceeded that the number of ice islands very much increased; and in lat. $6^{\circ} 31'$, and W. long. $142^{\circ} 54'$, he got into such a cluster of these islands that it was both difficult and dangerous to escape them. Finding it impossible to get any farther to the southward, he determined to explore a considerable tract of sea to the north of his present situation, and then again to stand to the south. But in this he was unsuccessful; no land being discovered either in sailing northward, eastward, westward, or southward; though he proceeded in the last direction as far as $71^{\circ} 10'$ S. lat. and $106^{\circ} 54'$ W. long. It was now impossible to advance; and it was the opinion of the captain himself, as well as of most of the gentlemen on board, that the ice by which they were now stopped extended as far as the pole. The most southerly land discovered by this persevering navigator was that on which he bestowed the name of "Southern Thule," and which is situated in S. lat. $55^{\circ} 13' 30''$, W. long. $27^{\circ} 45'$. Here not a single herb of any kind was seen, but very high and barren mountains, the tops of some of which reached above the clouds; and we may observe, that this seems to be the only part of the world hitherto discovered, altogether unfit for the support of animal life. This country was discovered on the 31st of January 1775. Upon the whole, it may be concluded, that the greatest part of the southern Continent, if it has any existence, must be within the polar circle, where the sea is so encumbered with ice, that the land must be inaccessible. So great is the danger in navigating these southern seas, that captain Cook asserts on the most probable grounds, that such lands as lie to the southward of his discoveries could not be explored; and that even no man could venture farther than he had done. Thick fogs, snow-storms, intense cold, and every attendant circumstance that can render navigation difficult and dangerous, must be encountered; and all these difficulties and dangers are heightened to a very great degree by the inexpressibly horrid aspect of the country itself. It is a part of the world deemed by nature never to feel the warmth of the sun's rays, but to be buried in everlasting snow and ice. Whatever ports there may be in the coast, they are almost entirely covered with frozen snow of a vast thickness. If however any of them should be so far open as to invite a ship into it, she would run the risk of being fixed there forever, or of coming out on an ice island. Besides, the islands and floats on the coast, the great falls from the ice-cliffs in the port, or a sudden snow-storm, might be attended with equally fatal effects. For these reasons captain Cook determined to abandon the pursuit of a land, whose existence was so equivocal, but whose utility, if it could be discovered, was certain.

After captain Cook's persevering and fruitless traverses through every corner of the southern hemisphere, who, for the future, says the editor of Cook's third voyage (vol. i. Int. p. 56.), will pay any attention to the ingenious reveries of Campbell, de Broiles, and de Buffon? or hope to establish an intercourse with such a continent as Maupertuis's fruitful imagination had pictured? A Continent equal, at least, in extent, to all the civilized countries in the known northern hemisphere, where new men, new animals, new productions of every kind, might be brought forward to our view, and discoveries be made, which would open inexhaustible treasures of commerce. (See Maupertuis's Letter to the King of Prussia.) The author of the Preliminary Discourse to Bougainville's "Voyage aux Isles Malvaines" computes, that the southern Continent (for the existence of which, he owns, we must depend more on the conjectures of philosophers, than on the testimony of voyagers) contains

8 or 10 millions of square leagues! We can now boldly take it upon us to discourage all expeditions formed on such reasonings of speculative philosophers, into a quarter of the globe, where our persevering English navigator, instead of this promised fairy land, found nothing but barren rocks, hardly affording shelter to penguins and seals; and dreary seas and mountains of ice, occupying the immense space allotted to imaginary paradises, and the only treasures there to be discovered, to reward the toil, and to compensate the dangers of the unavailing search.

CONTINGENCY, in *Metaphysics*, denotes the mere possible existence or non-existence of an object in any future time; and is opposed to *necessity*; which see. See also **CHANCE** and **PROBABILITY**.

CONTINGENCY of blood, in the writers of the laws of Scotland, is used for *proximity of blood*. Bayne, Crim. Law. p. 48.

CONTINGENT, literally signifies what may or may not happen, what is casual or uncertain, and depending upon chance. See **CHANCE**. But in military acceptation, it denotes the quota or proportion of troops, money, and ammunition, which each of a body of leagued or confederated sovereigns, or princes, furnishes on emergencies, when required or called on, in virtue of and in support of the confederation. In the wars of the German empire, each prince and state, and all the members of the Germanic body, were obliged to furnish their contingent. In like manner the princes forming the *confederation of the Rhine*, are, at present, obliged to furnish their respective contingents.

CONTINGENT bill, of a regiment, is an account of the extra charges, which a regiment, in the due course of service, is from circumstances unavoidably and accidentally under the necessity of incurring.

CONTINGENT line, or *tangent-line*, in *Dialling*, denotes the intersection of the planes of the dial and equinoctial, and it intersects the subtile or subltial line at right angles.

CONTINGENT legacy, is a legacy depending on the life of the legatee; if it be left to any person, *when or if* he attains the age of twenty-one, and if he dies before that time, it is a lapsed legacy; but if it is left to be paid when he attains that age, it is a vested legacy; and if the legatee dies, his representatives shall receive it out of the testator's estate at the time, when it would have become payable, if the legatee had lived.

CONTINGENT, or *Executory remainder*, in *Law*, is where an estate is limited to take effect, either to a dubious and uncertain person, or upon a dubious and uncertain event; so that a particular estate, which doth support a remainder, may or may not determine before the remainder may commence. This kind of remainder is opposed to *vested or executed remainders*. 3 Rep. 20. See **REMAINDER**.

CONTINGENT use, in *Law*, is an use limited in a conveyance of land, which may, or may not, happen, to vest, according to the contingency expressed in the limitation of such use. An use in contingency is such which by possibility may happen in possession, reversion, or remainder. 1 Rep. 121. See **USE**.

CONTINGENTS are sometimes also used by mathematicians in the same sense as *tangents*.

CONTINI, GIAMBATISTA, in *Biography*, an architect who enjoyed considerable reputation at Rome in the latter part of the 17th and the beginning of the 18th century. He was born in the year 1641, and after having acquired at the schools a competent knowledge of languages, the Belles Lettres, and geometry, was placed by his father, who was likewise an architect, under the tuition of the celebrated Bernini. The instructions of his master were not thrown away,

and Giambatista became employed by several of the first families of Rome. He constructed many of those magnificent altars and chapels with which the churches of Rome abound, and built the duomo of Vetralla as well as that of Vignarello. His works are enumerated by his biographer Lionc Pascoli, who informs us that he lived highly respected, and died in 1723. Pascoli.

CONTINUAL CLAIM. See **CLAIM continual**.

CONTINUAL proportionals. When in a series of quantities the first is to the second as the second to the third, and the third to the fourth, and the fourth to the fifth, &c. they are called *continual proportionals*: such are 1, 2, 4, 8, 16, &c. where the terms increase in a two-fold ratio; and 36, 12, 4, $\frac{4}{3}$, &c. where they decrease in a triple ratio. Such a series is otherwise called a *progression*.

CONTINUANCE, in *Law*, is much the same as *pro rogation* among the civilians. It denotes the continuing of a cause in court, by an entry upon the records there for that purpose. After issue or demurrer joined, as well as in some of the previous stages of proceeding, a day is continually given and entered upon the record, on which the parties are to appear, from time to time, as the exigency of the case may require. The giving of this day is called the "continuance," because thereby the proceedings are continued without interruption from one adjournment to another. If these continuances are omitted, the cause is thereby discontinued, and the defendant is discharged *sine die*, without a day, for this term: for by his appearance in court, he has obeyed the command of the king's writ; and, unless he be adjourned over to a day certain, he is no longer bound to attend upon that summons; but he must be warned afresh; and the whole must begin *de novo*. It may sometimes happen, that after the defendant has pleaded, nay, even after issue or demurrer joined, there may have arisen some new matter, which it is proper for the defendant to plead; as, that the plaintiff, being a feme-sole, is since married, or that she has given the defendant a release, and the like: here, if the defendant takes advantage of this new matter, as early as he possibly can, viz. at the day for his next appearance, he is permitted to plead it in what is called a plea *puis darrein continuance*, or since the last adjournment. For it would be unjust to exclude him from the benefit of this new defence, which it was not in his power to make when he pleaded the former. But it is dangerous to rely on such a plea, without due consideration; for it confesses the matter which was before in dispute between the parties (Cro. Eliz. 49.) And it is not allowed to be put in, if any continuance has intervened between the arising of this fresh matter and the pleading of it; for then the defendant is guilty of neglect or laches, and is supposed to rely on the merits of his former plea. Also it is not allowed after a demurrer is determined, or verdict given; because then relief may be had in another way, namely, by writ of *audita querela*. And these pleas *puis darrein continuance*, when brought to a demurrer in law or issue of fact, shall be determined in the same manner with other pleas. Blackst. Comm. vol. iii.

Continuances and essons are amendable upon the roll, at any time before judgment:—they are the acts of the court, and at common law they may amend their own acts before judgment, though in another term; but their judgments are only amendable in the same term in which they are given. (3 Lev. 431.) Upon an Original, one term, or two, or three terms may be mesne between the issue and the return; and this shall be a good continuance; for the defendant is not prejudiced by it, and the plaintiff may give a day to the defendant beyond the common day, if he will. But a continuance by *capias* ought to be made from term to term, and

there cannot be any mesne term, because the defendant ought not to stay so long in prison. (2 Dav. Abr. 150.) If a man recover upon demurrer, or by default, &c. and a writ of inquiry of damages is awarded, there ought to be continuance between the first and second judgment, otherwise it will be a discontinuance; for the first is but an award, and not complet, till the second judgment, upon the return of the writ of inquiry of damages. (Ibid. 153.) If the plaintiff be non-suited, by which the defendant is to recover costs; if the plaintiff will not enter his continuances, on purpose to save the costs, the defendant shall be suffered to enter them. (Cro. Jac. 316, 317.) The course of the court of King's Bench is to enter no continuance upon the roll, till after issue or demurrer, and then to enter the continuance of all upon the back, before judgment; and if it is not entered, it is error. (Trin. 16 Jac. B. R.) See DISCONTINUANCE.

CONTINUANCE of a writ, or action, is its holding in force from one term to another, in a case where the writ has not returned, or executed, a former writ issued out in the same action.

CONTINUANCE of assise. If a record in the treasury be alleged by one party, and denied by the other, certiorari shall be sued to the treasury and chamberlain of the exchequer; who, if they certify not that the said record is there, or likely to be in the Tower; the king shall then send to the justices, repeating the certificate, and will them to continue the assise.

CONTINUANDA assisa. See ASSISA.

CONTINUANDO, in *Lacu*, a term used in a declaration of trespasses, where a plaintiff would recover damages for several trespasses in the same action. To avoid multiplicity of suits, a man may in one action of trespasses recover damages for many trespasses; laying the first to be done with a *continuance* to the whole time in which the rest of the trespasses were done; which is done in this form: *continuando transgressionem predictam, &c. à predicto die, &c. usque, &c.* Terms de Ley. 2 Roll. Abr. 545. Lord Raym. 245. 7 Mod. 152.) This declaration of trespasses may be alleged, where the inquiry is continually renewed, as by spoiling or consuming the herbage with the defendant's cattle; in which case the *continuando* is good. (1 Lall. Abr. 307.) Thus also trespasses for breaking a house with *continuando* is good; and until a re-entry is made, the continuation of the possession is a continuing of the trespasses (Lutw. 1312.) But where the trespass is by one or several acts, each of which terminates in itself, and being once done cannot be done again, it cannot be laid with a *continuando*; yet if there be repeated acts of trespasses committed, (as cutting down a certain number of trees,) they may be laid to be done, not continually, but at divers times and days within a given period. Salk. 638, 639. Lord Raym. 823.

CONTINUANDO Processum. See PROCESSUM and CONTINUANCE.

CONTINUANS PUNCTUM. See PUNCTUM.

CONTINUATION OF MOTION. See MOTION and PROJECTILE.

CONTINUATIVE CONJUNCTIVES, in *Grammar*, are those conjunctions, uniting both sentences and their meaning, which join those sentences only, which have a natural connection; in contradistinction to copulative, which join all sentences, however incongruous in signification. The latter merely couple sentences, and are applicable to all subjects, whose natures are not incongruous. The former, on the contrary, by more intimate connection, consolidate sentences into one continuous whole, and are therefore applicable only to subjects which have no essential coincidence.

The principal copulative in English, is, *and*; the continuatives are, *if, because, therefore, that, &c.* E. G. "Lyfippus was a flutary, and Priscian was a grammarian."—"The sun shineth, because the sky is clear." Continuatives, according to the distribution of Mr. Harris (Hermes, p. 244.) are either suppositive, as, *if*; or positive, as, *because, therefore, &c.* E. G. "You will live happily, if you live honestly."—"You will live happily, because you live honestly." The difference between these continuatives is this; the suppositives denote connection, without asserting actual existence; and the positives imply both the one and the other. Moreover, positives are either casual, as, *because, since, &c.*; or collective, as *therefore, then, &c.*; and they differ in this respect, that the causals subjoin causes to effects, thus; "the sun is eclipsed, because the moon intervenes;" but the collectives subjoin effects to causes, thus; "the moon intervenes, therefore the sun is eclipsed." All these continuatives may be resolved into copulatives. Instead of "because it is day, it is light," we may say, "it is day, and it is light."

CONTINUATO, in the *Italian Music*, is used to direct a finger, or player, to continue or hold on a sound, in equal strength or manner; or to continue a movement in an equal degree of time all the way.

CONTINUED FEVER. A fever without remissions or intermissions. See FEVER.

CONTINUED QUANTITY. } See CONTINUUM, CONTINUITY,
CONTINUED BODY, &c. } and QUANTITY.

CONTINUED, or *through bass*, in *Music*, is that which continues to play constantly, both during the recitatives, and to sustain the choir, or chorus.

CONTINUED PROPORTION, in *Arithmetic*, is that in which the consequent of the first ratio is the same with the antecedent of the second: as, 3 : 6 :: 6 : 12. See PROPORTION.

On the contrary, if the consequent of the first ratio be different from the antecedent of the second, the proportion is said to be *discrete*: as, 3 : 6 :: 4 : 8. See DISCRETE.

CONTINUED SOLE, or *sole*, in *Architecture*. See SOLE.

CONTINUED ATTIC, Community, *Pedestal*. See the substantives.
