The os occipitis of the fœtus consists of four pieces, joined by cartilage; which at the end of the first year are very closely agglutinated; and soon after are consolidated by a bony union. These are; 1. The posterior, or *occipital* portion; 2. The two lateral, or *condyloid*; and, 3. The anterior, or *basilar* parts. The margins of these may be named, according to the bones with which they are connected; thus, the edge of the *occipital* portion will form the posterior or *lambdoid* margin; that of the *condyloid* parts, the middle or *mastoid*; and that of the *basilar*, the anterior or *petrous* edge of the bone.

The substance of the bone varies greatly at different parts; it is thick, strong, and compact, at the external transverse ridge and upwards; where its surface, covered only by the scalp, is exposed to the effects of accidental violence.

C R A N I U M.

lence. Its lower portion, protected by the muscles of the neck, is so thin as to be transparent in some parts. The basilar process is very thick, but consists chiefly of a cancellous structure.

That part of the *occipital portion*, which forms the back of the head, and is only covered by the scalp, has an uniform smooth surface. It is bounded below by an arched and prominent line, beyond which the bone turns forwards in the basis cranii. To this line, which varies in strength and projection in different persons, but is most distinctly marked in muscular subjects, the name of external transverse ridge is affixed. The muscles of the back begin to be attached at this part, and occupy a series of pits and eminences, which cover the surface as far as the occipital foramen. In the middle of the ridge, a more or less elevated prominence appears; and is called the occipital tubercle, (*protuberantia occipitis externa*;) from which a small longitudinal elevation extends to the foramen magnum (*spina occipitalis*). To this tubercle and spine the ligamentum nuchæ is attached.

Sometimes, but very rarely, a suture crosses the bone at the external transverse ridge; and in a very few instances the sagittal suture is continued along the middle of the occipital portion.

The inner surface of this division of the occiput presents a broad and deep groove, continued from that which runs under the sagittal suture, and lodging the termination of the superior longitudinal sinus. The back of the falx is fixed to the margins of this groove. The internal transverse ridge, which crosses the bone just opposite to the analogous external prominence, is hollowed into a similar channel; in which the former groove terminates; the right and left lateral sinuses occupy the last mentioned impressions, and are found at the point where the tentorium is fixed to the bone. A sharp-edged bony spine runs from the middle of the internal transverse ridge to the foramen magnum, and has the falx cerebelli attached to it (*spina, or cristula occipitalis interna*). A considerable groove is sometimes found on one side of this spine, and denotes the course and situation of an occipital sinus; but it is not found constantly.

The bony prominences, which we have now described, divide the surface of the bone into four large superficial cavities. The upper, smaller, and shallower fossæ, which are situated above the tentorium, hold the back lobes of the cerebrum. The lower, larger, and deeper hollows, contain the two lobes of the cerebellum, separated from each other by the lesser falx, and from the cerebrum by the tentorium.

The *condyloid* divisions of the occiput are chiefly distinguished by those oblong articular eminences called the condyles, which connect this bone to the atlas. These bodies are slightly convex on their articular surface, and placed just in front of the foramen magnum, with such an obliquity, that their anterior extremities approach to each other, and the posterior recede, or diverge. They are broadest in the middle, and have their external margin higher than the internal. An obscure line of division sometimes seems to divide them into two parts. Their outer edge has a rough groove for the capsular ligament; and the inner and anterior part presents a conspicuous impression from the attachment of the lateral ligaments of the vertebra dentata. A roughness near the styloid process of the temporal bone receives the attachment of the rectus lateralis.

The inner surface is excavated into a semilunar notch, which contributes to form the jugular foramen; and a considerable groove of the bone, leading from this notch, lodges the termination of the lateral sinus.

The *basilar portion* of the occiput consists of a rough bony triangle, sometimes called, from its figure, the cuneiform process. Its outer, or rather under surface, presents several asperities from the attachment of the pharynx, and of the *recti capitis interni* or *antici*. On its inner or upper surface it is slightly concave; and has the pons varolii lying on it. On the line of union between this part and the petrous portion of the temporal bone, the inferior petrosal sinus leaves an impression varying in its distinctness in different subjects.

The foramina of the occipital bone are; 1. *Foramen magnum occipitale*. This, which is placed in the centre of the bone, and near the middle of the basis cranii, is sufficiently distinguished by its superior magnitude. Its figure is that of an oval, with the long axis running from before backwards, and the short one placed transversely. All the four divisions of the fetal occiput contribute to this opening. It transmits the medulla spinalis, surrounded by a sheath of dura mater; the *nervi accessorii*, which are included in this sheath; and the two vertebral arteries. 2. *Foramen lacerum in basi cranii, or jugulare*, formed between the condyloid portion of the occiput, and the petrous part of the temporal bone. The internal jugular vein, and eighth pair of nerves, (consisting of its three portions; viz. the glossopharyngeal, nervus vagus, and accessorius,) pass through this opening. A thin plate of bone generally separates more or less completely the passage of the nerve from that of the vein. 3. *F. condyloideum anterius*, a round hole just in front of the condyle, giving passage to the 9th pair of nerves, or *n. lingualis medius*. 4. *F. condyloideum posterius*, which may be wanting on one or both sides of the bone. It is situated just behind the condyle, and sends a vein to the lateral sinus. 5. *F. mastoidea*, which are very irregular in size and situation; and sometimes entirely absent. They are formed in that part of the bone which adjoins the mastoid portion of the os temporis, or between the two bones, or in the temporal bone only. They are perforated by veins passing to the lateral sinus.

The occipital portion of the fronto-occipitalis, the trapezius, splenius capitis, and sterno cleidomastoideus are inserted in the external transverse ridge of the bone. The complexus fills a hollow just within the ridge. The two posterior recti, and the obliquus superior are fixed nearer to the occipital foramen. The rectus cap. lateralis; the recti anteriores, and the pharynx are also affixed to this bone.

The *sphenoid bone*, (*os sphenoidum*, from $\sigma\phi\eta\upsilon$, a wedge, and $\nu\delta\omicron\varsigma$, form; *os cuneiforme, basilare, polymorphon, multiforme, vespiforme*) is placed towards the middle and front part of the basis of the skull, and detaches several processes, which give it a very irregular figure, and connect it in an intricate manner to all the other bones of the cranium, and several of the face: at some parts the contiguous bones overlap the edge of the sphenoid; while in other situations that bone is overlapped by the neighbouring ones: hence it is considered to wedge, and hold firmly together, all the bones of the skull; from which circumstance its most common appellation is derived, and not from its bearing any resemblance in form to a wedge.

The Arabians called it *os colatorii*, or *os cribratum*, from the mistaken notion which prevailed for so many centuries, that the mucus of the nose flowed from the brain through its openings. The first physiologist who attempted to refute this long subsisting prejudice, who subverted the ancient error, and thereby threw a new light on a most important part of physiology and anatomy, particularly by disclosing the true structure of the sphenoid bone; was

C R A N I U M.

CONR. VICT. SCHNEIDER, professor at Wittenberg, in his classical, but really somewhat prolix work, "De Catarrhis."

The irregular figure of this bone renders it difficult and almost impossible to illustrate or explain it by any comparison: yet anatomists have likened it to a bird with the wings extended, and hence the names applied to some of its processes. In the fœtus at full time, it consists of three pieces; the *body* or central portion; and two large lateral productions, which include the *ala* and *pterygoid processes*.

On its anterior part, the sphenoid bone is joined to the orbital plates of the os frontis, to the ethmoid bone, vomer, and os malæ. The extremity of its great ala touches the anterior inferior angle of the parietal bone in the temporal fossa. The outer concave edge of the ala is extensively connected to the squamous and petrous parts of the temporal bone. At the back part it joins the basilar process of the occiput. Lastly, the pterygoid portions of the bone are connected with the superior maxillary and palatine bones.

The *body*, which appears like a continuation of the basilar process of the occiput, is the thickest part, and joins the ethmoid bone. It forms on its lower and anterior part a sharp lamina, which is connected above to the nasal lamella of the ethmoid bone, and passes below between the two layers of the vomer, under the name of the *azygous process*.

A variety is very frequently observed in the formation of the body of this bone; which is the more remarkable, inasmuch as deviations from the ordinary structure in the brain, or in the basis cranii, in other respects, are of very rare occurrence. In some skulls the basilar process of the occiput extends close to the posterior clinoid processes. In others, on the contrary, it terminates far short of this point; so that there is a peculiar oblique surface of the sphenoid bone, extending from the end of the basilar portion to the clinoid processes. Blumenbach proposes to distinguish this by the epithet of *clivus* (the declivity). This variation is so remarkable, that it changes completely the profile of the bone when viewed in a vertical section from behind forwards. Such a section represents a square in the former instance, and a pentagon in the latter. The upper side of this pentagonal figure is a line running from the posterior to the anterior clinoid processes: the second side forms the sharp edge on the front of the bone for the attachment of the septum nasi; the third is the part connected to the vomer; the fourth is the surface joined to the occiput; and the fifth is the above-mentioned clivus. When this formation exists, the fella turcica is deeper and narrower; and the space between the posterior clinoid processes and occiput is lengthened.

The upper surface of the bone is excavated for the reception of the pituitary gland; and the hollow thus formed is called the *fella turcica*. This cavity is bounded in front by a smooth prominence or tubercle, interposed between the two optic foramina, and supporting the conjoined portion of the optic nerves: behind by a thin perpendicular layer, which forms two rounded knobs, called the *posterior clinoid processes*; and it is open at the sides. The side of the body is excavated for the receptaculum, or cavernous sinus of the dura mater: and it bears a superficial impression made by the internal carotid artery just after it quits the canal of the temporal bone. The anterior clinoid process has sometimes been continued backwards to the body of the bone, so as to form a complete foramen, through which the carotid artery passes: this continuation has been distinguished by the name of the middle clinoid process.

The body of this bone, with the exception of its clinoid

processes, is formed into the two *sphenoidal sinuses*, which, in structure and office, resemble those of the os frontis. These are separated by a vertical partition; and open by round holes into the superior meatus of the nose. They are occasionally subdivided by bony laminae into smaller cells. Their lining resembles that of the frontal, ethmoidal, and maxillary sinuses; which has been described in the view of the os frontis: and, like all these cavities, they are not fully developed until many years after birth. Their openings appear smaller in the entire cranium than in the separate bone; as they are contracted in the former case by the *cornua sphenoidalia*. These are thin triangular bony plates connected to the back of the ethmoid bone; and placed at the sides of the azygous process, so as to diminish the apertures of the sphenoidal cells. Bertin calls them *cornets sphenoidaux*; Böhmer has delineated them in his *Institutiones Osteologicæ*, tab. 4. figs. 5 and 7. And Sue, in his splendid edition of Monro's *Osteology*, tab. 8. figs. 3 & 4.

Each lateral portion of the sphenoid bone consists of three parts: 1st. The lesser ala; 2dly. The greater ala; and, 3dly. The pterygoid portion.

The *superior* or *smaller ala* has a broad commencement from the front of the body of the bone: it runs outwards in an horizontal direction, and terminates in a sharp point; from which circumstance Monro has described it by the name of the transverse spinous process. Its anterior margin is joined by a suture to the ethmoidal and frontal bones, while the posterior edge is just opposite to the commencement of the fissura sylvii, by which the two lobes of the brain are divided. The origin of this ala forms a somewhat thick knob, called the anterior clinoid process.

The *great* or *middle ala* of the sphenoid bone is continued from the body in the lateral direction, and forms a considerable portion of the orbit, with part of the temporal fossa; in which latter situation it terminates by a thin squamous edge connected to the frontal, parietal, and temporal bones. It may be stated, in short, to fill up the vacancy left between these three portions of the cranium. The superior orbital fissure separates it from the lesser ala. Beyond the termination of the latter process it is joined to the os frontis by a broad surface; then towards its anterior and lower part to the os malæ; behind to the anterior inferior angle of the parietal bone, to the squamous portion of the os temporis by an extensive concave or semi-lunar margin, and, lastly, to the front edge of the petrous part of the temporal bone by its posterior margin. This last-mentioned portion, which contains the foramen ovale and spinosum, is called by Monro the spinous process; it cannot however be considered as forming a process distinct from the great ala, of which it is clearly a part. From its under surface a sharp pointed process is continued, which gives origin to the levator palati; this is the *styliform process*, and *apophysis spinosa* of different authors.

In its internal surface the great ala presents a large hollow, containing the convex anterior portion of the back lobe of the brain (the middle lobe of some writers). The bone is marked by the course of the spinous artery, and by the cerebral convolutions. The outer or temporal surface is the most extensive: it constitutes the lower portion of the temporal fossa, and is slightly concave. The anterior or orbital part is a smooth level surface, nearly of a rhomboid figure; separated from the former by a sharp ridge, and constituting chiefly the outer and back part of the orbit.

Between this portion of the bone, which is often called its orbital process, and the lesser ala, the *superior orbital fissure* (*foramen lacerum orbitale; fissura spheno-sphenoidalis*) is left.

The

The *inferior orbital, or sphenomaxillary fissure*, separates it from the os malæ.

Between the back of the great ala, and the adjoining petrous portion of the temporal bone, a rough and irregular groove is formed; which lodges the Eustachian tube.

The inferior ala, or *pterygoid portion* of the sphenoid bone, descends perpendicularly from the basis and greater ala, towards the superior maxillary and palatine bones. It consists of two thin plates: an *external*, which is broader and shorter, (*lamina muscularis*;) an *internal*, narrower, and longer one, (*lamina nasalis*;) forming the posterior opening of the nostrils, and terminating by a hook-like process (*hamulus*), round which the tendon of the *circumflexus palati* takes its course. The cavity left between these pterygoid plates (*fossa pterygoidea*) is occupied by the internal pterygoid muscle; and the fissure, which divides them from each other, is filled, in the entire cranium, by a process of the os palati, whence it has been denominated *fissura pterygo-palatina*.

Foramina of the Sphenoid Bone.

1. *Foramen opticum* in the base of the lesser ala, and just in front of the anterior clinoid process; for transmitting the optic nerve and ophthalmic artery. In very rare instances the artery has a distinct opening for its passage.

2. *Superior orbital fissure* (*f. lacrumum*) between the lesser and greater alæ: this is largest near the body of the bone, and grows gradually smaller. The third, fourth, ophthalmic branch of the fifth, and the sixth pairs of nerves pass through this opening; together with the ophthalmic vein, in its passage to the cavernous sinus.

3. *Foramen rotundum*, behind the former, and near the body of the bone; for the passage of the superior maxillary branch of the fifth pair of nerves.

4. *Foramen ovale*, near the back part of the great ala. It transmits the inferior maxillary branch of the fifth pair.

5. *Foramen spinosum*, between the last-mentioned opening and the pointed termination of the great ala, transmits the artery of the dura mater. This aperture is sometimes formed between the sphenoid and temporal bones.

6. *Canalis pterygoideus*, or *Vidianus*, formed at the root of the pterygoid processes, for the passage of a reflected branch of the superior maxillary nerve, of the same name. Its anterior opening is much larger than the posterior, and cannot be seen in the entire cranium: the latter cannot be discovered without difficulty; but it may be seen just at the root of the internal pterygoid plate, opening towards the broken anterior termination of the carotid canal.

There are other foramina found between the sphenoid and neighbouring bones, and which may therefore be called common holes.

1. A large irregular vacancy between the point of the petrous portion of the os temporis, and the side of the sphenoid bone. A mass of cartilage fills this in the recent subject. The carotid artery passes just over it within the cranium, and the Eustachian tube under it, without the cavity. The Vidian nerve enters the cranium by this aperture.

2. *Inferior orbital, or sphenomaxillary fissure* between the orbital portions of the sphenoid, superior maxillary, and malar bones. The infra-orbital nerve goes through this opening. 3. An opening between the body of the sphenoid, and the orbital process of the palate bone. See the description of the latter bone. The following muscles are attached to the sphenoid bone: *pterygoideus internus et externus*; the latter of which arises from the root of the external plate. The *circumflexus palati* arises from a hollow at the commencement of the internal plate. The temporal muscle and *levator palati* are also attached to the bone.

The *temporal bones* (*ossa temporum*, *ἡσποταφοί*;) constitute the inferior lateral portion of the cranium, and the outer middle part of the basis cranii. They contain the articular cavities in which the condyles of the lower jaw are received, and contribute to the formation of the zygoma. The organ of hearing is formed in their interior.

This bone consists of two pieces at the time of birth: the squamous portion, with the ring on which the *membrana tympani* is stretched; and the petrous portion. In a fœtus of five months, or more early periods, the auditory ring is not consolidated with the squamous portion; so that the bone consists then of three pieces. It is often divided into three parts, in describing it in the adult: these are the *squamous*, the *mastoid* (which is a part of the former division in the fœtus), and the *petrous*.

The temporal bone is joined to five others: 1. To the lower edge of the parietal by the squamous suture, and to the posterior inferior angle of the same bone by the *additamentum suture squamosæ*; 2. To the occipital bone, along the posterior margin of its mastoid and squamous portions, by the *additamentum suture lambdoidalis*; 3. By the front edge of the petrous and squamous portions to the sphenoid bone; 4. To the os malæ; and, 5. To the lower jaw, by means of a true joint.

The external surface will be described first, and then that which is placed towards the cavity of the cranium.

The squamous portion is a broad flat piece, terminating in a thin semicircular margin, which overlaps the corresponding edges of the parietal and sphenoid bones. The zygomatic process arises from its lower portion by a broad surface: this at first stands directly out from the bone; but becoming narrower, turns forwards, and is joined by a rough surface to the os malæ, to complete the bony arch, under which the tendon of the temporal muscle passes. The temporal fascia is affixed to the superior or sharp edge of the zygoma, and also to the prominent line, which, running backwards from the origin of this process, divides the squamous from the mastoid portion, and forms a continuation of the temporal ridge of the parietal bone. The fibres of the masseter muscle are affixed to the under edge of the bone. An oblong cavity is placed at the root of this process, (*cavitas articularis*, or *glenoidea*;) for the reception of the maxillary condyle. The position of this part is oblique; the outer end of the cavity being situated more forwards than the inner extremity: hence, if a line were drawn through the axis of the cavity on each side, the two lines would meet at an acute angle in the foramen magnum. In front of this glenoid cavity is placed an oblong convex surface, which is also included in the joint (*eminentia articularis, tuberculum articulare*). Behind is a thin plate of bone, forming the lower and anterior part of the meatus auditorius externus, and separating that passage from the articular cavity: this is sometimes called the *processus auditorius*. It is distinguished from the articular surface by the *fissura glaseri*, through which the *chorda tympani* proceeds. The large round opening of the meatus auditorius externus is found just behind the glenoid cavity: this passage will be more fully described presently, when we speak of the organ of hearing.

The posterior part of the bone, which is irregular on its surface, is distinguished by a large prominence, called the mastoid process, from a supposed resemblance to a nipple. This part is rounder or flatter, more pointed or obtuse, and more or less solid, in different subjects. It is excavated internally by numerous cells communicating with each other, and opening into the upper and back part of the tympanum. These cells are sometimes small and numerous; sometimes larger and fewer. The mastoid process does not begin to

C R A N I U M.

be formed until long after birth. The inner surface of this process exhibits a deep notch, which contains the origin of the posterior portion of the biventer maxillæ inferioris.

Behind this process there is occasionally observed a large opening for the passage of a vein to the lateral sinus (*foramen mastoideum, or occipitale venosum*).

From the broad plate of bone which forms the lower part of the meatus auditorius externus, the styloid process descends, arising as it were from a peculiar cavity, and surrounded at its root by the above-mentioned plate, as by an imperfect sheath; whence the term of *processus vaginalis* has arisen. The styloid process itself varies considerably in length; seldom, however, exceeding an inch. Its form is nearly cylindrical, its extremity is pointed, and it is generally straight; but varieties often occur in these points, as well as in the size of the process. It is usually connected by cartilage to the bone, even in the adult state; but is consolidated at a late period of life. Separate portions of bone are often connected to it by means of ligament; nay, the ligament which descends from it to the cornu minus of the os hyoides is sometimes converted almost entirely into bone, and appears as a prolongation of the styloid process.

Between the styloid and mastoid processes, but nearer to the former, is a round hole called the *foramen stylomastoideum*: this is the external opening of the aqueduct of Fallopius, through which the facial nerve passes.

A considerable excavation is formed in the bone near the root of the styloid process, for lodging a dilated portion of the internal jugular vein; and this contributes to the formation of the *foramen lacerum in basi cranii, or, f. jugulare*, through which that vein, together with the par vagum quits the cavity of the cranium. The passage of the nerve is separated from that of the vein by two projecting bony spines, which almost form a distinct opening.

The *foramen caroticum*, which is the entrance of the carotid canal, is a round hole placed towards the inner and anterior part of the last-mentioned opening. From this part the canal ascends first perpendicularly, for a very short space, and then is reflected at an obtuse angle forwards and inwards. Besides the internal carotid artery, the filaments which form the origin of the great sympathetic nerve pass through this canal.

We proceed to speak of the internal surface of the temporal bone. We observe here the extent to which this bone overlaps the parietal; which is often nearly half an inch in particular situations. The surface of the squamous portion is every where marked by the convolutions of the brain; and the bone is very thin between the eminences which rise in the intervals of the convolutions.

The mastoid portion is hollowed by a broad and deep channel containing the lateral sinus (*fossa sigmoidea*;) and the mastoid foramen, or foramina, open into this channel. The veins which occupy these holes are the emissaria of Santorini.

A sharp ridge, to which the tentorium cerebelli is affixed, and on which a groove is discerned for lodging the superior petrosal sinus, divides the petrous part of the bone into two uneven surfaces; of which one is superior and anterior, and the other inferior and posterior.

A very conspicuous convex eminence is placed on the former of these, and it denotes the situation of the superior semicircular canal. Towards the front and inner part of this prominence is placed a small hole, which enters the bone obliquely under a thin bony plate, and does not, therefore, come very readily into view, except in the separate bone. A branch of the Vidian nerve enters this opening to join the facial nerve: hence, it is very strange that

Blumenbach states the foramen in question to be the internal opening of the Fallopiian canal; which, on the contrary, is found in the meatus auditorius internus. (Beschreibung der Knochen, p. 129.) The carotid canal terminates towards the apex of the petrous portion by an irregular opening, which is completed in the recent subject by the attachment of the dura mater.

Just in front of this canal is a small opening, through which the Eustachian tube enters the tympanum. This is placed in the angle of junction between the squamous and petrous portions, at the front of the bone. The cartilaginous part of the tube, previous to its entering this opening, lies in a kind of broken and irregular groove, between the under surface of the petrous bone, and the posterior margin of the great sphenoid ala.

On the posterior surface of the petrous portion there is found, in front of the fossa sigmoidea, an oblique slit of various appearance in different subjects; through which the *aqueductus vestibuli* passes. Just over this is a slight indication of the upper end of the inferior semicircular canal. Still farther forwards is found a large opening leading into the bone, and appearing to terminate, on a superficial view, in a blind extremity. This, which is the *meatus auditorius internus*, receives the seventh pair of nerves, and will be more particularly described in the account of the bony organs of hearing. Just under this opening, and at the edge of the foramen lacerum, is a lunnet-shaped cavity (*apertura conoidea, Soemmerring*), at which the *aqueductus cochleæ* terminates.

Between the margin of the petrous portion, and the basilar process of the occiput, a groove is formed of various magnitudes in different subjects; in which the anterior petrosal sinus lies.

The following muscles are attached to the temporal bone. 1. Temporalis; 2. Masseter; 3. Sterno cleido-mastoideus; 4. Trachelomastoideus; 5. Splenius capitis; 6. Biventer maxillæ inferioris; 7. Stylohyoideus; 8. Styloglossus; 9. Stylopharyngeus; 10. Constrictor pharyngis superior; 11. Tensor tympani; 12. Laxator tympani; 13. Externus mallei; 14. Stapedeus; 15. Retrahentes auriculam.

The foramina of the bone are, 1st. One in the fissura Glaseri, for the passage of the chorda tympani; 2. A part of the *foramen lacerum in basi cranii*; 3. *F. caroticum*; 4. *F. stylomastoideum*; 5. *Meatus auditorius externus*; 6. *F. mastoideum*; 7. *Meatus auditorius internus*; 8. Entrance of the Vidian nerve; 9. Passage of the Eustachian tube; 10, 11. Terminations of the aqueducts of the labyrinth; 12. A common hole between the point of the petrous portion and the body of the sphenoid; described in the account of the latter bone.

Description of the bony Part of the Organ of Hearing.

The petrous portion of the temporal bone contains the organ of hearing, which we shall describe at present, since it is formed by the bone. As this seems to be the most natural arrangement, it has, consequently, been adopted by the most approved modern anatomists.

Few parts of the animal body afford a more attractive object of minute investigation than the organs of hearing; both on account of the admirable structure of the parts, and from the great importance of their functions. Hence, they have been so minutely examined by several great anatomists for the last two hundred years, that we possess more accurate and detailed descriptions of them, than of any other part in the body.

The great and modest Fallopius was the first who opened the

the right path in this investigation: he discovered most of the important points in the structure of the internal ear; and has described them in his invaluable "Observationes Anatomicae," Venet. 1561, 8vo. Of succeeding writers, who have illustrated this subject in particular works, we shall enumerate those only who may be considered as classical authors. Eustachius, who indulged, indeed, too much in a spirit of jealousy towards his contemporaries and rivals, but seems almost to have been born for the purposes of anatomical discoveries, will stand first on the list. His "Epistola de auditu Organis," is contained in the "Opuscula Anatomica," Venet. 1564, 4to.; and the same subject is illustrated in some of his plates, which did not appear till the year 1714.

Great progress was made in developing the structure of this organ by the cotemporary labours of several eminent anatomists about the end of the 16th and commencement of the 17th century. The first edition of Duverney's "Traité de l'Organe de l'Ouïe," appeared in 1683; and it is contained in the "Œuvres Anatomiques" of that author, which were not published till 1761. Mery opposed to this his "Description de l'Oreille," which came out with Lamy's "Explication Mécanique des Fonctions de l'Âme Sensitive."

Valsalva's "Tractatus de aure Humanâ," Bonon. 1704, 4to. is the produce of sixteen years' labour; during which time the author examined more than a thousand crania. Yet he met with a rival in Vieussens, whose "Traité Nouveau de la Structure de l'Oreille" appeared at Toulouse in 1714. He had, however, a more powerful defender in his illustrious friend Morgagni: who published Valsalva's works at Venice in 1740, accompanied with 18 epistles of his own, chiefly relating to the ear. A German anatomist, the indefatigable Cassebohm, who had prosecuted the investigation with that persevering industry which characterises the nation, had made greater progress in unfolding the structure of the ear, than either of the last-mentioned anatomists. His "Tractatus VI. de aure Humanâ," Halle, 1734 and 1735, present a model for such researches, which will hardly be exceeded. Lastly, a most perfect work on this subject has lately appeared in Germany; for which we are indebted to the celebrated Soemmerring. His "Abbildungen des Menschlichen Ohrorganes," Frankfurt on the Mayn, 1806, contain a most elegant series of engravings, representing the anatomy of the whole organ with that minuteness and fidelity, which the well-known abilities of the illustrious author would naturally lead us to expect.

Besides the above-mentioned works, in which the anatomy of the whole organ is considered, there are several excellent treatises on particular parts of the subject. Meckel's "Dissertatio de Labyrinthi Auris Contentis," Argent. 1777; Scarpa's "De fenestra rotunda," Mutinæ, 1772; and the "Disquisitiones Anatomicae de Auditu & Olfactu," Ticini, 1789, of the same author, are works of the highest merit: and the engravings in the last of these books are executed with unrivalled elegance. Much information may likewise be derived from the 4th book of Albinus's "Annotationes Academicæ;" from Monro's "Observations on the Nervous System;" and from Cotunnii's work "De Aquæductibus Auris Humanæ," Neapoli, 1760.

The organ of hearing, as formed in the bone, consists of three divisions. First, the external portion, or *meatus auditorius*; which terminates at the attachment of the membrana tympani; secondly, the middle portion, or *cavity of the tympanum*; and thirdly, the internal portion, or *laby-*

rinth. To these may be added the *officula auditus*, as a fourth division of the subject.

Of the Meatus Auditorius.

The external circumference of this canal is formed of the rough bony plate, passing obliquely from without inwards and forwards, which separates the meatus from the glenoid cavity of the temporal bone, and a part of which forms the processus vaginalis. The external opening of the passage is the broadest part of the canal: its greatest diameter is in a line passing from the upper and anterior, to the lower and posterior part. It penetrates the bone in an oblique direction, being inclined inwards and forwards. The upper surface of the meatus is considerably shorter than the lower, in consequence of the oblique position of the membrana tympani, which closes the canal internally, and forms the boundary between the external and middle divisions of the organ. This membrane has its superior margin directed considerably outwards, and its lower edge turned proportionally inwards.

In the foetal state the membrana tympani is stretched on a bony ring, *annulus auditorius*; which is somewhat oval in shape, more or less deficient at its upper part, where it joins the squamous portion, rough on its outer margin, and grooved internally, for the attachment of the membrane. Its posterior portion is thinner and sharper than the anterior part; which is grooved above for the reception of the long process of the malleus. This ring grows gradually broader, particularly at its lower part; and it is generally consolidated above to the temporal bone, before birth. The formation of the meatus proceeds, as the ossification of the skull advances; and it is completed about the age of puberty. This bony canal is therefore formed by a gradual increase in the breadth of the foetal annulus auditorius.

Cavity of the Tympanum.

This includes the space situated within the membrana tympani. Its surface is irregular, rough, and cellular in some parts. Its extent is much increased in the adult, by the formation of the mastoid cells. Besides the three *officula auditus*, which are contained in this cavity, we meet with the following parts.

The *fenestra ovalis*, is an oval opening, situated in a depression near the middle of the cavity of the tympanum; and filled by the base of the stapes. Its upper margin is more arched, and the lower more nearly straight. It opens into the vestibulum.

The *promontory* is a considerable rising, just below the fenestra ovalis. It indicates the commencement of the cochlea; and has the *fenestra rotunda*, which opens into the cochlea, placed just under it. This opening is occupied in the recent subject by a delicate membrane.

Above and behind the fenestra ovalis is placed a prominence, indicating the situation of the anterior extremities of the upper and outer semicircular canals. In front of the same fenestra is a considerable groove, which forms the opening of a canal running obliquely forwards, close to the Eustachian tube, and holding the tensor tympani muscle. The opening of the Eustachian tube itself is situated at the upper and anterior part of the tympanum. Just behind the fenestra ovalis is a very small hole, as if formed by the point of a needle, through which the thread-like tendon of the stapedeus comes out of the bony cavity in which the muscle itself lies. At some little distance towards the outside of the last-mentioned opening, and in the same horizontal plane with it, is another very small hole, leading to a canal, which terminates

C R A N I U M.

terminates in the aquæductus Fallopii, and transmits the chorda tympani. Over the fenestra ovalis, between the groove that holds the tensor tympani, and the opening for the tendon of the stapedeus, a portion of the aquæductus Fallopii appears. This canal conveys the facial nerve from the meatus auditorius internus, to the foramen stylomastoideum.

The mastoid cells open into the upper and posterior part of the tympanum. In the fœtus, where these cavities are not yet formed, there is a cell between the squamous and petrous portions of the bone, and therefore just over the tympanum: this forms in the adult the communication between the mastoid cells and tympanum.

The cavity of the tympanum contains the three *ossicula auditus*; viz. the *malleus*, *incus*, and *stapes*; which are distinguished by their diminutive size, and the elegance of their formation, and possess the important office of conveying the sound from the membrana tympani to the labyrinth. They are articulated to each other, connect the membrana tympani to the fenestra ovalis, and admit of being moved by three small muscles attached to them at different parts. They are the only bones in the body which acquire their complete size and form, and perfect ossification, before birth. Their structure is very constant on the whole, considered in their chief constituent parts; but variations in form are by no means unusual.

The *malleus* (which, together with the *incus*, was discovered about the end of the 15th century) has received its name from a supposed resemblance to a hammer. It resembles a short, knotty, and curved club; and is divided into the head, the handle, and two processes. The *handle* (*manubrium*) is closely attached, through its whole length, to the membrana tympani. The lower extremity of this part is placed about the middle of the membrane, which it draws inwards, so as to occasion a depression on the outer surface. At the upper end of the handle is placed the short process (*processus obtusus*) of the bone.

Rather higher than this process, there is a very slender sharp-pointed one, standing forwards from the neck of the bone: it is called the long process of the malleus (*processus spinosus*.) In young children it sometimes forms a very long curved and elastic bony spine. It rests in a groove of the annulus auditorius, and often becomes ankylosed to that part in the course of years.

Rau first discovered this part in the state in which it forms a bony spine, and hence arose the appellation of *processus Ravianus*. But the long process, as it is usually formed, was known long ago; (see S. Alberti "Hilior. plerarumque partium corp. hom." 1583. p. 84. & Fab. Hildanus "Die Fürtrefflichkeit der Anatomie," 1624. p. 190.) It is also delineated by Folius in his "Nov. Auris internæ delineat." Venet. 1645.

The *head* of the malleus stands off from the handle at an obtuse angle. It forms a rounded eminence connected to the handle by a contracted neck. It lies opposite to the upper margin of the annulus auditorius, and the articular surface, by which it is connected to the incus, is divided by a kind of groove into two parts.

The tensor tympani muscle is attached to the short process of this bone; and the externus mallei to the long process. The laxator tympani (of the muscular nature of which some entertain doubts) is inserted into the neck of the malleus.

The *incus* is shorter but thicker than the malleus; and its figure was compared not unaptly by Vesalius to that of a grinding tooth. It lies between the malleus and stapes, and is divided into a body, and two processes. The body of the bone forms an articular surface, with a middle eminence,

adapted to the head of the malleus. One of the processes (*the short leg* of the incus) is shorter and broader; and flattened in its form. This is placed in the same line with the processus spinosus of the malleus; but is turned backwards. The other (*the long leg*) is more slender, and projects into the middle of the tympanum, where it lies nearly parallel with the handle of the malleus; the chorda tympani passing between them.

Most anatomists describe a fourth bone, under the name of *os lenticulare*, or *orbiculare*, as being placed at the end of this long process, just where it is articulated to the malleus. On this subject we agree with Blumenbach ("Beschreibung der Knochen," p. 144.) in stating, that careful investigation in the most natural and ordinary structure of parts will shew this supposed fourth bone to be nothing else than an *epiphysis*, and not indeed a constant one, of the long *apophysis* of the incus. It is often wanting, even in *ossicula auditus*, which are in other respects most perfectly formed. This fact has been ascertained by Blumenbach in the crania of negroes and North American savages. It can only be separated in the adult by the application of some force; and the surface has afterwards a manifestly broken appearance, when examined with the microscope. And when, on the contrary, as sometimes happens, a really separate bit of bone is found between the incus and stapes, this can be no more considered as belonging to the ordinary natural structure, than those other supernumerary ossicula which are occasionally met with in man and animals. (See Teichmeyer "Vindicæ quorund. inventor. Anat." 1727. Cassebohm "Tractat. 4. p. 55.)

The third bone is the stirrup (*stapes*, *stapha*), which is the smallest in the skeleton, but very elegant in its formation, and possessing a peculiar and determinate figure, from which it derives its ordinary and well adapted name. It was first discovered by Ingrassias ("Comment. in lib. Galeni de ossibus," p. 57.) The situation of the stapes is horizontal; and it possesses a head, two crura, and a basis. The head is excavated into an articular surface for the long leg of the incus; and there is a slight prominence at its posterior part, denoting the attachment of the stapedeus muscle. The anterior crura of the stapes is straighter, and consequently shorter than the posterior, which is thicker and more curved. They are both grooved internally, for the attachment of a membrane which fills the opening between them. The basis is exactly adapted in form to the fenestra ovalis, which it fills; hence the superior margin is curved, and the inferior straighter.

The internal Division of the Ear, or the Labyrinth.

In a fœtus of six, seven, or eight months, the labyrinth consists of a peculiar firm, but thin and brittle bony substance, surrounded by an osseous matter, of a loose and spongy texture, which can be easily removed, so as to exhibit the labyrinth without much difficulty. The formation of this part is complete at the time of birth, like that of the *ossicula auditus*; but the ossification of the petrous portion in general is not so far advanced; for the superior femicircular canal is distinctly visible in the basis crani through its whole course; and there is a peculiar hollow within its curve, filled by a process of dura mater. The posterior canal comes also partially into view at this time; as the ossification of the skull advances, the petrous portion becomes more compact in its texture, and surrounds the canals more completely; it is consolidated at last into a particularly hard and dense bone, and the labyrinth at that time, instead of consisting of a substance distinct from the rest of the temporal bone, seems to have its cavities excavated in the hard

and almost impenetrable texture of the petrous portion. Hence the temporal bone of the fetus must be selected for the purpose of dissecting and examining the organ, and of making preparations of it.

The labyrinth consists of a *vestibulum*, or middle part; *cochlea*, or anterior; and *three semicircular canals*, or posterior portion.

The *vestibulum*, to which the fenestra ovalis leads, is a cavity of an elliptical form, in which two slight depressions are observable; an inferior and posterior one (*fovea hemisphærica*,) a superior and external one (*f. semielliptica*,) which terminates towards the orifice of the aquæductus vestibuli. These two foveæ are separated from each other by a sharp bony spine, with a denticulated extremity (the *pyramis* of Scarpa).

There are seven openings into the vestibulum: *viz.* five from the three semicircular canals (one end of the superior and posterior canal joining together, and terminating by a common orifice;) one from the superior scala of the cochlea; and one from the aquæductus vestibuli.

The *cochlea* is a convoluted bony tube, resembling externally a snail shell; from which circumstance its name is derived. It consists of two turns and a half, its axis is directed downwards and outwards. The base or broadest part is turned towards the termination of the meatus auditorius internus; and the first or largest turn forms at its commencement the promontory of the tympanum. The canal of the right cochlea turns towards the right; while that of the left follows just the opposite course. The bony canal, like the tube of the snail shell, turns round a central part called the *modiolus*, *nucleus*, or *columella*. This is hollow for the reception of a large branch of the auditory nerve; and in shape it is funnel-like; (*scyphus* of Vieussens.)

The canal of the cochlea is divided through its whole course into two passages or *scale*, a superior and an inferior one, by means of a most curious and artificially fabricated septum (*lamina spiralis*) which terminates at the extremity of the organ in a small hook (*hamulus*.)

Where this septum is attached to the modiolus it is bony; but it possesses a membranous structure towards the convolutions of the tube. The osseous portion of the lamina spiralis consists of two very thin plates, between which the ramifications of the auditory nerve are expanded in the form of a striated or net-like substance, to the fibres of which the bony plates are adapted. The branches of the nerve also leave impressions on the surface of the modiolus.

The lower scala of the cochlea terminates at the fenestra rotunda of the tympanum, and is therefore called *scala tympani*. The superior one opens into the vestibulum, and is distinguished by the name of *scala vestibuli*. Its aperture is just under the fenestra ovalis. The fenestra rotunda, which is closed by a thin membrane (*tympanum secundarium*,) is the termination of the scala tympani. The membrane is attached to a groove, which is visible on the inner margin of the opening, and is also connected to the membranous portion of the lamina spiralis.

The three semicircular canals are distinguished, according to their situation, by the epithets superior, inferior, and exterior. One extremity of each canal is rather larger than the other, and forms a dilatation called the ampulla. The smaller ends of the superior and inferior canals join to form a common opening, which is placed just opposite the fenestra ovalis.

The aqueducts of the ear are two very minute canals commencing in the labyrinth, and terminating by open orifices on the surface of the temporal bone. The *aquæductus cochleæ* begins in the scala vestibuli, and penetrating the bone, ter-

minates by an expanded orifice just under the meatus auditorius internus. The *aquæductus vestibuli* has its commencement just below the common opening of the superior and inferior semicircular canals, and terminates on the posterior part of the inner surface of the petrous portion, as mentioned in the description of the bone.

The meatus auditorius internus seems, on a superficial view, to terminate in a blind extremity. It is divided by a projecting bony ridge into two parts; an upper one, from which a canal commences, transmitting the facial nerve to the foramen stylomastoideum; the *aquæductus Fallopii*. The other portion of the meatus gives passage to the filaments of the auditory nerve. We may observe in it a considerable depression, which is the basis of the cochlea, and has therefore a convoluted spiral appearance; this is perforated through its whole extent with numerous foramina for the passage of those branches of the auditory nerve, which supply the cochlea; it is called by Scarpa *tractus spiralis foraminulentus*. By the side of this spiral impression are some smaller foveæ perforated in the same way for transmitting filaments of the auditory nerve to the ampullæ of the semicircular canals; these are the *maculæ cribrosæ* of Scarpa.

The *ethmoid bone*, so called from $\epsilon\theta\mu\omicron\varsigma$, a sieve, and $\epsilon\iota\delta\omicron\varsigma$, form, is known also by the name of *os cribroforme*, and is described by Galea under the term of $\sigma\pi\omicron\lambda\gamma\omicron\sigma\iota\delta\eta\varsigma$, or the *sponge-like bone*. It is the smallest of the eight bones of the cranium, and remarkably light on account of its numerous cells; but derives considerable importance from its delicate and intricate structure, and from the circumstance of its containing the chief organs of smelling. It has been excellently described by Schneider in his small, but invaluable work, "De ossæ Cribrosæ et sensu ac Organæ Odoratus." Witteb. 1655. 12mo. which forms an epocha in physiology, as refuting the twofold error which had previously been universally received; *viz.* that the odorous particles ascended through the ethmoid foramina into the brain, and that the mucus of the nose descended from the same part.

It appears, on a superficial view, to consist of an irregular assemblage of thin bony plates, intercepting various cavities; and not to admit of illustration by comparison with any known object.

It may be most conveniently divided into three parts. 1. The *cribriiform plate*: 2. The *nasal plate*, with the *crista galli*: 3. The intricate lateral portions.

The cribriiform plate, from the structure of which the whole bone has derived its name, fills up the ethmoidal fissure of the *os frontis*. This, with the *crista galli*, is the only part of the bone visible from the cavity of the cranium. Its position is horizontal, and lower than the orbital processes of the frontal bone, between which it is situated. It consists of a thin plate of bone, perforated by several small foramina, which lead to the nose, and are so numerous as to have suggested the comparison to a sieve. The filaments of the olfactory nerve penetrate this plate, which varies considerably in length, breadth, and general figure. The small ganglia of the olfactory nerves lie on this plate; one on either side of the *crista galli*.

The *crista galli*, which is the thickest and strongest part of the ethmoid bone, projects longitudinally from the middle of the superior surface of the cribriiform plate. It is situated towards the front of the bone; and is occasionally bent towards the right or left. Its superior edge is generally sharp, but sometimes obtuse. Towards the front it is joined by two small processes (*apophyses alares*) to the nasal portion of the *os frontis*, and thereby contributes to the formation of the foramen cæcum.

C R A N I U M.

The substance of the *crista galli* is generally occupied by medullary cavities; but it is occasionally formed into a hollow communicating with the frontal sinuses.

The *nasal plate* of the ethmoid bone is a thin, broad, generally flat, but sometimes curved lamina, descending perpendicularly from the middle line of the under surface of the cribriform plate into the cavity of the nose; where it forms the upper and anterior portion of the *septum narium*. It is connected in front to the nasal spine of the *os frontis*, and to the suture, which joins the *os nasi*. Its inferior margin, which is thicker than the rest, and has a somewhat spongy appearance, rests on the cartilaginous portion of the *septum narium*; its posterior edge is partly joined to the vomer, and partly to the body of the sphenoid bone.

The lateral portions of the ethmoid bone, which, on account of their complex structure, have been called the *labyrinth*, may be divided into three parts. The *concha narium*; the *cells*; and the *os planum*, or *papyraceum*.

The *concha narium superiores* (*ossa turbinata*, or *spongiosa super.*) are formed of a rough bony plate, having a spongy appearance, and placed parallel to the *septum* of the nose. Its superior margin is attached to the cribriform lamella, while the anterior extremity is connected to the nasal process of the upper jaw. There is a deep depression on this plate running from before backwards, and dividing it into two portions; each of which has a spongy convoluted appearance, and has a convex surface opposed to the *septum nasi*, while it is concave towards the orbit.

The lower of these two portions, which is much the largest, constitutes the *concha media* (*os turbinatum*, or *spongiosum medium*) of the nose. It hangs into the middle of the nasal cavity, and terminates by a convex unconnected margin, which runs longitudinally from before backwards. It has a more convoluted structure than the superior one. Its concave surface covers the *meatus narium medius*.

The upper portion (*concha super.* or *Morgagniana*; *os turbinatum*, or *spongiosum super.*) is much smaller than the preceding. It terminates in a projecting convex edge, turned towards the cavity of the nose. The space left between this and the preceding part is the *meatus narium superior*. Some unimportant varieties occasionally occur in these parts, as a division of the upper *concha* into two smaller ones by a groove, &c.

The ethmoid cells or sinuses fill up the space between the *conchæ* and the *os planum*. They are partially exposed along the upper and outer edge of the bone; but are covered at this part in the perfect cranium by the edge of the orbital process of the *os frontis*. The anterior cells are also covered extensively by the *os unguis* and the nasal process of the upper jaw, and the posterior ones by the orbital portion of the *os palati*. The number and arrangement of these bony cavities is very irregular. They open mostly into the superior meatus of the nose. The bony laminae, which divide them from each other, are the most delicate in the whole skeleton.

Just under the anterior cells there is a thin hook-like convoluted bony plate, connected to the cells or *concha media*, and extending backwards; it is called by Blumenbach *processus uncinatus*.

The cells of the ethmoid bone are covered towards the orbit by a thin plate of an oblong form, which, from its smoothness, has been termed *os planum*, and from its excessive thinness, *os papyraceum*. In conjunction with the *os unguis*, which is connected to the anterior margin of this plate, and covers the front cells of the ethmoid bone, it

constitutes the inner surface of the orbit, the partition which separates that cavity from the nose.

The nasal plate of the ethmoid bone, the *conchæ*, and the cells are all covered by the Schneiderian or pituitary membrane.

There is no muscle attached to this bone.

Foramina of the Ethmoid Bone.

1. Numerous small holes in the cribriform plate, transmitting the filaments of the olfactory nerve. These amount to two or three dozen. They are arranged, not indeed with perfect regularity, into two series; one of which, including the largest foramina, as Schneider rightly observed in his work "*De ossibus cribriformi*," runs by the side of the *crista galli*, and sends nerves to the *septum* of the nose; the other is placed towards the orbit, and dispatches the filaments, which are distributed on the surface of the two upper *conchæ*. These openings are the commencement of small and short canals, which run for various distances on the *septum* and *conchæ*, and terminate by open orifices through which the nervous ramifications come out to be distributed on the pituitary membrane of those parts. Some of these canals may be observed occasionally to reach as far as the lower edge of the middle *concha*.

Through a large opening in front, the nasal branch of the superior maxillary nerve, which enters the cranium through the anterior internal orbital hole, again quits that cavity.

Connections of the Ethmoid Bone.

1. By its cribriform plate and *crista galli*, to the orbital and nasal portions of the *os frontis*, and sphenoid bone: 2—5. By the nasal lamella, to the *os nasi*, vomer, and sphenoid bone: 6, 7. To the superior maxillary bones in the orbit and nose: 8, 9. To the *os palati*: 10, 11. To the *os unguis*.

In the *fœtus* at nine months, the formation of this bone is very incomplete; as indeed is the whole organ of smelling. The *septum* and *crista galli* are quite cartilaginous; ossification has scarcely commenced in the lateral portion of the bone; but the cribriform plate, which supports the large olfactory nerve is larger than the other parts.

Besides the well-known osteological works of Albinus and others, and the classical book of Schneider, which we have already quoted; much information concerning the structure of this bone may be derived from Santorini's "*Observat. Anat.*" and from his posthumous plates, edited by Girardi: from the 4th fasciculus of Haller's "*Icones*;" from the 6th of Morgagni's "*Adversaria Anatomica*;" and from the 2d book of Scarpa's "*Annotationes Anatomice*," the plates of which are executed with unrivalled elegance.

Bones of the Face.

The bones which have been hitherto described form the cranium properly so called: those which follow, namely, the upper jaw with the bones connected to it, the lower jaw, and the teeth are included under the appellation of bones of the face. These are chiefly concerned in forming the instruments of mastication; but they contribute likewise to the cavities of the nose and orbits.

As these tend, when viewed altogether in relation to the bones of the cranium, to distinguish the head of man from that of other animals; so they are of great importance, when considered particularly, in influencing the natural or

C R A N I U M.

individual form of the countenance. This will be more particularly considered in the general remarks on the head at the end of this article.

These bones are generally distributed into two divisions : those which form the upper jaw, or the upper immoveable share of the face ; and the bone of the lower jaw.

The upper jaw consists of six bones on each side, of a thirteenth bone, which has no fellow, placed in the middle, and of sixteen teeth. The thirteen bones are, two *ossa nasi*, two *ossa unguis*, two *ossa malæ*, two *ossa maxillaria superiora*, two *ossa palati*, two *ossa turbinata inferiora*, and the *vomer*.

The *ossa nasi* are placed at the upper part of the nose ; the *ossa unguis* are at the internal angles of the orbits ; the *ossa malæ* form the prominence of the cheeks ; the *ossa maxillaria* form the sides of the nose, with the whole lower and forepart of the upper jaw, and the greatest share of the roof of the mouth ; the *ossa palati* are situated at the back part of the palate, nostrils, and orbit ; the *ossa spongiosa* are seen in the lower part of the *naris* ; and the *vomer* helps to separate these two cavities.

The bones of the face are joined to those of the cranium by the transverse suture which runs across the orbits and roots of the nose, and by *schindylesis* ; which is the peculiar mode of connection of the vomer. They are connected together by sutures, like those of the cranium ; but they have not such conspicuous indentations, and approach therefore more nearly to the mode of union called *harmonia*. The various sutures will be mentioned in describing the individual bones, which they connect. The lower jaw, which consists of a single bone, and has sixteen teeth implanted in it like the upper ; is not joined to the other bones of the face ; but is connected by a moveable articulation with the basis cranii. It is evident from the manner in which the upper jaw is joined to the cranium, that it can have no motion, except in common with the cranium.

The *superior maxillary bones*, (*maxille superiores*.) are by far the largest bones of the upper jaw, whence the name of *maxillaria* has been appropriated to them. They serve as a basis or foundation, on which all the other facial bones rest, excepting the lower jaw. They are largely concerned in forming the cavities of the nose and orbit ; they contribute also considerably to the cheeks and palate ; and they contain the upper series of teeth.

Each superior maxillary bone may be divided into a body, and four apophyses or processes ; viz. the *nasal*, *zygomatic*, *alveolar*, and *palatine*.

The body of the bone displays four surfaces or sides ; viz. the external or *malar* ; the superior or *orbital* ; the inferior or *palatine* ; the internal or *nasal*.

The malar surface is the most extensive of all. It commences below, by an arched or convex margin, just above which it has some slight eminences, (particularly towards the anterior part, where it acquires from this cause a fluted appearance,) from the situation of the fangs of the teeth. It terminates behind in a rough prominence, called the *tubercle*, which, besides the tracks and foramina of the vessels and nerves proceeding to the upper teeth, contains a muscular impression from the origin of the buccinator, and is marked also, together with the neighbouring malar process, by the attachment of the masseter. The malar surface contains, towards the front of the face, a superficial hollow, called the maxillary fossa, in which the infraorbital canal opens, about a quarter of an inch below the margin of the orbit. Just over this a small suture is observed, continued from the fissure of that canal. It terminates on its inner

edge in forming a semilunar notch, which, with the excavation of the opposite bone, forms the heart-shaped external aperture of the nostrils ; in the middle and lower part of which a rough bony prominence is placed, called the nasal spine. Above this prominence commences the nasal process, which, growing gradually narrower, ascends between the *os nasi* and *unguis*, along the side of the nose. It is convex on its outer surface, and slightly hollowed within. Its upper extremity terminates in a rough broken surface, attached to the internal angular process of the frontal bone. Its posterior and inner surface is marked by a deep groove ; in which a part of the lacrymal sac and nasal duct is lodged. The bony cavity for containing these parts is completed by the apposition of the *os unguis*.

The *orbital surface*, which has a somewhat triangular shape, is continued towards its lower and outer part into the zygomatic process : this is a broad surface having numerous depressions, and pointed eminences, by means of which it is firmly connected with the *os malæ*. A groove appears towards the back part of the orbital surface, and gradually deepens into a bony canal, called the *infraorbital*, hollowed out in the substance of the bone, but displaying a fissure in that part of its sides which is towards the orbit. The infraorbital branch of the superior maxillary nerve, and an artery of the same name from the internal maxillary, go through this canal, and come out on the face at the infraorbital foramen. In other parts, the orbital surface of this bone, which constitutes the whole inferior part of the cavity, is perfectly smooth. Its inner edge is joined to the *os unguis*, *os planum*, and *os palati* ; in front it has a rounded margin, forming a small part of the rim of the orbit ; and towards the back part it constitutes, with the sphenoid bone, the inferior orbital fissure.

The palatine surface has an external elliptical margin, which forms the alveolar process, containing sockets for eight teeth. This process is made up of an external and thinner, an internal and thicker plate of bone ; with transverse processes connecting these together, and thereby separating the different alveoli. The three front sockets, which hold the incisor and canine teeth, are nearly round in their form, and are simple cavities ; that of the canine tooth is longer and deeper than any other. The two next alveoli, which hold the bicuspides, are rather flattened laterally, and divided towards their upper part into two slight hollows. The sixth and seventh, containing the first and second grinders, are the largest sockets, and are subdivided into three cavities ; one of which is placed towards the palate, and the other two towards the cheek. The eighth is subject to great variety ; and may be either simple, double, or triple. The posterior alveoli, and their septa, are much more spongy in their texture than the anterior ones.

As the use of the alveolar process is merely that of receiving the fangs of the teeth, this part is not formed until after the teeth have appeared through the gum ; it grows round the root of the tooth, in proportion as the body rises in the mouth. When these organs are lost, the alveoli are soon after removed, so that the jaw of an old person resembles, when all its teeth are gone, that of a young child, which has not yet got any. When a single tooth is lost, and the contiguous ones remain, the alveolus is not always absorbed ; but the vacancy is filled up by bony matter, as if the two laminæ of the alveolar process had been pinched together, and united in a sharp line running between the two alveoli, which remain before and behind that of the lost tooth. The length of the face must of course be most materially affected by these changes in the jaw ; as we shall explain

C R A N I U M.

pain more fully in that part of this article which relates to the teeth.

The palatine portion of the upper jaw is concave, and very rough on its surface, where the arteries and nerves leave very manifest traces, being sometimes surrounded by complete bony rings.

Towards the front a small transverse fissure crosses the palate, and is lost between the incisor and canine teeth; hence a slight analogy arises to the intermaxillary bone of brutes. But there is this very obvious and important distinction to be observed; that no vestige of future can ever be traced in the human subject between the alveoli, much less on the upper and anterior surface of the jaw: so that the similarity to the structure of the quadruped is very remote. The fissure in question is more distinct in young than old subjects, and it is called by Blumenbach *futura incisiva*. Although this has been overlooked by several modern osteologists, it was observed and accurately described by the great anatomists of the sixteenth century, Vesalius, Fallopius, and Columbus. It is also mentioned by Riolan (*Anthropog.* p. 649.) Galen has expressly enumerated an intermaxillary bone among the component parts of the human face; and Vesalius very justly inferred from this, amongst many other equally striking proofs, that the anatomical descriptions of that author, which had been universally received with the most implicit deference till that time, had not been drawn from the examination of the human subject. This attempt to rescue mankind from error and prejudice drew upon him nothing but hatred and reproaches from his contemporaries, who were driven to the most absurd and causeless arguments in defence of their idol, Galen. One of them suggested that an intermaxillary bone might have belonged to the human face in former times. See Jac. Sylvii *de pulso calumniarum vesalii eujusdam in Galenum*. The inner margin of the palatine surface is joined by the middle or longitudinal palate future to the corresponding part of the opposite bone. The posterior edge is united by means of the transverse palate future to the os palati.

The *nasal surface* displays; 1. A small sinus which covers some of the anterior ethmoidal cells. 2. Towards the front, a margin joined to the os nasi by the lateral nasal future. 3. A groove varying in depth, which lodges the nasal duct; this is sometimes almost a complete canal. 4. A rough line for the attachment of the inferior concha or turbinated bone. 5. A large irregular aperture leading to the maxillary sinus. Sometimes the superior margin of this opening forms cells, which join those of the ethmoid bone. The nasal surface is then continued into the floor or bottom of the nose, which is rather contracted towards the front. In the future, which joins it to the opposite bone, the inferior margin of the vomer is implanted. A rough prominence is formed at this part, with a groove in the middle (*crista nasalis*) for receiving the vomer.

The *maxillary sinus* (*antrum maxillare*, or *Higbmorei*) of which the rudiments may be perceived some time before birth, is the largest cavity in any bone of the head, and possesses a very irregular figure. The various surfaces of the upper jaw, which we have just described, are merely thin plates of bone forming the walls of the sinus. It is only separated above therefore by the orbital surface from the orbit: it extends behind to the tubercle, and rests below on the alveoli of the back teeth, which are separated from it by a very thin bony plate; nay, in some instances, the fangs of the teeth are visible within the sinus. The sockets of the three grinders, and two bicuspides lie under the sinus. It opens into the middle meatus of the nose;

the aperture being much contracted by the ethmoid, palatine, and inferior turbinated bones.

The substance of the upper jaw-bone contains medullary cells in its thicker parts only; for instance, at the root of the nasal process, and just below the entrance of the nostrils, for the palatine arch is considerably attenuated towards its back part.

Canals and foramina of the superior Maxillary Bone.

1. *Canalis infraorbitalis*, and foramen infraorbitale.
2. *Foramen incisivum*, or *palatinum anterius*: a round opening in the middle palate future, just behind the incisor teeth: it communicates by a small aperture with both nostrils. A small twig of the superior maxillary nerve, and some insignificant blood-vessels pass through it. The nose and palate sometimes communicate through this opening, while the bones are still covered by the soft parts.

3. *Canalis lacrymalis*.

4. *Canalis pterygopalatinus exterior*, and *foramen palatinum posterius*; are formed between the maxillary and palate bones, and transmit the palatine artery and nerve.

5. *Fissura orbitalis inferior*; or spheno-maxillary fissure; a vacancy at the lower and outer part of the orbit between the sphenoid and upper jaw-bones. The infraorbital artery and nerve pass through this fissure.

The following muscles are attached to the superior maxillary bone: 1. Orbicularis palpebrarum, to its nasal process; 2. Obliquus inferior oculi to the front of the orbital surface; 3—5, a part of the masseter muscle, of the pterygoideus externus, and buccinator; 6. Levator labii superioris and alæ nasi; 7. Levator anguli oris. 8. Nasalis labii superioris; 9. Compressor narium; 10. Depressor alæ nasi.

Connections of the superior Maxillary Bone.

By the upper end of the nasal process to the os frontis, by means of the transverse future;—at the side of this process to the os unguis by the lacrymal future;—to the os nasi by the lateral nasal future;—to the cheek-bone by the external orbital future;—to the os planum by the inner side of the orbital surface, by means of the ethmoidal future;—by the back of its tuberosity to the os palati by the palato-maxillary future;—by the posterior edge of its palatine lamella, to the os palati, by the transverse palate future;—to the opposite bone by the longitudinal palate future;—to the vomer, along the superior surface of the last-mentioned future;—to the inferior concha or turbinated bone;—to the teeth by gomphosis.

Superior Maxillary Bone of the Fetus.

In the fetus at full time this bone possesses the same general structure as in the adult; but its parts have a different relation to each other. It consists however of a single piece only. The length of the bone is much less than in the adult, from the different structure of the alveolar portion; and from the same cause the palate, which is considerably arched in the adult, is nearly on a level with the alveolar surface at this time. Hence the remarkable shortness of the face. The orbital surface and nasal process are the most completely formed. There is, properly speaking, no alveolar process; but six large cells, containing the rudiments of the teeth, are hollowed out in the substance of the bone. This occasions the external surface to assume a tuberculated appearance; which is most conspicuous in young fetuses. The maxillary sinus is very small.

The *os male*, or cheek-bone, is generally called, in Latin, *os jugale*,

C R A N I U M.

jugale, or *zygomaticum*, from the share which it contributes to the formation of the zygoma. It is a thick and strong bone, slightly convex on its outer surface, but hollowed internally; connecting the superior maxillary bone to the *os temporis*, and forming more than one-third of the margin of the orbit.

It possesses a somewhat quadrangular figure with three thick and one thinner sides; but the proportion of these margins to each other varies considerably.

It may be divided into three processes; the *maxillary*, *orbital*, and *zygomatic*.

The maxillary process is the broadest, and includes the whole of the thin edge, beginning near the infraorbital foramen, it runs downwards and outwards. It forms a very rough irregular surface, by which it adheres most closely to the zygomatic process of the upper jaw.

The orbital portion of the bone forms a smooth rounded margin, beginning from the front of the orbital surface of the upper jaw, running first outwards, and then turning upwards to be attached to the external angular process of the frontal bone. It is continued for a short space within the orbit, where it joins the orbital surface of the great sphenoid ala. Some anatomists distinguish three orbital processes in the *os male*; a superior, which joins the *os frontis*; an inferior connected to the superior maxilla; and an internal continued inwards towards the cavity. It is the last-mentioned plate of bone that separates the orbit from the temporal fossa, and which belongs only to the quadrumanous mammalia besides man.

The zygomatic process passes backwards, to join that of the temporal bone, by means of an oblique suture; which connects the processes in such a manner, that the temporal bone forms most of the superior margin, and the *os male* the greatest part of the lower edge of the zygoma.

The upper and posterior side of the bone, which is continued from the superior orbital process to the zygoma, and which is turned towards the temporal fossa, forms a sharp ridge for the attachment of the temporal fascia. The lower side, which runs from the maxillary process along the zygoma gives origin to the masseter, and hence acquires a very rough surface.

The inner or posterior surface of the *os male*, which is concave, bounds the temporal fossa in front, and affords origin to the fibres of the temporal muscle.

A small round hole is observed about the middle of this bone, and sometimes there are even two or three such: a superficial branch of the superior maxillary nerve penetrates this foramen, and blood-vessels sometimes pass in this direction.

The zygomatic muscles, the masseter, and the temporal, are attached to the *os male*.

The substance of the bone is thick, hard, and compact; including but little medullary structure.

Connections of the Os Male.

By its superior and internal orbital processes to the frontal and sphenoid bones, by means of the transverse suture;—to the superior maxillary bone by the internal orbital suture, within the orbit, and by the external orbital suture towards the cheek;—by the zygomatic suture to the temporal bone.

State of the Bone in the Fetus.

As the cheek bones are the chief means of uniting the upper jaw firmly to the cranium, their formation is considerably advanced at the time of birth. Their magnitude is

considerable at this period, but their form changes afterwards. The orbital surface is large and conspicuous, while the facial and temporal portions are comparatively small.

The bones of the nose (*ossa nasi*, or *nasalia*) fill up the vacancy left between the nasal processes of the superior maxilla and *os frontis*. When viewed together, their external surface is regularly convex, and they are concave behind.

They are thick but narrow at the upper part, much broader and thinner below, where they terminate in a sharp attenuated margin. We may notice in each bone an outer and inner surface, and four margins.

The external surface is gently convex and smooth. It has usually one or more small foramina, for the admission of nutrient vessels. The inner surface is proportionally concave, rough on its surface, and marked by deep vestiges of blood-vessels.

The superior margin, which is narrow, but very thick, presents a very rough surface, by which it is closely attached to the nasal process of the frontal bone. Along the inner margin the two *ossa nasi* are united together by the middle nasal suture. The gradual change in the thickness of the bone, from its upper to the lower margin, may be observed along this part of the bone. The nasal lamella of the ethmoid bone is usually connected to the *ossa nasi*, at their line of junction to each other. The external margin rests on the nasal process of the superior maxilla. The lower edge, which is connected to the cartilaginous ala nasi, forms the upper part of the entrance of the nostrils.

The frontal muscle and compressor narium are attached to this bone.

The connections of the bone have been sufficiently detailed in the above description. On this subject we have only to remark further, the immense strength of their attachment. Their arched form, and the broad rough surface by which they are joined to the *os frontis*, renders their position so secure, that no external violence could possibly drive them in; although their lower thin edge might be easily broken. The utility of this strong union is immediately apparent, when we consider that the delicate ethmoid bone, which the smallest force would demolish, is placed directly behind the *ossa nasi*; and if this were injured, the fragments would probably be driven in on the brain.

The form of the *ossa nasi* in the fetus is very different from that of the same bones in the adult. They are nearly square; the superior margin being of equal breadth with the inferior. Their size is considerable in proportion to that of the other bones; and their formation is more advanced.

The *os unguis* or *lacrymale* is the smallest bone of the face, of considerable delicacy and elegance in its structure, and may be compared to the scale of a fish.

It is situated at the inner margin of the orbit; connected above to the *os frontis*; in front to the nasal process of the superior maxilla; below to the orbital portion of the same bone; and behind to the *os planum*. The suture which joins it to all these is called by *Monro* the *lacrymal*.

It is not so large, nor completely formed in the embryo, as the *os nasi*; but its size and development are considerable, when compared with the other bones of the face.

It contributes by nearly its whole surface to the formation of the orbit; but the lower end of its anterior margin forms a small curved hook-like process (*hamulus*), which assists in inclosing the lacrymal duct.

The external surface of the *os unguis* is, on the whole, smooth; but it is divided into two unequal portions, by a prominent and very sharp ridge (*crista longitudinalis*), which terminates below in forming the above-mentioned hamulus.

The posterior division of the bone is the largest, and may be called the *orbital* surface: the anterior or smaller portion, which forms a fossicula, contributing to the bony cavity for lodging the lacrymal bag, forms the *lacrymal* surface of the bone.

The inner surface of the os unguis is concave, and does not possess the smoothness of the external; it is marked by a groove in the situation of the crista; and it covers the anterior portion of the ethmoid cells.

The substance of the bone is of extreme tenuity, so that it is broken with the slightest force; and it is often perforated by numerous small holes in its lacrymal portion, by which the membrane gains a more firm attachment.

The palatine Bone (Os Palati).

This bone appears in the roof of the mouth like a small square portion placed behind the upper jaw; but it is considerably more extensive, being continued up the back part of the nostrils to the orbit: hence it assists in forming the two latter cavities, and in completing the bony arch of the palate. Its figure is so irregular, that it cannot be illustrated by any comparison; and it is so intricately connected to the surrounding bones, that to procure it separate and perfect in the adult state is a matter of much difficulty.

It may be divided into four portions: 1. The square palatine plate; 2. The pterygoid process; 3. The nasal lamella; and, 4. The orbital process.

The palatine plate or process forms a square and nearly level surface, occupying the vacancy left in the superior maxilla, and appearing like an uniform continuation of the palatal surface of that bone. Its superior surface forms the back part of the floor of the nose, and is smooth; the under surface is rather rough, but not to the degree which is observed in the palatine portion of the superior maxilla. The upper part of its internal edge rises in a spine, after the same manner as the palatine plate of the superior maxillary bone does, to receive the posterior part of the lower edge of the vomer. Its anterior edge is unequally rugged, for a firmer connection with the palatine portion of the maxillary bone. The internal edge is thicker than the rest, and of an uniform surface, for conjunction with its fellow of the opposite side. The posterior margin of the bone is slightly semicircular, according to the form of the corresponding portion of the velum pendulum palati: and when the two palate bones are joined, a middle projecting point is formed, from which the azygus uvulæ arises.

This palatine plate is well distinguished from the pterygoid process by a perpendicular fossa, which, applied to such another in the maxillary bone, forms a passage for the palatine branch of the fifth pair of nerves; the opening of the canal thus formed, on the palate, constitutes the posterior palatine foramen. There is another small hole behind this, through which a twig of the same nerve passes.

The *pterygoid process* (*processus pyramidalis*) is somewhat triangular, having a broad base, and ending smaller behind. The back part of this process has three fossæ formed in it; the two lateral receive the ends of the two pterygoid plates, and the middle one makes a part of the pterygoid fossa: hence the pterygo-palatine fissure, which divides the two pterygoid plates of the separate sphenoid bone, does not appear in the entire cranium, where it is filled by this pterygoid process of the os palati. The fore-side of the palatine pterygoid process is an irregular concave, where it receives the back of the great maxillary tubercle. Frequently several small holes may be observed in this triangular process, particularly one near the middle of its base, which communi-

cates a little above with the openings before-mentioned, and transmits an artery or nerve.

The *nasal lamella* of the os palati is a broad, but extremely thin and brittle, bony plate, rising upwards from the upper surface of the external edge of the palatine plate, and from the pterygoid process. It is so weak at this part, and yet so firmly attached to the maxillary bone, as to be very liable to break in attempts at separation.

From the parts where the plate rises, it runs up broad on the inside of the tuberosity of the maxillary bone, to form a considerable share of the sides of the maxillary sinus; and to close up the space between the sphenoid and the great protuberance of the upper jaw, where there would otherwise be a large slit, opening into the nostril. A cross ridge is observed on the middle internal side of this thin plate, for the attachment of the back part of the inferior turbinated bone. On the outside of this plate the perpendicular fossa made by the palatine nerve is observable.

At the upper part of the nasal plate the palate bone divides into two processes, called *orbital*; between which and the body of the sphenoid bone a hole is formed, transmitting a branch of the internal maxillary artery and superior maxillary nerve to the nostrils. Sometimes, however, this hole is proper to the palate bone, being entirely formed out of its substance.

The *anterior* of the two orbital processes is the largest, and has its fore part contiguous to the back part of the maxillary sinus; while its upper surface appears as a small triangular point in the bottom of the orbit, behind the back part of the os maxillare and planum, difficultly discernible in the entire cranium, on account of its diminutive size and remote situation. It has cells behind, resembling those of the ethmoid bone, to which it is contiguous; and it is placed on the aperture of the sinus sphenoidalis, so as to have only a round hole at its upper fore part.

The other division of the orbital portion is extended along the internal side of the upper back part of the maxillary tuberosity, to the base of the sphenoid bone, between the root of the processus azygos and pterygoid process.

The palatine portion of this bone, and its pterygoid process, are firm and strong, with some cancelli; but the nasal plate and orbital processes are very thin and brittle.

The circumflexus palati, azygus uvulæ, and a portion of both pterygoid muscles are connected to the os palati.

Foramina, &c. of the Palate Bone.

1. *Spheno-palatine*, or *pterygo-palatine notch*, or *opening*; formed between this and the sphenoid bone for the transmission of nerves and vessels to the nose.

2. *Pterygo-palatine canal* commences from the last-mentioned notch, and receives the nerve of the same name from the second branch of the fifth pair. This canal is formed almost entirely towards the lower part in the substance of the os palati; but the superior maxilla contributes to it generally at its origin. It divides below into three canals, the largest of which (*canalis pterygo-palatinus anterior*, or *major*) opens at the posterior lateral part of the palate, close to the alveolar process, by the large *posterior palatine foramina*, the formation of which is assisted by the superior maxilla. The *posterior pterygo-palatine canal* opens on the under surface of the *pterygoid process*; and the *exterior* ends between the latter process and the alveolus of the dens sapientiæ.

The chief palatine nerve, and the palatine branch of the internal maxillary artery, come through the large canal: smaller twigs of nerve pass through the other openings. There is sometimes only a single opening.

These canals and foramina may be seen in the treatise of Mekel "De Quinto pare Nervorum," and in the second book of Scarpa's "Annotationes Anatomicæ," tab. 2.

Connections of the Palate Bone.

The palate bones are joined to the maxillary, at the fore-edge of their square portions by the transverse palatine suture; by the thin nasal plate and orbital portion to the same bone, by means of the palato-maxillary suture; by the pterygoid process to the sphenoid bone by means of the sphenoid suture; by the transverse ridge of the nasal plate to the inferior turbinated bone. This union is frequently ankylosed in old skulls. By the orbital processes to the os planum and ethmoid cells, at the inner edge of its square portion, to the opposite bone, by the longitudinal palate suture, and at the upper surface of the same part to the vomer.

This bone consists, in the *tætus*, of a single piece; but its formation is incomplete. The orbital and pterygoid portions are the most perfect at that period.

The inferior turbinated Bone (Concha inferior; Os spongiosum inferius).

This bone resembles very closely, in structure and shape, that process of the ethmoid called the concha media. Realduus Columbus was the first who ascertained it to be a distinct and separate bone, "De Re Anatomicâ," p. 58. Several modern osteologists have however represented it as a process or appendix of other bones of the face; thus, Winslow describes it as a part of the os unguis; Santorini as a process of the os palati, "Obf. Anat." p. 38; and Hunauld as a portion of the ethmoid bone, "Mem. de l'Acad. des Sciences de Paris," 1730, p. 560, as Fallopius had long ago considered it. "Obf. Anat." p. 35.

It happens, however, very rarely, that the inferior concha is consolidated with either of these three bones. It might more justly be regarded as a part of the superior maxillary bone, with which it is sometimes ankylosed in the crania of persons not advanced in years, and well formed in other respects.

It is placed in the lower part and external side of the nose, and has that irregular, spongy, convoluted surface from which its names of *turbinated* or *spongy* bone are derived. The name of *concha* has been given to it from a comparison to the shell of the fresh-water muscle (*mya pictorum*), which will indeed bear a resemblance to it, if we suppose the shell placed longitudinally, with its long margin below, the hinge above, and the convex surface towards the septum nasi. The bone, however, varies both in size and form, and may sometimes be found in very elegant crania, forming a sharp edge without the usual shell-like convexity.

It is attached chiefly to the upper jaw and os palati: sometimes, however, it is connected to the processus uncinatus of the ethmoid bone, or by its upper and anterior extremity to the inner surface of the os unguis.

Ossification commences in these delicate bones about the middle of pregnancy, at which time the cartilaginous conchæ possess throughout a loose reticulated bony texture. In the newly born infant their ossification is very complete.

The external surface of the bone is concave, and its internal convex. Three margins may be observed in it; an anterior, a superior, and a posterior.

The anterior margin is the shortest, and terminates by a smooth edge; it is placed obliquely on the inside of the upper jaw, near the root of the nasal process, and covers by its attachment the termination of the nasal duct: its anterior end reaches almost to the outer margin of the orbit.

The upper margin forms a thin hook-like lamina which

closes a considerable portion of the lower part of the opening of the antrum, and rests behind on the os palati.

The lower margin is the longest and thickest of the three; very rough and spongy on its surface, and convoluted so as to form a convex edge. This covers the lower meatus of the nose.

The vomer was first recognized as a distinct bone by Columbus and Fallopius, "De Re Anatom." p. 48. "Obf. Anat." p. 33; who gave it the name of *vomer* from its form. Vesalius, on the contrary, described it as an appendage of the ethmoid bone, and he was followed in this mistake by Santorini, "Obf. Anat." p. 88. Anthony Petit in his edition of "Palsyn's Anatomy," Lieutaud and Portal, "Anat. historique et pratique de Lieutaud par Portal," vol. i. p. 66. Vidus Vidius represented it as a process of the sphenoid bone.

With the exception of its superior margin, it forms a thin and flat bony plate, and constitutes a considerable portion of the septum narium.

It is connected above to the sphenoid and ethmoid bones, below to the superior maxilla and os palati.

It has already acquired a considerable magnitude about the middle of pregnancy; but its form in the newly born child is very different from that of the adult. Its two laminae are widely distant from each other in the whole length of the upper margin, and they unite below, not to form a sharp edge, but a flat surface. It does not possess the rhomboidal form which it has in the adult, but is much narrower and longer. In progress of time the two layers approach nearer together, and sometimes are completely consolidated; or they leave at least only a small vacancy in the middle. It becomes at the same time broader, and acquires a rhomboidal form, so that it possesses four margins, *viz.* a superior, inferior, anterior, and posterior.

The superior margin is the thickest and strongest; it forms a deeply grooved surface, the sides of which form two flattened plates. The vacancy left between these receives the zygous process of the sphenoid bone, and the cornua sphenoidalia are connected to their margins.

The anterior margin is the longest, and generally has an irregular spongy edge. Its upper part supports the nasal lamella of the ethmoid bone; and on the front it is joined to the cartilaginous portion of the septum narium, which is often received into a kind of groove or fissure formed by a separation of the bony laminae.

The lower margin represents the cutting edge of the plough-share, and is received into the groove of the *crista nasalis* formed at the junction of the superior maxillary and palatine bones. Blumenbach states, that in cases of hydrocephalus internus, he has known this under edge of the bone to be driven down by the mechanical pressure of the accumulated fluid, so as to cause a fissure of the palate. "Beschreibung der Knochen," p. 221.

The posterior margin is sharp and even; it divides the back opening of the nares into two halves, running obliquely downwards and forwards from the sphenoid to the palate bone.

The lower jaw bone (*maxilla inferior; mandibula*) is by far the largest and strongest of the bones of the face. Its resemblance in form to a horse shoe is well known. It is connected only to the temporal bone by means of an articulation.

This bone, as Vesalius long ago observed, is shorter in man than in any other animal. Yet the elephant would, perhaps, form an exception to this rule, as the bone there seems to be really as short as in the human subject. It appears remarkably large, comparatively speaking, in animals

C R A N I U M.

of the monkey kind, even in such genera as are on the whole most *anthropomorphous*.

Its ossification commences at a very early period, and it has attained a considerable magnitude in fœtuses of the second and third month after conception; but its form at this period differs much from that which it possesses subsequently. In the fœtus, and in the newly born child, it consists of two distinct halves, which are connected by a cartilaginous symphysis at the chin. On account of the want of teeth it is very narrow, particularly at the sides. Its substance is hollowed out into large bony cavities, which hold the rudiments of the future teeth. The synchondrosis of the chin becomes firmly ossified in the first month after birth. In proportion as the temporary teeth make their appearance, the form of the jaw, consisting of a single piece of bone, becomes more and more developed. (The changes of its form, &c. will be more fully considered in that part of this article which relates to the teeth.) In most animals, on the contrary, the lower jaw consists throughout life of two separate pieces joined by a mere synchondrosis, which is destroyed by boiling or maceration.

The lower jaw-bone may be divided into the arch-like *body*, and into the two lateral productions (*rami*) which ascend from the extremities of the arch towards the basis cranii.

The *body* of the bone includes the *chin*, and two *lateral portions*, which run backwards to the *rami*. The former part constitutes nearly a square piece in the front of the jaw, in the cranium of a strong and well-formed man; and the lateral portions are continued backwards from this at an obtuse angle. This square form of the chin is particularly observable in the negro. But very frequently the bone forms a regular curve or arch at this part; and sometimes the chin has almost a pointed appearance. The part, where the synchondrosis existed in the fœtus, is still called the symphysis of the bone. The name of *basis* is applied to the inferior edge of the jaw-bone; extending from the chin in front to the *angle*, or part at which the *ramus* commences.

The superior margin of the *body* is formed into an alveolar process, resembling in its structure the same process of the upper jaw. The front surface of this process, which lodges the incisor and canine teeth, has generally a fluted appearance, as it is moulded to the fangs of those organs. The form of the alveolar margin does not exactly resemble that of the superior maxilla, as it is contracted in front: whereas the other forms a regular arch. The front teeth of the lower jaw are smaller than those of the upper, by which they are overlapped; and hence arises the difference in the outline of the two parts. The outer plate of the alveolar process is the thinnest, as in the upper jaw; but an exception to this observation occurs in the sockets of the second molaris, and dens sapientiæ; and particularly in the latter, which is almost covered externally by the coronoid process.

On the forepart of the chin there is a slight longitudinal ridge in the middle, on each side of which the bone is depressed to contain the depressor labii inferioris, and levator menti; and below a small rising may be observed, where the depressor originates. On the middle and back part of the chin, one or two more or less prominent pointed protuberances are observed (*spina mentalis interna*), to which the genio-glossi and genio-hyoidei are affixed. Below these are two rough sinuosities denoting the attachment of the biventres maxillæ inferioris.

At the lower and forepart of the outer surface of the *lateral portion*, a small eminence may be observed, where the depressor labiorum communis arises. Above this, at about the mid-distance between the alveolar process and basis is a

round hole, called the *foramen mentale*, which transmits an artery and nerve of the same name. The posterior alveoli are separated from the root of the coronoid process by a small groove (*sulcus obliquus*), close to which is a rough line for the attachment of the buccinator muscle. An oblique impression from the origin of the mylohyoideus may be noticed on the inner surface of the bone: it commences just within the socket of the dens sapientiæ, and runs obliquely downwards and forwards.

The end of the base of the jaw, where it turns upwards at an obtuse angle towards the cranium, is called the *angle* of the bone. And the *ramus* includes the whole broad and flat production which is continued towards the skull. The masseter muscle covers the whole external surface of this part: but the strongest impressions of its attachment are observed just on the angle of the bone. The corresponding portion of the internal surface is marked in the same way by the pterygoideus internus.

The *ramus* of the jaw terminates above in forming two processes. The anterior of these, which is flattened at the sides, sharp-edged, and pointed, is called the *coronoid*; it has the tendon of the temporal muscle inserted in it, and passes just within the zygoma.

The posterior process, or *condyle*, terminates in an oblong smooth head, which is articulated to the temporal bone; and supported on a smaller part or neck. The condyle, whose greatest length is transverse, and whose convexity is turned forwards, is covered with a cartilage, as the articulated parts of all other moved bones are. The posterior sharp edge of the coronoid process is continued into the front of the condyle, near its outer extremity; forming a semilunar vacancy between these two parts (*incisura sigmoidæ*.) The inner and forepart of the condyle is a little hollowed out and rough to receive the insertion of the pterygoideus externus. The direction of the condyle is not exactly transverse with respect to the cranium; but its axis passes obliquely from without, inwards and backwards; so that the outer extremity is placed rather further forwards, than the inner end; and hence these eminences are adapted to the articular cavities of the temporal bones.

A large irregular hole is found about the middle of the inner surface of the *ramus*; this leads into a *canal* hollowed out in the substance of the bone, and running under the sockets of the teeth, as far as the *foramen mentale*, where it opens externally. From this point, however, a smaller canal is continued under the alveoli of the front teeth. A large branch of the inferior maxillary nerve, accompanied by the inferior maxillary artery, and its corresponding vein, run in this canal. The chief portion of the nerve comes out again at the *foramen mentale*, together with a minute twig of the artery; and a small branch of each enters the canal under the incisor teeth. A groove is observed on the inner surface of the bone, commencing at the origin of the canal, and running forwards; sometimes there is a complete bony tube for some distance. It holds a branch of the inferior maxillary nerve.

The surface of the lower jaw is hard and firm, except at the spongy sockets; where, however, it is stronger than the upper jaw. Its internal substance is cellular, without any solid partition between the cancelli in its middle. At the base, especially of the chin, where this bone is most exposed to injuries, the solid sides of it are thick, compact, and hard.

The following muscles are attached to different parts of the lower jaw-bone; depressor labii inferioris; depressor anguli oris; levator menti; platysma myoides; masseter; temporalis; pterygoideus externus et internus; biventres maxillæ

maxillæ inferioris; mylohyoideus; geniohyoideus; genio-glossus; buccinator.

The joint of the lower jaw with its motions, will be considered under the article MASTICATION.

Of the Teeth.

Parts common to all the Teeth.

Each tooth consists of three parts; the *body* or *crown*, which appears through the gum in the cavity of the mouth; the *root* or *fang*, which is lodged in the alveolar process; and the *neck*, round which the gum adheres, dividing the two first mentioned parts from each other. Every tooth has an internal cavity, which extends nearly the whole length of its bony part. This opens or begins at the point of the fang by a very minute aperture: it grows larger in its passage, and terminates in the body of the tooth, where it is the largest of all. This latter part is exactly of the shape of the body of the tooth to which it belongs; and, indeed, it may be stated in general terms, that the whole cavity is nearly of the form of the tooth itself, larger in the body, from whence it gradually diminishes to the extremity of the fang. Where the tooth has only one root, the cavity is simple; in others, each fang has its own hollow, which opens into the common excavation in the body of the tooth. This cavity is not cellular, but smooth on its surface; and is filled with a soft membranous and pulpy substance, which is made red by injection, and probably receives branches of the nerve, as it is exquisitely sensible, when exposed by decay of the tooth. The blood-vessels, when injected, can be traced through the whole cavity; but it is difficult to pursue the nerves even to the point of the fang. The surface of the crown of the tooth is the only bone in the body not covered by periosteum. The fang is, however, invested by a membrane of this description, from the neck to its extremity. This, though very thin, is vascular, and appears to be common to the tooth which it encloses, and the socket, which it lines as an investing internal membrane. At the neck of the tooth, it is attached to the gum.

Connection of the Teeth.

The fangs of the teeth, implanted in the alveoli of the jaws, are compared to nails driven into wood; and hence the mode of union is called *gomphosis* (from γομφος, a nail.) By the adhesion of the above-mentioned periosteum, and of the gum, and the close connection of the alveolar process, the teeth are so firmly retained in their situation in the living subject, that they can only be separated by considerable force. When, however, the soft parts are destroyed by macerating the cranium, those teeth, which have only one fang, drop out; while such as possess two or three diverging roots, are retained in their situation.

The Gums.

The alveolar processes are covered by a red vascular substance; called the gums. This is perforated by as many openings as there are teeth; the necks of which are covered by the closely adhering sides of the apertures. The external and internal gums are united by transverse fleshy partitions, which are higher than the other parts of the gum, and thence form an arch between every two adjacent teeth. The thickness of that part of the gum, which projects beyond the sockets, is considerable; so that when it shrinks from the tooth by disease, or is destroyed by boiling or maceration, the teeth appear longer, or less sunk into the jaw. The gum adheres very firmly, in the healthy state, both to the alveolar process and to the teeth, but its ex-

treme border is naturally loose all around the teeth. It approaches, in its substance, to a kind of cartilaginous hardness and elasticity. It is very vascular, so as to be rendered quite red by minute injection; yet it does not seem to possess any great degree of sensibility. For, though we often wound it in eating, and in picking the teeth, much pain is not felt on these occasions; and both in infants and old persons, where there are no teeth, the gums bear a very considerable pressure without pain. The advantages arising from this insensibility are obvious; for till the child has cut its teeth, the gums must perform their office, and be consequently exposed to considerable mechanical force, for which they are formed by having a hard ridge running through their whole length. Old persons, who have lost their teeth, have not this ridge. As the gums are not easily irritated by wounds in a sound state, they are not so liable to inflammation as other parts, and soon heal.

As the teeth are united to the jaw by the periosteum and gums, they have some degree of yielding motion in the living body. This circumstance probably renders them more secure; as by breaking the jar of bony contact, it may prevent fractures both of the sockets, and of the teeth themselves.

Component Parts of the Teeth.

These organs are composed of two substances, differing considerably in their structure and appearance, and existing in very unequal proportions.

The crown of the tooth is furnished with an exterior coat or crust of a substance, called *enamel* (*substantia vitrea, cortex striatus*), which terminates at the neck. This, which in texture and appearance resembles the porcellaneous shells, is the hardest substance in the whole body. It is of a milk-white colour, smooth, or as it were high polished on its external surface; and possessing a kind of semi-transparency in the living state, which is afterwards lost. It presents, on a fracture, a regular fibrous and crystalline appearance; but, in other respects, its texture is homogeneous. It differs so clearly in its colour and structure from the substance which it covers, that, in whatever direction the crown of a tooth be divided, a sharp line, defining the limits of the two parts, can be very readily distinguished. The exterior crust of enamel is thickest on those parts of the teeth, which are opposed to each other in mastication; that is, on the cutting edges of the incisor teeth, and the grinding bases of the grinders. It grows gradually thinner and thinner towards the gums; it is also generally rather thicker on the outer than on the inner surface of the teeth, particularly in the incisors. The fibres of the enamel, generally speaking, have the direction of radii proceeding from the centre of the tooth; but, near the gum, they become inclined towards the surface of the bony part.

The hardness of this substance is such, that it will strike fire with steel, provided the metal be good, and the surface of the enamel broken. It can only be divided by means of a file, as saws, even of the finest structure, do not affect it; and even files are soon worn smooth by it. When exposed to the action of fire, it becomes slightly discoloured, cracks, and flies off from the bone.

No pain is occasioned by filing, perforating, or eroding the enamel in the living subject; nor is there the slightest appearance of reproduction, when it has been partially destroyed or removed.

It acquires a temporary tinge by eating fruits, which have highly coloured juices, as mulberries and black cherries; for it seems, like all other calcareous substances, to attract colouring matters strongly. In this way some people tinge their

their teeth with particular colours, according to their notions of elegance; as the Javaneſe, and inhabitants of the Pelew iſlands.

The poſſibility of imparting an artificial colour to the teeth, *ab externo*, a circumſtance of conſiderable importance in the phyſiology of theſe organs, has been abundantly proved by the experiments of Mr. Moor, an ingenious ſurgeon dentiſt, and lecturer on the teeth, in London. He immerſed them in different coloured fluids, ſuch as ink and bile, and found that their ſubſtance became tinged throughout. He has found alſo that oil penetrates them completely, ſo as to render them tranſparent.

It is not hitherto decided, whether or no the enamel of a growing tooth receives any tinge from feeding the animal with madder; but if it does, the effect is certainly much leſs than that produced on the bony part. When, however, the enamel is formed, it certainly is not affected by mixing madder with the food, except on the external ſurface, which becomes ſtained by mastication. (Blake's Eſſay, p. 132→135.)

Chemical Compoſition of the Enamel.

Enamel conſiſts of phosphate and carbonate of lime, joined to a very ſmall proportion of animal ſubſtance: hence, when immerſed in muriatic or nitric acids, it is diſſolved with a rapid efferveſcence, occaſioned by the liberation of carbonic acid gas. Sulphuric acid ſeems at firſt to have no action; but in the courſe of an hour, ſmall bubbles are perceived; and in twelve hours the enamel burſts, cracks, and ſeparates, accompanied with an evident formation of ſelenite by the action of the acid on the lime. Diſtilled vinegar has a very trifling effect, but operates more powerfully when concentrated.

There is a ſlight flocculent appearance, after diſſolving the bony part of the enamel in dilute nitrous acid, ariſing from the ſmall proportion of animal matter which belongs to this ſubſtance.

The conſtituent ingredients of the enamel are ſtated by Mr. Pepys to be in 100 parts: phosphate of lime 78, carbonate of lime 6, *water* of compoſition 16. Should not the latter be rather conſidered as an animal ſubſtance?

The employment of acids in the living ſubject will impart a very white colour to the teeth; but it ſhould never be reſorted to, as it is extremely injurious by diſſolving the enamel. Cream of tartar (*acidulous tartrate of poſaſh*), containing an exceſs of the tartarous acid, exerts this deleterious ſolvent influence; ſo that a tooth immerſed in it for twelve hours became very rough. (Blake's Eſſay, p. 157.) Yet it is not an unfrequent ingredient of dentiſrices. Theſe powders ought never to poſſeſs any chemical properties; which muſt indeed be completely uſeleſs, if the proper attention be paid to brushing the teeth every morning. For the ſame reaſon, perſons who take nitrous or other acids medicinally, ſhould draw them into the mouth through a glaſs tube. It is in the ſame way, by a ſlight action on the enamel, that eating large quantities of fruit tends rather to whiten the teeth.

The enamel ſometimes ſeems to be depoſited irregularly on the ſurface of the tooth, producing the appearance called honey-comb teeth. It has been aſcertained by Mr. Moor, that this ariſes from inequalities in the bony part, over which the enamel is depoſited. Such teeth are more liable to decay than others. Sometimes, however, we ſee ſpots, in which no enamel has been laid down, and which appear black from caries of the expoſed bony part; and the colour

of the enamel itſelf ſometimes deviates partially from its ordinary appearance.

The uſe of the enamel muſt appear very clearly from the above deſcription of the ſubſtance. It oppoſes a hard and almoſt indelible ſurface to the action of the food which we maſticate. It is, however, at laſt worn off from the expoſed ſurfaces of the teeth, by the long continued and conſtant employment of theſe organs in chewing. And when this takes place, the bony ſubſtance is much more rapidly deſtroyed; ſo that the ſurface of the tooth becomes concave, in conſequence of the external cruſt of enamel reſiſting the trituration longer than the bony part. The enamel is alſo much leſs prone to caries than the oſſeous ſubſtance of the tooth.

Bony Part of the Tooth.

The whole body, with the exception of its exterior ſurface, and the entire fang, are compoſed of what is called the *bone of the tooth*.

The term *bone of the tooth* is here employed in compliance with eſtabliſhed cuſtom, which has arranged the teeth among the bones of the body, and generally induced anatomists to deſcribe them with the bones. The general reſemblance which they bear to bone, particularly in the hardneſs of their texture, and in the nature of their conſtituent elements, has probably led to this arrangement. There are, however, ſo many differences in ſtructure between theſe parts, that we ſhould be fully warranted in aſſerting that the *teeth* are not *bones*. The proceſs, by which theſe organs are formed, is alſo ſo entirely different from the formation of bones, that the term *oſſification* is certainly very improperly uſed, when applied to the development of the teeth, and could only lead us to form erroneous concluſions. To perſons who have not conſidered the ſubject minutely, theſe remarks may appear rather paradoxical. Yet we may repel this charge by obſerving that other anatomists have conſidered the ſubject in the ſame point of view. Eyſſon, who published ſome obſervations on the bones of children, in the year 1659, has the following very juſt remark: "Poſtquam dentium procreatio longe diverſa eſt ab oſſium generatione, liquidem oſſa ſunt per intereſſionem cartilagineum, dentes ex converſione mucoris in dentium ſubſtantiam, opinor dentem non eſſe os, ſed proprium aliquod corpus eſſe, durius, candidius, toidius." (Tractatus Anatomico-medicus de Oſſibus Infantum, Groningæ, 12mo. p. 188.) To this we may add the deciſive opinion of one of the ableſt anatomists of the preſent day. I allude to Cuvier, the learned ſecretary of the French national inſtitute. "We may," ſays he, "ſafely aſſert, that it is very improperly that ſeveral anatomists have given to the internal ſubſtance of the teeth the name of *oſſeous ſubſtance*; and equally improperly have they given the name of *oſſification* to the operation which develops and hardens them. This is to confound two things eſſentially different, and to give, by ill applied names, falſe ideas, which may even have an influence upon practice." (Philoſophical Magazine, vol. xxviii. p. 264. from the Memoires de l'Inſtitut National.)

This is much leſs hard and brittle than the enamel; but it is more denſe and compact than any other bony ſubſtance. It is more inclined to a yellow colour than the enamel; and this is particularly obſervable towards the fang, where it is often at the ſame time ſemi-transparent like horn, and ſofter in its texture. This is deſcribed by Blumenbach as a third ſubſtance of the tooth, by the name of *ſubſtantia cornea*. (Beſchreibung der Knochen, p. 244.) Its fracture has a

C R A N I U M.

fibrous appearance, and it is susceptible of a very high polish.

It differs from other bone, in never containing any medullary cells, nor indeed any reticular texture, however large the tooth or its cavity may be.

It consists of the same earthy substances with those that belong to the enamel; but they are united to a much larger share of animal matter. The latter constituent exists in the teeth in such abundance, that although their earth be dissolved by acids, the form of the tooth is still retained by a firm cartilaginous substance, which remains. This residue is indeed more dense than that of other bones.

The different proportions of animal matter, contained in the enamel and bone of the tooth, are best shewn by the common method of exhibiting the arrangement of the former substance on the tooth. Let a section of the tooth be made in any direction, and burn the cut surface; then wash it with a weak acid. The bone is perfectly blackened by the action of the fire on its animal matter, while the enamel, consisting almost entirely of earth, retains nearly its original whiteness.

According to Mr. Pepys, the bone of the tooth consists, in 100 parts, of 64 parts of phosphate of lime, 6 of carbonate of lime, and 20 of gelatine. The remaining 10 he sets down as water of composition and loss.

The existence of fluoric acid in the teeth has lately been announced by some foreign chemists; but the fact of its existence, as a component part of these organs, is not yet definitely ascertained. Sig. Morichini of Rome discovered fluoric acid in the fossil tooth of an elephant; and thence was led to examine that of the human subject. He states that 100 parts of it contain 30 of animal substance, and 22 of fluate and phosphate of lime. He supposes the phosphoric acid to be in very small quantity. They contain also some magnesia, alumine, and carbonic acid. The very small proportion of earthy matter, and the large quantity of animal substance, which this analysis assigns to the enamel, differ so much from the results obtained by other chemists, that the accuracy of the experiments must incur suspicion. Mr. Brande could not discover any fluoric acid in the enamel. He powdered it, and subjected it with sulphuric acid to the action of heat; but its presence was not shewn by any action on glass: nor was he more successful by collecting the gas produced by exposing the enamel to heat with sulphuric acid. (Nicholson's Journal, vol. xiii. p. 214.)

Fourcroy and Vauquelin have obtained fluoric acid from tusks and teeth, altered by remaining in the earth; but not from fresh ones. (Philosophical Magazine, vol. xxvii. p. 88.)

Mr. Berzelius of Stockholm states, that he has found fluoric acid both in the bone and in the enamel of the teeth; as also in the bones in general, both in man and in the ox. He gives the following analysis.

Enamel of human Teeth.

Phosphate of lime, - - -	85.3
Fluate of lime, - - -	3.2
Carbonate of lime, - - -	8.0
Phosphate of magnesia, - - -	1.5
Soda, animal matter, and water, - - -	2.
	100

Osseous Part of human Teeth.

Phosphate of lime, - - -	61.95
Fluate of lime, - - -	2.10
Carbonate of lime, - - -	5.50
Phosphate of magnesia, - - -	1.05
Soda, with a little muriate of soda, - - -	1.40
Gelatine, water, &c. - - -	28.00
	100

Nicholson's Journal, vol. xviii. p. 75.

Formation of the Teeth.

This can be best examined, by observing the contents of the jaw of a newly born child. The bone is hollowed out into a number of cells, separated from each other by imperfect bony septa, and rather contracted at their mouths, which are towards the gum. By removing the external or internal plate of the jaw, the contents of these cells are exposed. They consist of membranous bags, called the *capsules* of the teeth, inclosing the rudiments of the bodies of these organs, and certain soft vascular substances, termed the *pulps*, on which the bodies of the teeth are forming.

The bone of the body of the tooth is the part first formed; the enamel is added to this; and the fang appears the last in order.

The *pulp* exactly resembles in shape the body of the tooth, which is to be formed on it. It is a soft vascular substance, and its vessels are most numerous in that part which is covered by the portion of tooth already formed; so that this appears much the reddest after injection.

The *capsule* is a membrane of whitish appearance externally, but very vascular on its inner surface. It includes the pulp, round the basis of which it adheres, and the rudiment of the imperfect tooth. On its outer surface it adheres firmly to the gum; so that if we attempt to tear the last-mentioned part up from the jaw of a fœtus, the capsules and their contents will come away at the same time. These membranes adhere less closely to the bony cells, in which they are contained. The office of the capsule is that of secreting the enamel. Its cavity contains a small quantity of a fluid resembling synovia.

The ossification commences by the formation of the cutting edge of the incisors, and the grinding bases of the grinders. The bony substance being deposited on the pulp, as on a mould, the rudiments of the teeth are necessarily hollow; and the bony layers first formed are those which will be in contact with the enamel, when that substance is deposited. The ossification commences by as many points as there are prominences on the masticatory surface of the tooth. In the incisors there are generally three points; the middle one being the highest, and the first that begins to ossify. The cuspidatus begins by one point only; the bicuspidatus by two, one external, which is the first and the highest, and the other internal. The molares begin by four or five ossifications, of which the external are always the first. When the teeth begin to form by one point only, they gradually proceed, until the ossification is completed. But if there are more points than one, each ossification increases till their bases come in contact, when they unite and proceed in their formation as a simple tooth.

The ossifications in their progress become thicker and thicker where they first began; but they increase faster at the edge, which is always thin and elastic: hence the cavity

of the tooth becomes deeper in the progress of the ossification. As the formation advances, the pulp is gradually surrounded, till the whole is covered by bone, except its base.

The adhesion of the pulp to the newly formed tooth or bone is very slight; for it can always be separated without any apparent violence, nor can we discern any vessels going from the one to the other. It is, however, most strongly attached round the thin elastic edge, which is the last part formed. When the bone has covered all the pulp, it begins to contract a little, and becomes somewhat rounded, making that part of the tooth which is called the neck; and from this place the fangs begin. The formation of the fangs occasions the bodies of the teeth to ascend through the sockets, and afterwards through the gum, which is absorbed in consequence of the pressure of the tooth.

The pulp has originally no process answering to the fang; but as the cavity in the body of the tooth is filled up by the ossification, the pulp is lengthened, and the fang forms over it. The latter part grows in length, till the whole body of the tooth is pushed through the gum: the socket, at the same time, contracts at its bottom, and grasps the neck or beginning fang, adheres to it, and rises with it. This contraction is continued through the whole length of the alveolus as the fang rises; or the socket, which contained the body of the tooth, being too large for the fang, is wasted or absorbed into the constitution, and a new alveolar portion is raised with the fang: whence in reality the fang does not sink or descend into the jaw.

Both in the body and in the root of a growing tooth the extreme edge of the ossification is so thin, transparent, and flexible, that it seems to be rather horny than bony; very much like the mouth or edge of the shell of a snail.

As the tooth grows, its cavity becomes gradually smaller, especially towards the point of the fang. It is formed by a successive deposition from without inwards; the exterior lamina, or that which adjoins the enamel, being the first formed, and the succeeding layers being added within this. Thus the cavity is gradually diminished, as the ossification advances; and it is always proportionally largest in the most incomplete teeth.

In tracing the formation of the fang of a tooth, we have hitherto supposed it to be single; but where there are two, or more fangs, it is somewhat different, and more complicated.

When the body of a molaris is formed, there is but one general cavity in the tooth, from the brim of which the ossification is to shoot, so as to form two or three fangs. If two only, then the opposite parts of the margin of the cavity shoot across where the pulp adheres to the jaw, meet in the middle, and thereby divide the mouth of the cavity into two openings, from the edges of which the two fangs grow. Sometimes a distinct ossification begins in the middle of the general cavity upon the root of the pulp, and two processes, coming from the opposite edges of the bony shell, join it; which answers the same purpose as the more ordinary structure. When there are three fangs, three processes come from as many points of the brim of the cavity, meet in the centre, and divide the whole into three openings; from which the three fangs are formed.

When the surface of the tooth first appears through the gum, the formation is far from being completed: the body is at this time much hollower than in the perfect tooth, and the fang is only in an incipient state. The hollow of the body is gradually filled up, and the fang is lengthened in proportion as the tooth rises through the gum. Even when

the whole body has passed the gum, the formation of the root is not completed, as it still remains hollower than in the perfect tooth.

When the bone of the body of the tooth is somewhat advanced in its formation, the enamel begins to be deposited on its surface, from the vessels of the capsule. This deposition commences on the malting surface of the tooth, and thence extends towards the root. It is first soft and moist, and presents a rough appearance when dried. It continues in this state until it has acquired the full degree of thickness, when it becomes white and hard, and assumes its natural shining and polished surface. The deposition of this substance is completed when the fang of the tooth begins to form; for at that time the body penetrates the gum, and thereby lays open the capsule, which will be found at this period to have undergone great alteration in its texture and appearance. Instead of the soft vascular surface, which it exhibited while the deposition of the enamel was proceeding, it is now dense, compact, and almost tendinous, with very few blood-vessels. The capsule, which before possessed no adhesion to the tooth, becomes connected to it when the formation of the fang commences; and it forms the peristeme of the fang. Mr. Hunter states, that the enamel is deposited from a pulp, analogous to that on which the bone forms. There is no foundation for this assertion; and the mistake, which has been noticed by Blake in his valuable Essay (chap. iv.), arose probably from the situation of the rudiments of the permanent incisors behind, and close upon the capsules of the temporary ones at the time of birth; and partly also, perhaps, from the analogy of graminivorous quadrupeds, where pulpy processes descend from the capsule into the teeth, to deposit the processes of enamel, intermixed with the bony substance of the organ.

The regular striated appearance of the enamel has led some to suppose, that it forms on the tooth by a process of crystallization; being contained in a dissolved state in the mucous fluid, which exists in the cavity of the capsule. We cannot attach much weight to this explanation, when we consider that that fluid does not contain a greater proportion of phosphate of lime than other similar animal liquors; that the deposition, in the teeth of some animals, is confined to a particular part of the tooth; and that there are instances, occasionally, in which a small spot has no enamel.

Classification and Description of the adult Teeth.

The whole number of the adult teeth is thirty-two; and they are equally divided between the two jaws, so that each of these contains sixteen. Occasionally there are only twenty-eight or thirty. Of the sixteen teeth contained in each jaw, those on the left side are just the same with those on the right, so that they are arranged in pairs; and the teeth in the upper jaw nearly resemble those of the lower jaw in situation, figure, and use.

The teeth have been commonly divided into *incisors*, *canine*, and *grinders*. This arrangement is not adopted by Mr. Hunter, who substitutes in its place a more eligible one. He distributes these organs into four classes. 1. The *incisors*, or cutting-teeth, which include the four front ones of each jaw. 2. *Cuspidati*, two in number; one on each side of the incisors. These were formerly called *canine teeth*, from a comparison to the corresponding ones in the dog, and other carnivorous animals, to which they bear no resemblance. 3. *Bicuspides*, four in each jaw, two on either side. These are most clearly distinguished by their smaller size from the back teeth, with which they were before included,

cluded, in the common denomination of grinders. 4. *Molares*, six in number, three on each side, behind the bicuspidates.

There is a regular gradation, both in growth and form, through these classes, from the incisors to the molares; in which respect the cuspidati are of a middle nature between the incisors and bicuspidates, as the last form the connecting link between the cuspidati and molares. Consequently the incisors and molares are the most unlike in every circumstance.

The following description is taken from the teeth of the lower jaw, and the differences between these and the upper teeth are noticed subsequently.

The *incisor teeth* (*primores* of Linnæus; *tomici, risorii*) have an anterior and posterior flat surface, which meet in a cutting edge. The anterior surface is convex, and placed almost perpendicularly; the posterior is concave, and sloping, so that the cutting edge is directly over the front surface.

The two surfaces are broadest at the cutting edge, and they grow gradually narrower from that part to the neck. The side of the tooth, on the contrary, is narrowest at its cutting edge, and becomes thicker and thicker towards the neck; so that it is of a wedge-like form. The fang, on the contrary, is compressed laterally; so that its sides are broadest, and the anterior and posterior surface are narrowest. It follows, therefore, that an incisor tooth, when viewed on its anterior or posterior surface, is broadest at the cutting edge, and grows constantly narrower to the extremity of its fang; but in a side view, it is thickest or broadest at its neck, and thence becomes gradually more narrow, both to its cutting edge and to the point of its fang. The enamel is continued farther down, and is thicker on the anterior and back part of the incisors than on their sides; it is also rather thicker on the fore part than on the back of the tooth. They stand almost perpendicularly; their bodies being turned a very little forwards. The two middle ones are smaller than the two exterior: they are indeed the smallest teeth in the mouth, and are distinguished by the epithet of *small incisors*, from the lateral ones or *large incisors*.

The upper incisors are considerably broader, thicker, and stronger, than the corresponding lower teeth. The two middle ones are considerably the largest, and are distinguished by the term of *large incisors*. The fangs of these teeth are round, instead of flattened, especially those of the large incisors. They project in front more than the lower teeth, so that their axis points downwards and forwards; and they usually overlap those of the lower jaw to a small extent.

The upper large incisor covers the lower small ones and half of the large; and the upper small one covers the other half of the lower large incisor, and more than half of the cuspidatus. The edges of these teeth generally become blunt and thicker by the friction of mastication; but in some persons they are rendered thinner by the mutual attrition.

The Cuspidati (Canini of Linnæus; canini).

These teeth are thicker and stronger than the incisors, possessing a large and long fang, which causes a marked prominence of the outer plate of the alveolar process. Their body, which is thick, and nearly cylindrical at the root, terminates above in a point, which projects beyond the other teeth, particularly in the lower jaw. Their fang is compressed laterally, and occasionally divided through its lower half, into two. Their sides are more extensively covered

with enamel than those of the incisors: and they stand almost perpendicularly. They are considerably larger in the upper jaw; and their fangs are longer than those of any teeth; from which circumstance they have acquired the name of *eye-teeth* in common language.

When the jaws are closed, the upper cuspidatus falls between the lower corresponding tooth, and the first bicuspid; and projects a little over them. Their points are soon worn away by mastication, and then they rather resemble the incisors, but as the friction goes on the worn surface is much more cylindrical.

The Bicuspidates.

The two bicuspidates resemble each other so much, that a description of the first will serve for both. The first indeed is frequently the smallest, and has rather the longest fang, approaching more nearly than the second to the shape of the cuspidatus. Its body is flattened laterally, and it terminates above in two obtuse tubercles, an external, and an internal one; of which the former is the longest and thickest; so that on looking into the mouth from without, this point only can be seen, and the tooth has very much the appearance of a cuspidatus. The internal point is the least, and indeed sometimes so very small, that the tooth greatly resembles a cuspidatus in any view. It is broadest in the lateral direction at the union of the two points, and thence it diminishes to the pointed extremity of the fang. The fang itself, which is broad, and compressed laterally, is sometimes forked at its extremity. The enamel extends nearly equally all round the neck of these teeth. They stand perpendicularly in the jaw.

In the upper jaw they are more flattened laterally, and broader from within outwards, than in the lower; and are inclined a very little forwards and outwards. They possess here frequently two fangs, instead of the single broad one which they have in the lower jaw; but the division does not in general extend to the neck of the tooth, when there is only one broad fang, it contains two cavities; one towards each margin. The first upper bicuspid falls between the two corresponding lower teeth; the second between the second lower bicuspid, and the first grinder; and they project a little over those of the lower jaw.

These teeth are more frequently wanting than any others, excepting the dentes sapientia.

Molares, or Grinders.

The first and second of these nearly resemble each other in their form, so that they may be considered together: the third differs from these in some circumstances.

The grinders differ from the bicuspidates, in being much larger; in having more numerous points on the body, and more fangs. Their grinding base forms a square, with rounded angles. The surface has commonly five points or protuberances; two of which are on the inner, and three on the outer part of the tooth: there are also generally some smaller points at the root of these larger protuberances. These inequalities, being situated at the margins of the grinding basis, leave an irregular superficial cavity in the middle of the tooth. The three outer points do not stand so near to the outer edge of the tooth, as the inner ones do to the inner margin; so that the body swells more from the points, or is more convex, on the outer surface. The body is but slightly contracted at the neck, where it divides into two broad and flat fangs, an anterior and a posterior one, which are generally bent a little backwards. The flat surfaces of these fangs are placed directly across the jaw, so that

that one is precisely *anterior* and the other *posterior*; their edges are turned towards the two plates of the alveolar process, and are consequently *exterior* and *interior*. They continue broad nearly to their extremities, which are sometimes bifurcated. There are two cavities in each fang: one towards each edge, leading to the general cavity in the body of the tooth. The fang is therefore thicker at these parts, and thinner in its middle, where it is marked externally by a longitudinal groove. The enamel is much thicker on the grinding surface of these teeth than in other parts, but it terminates at the same line all round the neck.

The first grinder is somewhat larger and stronger than the second; it is turned a little more inward than the adjacent bicuspides, but not so much as the second grinder. Both of them have generally rather shorter fangs than the bicuspides.

There is a greater difference between these grinders in the upper and lower jaw, than in any of the other teeth.

They are rather rhomboidal than square in the upper jaw; having one sharp angle turned forwards and outwards, the other backwards and inwards. They have three smaller and round fangs, which diverge and terminate in a pointed manner; each of them having a simple cavity. Two of these are placed near each other, perpendicularly over the outside of the tooth; and the other, which is generally the largest, stands at a greater distance on the inside of the tooth, slanting inwards. They are inclined outwards and a little forwards; projecting slightly over the corresponding teeth of the lower jaw, and placed further back in the mouth, so that each is partly opposed to two of the lower jaw. They are placed directly under the maxillary sinus, and the second is rather the smallest of the two.

The third molaris in each jaw is called, from the circumstance of its appearing late in life, *dens sapientia*, or the *wise tooth*. It is shorter and smaller than the others. Its body is rounder, but possesses the same general formation with the other grinders. The fangs are not so regular and distinct; generally appearing as if squeezed together into one; and sometimes there is only one thick conical fang. It varies more in the upper than in the lower jaw; and is smaller in the former than in the latter, so as to be directly opposed to it. And but for this circumstance the grinders would reach further back in the upper jaw than in the lower.

When the natural number of the teeth is less than usual, it arises from a want of these *denes sapientia*.

General Observations on the Teeth, as viewed in Conjunction.

From the incisores to the first grinder, the teeth become gradually thicker at the extremity of their bodies; and smaller from the first grinder to the *dens sapientia*. From the cuspidatus to the wise tooth, the fangs become shorter; the incisores are nearly of the same length with the bicuspides.

From the first incisor to the last grinder, the teeth stand out less from the sockets and gum.

The bodies of the lower teeth are turned a little outwards at the front of the jaw; and thence to the third grinder they are inclined gradually more inwards. The upper teeth project over those of the under jaw, especially at the forepart, where the cutting edges of the upper incisores overlaps that of the lower, so that they act like the blades of a pair of scissors. This arises from the upper teeth being placed more obliquely, for the circle of the sockets is nearly the same in both jaws. This obliquity becomes constantly less from the incisores to the last grinder; so that instead of overlapping, the outer edge of the upper

teeth projects a little over the opposed margin of the lower ones.

The teeth in the upper jaw are placed farther back in the circle, than the corresponding ones in the lower; in consequence of the upper incisores, particularly the two front ones, and the cuspidati being broader than the lower teeth. Yet this is compensated by the lower back grinders being larger than the upper ones, so that the upper *dens sapientia* falls on the surface of the lower one.

The size of the fangs bears a proportion to the bodies of the teeth for reasons which must be obvious. They seem to be rather less firmly fixed in the upper than in the under jaw, or, in other words, the alveolar process is strongest in the former. This difference may be partly accounted for by the situation of the antrum. The upper grinders, instead of possessing two strong and straight fangs, have three smaller diverging ones, inclosing, as it were, the bottom of the antrum. That all this weakness of the upper jaw is for the increase of the antrum, is rendered probable by considering that the upper teeth are generally similar to those of the lower jaw, excepting just where they are opposite to the maxillary sinus; and here they differ principally in the fangs, without any other apparent reason. And this is further confirmed by observing, that the *denes sapientia* of both jaws are more alike than the other grinders, because they do not interfere so much with the sinus.

The arch formed by the teeth altogether is generally parabolic, sometimes elliptical, but very rarely semicircular. Sometimes it forms nearly a straight line in front, and this joins the sides by two angles. It is more capacious in the upper than in the lower jaw, on account of the greater breadth of the front teeth; but the difference is trivial at the back part.

The line formed by the junction of the teeth is not perfectly straight, being slightly elevated before and behind, and depressed in the middle. Hence the front and back teeth of the lower jaw are rather higher than the middle ones, in order to meet the upper teeth.

The arch of the teeth forms a simple line at the anterior part of their masticating surface: but from the point of the cuspidatus backwards, in consequence of the breadth of the bicuspides and molares, there is a double line, constituting an outer and an inner margin.

The number and disposition of the teeth are usually found as we have above described them. There are occasionally supernumerary ones, which are most frequent about the incisores and cuspidati of the upper jaw. And sometimes, where the number is not greater than usual, from want of room or other causes, the teeth deviate in various ways from their ordinary position, so as even, in some instances, to give the appearance of a double row in the front of the mouth. The exact description, and the mode of remedying such deformities, fall within the province of the dentist.

Wearing of the Teeth by Mastication.

The true and exact form of the teeth can only be observed just after they have appeared in the cavity of the mouth.

For afterwards, the constant friction, which they experience in the act of mastication, wears away their opposed surfaces, and thereby changes their form. Thus the incisores, which at first possess three prominent points on their cutting edge, soon have these projections removed; the apex of the cuspidatus is speedily worn off, so as to render the body obtuse; and the prominences of the grinders are removed in the same manner at a more remote period. Af-

ter a certain time the enamel is consumed from the masticating surfaces of the teeth; this happens tolerably soon in the incisors and cuspidati. After the exposure of the bone the tooth wears down much more rapidly while the superior hardness of the enamel causes that part to resist longer and thereby to form an elevated margin. The body is at last consumed in the progress of time down to the very neck; and it is obvious that the cavity would be exposed by this process, were it not filled up by new matter, in proportion as the surface is worn off. This newly formed matter may be readily distinguished as it forms a more transparent spot in the middle of the tooth. The effects of the friction of mastication on the teeth are most strikingly exhibited in the crania of savages; or of such persons as have lived most nearly in a state of nature, or on the most simple kinds of food. Here we often find the grinders with their prominences destroyed, and worn down to a level surface. This may be partly accounted for by the food being less softened by the artificial aid of the processes of cookery, and partly by the natural effects of attrition being anticipated in us by caries of these organs.

It must be obvious from this description, that there is no process of reparation going on in the teeth to supply the loss of substance occasioned by mastication. We shall prove in a subsequent part of the article that these parts possess no vessels nor nerves, and that they must consequently be completely incapable of such processes. How indeed can we suppose, that organs destined for the mechanical reduction of the food, and which therefore can only be compared to mill-stones, should be indued with vascularity and sensibility? These parts are constantly becoming less after they have cut the gum, by their surface wearing away in the manner above described. Yet in some books even of such distinguished authors, as ought to have been better acquainted with the subject (for instance, in Monro's very excellent description of the Bones, p. 115.) it is stated that they are constantly growing larger. The proofs of this fact are said to be, that when an upper or lower tooth is lost, the opposite one grows longer, and that the teeth before and behind the vacancy grow broader. The appearances in these cases are truly stated; but we have a more natural solution of them, than by the hypothesis of ascribing vascularity to the teeth. When a tooth has lost its opposite one of the other jaw, it seems to become longer than the others, in proportion as these have become shorter by abrasion; which cannot now affect the apparently lengthened tooth. The effect may possibly be further increased in this instance by the loss of pressure giving the alveolar process of the opposite tooth a disposition to rise higher, and fill up below. Where the interval left by a fallen tooth seems to be contracted by the increased thickness of the adjacent teeth, the appearance is occasioned by the teeth moving from that side, where they are well supported, to the other side, where they are not. Thus they get an inclined direction, which extends to the adjacent teeth in a proportionally less degree, and affects those which are behind, more than those which are before the vacant space. This kind of effect is most observable in the lower jaw, where the back teeth are naturally inclined forwards.

Use of the Teeth.

The grand utility of the teeth in masticating the food, will be considered under the article MASTICATION. They are moreover of great service in the pronunciation of several letters; particularly the front teeth, the loss of which occasions a peculiar defect of the speech, called lispings. The loss of all the teeth, and the alveolar processes in old

persons, still further impedes pronunciation by obstructing considerably the motions of the tongue.

Are the Teeth of Man Carnivorous?

We cannot decide this question better than in the words of Mr. Hunter: "Natural historians have been at great pains to prove from the teeth, that man is not a carnivorous animal; but in this, as in many other things, they have not been accurate in their definitions; nor have they determined what a carnivorous animal is. If they mean an animal that catches and kills his prey with his teeth, and eats that flesh of the prey, just as it is killed, they are in the right; man is not in this sense a carnivorous animal, and therefore he has not teeth like those of a lion; and this, I presume, is what they mean.

"But if their meaning were that the human teeth are not fitted for eating meat that has been caught, killed, and dressed by art, in all the various ways that the superiority of the human mind can invent, they are in the wrong. Indeed from this confined way of thinking, it would be hard to say what the human teeth are fit for; because, by the same reasoning, man is not a graminivorous animal, as his teeth are not fitted for pulling vegetable food, &c. They are not made like those of cows or horses, for example.

"The light in which we ought to view this subject is, that man is a more perfect or complicated animal than any other; and is not made like others, to come at his food by his teeth, but by his hands, directed by his superior ingenuity; the teeth being given only for the purpose of chewing the food, in order to its more easy digestion. These as well as his other organs of digestion, are fitted for the conversion of both animal and vegetable substances into blood; and thence he is enabled to live in a much greater variety of circumstances than any other animal, and has more opportunities of exercising the faculties of his mind. He ought therefore to be considered as a compound, fitted equally to live upon flesh and vegetables."

Of the Temporary Teeth.

The teeth being, as we have already observed, destitute of any principal of growth within themselves, have not the power of increasing in size as the jaws grow. Hence the small teeth, which occupy the alveolar processes of the child, are discharged, at a certain period, to make room for a new set, adapted in form and magnitude to the dimensions of the adult jaw. The former are therefore distinguished by the epithets of the *temporary* or *deciduous* teeth, from the latter, which are called the *adult* or *permanent* set.

There are ten temporary teeth in each jaw; consisting of four incisors, two cuspidati, and four grinders. In position and form these resemble the corresponding permanent ones, which have been already described; and the chief difference consists in their being very much smaller. The temporary set contains therefore no teeth corresponding to the adult bicuspidates. The cuspidatus has a more pointed form than in the adult; and the front grinder is smaller than the posterior one.

Formation and Time of Appearance of the Temporary Teeth.

At the ninth or tenth week after conception there is a simple longitudinal groove in the jaw; containing a soft jelly-like vascular substance, without any distinction of parts; at the fifth month bony partitions begin to shoot across the alveolar grooves; the pulps and capsules can now be distinguished, but are still in a gelatinous state; small hollow shells have formed on the incisors and cuspidati, and ossification

erian has commenced by some angular depositions on the points of the grinders. The canal of the vessels and nerve is open at the bottom of the alveolar groove, and the capsules adhere so strongly to the gum, that they come away, if that part be torn up from the jaw.

In the full-grown fœtus, the rudiments of the teeth are contained in almost complete bony cells. The different capsules are separated by bony septa; and the mouths of the cavities, which are situated towards the gum, are rather contracted in order to support that part, and to prevent the still imperfect rudiments from being injured by any mechanical pressure. At this time the pulps of the incisors and cuspidati are nearly covered by bony shells; the points of ossification of the grinders are united or very nearly so. There are the rudiments of six teeth in each side of the jaw at this time; *viz.* of the five temporary ones, and of the first or anterior adult grinder, which is contained in the same bony cell with the second temporary molaris; and is situated under the coronoid process of the lower jaw, and in the tubercle of the upper.

As ossification does not commence on all the pulps at the same time, those on which it first commenced are in general the soonest completed, and of course they appear through the gum first. At the time of birth the bodies of the middle incisors of both jaws are the most perfect; the lateral incisors and the small grinders are the next in order; and the cuspidati and large grinders are the least complete. In general the teeth begin to appear about the sixth, seventh, or eighth month after birth; but there are some exceptions to this rule; owing to the rapid progress of ossification in some children, and the slowness of it in others. There are a few instances of children at birth having one or two of the incisors already cut, and in such cases it is often necessary to remove them immediately; on the contrary, in children apparently healthy they have not begun to appear till the first, second, and even the third year. For the most part they appear in pairs; that is, the two corresponding teeth on either side of the jaw come through the gum at the same time. The first teeth are the middle incisors of the under-jaw, and in a few weeks after the middle incisors of the upper appear. In a month or six weeks afterwards, we have reason to expect the under lateral incisors; which are followed in a short time by those of the upper jaw. About the twelfth or fourteenth month the under anterior grinders appear, and those of the upper jaw about the same time. At the sixteenth or twentieth month the cuspidati appear, and first in the lower jaw. The posterior or large grinders come through the gum from the twentieth to the thirtieth month. Thus, in general, about the second or third year, the twenty temporary teeth are complete. We must not however expect to find the teeth always appear in the precise order which has been just described. Some irregularities are frequently met with; such as, one tooth appearing a considerable time before its fellow; all the incisors of the under jaw before any of the upper; or the reverse, which is very rare. The anterior grinders sometimes come through before the lateral incisors; and the posterior grinders before the cuspidati; but the cuspidati are never cut before the small grinders. Three or four teeth sometimes appear nearly at the same period. The small grinders have been known, in a very few instances, to come through first of all.

Formation, and Time of Appearance of the permanent Teeth.

The adult teeth are formed in the same manner with those of the temporary set; and their capsules are contained

in peculiar cavities of the jaws, situated for the most part near those of the deciduous clats.

The rudiments of the incisors and canine teeth are found at the time of birth closely adherent to the posterior surface of the capsules of the temporary ones, as Eustachius has justly observed. At this time, therefore, they are contained in the same sockets with the deciduous teeth; and there is a very distinct foveola on the inner plate of the alveolar process at this period, caused by the situation of the adult large incisor, the pulp of which is now tolerably advanced.

The fics of the permanent teeth, situated as we have just mentioned, are so intimately connected with the membranes of the temporary set, that they cannot be separated without tearing one or both. As their formation proceeds, they become surrounded by a complete bony cell, which, as the temporary teeth rise in the jaw, is situated below and behind them in the lower maxilla, above and behind them in the upper jaw. Ossification has commenced on these teeth at the age of six or seven months. Their formation is considerably advanced at the age when the temporary incisors have appeared. The ossification of the lower adult cuspidati has now commenced, and the pulp of the upper cuspidati is formed; this begins to ossify about the sixteenth month.

The capsules of these permanent teeth are connected to the gum by processes passing through certain openings of their bony cells, which form small foramina just behind the corresponding temporary teeth.

As the adult incisors and cuspidati form in that portion of the jaw which holds the analogous temporary teeth, and are so much larger than these, they are consequently crowded; the lateral incisors are rather behind the middle ones, and the cuspidati are placed at a great distance from the alveolar portion of the jaw; being just under the orbital plate of the upper maxillary bone, and close to the basis of the lower jaw. Hence the process connecting its capsule to the gum has the appearance of a slender thread passing through the bone.

The adult bicuspides form over and under the temporary molares. Ossification has commenced on the points of these in the lower jaw about the third year, and they are all considerably advanced at the age of six years.

The adult molares are not formed in the neighbourhood of any temporary teeth, but completely behind them. These are successively produced under the coronoid process of the lower jaw, and in the tubercle of the upper. The anterior grinder is the first permanent tooth that can be discovered. This is discerned some time before birth; and ossification has commenced on one or more of its points at the time of birth. At the fourth year this grinder has left its original situation under the coronoid process and in the tubercle, and has advanced in the jaw. Its place is supplied by the second grinder, which comes forwards in the same way; and the situation of this tooth is occupied at the eighth or ninth year by the dens sapientie, which then begins to form.

The various teeth of the adult set proceed in their formation in the situations just described until they have attained such a state of perfection as to come through the gum. The temporary teeth are then shed to make room for them. This is effected by the gradual absorption of their fangs, which being completely removed, the neck only holds by the gum, and the tooth then falls out with the slightest force. The appearance of the temporary teeth, when thus discharged, has led some to the erroneous idea that they possess no fangs.

C R A N I U M.

It has been often stated, that the absorption is produced by the pressure of the new teeth, which mechanically push out the old ones. But that this is not true, is shown by this circumstance, that the fangs are often absorbed long before the permanent tooth appears; and sometimes even where no permanent tooth succeeds. On the contrary, some of the deciduous set occasionally remain in the jaw among the adult teeth. This is the case where no corresponding permanent teeth are formed; so that, if the absorption of the temporary fangs be not owing to any actual pressure, the formation of the permanent set must considerably influence the process. The temporary incisors, both of the upper and under jaw, sometimes continue during life; and occasionally one or more of the bicuspidis are wanting. A person has been known to have only four teeth of the permanent set in each jaw. (Fox's "Natural History of the Human Teeth," p. 41.) The shedding of the teeth generally commences at the sixth or seventh year. The rising of the permanent tooth destroys the partition which separated its cell from the temporary socket, through which therefore the adult tooth appears. But if the fang of the temporary tooth should not have been absorbed in proportion to the advancement of the permanent one, the latter protrudes at the opening through which its capsule was connected to the gum, so as to appear behind the temporary tooth.

The membranous processes, which pass through the foramina of the jaws to connect the capsules of the permanent teeth to the gum, seem to have been first noticed by Blake, although the openings themselves, and their situation, were known to, and accurately described by Albinus. The former author considers the rudiments of the permanent teeth to be processes of the temporary capsules, and that the membranes unite the permanent capsules to the necks of the temporary teeth. To us this representation has never appeared quite correct: the capsules of the permanent incisors and cuspidati, when they can be first observed, are contained in the same sockets with the temporary teeth, and undoubtedly are most closely connected to their capsules; but when they have become included in complete bony cells, the connection between the two sets ceases; the process which goes through the opening of the jaw to the gum has no particular connection to the temporary tooth, except inasmuch as the gum adheres to the neck of the tooth. That the permanent capsules in some instances are not at all formed by any processes of the temporary ones, is evident from the bicuspidis; the rudiments of which are not perceptible until after the child's grinders have completed their growth. Neither have we noticed that connection, which Blake speaks of, between the first and second, and the second and third adult molares. (See his fourth chapter.)

It will be easy, from what we have already said, to determine the number of teeth which are formed and forming in the jaw at any given time. Thus at the time of birth there are in each jaw the rudiments of the ten temporary teeth; of the two anterior molares; and those of the adult incisors at least, in an incipient state, if not of the cuspidati. The greatest number is found in the jaw, just before the shedding of the teeth commences; that is, about the sixth year. There are then twenty-four teeth in each jaw-bone; *viz.* the ten temporary ones, and all the permanent set, excepting the *dentes sapientie*. It is stated however by Blake, who, in his over-zealous zeal to detect every trivial mistake of Mr. Hunter, not uncommonly commits errors himself, that there is a greater number in the jaw at the age of four years; and he makes this number amount to twenty-six, which includes the whole of the deciduous and permanent

set. We have never found the *dentes sapientie* beginning to be formed at so early a period as this; but if they begin very soon, or the shedding does not commence until late, there may undoubtedly be twenty-six teeth in each jaw at once, although this is not usual.

The usual time for the shedding of the teeth to begin is about the sixth or seventh year; it may commence as early as the fifth, or be delayed until the eighth. The anterior molares being rather earlier in their formation than the incisors, usually appear first; and soon after these have been cut, the shedding of the temporary teeth may be expected to begin. The central lower incisors are first removed, and succeeded by the permanent ones: those of the upper jaw appear about two or three months after. The lateral incisors of the under jaw follow next in succession, and then those of the upper. The temporary molares begin to loosen in about six or twelve months more, and are usually shed before the cuspidati. The first bicuspidis come into the place of the anterior grinders about the ninth year; and soon after the temporary cuspidatus is succeeded by the permanent one. The second temporary molaris then gives place to the posterior bicuspidis; and the middle permanent molares appear about the twelfth year; the last grinders, or *dentes sapientie*, usually come some time between the seven-teenth and twenty-third year; although occasionally they are not cut until a much later period of life.

In some rare instances a greater or smaller number of teeth has appeared at very late periods of life, and have been described as constituting a *third set*. The individuals in whom this circumstance has been observed, have invariably been considerably advanced in years, yet strong and healthy for their age. Lord Bacon states that the countess of Desmond was an example of this occurrence. ("Works," vol. 3, p. 152.) Mr. Hunter knew an instance in which two fore teeth appeared in the lower jaw late in life. (p. 85.) John Moore, aged 102, the oldest man at present in Chelsea Hospital, has had four new front teeth within the last five years. Sir John Sinclair, who mentions this circumstance, ("On Health and Longevity," Appendix to vol. 2, p. 147.) cites other instances; and one of them is a person whom he himself saw. He found the new teeth of a softer consistence than teeth usually are, and he considered them as imperfect in their formation. In the last volume of his ("Elements of Phytology," part 2, p. 85.) Haller has collected several cases mentioned by preceding authors. These evidences must be allowed to prove clearly that teeth have appeared at a late period of life, although the number in any one instance has been small, and the examples of the occurrence very rare. It has never occurred to any anatomist to detect the rudiments of these teeth in the jaw, during their formation; and perhaps a strict examination might shew that in some instances the appearance has only arisen from some of the permanent teeth being cut unusually late: as we know that the cutting of these teeth is sometimes delayed for many years beyond the usual time. At all events, we ought not to admit any case as clear proof of the fact, unless it could be ascertained that the person in whom it appeared had had the two ordinary sets of teeth, consisting each of its natural number, and this probably has not been made out in any one instance. The "Account of a Case of three different Growths of Teeth succeeding one another in the Jaw of a Child," in the third volume of the London Medical Observations and Inquiries, is so imperfect and omisive, that we can draw no conclusions from it.

CRANIUM.

Form of the Jaws as influenced by the Teeth.

These bones may be said perhaps to grow equally in all directions until the time of birth. Yet in the latter months of fetal existence they probably increase rather more towards their posterior part than in other situations; for although about five months we find only five rudiments in each side of the bone, there are six discoverable at the seventh or eighth month; and the sixth occupies the situation which was before filled by the fifth.

At twelve months after birth, the ten temporary teeth are tolerably complete in their size; and, after this time, the jaws grow no more in that part which holds these teeth, than in proportion to the difference of size between the deciduous and temporary teeth. The front arch of the jaw is therefore very nearly as large at this time as in the adult, and hence the face of the child has a flattened appearance at its anterior part.

But these bones still increase very considerably towards their posterior parts; and as they do so, the adult molares advance successively from the tubercle of the upper jaw, and the coronoid process of the lower. The sixth tooth (first adult molaris), which was in these situations in the newly-born child, has advanced completely in front of them at the age of four years, when its place is occupied by the second adult grinder, which coming forwards in the same way, as the jaw increases at its posterior part, is succeeded by the third, or dens sapientie; and this last advances into the alveolar circle at a later period.

There are also most remarkable changes at different periods in the alveolar portions of the jaws. The substance of the bones is hollowed out into cells at the time of birth to contain the rudiments of the forming teeth; but alveolar processes in the proper sense of the term cannot be said to exist at this period. The gums in the upper jaw are nearly on a level with the glenoid cavity of the temporal bone; and in the lower jaw with the condyle. The surface of the palate is nearly level. As the teeth advance into the mouth, the margin of the jaw is lengthened into an alveolar process, so that the gum is now very considerably below the level of the glenoid cavity. The ramus of the lower jaw must be proportionally lengthened; and still more so, as the breadth of the lower jaw is equally increased with that of the upper, by the growth of the alveolar process. This increased depth of the jaws, with the addition of the teeth, must of course very greatly lengthen the face; which recovers its former shortness in old age by the loss of the teeth, and the consequent removal of the alveolar processes. A diminution is hence effected of not much less than two inches in some cases. The edge of the upper gum now again is on a level with the glenoid cavity; and the palate, instead of its strongly-arched form, is again nearly flat. The length of the ramus of the lower jaw cannot however be altered; hence it shuts in front over the upper one, so as to bring the upper and lower gums into contact at the back of the mouth, where the greatest force can be exerted in mastication. If the jaws of a toothless person came in contact in their anterior part, they would not touch behind. The degree of diminution in breadth of the lower jaw may be easily estimated by comparing the situation of the foramen mentale. This opening in the perfect jaw is rather nearer to the under than to the upper margin of the bone; but after the loss of the alveolar process, it is close on the upper edge.

Are the Teeth Vascular?

The question concerning which anatomists and physiologists are divided in opinion on this subject is, whether the

bone of the tooth possess any vessels or nerves in its substance, so as to be capable of those actions and changes which we may observe in other vascular and living parts? Or whether it be destitute of vessels and nerves, unpossessed of vitality, and obnoxious to such changes only as can be effected by mechanical and chemical agency? The arguments in favour of the latter opinion are beyond all comparison the most numerous and direct, so that we cannot help being greatly surpris'd that the opposite sentiment should have acquired any partizans amongst persons acquainted with the structure, formation, and diseases of these organs. In considering this question, the enamel does not come under our observation; as that part is allowed to be destitute of vessels, even by the persons who argue for their existence in the bone of the tooth; and we shall, therefore, in the following discussion, assume that it is not vascular.

The office which the teeth perform affords a strong presumption against their possessing vessels and nerves. Is it at all probable that a vascular and sensible part should be destined to perform the trituration of the different hard bodies, which constitute our food, and be exposed to the mechanical attrition which this office must necessarily occasion? Here it may be said, that the enamel is an insensible external covering, intended to resist the effects of the hard bodies, which are masticated, and to protect the vascular and sensible bone. But the time comes, when the enamel being worn away, the bone of the tooth is itself exposed to friction, and exposed in that part where the greatest effects are produced. Another argument, to the same effect, arises from the formation of two sets of teeth. As these organs are formed at once of the size of which they always remain, and as the jaw-bone, which contains them, increases like all other vascular parts of the body, the teeth of the child do not correspond in size to the jaw of the adult: hence, the necessity of a second set of teeth. Surely, if these organs were vascular; if they possessed in themselves the means of growth they would increase, so as to accommodate themselves to the size of the jaw, and we should not have this tedious and complicated process of forming a new set of teeth, of discharging the old ones to make room for these, and of bringing them forwards at long and regular intervals; a process which gives rise to so many troublesome complaints, and affords so much employment for the dentist.

The teeth never exhibit any appearances of reparation, under circumstances of accidental injury, or of supposed disease. The loss of substance occasioned by the friction of mastication is not repaired; a part broken off is never renewed, but the fractured surface remains unchanged; a hole occasioned by decay is never again filled up. None, in short, of those processes of restitution, which so strikingly characterize all organized bodies, for which alone powers of life and growth can ever be required, take place in the present instance; so that if the teeth possess vessels, they exist to no purpose, and manifest their presence by none of the usual phenomena.

Such is, precisely, the reasoning employed to shew that the enamel is not vascular: and every argument, tending to prove that position, will apply with equal force to shew the want of vascularity in the bone of the tooth. If it be broken off, it is never regenerated; if it be filed away, it is never reproduced. The same facts hold good of the bone of the tooth, and should lead us to the same conclusion.

There is another effect of injury on the teeth, equally conclusive with the former, as to the non-existence of vessels in their substance. A violent blow will cause a general discolouration of a tooth, as if from a general effusion of

blood throughout its texture. This effect never goes off. There are two ways of accounting for the appearance. 1. By supposing vessels to exist throughout the substance of the tooth, which pour out the blood in consequence of the injury; or, 2dly, by supposing that the vessel in the fang is ruptured, and that the effused blood mechanically discolours the substance of the tooth. If we adopt the former explanation, the colour ought not to be permanent; for, wherever there are arteries, there must also be absorbents; and these absorbents ought to remove the effused blood as they do in bruises of the soft parts. By the latter explanation, we gain a satisfactory solution of the difficulty; we account for the duration of the colour in the same manner as of that which arises from feeding an animal with madder.

The teeth are exempted from all those diseases which ravage the other bony structures of the body. Lues venerea, ferotula, and rickets, which attack all other bones, never produce the slightest effect on these organs, which remain unaltered, even in cases of mollities ossium, where all the other earthy matter of the system is absorbed. In short, the teeth never become constitutionally diseased, nor do they appear, in any instance, to participate in the least in general affections of the frame.

Their substance never swells from inflammation; it never throws out a fungus nor exostosis; it never exfoliates. By the latter expression, I mean, that a part of a tooth never undergoes that process of death, and subsequent separation from the living parts, which we call exfoliation in bones. Whole teeth are sometimes included in an exfoliated portion of the jaw; but then they are not at all altered in structure or appearance, which is another proof of their want of connection with the rest of the body. If it be said that these teeth are dead, like the bone which incloses them, I would wish to be informed, what are the distinctions in appearance between a dead and a living tooth? Are they to be ascertained by external inspection in the living body, or can they be even demonstrated by anatomical investigation? The absorption of the fangs of the temporary teeth cuts off the vessels long before these teeth are actually shed: yet there is no sign or character by which a tooth, whose vascular supply is thus intercepted, can be distinguished from another, in which it remains unimpaired.

A consideration of the mode of formation of the teeth will lead us to the same conclusion, as the arguments already adduced so clearly and irrefragably establish. In this view of the subject, we must inevitably be struck with the great difference between the growth of the teeth, and that of all other bones; a circumstance which would naturally lead us to expect the differences which are found in their structure and economy. In the cartilaginous epiphysis of a young bone, vessels are seen entering from all sides: in the centre there is a small bit of bone of a loose and spongy texture, which can be made quite red by injection. We can trace this hardening through every intermediate stage to that of perfect bone, the vessels of which, even in its most compact state, are still easily demonstrable by the anatomist. Let us compare with this the growth of a tooth. If we examine it at ever so early a period, when a speck of ossification only can be discerned, the part, which is then formed, is complete, and has all the properties which belong to the bone of the perfect tooth. It does not undergo that gradual process of development, which is seen in the growth of bones; but the smallest point, when once formed, never alters. The mode of connection of the tooth to its pulp is highly worthy of consideration. In cartilaginous epiphyses, the central portion of bone is imbedded in the

cartilage: vessels can be traced in numbers entering it on all sides. Observe the contrast in the tooth: the ossification does not go on in the centre of the pulp; but the bone of the tooth covers that part exteriorly like a shell. The connection between them is merely that of contact of surface; there is no discoverable vascular union: a small degree of force suffices to separate them, and the surface of each remains smooth and uninjured.

The arguments and illustrations which we have now offered, tend most strongly to shew, that the teeth possess no vessels in their substance: the point is undeniably proved by the result of anatomical injections, and the effect of feeding animals with madder.

Anatomists have not hitherto succeeded in their attempts to inject coloured fluids into the vessels of the teeth after death. The pulpy substance in the cavity of the tooth may be made red by the injection; but no trace of vessels entering the bone can be discovered. Yet the arteries of other bones, even of such as possess the most compact structure, can be readily demonstrated. No vessel can be shewn in a tooth at any period of its growth; although the proportion of animal matter in the bone of the tooth is not less than what we find in any other bone. To us this argument appears most strong and convincing; but it has sometimes been evaded by stating, that there are other parts in the body possessing no demonstrable vessels, which are yet proved, by various phenomena, to be vascular. Without entering particularly into the general question, we may just observe, that an example, to carry any weight with it, should be adduced from parts of a similar structure; some bone for instance.

The effects produced on the teeth, by feeding animals with madder, tend most directly to prove that these parts possess no vessels. We shall present the reader with the results of Mr. Hunter's experiments in his own words:

"Take a young animal, viz. a pig, and feed it with madder for three or four weeks: then kill the animal, and you will find, upon examination, the following appearances: First, if this animal had some parts of its teeth formed before the feeding with madder, these parts will be known by their remaining of their natural colour; but such parts of the teeth as were formed while the animal was taking the madder, will be found to be of a red colour. This is different from what happens in all other bones; for we know that any part of a bone, which is already formed, is capable of being dyed with madder, though not so fast as the part which is forming. Therefore, as we know that all other bones, by being vascular, are susceptible of the dye, we may conclude that the teeth are not vascular, because they are not susceptible of it when once formed." It is further stated, that the dye communicated to a growing tooth by means of madder is never afterwards discharged, although all other bones lose their colour in time. Nat. History of the Human Teeth, 2d. edit. p. 37 and 38.

The arguments advanced by persons who hold a contrary opinion, who consider the teeth to possess vessels and nerves, and to be endowed with vitality, are so weak and indirect, in comparison with those which are to be urged against these positions; that we should, perhaps, stand excused, if we entirely omitted to notice them. Yet, as the subject is interesting, and as we wish to exhibit a complete view of the question, we shall bestow a few words on their refutation.

It is said, that a part containing so much animal matter as the teeth, could not exist in the temperature of animal body, without undergoing chemical changes. This is merely begging the question. If it can be shewn, by
incon-

incontrovertible arguments, that these organs are destitute of all circulation and living principle, that will prove that they can exist in such a temperature without experiencing these alterations. But the futility of the objection is shown by the circumstance of artificial teeth remaining in this situation unaltered.

The fangs of the tooth are said to become united to each other by ankylosis, and to be deformed by depositions of bony matter like exostoses; also to become transparent and horny in old age.

These are all instances of original formation. They exhibit none of those irregularities on the surface which characterize an ankylosis, or exostosis, in other bones; nor is the substance different in any one point from the healthy part of the fang. It is, in short, merely an accidental difference of form; where, as the offices of the part require no definite figure, variations in form occur daily. The transparency, or horny appearance of the fang, belongs so decidedly to the natural structure, that a *substantia cornea* is enumerated by Blumenbach among the ordinary constituent substances of the teeth.

A question has been triumphantly stated to the opponents of the vascularity of the teeth; why blood is sent into the cavity of the tooth, except for purposes of growth and action? There is one very obvious end answered by this structure; that of filling up the cavity of the tooth, in proportion as it becomes exposed by the friction of mastication. This indeed only shifts the difficulty a step further; for why should there be any cavity at all? We will give an answer to this question, when we shall have been satisfactorily informed why male animals possess mammae and nipples, which are never of the least use to them in any part of their lives: or why a thousand other parts of the body, where we are either ignorant of the office, or can discover no connection between it, and any specific form or organization, should be framed as they are.

The yellow colour imparted to the bone of the teeth in jaundice has been urged in proof of their vascularity. This is an argument that would prove too much. The vessels of the teeth, if any such exist, are obviously so minute, that they neither convey red blood, nor coloured injection; yet they are capable of carrying so much bile as to tinge the tooth of an uniform yellow to a certain distance from the cavity. If this colour be then owing to a yellow fluid, contained in vessels, these tubes must be so numerous as to render the tooth much more vascular than other bone. The real state of the fact is this, the vessels of the pulp become loaded with bile, and dye that part of an uniform yellow colour; this tint is mechanically imparted to the adjacent bone, and colours it in the neighbourhood of the cavity; the effect gradually ceasing at a little distance from that part. The appearance, in short, is produced in the same way as by immersing the teeth in bile after death. We are informed that the teeth in old age become changed in colour, and particularly that they acquire a greater transparency. No one pretends to affirm, that such a change cannot happen; but why may not this change be produced by mechanical or chemical means? Have we not reason to expect that a long residence in the moisture of the mouth, and contact with all the substances that form our food, should influence the appearance of these organs; and that this effect should be produced to a greater extent, where the destruction of the enamel by mastication, as in old persons, has exposed the bone of the tooth?

Transplanting the teeth from the head of one person to that of another, or to parts of another animal's body, as the comb of a cock, where they will become adherent, has

been considered as a proof of their possessing vessels. These experiments will succeed with dead teeth; and the truth of this fact, in respect to the latter circumstance, has been ascertained by Mr. Moor, whose ingenious experiments on the teeth we have before had occasion to mention. We have seen a cock, in whose comb he had inserted a tooth, which had previously lain many months in a drawer, and it was firmly adherent.

The advocates for the vascularity of the teeth have laid great stress on the phenomena attending the decay of these organs; and particularly on the pain, which is occasioned in some parts of the process. We are firmly convinced that an attentive investigation of the origin, progress, and symptoms of this affection will most materially support and illustrate those opinions, which we have all along endeavoured to inculcate.

This disease begins by a speck on the surface of the enamel, and, when it has destroyed that part, it attacks the bone of the tooth. Its progress is now much more rapid: the bone becomes excavated, and the enamel remains in the form of a shell. The surface assumes more or less of a brown colour, and becomes considerably softened, gradually crumbling away until the cavity of the tooth is exposed. The exposure of the vascular and sensible pulp to the air and to the food, occasions that acute pain which attends the decay in this stage.

It would perhaps be difficult to ascertain, beyond the possibility of a doubt, whether or not the pain of toothache ever comes on before the exposure of the cavity. This, at least, is certain, that if the affirmative were most clearly established, it would by no means prove the teeth to be vascular. If we take any very warm or cold fluid into the mouth, it occasions pain of the teeth; this cannot prove the surface of contact to be sensible, for that is enamel, which no one supposes to possess nerves or vessels. The impression is communicated through the substance of the tooth to the nerves in its cavity. When the enamel and a part of the bone is removed by decay, there is so much of the medium between the impressing body and the nerve taken away, that an impression which before only excited a slight sensation, may now cause actual pain. The influence, which variations in the insensible medium between the nerves and external bodies produce on the sensation arising from their contact, is strikingly evinced in the skin; the removal of the cuticle occasions pain to follow the contact of any body, instead of its conveying to our minds impressions of its tangible properties; and a thickened state of this integument entirely obstructs sensation. It is moreover certain that the effect of the decay is not limited to the surface of the tooth, but that the discolouration extends for some depth into its substance; the change, which is indicated by this alteration of colour, may bring on a painful affection of the nerve of the tooth, without an exposure of the cavity.

The following reasons shew that this decay is not the effect of vascular action. It first attacks the enamel, which is confessedly not vascular. There is no attempt at reparation during the whole process; so that if it be, as some persons call it, an ulcer, it must, we presume, be of a cancerous nature. If any doubt could remain on the subject, it will be removed by the fact, that artificial teeth are as much subject to decay as natural ones. The appearance and progress of the caries is exactly the same as in teeth naturally contained in the jaws. The discolouration appears to me to be more deep and extensive in the artificial teeth formed of the tooth of the hippopotamus, than in the natural human teeth. But in engrafted human teeth the decay is precisely similar to that of the natural ones.

C R A N I U M.

The alleviation of the pain of the tooth-ache by caustic applications to the surface, as muriatic acids or argertum nitratum, has been considered as a proof that the caries is an ulcer in an irritable state, and that its irritability is destroyed by these applications. Since however these remedies may act upon the exposed vascular contents of the cavity of the tooth, or may affect these contents, before actual exposure, by penetrating through the thin medium which remains, it is obvious that they can afford no proof of the point in question. Other means however of stopping the pain of tooth-ache afford a strong proof that the pain does not arise from the ulcerated surface, but from the nerves in the cavity. Let the decayed hole be stopped up (which is rather a rude method of using an irritable ulcer), so as to cut off the access of the external air, and of foreign bodies, and the pain will cease.

It is not perhaps so easy to determine what the decay is, as what it is not. Those who consider the teeth as destitute of vessels, ascribe their decay to the chemical action of the juices of the mouth, and of the substances which are taken in for food. It is difficult to comprehend how a cause, which must necessarily be so general in its application, should be so circumscribed in its effects: never producing decay in an extent of surface, but being limited at its commencement to a small spot. Here however it may be observed, that a large surface sometimes decays in artificial teeth, under circumstances favouring an accumulation of fluids in a particular part; *viz.* the portion which corresponds to the gum, which is usually grooved; and thereby more likely to retain any fluids.

Many arguments may be adduced to prove, that the decay of the teeth originates from the causes above-mentioned. It commences in those situations, which favour the lodgement of food or extraneous matters; as between the teeth, and near the neck, just where the gum adheres. It is cured by stopping up the hole, and preventing the introduction and accumulation of the food, and the juices of the mouth. It is most frequent in the higher classes of society, where the food is of the most unnatural kind, and the appetite is pampered with all the refinements of cookery; and is much less common in the peasantry, which take more simple food, and employ it in a more natural form. It is very rare to see it in the teeth of savages, or such persons as have lived nearly in a state of nature; and it never, we believe, occurs in animals. In twelve or fourteen crania, discovered in two barrows opened in Gloucestershire, there was not a single decayed tooth. This mode of burial has not been employed for the last six centuries, so that the heads in question must be referred to a remote period of history, to a time when the modern habits of luxury and indulgence, in respect to food, were unknown, and where the effects of such habits on the teeth were of course not discernible.

A similar observation is made by Sir John Sinclair, in his "Code of Health and Longevity," vol. i. p. 69, respecting the state of the teeth in the crania, found on opening a place of interment at Scone, near Perth in Scotland. This had not been touched for two hundred years; and among a great number of skeletons there was hardly one, whose teeth were not entire and found. This fact leads the worthy baronet to suppose that our ancestors enjoyed advantages over us in the structure of their teeth; but our explanation of the appearance will be collected from the remarks made above. The practice of smoking, which is universally prevalent in some countries on the continent, is attended with a most marked deleterious effect on the state of the teeth; inasmuch that the discoloured and unsound state of these organs,

in inhabitants of such countries, attracts the notice of every traveller.

As all the attempts to prove the vascularity of the human teeth by direct arguments, drawn from the structure and diseases of these organs, have so completely failed, recourse has been had to comparative anatomy; and the constant growth of the teeth of glires, and the appearances caused by the presence of bullets in elephant's tusks, have been brought forwards in support of their opinions by the partisans of the vascularity of the teeth.

Animals of the class glires of Linnæus, such as the beaver, hare, rabbit, squirrel, rat, mouse, &c. are distinguished by possessing two very large incisor teeth in each jaw, which being employed by the animal in cutting various hard bodies, wear down very rapidly. Hence if these animals be kept to soft food, their teeth grow out to a great length; and if these teeth be lost from one jaw, the opposite ones grow out in the same way. This constant growth of these organs is effected in the same manner as their original formation. They are hollow internally, and contain a pulp, which continues to deposit fresh substance below, in proportion as the tooth wears away above. The tusks of the elephant possess the same constant growth, as also those of the hippopotamus, and all similar organs.

When an elephant's tusk has been shot with a leaden bullet, it is said, that the opening, through which the ball entered, is filled up again by the vessels of the tooth. The bullet is closely surrounded by the ivory, and there is a swelling towards the cavity of the tooth opposite to the situation of the foreign body, ascribed to the inflammation caused by its irritation.

It may be observed in the first place, that the appearances exhibited by the teeth in question, are by no means what we should reasonably expect in such a case. When a bullet has entered the substance of the body, the surrounding lacerated and confused parts do not grow to the metal and become firmly attached to its surface, but they inflame and suppurate, in order to get rid of the offending matter. If the ivory be vascular and sensible, why do not the same processes take place in it?

We can explain very satisfactorily how a bullet may enter the tusk of an elephant, and become imbedded in the ivory without any opening for its admission being perceptible. We have already mentioned, that these tusks are constantly growing during the animal's life, by a deposition of successive laminae within the cavity, while the outer surface and the point are gradually worn away; and that the cavity is filled for this purpose with a vascular pulp, similar to that on which the teeth are originally formed. If a ball penetrate the side of a tusk, cross its cavity, and lodge in the slightest way on the opposite side, it will become covered towards the cavity by the newly deposited layers of ivory, while no opening will exist between it and the surface, to account for its entrance. If it have only sufficient force just to enter, it may sink by its own weight between the pulp and tooth, until it rests at the bottom of the cavity. It there becomes surrounded by new layers of ivory, and as the tusk is gradually worn away, and supplied by new depositions, it will soon be found in the centre of the solid part of the tooth. Lastly, a foreign body may enter the tusk from above, as the plate of bone which forms its socket is thin: if this descends to the lower part of the cavity, it may become imbedded by the subsequent formations of ivory. This must have happened in a case where a spear head was found in an elephant's tusk. The long axis of the foreign body corresponded to that of the cavity. No opening for its admission could be discovered, and it is clear that no hu-

man strength could drive such a body through the side of a tusk. See Philof. Transact. 1801. part 1.

Having now enumerated the reasons which prove that the substance of the teeth is destitute of vessels and nerves, and having briefly answered some objections which may be made to that opinion, we shall terminate the present division of the article by putting one question to the supporters of a contrary doctrine. Of what use could vessels and nerves be in a part like the tooth, which undergoes no natural change except the mechanical one of abrasion of surface, which is subject to no disease except one, that is referable to chemical action; which sets up no process of regeneration to repair the effects of either of these changes, or the consequences of accidental injury, and which in every known state is totally destitute in itself of all sensation? We desire to know what end could be answered by making these parts vascular and sensible?

The following are the most useful works on the teeth, and contain representations of most parts of their structure and anatomy. Eullachii "Libellus de Dentibus." Albini "Annotationum Academicarum," lib. ii. J. Hunter's "Natural History of the Human Teeth." Girardi "Oratio de Re Anatomicâ." Parma, 1781, 8vo. Blake's "Essay on the Structure and Formation of the Teeth in Man and various Animals." Dublin, 8vo. 1801. Fox's "Natural History of the Human Teeth." Soemmering, *de dentibus*, in the first vol. of his "Anatomy."

In the description which we have thus given of the individual bones of the cranium and face, all the particulars relating to their structure and formation are detailed. It remains for us to view the skull as forming one whole, which is indeed the proper way of considering it, as the connection of the various bones, by means of sutures, is so firm, that the adult cranium may be considered as consisting of a single piece of bone. Hence it becomes necessary to describe the form of the cranium and face in a general way.

Many of the cavities and depressions in the skull and face, which are formed of processes of several bones, would not be at all understood by reading the descriptions of the individual bones. These, therefore, must be described as they exist in the entire cranium, in order to give the reader a notion of their form, extent, &c. Hence we shall add to the account of the form of the cranium and face, a description of the *calvaria* (skull cap), *basis cranii*, *temporal fossa*, *orbit*, and *nose*, and a general enumeration of the openings on the surface of the skull. This will be followed by a description of the *national differences in the form of the skull*, and the article will be concluded by an enumeration of the characters of the human head; by an account of those points of structure which distinguish the cranium of man from that of other animals.

Form of the Cranium and Face.

The external surface of the cranium, considered on its anterior, superior, and posterior parts, is pretty regularly elliptical; the narrower part of the ellipse being placed in front, and the broader part behind. The radius of the anterior part is to that of the posterior as three to four, or two to three, in the infant; as thirty to thirty-one in the adult. The largest horizontal circumference of the cranium presents likewise an oval figure, and is narrow or contracted in front, broader behind. The anterior, posterior, and upper parts of the bony arch are uniformly convex on their surface; but the sides of the cranium are rather flattened by the temporal muscles. These, however, are convex like the rest of the surface in infants.

The greatest diameter of the cranium is from the os fron-

tis to the occiput, and measures six inches and a half; the greatest *transverse* diameter is five inches and a half; and the greatest *perpendicular* (*viz.* from the middle of the foramen magnum to the vertex) five inches.

A longitudinal section of the cranium, in the direction from before backwards, would form an oval rather contracted in front, if its curve were continued from the occipital foramen to the root of the nose. The great axis of the oval would be nearly parallel to the floor of the nostrils, or at least it would slope backwards very slightly. The ratio of the great to the small axis would be as five to four. But the space included between the two points above-mentioned, which form the boundary of the cranium and face, instead of presenting a curved line, forms an irregular projection within the cavity of the oval. The section of the face forms, therefore, a triangle, the longest side of which is that which touches the cranium, and the shortest is the anterior one.

The external surface of the cranium, on its upper and back part and sides, is generally smooth and uniform, with the exception of the slight inequalities noticed in the frontal, parietal, and occipital bones. It is also solid or imperforate, with the exception of a few small apertures. The basis on the contrary is very irregular and broken in its surface, and pierced by numerous apertures, which transmit arteries to the interior of the cranium, give exit to the corresponding veins, and allow passage to the various nerves originating from the brain. On either side of its anterior part it is excavated to contribute to the formation of the orbits. Between these two hollows it descends towards the cavity of the nose, and behind the palate. A prominence on either side assists in forming the zygomatic arch; the malleoid processes form large protuberances behind, and the articular condyles of the occiput smaller ones near the centre of the basis.

Description of the Calvaria, or Skull-cap.

An horizontal section of the cranium, at whatever part, represents an ovate figure, of which the small end is placed anteriorly and the larger posteriorly.

The bony arch which forms the upper part of the head, consists of the greatest part of the frontal and parietal bones, with a small share of the occipital. Its internal surface is nearly smooth. It only presents the impressions made by the vessels and glandulæ pæchioni of the dura mater, or by the convolutions of the brain. A broad, but superficial groove runs along the middle of the bony vault in its whole extent; it holds the superior longitudinal sinus of the dura mater. The pits of the glandulæ pæchioni are found in considerable number, but of various sizes and depths, on either side of this groove. Frequently the bone is so thin in these pits that it appears transparent when held against the light.

Basis Cranii.

The basis or floor of the cranium is very unequal on its surface, and presents considerable prominences and depressions, adapted to the various parts of the basis of the encephalon. It may be divided into *three regions*, of which the anterior exhibits a convex surface, while the two posterior are considerable depressions or fossæ.

The *posterior region*, which is chiefly occupied by the cerebellum, may be named fossa cerebelli. It is the deepest of the three, and has been called the lower occipital fossa.

The great occipital foramen is formed in the middle and lower part of this division. From the front of this opening a slight excavation extends obliquely upwards and forwards,

and

C R A N I U M.

and is terminated anteriorly by a thin projecting bony plate, the two corners of which form the *posterior orbital processes*. The ethmoid lamina, which forms the boundary of this excavation, belongs to the sphenoid bone; the concavity itself is chiefly formed by the basilar process of the occiput, and may be called the *basilar fossa*. The medulla oblongata rests in it, and sends from its lower or posterior part the medulla spinalis through the foramen magnum.

From each posterior ethmoid process, a sharp ridge is continued obliquely backwards and outwards, and marks the termination of the fossa cerebelli in this direction. To this part, which belongs to the petrous portion of the temporal bone, the tentorium cerebelli is affixed. The posterior boundary of this fossa is formed by the internal transverse ridge of the occiput; from the middle of which a longitudinal spine descends to the foramen magnum, so as to divide the fossa cerebelli into equal portions; in which the two lobes of the cerebellum are contained.

The *anterior region*, which supports the front lobes of the cerebrum, is formed by the roof of the orbits and nose. It is not separated, by any mark of distinction, from the calvaria. Its posterior boundary is the sharp concave edges of the lesser sphenoid alæ. These terminate towards the inner and back part by two rounded projections (*anterior ethmoid processes*;) situated nearly opposite the posterior ethmoid processes. A slight prominence of the bone between these projecting points completes its posterior boundary. The middle of this region is the deepest part; it is the cribriform lamella of the ethmoid bone, having the crista galli standing up from its middle, and dividing the two anterior lobes of the cerebrum. The sides, which are formed by the roofs of the orbits, are convex and irregular on their surface, from the prominences which rise between the convolutions of the brain.

The *middle region* consists of a large fossæ on either side of the skull, formed by the upper surface of the great sphenoid ala, and of the petrous bone. The boundaries of the anterior and middle regions will of course form the limits of these middle fossæ of the cranium. The surface of this division occupies the intermediate degree between the level of the anterior and posterior regions. As these latter extend considerably farther in the middle of the cranium than at the sides, they nearly meet together in the centre, where they are only separated by the *fella turcica*; which cavity belongs to the middle region, although it is more elevated than the fossæ, which lie on either side of it.

These middle fossæ of the basis cranii hold the anterior convex portions of the posterior lobes of the cerebrum (the middle lobes of some writers.)

The Temporal Fossa.

The flat surface which is observable towards the anterior part at the side of the cranium affords attachment to the temporal, or erotaphyte muscle. A white and somewhat prominent line commences behind the outer edge of the orbit, and runs upwards and backwards over the frontal and parietal bones, so as to describe a semicircle on the side of the skull. From the termination of the parietal bone it turns forwards over the os temporis to the root of the zygoma. This line, the superior edge of the zygoma, and the posterior margin of the os malæ have the strong temporal fascia attached to their surface. The side of the skull with in the line, which is obviously compressed or flattened, including a small portion of the os frontis, a very large share of the parietal bone, the whole squamous portion of the temporal bone, a considerable surface of the sphenoid ala, and of the os malæ, gives origin to the fibres of the

muscle. The internal orbital process of the cheek-bone separates this fossa from the orbit; and the zygoma is a bony arch at the lower part, where it is deepest, within which the tendon passes.

The surface of the temporal fossa is much more extensive, and the depression is more strongly marked, in the negro than in the European.

Cavity of the Orbit.

Those deep bony cavities of the face, called the *orbits*, which hold the organs of vision, are separated from each other by the nose; and are situated under the front of the cranium. They represent in form four-sided pyramids, of which the angles are rounded off; the basis is placed towards the front, and the apex backwards. The margin or front entrance of the cavity has the same square form with rounded angles; and hence it consists of a superior, inferior, external, and internal margin; the junction of which to each other, forms the frontal, temporal, malar, and lacrymal angles. The orbit has also four surfaces; a superior, which extends nearly in the horizontal direction, and is concave; an inferior, which slopes very slightly backwards and upwards; an internal gently convex; and an external which is level. They are all very smooth.

The internal surfaces of the two orbits are parallel to each other; while the outer surfaces are situated very obliquely, passing from before backwards and inwards. Hence the axes of the two cavities would join at an angle in the *fella turcica*. In consequence of this construction the eyes command a wider field of vision than they would if the axes were parallel to each other.

Seven bones contribute to form this cavity: the upper surface is formed by the os frontis only; the inner by the os unguis and os planum; the inferior by the superior maxilla, os malæ, and palati; the outer by the os malæ, and sphenoid bone.

The form of the cavity is subject to considerable variety.

It is only in comparatively modern times that the orbits have been described in their true connection and relations. Besides the few remarks which Winslow has made on the subject in the "Memoires de l'Acad. des Sciences de Paris," 1721; much information may be derived from the 1st chap. of Camper's "Diff. Physiol. de quibusdam oculi partibus. L. B." 1746; and from the 7th chap. of Zinn's immortal work "Descript. Anat. oculi humani." Götting. 4to. 1755.

Cavities of the Nose.

The bony hollows, on which the olfactory membrane is expanded, are placed between the orbits and below them. Fourteen bones contribute to their formation; viz. all the bones of the upper jaw, excepting the ossa malæ, the ethmoid, sphenoid, and frontal bones.

The extent of the cavity from its commencement in front to its termination at the back of the palate, is not very considerable: but it is greatly increased by the numerous cells of the cranium and face, which open into it at different parts. A broad perpendicular septum divides it into a right and left cavity; but this division is generally an unequal one, as the bony partition commonly inclines to one side or the other.

The *septum narium* is formed by the nasal lamella of the ethmoid bone, and the vomer. The *entrance* of the nose is constituted by the ossa nasi and superior maxillæ; and, as far as the bony compages is concerned, consists of a single heart-shaped aperture, common to both nostrils. The upper and anterior part of this opening possesses a sharp edge; and

C R A N I U M.

and there is a curved spinous process projecting from its middle and lower part.

The termination of the nasal cavity, or its *posterior opening* (*choana*.) instead of being common to both nostrils, consists of two apertures; one for each side. They are formed by the internal pterygoid plates of the sphenoid bone, the *ossa palati* and vomer. Their figure is somewhat oval, and the length exceeds the breadth.

The *bottom* or floor of the nose, which is concave, is formed by the superior maxillæ and *ossa palati*. The *inner surface* of each nostril is smooth, uniform, and perpendicular, as being formed by the septum narium. The outer surface is very irregular, chiefly from the projection of the three conchæ or turbinated bones, which hang into the cavity.

By these projecting conchæ three cavities are formed in the nostril, called the *canales* or *meatus narium*. The *inferior* is the largest, and is included between the floor of the nostril, and the inferior turbinated bone. The *middle* is the space left between the last mentioned part, and the middle concha; and the *superior*, which is the smallest, is between the middle and superior conchæ. The last of these does not open anteriorly; but the two former communicate with the nostrils in front as well as behind.

The superior surface or roof of the nose is the least extensive of all; and is formed by the cribriform plate of the ethmoid bone only.

The ethmoidal and sphenoidal cells open into the superior meatus: the frontal and maxillary sinuses terminate in the middle; and the nasal duct ends in the lower meatus.

Casserius furnished the first accurate description and delineation of the cavities of the nose, in the human subject, and in different animals, ("De Fabrica nasi," in his "Pentæthescion," p. 115. et seq. 1610.) Among modern writers on this subject, Aurivillius deserves particular mention, ("Diff. de naribus internis," Upsal. 1760.) The reader may consult likewise Duverney's "Œuvres Anat." vol. i. tab. 14. Haller's "Tab. narium internar." in the 4th Fascic. of his "Icones." Santorini's "Tab. posthum." editæ à Girardo. tab. 4. Blumenbach's "Prolusio Anatom. de Sinibus Frontalibus."

General Enumeration of the Foramina, Fissures, Canals, &c. in the entire Cranium.

I. On the external surface.

- a. On the *vertex*, or upper part of the head.
 1. *Foramina parietalia* for a small artery and vein.
- b. In the *orbit*.
 2. *F. s. supraorbitalia* for the frontal nerves and arteries.
 3. *F. s. infraorbitalia*; the openings of the infraorbital canals for the arteries and nerves of the same name.
 4. Superior openings of the lacrymal canals.
 - 5, 6. *F. orbitalia interna* for the nasal branches of the ophthalmic nerves, and the ethmoidal arteries.
 7. *F. optica* for the optic nerves and ocular arteries.
 8. *Fissura orbitalis superior* (*foramen lacerum orbitale*) for the 3d, 4th, and 6th pairs of nerves, the ophthalmic branch of the 5th pair, and the ocular veins.
 9. *Fissura sphenopalatina*, at which the 2d branch of the 5th pair divides.
 10. *Inferior orbital*, or *spheno-maxillary fissure* for the passage of the infraorbital nerve.
- c. In the *palate*.
 11. *Foramen incisivum*, or *palatinum anterius*.
 12. *Foramen palatinum posterius* for the palatine artery and nerve.

- 13, 14. Two smaller palatine holes for more minute twigs of nerve or artery.
- d. In the *ear*.
 15. *Meatus auditorius externus*.
 16. *Fissura glaseri* for the chorda tympani, and origin of the externus mallei.
- e. In the *basis cranii*
 17. *Foramen sphenomastoideum* for the facial nerve, and an artery and vein.
 18. *Foramen ovale* for the 3d branch of the 5th pair.
 19. Opening of the *pterygoid canal* for the Vidian nerve.
 20. *Foramen spinosum* for the art. meningea media.
 21. Entrance of the *carotid canal* for the carotid artery, and a branch of the 6th pair of nerves.
 22. *Foramen lacerum in basi cranii* (*f. jugulare*) for the jugular vein and par vagum.
 23. *Foramen condyloideum anterius* for the nervous linguualis medius.
 24. *Foramen condyloideum posterius* for the passage of veins.
 25. *Foramina mastoidea* for the passage of veins.
 26. *Foramen occipitale magnum* for the medulla spinalis, with its coverings; the vertebral arteries; and the nervi accessorii.
- f. In the lower jaw.
 27. *Foramen maxillare posterius* for a branch of the inferior maxillary nerve, and an artery and vein.
 28. *Foramen mentale* for the mental nerve.

II. On the inner Surface of the Skull.

- a. in the *vertex*.

Foramen parietale, mentioned above.
- b. In the *basis cranii*.
 29. *Foramen cæcum* for the attachment of the falx cerebri.
 30. *Foramina laminae cribosæ* for the olfactory nerves, and nasal branch of the ophthalmic nerve.
Foramen opticum, mentioned above.
Fissura orbitalis superior, mentioned above.
 31. *Foramen rotundum* for the 2d branch of the 5th pair.
Foramen ovale, mentioned above.
Foramen spinosum, mentioned above.
 32. *Termination of the carotid canal*
 33. *Foramen on the petrous bone* for a branch of the Vidian nerve.
 34. *Meatus auditorius internus* for the 7th pair of nerves.
 35. Opening of the aquæductus vestibuli.
 36. Opening of the aquæductus cochleæ.
Foramen lacerum in basi cranii, mentioned before.
Foramen condyloideum anterius, mentioned before.
Foramen condyloid. poster. mentioned before.
Foramina mastoidea, mentioned above.
Foramina occipitale magnum, mentioned above.

National varieties in the Form of the Cranium.

It is only of late years that this subject, which offers a most important and interesting field of investigation, has been examined with that attention which it deserves. With the exception of a few desultory observations, which are scattered through the works of different writers, Daubenton's paper, "Sur la difference du grand trou occipital dans l'homme, et dans les autres animaux," in the memoirs of the Royal Academy of Sciences for 1764, contains the first attempt at any general remarks on the subject: and this, indeed, is more important in pointing out the differences between the human structure and that of animals, than in

defining the characters of the cranium in the different races of mankind. Camper has attempted a more systematic account of the national forms of the cranium. (See the 1st. vol. of his "Kleinere Schriften;" his "Naturgeschichte des Ours, et Outang;" and particularly the "Dissertation physique sur les differences reelles que presentent les traits du visage chez les hommes de differens pays et de differens ages," Utrecht, 1794, translated from the original Dutch.) The observations of this illustrious anatomist on the present subject, as on all others which he has treated, are ingenious and interesting; but cannot be considered as even approximating to a systematic account of the national varieties of the skull. He does not appear to have possessed a sufficient collection of crania for this purpose; and the differences which he has pointed out, regarding merely the various degrees of prominence of the jaws, afford very insufficient criteria for determining the numerous points of distinction which characterise the skulls of different nations. We are indebted to the celebrated Blumenbach of Göttingen for the most complete body of information on this subject: which he has been enabled most successfully to illustrate, by means of a collection, containing above a hundred specimens, of the crania of different nations from all parts of the globe. His admirable work, "De generis humani varietate nativâ," contains a short sketch of the various formations of the skull in different nations: but he has treated the matter at greater length, and with more minute detail in an express work, where the various crania are represented of their natural size: the book is entitled, "Decades craniorum diversarum gentium illustratæ," Göttingen, 1790, 1800, 4to. Four decades, containing representations of forty crania, have hitherto arrived in this country. The following account will be chiefly derived from the two last-mentioned books.

It is sufficiently obvious that there must be a close connection between the external parts of the face, or the features, and the bony compages which lie under and support these. So that we might venture to affirm, that a blind man, if he knew the vast difference which exists between the face of a Calmuck and that of a Negro, would be able to distinguish the crania of these two races of mankind by the mere touch. Nor could you persuade any person, however ignorant of the subject, that either of these skulls belonged to a head, similar to those from which the divine examples of the ancient Grecian sculpture were copied. Thus much is clear and undeniable, as to the general habit and appearance of the skull. A more careful anatomical investigation of genuine specimens of the crania of different nations promised to throw still further light on the subject of the varieties of the human race. For, when freed from the soft parts, which are less constant and regular in their formation, they exhibit the firm and solid foundation of the head; they can be conveniently handled and examined; considered in various points of view, and compared with each other.

Such a comparison will shew us, that the form of the cranium differs no less than the colour of the skin, or other characters, in different individuals; and that one kind of structure runs by gentle and almost inobservable gradations into another: yet that there is on the whole an undeniable, nay, a very remarkable, constancy of character in the crania of different nations, contributing very essentially to national peculiarities of form, and corresponding exactly to the features which characterise such nations. Hence, anatomists have attempted to lay down some scale of dimensions to which the various forms of the skull might be referred; and by means of which they might be reduced into certain

classes. Of these endeavours, the *facial line* of Camper seems to claim the most attention.

The cranium, being placed laterally, two imaginary lines are drawn on its surface to intersect each other at a particular point. The first proceeds horizontally through the meatus auditorius externus, and the floor of the nostrils. The other, or the proper *facial line*, is continued from the most prominent portion of the forehead above the nose, to the front of the alveolar margin of the upper jaw-bone. From the angle formed at the junction of those two lines, this excellent anatomist conceived that we might estimate the differences of the cranium in animals, as well as in the various races of mankind. (A further account of the results of its application will be given in the division of this article on the characters which distinguish the human cranium from that of animals.)

This criterion is exposed to some very serious and essential objections. It is sufficiently obvious, that the *facial line* can at most be applicable to such varieties only of the human race as differ from each other in various degrees of prominence of the jaws; and that it will not at all exhibit the characters of those which vary in the opposite way, *viz.* in the greater or less breadth of the face. It often happens that crania of the most different nations, which differ *totò celo* from each other on the whole, have the same facial line; and, on the contrary, that skulls of the same nation, which agree in general character, differ very much in the direction of this line. Thus, in the *decades* of Blumenbach, we have represented the crania of a Negro and of a Pole, which possess exactly the same facial line. Yet the general character of the two skulls is most widely different, when the narrow and almost keel-shaped head of the Ethiopian is compared to the broad square form of the Lithuanian. (*Decas Altera*, tab. 10. *Decas Tertia*, tab. 22.) There are, on the contrary, in the same work two Negro crania of very different facial lines, which, when viewed in front, betray their Ethiopic origin most incontestably, by the same characters of a narrow and compressed cranium and arched forehead. (*Decas Prima*, tab. 7 and 8.) Lastly, Camper himself has employed his two lines, in the plates subjoined to his work, in so arbitrary and inconstant a manner, changing frequently the point of contact, on which their whole utility must depend, that he clearly appears to be hesitating and uncertain in their employment.

Blumenbach states, that in the examination and classification of his immense collection of the crania of different nations, he finds it every day more and more difficult, amidst such numerous differences in the proportion and direction of various parts, all of which contribute more or less to the national character, to reduce these to the measurements or angles of any single scale. Since, however, in distinguishing the characters of different crania, such a view will gain the preference to all others, as offers at one glance the most numerous and important points, and such as contribute especially to the comparison of national characteristics, he has found by experience that to be the best adapted to this purpose, which is obtained by placing the different crania (including the lower jaws), with the zygomas, in the same perpendicular line, on a table in a row, and contemplating them from behind. When crania are thus arranged, those circumstances which contribute most to the formation of the national character, the direction of the jaws and cheek-bones, the breadth or narrowness of the head, the arched or flat form of the forehead, are all distinctly perceived at one view. This method of considering the cranium is called by Blumenbach *norma verticalis*. It is exhibited in the three first figures of the second plate of the anatomy of the cranium,

C R A N I U M.

nium, where three heads are represented in this point of view, in order to illustrate the subject. The middle of the three (*fig. 1.*), distinguished by the symmetry and beauty of all its parts, is that of a Georgian female; the two outer ones are examples of heads differing from this in the opposite extremes. That which is elongated in front (*fig. 2.*) is the head of a Negress, from the coast of Guinea; the other, which is expanded laterally, and flattened in front (*fig. 3.*), is the cranium of a Tungoose, from the north-east of Asia. The margin of the orbits and the zygoma are elegantly contrasted in the Georgian; and the jaws are hidden by the symmetrical expansion of the forehead. In the Ethiopian, the maxillary bones, and indeed the whole face, are compressed laterally, and project in front. In the Tungoose, on the contrary, the ossa maxæ, ossa nasi, and glabella, are situated on the same horizontal level, and are enormously expanded on either side.

The national varieties in the form of the cranium may be considered in the five chief divisions, under which the different nations of mankind have been distributed by Blumenbach. The first of these comprehends the inhabitants of Europe; together with the western Asiatics, or those which are found on this side of the Caspian sea, and the rivers Ob and Ganges; and the northern Africans: in a word, the inhabitants of the world as known to the ancients. In this, which Blumenbach calls the *Caucasian* variety of the human race, the form of the cranium is somewhat globular; the forehead moderately expanded; the cheek-bones narrow, and not prominent, but descending in a straight line from the external angular process of the os frontis. The alveolar margin of the jaws is rounded; the front teeth are placed perpendicularly in both jaws. The angle formed by the facial line is 80 degrees.

As a specimen of this variety, we have selected from the third decade of Blumenbach's work the cranium of a Georgian woman; which, on account of the exact symmetry and beauty of its formation, may be regarded as the model of a perfect head. (*Anatomy of the Cranium. Plate I. fig. 1.*) The form of this head is of such distinguished elegance, that it attracts the attention of all who visit the collection in which it is contained. We present the reader with the description of this cranium, in the words of Blumenbach. "Calvaria subglobosa, versus tempora paulo compressior; frons modicè explanata; ossa jugalia angustiora, inde a processu malari ossis frontis leniter utrinque descendunt et retrorsum flexa; arcus superciliares æquabiles nullo ad glabellam interstinio distincti, sed eo loco molli potius tubere cum nasi dorso confluentes; limbus alveolaris æquabiliter arcuatus; mentum pleniuseculum, pulchrè rotundatum; verb, in universo capitis hujus ossi ambitu nihil asperi, nihil præter modum profilientis, ita ut perfectè medium teneat locum inter hinc faciei gentilitæ in humano genere extrema; Mongolicum nempe alterum, facie complanata et quasi repressâ, ac ossium jugalium extrorsum utrinque directâ eminentia insigni; alterum Æthiopicum, fronte contra tuberoso et fornicato, ac mandibulis angustis sed antrosum porrectis, conspicuum."

The symmetry and beauty of this Georgian head are further evinced by comparing it with the proportions observed in the invaluable remains of the ancient Grecian sculpture. It corresponds exactly with the marble statue of a nymph, in the collection of the late Mr. Townley, of which Blumenbach possessed a plaster cast. It tends also to confirm the testimony of the numerous travellers who have unanimously concurred in extolling the beauty of the inhabitants of Georgia, and the neighbouring countries. The expressions of Chardin are so warm and animated on this sub-

ject, that the reader will not be displeased by seeing the original passage. "Le sang de Géorgie est le plus beau de l'orient, et je puis dire du monde. Je n'ai pas remarqué un visage laid en ce pays là, parmi l'un et l'autre sexe; mais j'y en ai vu d'angeliques. La nature y a répandu sur la plupart des femmes, des graces qu'on ne voit point ailleurs. Je tiens pour impossible, de les regarder sans les aimer. L'on ne peut peindre de plus charmans visages, ni de plus belles tailles, que celles des Géorgiennes." (Vol. i. p. 171. Ed. of 1735.)

Another specimen of this variety (the cranium of a Turk) has been inserted in the first plate of the anatomy of the cranium, on account of a singularity in its form, arising probably from artificial causes. (*Anatomy of the Cranium, Plate I. fig. 2.*) The cranium is here completely globular. The occiput can hardly be said to exist, as the foramen magnum is placed nearly at the posterior part of the basis cranii. The forehead is broad, and the glabella prominent. The proportions of the face are, on the whole, symmetrical and elegant. The alveolar portion of the upper jaw-bone is singularly short; it does not measure more than the breadth of the little finger under the nose.

The cranium of a Turk, in the possession of the writer of this article, exactly resembles the plate of Blumenbach, (*Decas Prima, tab. 2.*) from which the engraving in the present work was copied. It corresponds also with the form of the head, as observable in the living subject, and with the most faithful delineations of such persons. This peculiarity of form has been observed by several authors: it is indeed so striking, that it could hardly have escaped observation. "It appears," says Vesalius, "that most nations have something peculiar in the form of the head. The crania of the Genoese, and still more remarkably those of the Greeks and Turks, are completely globular in their form. This shape, which they esteem as elegant, and adapted to the turbans, which they wear on the head, is produced by the midwives, at the solicitation of the mothers." (*De Corporis humani Fabricâ, p. 23. ed. of 1555.*) This statement is confirmed by a letter from baron Asch to Blumenbach; in which he says, that the midwives at Constantinople commonly inquire of the mother, after parturition, what form she would like to have given to the head of the child; and that they commonly prefer that which results from subjecting the forehead and occiput to a close compression, as they think that their turbans sit better on the head, when of that shape. (*Decas Prima, p. 16.*)

The other nations, included under this first division, do not seem to be distinguished in general by any remarkable peculiarities; although some slight characteristics have been pointed out. The cranium is broad and square, and the face flattened, in the Laplander; so that he approaches in that respect to the Mongolian variety. According to Vesalius (*loco citato*), the Germans are generally conspicuous for the breadth of the head, and flattened form of the occiput; because, says he, the children always lie on their backs. The assigned cause does not appear adequate to the production of the effect; yet, that such a form does belong, in some cases, to the German cranium, is proved by a skull in the possession of the writer of this article, which, in its globular form, in the flattened state of the occiput, and in the approximation of the great occipital foramen to the posterior part of the basis cranii, exactly resembles the Turkish cranium. Soemmering, however, whose authority on this point cannot be disputed, states that there is no well-marked difference between the German, Swiss, French, Swedish, and Russian crania, according to the specimens in his possession; except that the orbits are contracted in the Russian, and their margins

C R A N I U M.

quadrangular, and the teeth are small. (De Corporis humani Fabricâ, tom. i. p. 63.)

It is well known that the inhabitants of the northern division of our own island are characterized by the height of their cheek-bones.

The second, or *Mongolian variety*, includes those Asiatics, which do not come under the first division, and the inhabitants of the northern parts of America. The head is of a square form; and the cheek-bones stand out widely to either side. The glabella, and ossa nasi, which are flat and very small, are placed nearly in the same horizontal line with the ossa maxilaria. There are scarcely any superciliary ridges: the entrance of the nostrils is narrow; the malar fossa forms but a slight excavation. The alveolar edge of the jaws is obtusely arched in front; the chin rather prominent. This formation is most strikingly exhibited in the Mongolian tribes, which are widely scattered over the continent of Asia, and which have generally, but erroneously, been included with some of very different origin and formation under the name of Tartars; whereas the last-mentioned tribes, properly so called, belong to the first division of the human race. The Calmucks, and other Mongolian nations, which overran the Saracen empire, under Zengis-Khan, about the middle of the thirteenth century, and had entered Europe, are described in the "Historia Major," of Matthew Paris, under the name of *Tartars*, (p. 530, London, 1686, folio); whereas that appellation properly belongs to the western Asiatics, who had been vanquished by the Monguls. The error, however, arising from this source, has been propagated down to the present day, so that in the works of the most approved naturalists, as Buffon and Erxleben, we find the characters of the Mongolian race ascribed to what they call the Tartars. The mistake has not even been detected by the most celebrated and classical modern historians; as Dr. Robertson speaks of Zengis as the emperor of the Tartars ("History of America," vol. i. p. 45.) The reader, who wishes for further information on this subject, may consult J. E. Fischer *conjectura de gente et nomine Tartarorum*, in his "Quæstiones Petropolitanæ," p. 46 *et seq.*

We have selected the cranium of the Calmuck from the third decade of Blumenbach to exemplify this variety. (*Anatomy of the Cranium*, Pl. 1. fig. 4.) The whole formation and proportions of this cranium correspond exactly to the well known Calmuck physiognomy; and the representation perfectly resembles that of the skull delineated by Fischer ("Diff. de modo, quo ossa se vicinis accommodant partibus," Lugd. Bat. 1743, 4to. tab. 1.) The strong characters, which are so clearly exhibited in this cranium, are altogether different from those of the head, which Camper has exhibited for that of a Calmuck, in his work on the facial line. The last-mentioned engraving represents a head, in which the negro character, the very opposite extreme to that of the Calmuck, is so unequivocally exhibited, that we cannot doubt that the drawing was taken from an African head. The work of Camper contains therefore, besides European skulls, only two African ones; it must consequently be completely inadequate to give any correct systematic account of the subject.

The third, or *Ethiopian variety*, includes the Africans, which do not come within the first division. The cranium is narrow, being compressed at the sides, where the temporal fossa is of immense extent. The forehead strongly arched; the cheek-bones project anteriorly; the nostrils are large; the malar fossa is considerable and deep. The alveolar edges of both jaws stand very much forwards; they

are narrow, elongated, and of an elliptical figure. The front teeth of the upper jaw are oblique in their position. The lower jaw is large and strong; but the chin, instead of projecting as far as the teeth, as it does in the European, recedes considerably, as in the monkey. The substance of the cranium is generally thick, and the skull is consequently heavy. The facial angle is about 70 degrees. A more detailed comparison of the Negro cranium to that of the European may be seen in Soemmerring ("De corporis humani fabrica," tom. 1. § 65.) An African head is represented from the decades of Blumenbach in the first plate of the *Anatomy of the Cranium*, fig. 3. A slight comparison of the negro with the European skull will suffice to shew, that the cranium is much more capacious in the latter than in the former case, consequently that it must possess a larger brain. The lateral compression of the Ethiopian head, together with the narrow arched forehead compared to the almost globular European cranium, with its broad expanded frontal portion, sufficiently account for this difference. At the same time the bones of the face are proportionally larger in the African; the foramina for the transmission of the nerves are more ample; and, according to Soemmerring, the nerves arising from the basis of the brain are more considerable. (Ueber die körperliche Verschiedenheit des Negera vom Europaer, § 56.)

The result of these observations, together with the unequivocal similarity in external form between the African cranium, and that of the monkey, leads us inevitably to the inference that the Negro approximates in structure to those animals. The facts, which we possess on this subject, confirm the conclusion which would naturally be drawn from these premises, that the mental faculties of the Negro are inferior to those of the white nations. Let it not however be conceived that these remarks are intended to degrade the African to a level with brutes, or to justify those who consider them merely as a species of monkey. He is distinguished from all animals by the same grand and constant characters which belong to every variety of the human race. We merely state the obvious inferences deducible from acknowledged facts; and consider that a difference in mental powers cannot afford any stronger argument in proof of a diversity of species, than the numerous distinctions in bodily structure. Indeed, when we find the different races of mankind characterized by such numerous differences in bodily structure, it would be a matter of surprise if no diversity could be discovered in their mental endowments.

The description, which we have given above, of the Negro cranium must be understood in a general sense, and not as universally and unexceptionably applicable. Travellers inform us that several Africans differ from the European features and physiognomy only in colour; so that the peculiar formation of the cranium, on the faith of which some philosophers would class these people as a distinct species, is by no means a constant character.

This diversity of features is proved by delineations of Africans, executed by the most skillful artists; and by the views, which Blumenbach has exhibited, of six African heads, all differing from each other. ("Decas prima," tab. 6, 7, 8. "Decas altera," tab. 17, 18, 19). These drawings fully justify his conclusion; "genuinos Æthiopes, si cranium formam spectes, non minus certè, imo vero magis passim inter se ipsos ab invicem differre, quam nonnulli eorum a multorum Europæorum capitis forma differunt." "Decas altera," p. 13.

In the two following varieties the form of the cranium is not so strongly characterized, as in the three which we have

have already considered. They form indeed two intermediate gradations, between the European and the Mongolian, on one side, and the African on the other.

The fourth, or *American variety*, includes all the Americans, excepting the inhabitants of the northern part of the continent, which we have classed with the Mongolian division.

In this variety the cheeks are broad, but the malar bones are more rounded and arched than in the Mongolian; and not expanded to such an extent on either side, nor possessing such an angular form. The orbits are generally deep. The form of the forehead and vertex is influenced in many instances by the efforts of art. The cranium is generally smooth.

The two crania, which are exhibited in the first plate of the *Anatomy of the Cranium*, (figs. 5 & 6,) in illustration of this variety, are taken from the 10th and 20th plates of Blumenbach's work. Both of them display the effects of art in the form of the forehead; but the operation of this cause is most unequivocal in that which wants the lower jaw. Two crania, exactly similar to this latter one, are delineated in the ("Memoires de l'Academie des Sciences de Paris," 1740, by Hunauld; and in the "Journal de Physique," of April 1789, by Arthaud.)

The concurring reports of several travellers concerning the methods employed by the Caribs to effect this alteration in the shape of the cranium, leave no doubt as to the truth of the fact. Hence we cannot help admiring the sceptical diffidence of various moderns, who have questioned the possibility of impressing these unnatural formations on the cranium. (Sabatier in his "Traité complet d'Anatomie," Camper in his "Dissertation sur les differences," &c. and Arthaud in the "Journal de Physique," 1789.) It should appear from the relation of travellers, that the Caribs practise different methods of accomplishing their object; as by tying a plate of wood on the forehead; or by compressing the head between two plates; (Thibault de Chanvalon "Voyage à la Martinique," p. 39.) or by pressure with the hand. The former is probably the most common method. "The Caribs," says Labat in his "Voyage aux îles de l'Amerique," tom. ii. p. 72, are all well made and proportioned; their features are sufficiently agreeable, excepting the forehead, which appears rather extraordinary, as it is very flat, and, as it were, depressed. These people are not born so, but they force the head to assume that form, by placing on the forehead of the newly born child, a small plate, which they tie firmly behind. This remains until the bones have acquired their consistence; so that the forehead is flattened to that degree, that they can see almost perpendicularly above them without elevating the head." To remove all further doubt on the subject, the instruments and bandages, by which the pressure is made, are delineated and described by Dr. Amic of Guadaloupe, in the 39th vol. of the Journal de Physique.

The fifth, or *Malay variety*, including the inhabitants of the numerous Asiatic islands, and those of the great Pacific ocean, constitute an intermediate link between the European and Negro. The cranium is moderately narrowed at its upper part; the forehead rather expanded; and the upper jaw slightly prominent.

The characters which distinguish the crania of the different varieties are sufficiently striking and constant to be observed in very young subjects. This is shewn by the three last plates of the third decade of Blumenbach, which represent specimens of the three first varieties.

Causes of the peculiar national forms of the Cranium.

We cannot, at present, deliver any satisfactory account of the causes of those differences which unquestionably prevail in the form of the cranium in the different varieties of the human species; much less are we able to understand the manner, in which any assigned cause may be supposed to operate in producing its effect. Yet we think it right to lay before the reader Blumenbach's remarks on this point, as they tend, in some degree, to elucidate the subject.

The bones are the most solid parts of the human body, and form a kind of firm support and foundation on which the softer structures rest. Yet physiological experiments, and the phenomena of disease prove, that they are much more subject to change, than the softer parts of the body. Their elements are continually melted down, and removed in an imperceptible manner by the absorbents; while the loss thus occasioned is repaired by the deposition of other particles newly secreted from the blood. This continual change in the bony materials of our body, which is going on from the first period of their formation, occasions them to accommodate themselves to the neighbouring parts, and to become, as it were, formed and fashioned by their action.

The conformation of the head in the more advanced periods of life affords the most unequivocal proof of this circumstance. The internal surface of the cranium exhibits a mould of the lobes and convolutions of the brain, to which it was adapted; and the external surface displays the most manifest impressions from the actions of the muscles, as well as traces of the form of the features, the general expression and configuration of which may be easily conjectured from the view of the denuded cranium.

If then it can be proved that climate has a great effect in modifying the form of the face, (and that it has that effect can be clearly shewn, see Blumenbach's "De generis humani varietate nativa," § 57. ed. 3.), the same cause must exert a powerful influence on the cranium, and particularly on the bones of the face, although in a less direct way.

Besides the chief and leading cause, other accessory ones may contribute to the same effect. Thus there is we think no inconsistency in allowing that considerable and long continued pressure may have an effect on the bones of the face. The skull of a New Hollander in the possession of Blumenbach ("Decas tertia," tab. 27.) is characterized by a remarkable flatness of the upper jaw, where it contains the incisor and canine teeth. This formation can only be attributed to the whimsical custom which those barbarians have, of wearing ornaments in a perforation of the septum nasi, of such magnitude as to obstruct the nostrils, and prevent them from breathing through those openings.

It happens, however, much more frequently that the bones of the skull receive a peculiar, and, as it may be called, national form, from various artificial causes. Not to mention the flattened occiput of the Germans in the time of Vesalius, who attributed it to the manner in which children were placed in their cradles, there can be no doubt, as we have already stated, that the form of the forehead in the Carib cranium is owing to artificial pressure. A similar rage for improving the shape of the head has been very prevalent in the continent of America. "The Indians," says Adair, "flatten their heads in divers forms; but it is chiefly the crown of the head they depress, in order to beautify themselves, as their wild fancy terms it: for they call us *long-heads*, by way of contempt." (History of the American Indians, p. 8.) The method by which they accomplish their purpose is thus described by the same author: "They

fix the tender infant on a kind of cradle, where his feet are tilted above a foot higher than a horizontal position; his head bends back into a hole made on purpose to receive it, where he bears the chief part of his weight on the crown of the head, upon a small bag of sand, without being in the least able to move himself. By this pressure, and their thus flattering the crown of the head, they consequently make their heads thick, and their faces broad." (p. 9.)

Various other methods have been practised, both by manual pressure, bandages, and other instruments, for reducing the cranium to certain particular forms, both in ancient times, and in European as well as other more remote nations. We know that such customs have existed formerly, or do exist at present in some parts of Germany, in the Netherlands, among the French and Italians, the inhabitants of the Grecian Archipelago, the Turks, the Macrocephali near the Euxine sea, the modern Sumatrans, the inhabitants of the Nicobar islands, and particularly in many parts of America, as the inhabitants of Nootka Sound, the Chactaws of Georgia, the tribes of Carolina, the Caribs, the Peruvians, and the Maroon Negroes of the Antilles. (For the numerous quotations in which this fact is stated of the above-mentioned nations, the reader is referred to Blumenbach "De Gen. Hum. Var. Nat." p. 216, 218.) It is a matter of surprise that any person should have dared to call in question the truth of a fact which is supported by the concurrent testimony of so many eye-witnesses. The practice in question has given rise to the names by which several tribes both in North and South America are distinguished. "The word *Omaguas* as applied to a nation of Peru, as well as that of *Cambevas*, in the language of Brazil, signifies *flat-head*: for these people have the strange custom of pressing the forehead of their newly-born children between two plates, in order to make them, as they say, resemble the full moon." (Condamine in the "Memoires de l'Acad. des Sciences de Paris," 1745. p. 427.) Hence also the "têtes de boule," and "têtes plates," of Charlevoix. ("Histoire de la Nouvelle France," tom. 3. p. 187, 323.) In further proof of these practices, we find that they have been prohibited by the Spanish ecclesiastical councils. J. S. de Aguirra, in the "Collectio maxima conciliorum omnium Hispaniæ et novi orbis." Romæ, 1755. fol.) relates a decree which passed in the third synod of the diocese of Lima, against the Indian method of deforming their children's heads. "Cupientes penitus extirpare abusum, et superstitionem, quibus Indi passim infantum capita formis impriment, quas ipsi vocant *Caito, coma, opalia*; statuimus & precipimus," &c. &c. recounting various punishments against the delinquents; as, for instance, that a woman who has committed such an offence, "frequentet doctrinam per continuos decem dies mané & vesperi pro primâ culpâ; pro secundâ vero, per viginti," &c.

Nevertheless, however clearly the fact itself may be proved, people will still be inclined to doubt of what has been often asserted since the time of Hippocrates; *viz.* that these peculiar forms of the head, produced in the first instance by artificial pressure continually practised for a long series of generations, have passed at length, in the progress of time, by a kind of hereditary descent, to the offspring, so as to have become a second nature. There is a well known passage in the celebrated work of Hippocrates, "De aeribus, aquis & locis," concerning the Macrocephali, a nation situated near the Euxine sea. He states that no other people have the cranium of such a form as these. It was the great object of their ambition to have the head as long as possible: hence arose the practice of moulding with their hands the tender heads of their children. When in its plastic state it

might be compared to the "udum & molle lutum," so as to compel it to assume an elongated form, and of compressing it by means of appropriate bandages and instruments, so as to prevent its growth, except in the direction which they desired. When this custom had been long continued, the peculiar form remained without any farther efforts.

The father of medicine has endeavoured to explain this singular phenomenon by his hypothesis of generation, which is nearly similar to that of Buffon. He supposes the genital fluid to be collected from all parts of the body; and hence that the members of the fetus are fashioned according to those of the parents, from whom this fluid is derived: so that a Macrocephalous father would beget a son of the same formation, &c.

The opinion which supposes that artificial forms of the cranium may ultimately be transmitted to the offspring, so as to constitute national characters, has been contradicted by some physiologists. We cannot at present perhaps determine the question satisfactorily on either side. The transmission of other national marks, as peculiar forms of the features, and of organic diseases, as defects of pronunciation, not to mention various instances in which casual mutilations have passed to the offspring, will induce us to reflect a little before we adopt implicitly the negative side of the question.

We have one remark only to add on this part of the subject; *viz.* that the differences in the form of the cranium are by no means sufficient to authorise us in assigning the different races of mankind, in which they occur, to species originally different; for they are not more considerable, nor even so remarkable as some variations which occur in animals confessedly of the same species. Thus the head of the wild boar is widely different from that of the domestic pig. The different breeds of horses and dogs are distinguished by the most striking dissimilarities in the head: in which view the Neapolitan and Hungarian horses may be contrasted. The wild original of the cow possesses large lacrymal fossæ, which are completely lost in the domesticated animal. The very singular form of the head in the Paduan fowl is a more remarkable deviation from the natural structure than any variation which occurs in the human cranium.

National Peculiarities in the Form of the Teeth.

In the year 1779 Blumenbach discovered a peculiarity in the form of some of the teeth in two Egyptian mummies. The incisors, instead of possessing their ordinary thin cutting edges, were thick in their bodies, and resembled truncated cones: and the canine teeth were only distinguishable from the bicuspides by their situation. The same circumstances have been observed in other specimens; as in a mummy at Cambridge, described by Middleton ("Monumenta Antiquitatis," in his Works, vol. iv. p. 170.); in another at Cassell, (Brückmann's "Description," Brunswick, 1782, 4to.); and in a third at Stutgard ("Storr, prodromus Methodi Mammalium," p. 24.) Blumenbach discovered the same structure in another head of a young mummy, which he opened in London. ("Philosophical Transactions," 1794. part 2.) There must, he observes, be great differences in the crania of various mummies, when it is considered, that the practice of treating the dead body in this manner prevailed in Egypt for so many ages, during which great vicissitudes occurred in the dominion and inhabitants of the country; and consequently that we cannot reasonably expect to find this formation of the teeth in every specimen. Yet it constitutes a singular variety, and deserves mention, as it may assist in distinguishing the mummies of some particular age or nation. It is difficult to assign a cause for this peculiarity of conformation. Blumenbach

menbach ascribes it to the kind of food, which, on the authority of Diodorus Siculus, he states to have consisted chiefly of vegetables, roots, &c. This, he says, would occasion great mechanical abrasion; which, according to him, is attended with an increased thickness of these organs, both in man and animals. If he means that the teeth grow thicker by this cause, after their first formation, the reader will perceive that the explanation must completely fail; as such a growth is quite incompatible with every fact which we possess concerning the structure and economy of these organs.

A similar formation of the teeth was noticed by Winslow in the cranium of a Greenlander from the isle of Dogs, (*Hond-Eyland*) on the west coast of Greenland. "The incisors, says this anatomist, are flat from before backwards, and short; instead of having a cutting edge; hence they resemble grinders more than cutting teeth. The gentleman, who presented me with this cranium, laid that the inhabitants of *Hond-Eyland* eat their meat raw. They move their jaws in a very singular manner, and make several grimaces while chewing and swallowing. It was the observation of this singular spectacle that induced him to seek for an opportunity of discovering whether these islanders possessed any peculiarity of construction in their jaws or teeth." "Memoires de l'Acad. des Sciences de Paris," 1722. P. 323.

This account is confirmed by two Eskimaux crania in the possession of Blumenbach, from Labrador, "Decas Cranior. Tertia." tab. 24. 25, which exhibit the same thickened form and worn appearance of the teeth. It is well known that the Eskimaux are derived from the same race with the Greenlanders, and that their name has its origin from their practice of eating raw flesh.

We doubt much whether there be any real original difference in the form of the teeth in the instances just mentioned: and are rather inclined to refer the observed peculiarity of form to the mechanical attrition, which it appears that the teeth had experienced in all cases. We know very well that the incisor teeth are wedge-shaped, and increase gradually in thickness from their cutting margin to the gum. Hence, if one of these organs be half worn away, it will entirely lose its natural appearance as a cutting tooth, and will resemble in form the teeth found in the crania above-mentioned.

The assertion of Buffon, Erxleben, and others, that the teeth of the Calmucks are longer, and separated by wider intervals from each other, is contradicted by the specimens of their crania in the possession of Blumenbach.

Some other peculiar shapes of the teeth are produced by artificial means. Thus some tribes of Negroes file them so as to make them conical and sharp pointed (Churchill's "Collection of Voyages," vol. v. p. 139. 143. 385. Philof. Transl. vol. 73. pt. 1, p. 92): some of the Malays destroy a great part of the enamel (Forrest's "Voyage to New Guinea, p. 237. Marsden's "History of Sumatra, p. 46); or make grooves on its surface, (Hawkesworth's "Collection of Voyages," vol. iii. p. 349, of the Javanese). Blumenbach states, that he has seen some Chinese and Javanese, who had carefully removed the enamel from the edge of the teeth by means of a stone.

Comparison of the Human Skull with that of Animals.

A very striking difference between man and all other animals consists in the relative proportions of the cranium and face; which are in general indicated by the direction of the facial line.

The two organs, which occupy most of the face, are those of smelling and tasting (including the instruments of mastication, &c.) In proportion as these parts are more developed; the size of the face compared to that of the cranium, is augmented. On the contrary, when the brain is large, the volume of the cranium is increased in proportion to that of the face. A large cranium and small face indicate therefore a large brain with inconsiderable organs of smelling, tasting, masticating, &c.: while a small cranium with a large face shews that these proportions are reversed. The nature and character of each animal must depend in great measure on the relative energy of its different functions: it is in a manner subdued and mastered by its most powerful sensations. We meet with examples of this daily in the human species; but the differences which can be observed between one man and another in this respect, must be much less than those which occur between animals of different species. The brain is the common centre of the nervous system: all our perceptions are conveyed to this part, as to a sensorium commune; and this is the organ by which the mind combines and compares these perceptions, and draws inferences from them—by which in short it reflects and thinks.

We shall find that animals partake in a greater degree of this latter faculty, or at least approach more nearly to it, in proportion as the mass of medullary substance, forming their brain, exceeds that, which constitutes the rest of the nervous system; or, in other words, in proportion as the organ of the mind exceeds those of the senses. Since then the relative proportions of the cranium and face indicate also those of the brain, and the two principal external organs, we shall not be surprised to find that they point out to us, in great measure, the general character of animals; the degree of instinct and docility which they possess; and hence the study of these proportions is of great importance to the naturalist. *Man combines by far the largest cranium with the smallest face:* and animals deviate from these relations in proportion as they increase in stupidity and ferocity.

One of the most simple methods (though sometimes indeed insufficient) of expressing the relative proportions of these parts, is the facial line, which we have already described. In man only is the face placed perpendicularly under the front of the cranium; so that the facial line is perpendicular. Hence the angle formed between this line, and the horizontal one, which passes through the nose and meatus auditorius, is most open, or approaches most nearly to a right angle in the human subject. The face of animals is placed in front of the cranium instead of under it: that cavity is so diminished in size, that its anterior expanded portion, or forehead, is soon lost, as we recede from man. Hence the facial line is oblique: and the facial angle is acute: it becomes more and more so as we descend in the scale from man; and in several birds, in most reptiles and fishes, it is lost altogether, as the cranium and face are completely on a level, and form parts of one horizontal line.

The idea of stupidity is associated, even by the vulgar, with the elongation of the snout, which necessarily lowers the facial line, or renders it more oblique: hence the crane and snipe have become proverbial. On the contrary, when the facial line is elevated by any cause, which does not increase the capacity of the cranium, as in the elephant and owl, by the cells, which separate the two tables, the animal acquires a particular air of intelligence, and gains the credit of qualities, which he does not in reality possess. Hence the latter animal has been selected as the emblem of the goddess of wisdom; and the former is distinguished in
the

CRANIUM.

the Indian language by a name which indicates an opinion that he participates with man in his most distinguishing characteristic, the possession of reason.

The invaluable remains of Grecian art shew that the ancients were well acquainted with these circumstances: they were aware that an elevated facial line formed one of the grand characters of beauty; and indicated a noble and generous nature. Hence they have extended the facial angle to 90 degrees in the representation of men on whom they wished to bestow an august character. And in the statues of their gods and heroes they have carried it beyond a right angle, and made it 100°.

The facial line of the European forms an angle of	80°
Negro - - - - -	70°
Orang-utang - - - -	58°
Monkey - - - - -	42°

These are represented in the second plate of the *Anatomy of the Cranium* (figs. 4, 5, 6, 7, & 8). In some other mammalia the angle is no more than about 20°.

The boundaries of the facial angle in the human subject are therefore 70° and 80°. A smaller angle than the former constitutes an approach to the monkey. Yet it may be extended beyond the latter, as the Greeks have done in their representations of the deity: here however 100° seems to be the *ne plus ultra*; beyond which the proportions of the head would appear deformed.

That angle, according to Camper, constitutes the most beautiful countenance, and hence he supposes the Greeks adopted it. "For," says he, "it is certain that no such head was ever met with; and I cannot conceive that any such should have occurred among the Greeks, since neither the Egyptians, from whom they probably descended, nor the Persians, nor the Greeks themselves ever exhibit such a formation on their medals, when they are representing the portrait of any real character. Hence the antient model of beauty does not exist in nature, but is a thing of imaginary creation; it is what Winkelmann calls "*beau ideal*."

A vertical section of the head, in the longitudinal direction, shews us more completely the relative proportions of the cranium and face. In the European, the area of the section of the cranium is four times as large as that of the face; the lower jaw not being included. The proportion of the face is somewhat larger in the Negro; and it increases again in the orang-utang. The area of the cranium is about double that of the face in the monkeys; in the baboons, and in most of the carnivorous mammalia, the two parts are nearly equal. The face exceeds the cranium in most of the other orders of mammalia. In the ruminant animals the area of the face is about double that of the cranium, and it is nearly four times as large in the horse.

The outline of the face, when viewed in such a section as we have just mentioned, forms in the human subject a triangle; the longest side of which is the line of junction between the cranium and face. This extends obliquely backwards and downwards from the root of the nose towards the foramen occipitale. The front of the face, or the anterior line of the triangle is the shortest of the three. The face is so much elongated, even in the monkeys, that the line of junction of the cranium and face is the shortest side of the triangle; and the anterior one is the longest. These proportions become still more considerable in the other mammalia.

The *great occipital foramen* holds a very different situation in animals from that which it possesses in the human subject; and its position again differs considerably in the various species. These differences arise chiefly from the ordinary

attitude of the body, and from the form of the head. The head and neck of man being directed vertically, his head is placed in a state of equilibrium on the vertebral column, in order to facilitate its motions, and to maintain it firmly on the point of support, which it possesses in the natural attitude of the body. Hence the great occipital hole is placed in the human subject nearly in the centre of the *basis cranii*; and is very little more distant from the front of the jaws, than from the posterior extremity of the occiput. The position of the head is so favourable for its being held in a state of equilibrium, that if the vertical line of the trunk and neck were continued upwards, it would pass through the top of the head.

The occipital hole differs therefore considerably from that of animals in its direction. Let us draw a line according to the course or level of this opening: it will pass from the posterior edge of the foramen, along the surface of the condyles, and if continued anteriorly, will terminate just under the orbits. It forms in short almost an horizontal line, which intersects, nearly at right angles, the vertical line of the body and neck, when the head is held straight, without being inclined forwards or backwards.

In this attitude, the face is in a vertical line parallel to that of the body and neck; and consequently the jaws hardly extend in front beyond the forehead. They are very short in comparison with those of most animals: for the length of the lower maxillary bone of man, measured from the chin to the posterior edge of the condyle is only half the length of the whole head, as taken from the chin to the occiput; and scarcely the ninth part of the height of the body from the anus to the vertex: and about the eighteenth part of the whole length of the body from the top of the head to the feet. This latter point of comparison is however scarcely applicable to the subject; inasmuch as there is hardly any other animal but man, which has the hind legs as long as the trunk, neck, and head taken together, and measured from the vertex to the pubis.

The principal constituent parts of the human structure are the same with those of animals; but there is as much difference in the mode of union, and form of the bones, as in the attitude of man, compared to that of animals. Let us suppose a man to assume the attitude of a quadruped, and that he should attempt to walk on all fours; he will find himself in a very unnatural position. The motions of his arms, legs, hands, feet, and head, will be very laborious; and it will be impossible for him to acquire a firm gait and regular progression. The obstacles, which he experiences, arise from the conformation of the pelvis, hands, feet, and head: the latter only come within the scope of the present article.

In proportion as the volume of the brain increases in comparison to that of the whole body, so does the occiput become more convex and prominent; the foramen magnum is removed further from the back of the head; and the level of this opening approaches the horizontal direction. Hence, as we have already remarked, it is but little further in man from the extremity of the jaws than from the back of the head, and its direction is nearly horizontal. This position of the opening, which places the head in a state of equilibrium upon the neck, and brings the face forwards in the natural erect posture, would, if man went on all fours, prevent him from elevating the head sufficiently to see before him, because the motion of the head would be stopped by the projection of the occiput meeting the vertebrae of the neck.

In most animals the great occipital foramen is placed at

the back of the head; the jaws are considerably elongated; the occiput forms no projection beyond this opening, the level of which is in a vertical line, or at least very slightly inclined. Hence the head is connected to the neck by its back part, instead of being articulated, as in man, by the middle of its basis; and, instead of being in equilibrium, it hangs to the front of the neck. This structure bestows on quadrupeds the power of using their jaws for seizing what is before them; of elevating them to reach what may be above the head, although the body be placed horizontally; and of touching the ground with the mouth by depressing the head and neck as low as the feet. The latter motion could not be performed by man, even if he were in the attitude of a quadruped; for if he lowered the head to the ground, he would only touch it with the forehead or vertex.

In several animals there is some distance between the foramen magnum, and the posterior extremity of the occiput; but this interval is no where so considerable as in the human subject, and in proportion as it is increased does the direction of the occipital foramen approach more to the horizontal one.

Animals of the monkey kind approach more nearly to the human structure in the position and direction of the occipital foramen than any others. In the orang-utang it is twice as far from the jaws as from the back of the head; and it is considerably inclined downwards, so that a line drawn in its level passes below the lower jaw, instead of going just under the orbit as in man.

The difference in the direction of the foramen may be estimated by noting the angle formed by the union of a line drawn in the manner above-mentioned, according to the direction of the opening, with another line passing from the posterior edge of the foramen to the inferior margin of the orbit. This angle is of 3° in man, and of 37° in the orang-utang. The length of the jaws in this animal must exceed that of the human subject in the same proportion: the lower maxilla is one fourth of the length of the trunk and head, taken from the vertex to the anus, while in man it is only one seventh.

The occipital angle is of 47° in the lemur; it is still greater in the dog; and in the horse it is of 90° , or a right angle, the position of the opening being completely vertical.

The want of the intermaxillary bone has been set down by Camper as one of the grand characteristics which distinguish the human head from that of other animals. The superior maxillary bones of the human subject are united to each other, and contain the whole of the upper series of teeth. They are, however, separated in brutes by a third bone of a wedge shape, which contains the incisor teeth, and therefore was called *os incisivum*. It is united by peculiar sutures to the neighbouring bones.

That man possesses nothing analogous to the intermaxillary bone of brutes is so clear, that we must be surprised how so excellent an anatomist as Vicq-d'Azyr could discover any analogy in the human jaw to the structure of quadrupeds. "Memoires de l'Acad. des Sciences de Paris," 1780. The transverse slit behind the incisor teeth, which is constantly observable in the young subject, and sometimes distinguishable in the adult, was very well known to the older anatomists. But that this fissure could not deserve the name of a suture, was very correctly observed more than two hundred years ago by the acute Fallopius. (See its description in the account of the bones of the face.)

Whether all other mammalia, besides the human subject, possess this bone, is not so decidedly ascertained, as that man has it not. Blumenbach mentions, that it does not appear

in several crania of the genus *simia*, which he examined. "De Gen. Hum. var. Nat." p. 38. Neither Tyson nor Daubenton found it in the ourang-utang. However this question may be decided, there can be no doubt that the crania of all the quadrumanous mammalia, which are the most anthropomorphous animals, as well as of all other quadrupeds, are distinguished from the human skull by the great length and projection of the jaws.

The teeth of the human subject differ from those of all mammalia in being placed close to each other, and arranged in an uniform and unbroken series. The lower incisors are perpendicular, which is altogether a peculiar character of the human head. The cuspidati do not project beyond the others, nor are they separated by any intervals from the neighbouring teeth. The molares are furnished with peculiar blunt prominences or tubercles very different from those of any of the monkey kind.

The lower jaw of the human cranium is characterized by three very remarkable circumstances: its peculiar shortness; the prominence of the chin, which arises from the perpendicular position of the lower incisor teeth; and by the form, direction, and mode of articulation of the condyles, which circumstances differ from the structure of all other animals, and clearly shew that man is designed by nature to be an omnivorous animal.

CRANIUM, in *Natural History*, the name of a species of the *Anomia*, with a smooth ventricose shell, transversely striated, found in the Norwegian sea. Also, a species of *Alcyonium*, tuberiform, white, and setose; found in the same sea with the former.

CRANK, a contrivance in machines, in manner of an elbow, only of a square form; projecting out from an axis, or spindle; and serving, by its rotation, to raise and fall the pistons of engines for raising water, or the like.

CRANK, in *Sea Language*. A ship is said to be *crank-sided*, when, for want of a sufficient quantity of ballast or cargo, she cannot bear her sails, or can bear but small sail without danger of oversetting.

She is said to be *crank by the ground*, when her floor is so narrow, that she cannot be brought on ground without danger.

CRANK is also an iron brace which supports the lanterns on the poop-quarters, &c.

CRANMER, THOMAS, in *Biography*, the most eminent prelate that ever filled the see of Canterbury, was born July 2, 1489, at Ashtedon, in Nottinghamshire. At the age of 14 he was admitted to Jesus College, Cambridge. By his great diligence in his academical studies, and by his zeal in the pursuit of biblical knowledge, he acquired very high reputation, and quickly obtained a fellowship and the degree of M. A. The former he soon lost by marrying; but his wife dying within a year of his entering the holy state, he was again admitted fellow of his college, a rare circumstance, and at the same time a signal proof of the respect and affection in which he was held by his friends. By Cardinal Wolsey he was offered a fellowship at Oxford, which he did not accept; and in 1523 he took the degree of D.D., and was appointed theological lecturer and examiner: in both capacities he rendered the most essential services to the interests of learning and religion. He had not, however, long retained these offices before the plague obliged him to retire for safety to Waltham Abbey, where, meeting with Dr. Fox, the king's almoner, and Dr. Stephen Gardiner, the secretary, the conversation turned on the subject of the king's divorce from Queen Catharine. In giving an opinion on this subject, he said the question must be reduced to this; "Whether a man may marry his brother's

S f wife?"

wife;" which might be discussed and decided by the authority of scripture, in this country as well as at Rome. When Henry was informed of this reply, he not only applauded Cranmer's sagacity, affirming that "he had got the right fow by the ear," but desired to be introduced to him. He immediately appointed him one of his chaplains, and commanded him to write in justification of the intended divorce. The doctor quickly produced a work which completely coincided with the monarch's views, by proving from the scriptures, and by an appeal to the decisions of general councils and ancient writers, that the pope possesses no power to dispense with the word of God. Cranmer argued the point so successfully at Cambridge, and made so many converts to his opinion, that he was sent by his sovereign to debate the matter on the continent with the divines of France, Italy, and Germany. While on this mission he married a second wife at Nuremberg; and on his return in 1533, he was raised to the high office of archbishop of Canterbury, with the sole view, no doubt, of sanctioning the conduct of the king; and accordingly in the following May, he pronounced the sentence of divorce between Henry VIII. and Catharine, and confirmed the king's marriage with Anne Boleyn. These acts excited the vengeance of the pope, who threatened to excommunicate the archbishop; but he had already set at defiance his power, by refusing to accept his office, unless it were bestowed immediately by his own sovereign without the intervention of his holiness. He therefore heard the denunciations uttered against him without anxiety, and exerted all his powers in behalf of the Reformation. In the same year he was very instrumental in procuring an act of parliament which abolished for ever the pope's supremacy in these realms, and which declared the king supreme head of the church. His next objects were, the translation of the scriptures into English, and the dissolution of monasteries, which had long been regarded as incompatible with those principles of virtue and religion, in behalf of which they had been originally instituted. In these efforts the primate was successful, and having already joined the king in so many of his projects, he was obliged to follow him still farther, and in 1536 he pronounced a second divorce between Henry and Anne Boleyn. In all the changes and reforms introduced by the king, his sole object was the acquisition of new power and increased wealth, and when he had secured his wishes in these respects, he began to counteract farther innovations, and caused an act to be passed which impeded the progress of reformation during the remainder of his reign. By a provision in this law, the archbishop was obliged to banish his wife to her native home. With this act of violence Cranmer did not comply without exhibiting a manly opposition, which extorted the admiration and respect of the monarch, though his enemies fondly imagined it would effect his ruin. In 1540 he was appointed a commissioner for inspecting into matters of religion, and for explaining some of its chief doctrines: the result of this commission was the circulation of a work, chiefly composed by Cranmer, entitled "A necessary Erudition of any Christian Man." After the death of Thomas Cromwell, earl of Essex, in whose behalf he interceded with all the warmth of friendship, though ineffectually, he retired from court, and gave himself up to his own affairs as an ecclesiastic. The high rank to which he had attained, rendered him an object of envy to those less honoured, and who eagerly sought his ruin; but in every change he was protected by the king, who eventually appointed him one of the executors of his last will, and one of the regents of the kingdom.

Upon the demise of Henry, in 1546, Cranmer crowned

the young king, and was, during the short reign of that sovereign, very zealous in promoting the reformation. He took a very active part in composing, correcting, and establishing the liturgy, and in compiling the 39 articles. At this period, it cannot be denied, the archbishop exercised his power with cruelty, and without that regard to the rights of conscience in others, which he had formerly claimed for himself. He sanctioned, and was even the abettor of persecution, in the cases of Gardiner bishop of Winchester, and Bonner bishop of London; and by his authority and approbation other considerable men of the Romish church were imprisoned and persecuted, on account of their opinions and attachment to rites and ceremonies, against which he had set his face. It does not appear what part he took in the persecution of Lambert and Askew during the reign of Henry, who were cruelly murdered for avowing doctrines to which Cranmer himself afterwards adhered: but his conduct in regard to Joan Bocher and George Van Paris cannot be too strongly reprobated. These, says Mr. Gilpin, were accused, one for maintaining, and the other for denying the divinity of Christ. The woman was highly respected, and zealously attached to the reading and explaining of those scriptures which Cranmer had caused to be put into her hands, in common with those of her countrymen. He was the cause, therefore, as well as the instrument of her cruel death. The good woman saw, or thought she saw, that Jesus of Nazareth was a man, like other men, only in the high degree of inspiration which he had from his Almighty Father. Being exhorted to abjure so damnable a doctrine, she refused, and preferred death rather than life on such ignominious terms, and she was accordingly committed to the flames. To the honour of the young king, and the disgrace of his minister, let it be noted, that the mind of the former revolted against the signing of the warrant for Bocher's execution, and it was only by Cranmer's persuasions and importunity that he was brought to yield. Even then he deprecated the act, and with tears declared, that if he did wrong, the archbishop must answer for it at the tribunal of heaven.

In the year 1553, he shewed himself adverse to the settlement of the crown on Lady Jane Grey, though he was at length persuaded to set his hand to it; and on the death of Edward he avowedly espoused her cause, and became a member of her council. The triumph of Mary forewarned him that he had little to hope for. Clemency, and even justice, were well nigh banished from the new court, and the friends of Cranmer urged him to seek for safety by retiring to a foreign country. But feeling that the dignity of his character, and the cause of the reformation required him to make a stand, he replied it would not be fit for him to leave his post, and thus, as it were, disavow the changes that had been made, by his means, in religion, during the late reign. It was now, probably, that the prediction of Christ to Peter must meet the mind of Cranmer: "They that take the sword shall perish by the sword."

He had been a persecutor, and must fall by the same merciless means. He was tried on a charge of high treason, in joining the party of Lady Jane; of this he was convicted, when his see was declared vacant, and the fruits of it sequestered. He supplicated for pardon, which was granted, but only that he might be tried on the charge of heresy, of which he was also convicted. As yet the pope's authority had not been re-established in England, and it was thought necessary to repeat the mock trial, on an indictment charging him with blasphemy, perjury, incontinency, and heresy. On this occasion Cranmer refused every testi-

mony of respect to the representative of the pope, and defended himself with ability, and much firmness. But reason had no effect with judges who were endeavouring to banish reason from the world: he was condemned, and most cruelly treated, especially by Bonner, whose name has been transmitted to posterity with the infamy it merits. The archbishop bore all with an undaunted heroism, till the prospect of death overcame his virtuous resolution; then he signed a recantation of his religious principles. His enemies having thus obtained a signal victory, lost no time in printing and dispersing every where the recantation, determined, at the same time, to take away his life. On the 24th of February, a writ was signed for burning Cranmer, and on the 24th of March he was brought to St. Mary's church, Oxford, to hear a discourse, previously to the fatal tragedy. Dr Cole, provost of Eton, was appointed to preach on the occasion; while he was haranguing the audience, the unfortunate prisoner expressed the greatest contrition for having been betrayed into the dastardly act of recantation, but the spectators supposed that the tears which he shed were on account of his former heresy. At length, Cole, with a malignant countenance, desired him to make an open profession of his faith; when Cranmer avowed his belief in all that had been taught by Christ and his apostles, in the New Testament, and by the prophets in the Old. "And now," added he, "I come to that which hath so much troubled my conscience, more than any thing I ever did or said in my whole life; and that is the setting abroad a writing contrary to the truth, which I here now renounce, as things written with my hand contrary to the truth which I thought in my heart; and written for fear of death, and to save my life if it might be. And so far as my hand offended, contrary to the dictates of my heart, my hand shall be first punished." Astonished and enraged at this unexpected declaration, the bigotted and savage mob dragged him to the place of martyrdom, where he was quickly fastened to the stake; here his resolution was undaunted, and he nobly obliterated the stain which had been made upon his character by recantation. "This is the hand that wrote it," says he, "and therefore it shall first suffer punishment." He accordingly stretched his right hand into the flame, where he kept it unmoved till it was consumed. In a short time the fire attacked his vital parts, and he died repeating the words of the martyr Stephen, "Lord Jesus, receive my spirit." Such was the end of Thomas Cranmer, in the 67th year of his age: that he was a great and good man in many respects none will deny; but it would be foolish, and to posterity unjustifiable, to attempt to conceal his faults. He was, says Mr Hume, "undoubtedly a man of merit, possessed of learning and capacity, and adorned with candour, sincerity, and beneficence, and all those virtues which were fitted to render him useful and amiable in society. His moral qualities procured him universal respect, and the courage of his martyrdom, though he fell short of the rigid inflexibility observed in many, made him the hero of the Protestant party." There are, however, others who can better appreciate the worth of the archbishop than our historian. Mr Gilpin, speaking of the noble stand which Cranmer made against the king with regard to the six articles, says, "The good archbishop never appeared in a more truly Christian light, than on this occasion. In the midst of so general a defection, he alone made a stand. Three days he maintained his ground, and baffled the arguments of all opposers. But argument was not their weapon, and the archbishop saw himself obliged to sink under superior power. Henry ordered him to leave the house. The primate refused. "It was God's business," he said, "and not

man's:" and, when he could do no more, he boldly entered his protest. Such an instance of fortitude is sufficient to wipe off many of those courtly stains which have fastened on his memory." His behaviour as a Christian, in the forgiveness of injuries, which is the touchstone of pure principles, was exemplified in the cause of the duke of Norfolk. "The last act of this reign," says Gilpin, "was an act of blood, and gave the archbishop a noble opportunity of shewing how well he had learned to forgive an enemy." Henry had ordered the duke of Norfolk to be attainted contrary to justice. No man had been more the enemy of Cranmer than the duke; yet, so far was he from exulting in the opportunity of vengeance, that he viewed the measure with horror, and opposed the bill with all his might; and, when his opposition was vain, he left the house with indignation, and retired to Croydon.

To men of learning, Cranmer was a generous patron and friend; he maintained an intimate and constant correspondence with most of the distinguished scholars in Europe. He was a great economist of his time, rising generally, at all seasons, at five in the morning, and employing every hour with industry and care. In his manner he was pleasing and amiable; mild and cheerful in his temper; and given to hospitality, often beyond the ample means which he enjoyed. As a preacher, he is said to have been plain, practical, and impressive; and the character of his writings is that they are more sensible and nervous, than elegant and polished. He left behind him a widow and children, that had been amply provided for by Henry VIII., who, without any solicitation, gave him a considerable grant from the abbey of Welbeck in Nottinghamshire, which his family enjoyed after his decease. King Edward made some addition to his private fortune, and his heirs were restored in blood by an act of parliament, passed in the reign of Elizabeth. The writings of the archbishop are not stamped with the marks of great superiority; though some have been translated into Latin by Young and Sir John Cheke. Some posthumous pieces were published by Strype and Burnet, and there remain, in the library at Lambeth, two large volumes of MSS. chiefly collections from the Scriptures, and the writings of the Fathers. Cranmer was, according to Burnet, very anxious in obtaining the sense of ancient writers upon all the topics of religion, by which he might be directed in the cause of the reformation. *Biog Brit.*

CRANNICHFELD, in *Geography*, a small town of Germany, in the duchy of Saxe-Gotha, situated on the river Ilm, and surrounded on all sides by mountains. It has 250 houses, and 1300 inhabitants, most of whom are tradesmen and manufacturers, chiefly basket-makers and stocking-weavers.

CRANNY, in the *Glass Trade*, a round iron, whereon the workmen in the glass-houses roll the glass, to make the neck of it small.

CRANON, in *Ancient Geography*, a town of Thessaly, in the valley of Tempe; east of Pharsala, and west of the lake Bœbeis, 100 stadia south-west of Gyrtora—Also, a town of Greece, in Athamania, towards the source of the Achelous.

CRANSAC, in *Geography*, a small town of France, in the department of the Aveyron, fifteen miles from Rhodéz, famous for its mineral waters. The springs are in the midst of arid mountains which emit clouds of black smoke of rather a disagreeable smell. They have not all the same properties. That which is called the new spring is most frequently used. The water is cold, limpid, and without smell; it tastes like a slight solution of sulphate of iron. It appears that it holds little saline matter, since it has been found that

367 grammes (twelve ounces) of this water give only 1 gramme 6 decigrammes (eighteen grains) of saline residue in which there is sulphate of iron.

A sensible analogy has been observed between the water of Cranfac, and that of Passy near Paris, with respect to their component parts, as well as to their effects. Physicians therefore prescribe the two waters indiscriminately.

Cranfac water is reckoned good for the stomach. It is ordered in cases of green-sickness, liver complaints, cutaneous affections and diseases of the bladder. It is extremely purgative at first, and even creates vomiting, but at the end of four or five days it operates less violently, and is generally beneficial. It must be used cold.

CRANSTON, a township of America, being the south-easternmost of Providence county, in Rhode Island, situated on the west bank of Providence river, five miles south of the town of Providence. The compact part of the town contains 50 or 60 houses, a baptist meeting-house, handsome school-house, a distillery, and a number of saw and grist mills; and is called Pawtuxet, from the river on both sides of whose mouth it stands, and over which is a bridge connecting the two parts of the town. The whole township contains 1877 inhabitants.

CRAN-TARA, an implement used in war among the ancient Britons. It was a stick burnt at the end and dipped in the blood of a goat, which, after striking the shield and sounding the horn, was sent by a swift messenger to the nearest hamlet, where he delivered it, without saying one word, except the name of the place of rendezvous. This crantara, which was well understood to denounce destruction by fire and sword to all who did not obey this summons, was carried with great rapidity from village to village; and the prince, in a little time, found himself surrounded by all his warriors, ready to obey his commands.

CRANTIA, in *Ancient Geography*, a maritime town of Spain.

CRANTOR, in *Entomology*, a species of *Sphinx*; which see.

CRANTOR, the *Moralist*, in *Biography*, the last celebrated philosopher of the Old Academy, the intimate friend of Arcefilaus, a native of Soli in Cilicia, who flourished about 300 years B. C., and died about the 270th year B. C. He studied under Xenocrates and Polemo; and adhering to the Platonic system, he was the first who wrote commentaries on the works of Plato; but as he died before Polemo and Crates, he could not succeed them in the Academic chair. Crantor was highly celebrated for the purity of his moral doctrine, as we may infer from the praises that are bestowed by the ancients upon his discourse "On Grief," which Cicero (*Acad. Quest.* l. iv. c. 44. *Tusc. Qu.* l. iii. c. 6.) calls "a small but golden piece, adapted to heal the wounds of the mind, not by encouraging stoical insensibility, but by suggesting arguments drawn from the purest fountains of philosophy." That Crantor acquired great reputation as a moral preceptor is intimated by Horace. (*Ep.* l. i. ep. 2. v. 3.)

"Qui, quid sit pulchrum, quid turpe, quid utile, quid non,
Planius et melius Chryssippo et Crantore dicit."

"Who better taught fair virtue's sacred rules,
Than Crantor and Chryssippus in the schools."

Diog. Laert. lib. iv. 24.

CRANTZIA, in *Botany*, Swartz. Vahl. See *TRICERA*.

CRANTZPERG, in *Geography*, a castellated town of Germany, in the circle of Bavaria; 16 miles N.N.E. of Munich.

CRANZIA, in *Botany*, Schreb. See *SCOPOLIA*.

CRAON, in *Geography*, a small town of France, in the department of Mayenne, chief place of a canton, in the district of Chateau Gonthier. It has 1494, and the canton itself 12 746 inhabitants. The latter comprises 15 communes, on a territorial extent of 240 kilometres.—Also, a castle, and formerly a principality, in the department of Meurthe; 3 miles E. of Luneville.

CRAONNE, a small town of France, in the department of Aisne, 12 miles S.E. of Laon. It is the chief place of a canton, in the district of Laon, with a population of 830 individuals. The canton itself has 40 communes, and 12,148 inhabitants, upon a territorial extent of 207 kilometres.

CRAP, in *Agriculture*, a name sometimes given by farmers in some districts to ray-grass, rye-grass, or red darnel (*lolium perenne*), and in others to buck-wheat (*polygonum sagopyrum*); the former of which is often very troublesome among wheat crops.

CRAPACH, or KRAPACH, in *Geography*, is the name of that chain of mountains called the *Carpathian hills*, which form the western boundaries of Hungary, and separate Transylvania from Gallicia. They are now called, in the language of the country, *Tatra*.

CRAPE, a light transparent stuff, in manner of gauze; made of raw silk, gummed and twisted on the mill; woven without crossing, and much used in mourning.

Crapes are either *craped*, i. e. *crisped*; or *smooth*: the first *double*, expressing a closer mourning; the latter *single*, used for that less deep. Note, White is reserved for young people, or those devoted to virginity.

The silk destined for the first is more twisted than that for the second; it being the greater or less degree of twisting, especially of the warp, which produces the crisping given it when taken out of the loom, steeped in clear water, and rubbed with a piece of wax for the purpose.

Crapes are all dyed raw. The invention of this stuff came originally from Bologna; but the chief manufacture of it is said to be at Lyons.

History tells us, that St. Bathilda, queen of France, made fine crape, *crepa*, of gold and silver, to lay over the body of St. Eloy. The Bollandists own they cannot find what this *crepa* was. Binet says, it was a frame to cover the body of the faint; but others, with reason, take it to be a transparent stuff, through which the body might be seen; and that this was the *crepa* whence our word crape was formed.

CRAPENO, in *Geography*, a town of Naples; 20 miles W. of Vieste.

CRAPONNE, a town of France, in the department of the Upper Loire, 15 miles N. of Le Puy. It is the chief place of a canton, in the district of Le Puy, and contains 3293 inhabitants. The canton itself has but 6 communes, and a population of 7956 individuals, upon a territorial extent of 127 kilometres and a half.—Also, a canal, in the department of the Bouches du Rhône, fed with the water of the river Durance; which, after having traversed and fertilized the plain called *La Crau d'Arles*, falls into the Rhône at Arles. It is not navigable, but it serves to set a great number of mills in motion.

CRAPULA, a surfeit by over-eating and drinking. See *SURFEIT*.

CRASHAW, RICHARD, in *Biography*, an English poet, was the son of a clergyman, and educated first at the Charter-house, and then at Pembroke-hall and Peter-house, Cambridge, of which last he was a fellow in the year 1637. At college he was distinguished for his talents in poetry, Latin as well as English; but being a man of strict integrity, he sub-

mitted,

mitted, in 1644, to expulsion from the university with others, rather than take the covenant. From Cambridge he retired to France, where he embraced the Roman Catholic religion, not, as has been imputed to him, from sordid motives, as his distressed circumstances shortly after abundantly proved. By Cowley he was recommended to Henrietta Maria, who gave him letters of introduction to her friends at Rome, where he first acted as private secretary to a cardinal, and afterwards obtained a canonry at Loretto. Here he died of a fever about the year 1650. As a poet Crashaw has much merit, though conceit and puerilities are too frequently mingled with his works. The subjects of his poems, of which a collection was made in 1646, were chiefly devotional. Of these some were selected and published, about twenty years ago, by Peregrine Phillips. They are still but little known; nevertheless, the name of Crashaw merits this short notice, for, however neglected in the present day, he was the companion of Selden, and the idol of Cowley; and he was, moreover, the author of the fine Latin epigram on the Marriage of Cana, which has not always been justly appropriated, and which concludes, "Nympha pudica deum visit et erubuit," "The modest water saw its God, and blushed." Biog. Brit.

CRASIS, in *Medicine*, a term used by the older writers, who adopted the humoral pathology, to denote the constitution or temperament of the blood, and other fluids. Thus, in those diseases, in which symptoms of what has been called putrescence appeared, as in scurvy, malignant fever, &c. the hæmorrhages and purple spots were said to shew a dissolved crasis of the blood. This morbid condition has also been termed *dyserafy*.

CRASIS, in *Grammar*, is a figure, whereby two different letters are either contracted into one long letter, or a diphthong. Such, e. g. is $\sigma\phi\iota\varsigma$ for $\sigma\phi\iota\omega\varsigma$; $\alpha\lambda\eta\theta\eta$ for $\alpha\lambda\eta\theta\epsilon\alpha$, &c. $\tau\upsilon\chi\eta\varsigma$ for $\tau\upsilon\chi\eta\omega\varsigma$, &c. where ι and α are contracted into ι ; ϵ and α into η ; and ϵ and \omicron into υ . See CONTRACTION.

CRASPEDARIA, from $\kappa\rho\alpha\sigma\pi\epsilon\delta\omicron\nu$, *fringe*, in *Zoology*, a genus of animalcules, without any visible limbs or tails; but with an apparent mouth, and a series of limbræ round it in the manner of a fringe.

Of this genus there are three species: 1. The *craspedarium* with a roundish body. 2. The *craspedarium* with an oval body. 3. The *craspedarium* with a cylindrical body. They are species of the *Vorticella* in the class of *Vermes Infusoria*. See VORTICELLA.

CRASPEDIA, in *Botany*, (from $\kappa\rho\alpha\sigma\pi\epsilon\delta\omicron\nu$, a *fringe*;) Schreb. 1350. Willd. 1574. Forst. Fl. 58. Class and order, *syngenesia polygamia segregata*.

Gen. Ch. *Cal.* common imbricated; proper perianth none. *Cor.* Florets in a few depressed bundles, tubular, hermaphrodite. *Stam.* Filaments five; anthers united in a hollow cylinder. *Pist.* — *Seeds* with a feathered down. *Receptacle* chaffy.

Sp. *C. uniflora*; Forst. Prod. 306. A native of New Zealand.

CRASPEDITES SINUS, in *Ancient Geography*, a gulf of Asia Minor, in Bithynia, according to Pliny; called the gulf of *Olbia* by Mela.

CRASPEDIUM, in *Botany*, Lour. Flor. Cochin. Class and order, *polyandria monogynia*.

Gen. Ch. *Cal.* five-leaved; leaves oval, acute. *Cor.* Petals five, wedge-shaped, with numerous linear segments; nectaries five, kidney-shaped, villous at the inner base of the petals. *Stam.* Filaments thirty, short, inserted into the receptacle. *Pist.* Germ superior; style tubular; stigma simple. *Peric.* Berry small, one-celled. *Seed* solitary.

Sp. *C.* —. A large tree. *Leaves* oval-oblong, cre-

nulate, acute. *Flowers* greenish-yellow, in terminal clustered spikes. A native of Cochinchina. It is very nearly allied to *clæocarpus*, and perhaps ought to be referred to that genus.

CRASSAMENTUM of the *Blood*, in *Anatomy*, is one of the two parts into which blood, when left to itself, always separates. This crassamentum, which is also called *cruur*, consists of the coagulating lymph and the red globules. See BLOOD.

CRASSINA, in *Botany*. See ZIMMIA.

CRASSIROSTRÆ, in *Ornithology*, the name of a genus of small birds, distinguished by the thickness of their beaks; as the sparrow, greenfinch, and the like.

CRASSULA, in *Botany*, (a diminutive of *crassus*, thick; alluding to the fleshiiness of the leaves.) Linn. Gen. 392. Schreb. 533. Willd. 594. Juss. 207. Vent. 3. 273. Class and order, *pentandria pentagynia*. Nat. Ord. *Succulentæ*, Linn. Vent. *Sempervivæ*, Juss.

Gen. Ch. *Cal.* Perianth one-leaved, five-cleft; segments lanceolate, erect, acute, permanent. *Cor.* Petals five, generally narrowed into erect claws, which are sometimes connivent near the base, so as to have the appearance of a tube, with a border consisting of five oval or lanceolate segments, and generally expanding. *Stam.* Filaments five, inserted at the base of each petal; anthers roundish. *Pist.* Germs five, superior, oblong, acute, with a small emarginate nectariferous scale at the base of each; styles the length of the stamens; stigmas obtuse. *Peric.* Capsules five, erect, oblong, acuminate, compressed, opening longitudinally at their interior side. *Seeds* small, numerous.

Eff. Ch. Calyx one-leaved, five-cleft. Petals five; nectareous scales five, at the base of the germ. Capsules five. Seeds numerous. It differs from *sedum* chiefly in the number of stamens.

* *Shrubby*.

Sp. 1. *C. coccinea*. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Bot. Mag. 495. (Cotyledon; Comm. Rar. 24. tab. 24. Bradl. Succ. 5. 7. tab. 5. Breyn. Prod. 3. 30. tab. 20. fig. 1.) "Leaves egg-shaped, flat, cartilaginous-ciliated, connate-sheathing at the base." *Stem* from one to three feet high, reddish, erect, cylindrical, branched. *Leaves* covering the stem almost from the bottom, opposite crosswise, so close together that they appear imbricated in four rows. *Flowers* scarlet, large, tubular, in a terminal umbel or fascicle; claws of the petals linear, closely connivent, and forming a tube at least an inch long; segments of the calyx erect, linear-lanceolate, acute, slightly ciliated or toothed like the leaves. A native of Africa. 2. *C. capitata*. Lam. 5. "Leaves linear, acute, cartilaginous-ciliated, connate-sheathing; heads of flowers generally three, clustered, terminal." *Stem* six or seven inches high, woody; branches numerous, erect, simple, leafy, almost smooth, channelled on two opposite sides, with a few short hairs at the edges of the channels. *Leaves* six or seven lines long, opposite, acute, flat or a little concave above, smooth, appearing jointed at the sheath, which remains after they are fallen off. *Flowers* in two or three small clustered heads at the extremity of each branch; petals narrow, almost linear in their upper part. A native of the Cape of Good Hope, described from a dried specimen communicated by Sonnerat. 3. *C. flava*. Linn. Mant. 60. Mart. 3. Lam. 2. Willd. 3. Burm. Afr. 37. tab. 23. fig. 2. (*Sedum africanum umbellatum*; Pluk. Alm. 340. tab. 314. fig. 2.) "Leaves flat, connate-perfoliate, even-surfaced; flowers corymbose-panicled." β . Pluk. Alm. 340. tab. 314. fig. 3. "Leaves cartilaginous-crenulated." *Stem* six or seven inches high, erect,

C R A S S U L A.

erect, cylindrical' with two or three branches near the top, entirely covered with leaves except near the bottom, where the remaining sheaths of the leaves give it the appearance of being jointed. *Leaves* nearly an inch and half long, lanceolate, very acute, erect, in pairs. *Flowers* yellowish, erect, peduncled, clustered, in a branched terminal corymb; petals erect, lanceolate, a little longer than the calyx, very acute. A native of the Cape of Good Hope. 4. *C. pubescens*. Linn. jun. 190. Mart. 46. Willd. 4. Thunb. Prod. 55. "Leaves connate, egg-shaped, acute, villous; stem branched; flowers in a corymb." *Stem* about seven inches high, red, filiform, erect, smooth, branched; branches somewhat whorled, in threes, subdivided, pubescent. *Leaves* thick, spreading, the length of the internodes, flattish above, gibbous underneath. *Corymb* compound, trichotomous. A native of the Cape of Good Hope. 5. *C. pruinosa*. Linn. Mant. 60. Mart. 4. Lam. 3. Willd. 5. "Stem dichotomous; leaves awl-shaped, frosted-scabrous; flowers somewhat corymbed." A foot high. Whole plant covered with the appearance of a crystalline hoar-frost; small branches cylindrical, blood-red. *Leaves* opposite, fleshy, flat above, the length of the internodes, slightly connate. *Corymbs* terminal, unequal, small; petals white, lanceolate, spreading. A native of the Cape of Good Hope. 6. *C. scabra*. Linn. Sp. Pl. 14. Mart. 5. Lam. 4. Willd. 6. Dill. Elth. 177. tab. 99. fig. 117. (Cotyledon; Mart. Cent. 24. tab. 24.) "Leaves opposite, spreading, connate, scabrous, ciliated; stem scabrous, with cartilaginous asperities pointing downwards." The habit of a mesembryanthemum. *Leaves* oblong, acute. *Flowers* yellowish-green, in a terminal cyme; anthers saffron-coloured; filaments white. A native of the Cape of Good Hope. 7. *C. vestita*. Linn. jun. Supp. 188. Mart. 31. Willd. 8. Thunb. Prod. 8. "Leaves connate, deltoid, obtuse; stem covered with leaves; flowers terminal, in a head." *Root* spindle-shaped, creeping. *Stem* three inches high, almost upright, naked at the base, branched; branches and branchlets alternately scattered. *Leaves* very gibbous underneath, quite entire, covered with a white meal, sprinkled with minute green spots, imbricated in four rows. *Flowers* yellowish, sessile. A native of the Cape of Good Hope. 8. *C. coralina*. Linn. jun. Supp. 188. Mart. 32. Willd. 7. Thunb. Prod. 56. "Leaves connate, deltoid, obtuse; stem covered with leaves; flowers in an umbel." *Root* spindle-shaped. *Stems* several, dichotomously branched, erect; branches alternate, erect, divided, fastigiate. *Leaves* entire, green at the base, mealy at the tip, with impressed greenish dots, in four rows, longer than the internodes. *Flowers* numerous, terminal; peduncles filiform, smooth, one-flowered, scarcely longer than the leaves. This and the preceding resemble sea corallines in the curious structure of their leaves. 9. *C. argentea*. Linn. jun. Supp. 188. Mart. 30. Willd. 9. Thunb. Prod. 56. "Leaves connate, egg-shaped, entire, silvery; stem covered with leaves; corymb supradecom-pound." *Stem* a foot high or more; branches cylindrical, smooth. *Leaves* fleshy, blunt with a point, sharp-edged. A native of the Cape of Good Hope. 10. *C. fascicularis*. Lam. 6. "Leaves linear-lanceolate, cartilaginous-ciliated, sheathing at the base; flowers fascicled, tubular, sessile; border small, spreading." *Leaves* three lines long, erect, connate by pairs, with a remarkable sheath at their base. *Flowers* nearly resembling those of *crassula coccinea*, but a little smaller, eight or ten together in a sessile terminal fascicle, furrounded by lanceolate ciliated bractes; claws of the petals linear, forming a tube; calyx half the length of the corolla; segments lanceolate, acute, ciliated. A native of the Cape of Good Hope, found by Sonnerat. 11. *C.*

perfoliata. Linn. Sp. Pl. 2. Mart. 6. Lam. 7. Willd. 10. Dill. Elth. 114. tab. 96. fig. 113. (Aloe; Comm. Prælec. 74. tab. 23.) "Leaves lanceolate-awl-shaped, sessile, connate, channelled, convex underneath." *Stem* three feet high and more; Lam. (ten or twelve feet high, if it be not broken or injured; but it is weak and requires support; Mill.) glaucous, leafy, nearly simple. *Leaves* from three to five inches long, an inch and half broad at the base, glaucous, rather stiff, spreading. *Flowers* greenish-white, in large terminal clusters on a common thickish peduncle, which is four inches long and divided into several short ramifications; petals oblong, obtuse, with claws forming a short tube. A native of Africa. 12. *C. perforata*. Linn. jun. Supp. 190. Mart. 51. Lam. 33. Willd. 11. Thunb. Prod. 56. "Leaves opposite-perfoliate, egg-shaped; stem simple; flowers peduncled, somewhat whorled." *Stems* a foot and half high, cylindrical, red, rather naked. *Leaves* somewhat acute, entire, even-surfaced. *Flowers* in a long terminal raceme, small, clustered, on opposite common peduncles. A native of the Cape of Good Hope. 13. *C. fruticulosa*. Linn. Man. 60. Mart. 7. Lam. 8. Willd. 12. "Leaves opposite, awl-shaped, acute, spreading, a little recurved." β . *C. caffra*; Linn. Mant. 222. *Stem* a foot high, somewhat branched, the thickness of a finger, sometimes throwing out lateral roots. *Leaves* sessile, cylindrical, even-surfaced. *Flowers* white, small; peduncles terminal, filiform, much longer than the leaves, furnished with a pair or two of bractes, nearly forming an umbel; calyx erect, half the length of the corolla; petals oblong-egg-shaped, without claws, concave, acute; anthers blood-red or brown; germs white, scabrous. A native of the Cape of Good Hope. 14. *C. ramosa*. Mart. 9. Willd. 13. Thunb. Prod. 55. Hort. Kew. 1. 390. (*C. dichotoma*; Linn. jun. 188.) "Leaves awl-shaped, flat above, connate-perfoliate, even-surfaced, very widely spreading; peduncles elongated; flowers in cymes." *Stem* a foot high, filiform, smooth, leafy, branched at the bottom; branches alternate, long, smooth, rufescent. *Leaves* longer than the internodes, entire, smooth. A native of the Cape of Good Hope. 15. *C. mollis*. Linn. jun. Supp. 189. Mart. 37. Willd. 14. Thunb. Prod. 55. Hort. Kew. 1. 391. "Leaves semi-cylindrical, acute, gibbous underneath, even-surfaced, nearly erect; cymes terminal, compound." *Stem* a foot high, almost the thickness of a goose-quill, angular, jointed, rufescent, very finely tomentous. *Leaves* acute, smooth or very finely tomentous, soft, spreading. A native of the Cape of Good Hope. 16. *C. tetragona*. Linn. Sp. Pl. 4. Mart. 8. Lam. 9. Willd. 15. (Cotyledonoides; Bradl. Succ. 5. 18. tab. 11. fig. 41.) "Leaves awl-shaped, somewhat incurved, obsoletely tetragonal, spreading; stem erect, throwing out lateral roots." *Stem* arborescent, two or three feet high, erect, even-surfaced, reddish, branched. *Leaves* longer than the internodes, about the thickness of a goose-quill, acute, green, smooth, opposite in cross pairs so as to form four very regular rows. *Flowers* very small, white, in a terminal trisid much branched cyme; common peduncle slender, naked; anthers purplish. A native of Africa. 17. *C. muricata*. Willd. 16. Thunb. Prod. 55. "Leaves connate, three-sided, ciliate-scabrous; branches tetragonal." A native of the Cape of Good Hope. 18. *C. imbricata*. Mart. 55. Willd. 17. Hort. Kew. 1. 393. "Leaves egg-shaped, acute, even-surfaced, imbricated in four rows; flowers axillary, sessile." A native of the Cape of Good Hope. 19. *C. cultrata*. Linn. Sp. Pl. 9. Mart. 11. Lam. 11. Willd. 19. (*C. auacampferotis* toliio; Dill. Elth. 115. tab. 97. fig. 114.) "Leaves opposite, connate, inversely egg-shaped, rather sharp at the edges, oblique,

C R A S S U L A.

oblique, quite entire." *Stems* cylindrical, a foot high or more, leafy on the upper part, a little branched, weak, inclining or procumbent unless supported. *Leaves* in distant pairs, about an inch and half long, and nine lines broad, fleshy, almost flat, narrowed at the base, green, smooth. *Flowers* in an oblong panicle, small, greenish-white, never expanding; common peduncle rather long, cylindrical, almost naked; petals ending in a remarkable point. A native of Africa. 20. *C. ovalata*. Linn. Mant. 61. Mart. 10. Lam. 10. Willd. 18. Thunb. Prod. 56. "Leaves opposite, somewhat lanceolate, sharp-edged, approximate." Similar to the preceding in the sharp edges of its leaves and the character of its flowers, but it has a shorter stem, and its leaves are nearer together. *Stem* three or four inches high, closely branched from the base. *Leaves* near two inches long, five or six inches broad, a little convex underneath. A native of the Cape of Good Hope. 21. *C. portulacæa*. Lam. 12. "Leaves oval, fleshy, resembling those of purslane, opposite; stem arboreous, very thick." The habit of portulacaria afra (*crassula portulacaria*: Linn.), but is much larger, and has not obtuse leaves. *Stem* four feet high, thicker than a man's arm towards the base; branches cylindrical, fleshy, smooth, paniced, leafy. *Leaves* about an inch and half long, an inch broad, rather acute, somewhat sharp at the edges, a little shining yellowish-green. *Flowers* rather large, pale rose-coloured, in a terminal peduncled cyme or umbel; calyx short; petals narrow, linear-lanceolate, expanding; germs scabrous. A native of Africa. 22. *C. obliqua*. Mart. 56. Willd. 20. Hort. Kew. 393. (*C. ovata*; Mill.) "Leaves opposite, egg-shaped, oblique, quite entire, acute, distinct, somewhat cartilaginous at the edge." *Stem* near three feet high, much branched. *Leaves* of a lively green, half embracing the stem. A native of the Cape of Good Hope. 23. *C. spatulata*. Mart. 60. Willd. 21. Thunb. Prod. 57. Hort. Kew. 1. 395. "Leaves petioled, cordate-rounclish, rather acute, crenate; corymbs forming a panicle." A native of the Cape of Good Hope. 24. *C. cotyledon*. Tree crassula. Lam. 13. Jacq. Misc. 2. 295. tab. 19. Bot. Mag. 384. (*C. arborescens*; Willd. 26. Mill.) "Leaves roundish, fleshy, dotted above; stem arboreous." The habit of cotyledon orbiculata. *Stem* two feet high or more, very thick, erect, branched near the top; branches greyish or reddish, cylindrical, fleshy, smooth, leafy. *Leaves* opposite, glaucous with purple edges, a little convex underneath, more than an inch and half in diameter. *Flowers* reddish-white, in a terminal paniced cyme; some of them are quadrifid. A native of Africa. A singularity of this species is its indisposition to flower. Mr. Fairbairn informed the late Mr. Curtis, that he never saw it produce blossoms in Chelsea garden till the summer of 1797. Mr. Miller never saw it in flower; nor does it appear that the late Mr. Aiton ever did. Bot. Mag. 25. *C. punctata*. Linn. Sp. Pl. 14. Mart. 20. Willd. 22. (*C. perfolia*; Lam. 14?) "Leaves opposite, egg-shaped, dotted, ciliated; lower ones oblong." Linn. "Leaves connate-perfoliate, approximate, heart-shaped, dotted, quite smooth, purple at the edges." Lam. *Stem* cylindrical, even-surfaced, simple. *Leaves* opposite, in two rows, oblong, sessile, fleshy, sprinkled with concave dots, convex underneath, very tenderly ciliated; floral leaves egg-shaped. *Corymbs* axillary, very short, fastigiate. *Corollas* campanulate, white, with a reflexed border; anthers purple. Linn. La Marck doubts whether Linnæus saw his plant, because he makes no mention of the very peculiar growth of its leaves, and moreover describes those of his *punctata* as ciliated, growing in two rows, with the lower ones oblong; characters which he himself has not found. He gives the

following description of his *perfolia*. *Stem* from six to ten inches long, slender, feeble, unable to support itself on account of the weight of the leaves, cylindrical, hard, smooth, simple. *Leaves* almost heart-shaped, so connate that each pair seems to be only a single elliptical leaf, a little pointed at each end, slightly concave and dotted above, somewhat convex underneath, glaucous, with a very smooth purple border. These leaves, or pairs of leaves, are placed very near together, and seem strung on the stem, which runs through their centre in the manner of an axis; the lower ones are the smallest. A native of Africa, cultivated in the botanic garden at Paris, 26. *C. lycopodioides*. Lam. 15. (*C. pyramidalis*; Linn. jun. Mart. 40. Willd. 38?) "Leaves small, ovate-acute, margined, imbricated in four rows, entirely covering the stem and branches." Lam. "Leaves connate, egg-shaped, obtuse, in four rows, incumbent; heads of flowers sessile." Linn. jun. *Stems* from seven to ten inches high, the thickness of a goose-quill, somewhat branched, rather stiff. *Leaves* convex at the back, a little flattened at the sides so as to produce the appearance of a border, sessile, fleshy, green. In habit rather resembling a lycopodium than a crassula. Lam. A native of Africa. 27. *C. marginalis*. Mart. 61. Willd. 23. Hort. Kew. 1. 396. "Leaves heart-shaped, perfoliate, acuminate, flat, spreading, dotted within the margin." A native of the Cape of Good Hope. 28. *C. laëta*. Mart. 62. Willd. 25. Hort. Kew. 1. 496. Smith Exot. Bot. tab. 33. "Leaves egg-shaped, attenuated at the base, connate, quite entire, with a row of dots within the margin; cymes paniced." Whole plant smooth. *Stem* much branched, cylindrical, leafy. *Leaves* crowded, crossing each other in pairs, thick, pointed. *Flowers* white, in a terminal panicle; anthers rose-coloured; scales at the base of the germ scarcely perceptible; petals, filaments, and germs often six. Dr. Smith. A native of the Cape of Good Hope. 29. *C. cordata*. Linn. jun. Supp. 189. Mart. 35. Willd. 34. Hort. Kew. 1. 396. "Leaves petioled, heart-shaped, obtuse, quite entire; cymes paniced." A native of the Cape of Good Hope. 30. *C. rupestris*. Linn. jun. Supp. 389. Mart. 43. Willd. 27. Thunb. Prod. 56. "Leaves connate, egg-shaped, entire, smooth; corymb supra-decompound." *Stem* three inches high or more, cylindrical, branched. *Leaves* alternately opposite, acute, a little concave above, convex, and keeled underneath, approximating, longer than the internodes, green, with a reddish margin. *Flowers* in trichotomous fastigiate corymbs; peduncles and pedicels smooth, white, tinged with purple; bracte minute, white, egg-shaped under each pedicel. A native of the Cape of Good Hope. 31. *C. lucida*. Lam. 16. "Leaves opposite, petioled, somewhat heart-shaped, finely crenate, shining above; stems branched, weak." *Stem* sometimes a foot long, smooth; upper part of the branches green, and somewhat herbaceous. *Leaves* seldom more than six lines broad, fleshy, flat above, with a slight furrow, which is continued along the petiole, bright green. *Flowers* white within, purplish on the outside, small, expanding, in a peduncled nearly terminal cyme; petals narrow, acute, much longer than the calyx. A native of Africa. 32. *C. pinnata*. Linn. jun. Supp. 151. Mart. 13. Lam. 17. Willd. 28. Lour. Cochin. 131. "Leaves pinnated; stem arboreous." *Stem* rufescent, even-surfaced, with alternate branches. *Leaves* alternate, unequally pinnated; leaflets seven or nine, petioled, heart-shaped, quite entire, acute, even-surfaced; petioles thickest at the base. *Flowers* red, in an axillary panicle, shorter than the leaves. A native of China.

* Herbaceous.

33. *C. retroflexa*. Linn. jun. Supp. 188. Mart. 33. Willd. 30. Thunb. Prod. 55. "Leaves connate, oblong, remote, flat; stem simple; cyme compound; pedicels bent back." *Root* annual. *Stem* a finger's length, filiform, zig-zag, erect, smooth, purple. *Stem-leaves* two or four, obtuse, spreading. It varies with orange-coloured, yellow, and white flowers. 34. *C. lineolata*. Mart. 53. Willd. 31. Hort. Kew. 1. 331. "Leaves heart-shaped, sessile; peduncles nearly terminal, axillary, approximating, forming an umbel." *Root* biennial. 35. *C. centauroides*. Linn. Sp. Pl. 5. Mart. 14. Lam. 18. Willd. 32. (Sedivides, Herm. Par. 169.) "Stem dichotomous; leaves sessile, oblong-ovate, heart-shaped, flat; peduncles axillary, one-flowered." *Root* annual or biennial. *Stem* three or four inches high, nearly cylindrical, brachiate, somewhat pubescent. *Leaves* often opposite, fleshy, acute, shining, marked with hollow dots. *Flowers* yellowish-red. A native of Africa. 36. *C. dichotoma*. Linn. Sp. Pl. 6. Mart. 15. Lam. 19. Willd. 33. (Sedum; Herm. Lugbd. 550. tab. 553.) "Stem dichotomous; leaves sessile, ovate-oblong, channelled, recurved; peduncles axillary, one-flowered." Nearly allied to the preceding; but its leaves are smaller, and its flowers larger. *Root* annual. *Stem* four or five inches high, slender, cylindrical, pale green, branched, and dichotomous near the top. *Leaves* opposite. *Flowers* purple on the outside, yellow within; each petal marked at the bottom with a blood-red, heart-shaped spot. A native of Africa. 37. *C. glomerata*. Linn. Mant. 60. Mart. 16. Lam. 20. Willd. 34. "Stem dichotomous; leaves lanceolate; last flowers fascicled." *Root* annual. *Stem* three inches high, slender as a thread, reddish, very dichotomous, and forming a tuft with its branches. *Leaves* opposite, sessile, green, somewhat fleshy, expanding, shorter than the internodes. *Flowers* sessile; some almost sessile in the forks of the stem; others clustered, two or three together at the end of the branches; bracts and divisions of the calyx hispid, with short hairs near the summit; petals white, much shorter than the calyx. A native of the Cape of Good Hope. 38. *C. pulchella*. Mart. 54. Willd. 35. Hort. Kew. 1. 392. "Stem dichotomous; leaves ovate-oblong, fleshy, reflexed; flowers in the forks peduncled; peduncles top-shaped." *Root* annual. Nearly allied to the preceding, but differing in having its leaves shorter and reflexed; its peduncles top-shaped, so as to look like an inferior germ; its calyxes obtuse, and its corollas rather longer than their calyx. A native of the Cape of Good Hope. 39. *C. strigosa*. Linn. Sp. Pl. 7. Mart. 17. Lam. 21. Willd. 36. "Stem dichotomous, erect; leaves inversely egg-shaped, bristly; peduncles one-flowered." *Root* annual. *Stem* six or seven inches high. *Leaves* opposite, somewhat fleshy, quite entire; lower ones peduncled. *Flowers* several together, terminal; petals the length of the calyx. 40. *C. muscosa*. Linn. Sp. Pl. 8. Mart. 18. Lam. 22. Willd. 37. "Stem prostrate; leaves opposite, egg-shaped, gibbous, imbricated; flowers sessile, solitary." *Root* annual. *Stems* filiform, seldom branched, covered with leaves. *Leaves* small, sessile. *Flowers* very small, axillary. A native of Africa. 41. *C. columnaris*. Linn. jun. Supp. 191. Mart. 28. Lam. 34. Willd. 39. (Euphorbinum; Burm. Afr. 19. t. b. 9. fig. 2.) "Stem an inch high; leaves round, imbricated; fascicle roundish, terminal." *Stem* thick, cylindrical, smooth. *Leaves* obtuse, horizontal. *Flowers* white, numerous; divisions of the border linear, spreading. A native of the Cape of Good Hope. 42. *C. hemispherica*. Willd. 40. Thunb. Prod. 57. "Leaves

ovate, roundish, ciliated, hemispherically imbricated; stem without leaves; flowers in a thyrse." *Root* annual. A native of the Cape of Good Hope. 43. *C. alfoides*. Mart. 57. Willd. 41. Hort. Kew. 1. 394. "Leaves egg-shaped, distinct, acute, ciliated; stem simple, a little hairy; raceme compound; branches panicled." *Root* biennial. *Stem* about six inches high. *Leaves* fleshy, smooth; sprinkled with minute, red, impressed dots. *Flowers* in a terminal raceme; peduncles distant, spreading, subdivided into trichotomous cymes; divisions of the calyx smooth, a line long; petals white, greenish underneath, twice the length of the calyx; nectaries yellow; filaments white; anthers small, roundish. A native of the Cape of Good Hope. 44. *C. capitella*. Linn. jun. Supp. 190. Mart. 45. Willd. 42. Hort. Kew. 1. 394. "Leaves oblong-lanceolate, acute, connate, ciliated; stem even-surfaced; raceme elongated; flowers fascicled, nearly sessile. *Root* biennial. *Stem* seven inches high, erect, cylindrical, smooth, sometimes branched at the top. *Leaves* remote, longer than the internodes, smooth. *Flowers* white. A native of the Cape of Good Hope. 45. *C. cotyledonis*. Linn. jun. Supp. 19. Mart. 49. Willd. 43. Thunb. Prod. 56. "Leaves connate, oblong, tomentous, ciliated; stem almost leafless; flowers in corymbs, aggregate. *Stem* simple, erect, slightly quadrangular, about a foot high, the thickness of a quill. *Root-leaves* fastigiate opposite, much crowded, obtuse, flat above, convex beneath, entire, a finger's length, erect; stem leaves in three pairs, smaller. *Flowers* white, pedicelled; peduncles trichotomous, forming a decomposed corymb; bracts on the peduncles, fastigiate opposite, connate-sheathing, egg-shaped, obtuse, pressed close, tomentous. A native of the Cape of Good Hope. 46. *C. barbata*. Linn. jun. Supp. 188. Mart. 29. Willd. 44. Thunb. Prod. 46. "Leaves connate, jointed, bearded, hemispherically imbricated; stem nearly cylindrical; flowers in whorls." *Root* biennial. *Stem* about seven inches high, nearly the thickness of a quill, erect, smooth. *Root-leaves* numerous, aggregate, thin, smooth, with bundles of hair at the edge; stem-leaves in two pairs, remote. A native of the Cape of Good Hope. 47. *C. ciliata*. Linn. Sp. Pl. 10. Mart. 19. Lam. 23. Willd. 43. Dill. Elth. 116. tab. 98. fig. 116. "Leaves opposite, oval, flattish, distinct, ciliated; corymbs terminal." *Root* perennial, slender, fibrous. *Stem* short, divided into several leafy branches, some of which are lengthened into slender cylindrical shoots, nine or ten inches long. *Leaves* obtuse, green, and smooth on both sides, thickly fringed with white hairs. *Flowers* small, yellow, collected into two or three small terminal corymbs. A native of Africa. 48. *C. gentianoides*. Lam. 24. (Gentianella Africana, Pluk. Mant. 89. tab. 415. fig. 6.) "Leaves opposite, ovate-acute, smooth; stem simple, dichotomous near the top; peduncles trichotomous." *Root* fibrous. *Stem* two or three inches long, slender. *Leaves* in about three pairs, oval, a little pointed, concave above, succulent, quite smooth. *Flowers* pale blue, large for the size of the plant, in an umbellated terminal cyme; bracts in pairs, at the foot of the peduncles, small, narrow; corolla monopetalous, campanulate, divided more than half way down; segments narrowed at the base, oval upwards. A native of Africa, communicated to La Marek by Sonnerat. *Olif.* It has the corolla of a cotyledon, and the number of stamens of a crassula. 49. *C. thyrsoflora*. Linn. jun. Supp. 190. Mart. 44. Willd. 46. Thunb. Prod. 55. "Leaves perfoliate, egg-shaped, ciliated, spreading; corymb compound, attenuated." *Stem* about six inches high, erect, cylindrical, smooth. *Leaves* obtuse, shorter than the internodes, smooth. *Flowers* white; bracts at the foot of the peduncles

duncles and pedicels, like the leaves, but smaller. A native of the Cape of Good Hope. 50. *C. umbella*. Mart. 64. Jacq. Collec. iv. 172. Icon. Rat. 2. "Leaves perfoliate, roundish; racemes axillary and terminal; upper peduncles in whorls. *Root* perennial. Whole plant smooth. *Stem* one or two, about seven inches high, the thickness of a quill, nearly erect, cylindrical, fleshy, pale flesh-coloured, almost pellucid, simple. *Root-leaves* none; stem-leaves two, sometimes only one, the largest three inches in diameter, convex, repand, brittle, green, with pale rays above, red-purple underneath. *Racemes* to each leaf two, erect, slender, opposite, from an inch to two inches long. *Flowers* white within, flesh-coloured without, small, most commonly with six stamens and six styles. A native of the Cape of Good Hope. 51. *C. spicata*. Linn. jun. Supp. 189. Mart. 41. Willd. 47. Thunb. Prod. 55. "Leaves connate, linear-awl-shaped; stem nearly leafless; spike whorled; lower whorls more remote." *Stem* about six inches high, cylindrical, erect, smooth. *Root-leaves* a finger's length, erect, concave above, convex underneath, smooth, much crowded; stem-leaves opposite, smaller. *Flowers* sessile. A native of the Cape of Good Hope. 52. *C. cymosa*. Linn. Mant. 222. Mart. 2. Lam. 35. Willd. 2. Berg. 84. (*Spiræa capensis*, Pet. Gaz. tab. 89. fig. 6.) "Leaves connate-sheathing, linear, cartilaginous-ciliated; cyme compound, terminal." *Root* perennial. *Stems* herbaceous, about seven inches high, simple, erect, smooth. *Leaves* two inches long, acute, spreading, smooth on both sides. *Cyme* small, dense, bifid, scaly. A native of Africa. La Marck supposes that his capitata (N^o 2.) is nearly allied to this species, but it differs in having a woody perennial stem. 53. *C. subulata*. Linn. Sp. Pl. 3. Mart. 21. Lam. 25. Willd. 48. Berg. 83. (*Spiræa*, Pet. Gaz. tab. 89. fig. 8. *Sedum*, Herm. Lugdb. 550. tab. 552.) "Leaves awl-shaped, cylindrical, spreading." *Stem* six or seven inches high, erect, with two or three branches, entirely covered with truncated ciliated sheaths of the leaves. *Leaves* about an inch long, opposite, linear, fleshy, obtuse, flat above and below, fringed with cartilaginous cilia. *Flowers* white (scarlet, Berg.), in a terminal nearly sessile head, with a many-leaved imbricated involucre. A native of the Cape of Good Hope. 54. *C. acutifolia*. Lam. 26. "Leaves opposite, fleshy, cylindrical-awl-shaped, quite smooth, spreading; cyme small, peduncled." *Root* perennial. *Stems* three inches long, cylindrical, leafy, a little branched. *Leaves* a little connate, not sheathing, six or seven lines long. *Flowers* white, from twelve to eighteen in a very small, often dichotomous cyme; common peduncle two inches long, lateral, almost naked. A native of Africa. 55. *C. alternifolia*. Linn. Sp. Pl. 12. Mart. 22. Lam. 27. Willd. 49. Burm. afr. 53. tab. 24. fig. 1. (*Cotyledon flore luteo, media*; Herm. Lugdb. 191.) "Leaves serrate-toothed, flat, alternate; stems quite simple; flowers pendulous." *Stems* several, two feet long, purple, hairy. *Leaves* oval-lanceolate, with a very long point, sessile. *Flowers* yellow, axillary, solitary, on short peduncles. A native of Africa. 56. *C. rubens*. Mart. 23. Lam. 28. Willd. 50. (*Sedum rubens*; Linn. Sp. Pl.) "Leaves scattered, semi-cylindrical, smooth; flowers lateral, solitary, nearly sessile; branches villous." *Root* annual. *Stem* about three inches high, cylindrical, a little villous, reddish, simple below, branched near the top. *Leaves* sessile, a little attenuated and red near the tip; lower ones an inch long. *Flowers* white, with a purple longitudinal line on the outside segments of the calyx, fleshy, convex on the outside, slightly villous; petals three times as long as the calyx; nectaries white, very small; stamens generally observed to be five; but

Haller asserts that these are naturally ten, five of them soon withering. *Fruit* stellate, red; capsules armed with the permanent style. It has the habit of a sedum, and perhaps might with more propriety have been left where Linæus and the older botanists placed it. A native of the south of Europe. 57. *C. cespitosa*. Willd. 51. Cavan. ic. 1. 50. tab. 69. fig. 2. "Leaves globular-egg shaped, imbricated; flowers terminal, sessile. *Stem* somewhat divided." *Root* annual. *Stem* three lines long. *Flowers* solitary, or three together. A native of Spain. 58. *C. minima*. Willd. 52. Thunb. Prod. 57. "Leaves petioled, roundish, entire; peduncles one flowered." A native of the Cape of Good Hope. 59. *C. meschata*. Willd. 53. Forst. Comment. Geett. 9. 26. "Stem procumbent; leaves connate, oblong, acute; peduncles axillary, one-flowered; flowers tetrandrous." It differs from tillæa in the nectary, though it agrees in the number of parts. 60. *C. verticillaris*. Linn. Mant. 261. Mart. 24. Lam. 29. Willd. 54. (*Tillæa erecta*; Hort. Ups. 24.) "Leaves spreading; flowers in whorls, awned." *Root* annual. *Stem* the length of a finger, much branched, diffuse; branches opposite. *Leaves* opposite, crowded, oblong-egg-shaped, sessile, gibbous, sprinkled with minute pimples, scabrous at the tip. *Flowers* axillary, sessile, very minute; calyx the length of the corolla, awl-shaped; petals shorter than the calyx, lanceolate, acuminate so as to be almost awned, red in the middle; stamens very short, red at the tip; stigmas red. A native of the south of Europe. 61. *C. expansa*. Mart. 52. Willd. 55. Hort. Kew. 1. 390. "Leaves semi-cylindrical-awl-shaped, spreading; peduncles axillary, solitary, one-flowered; stems dichotomous." *Root* annual. A native of the Cape of Good Hope. 62. *C. dentata*. Willd. 56. Thunb. Prod. 57. "Leaves petioled, heart-shaped, toothed." A native of the Cape of Good Hope. 63. *C. nudicaulis*. Linn. Sp. Pl. 13. Mart. 25. Lam. 30. Willd. 57. Dill. Elth. 116. tab. 99. fig. 115. "Leaves awl-shaped, radical; stem naked." *Root* perennial, branched. *Leaves* three inches long or more, numerous, linear narrow, pale green, succulent, almost semi-cylindrical, making a kind of head on the ground. *Stem* or scape six inches high or more, with two or three joints, and three or four bractes in a whorl at each joint. *Flowers* greenish, not expanding, in several compact heads, some of which are terminal, and others a little below, almost in a whorl. A native of Africa. 64. *C. teza*. Linn. jun. Supp. 190. Mart. 50. Willd. 58. Thunb. Prod. 56. "Leaves connate, egg-shaped, obtuse, cinereous-lamellated; scape naked; head terminal." *Stem* scarcely any. *Leaves* nearly radical, very abundant, imbricated, concave above, convex underneath, thick, covered with an ash-coloured meal resembling the scales of a butterfly's wing, naked at the base, cartilaginous-ciliated. *Scape* erect, filiform. *Flowers* minute, collected into a head. A native of the Cape of Good Hope. 65. *C. cephalophora*. Linn. jun. Supp. 190. Mart. 47. Willd. 59. Thunb. Prod. 56. "Leaves connate, linear-oblong, obtuse, entire; heads of flowers lateral, peduncled." *Root-leaves* the length of a finger, erect, somewhat tomentous; stem-leaves none. *Scape* six or seven inches high, erect, cylindrical, somewhat tomentous. *Heads* of flowers opposite, the size of a pea. A native of the Cape of Good Hope. 66. *C. montana*. Linn. jun. Supp. 189. Mart. 36. Willd. 60. Thunb. Prod. 55. "Leaves connate, egg-shaped, acute, ciliated; stem nearly naked; flowers aggregate." *Stem* the length of a finger, erect, filiform, purple. *Root-leaves* numerous, spreading, concave, smooth, green tinged with purple; stem-leaves in about three remote pairs. *Flowers* sessile, in heads usually

solitary, sometimes in two lateral ones together. A native of the Cape of Good Hope. 67. *C. turrita*. Linn. jun. Supp. 189. Mart. 42. Willd. 61. Thunb. Prod. 55. "Leaves connate, imbricated in four rows, ovate-oblong, acute, ciliated." *Root* annual. *Stem* about three inches high, erect, weak, cylindrical, jointed, covered with leaves, smooth. *Leaves* alternately opposite, thick, smooth, red; lower ones oblong, concave above, convex underneath; upper ones egg-shaped, flat above. A native of the Cape of Good Hope. 68. *C. alpestris*. Linn. jun. Supp. 189. Mart. 39. Willd. 62. Thunb. Prod. 55. "Leaves connate, egg-shaped, acute, imbricated in four rows; heads of flowers peduncled; stem leafy." *Stem* three inches high, purple, erect, cylindrical, smooth, branched at the bottom, before flowering time entirely covered with leaves. *Leaves* concave, entire, purplish green. *Flowers* in several small terminal heads; peduncles purple. It resembles *C. montana*, but the leaves are more acuminate and not ciliated, the stem thicker and covered with leaves; the heads and flowers larger. A native of the Cape of Good Hope. 69. *C. marginata*. Willd. 63. Thunb. Prod. 55. "Leaves connate, egg-shaped, membranous at the edges; peduncles one-flowered; stem weak." A native of the Cape of Good Hope. 70. *C. tomentosa*. Linn. jun. Supp. 190. Mart. 48. Willd. 64. Thunb. Prod. 56. "Leaves connate, lanceolate, villous, ciliated; stem almost without leaves; flowers in whorls." *Stem* a foot high, erect, angular, villous. *Root-leaves* bluntnish, hirsute, imbricated; stem-leaves in three pairs, smaller. A native of the Cape of Good Hope. 71. *C. crenulata*. Linn. jun. Supp. 189. Mart. 38. Willd. 65. Thunb. Prod. 56. "Leaves connate, lanceolate, dotted and crenulated; stem leafy; corymb decomposed." *Stem* a foot high, erect, cylindrical, leafy, jointed, smooth, green variegated with white lines. *Leaves* sessile, obtuse, concave above, convex beneath, smooth, longer than the internodes, the length of a finger, upright, but spreading at the tip. *Flowers* white, in a trichotomous, fastigate corymb; bractes two under each pedicel, minute, opposite. A native of the Cape of Good Hope. 72. *C. deltoidea*. Linn. jun. Supp. 189. Mart. 34. Willd. 66. Thunb. Prod. 56. "Leaves connate, deltoid, spreading, acute; stem covered; flowers in a corymb." *Stem* fleshy, erect, cylindrical, naked at the bottom, leafy above, branched. *Leaves* alternately opposite, imbricated, spreading at the tip, entire, glaucous, mealy. *Corymb* terminal, compound, somewhat fastigate. The leaves resemble those of *mesembryanthemum deltoideum*. A native of the Cape of Good Hope. 73. *C. orbicularis*. Linn. Sp. Pl. 15. Mart. 26. Lam. 31. Willd. 67. Dill. clth. 119. tab. 100. fig. 118. "Runners prolific, regularly leafy at the end; leaves widely spreading, imbricated." *Root* perennial, producing laterally from its crown numerous filiform, procumbent, prolific runners. *Leaves* in regular rosaceous tufts proceeding from the original root and from the ends of the runners where they take fresh root and send out other runners, oval, or oval-oblong, rather acute, fleshy, edged with very fine cartilaginous cilia. *Scapae* four or five inches high, rising from the centre of the tufts of leaves, erect, furnished with two or three pair of very small bractes. *Flowers* small, whitish red, in several small clusters disposed in a short branched spike, sweet scented; petals the length of the calyx. A native of the Cape of Good Hope. 74. *C. sparsa*. Mart. 58. Willd. 68. Hort. Kew. 1. 395. "Leaves alternate, somewhat spatula-shaped, acute, quite entire; raceme compound." *Root* biennial. A native of the Cape of Good Hope. 75. *C. diffusa*. Mart. 59. Willd. 69. Hort. Kew.

1. 395. "Leaves oblong, attenuated at the base, remotely crenated; peduncles solitary, opposite to the leaves and axillary." *Root* annual. A native of the Cape of Good Hope. 76. *C. prostrata*. Willd. 70. Thunb. Prod. 54. "Decumbent, pellucid; leaves lanceolate, acute." A native of the Cape of Good Hope. 77. *C. pellucida*. Linn. 16. Mart. 27. Lam. 32. Willd. 71. Dill. clth. 119. tab. 100. fig. 119. "Stem flaccid, creeping; leaves opposite." *Root* perennial. The habit of a purslane. *Stems* from six inches to a foot long, putting out roots at the joints, red, almost transparent, slender, trailing, smooth. *Flowers* white, with a blush of purple at the edge, in small clusters at the ends of the branches. A native of Africa. Common in botanical collections in England and other parts of Europe.

Obf. Jussieu, disregarding the number of stamens, has referred all the tubular species to cotyledon.

CRASSULA decumbens, inanis, natans et umbellata; Thunb. See TILLÆA.

CRASSULA fruticosa; Mill. See OTHONNA tenuifolia.

CRASSULA portucalaria; Linn. See PORTULACARIA *Afra*.

Propagation and Culture.—Most of the species are hardy, and may be treated like the mesembryanthemums and other hardier kinds of succulent plants, but should not have much water: and some of them, particularly *C. coccinea*, and *C. perfoliata*, must not be so long exposed to the open air in summer, but removed early to a warm, dry glass case.

CRASSULA, in *Gardening*, comprises plants of the succulent kind for the green-house and stove collections. Of which the species cultivated are the scarlet flowered crassula (*C. coccinea*), the perfoliate shrubby crassula (*C. perfoliata*), the sharp leaved crassula (*C. cultrata*), the dotted leaved crassula (*C. punctata*), the naked stalked crassula (*C. nudicaulis*), hairy crassula (*C. orbicularis*). Besides which there are several other species that may be cultivated.

Method of Culture.—Of these plants the first three sorts are capable of being easily increased, by planting the cuttings of the stems and branches in the later spring and summer months. After having been exposed in a dry situation for a few days, to heal over the cut parts, in pots filled with sandy earth planting them in the bark-bed of the stove, or in a frame shaded from the sun. When well rooted, they should be removed into separate pots and be replaced in the same situation till fully established, when they may be removed into the green-house, where they should have a sunny situation in winter and but little water, as it is apt to destroy them.

The other sorts may be increased by planting the offsets from the roots in the same manner as directed above.

These being plants of a succulent nature in their stems, branches, and leaves, as well as curious in their growth, they afford much variety among collections of other plants of similar kinds. They are capable in dry warm situations of bearing the open air in the summer season.

CRASSUS, LUCIUS LICINIUS, in *Biography*, an eminent orator of Rome, born, B. C. about 140, was brought into notice principally by the part that he took in the impeachment of Papirius Carbo, which he managed with the utmost skill, displaying, in the pleadings, the most consummate eloquence. Crassus from this circumstance immediately rose to the highest reputation. At the age of 27 he defended the vestal virgin Licinia, accused of unchastity. He was the advocate of many very popular measures; and he passed with distinguished honour through all the principal offices

offices of the state. He died in the year B. C. 91, in consequence of some over-exertions in vindicating the senate from the censures passed upon it by the consul Philippus, who threatened to silence him: in reply to which the orator exclaimed; "If you would silence Crassus, you must cut out his tongue; and even then, liberty will inspire my breath itself to resist your tyranny." He perished in the contest, and carried his point, but the violence of his agitation brought on a pleurisy, of which he died, in a few days, to the great regret of his fellow-citizens, who considered him as a martyr to his country's cause. Cicero, in speaking of Crassus, says, "His language was accurate and elegant, without being too studied. He had wonderful clearness of argument and illustration, as well on subjects of civil law as of common equity. As Scævola was the most eloquent of lawyers, so Crassus was accounted the best lawyer among the eloquent. What is very difficult to attain, he was at the same time highly ornate, and very concise. He had no equal in attack or reply. He was conversant in almost all kinds of causes, and early took his station among the principal orators." Univer. Hist. Cicero.

CRASSUS, MARCUS LICINIUS, a distinguished Roman, who must hereafter be noticed in the article ROME, as taking a very leading part in her affairs in the latter days of the republic, but who nevertheless cannot be passed over in our biographical sketches. He was descended from a family of high rank; enjoyed all the advantages of a liberal education, and selected as his principal pursuits, oratory, history, and the philosophy of the age. His father and mother were slaughtered under the tyrannies of Marius and Cinna, and he himself escaped by leaving his country for Spain, where he was concealed in a cave for the space of eight months. On the death of Cinna, he joined Sylla, whom he served with zeal and fidelity. During the civil wars Crassus enriched himself by means not at all honourable. He was prætor, B. C. 71, and was appointed to the command of the army, in which office he exercised much severity against those who neglected to perform their duty. In the following year Crassus was associated with Pompey in the consulship. They had been long rivals, and were now exceedingly jealous of each other's authority; a seeming reconciliation took place, which was probably not sincere on the part of either. Cæsar, on his return from Spain, found the consuls at open variance; he, however, soon convinced them that it was the mutual interest of all three to come to an agreement, and this was the foundation of that triumvirate which superseded and demolished all the powers of the old constitution. In the year 55, Crassus and Pompey were again consuls, and in the distribution of the provinces, Syria fell to the lot of Crassus, which afforded him new opportunities of enriching himself, by the plunder of the oppressed inhabitants. He proceeded to Syria, marched to Jerusalem, and seized upon all the treasures of the temple which the moderation of Pompey had spared. He next crossed the Euphrates, invaded the Parthian territories, and leaving garrisons in the principal cities which fell into his power, he recrossed the river and took up winter quarters in Syria. Here he was safely and infamously employed in plundering the temples, and raising money by every species of extortion, while to ingratiate himself with his army and to secure their affection, he suffered the soldiers to indulge in every kind of licentiousness. At the proper season he passed the Euphrates a second time, with 40,000 men. Cassius his lieutenant urged him by all means to keep close to the bank of the river, but the king of Edessa, Abgarus, with a view of betraying the Romans, persuaded Crassus to

take an inland course. He decided on this course, and led the army over barren plains, where they endured extreme hardships from thirst and fatigue, till they came in sight of the Parthian host. Scarcely had Crassus drawn up his legion into a hollow square when he was attacked on all sides and defeated. In this important battle the Romans lost 20,000 in killed, and 10,000 in prisoners. The darkness of the night favoured the escape of the rest, and Crassus, forced by the mutiny and turbulence of this fragment of his army, and the treachery of his guides, trusted himself to the general of the enemy, on pretence of proposing terms of accommodation, and he was put to death, B. C. 53. His head and right hand were cut off, and shewn to his troops, of whom some surrendered, and others attempted to escape, who were mostly cut off by the Arabs. His head was afterwards sent to the Parthian monarch, who caused melted lead to be poured into it, and otherwise insulted his misfortunes.

Crassus, in his youth, was free from those vices which stained the noble Roman youth of the times; as he advanced in years, the love of money, not for its own sake, but with a view of enhancing his importance among his contemporaries, was the rock on which he split. Few among the ancients seem so systematically to have followed the plans of pecuniary profit: and he acquired a greater mass of wealth than any other Roman citizen; hence he obtained the name of Crassus the *Rich*. He was, however, at times exceedingly prodigal of his wealth: once he gave a sumptuous entertainment to the people at ten thousand tables, and he bestowed upon each guest corn enough to supply his wants, and those of his family for three months. He was likewise ready on almost every occasion to lend his money to his friends without interest, which shewed a mind superior to the principles of common avarice; and to the last, when disengaged in projects of ambition, he was fond of philosophy, and took great delight in the study of history. Plutarch. Florus. Univer. Hist.

CRASSUS, JUNIUS PAULUS, a learned and ingenious physician, and native of Padua, where he appears to have been held in high estimation, published in 1581, in 4to. "De purgativis Medicamentis Questiones Medicæ et naturales;"—also, "Meditationes de Theriaca, et Mithridatis," 4to. 1576; and "Mortis repentinæ examen." But his principal merit consists in his being one of the earliest, and most judicious commentators on the works of Hippocrates, Galen, Palladius, and Aretæus, and introducing those authors to more general notice:—contemporary with this writer flourished,

CRASSUS, JEROM, a disciple of Fallopius, but who, although he obtained the dignity of Doctor in Medicine, appears to have confined himself to the practice of surgery, in which branch he published several treatises, which continued to be in great estimation, long after his demise. The principal of those are, "De Calvariæ curatione, et de solutione continui," 4to. 1560, Venet. "De tumoribus præter Naturam et de Ulceribus," 1562. "De Cerafte; seu Basilisco, Morbo Novo, Medicis incognito, Utini," 1593, 8vo. and "De Cauteriis, five de cauterifandi oratione," (of which he made frequent use) 8vo. 1594. Haller. Bib. Med. Chirurg.

CRASTA, in *Geography*, a mountain of European Turkey, in the province of Albania; 4 miles north of Albanof.

CRASTANOVITZA, a town of Croatia, on the river Unna; 26 miles N. W. of Banjaluka, and 20 S. W. of Gradisca.

CRASTONA, or CRISTONA, GIOSEFFO, in *Biography*, a painter.

a painter, born in Pavia, in the year 1664. He studied some time under Bernardino Ciceri, and afterwards went to Rome for improvement. Upon his return to his own country, he employed himself many years in painting small pictures of figures with landscapes, esteemed for the spirit and lightness of their foliage. He died in Pavia after the year 1718. Lanzi. Orlandi.

CRASTUS, in *Ancient Geography*, a town, and also a mountain, of Sicily.

CRASUS, a town of Phrygia Major.

CRATÆGELLA, in *Entomology*, a species of *Tinea*, in the class of *Phalena*.

CRATÆGUS, in *Botany*, Linn. See *MESPILUS* and *PYRUS*.

CRATÆGUS, in *Gardening*, comprehends plants of the hardy deciduous tree and shrub kinds; of which the sorts most commonly cultivated are the hawthorn or white-thorn, (*C. oxyacanthus*); the white beam, or white leaf tree (*C. aria*); the wild service forb, or maple-leaved service (*C. torminalis*); the great American hawthorn (*C. coccinea*); the green-leaved Virginia hawthorn (*C. viridis*); the cockspur hawthorn (*C. cruf-galli*); the woolly-leaved hawthorn (*C. tomentosum*); and the parsley-leaved hawthorn, or azarole (*C. azarolus*).

The first sort is well known to rise with an ascending round much-branched stem or trunk, having a smooth whitish coloured bark, and being beset with sharp thorns, affording flowers of a white colour in May, which are succeeded in the autumn with bunches of dark red berries.

Of this sort there are different varieties, as with large oblong smooth bright scarlet fruit; with buds appearing of a fine bright yellow, and the fruit of a golden colour, being retained all the winter; with white berries and double blossoms, in large bunches: the maple leave at first of a pure white, then turning to faint red; and the Glastonbury thorn, or early flowering thorn.

The second sort is a tree which rises to the height of thirty or forty feet, having a large trunk with numerous branches, with large bunches of flowers of a white colour at the ends of them. It is a native of most parts of Europe, flowering in May.

It has varieties with deeply sinuated pinnatifid leaves, as the Swedish; and with leaves which are not white underneath.

Those of the third sort rise to the height of forty or fifty feet, having a large trunk, spreading at top into many branches so as to form a large head. The flowers are produced in large bunches at the ends of the branches, of a whitish colour, being succeeded by a roundish compressed fruit similar to the haw, but larger. It is a native of Denmark.

And it has a variety, with oblong ovate-leaves, or short foot-stalks.

The fourth kind reaches the height of about twenty feet, having a large upright trunk, branching at top so as to form a large head. The flowers are in large clusters, making a fine show in May, and being succeeded by large pear-shaped fruit of a bright scarlet colour, which becomes ripe in the beginning of autumn. It is a native of Virginia.

The fifth sort has the stem and branches thornless; the leaves being smooth and green on both sides. It has been supposed a variety of the above by Martyn.

In the sixth kind the stem is strong, being ten or twelve feet in height. The flowers are in roundish clusters of a bluish red colour, and the fruit of a globular form having a fine red colour. It is a native of North America, flowering in June.

In the seventh sort the stem is slender and shrubby, rising to the height of six or seven feet, with many irregular branches, armed with long slender thorns. The flowers are small and appear in June, and are succeeded by small roundish fruit which ripens late in the autumn. It is also a native of North America.

It has a variety usually known under the title of Carolina hawthorn, in which the leaves are longer and whiter, and the flowers and fruit larger, but it is without thorns.

The eighth kind has a strong stem twenty feet in height, with numerous strong irregular branches. The flowers in small clusters at the side of the branches, similar in shape to those of the common hawthorn, but greatly larger as well as the fruit which, when fully ripened, has a pleasant acid taste. It is a native of the southern parts of Europe.

Method of Culture.—All the different sorts are capable of being increased with facility, by sowing the seed in the open ground, either in the autumn or spring months, in drills, or broadcast, covering them to the depth of about an inch. The seeds, or haws, may be gathered from the hedges in many of the sorts, and the others be procured from the nursery-men, being employed, when fully ripened. The plants mostly appear in about twelve months. They should be kept perfectly clean from weeds, and be occasionally watered when the weather is hot and dry. When they have had one or two years growth in the seed-beds, they may, in most of the sorts, be removed into nursery-rows, and set out at the distances of from eight inches to two feet, according to the sorts, and from six inches to a foot in the rows; to remain till wanted for the purpose of forming hedges, or planting out in other places, having the top shoots and other parts cut and pruned, as there may be occasion. See *HAWTHORN* and *WHITE-THORN*.

The more beautiful and curious sorts are generally proper for the purpose of planting out, when they have attained three, four, or five feet growth.

For these kinds, in order to continue the varieties, recourse must be had to the practice of budding, grafting, or laying the young branches. The two first methods may be performed upon stocks of the common hawthorn, as any of the sorts will take upon that sort of stock; or upon those of one another; but the former mode is the best. The operations should be performed at the usual season in the manner that is directed under their proper heads. See *BUDDING* and *GRAFTING*.

The young shoots should be laid down in the autumn, and when they have stricken good roots, which, in most cases, happens in twelve or eighteen months, they should be taken off, and planted out in nursery rows, or other places, as above. See *LAYER* and *LAYERING*.

The cuttings of the young shoots, planted out in the spring, in rather moist situations, will sometimes take root, and become good plants. See *CUTTING*.

All the various sorts are hardy, and capable of succeeding in almost any soil or situation, where proper care is taken in their management.

The first sort is a highly useful plant for the purpose of forming hedges for the farmer, being extremely useful in enclosing lands where this sort of fence can be made use of. See *FENCE*.

And all the other species and varieties may be employed as ornamental plants in the clumps and other parts of extensive shrubberies, and other pleasure-grounds and plantations. Many of the sorts have likewise a very ornamental effect, when planted out singly on lawns, or other similar parts of pleasure-grounds, especially when in flower from their beautiful blossom. On this account they have also a fine effect

effect in mixed plantations in various cases of ornamental planting.

CRATÆOGONUM, in *Botany*, Rumph. See *PARIETARIA indica*.

CRATÆOGONUM *amboinicum*, Rumph. See *OLDENLANDIA verticillata*.

CRATÆRIFORMIS, a technical term in *Botany*, somewhat like *Calathiformis*, but not so much bellying out, rather approaching to more dilute forms.

CRATAIS, in *Ancient Geography*, a small river at the extremity of Italy, which ran between Columna and Cœnys, and discharged itself towards the west into the strait of Sicily.

CRATCH, in *Rural Economy*, a name applied in some districts, to signify a cattle rack. It is also occasionally used to denote a creel. See *CREEL*.

CRATCHES, in *Farriery*, a swelling on the pattern under the fetlock, and sometimes under the hoof.

CRATEÆ, or CRATEIÆ, in *Ancient Geography*, islands of the Adriatic gulf, between those of Pharos and Issa.

CRATER, *Cup*, in *Astronomy*, a constellation of the southern hemisphere; whose stars, in Ptolemy's catalogue, are seven; in Tycho's, eight; in Hevelius's, ten; in the Britannic catalogue, thirty-one. See *CONSTELLATION*.

CRATER, in *Falconry*, denotes a line on which hawks are fastened when reclaimed.

CRATER, in *Ancient Geography*, a name anciently given, from its form, to the gulf of Naples.

CRATERII PORTUS, a port of Asia Minor, in the Æolide; it is placed by Thucydides in the territory of the town of Phocæa.

CRATERITES, in *Natural History*, the name of a gem mentioned by Pliny, and said to be extremely hard, and of a middle colour between that of the chrysolite, and of the common yellow amber. This was plainly a species of Chrysolite.

CRATERO, in *Biography*, an ancient painter, from whose works there were some comic figures in the edifice at Athens, which was called *Pompeio*, from the utensils used in their pomps and sacrifices being there deposited. There was also a sculptor of this name, who is said to have been employed at the palace of the Cæsars upon Mount Palatine. Della Valle.

CRATERUS, a famous Macedonian general, who accompanied Alexander in his expedition to India, and enjoyed a greater share of his esteem and confidence than any other commander in his service. Whilst Alexander was marching with his army towards Bactriana, some of his officers formed a conspiracy against his person; and Philotas, the son of Parmenio, was suspected of being a confederate in the treason. Craterus, who regarded him as a rival, availed himself of the opportunity which now offered itself, of extorting by torture a confession of his guilt, in consequence of which both Philotas and also his father, whom he had accused as one of his accomplices, were put to death. That Alexander duly appreciated the character of Craterus is plain from the reflection which he uttered on the death of his favourite Hephæstion: "Craterus," says he, "loves the king, but Hephæstion loves Alexander;" intimating that, whilst the latter had devoted himself in an affectionate manner to his person, the former was concerned for his reputation, and was sometimes less obsequious to his will than he was zealous for his glory and interest. Craterus was no less beloved by the Macedonians in general than by Alexander himself. Whilst he was entrusted by his sovereign with the command of the 10,000 veteran troops who were sent to Ma-

cedonia, on account of their age, wounds, or other infirmities, which rendered them incapable of service, he was appointed to the government of Macedonia, Thessaly, and Thrace, in the room of Antipater, who was recalled to Babylon. After the death of Alexander, the provinces of Macedonia, Epirus, and Greece, were assigned to Craterus and Antipater, who governed them jointly; and in this government Craterus approved himself a prudent and faithful associate; more especially in the operations of the war in which they were unavoidably engaged by the discovery of the designs which Perdicas was forming. So highly was Craterus respected by the Macedonians, that they were desirous of having him for their leader after the death of Alexander; and such was their known attachment to him that Eumenes in the engagement in Cappadocia, which proved fatal to Craterus, took particular care not to oppose any Macedonian against him. Having acquitted himself with great valour on this occasion, and killed several of the enemies with his own hand, he was at last wounded by a Thracian in the back, and falling from his horse was trampled to death by the enemy's cavalry. Eumenes could not forbear shedding tears over a vanquished enemy, whom he had formerly esteemed as a friend; and he caused the last honours to be paid him with all possible magnificence. His bones were conveyed to Macedonia for the disposal of his wife and children. The wife of Craterus was Phila, the daughter of Antipater, one of the most accomplished princesses of her age, no less distinguished by the amiableness of her disposition than by the beauty of her person. Rollin's Anc. Hist. vol. iv.

CRATES, the most distinguished philosopher of the Cynic sect after Diogenes, was by birth a Theban, and flourished about the 113th Olympiad (B. C. 328.) and died after the year 287, B. C. He was honourably descended, and inherited a large estate; but, when he devoted himself to philosophy, that he might be free from the dominion of those passions which are fostered by wealth, he distributed his whole property among the poorer citizens. Leaving his native city, where he had been a disciple of Bryo, reckoned among the Cynic philosophers, he went to Athens, and became a zealous disciple of Diogenes; adopting all the singularities of his master. In his natural temper, however, he was not, like Diogenes, morose and gloomy, but cheerful and factious. This disposition attached to him many friends, and procured for him access to the houses of the most wealthy Athenians. Among the citizens at large he acquired a degree of confidence, which gained him admission into their domestic circles; and he frequently became an arbiter of disputes and quarrels among relations. His influence in private families is said to have had a great effect in correcting the luxuries and vices which prevailed at that time in Athens. His wife, Hipparchia, who was rich and of a good family, and had many suitors, preferred Crates to every other, and when her parents opposed her inclination, so determined was her passion, she threatened to put an end to her life. After marriage she adopted all the peculiarities of the Cynic philosophy. Laertius, l. vi. § 85, &c. Suidas. Apul. Apol. p. 202.

CRATES, an Athenian, succeeded Polemo in the direction of the old academy. Long attached to one another by a similarity of dispositions and pursuits, their friendship was uninterrupted whilst they lived, and they were both buried in the same grave. Crates died about the year 250, B. C.

CRATES, Lat. *Hurdle*. The ancients made use of machines formed of boards and hurdles for covering their men at work as they approached the walls of a town besieged.

CRATEVA,

C R A T E V A.

CRATEVA, in *Botany*, (so called from Cratevas, a Greek physician, celebrated by Hippocrates for his knowledge of plants). Plum. 21. Linn. Gen. 599. Schreb. 818. Willd. 943. Juss. 244. Vent. 3. 121. (Papier; Encyc.) Class and order, *dodecandria*, or rather *polyandria monogynia*. Nat. Ord. *Putamineæ*, Linn. *Capparides*, Juss.

Gen. Ch. Cal. Perianth inferior, one-leafed, flat at the base, deeply four-cleft; segments egg-shaped, deciduous. Cor. Petals four, attached by the claws to the calyx. Stam. Filaments indeterminate in number, bristle-shaped, inserted into the pedicel of the germ; anthers erect, oblong. Pist. Germ on a long filiform column or pedicel; style none; stigma capitate. Peric. Berry pedicelled, fleshy, one-celled. Seeds numerous, bedded in the pulp, roundish, emarginate.

Ess. Ch. Calyx four-cleft. Petals four. Filaments inserted into the pedicel of the germ. Stigma sessile. Berry one-celled, with many seeds.

Obs. In *capparis*, which is very nearly allied to the present genus, the filaments are attached to the edge of the receptacle; but this, as Dr. Sims rightly observes, (see *Botanical Magazine*, 596.) is only a slight difference, as the column or pedicel itself is only an elongation of the centre of the receptacle. In the habit of the plants there is, however, this striking distinction, that the leaves are ternate in *crateva*, and simple in every species of *capparis*, except the *falcata* and *magna* of Loureiro (*n.* 27 and 41 of this dictionary) and a farther investigation of the attachment of the filaments will perhaps shew that these species ought to have been referred to *Crateva*.

Sp. 1. *C. tapia*. Linn. Sp. Pl. 2. Mart. 2. Poir. 1. Willd. 2. (*Agioscorodon*; Pluk. *Almag.* 34. tab. 137. fig. 7. *Malus americana*; *Comm. hort.* 1. 129. tab. 67. *Tapia*. Plum. gen. amer. 22. tab. 21. *Mareg. Brasil.* 89. Pil. *Eraf.* 68. tab. 69.) "Leaflets egg-shaped, acuminate; petals ovate-roundish; germs globular." A large tree, from thirty to thirty-six feet high, covered with a dark green bark, divided near the top into numerous branches, which form a thick and spreading head. *Leaves* alternate, petioled, ternate; leaflets unequal, entire, smooth, and green on both sides. *Flowers* on long, alternate, smooth peduncles; forming a loose, spreading, terminal panicle; segments of the calyx egg-shaped, scarcely acute, much shorter than the corolla; petals roundish-egg-shaped, obtuse, spreading, all inclined to the same side; claws as long as the laminae; filaments twice the length of the petals; anthers purple; germ globular. *Fruit* the size of an orange, with a hard brown rind. *Seeds* kidney-shaped. A native of Jamaica, Brazil, &c. 2. *C. gynandra*. Linn. Sp. Pl. 1. Mart. 1. Poir. 3. Willd. 2. Brown. *Jam.* 246. (*Anona*; Sloan. *Cat.* 206. list. 2. 170. *Arbor americana*; Pluk. *Phyt.* 147. fig. 6.) "Leaflets membranous, egg-shaped, quite entire; petals lanceolate." A tree, twelve feet high and more, with spreading branches. *Leaves* alternate, on long petioles, ternate; leaflets petioled, acute, nerved, veined, very smooth, thin, deep green. *Flowers* numerous, in panicled racemes; peduncles simple, smooth, scattered; segments of the calyx egg-shaped, acute, spreading; petals sometimes four, but more frequently only two, whitish; filaments from twenty to twenty-four, longer than the petals, declining, green, tinged with purple; anthers dark purple; pedicel of the germ the length of the calyx. *Fruit* brown, spherical, having, like that of the preceding species, a smell of garlic. A native of Jamaica. Obs. Linnæus calls this species gynandrous, from a misconception of the nature of the pedicel of the germ, which cannot be considered as sustaining the office of a style; the stamens, therefore, are

by no means inserted on any part of the pistil; but, even if they were, the specific name would in this case be improper, all the other species having a similar character. The only difference is that some of them are inserted higher on the pedicel than the others. 3. *C. abbrevata*. Mart. 5. Poir. 2. Willd. 3. Vahl. *Symb.* 3. 61. "Leaflets and petals inversely egg-shaped; germ oblong." A tree with numerous smooth branches near the top. *Leaves* alternate, petioled, ternate; leaflets unequal, mucronate, smooth, veined underneath. *Flowers* in a spreading, terminal panicle; peduncles alternate, simple, long; segments of the calyx oblong; petals with long claws; filaments three times the length of the petals. A native of Madagascar. 4. *C. religiosa*. Mart. 4. Poir. 4. Willd. 4. Lam. *II.* Pl. 395. Forst. *Prod.* 203. plant. succ. 45. Vahl. *Symb.* 3. 62. Nürvaia; Rheed. *Mal.* 3. 49. tab. 42.) "Leaflets and petals lanceolate-elliptical, narrowed at both ends." A middle-sized tree. *Branches* spreading, smooth, olive-coloured, dotted with white. *Leaves* alternate, on long petioles, ternate; leaflets almost equal, on short petioles, smooth on both sides, netted with many nerves and veins, an inch long and more. *Flowers* greenish white, in a loose terminal panicle; peduncles long, cylindrical, simple, smooth; segments of the calyx small, egg-shaped; its base remaining on the pedicel of the fruit; petals narrow, much longer than the calyx; stamens twelve; filaments twice the length of the corolla or a little longer; pedicel of the germ longer than the stamens. *Fruit* globular, the size of a small plumb. A native of the East Indies and the Society Islands. In the latter it is planted in their burial-grounds, and is supposed to be sacred to their idols. The fruit is eaten by the natives. 5. *C. fragans*. Bot. *Mag.* 596. (*C. capparoides*; Bot. rep. 176.) "Stem twining; corolla regular; petals very long, undulated." *Stems* several, extending from 10 to 20 feet, with a multitude of branches. *Leaves* alternate, petioled, ternate; leaflets almost sessile, egg-shaped, entire, shining. *Flowers* in terminal clusters, on long peduncles, yellowish-green, very fragrant; segments of the calyx large, ovate-acuminate, concave, equal; petals very narrow; claws long; laminae undulated and convolute towards the base, regularly spreading; stamens numerous, longer than the calyx, shorter than the petals, attached to the pedicel of the germ near its base, incurved; stigma annular; pedicel of the germ longer than the stamens. A native of the island of Bananas, and of Sierra Leone in Africa; discovered by Dr. Afzelius, and raised in England from seeds sent by him to T. Evans, esq. of Stepney; but it has not yet ripened its fruit in this country. It is propagated easily by cuttings, but to thrive well requires more room for its roots than a pot. 6. *C. marmelos*. Linn. Sp. Pl. 3. Mart. 3. Poir. 5. Willd. 5. (*Cucurbitifera*; Pluk. *Alm.* 125. tab. 170. fig. 5. *Cydonia exotica*; Bauh. *Pin.* 425. *Bilanus*; Rumph. *Amb.* 1. 191. tab. 81. *Covalam*; Rheed. *Mal.* 3. 37. tab. 37. *Burm. Flor.* Ind. 109.) "Thorny; leaves serrated." A tall tree, with a large trunk; branches numerous, thick, cylindrical, smooth, leafy, armed between the leaves with divaricating pairs of long acute spines. *Leaves* alternate, petioled, ternate; leaflets oblong, acute, smooth on both sides; common petiole very long. *Flowers* green on the outside, whitish within, sweet-scented, six or seven together on a common branched peduncle, forming small terminal and lateral racemes. *Fruit* the size of an orange; containing, in a hard rind or shell, a thick, viscid, yellowish pulp, which has an agreeable flavour, and is frequently served up by the East Indians in their deserts, mixed with orange and sugar.

Obs.

Obs. Linnæus placed the last species under this genus, though he was aware that it does not correspond with his generic character, observing that it has a five-cleft calyx, sixty stamens, and no petals; but with respect to the last particular, he has since been found to have fallen into an error. Jussieu afterwards remarked, that it seems to have more affinity to his natural order aurantia than to his caparides, to which the other species of *crateva* properly belong. The well-known Dr. Correa has confirmed the suggestion of Jussieu; and in an excellent paper, inserted in the fifth volume of the Linnæan Transactions, p. 218, has established for it a new genus, which he has called *Aegle*, the name of one of the Hesperides. As this new genus has, through some oversight, been omitted by us in its proper place, we shall here give its natural character. *Cal.* Perianth one-leaved, small, five-lobed, falling off before the maturity of the fruit. *Cor.* Petals five, many times larger than the calyx, ovate-acute, spreading. *Stam.* Filaments very numerous, short, awl-shaped, inserted into the outer side of an elevated receptacle or hypogynous disk; anthers oblong, erect. *Pist.* Germ superior, egg-shaped; style short, thick; stigma oval; (according to Kœnig, marked with many obsolete furrows.) *Peric.* Berry globular-top-shaped, with a smooth pitted rind, which finally becomes woody; cells in Correa's specimen ten, surrounded with a spongy flesh, which, after the fruit ripens, soon disappears. *Seeds* numerous in each cell, egg-shaped, compressed, hairy, attached in a single series to a short, straight, umbilical cord. There are in the herbarium of sir Joseph Banks two seemingly distinct species of this genus, both arboreous, and both natives of the East Indies. The *crateva* balangas of Kœnig is considered by Dr. Correa as another distinct genus, which he has described under the name of *feronia*. See FERONIA.

CRATEVA foliis singularibus; BROWN. See CAPPARIS ferruginea.

CRATEVA, in *Gardening*, comprehends plants of the exotic tree kind for the stove; of which the sorts mostly cultivated are the smooth *crateva* or garlic pear (*C. tapia*), and the prickly *crateva* (*C. marmelos*).

Method of Culture.—These two plants are capable of being increased by sowing the seeds, which have been procured from the places where they grow naturally, as soon as they arrive, in pots of light rich earth, and plunging them immediately in the bark bed of the stove. The plants, after they have obtained the growth of about three inches, should be removed and placed out in separate pots, a very little water being given at the time, replunging them immediately in the hot bed.

The plants require afterwards to be kept constantly in this situation, and to have the care and management of other tender woody plants of the exotic kind, which have similar habits of growth.

CRATHES, in *Ancient Geography*, *Crati*, a small river of Italy, in Brutium. It commenced S.E. of Consentia, pursued a northern course to Caprafæ, whence it flowed by the north-east, and discharged itself into the gulf of Tarentum, near Sybaris. Strabo says, that the waters of this river gave a white colour to the hair of those who drank them; and they are said to have been useful in medicine. Herodotus and Pausanias inform us, that the river derived its name from Crathis of Achaia. Near its mouth was a temple of Minerva, surnamed *Crathian*. See CRATI.—Also, a river of Achaia, E. of Bura, which had its source in a mountain of the same name in Arcadia, near Cyllene, and ran from the S.W. to the N.E. into the gulf of Corinth. It received, in its course, the Alysson and the Styx.—Also, a river of Asia, in Cilicia.

CRATI, in *Geography*, a river of Naples, which, proceeding from the eastern vallies of the Sila, passes by the foot of the declivity on which Cosenza stands, and receives the waters of the Busifento; which torrent is remarkable for containing within its bosom the bones of Alaric, the mighty leader of the Visigoths. See CRATHIS.

CRATIA, in *Ancient Geography*, an episcopal city of Asia.

CRATICULA, a chemical instrument, made of square pieces of iron of about a finger's thickness, placed so as to have half a finger's space betwixt them. It is used in making of fires to keep up the coals.

The word is Latin, importing a roaster, or gridiron.

CRATICULAR ECTYPE and *PROTOTYPE*. See ANAMORPHOSIS.

CRATINOPOLIS, in *Ancient Geography*, an episcopal city of Africa, in Mauritania Cæsariensis.

CRATIPPUS, in *Biography*, a peripatetic philosopher, born at Mitylene, where he was brought up, and where for some time he was engaged in teaching others the tenets of the philosophy which he embraced. At Athens, whither he removed, he rose to great celebrity, and acquired the esteem and friendship of some of the most eminent men of his age. Cicero sent his son to be educated by Cratippus; and so highly did the orator think of his talents, that he took pains to obtain for him, of Cæsar, the freedom of Rome; and afterwards moved the Arcopagus to make a decree, to desire Cratippus to live at Athens, as an ornament of the city, and for the purpose of instructing the young. Pompey and Brutus were likewise among his admirers. The former, after the battle of Pharsalia, visited the philosopher, when their discourse turned upon the ways of Providence, which the warrior, depressed by his misfortunes, seemed willing to blame, but which Cratippus vindicated with manliness, but with a delicacy which the situation of Pompey seemed to require. Brutus attended the lectures of this wise man, when he was on the point of engaging in war with Marc Antony. These are the proofs mentioned by Bayle and others, to shew that Cratippus recommended himself to persons of consideration, not only by the extent of his learning, and the wisdom of his precepts, but by the agreeableness of his manners, and the pleasantry with which he enlivened the hours of social intercourse. By these qualities he is said to have attached the youth entrusted to his care to himself, and to the pursuits of literature. He wrote some treatises concerning divination, which were regarded as hypothetical and fanciful, rather than argumentative and philosophical. Tertullian is supposed to have referred to the works of Cratippus, when he is speaking of a treatise on dreams, ascribed to a person of that name. Bayle.

CRATIUM, in *Natural History*, a name given by Argenville to the *MYTILUS frons* of Gmelin.

CRATO, in *Geography*, a town of Portugal, in the province of Estramadura, surrounded with an ancient wall, and containing a church, hospital, and convent; 10 miles W. of Portalegre.

CRATON, also called *CRAFTHEIM*. JOHN, in *Biography*, was born at Breslaw in 1519. He received his first instruction under Philip Melancthon, and being intended for the church, he afterwards studied for six years under Martin Luther at Wittenburgh. Being more inclined to the practice of medicine, he was sent to Padua, and placed under professor Monti. He here took the degree of doctor, and returned and settled at Breslaw, whence, at the end of a few years, he was called to Vienna, and made physician and aulic counsellor to the emperor, Ferdinand I. He filled the same post under the two succeeding emperors, Maximilian and Rodolph,

dolph, which he notices in an epigram he composed a short time before his death :

“ Cæsarius placuisse tribus, non ultima laus est,
Me pater hac ornans, filius atque nepos.”

His works were numerous: the titles of the principal of them were, “ De Morbo Gallico Commentarius,” Franc. 1594, 8vo.; “ De vera præcavendi et curandi Febrem contagiosam pestilentem Ratione,” 1594; “ Methodus Therapeutica ex Galeni et Montani Sententia.” There were also published seven volumes in 8vo. of Epistles and Consultations. He died Nov. 9th, 1585. Haller Bib. Med. Eloy Dict. Hist.

CRATOWNESS, a cape on the E. coast of Scotland, in the county of Kincardine; 3 miles S. of Stonehaven.

CRAVALIDÆ, or CRAUGALIDÆ, in *Ancient Geography*, a small country of Greece, in the territory of Phœcia, near the town of Cyrrha. Suidas.

CRAVAN, in *Geography*, a small town of France, in the department of the Yonne, 12 miles S. of Auxerre, near the junction of the rivers Cure and Yonne, famous for a good sort of Burgundy wine.

CRAVANT, in *Ornithology*, a name by which Bellonius and some others have called the barnacle, a small species of wild goose, common in winter on the coasts of Lancashire, the *ANAS Bernicla* of Gmelin, and the *Brent-goose* of other writers. See *BARNACLE Goose*.

CRAVATES. See *CROATES*.

CRAU D'ARLES, LA, in *Geography*, is a considerable extent of very stony ground in the department of the Bouches du Rhône, in France, in the commune of Arles, which has lately been fertilized by a canal from the river Durance, called the canal of Craponne. The numerous flocks of sheep which are kept here leave this plain in summer, to feed on the high mountains of the neighbouring departments, for which reason they are called *bêtes à laine transhumantes*, wandering sheep.

CRAVEN, or CRAVENT, in *British Antiquity*, a term of reproach used in trials by battle.

The law was, that the victory should be proclaimed, and the vanquished acknowledge his fault, in the presence of the people, or pronounce the word *cravent* in the name of recreantice, or cowardice, &c. and, presently, judgment to be given; and the recreant *amittere legem terræ*, i. e. become infamous.

Coke observes, that if the appellant join battle, and cry *craven*, he is to lose *liberam legem*. If the appelled cry *craven*, he is to be hanged. See *Wager of BATTLE*, and *COMBAT*.

CRAVEN, in *Geography*, a county of America, in the state of N. Carolina, and district of Newbern, bounded N. by Pitt and S. by Carteret and Onslow counties. Its chief town is Newbern: it contains 10,469 inhabitants, of whom 3658 are slaves.

CRAVETTA, AIMONE, in *Biography*, an eminent lawyer in Piedmont, was born in 1504. When young he was of so delicate a constitution, that his parents had little hopes of rearing him; and in proportion to their great anxiety, they prevented him from pursuing his studies. Notwithstanding these disadvantages, he made so much proficiency as to be highly esteemed as a professor at the age of twenty; and in three years after, having received the title of doctor, he was sent as jurist to Curio, and thence he practised as advocate at Turin. Upon the breaking out of a war in Piedmont, he was imprisoned two years, and not allowed the use of his books. In 1558 he was successively professor of law at Grenoble and Lyons: at the latter city

he printed his “ Consultations.” He was also public teacher of his science at Avignon and Ferrara, and was invited to Pavia, and at length returned to Turin, where he obtained a stipend of 1200 crowns. In this city he died in 1569, highly respected for his talents and indefatigable application. Besides his “ Consultations,” he was author of a work on the subject of jurisprudence, entitled, “ *Traçtatus de Antiquitatibus Temporum*,” printed after his death in 1581.

CRAUGIÆ, in *Ancient Geography*, small islands on the coast of the Peloponnesus, near Cape Spiræa, according to Pliny.

CRAULA, or CRAULAU, in *Geography*, a small town of Germany, in the duchy of Saxe-Gotha, containing 117 houses, and 354 inhabitants, who are chiefly hop-planters.

CRAW, CROP, or *Ingluvies*, a part in granivorous fowls which serves for the immediate reception of the food; where it remains some time for maceration, before it be transmitted to the stomach.

This *ingluvies* is furnished with glands, which, the patrons of fermentation maintain, convey a menstruum thither, that impregnates the aliment, and serves instead of mastication.

CRAW, or *Cray Fish*, in *Ichthyology*, a species of the *Cancer*, the *cancer asclacus* of Linnæus. (See *CANCER fluviatilis*, under the genus *Asclacus*.) The flesh is good and nutritious, and has been recommended to persons under atrophies. There are various methods of preparing these animals: they may be either boiled or fried, and then taken out of their shells and made up in variety of dishes; but no parts of them are eatable except their claws and tail. Preparations and broths of *cray-fish* have been celebrated not only for a palatable aliment, but also for answering some medicinal intentions, as being of a moistening quality, and correcting acrimony. The broth is prepared of four or five *cray-fish*, which, having their heads cut off, and their intestines extracted, are to be bruised and boiled in the broth of flesh or poultry, until they become sufficiently red; after which the liquor is to be strained off and seasoned, as the case may require. This broth may be rendered still more medicinal by the addition of herbs, snails, or other substances; according to the intention of the physician. The flesh is counted best in the summer months.

The delicate flavour of these fish depends in a great measure on their food. When they have well-tasted food, their flesh preserves the relish of it; but when they feed on other things, they are often rendered of no value, by the flavour communicated to their flesh by them. There are great quantities of these fish in the river Obra, on the borders of Silesia; but the people find them scarcely eatable, because of a bitter aromatic flavour, very disagreeable in food. It has been since observed, that the *calamus aromaticus* grows in vast abundance on the banks of that river, and that these creatures feed very greedily upon its roots. These have a very remarkable bitterness mixed with their aromatic flavour, while fresh, which goes off very much in their drying; and on comparing the taste of these roots with that of the *cray-fish*, there remains no doubt of the one being owing to the other. Aët. Léipl. 1690.

They abound in the river Don in Muscovy, where they are laid in heaps to putrefy; after which the stones, called *crab's eyes*, are picked out.

These animals are very greedy of flesh, and flock in great numbers about earcases thrown into the water where they are, and never leave it while any remains. They also feed on dead frogs when they come in their way. James.

In Switzerland, there are some *cray-fish* which are red,
while

while they are alive, and others blueish. Some kinds of them also will never become red, even by boiling, but continue blackish.

The cray-fish discharges itself of its stomach, and as M. Geoffroy thinks, of its intestines too. These, as they putrefy and dissolve, serve for food to the animal; during the time of the re-formation, the old stomach seems to be the first food the new one digests. It is only at this time, that the stones are found called *CRAE'S eyes*; they begin to be formed when the old stomach is destroyed, and are afterwards wrapped up in the new one, where they decrease by degrees till they entirely disappear.

CRAWFORD, *New*, in *Geography*, a town of the island of Jamaica; about 16 miles N. of Kingston.

CRAWFORD, *Old*, a town of Jamaica, now deserted, about 13 miles N. of Kingston.

CRAWFORD, a town of America, in the state of Virginia; 5 miles N. of West Point.

CRAWINKEL, in ancient documents *Gravincella*, is a small town of Germany, in the duchy of Saxe-Gotha, near the forest of Thuringen. It has 209 houses, and 934 inhabitants, who derive their chief subsistence from burning charcoal, making lamp-black, and acting as waggoners.

CRAWLEY, or *HUSBORN-CRAWLEY*, a vicarage in Bedfordshire, in the hundred of Marhead. The southern parts of this parish are situated on the Woburn-sand stratum, and the remainder upon the Clunch clay stratum, which here crops from beneath the sand. The sand-hill on which the church stands has a layer of fuller's earth in it, beneath which some very large specimens of petrified wood were a few years ago dug out, that are in the possession of Richard Howe, esq. of Aspley, an adjoining village. The clay hill north of the church is occasioned by a considerable fault which crosses the parish in a north-east direction, with an extensive depression of the sand stratum to the south of it. The top of the clay above-mentioned, abounds with large and thick gryphites, or oyster-like shells, perforated by some other fish, at the time the fish were alive in these gryphites; very beautiful small cornua-ammoni in golden pyrites, are also found in this clay at the brick-kilns, and a stoney subitance, here called *CLUNCH*, see that article. In 1796, this parish was inclosed under an act of parliament, and a large heath was in consequence taken into the duke of Bedford's park, and cultivated, except the steep and most barren parts, which were planted. A very extensive peat bog, between the village, or Town-street, and the church, which had long exerted its deleterious influence on the health of the inhabitants; as a comparison of the proportions of births to burials in this parish and many adjoining villages proved; was effectually drained in consequence of the inclosure, under the directions of Mr. Farcy, the agent of the late duke of Bedford, and preparations were at the same time made for an extensive irrigation in this vale. The situation of Crawley iteple was ascertained in the government trigonometrical survey, by an observation from Bowbrick hill station, distant 15,998 feet, and bearing 65° 44' 61" south-west from the parallel to the meridian of Greenwich, and another from Trusser hill station, distant 8,867, whence was deduced its latitude 52° 0' 57" north, and its longitude 0° 36' 19".8, or 2^m 25'.3 west of Greenwich. A new barn and premises, erected on a hill in the new park, were also observed, and the centre of the front or south side was found to bear 53° 55' 2" south-west of the parallel above-mentioned, and to be distant 6023 feet from the centre of the iteple. A new and excellent turnpike road was, in 1796, made through this village, at the expence of the late duke of Bedford, in lieu of one which formerly went through his park; the cottages were, in general, re-

paired, and several new ones built; gardens were allotted to each of them, and as great an alteration made for the better, in the appearance and comforts of this village, as perhaps has any where else been witnessed.

CRAE, in *Ornithology*, a genus of the gallinaceous order. The bill is strong and thick, with the base of both mandibles covered with a cere; nostrils small, and placed in the middle of the cere; head crested with revolute feathers; tail large, straight, and expandible.—Curassow.

Species.

ALECTOR (*male*.) Cere yellow; body black; belly white; (*female*) red; head blueish; crest white, tipped with black. *CRESTED CURASSOW*.

Linnæus describes the male and female as two distinct species, the first under the name of *alector*, the other *rubra*. The male is about the size of a small turkey; the bill an inch and three quarters long, dusky, and covered from the middle with a skin which passes backwards round the eyes. The general plumage is deep black. The top of the head is elegantly crested with upright twisted feathers of a black colour, the longest of which are nearly three inches long, the others shorter; the lower part of the belly, vent, and thighs white; its tail is eleven inches long, and consists of fourteen feathers, which are a little rounded in shape, and of a black colour. The legs strong and dusky brown. This is the *Crax guianensis* of Brisson, *Mituporanga* of Ray, *Hocco de la Guiane* of Buffon, *Indian cock* of Pitfield, *Guiana peacock pheasant* of Bancroft, and *Crested Curassow* of Brown. The female is about the size of the male; the bill ash-coloured; irides red, and the head crested as in the other sex, the feathers white with black tips. The head, and hind part of the neck ash-coloured; fore part of the neck, and rest of the plumage red-brown; tail plain and dusky black; legs brown. This is called *Hocco de Perou* by Buffon, and is the *Red Peruvian hen* of Albin.

The crested Curassow is a native of the mountainous parts of Mexico and Peru, where, in their natural state, they feed on fruits, and roost in trees. They are remarkably docile, and have been cultivated, with much success, in the warmer parts of America, and the West Indian islands. At Guiana, where they constitute a principal article of food among the planters, these birds are known by the name of Powese, and they are also common in the (late) Dutch settlements of Berbice, Essequibo, and Demerara. At the Brasils it is known by the name of Curasso. The flesh is white, and well-flavoured. Some endeavours have been made to naturalize these birds in England, but the climate is neither sufficiently warm, nor dry enough for this purpose, and they are hence rather more likely to remain an ornament to our menageries, than become of permanent utility in our yards of poultry.

There are several interesting and beautiful varieties of this species, among which may be mentioned the *Crax Mitu* of Linnæus, which latter observation has proved to be only a variety of the *Alector*; it is the size of the others, and has the bill crooked, about an inch and a half in length, the upper chap four times as large as the lower, and of a flesh colour, with the tip whitish. Behind the ear is a white naked spot; and the head is crested with long feathers which may be elevated at the pleasure of the bird, into a conspicuous crest. The feathers on the head, neck, and breast are velvety; the rest of the plumage black, except the belly and under the tail, which are of a brown colour, almost like that of a partridge. Another variety *Hocco, Faisan de la Guiane* of Buffon, differs in having the tip of the tail white; and a fourth kind has the crest white tipped with black; neck barred with black and white; thighs brown; and vent white. Sometimes also, the tail is barred alternately

black and white. The above are varieties of the male bird; the females vary also very considerably. Some of the latter have the neck annulated with black and white; belly white; and tail brown: and others have the body barred with red-brown, and yellowish or cream colour. But one of the most elegant varieties is of a red brown colour, palest beneath: the bill yellow-ochre, with the tip brown: sides of the head covered with feathers, and black; crest white, and black at the tip; neck ringed, black and white; tail brown, crossed with nine yellowish-white bands, bounded on both sides with black; legs yellowish, with dusky claws.

GLOBICERA.—Yellow; gibbosity of the nostrils globular; body blackish-blue; lower part of the belly white.—*Crax Curassow*, Brisson, *Gallina Indica*, Aldrovandus, *Curassow bird*, Edwards, *Globose Curassow*, Latham.

This is the size of the last, and has the bill yellow with the tip cinereous, and at the top over the nostrils a round gibbosity somewhat resembling a cherry in its form, very hard, and of a fine yellow colour. The irides are red, and the space round the eyes white. The feathers on the head are long, and form a crest pointing forwards, the feathers are black with white tips, and rather inflected. The general colour of the plumage is black, except the lower part of the belly, vent, and space across the thighs, all which are white; legs pale ferruginous. The female has the head and hind part of the neck black; the crest black, with a white band. Some of the neck feathers have the tip white; the fore part of the neck, and breast, back and wings are dull brown; the upper part of the belly white, with some of the feathers tipped with black; lower part of the belly, vent, and thighs pale yellowish-brown; the tail crossed with four broad bands of white; the knob on the bill is yellow as in the male, and the bill is cinereous, but the legs are ash-coloured. This is a native of Guiana.

PAUXI. Cere blue; gibbosity of the nostrils crested; body blackish; belly and tip of the tail white.—*Crax Pauxi*, Linn. *Crax Mexicanus*, Brisson. *Pauxi*, Hernandez, *Hocco du Mexique*, Buff. *La Pierre de Cayenne*, Buff. *Cushew Curassow*, Edwards.

Size of the preceding, but of a more slender form. The bill is red, with a gibbosity at the base as large as a small pear, and not unlike it in form, very hard, and of a fine blue colour; the base of the mandible is also blue. The plumage is glossy blue-black, with a tinge of purple; lower part of the belly, under tail coverts, and tip of the tail, white; legs pale red; claws black. The female is distinguished by having those parts brown, which in the male are black. The species inhabits Mexico.

GALEATA. Crown horny; body black; vent white. *Le Hocco à tête calleuse*, Brisson. *Galeated Curassow*, Lath.

This is nearly as large as a turkey. The general colour black, except the vent, and under tail coverts, which are white; on the crown of the head is a horny substance about two inches in height, broad at bottom, and ending above in a blunt point, resembling altogether a kind of cone. The bill and legs are red. Inhabits Curassow.

VOCIFERANS. Brown; bill and breast blue; belly whitish.—*Penelope Vociferans*, Gmel. *Le Chacamel*, Buffon, *Chachalacamel*, Fernandez, *Crying Curassow*, Lath.

Described from an account given of it by Fernandez. It is the size of the common fowl; and is remarkably clamorous and noisy, whence the Mexican name *Chachalacamel*, or crying bird. This kind inhabits mountainous situations in South America.

CRAY, in *Geography*, a river of England, which runs into the Darent near Dartford, in Kent.

CRAYE, a river of Wales, which runs into the Ustk in Glamorganshire.

CRAYER, a kind of small sea-veffel or ship. It is mentioned in the Stat. 14 Car. II. c. 27. and in old records, *Et transitus craerarum & battellorum cum vicualibus & aliis necessariis, &c.* Parl. 6 Ric. II. Par. 2. M. 13.

CRAYER, DE, CASPAR, in *Biography*, a painter of some eminence, born in 1592. He was a native of Antwerp, and was the scholar of Raphael, the son of Michael Coxie of Brussels. He soon, however, surpassed his master, and, aided by the study of the best pictures, to which he could have access, acquired a skill, according to the opinion of his cotemporaries, only inferior to that of Rubens and Vanduyke.

Caspar was held in such esteem at Brussels, that the government proposed to confer upon him several offices and a pension, aiming thereby to prevent his quitting that city; but he declined the honours that were offered him, and afterwards resided at Antwerp, where he was visited by Rubens, who bestowed the highest encomiums on a picture (a large composition) which Caspar was then painting, of the Centurion alighting from his Horse to prostrate himself at the Feet of our Saviour. Sir Joshua Reynolds, however, does not seem to entertain so high an opinion of this artist's merit, as will appear from the following extract from his journey into Holland.

“Here is an immense picture of Gaspar de Crayer, mentioned not on account of its excellence in my own opinion, but from its being in such high estimation in this country, and it is certainly one of his largest works. Though it cannot be said to be defective in drawing or colouring, yet it is far from being a striking picture. There is no union between his figures and the ground; the outline is every where seen, which takes away the softness and richness of effect; the men are insipid characters, and the women want beauty. The composition is something on the plan of the great picture of Rubens in the St. Augustins at Antwerp: that is, the subject is of the same kind, but there is a great difference indeed in their degree of merit. The dead and cold effect of this picture, as well as many others of modern masters in this gallery, sets off those of Rubens to great advantage. It would be a profitable study for a young painter to look from those pictures to Rubens, and compare them again and again, till he has investigated and fixed in his mind the cause and principles of such brilliant effects in one instance, and of failure (when there is failure) in the other.”

Caspar, after having devoted a long life to retirement and the constant study of his profession, died in 1669. The following are amongst the principal pictures which he painted in the churches of Brussels and of Gand: A Resurrection, an Altar-piece in the church des Freres de la Charité in the latter town; another Altar-piece in the church of the Augustins, representing the crowning of several saints; and in the church of Notre Dame, behind the altar, an Ascension. Descamps.

CRAYFORD, in *Geography*, a rectory in Kent, in the lath of Sutton. The Darent and Cray rivers are navigable for barges, and the tide flows up to the calico-printing mills within a mile of this town. The church stands high on the top of the sand stratum covering the chalk, in a lifted or very dislocated part, a considerable thickness of gravel covers the loam on the top of this sand, to the westward of the church, extending towards the windmill on the common. A station was chosen in 1799 upon the top of this steep for the small instrument in the trigonometrical survey, its situation being determined by an observation from Severndroog tower, distant 26,479 feet, and bearing 80° 50' 1" N.W. from the parallel to the meridian of Greenwich, and another from Well-hill station, distant 37,840 feet, and bearing 9° 14' 45" S.W. from the said parallel; whence

whence is deduced its latitude $51^{\circ} 27' 17''.8$ N. and its longitude $0^{\circ} 10' 32''.2$ E. of Greenwich. This station was used with Ash steeple for determining the place of Dartford Brent mill, and Northfleet church; with Charlton farm station for Darent steeple; with Dartford Brent mill for Stone steeple; with Severndroog tower for Buxley spire; and with Well-hill station for Ash steeple, Charlton farm.

In the village of Crayford, formerly called "Creccanford," Hengist, two years after the death of his brother Horsa, A.D. 455, gained a great victory over the Britons under Vortimer, which gave him possession of all Kent, and emboldened him to assume the name of *king*, having before this event contented himself with the more humble title of "heretogen" or general. Thus was the first Saxon kingdom, that of Kent, founded, about eight years after the arrival of Hengist and his followers in this island. The river Cray, that passes through this village, serves to work a mill for slitting and rolling iron, and another for a cotton manufacture. Crayford is 2 miles W. of Dartford, and 13 E.S.E. of London.

CRAYON, a general name for all coloured stones, earths, or other minerals and substances, used in designing, or painting in pastel; whether they have been beaten and reduced to a paste, or are used in their primitive consistence, after sawing or cutting them into long narrow slips.

In this last manner are red crayons made, of blood-stone, or red chalk; black ones, of charcoal and black lead. The best charcoal is that of willow, on account of its softness. Crayons of all other colours are compositions of earths reduced to paste.

Good crayons for the purpose of drawing and painting are not easily procured. Those formed from red chalk, which are in common use, are almost always hard, gritty, and destitute of an uniform consistence. The only good crayons used in France are manufactured exclusively at Paris, where they are sold at a very high price: the best fort having been long known there by the name of the paste crayons of Desmarests, who seems to have been the inventor. Induced by these considerations, M. C. F. Lomet made a variety of experiments with a view of ascertaining the best combinations of various substances adapted to the fabrication of crayons; and the results that were satisfactory are here subjoined. These crayons are composed of the softer kind of ochre or redde, which is an oxyde of iron mixed with earth of an argillaceous nature, and called hematites or bog-ore. This must be incorporated with some agglutinating substance, such as gum, glue, or rosin, to which is sometimes added soap for softening the composition. Instead of redde, the other red oxydes of iron may be used, such as colethar of vitriol, &c.: but these should be chosen soft to the touch and of a lively colour; whereas those made for sale are often mixed with too much clay, which gives them a dull yellowish cast that ought to be avoided. The best redde, in lumps, should be selected, and ground with pure water on a marble slab, as is done in the preparation of colours for painting: moistening it with a little water, just sufficient to make the grinding stone slide. For preparing a large quantity, the redde must be pounded and sifted through a fine sieve, then diluted with a large quantity of water in a trough, where, after being well stirred, it should be left for a few minutes to settle, that the grosser particles may subside to the bottom. The water, strongly impregnated with the finer particles, must then be poured off, and allowed to settle for 24 hours: when the clear water has been poured off, a fine sediment will be obtained, which must be again pounded and washed. The process is repeated till the whole is reduced to the utmost fineness. The

gum, glue, or soap, necessary for giving to the crayons a due degree of solidity, must be separately dissolved. The solutions must then be carefully mixed with the pounded ochre or redde, and the water evaporated by exposure to the sun or the heat of a gentle fire, taking care frequently to turn the paste till it has acquired a consistence somewhat harder than butter; the crayons are then to be formed in the moulds, which may be done two ways: first, by spreading out the paste on a board, in which are cut grooves rather broader at the top and round at bottom, and of any length, size, and depth, according to the proposed bulk of the crayons; or otherwise, which is the better method, by forcing the paste through a pipe or funnel of an orifice equal to the size of the crayon. The paste thus formed may be left to dry in a cool place under the shade, in order to prevent cracks, which a more rapid desiccation would produce. When the rods are dry, they are to be cut into a proper length; and the edges should be taken off; after which they must receive the first cutting, in order to give them a blunt point. The last operation is that of scraping them, for the purpose of taking off the hard outward coat formed on the surface in drying, and which would prevent their making any marks. It may be necessary to rub a small portion of oil into the grooves of the wood, that the paste may not adhere too closely to the moulds. Gum arabic and isinglass are the two best substances for mixing with the powder. The gum and soap may be dissolved in cold water; but the isinglass must be cut in small pieces, put into hot water, and dissolved in Balneo Mariæ. These solutions should be well diluted with water, that they may be made to pass through a hair sieve in order to remove any foreign particles. As it is difficult to incorporate the paste with the isinglass, they must both be heated and mixed over a fire with a heat equal to that of boiling water. The paste should be well mixed before it is moulded. The best mode is to beat it with a pestle or mallet, and so pound it again for some time before it is put into the moulds. No soap must be employed but for those crayons in which gum is used. M. Lomet observes, that, as the crayons for which soap has been used are of a browner cast, it would appear that this combination abstracts the oxygen from a part of the red oxyde of iron, and gives it a brown tint by causing it to approach the state of martial æthiops. All the pastes prepared with oxyde of iron, even when pure water alone is used, become brown on the exterior surface as they dry; and still more sensibly when they are exposed to the action of the sun; which seems to arise from the light's abstracting a portion of the oxygen from the oxyde of iron.

The crayons, says our author, composed in this manner, have every good property that can be desired; they do not cost one-quarter of the common price; but it ought to be considered, that their composition requires great nicety in regard to the quantity of the materials, because the least variation occasions considerable difference in the quality of the paste. The best means to prevent waste, during the operation, will be to fix by experiments the quantity of water and of ingredients which the pounded redde and the solutions form before the mixtures are made. The following statements will serve this purpose. 1. Dry redde, or red oxyde of iron, 1 oz.; gum arabic dry, 18 grs. Crayons thus made are very friable, but they may be used for large designs. 2. Redde, &c. 1 oz.; gum 21 grains, will yield strong crayons, rather friable, but excellent for large drawings. 3. Redde, 1 oz.; gum 24 grains, or rather $25\frac{1}{2}$ gr., will give smooth and solid crayons, the best for common use. 4. Redde, 1 oz.; gum 27 gr. will produce soft firm crayons, fit for drawings which require delicacy and precision. 5. Redde 1 oz.; gum 30 gr., will yield very firm

crayons, fit for small drawings which are to be highly finished. 6. Reddie 1 oz.; gum 33 gr. will give very hard crayons, that cannot be used without some force. This is the greatest quantity of gum that can be employed in their composition; with more they would be useless. 7. Reddie 1 oz.; gum 22 gr.; white hard soap 30 grains. Crayons thus formed have a somewhat browner cast than the former. Their consistence is good, and they may be easily cut. All crayons with soap in their composition have this fault, that the strokes made by them have a shining appearance if the touches are repeated somewhat too strongly. These crayons perfectly resemble those of Desmarts. 8. Reddie, 1 oz.; singlass 56 grains, produce crayons of a brilliant colour, and excellent for use. With less singlass, they become brittle; with more, too hard. *Annal. de Chémie. No. 90. An. 7.*

CRAZE mill, or **CRAZING mill**, a mill in all respects like a grist-mill to grind corn, and is so called by the tinminers, who use it to grind their tin, which is yet too great, after trampling, and then it is trampled only.

CRAZEY, in *Agriculture*, a name not unfrequently applied in different districts to a weed in pasture lands, the (*Ranunculus repens*) or creeping crowfoot.

In the vale district of the county of Gloucester, it is, according to Mr. Marshall, a plant which is greatly esteemed as producing a valuable sort of pasture or herbage; while the common and bulbous species of it are considered as highly pernicious, particularly when made into hay. This distinction, he suggests, as doing the vale farmers of that district great credit, because it has been found by experience that these two latter species are extremely acid and noxious, having the tendency to produce an effect similar to that of caustic substances on the mouths of the animals which feed upon them; while the first species is perfectly mild and agreeable in its nature, so as to be highly beneficial to such cattle as feed upon it. This circumstance may lead the industrious and attentive farmer to extirpate the noxious species of this sort from his pastures, while he encourages the growth of the mild sort in them. See **CROWFOOT**.

CREALS, are a sort of jetties or weir-hedges, sometimes erected on the shores of rivers or the sea, for checking the force of the current or tide, in particular places, and occasioning a deposit of silt or mud, in place of a constant wear and encroachment of the water upon the land. *Smeaton's Reports, i. p. 4.*

CREAM, in *Rural Economy*, the name of the fat, oily, or unctuous fluid which rises on the surface of milk on standing, being specifically lighter than the other parts, and from which the well known article butter is made. See **BUTTER** and **DAIRYING**.

It is supposed by Dr. Anderson, that the separation of this oily fluid from milk takes place in consequence of an acid being formed, or that it is greatly promoted by it. Cream contains all the butter, some of the cheese, and also a portion of the other principles of the milk. Violent agitation converts the cream into thick froth; in which state it is called "whipped cream." The word is derived from *cremar*, which signifies the same; though in the lower Latin we find *crema lactis*.

A variety of elegant preparations, for the purpose of diet, are made from cream in other countries, especially in Germany; and in the northern part of this island a preparation is formed from it which affords an agreeable and nutritious article of food, and which is known under the title of *Corforth's Cream*, probably from the village of that name, where it is said to have been first made. It is usually sold through the streets of Edinburgh under the denomination of *sweet cream*.

The process by which it is prepared is this: a portion of skimmed milk, which has only acquired a moderately acid taste, is put into an upright wooden vessel, mostly the common upright churn, which being provided with spigot and fossat at the bottom, is placed in a tub of a sufficient size to hold it, when hot water is poured into the tub till it rises nearly to the height of the milk in the vessel which contains it. The whole is then covered with a cloth in order to preserve the heat. In a few hours the milk is found to be separated into two parts, the upper part having the consistence of thick cream, which has much the taste and appearance of good cream, being only moderately acid, while the other interior portion consists of a thin watery liquid, which is of a pungent acid taste, and is easily let off by means of the spigot. This fluid is then termed *coigg*. The cream is now fit for being made use of, and is scarcely capable of being distinguished from real cream. Its goodness, however, in a great measure depends upon the skill of the person who is employed in making it, as it is much affected by different circumstances of the process, as the degree of heat to which it is subjected, and the acidity of the milk. It is eaten in mixture with sugar as a great delicacy. The "clouted cream" of the west of England is well known.

CREAM of lime, is that matter which separates from lime-water by crystallization, during the evaporation of the water; forming on the surface a semi-transparent pellicle, which gradually thickens, till at length it subsides in the form of scales. This is a calcareous earth, which, having once lost its gas, fixed air, or carbonic acid, by calcination, is recombined with it after being dissolved in water, and exposed again to the air, and hereby becomes mild, crystallizable, unsoluble in water, and recovers its original state before calcination. See **LIME**.

CREAM of roses, a vegetable perfume, which M. Chaptal prepares by mixing equal parts of rose water, spirit of wine à la rose, and syrup of sugar; and colouring the mixture with the infusion of cochineal.

CREAM of lice, in *Rural Economy*, the name usually applied to a sort of wooden knife, twelve or fourteen inches in length, which is employed in removing the cream from the vessels in which it is contained.

CREAM of tartar, *cremor tartari*, is that part of the concrete acid of tartar which crystallizes first, and forms a pellicle on the surface of the water in which tartar has been boiled. This has been a general name comprehending this saline pellicle and the crystals of tartar.

The manufacture of this purified tartar has been chiefly carried on at Montpellier and at Venice. The following is the process at the former place, as it is stated by Chaptal. The tartar is dissolved in water, and suffered to crystallize by cooling. The crystals are then boiled in another vessel, with the addition of 5 or 6 pounds of the white argillaceous earth of Murviel to each quintal of the salt. After this boiling with the earth, a very white salt is obtained by evaporation, which is known by the name of cream of tartar, or acidulous tartrate of potash. M. Desmarts informs us, "*Journ. de Physique, 1771*, that the process used at Venice consists, 1st, in drying the tartar in iron boilers: 2. pounding it and dissolving it in hot water, which by cooling affords purer crystals: 3. redissolving these crystals in water, and clarifying the solution with whites of eggs and ashes. The process at Montpellier, says Chaptal (*El. Chem. vol. iii. p. 266*), is preferable to that at Venice; as the addition of the ashes introduces a foreign salt, which alters the purity of the product. The acidulous tartrate of potash crystallizes in tetrahedral prisms cut off slantwise. The salt is used by the dyers as a mordant; but its greatest consumption

sumption is in the north, where it is used at table as a feasoner. See TARTAR.

CRE'ANCE, in *Geography*, a small town of France, in the department of La Manche, 9 miles N.W. of Coutances. —Also, formerly a marquisate in the department of La Moselle, 7 miles E. of Metz.

CREANGE, or KRICHLINGEN, a town of Germany, in the circle of the Upper Rhine, and capital of a county; 38 miles W.S.W. of Deux Ponts.

CREASE-TYLES. See TYLE.

CREAT, in the *Mangee*, an usher to a riding master.

CREATION, in its strict and primary sense, denotes the causing of a substance or being to exist, which had no existence before; and, therefore, it implies no contradiction. That there is one underived and self-existing cause, from which all other beings derive their existence, and upon which they entirely depend, is a truth capable of incontestible demonstration. Consequently, all beings, except the first Cause, must have been produced, or brought into being, by the power and agency of the first Cause: not produced "out of nothing," as some have inaccurately expressed it, but out of nothing besides the immense and inconceivable fullness of the self-existent Being, who must have in himself the power and possibility of all being; though we cannot comprehend or conceive in what manner, or by what kind of agency, he creates or communicates existence to beings distinct from himself. The term *creation* is used, in a secondary and less proper sense, when any particular bodies are formed out of such a mass of matter as seems to be utterly unfit for that purpose; when such changes are made in any substance as are generally supposed to be above the power of creatures, and to belong to God alone:—thus God created fish and fowls out of the water, and man and beasts out of the earth; though the creation of the substance of water or earth, or the matter out of which they were made, is the original sense of the word. The Hebrew word, בְּרָא, (Gen. i. 1.) rendered *created*, has, it is said, chiefly on the authority of Maimonides, been considered as implying what theologians call "an absolute creation out of nothing." But this, it has been alleged, is not its appropriate meaning. It rather means to *fashion, form*, and *decorate* a matter already existing; and in this connection especially, it means to retrieve from a state of desolation, and to embellish this little spot of earth, so as to render it fit for its inhabitants. In this limited sense God is afterwards (ch. ii. 7.) said to have *created* man, not out of *nothing*, but out of the *dust* of the ground. Joshua (xviii. 15, 18.) bids the children of Joseph *create* to themselves a more ample possession, by cutting down the woods. Goliath (1 Sam. xvii. 8.) desires the Israelites to *create*, that is, *choose* or *prepare*, a proper champion to fight with him. In Numb. xvi. 30., 1 Kings xii. 33., and Nehem. vi. 8., it signifies to *devise*, as it is rendered in the cited passage of Kings; and the word *devise* would have been more proper in the other places. The word בְּרָא appears to have the same meaning, and, if etymology be regarded; to be the self-same word, with the Latin *parō*; and it is so rendered by Theodotus, ἑτοιμασθαι, Ezek. xxi. 19., and by the Chaldee Paraphrast, תַּתְקַן, Josh. xvii. 15.

Moses, in the *first* chapter of Genesis, has given us a summary account of the creation, at least of our earth, and its inhabitants; not, indeed, in a precise philosophical manner, but so as to give the men of the age in which he wrote just and affecting notions of this stupendous work of divine wisdom, power, and benevolence, so far as was necessary to the purposes of religion, and no further. It is sufficient, therefore, that his account is true, so far as it goes, and not in any respect inconsistent with the most accurate discoveries,

which have been made in later ages concerning the system of the universe, or any part of it.

In the beginning God created the heaven and the earth. (v. 1.) The *heaven* and the *earth* may comprehend either the whole universe, or all things visible and invisible. It does not therefore absolutely follow from this phraseology, that the whole universe was created all together at once, or at some one period of time: but the meaning of the expression may be, *at first*, referring to a prior epoch, or *originally*, when the universe was produced, it was brought into being by the sole power and wisdom of the almighty and eternal God. This is true, though the several parts of the universe may have been produced at different times, or at any distance of time from each other: and though God may be still creating new worlds in the immensity of space, which is not improbable, it is nevertheless true, that *in the beginning* of their existence, whenever that was, God created, and is still creating, them all. Thus, the sentiment which Moses seems to have been desirous of inculcating was, that the whole universe, whenever created, doth not exist by necessity or by chance; but had a beginning, and was created by the sole power of God. But as Moses here gives us a particular account of the formation of our earth, this phrase, *in the beginning*, may be understood proleptically with a reference to the six days' creation. Accordingly, the first thing which God did, in order to make the earth a suitable habitation for man, was to give to it and to the heavens the reciprocal appearances which they now have. Before that period, the earth was immersed in water, and covered with thick darkness, &c.: in a word, it was a chaos (see CHAOS); and with respect to it, the *heavens* existed not; that is, all those ethereal phenomena, which constitute what we call the *heavens*, were yet invisible. Such a change or revolution might justly be denominated a creation, according to the sense already given of the word בְּרָא. Upon the whole we may observe, that it seems to have been a current opinion among the ancient Jews and earliest Christians, that the world was created by God of pre-existing unshaped matter. The matter of which the earth was created, or rendered a habitable world, was "without form and void," (v. 2.) or a desolate waste, or in a state of desolation; that is, as some have supposed, a pre-existing earth reduced by some awful calamity to a chaotic state. (See CHAOS.) The earth was covered with deep water, and that water was covered with a thick darkness. But "the Spirit of God moved upon the face of the waters," *i. e.* the influences and exertions of the divine power actuated this dark confused mass, and digested and reduced its parts to the beautiful state and order in which we now behold them. Some have rendered רוח אלהים, a mighty wind, instead of the Spirit of God, which of course must be considered as the agent or instrument of divine operation. The first step in the recovery of the earth from its chaotic or desolate state, and the commencement of the six days' creation, was the production of light. This operation is expressed in the original with a beautiful conciseness and emphasis, אור היה-אור, which even Longinus has admired, and better rendered by Wielſſe than in our translation, "Be light; and light was." The light here mentioned, says a learned annotator (Dr. Geddes), may readily be conceived to have been a partial incipient light, which progressively penetrating the dense atmosphere that enveloped the sea-covered earth, so rarefied and expanded it in the course of three days, as to admit the clear and uninterrupted light of the celestial luminaries. The appearance of light three days before what some conceive to have been the creation of the sun has occasioned a difficulty, which indeed is not easily resolved upon this hypothesis. Some, as Dr. Taylor in his "Scripture

CREATION.

Divinity," and the author of "Nature Displayed," have adopted the notion that light is a distinct substance from every other, and that it exists independently of the sun and other luminous bodies; and that these serve merely to excite it. Light, say they, exists in a state of expansion or diffusion through the whole universe, and at all times, by night as well as by day; and that, in our system, the sun is the great exciter, by which the substance of light is impelled, and becomes visible: and they add, that if no substance of light previously existed through the whole system, no light would appear, though 10,000 suns should at once be placed in our hemisphere. Hence it is argued, that the element or substance of light was created on the first day, and that the divine power alone might be the exciter, which made the light appear for the three first days of creation, until the sun, the instrumental exciter, was produced. "God," says the author of "Nature Displayed," "and not the sun, was the author and parent of light, and it was created by his almighty fiat, before there was a sun to dart it over one part of the earth, and a moon to reflect it on the other." (See also Patrick on Gen. i. 3, &c.) But waving any remarks on this hypothesis, it is more reasonable to conceive, as others have done, that the light, which was made to appear on the first day, was nothing more nor less than an emanation from the same sun, previously existing, that still enlightens us; and which, though it had not yet appeared in its full glory, yet shed sufficient light through the dense atmosphere to make the surface of the terraqueous globe visible. This was evidently the idea of Origen, and probably of Basil also. The former affirms, that no one of a sane mind can imagine, that there was an evening and a morning, during the three first days, without a sun: the latter ascribes the darkness that covered the earth, before the appearance of light, to the interposition of a dense body.

In order to dispose of the waters, which still overspread the face of the earth, and farther to attenuate the ambient air, God said, on the *second day*, (v. 6.) *Let there be an expanse*, רָקִיעַ from רָקַע, the primary meaning of which is expansion, outstretching, attenuation, elasticity; which are the properties of our atmosphere. The word στεγνυμα, used by the Greek translators, and the long prevailing idea that the heavens were a solid body, led latter interpreters to render it by the word "firmament;" and this, as well as στεγνυμα, is admissible, if by solidity be meant no more than that the fluid atmosphere has density or consistence sufficient to sustain the waters above it. This is the sense in which St. Basil understood the Greek term, although he had not the Hebrew to direct him to it. In his homily on the six days, he calls it a childish idea to suppose any other solidity in the firmament than that of a dense fluid; and he very justly observes, that as such the scripture every where represents the lower region of the heavens. The effect of this expansion was the separation of a part of the waters from the great mass. The lighter particles were exhaled, rarefied, and carried up into clouds, and formed the element of air. The water contained in those clouds is called the waters above the expanse, in contradistinction to those which still remained upon the earth.

Having now a purer atmosphere and a clearer sky, it is farther necessary to remove the water that still drenched the earth, and rendered it unfit for production. The *3d day* was assigned to this operation. (v. 9—13.) The waters were caused to retire into their destined receptacles, and left a portion of the chaotic mass so dry as to be fit for vegetation. Accordingly, the earth was vested in verdure, and replenished with all sorts of herbs and trees; with inherent powers to re-produce themselves, and continue their propagation to the end of time.

The next operation was performed on the *4th day*, which some have supposed to have been the creation of the sun and the moon, and also the stars; but it is not necessary to infer from the history, that these did not exist at various intervals before this period. God said, as the historian proceeds with his detail, (v. 14—19), *Let there be lights* (or luminaries) in the expanse of the heavens to illuminate the earth, and to distinguish the day from the night; i. e. let these luminaries appear; or let the luminaries, which are in the expanse of the heavens, be for the purpose of illuminating the earth, &c. The sun and moon are equally called *great luminaries*, from their apparently equal size, and not from the degree of light which they give.

On the *5th day* God created all the fishes and inhabitants of the waters, and also the fowls of the air, (v. 20—23.)

On the *6th day* God made animals, according to their kinds; cattle, wild beasts, and reptiles; terminating his works of creation with the formation of man in his own image, whom he constituted sovereign of the earth, and whom he provided with a suitable companion. See ADAM and EVE.

Many absurdities have been charged, both by ancient and modern writers, upon the Mosaic account of the creation; some of which, we conceive, might have been precluded by restricting this account to the formation of the earth into a habitable globe, without extending it to the creation of the sun, moon, and stars, which are here mentioned merely as they bear relation to the earth, and serve for its accommodation. According to this interpretation, the operation of the 4th day was not the creation of the sun, moon, and stars, but that of assigning to them their appropriate use, with respect to the new-formed earth. The whole passage describing this operation may be read, from a collation of different copies, in the following manner, (v. 14—18.):—*"Let there be luminaries in the expanse of the heavens, to illuminate the earth, and to distinguish the day from the night; let them, also, be the signals of terms, times, and years."* And let them be for luminaries in the expanse of the heavens, to illuminate the earth, (conjectured to be an interpolation:) And so it was. For God having made the two great luminaries (the greater luminary for the regulation of the day, and the smaller luminary for the regulation of the night), and the stars; he displayed them in the expanse of the heavens to illuminate the earth, to regulate the day and the night, and to distinguish the light from the darkness." Dr. Geddes, in a note on v. 14, "let there be luminaries, &c." observes, that it is not necessary to suppose that these luminaries were now first created. The text does not say so; and there are many strong reasons for believing the contrary. The objection, that may seem to arise from v. 16, "God made two great lights, &c." in our version, has no force but what it derives from theological system, and an ignorance of the Hebrew idiom. To *make* is often equivalent to *appoint* to a certain use. The luminaries, then, may have long existed, and most probably did long exist before this period; although now, for the first time, they shone forth in their full splendour on this little world of man. The opinion above stated, was maintained not only by the most learned of the Jewish rabbins, but by the most learned of the Christian writers. Origen affirms, as we have already observed, that "no man of a sound mind can imagine, that there were an evening and a morning, during the first three days, without a sun." St. Basil ascribed the darkness that covered the earth, before the appearance of light, to the interposition of an opaque body between it and the heavens. In this simple hypothesis, the whole Hebrew cosmogony is clear and consistent. It is plain that the light, if it emanated from the sun, or were excited by the sun, could not, even imperfectly, illuminate

CREATION.

minate more than one half of the world at once; and that while that half was illuminated, the other would remain in darkness; and this is fitly called "separating the light from the darkness;" namely, by that ever-changing boundary the "horizon." But, in order to move this boundary, and to carry alternate light and darkness to every part of the globe, it was necessary either to make the sun revolve gradually round the earth, or the earth to turn gradually round its own supposed axis toward the sun; which latter motion we now know to be the fact. Light being thus separated from darkness by the aforesaid ideal boundary, they would follow one another without interruption, and produce successively those vicissitudes which we call "day" and "night;" two other terms, only, for "light" and "darkness;" and the former, being justly considered as the principal and most precious portion of time, an entire revolution of light and darkness was denominated "one day;" the "evening" being the term of "light," and the "morning" the term of "darkness."

By the "six days," in which the work of creation is said to have been performed, the generality of critics and commentators have understood, literally and strictly, so many days. Some by these days have understood as many years; some in order to favour a slow progressive creation, have made one day a period of 1000 years; and others, again, have thought the creation of the world to have been instantaneous, and that the number of days mentioned by Moses is intended only to assist our conception, who are best able to think of things in the order of succession. It has also been supposed, that the distribution of the work of creation into six days, followed by a day of rest, was designed to enforce the observance of a weekly sabbath, both as a day of religious worship, and as a day of solacing repose to the human, and even to the brute creation.

Many among the ancients and moderns have objected to a literal interpretation of the cosmogony of Moses. Whilst it has been a source of doubts and difficulties to the best commentators, it has furnished occasion of indecorous and misapplied raillery and ridicule to the enemies of revealed religion in all ages. Eusebius, by way of apology for the Mosaic account of the creation, says, (Præp. Evang. l. ii. 7.) "that it was not Moses's intention to give a philosophical account of the formation of the world, but to signify only, that it did not exist of itself, or by chance, but was the production of an all-wise and powerful creator." Cyril makes a similar reply to the scoffs of Julian, that Moses's view was to accommodate his story to the ignorance of the Jews; not to reason accurately on the origin of things, but to shew that there was one God, who created them all." (Julian, Oper. and Cyril Contr. vol. ii. l. 3. p. 50, &c. Ed. Lips.) Philo, (Cosmog. l. i. tom. i. p. 123.) calls it a "piece of rustic simplicity to imagine, that God really employed the labour of six days in the production of things; in which he is followed by Origen, Austin, Ambrose, &c. Accordingly, several ancient writers have adopted an allegorical interpretation. Josephus, in the first chapter of his "Jewish Antiquities," intimates "that the story of the creation was of the allegoric kind." Philo is evidently of the same opinion. Among the moderns, and especially among those who have been referred to the class of sceptical writers, the same allegorical interpretation has been generally adopted. See Blunt's "Oracles of Reason;" Toland's "Pantheisticon," and "Letters to Serena;" Burnet's "Archæologia (l. ii. c. 8, 9.);" Middleton's "Essay on the allegorical and literal Interpretation of the Creation and Fall of Man," in his "Works," vol. ii. p. 123—126. and his "Examination of Sherlock's Discourse on Prophecy," in his "Works," vol. iii. p. 192,

&c. Dr. Burnet, in particular, maintains, that the Mosaic account was merely a *fable*, though, according to his representation of it, a fable too absurd for a wise man, and much more for an inspired person to have formed. But surely there can be no reason for admitting this hypothesis, if the literal interpretation be capable of a philosophical explanation; more especially as Moses does not inform us where his fable ends, and where his true history begins, and as Christ and his apostles refer to the story of the creation and that of the fall (see FALL), inseparably connected with it, not as an *allegory*, but *true history*, 2 Cor. iv. 6. xi. 3. 1 Cor. xv. 45. Matt. xix. 4, 5. 1 Tim. ii. 13, 14. 1 Cor. xi. 9. Besides, it is not very natural to suppose that God would so solemnly, from mount Sinai, make the circumstance of a fable the foundation of the fourth commandment. Exod. xx. 11. Heb. iv. 3, 4.

A late biblical critic (see Dr. Geddes's *Critical Remarks*, vol. 1.), rejects both the literal narration and the pure allegory, and alleges that the Mosaic account is a most beautiful *mythos*, or philosophical fiction, contrived with great wisdom, dressed up in the garb of real history, adapted to the shallow intellects of a rude barbarous nation, and perfectly well calculated for the great and good purposes for which it was contrived; namely, to establish the belief of one supreme God and Creator, in opposition to the various and wild systems of idolatry which then prevailed; and to enforce the observance of a periodical day to be chiefly devoted to the service of that creator, and the solacing repose of his creatures. In fact, says this writer, what stronger motive could be urged to preserve a people from idolatry, than by shewing, in so minute a detail, that all the worship-objects of the surrounding nations were themselves but mere creatures, the great celestial luminaries (most probably the first objects of adoration) not excepted? He had, no doubt, particularly in view the idolatry of Egypt; where, as Bossuet elegantly says, "Tout étoit Dieu, excepté Dieu même; et cette Terre, qu'il avoit fait, pour y manifester sa gloire, sembloit être devenue un temple d'Idoles." (Disc. sur l'Hist. Univ.) Beside the sun, moon, and stars, they adored the fishes of the sea, the birds of the air, the animals of the earth, and even the herbs of the field, radishes, leeks, and onions.

• O sanctas gentes! quibus hæc nascuntur in hortis
Numina!"

It was then of the utmost importance to persuade the Israelites, who had, during their stay in Egypt, been more or less contaminated by those idolatrous rites, that every plant of the field, fish of the sea, bird of the air, and beast of the earth; the whole visible world, in short, was the production of a superior BEING, to whom alone divine worship could be due. In particularising the greater quadrupeds הבהמה, and the great sea-monsters, תנין, it is supposed that he alluded in the former, to the worship of Apis in the form of a bull, and in the latter to the crocodile, which, in some parts of Egypt, was held in the greatest veneration. The hypothesis, says Dr. Geddes, of a mere poetical mythos, historically adapted to the senses and intellects of a rude unphilosophical people, will remove every obstacle, obviate every objection, and repel every sarcasm; whether it come from a Celsus or Porphyry, a Julian or a Frederic, a Boulanger or a Bolingbroke. See *Theory of the EARTH, FALL of Man, and GENESIS.*

CREATION, *Epocha of.* See EPOCHA.

CREATION, in a figurative sense, is used to denote a change of character and state. Thus the Jews, whom God by his providence rescued from the most abject slavery, and advanced to a new and happy state of being, attended with distinguishing

distinguishing privileges, enjoyments, and marks of honour, are said to have been created, made, formed, and begotten. If. xliii. 1. 7. 15. 21. xlv. 1. 2. 21. 24. In consequence of this creation, they received a being or existence. If. lxiii. 10. 1 Cor. i. 28. Thus also, when G d formed believing Jews and Gentiles into one body, and brought the Gentiles out of darkness and idolatry into a new and happy state of existence, he is said to create and make them, and they are his work and workmanship. Eph. ii. 10 15. Col. iii. 10. Jam. i. 18. And as God hath created us Christians, and made us to live, we have received a new existence. 1 Cor. i. 20. 2 Cor. v. 17. Accordingly, the new state of life into which Christians are brought under the gospel, by its doctrines and motives, and the agency of a divine spirit, is called the new creation in Christ Jesus. Many passages might be cited, in order to shew that the term creation is applied, in a moral or spiritual sense, to a change of principles, character, and state. As ignorance, vice, and guilt are, if we may so express it, the chaos of an intelligent, moral, accountable, and immortal being, a recovery from this state to knowledge, holiness, pardon, and hope, may be fitly denominated a new creation. And as God is the primary cause of this change, and we are the subjects of it, he is our creator, and we are his creatures. Christianity, the appointed means and powerful instrument of producing it, is, in reference to its effects, a new creation.

CREBILLON, PROSPER JOLYOT DE, in *Biography*, a celebrated French tragic poet, was born at Dijon the 15th of February, 1674, educated at the College Mazarin in Paris, and brought up for the bar. The lawyer, with whom he was placed for that purpose, observing the impetuosity of his passions, urged him to attempt dramatic compositions. His two first tragedies were "Idomenée," and "Atrée." Both met with great success. In the midst of his triumphant career as a dramatic poet, he married an apothecary's daughter, against the consent of his father, who disinherited him; but re-established him in his rights a short time before his death, which happened in 1707. Crebillon, however, was not benefited by this circumstance; the fortune of his father being hardly able to pay his debts. A few years after, the death of his wife added to the troubles of the poet, who continued involved in distress, until he obtained the employment of censor of the police, and, in 1731, a place in the French academy. The speech which he delivered at his reception was in verse.

Crebillon's manner of life was extremely singular. He slept little, and lay very hard: he was always surrounded with about thirty dogs and cats; and used to smoke tobacco, to keep his room sweet against their exhalations. He made a jest of physic and physicians; and was for a long time afflicted with the erysipelas in his legs, which brought him at last to his grave, on the 17th of June, 1762, when he was 88 years old.

Crebillon was of a cheerful temper. Being one day asked, in a large company, which of his works he thought the best? "I don't know," answered he, "which is my best production; but this (pointing to his son, who was present) is certainly my worst."—"It is," replied the son, with vivacity, "because no Carthusian had a hand in it:" alluding to the report, that the best passages in his father's tragedies had been written by a Carthusian friar, who was his friend. Terror is the predominant character of Crebillon's tragedies. Being asked for the reason of this peculiarity, he replied, "I had no choice: Corneille has exhausted heaven; Racine, the earth; I had nothing left but hell, and I have thrown myself headlong into it." His "Atrée" was performed eighteen nights running. An Englishman, who was at its first representation, observed that this tragedy was

better calculated for the London than for the Paris stage; and that, although an Englishman, he had shuddered with horror at the cup-full of blood. "Electre" had less success; "Rhadamille," in 1711, was performed thirty times, and ran through two editions in a week; "Xerxes," in 1714, had but two representations; "Semiramis," in 1717, was much criticised; "Pyrrhus" had some success when it came out, but failed when it was again performed in 1778; "Catilina" was performed in 1749, when Crebillon was 72 years old: and he wrote the "Triumvirate," his last tragedy, when he was 80 years of age.

Crebillon's style is unequal and incorrect: he has been much criticised on that account by Boileau, who witnessed his first successes, and by Voltaire, to whom he was opposed as a rival for dramatic fame. In order to remove Voltaire from court, Crebillon was recommended as a superior poet to Madame de Pompadour. Hearing that he was poor, this lady obtained for him a pension of 2400 French livres. When Crebillon went to thank his patroness, she received him uncommonly well, being struck with his venerable and interesting figure; but she was in bed, and at the instant the old poet was kissing her hand, the king entered the room. "Alas! Madame!" exclaimed Crebillon, "the king has surprised us: I am undone." This exclamation, from the mouth of an old man of 80, diverted Louis XV. exceedingly. The monarch zealously patronized Crebillon ever since, got his works printed at the press of the Louvre, and, after his death, erected a marble monument to his memory in the church of St. Gervais, where his remains are interred.

The best editions of Crebillon, besides that of the Louvre, in 2 vols. 4to., are that of 1759, in 2 vols. 12mo.; that of 1772, in 3 very neat volumes, small 12mo.; that of 1785, in 3 vols., 8vo., with cuts; and the last Paris edition by Desray, published a few years ago.

Laharpe, in his "Cours de Littérature," pronounces that Crebillon, though a bad writer, will maintain his station among men of genius, but cannot be ranked in the class of masters and models. Marmontel calls his verses *après et durs*, stiff and harsh. Nouveau Dictionnaire Historique. Mémoires de Marmontel.

CREBILLON, CLAUDE PROSPER JOLYOT DE, son of the poet, was born at Paris on the 12th of February, 1707, and died on the 12th of April, 1777, at the age of 70. If his father has sometimes been called the Æschylus of the French, he may be denominated their Petronius. With a masterly hand he has delineated in his novels the vices, follies, and levity of the French. His style is rather defective; but his works betray an intimate knowledge of the most hidden recesses of the human heart. He lived with his father as with a friend and brother. His marriage with an English woman, of which the poet disapproved, caused but a very slight alteration between them.

The principal works of Crebillon the Younger are, "Tangai & Néadarné;" "Les Egaremens du Coeur et de l'Esprit;" "Le Sopha;" and "Les Lettres Athéniennes." A complete edition of them has been published in 1779, in 11 vols., 12mo. Nouveau Dictionnaire Historique.

CRECCA, in *Ornithology*, the ANAS crecca, with a green spot on the wings, and a white line above and below the eyes; the common teal of English writers. See ANAS and TEAL.

CRECCHIO, in *Geography*, a town of Naples, in the province of Abruzzo Citra; 10 miles E. of Civita di Chieti.

CRECY, or, as it is improperly spelled in English, *Cressy*, a small town of France, in the department of the Somme, 36 miles N.W. of Amiens, and 120 N. of Paris, chief place of a canton, in the district of Abbeville, with 1378 inhabitants.

habitants. The canton has 25 communes, and a population of 12,317 individuals, upon a territorial extent of 217 kilometres and a half. There was anciently near this place a royal seat, called *Crécy en Pontbieu*, *Crethiacum in Pontivo*, famous for the battle which was fought here, in 1346, between Philippe de Valois, king of France, and Edward, king of England.

The king of France, hearing that Edward had made a stand at this place, and dreading nothing so much as the escape of the English, began the march of his great army from Abbeville early in the morning of the 26th of August, and continued it for several hours with great eagerness; but was advised not to engage, on account of the fatigue of his troops. His orders for halting were, however, not obeyed. Edward had employed the forenoon in drawing up his army in three lines. The first, which consisted of 800 men at arms, 4000 English archers, and 600 Welsh foot, was commanded by his heroic son, the prince of Wales, assisted by the earls of Warwick and Oxford; the second line, composed of 800 men at arms, 4000 halbardiers, and 2400 archers, was led by the earls of Arundel and Northampton; the last line, or body of reserve, in which were 700 men at arms, 5300 billmen, and 6000 archers, was ranged along the summit of the hill, and conducted by the English king in person. When the army was completely formed, Edward rode along the lines, and by his words and looks inspired his troops with the strongest hopes of victory. He then commanded the cavalry to dismount, and the whole army to sit down upon the grass in their ranks, and refresh themselves. As soon as the French army came in view, they sprang from the ground, ready to receive them.

The king of France, assisted by the kings of Bohemia and Majorca, the dukes of Lorraine and Savoy, and several other sovereign princes, with the flower of the French nobility, laboured to restore some degree of order to his large army, and drew it up also in three lines, but very indistinctly formed. The first line was commanded in chief by the king of Bohemia; the second by the earl of Alençon, brother to the king of France; and the third by the king in person. Each of these lines contained a greater number of troops than the whole English army.

The battle was begun about 3 o'clock in the afternoon by a body of Genoese cross-bowmen in the French service, who, letting their weapons fly at too great a distance, were presently routed by a shower of arrows from the English archers. The earl of Alençon, after trampling to death many of the flying Genoese, made a furious attack on the corps commanded by the prince of Wales. The earls of Arundel and Northampton advanced with the second line to sustain the prince. The battle raged for some time with uncommon fury. Anxious for the safety of the prince, the earl of Warwick sent to intreat the king to advance with the third line. But Edward, who had taken his stand on the top of the hill, from whence he had a full view of both armies, asked the messenger whether his son was unhorsed, wounded, or killed; and being answered that he was unhurt, and performed prodigies of valour: "Go, then," said the king, "and tell my son and his brave companions, that I will not deprive them of any part of the glory of their victory." This flattering message inspired the prince and his troops with redoubled ardour. The king of Bohemia, the earl of Alençon, and many other noblemen, being slain, the whole first and second line of the French were put to the flight. Undismayed at the slaughter of his troops, and at the fall of so many princes, the French king advanced to the charge with the line under his immediate command. But it soon shared the same fate with the other two.

VOL. X.

Philippe, unhorsed and wounded, was carried off the field by John de Hainault. Of his mighty army, which at the commencement of the battle consisted of 120,000 men, only five knights and about 60 soldiers fled with him. Such was the celebrated victory of Crécy, the greatest ever gained by any king of England. Henry's History of England.—There is another Crécy, a small town of France, in the department of Seine and Marne, in the district of Meaux, with 1007 inhabitants. It is situated 3 miles S. of Meaux, and is the chief place of a canton, which, upon a territorial extent of 145 kilometres, has 23 communes and 12,725 inhabitants.

CRÉCY *sur Serre*, a small town of France, in the department of Aisne, on the river Serre, which flows into the Oise, 9 miles N.W. of Laon, and 15 miles S. of Guise. It is the chief place of a canton, in the district of Laon. Its population amounts to 1862 individuals. The canton itself has 22 communes, 10,695 inhabitants, and a territorial extent of 167 kilometres and a half.

CRE DAN HEAD, a cape of Ireland, on the west coast of Waterford harbour. W. long. 6° 59'. N. lat. 52° 10'.

CREDDY, a river of England, which runs into the Ex, near Exeter.

CREDENCE TABLE, from *Credentia*, low Latin, "Tabula seu mensa in qua vasa ad convivia reponuntur," Du Cange; a small table placed on the right hand side of the high altar, in Roman Catholic churches, for the purpose of holding several articles made use of in the service of the mass. *Cæremoniale Episcop. lib. i. cap. 12.*

CREDENTIALS, letters of credit and recommendation; especially such as are given to ambassadors, plenipotentiaries, &c. sent to foreign courts.

CREDI, DI, LORENZO, in *Biography*, a Florentine painter, born in 1452. His family name was *Sciarpelloni*; but being placed, when young, under a goldsmith called Credi, he assumed that name, according to the ancient Florentine custom. He afterwards entered the study of And. Verrochio, and, with the exception of his disciple, the celebrated Lionardo da Vinci, may be considered the best scholar of that master. His works were designed with great diligence, and painted with a delicacy and neatness which are peculiar to him; inasmuch that his picture of the S. S. Nicolo and Giuliano, in the church of Sta. Maria Maddalene at Florence, is adduced by Vafari as an example of clear and beautiful execution. He sometimes is said to have copied the works of Lionardo with such wonderful exactness, that the original could not be distinguished from the imitation. His style appears to unite something of the early manner of Da Vinci with that of Pietro Perugino, the other friend of Credi; but he never attained the boldness and breadth of chiaro-scuro which characterized the works of Lionardo, although he continued to live many years after the decease of that great artist. His most celebrated picture is the Nativity, in the church of St. Chiara at Florence. Several circular pictures of the Holy Family, by this artist, are dispersed in that city, which unite a considerable portion of grace to some originality of design. He died in 1530. Lanzi. Orlandi.

CREDIBILITY, a quality in objects whereby they become fit to be believed. See FAITH.

A thing is said to be credible, which is not apparent of itself, nor is certainly to be inferred either from the cause or effect: and yet has the attestation of a truth. Things which appear immediately true, as the whiteness of snow, or that the whole is equal to its parts; are not said to be credible, but evident. Those to which we only give our assent in virtue of some competent authority or testimony

of others, are, by the schoolmen, said to be credible. In the Philosophical Transactions we have a mathematical computation of the credibility of human testimony. See EVIDENCE.

CREDIT, in *Commerces*, a mutual trust or loan of merchandize or money, on the reputation of the probity and solvability of a dealer.

Credit is either *public* or *private*; the latter being that of individuals, and the former belonging to individuals connected by social intercourse, and forming communities or nations.

Every trader ought to have some estate, stock, or portion of his own, sufficient to carry on the traffic he is engaged in: they should also keep their dealings within the extent of their capital, so that no disappointment in their returns may incapacitate them from supporting their credit. Yet traders of worth and judgment may sometimes lie under the necessity of borrowing money for carrying on their business to the best advantage; but then the borrower ought to be so just to his own reputation and to his creditors, as to be well assured that he has sufficient effects within his power, to pay off his obligations in due time. But if a trader should borrow money to the extent of his credit, and launch out into trade, so as to employ it with the same freedom as if it was his own proper stock; such a way of management is very precarious, and may be attended with dangerous consequences. Merchants ought never to purchase their goods for exportation upon long credit, with intent to discharge the debt by the return of the same goods; for this has an injurious influence on trade several ways: and if any merchant has occasion to make use of his credit, it should always be for the borrowing of money, but never for the buying of goods; nor is the large credit given to wholesale traders, a prudential or justifiable practice in trade.

The public credit of a nation is said to run high, when the commodities of that nation find a ready vent, are sold at a good price, and when dealers may be safely trusted with them: also when lands and houses find ready purchasers; when money may be easily obtained for commercial purposes, the promotion of important objects of a national kind, or the service of the state; and when it may be borrowed either at a low interest or without difficulty on higher terms; when people think it safe and advantageous to venture large stocks in trade: and when notes, mortgages, &c. will pass for money. See BANK and PAPER MONEY.

CREDIT, *letters of*, are those given to persons in whom a merchant, &c. can trust, to take money of his correspondent abroad, in case they happen to need it.

CREDIT is also used for the currency which paper, or bills, have with the public, or among dealers.

In this sense, credit is said to rise, when in negotiating the shares of a company, they are received and sold at prices above *par*, or the standard of their first creation.

Discredit is opposed to credit, and is used where money, bills, &c. fall below *par*. These terms, however, are used in a more lax sense, when they are applied to the rise or fall of the shares or stocks of any public company, whether they were at, above, or below *par*. The gage of public credit in England was formerly the rise and fall of its public or national funds; but since the plan of annexing to any capital borrowed and funded, a certain sum designed to form a sinking fund for liquidating or reducing it, has been adopted by modern policy, and the gradual increase of this fund is regularly applied to the purchase of floating stock, the funds admit of very little advancement or de-

pression; and of course they are a less decisive criterion of the state of public credit. See NATIONAL DEBT and FUND.

CREDIT was also anciently a right which lords had over their vassals; consisting in this, that during a certain time they might oblige them to lend them money.

CREDITON, commonly called KIRTON, in *Geography*, is an ancient and populous town in Devonshire, England, situated near the river Creedy, between two hills; one of which rises gradually towards the north, the other, with a quicker ascent southward, overlooks the tops of the houses. The town is divided into two parts, distinguished by the appellations of the East Town and the West; the latter was formerly of much greater extent than at present, upwards of 450 houses having been consumed by fire in the year 1743; and when in some degree restored, many of the new buildings, with the market house and shambles, were again destroyed by a second fire in 1769, but have since been rebuilt in a handsome manner. Crediton was probably of considerable note in the Saxon times; twelve bishops having successively their seats here between the years 924 and 1049, when the see was removed to Exeter. The old church or cathedral was situated, according to Ireland, on the spot which is now occupied by houses on the side of the burial ground; but no part of it is now remaining.

From the time of the removal of the see, there continued a chapter, under the peculiar patronage and jurisdiction of the bishops of Exeter. After the dissolution, the site of the college was granted by Henry VIII. to Elizabeth countess of Bute and sir Thomas d'Arcy; but the church with its appropriate lands was given by Edward VI. to the master and governors of the free grammar school, which about that time was established in this town. The present church is a very spacious structure, built in the form of a cross, with a tower rising at the intersection of the nave and transept, and supported by four pillars of uncommon magnitude. The interior displays particular neatness, being furnished with a raised floor, and covered with pews of the best wainscot. The east and west windows are very large, and are adorned with rich tracery. Besides the grammar school above-mentioned, here are a free English school, a charity school, and two Sunday schools. Crediton is 180 miles W. from London; contains 1503 houses, and 4929 inhabitants: many of whom derive their support from the manufacture of serges, which is carried on here to a considerable extent. There are three annual fairs; and a weekly market on Saturdays where vast quantities of wool, yarn, and all kinds of provisions are sold. The town is governed by a Portreve; and was once represented in parliament, 35 Edward I.

A degree of celebrity attached to it, as being the birth place of Winiford, surnamed Boniface, archbishop of Mentz, who flourished in the 8th century. "History, &c. of Devonshire, by R. Polwhele," fo.

CREDITOR, a person to whom any sum of money is due, either by obligation, promise, or otherwise.

The laws of the Twelve Tables, which were the foundation of the Roman jurisprudence, allowed the creditor to tear or cut his debtor to pieces, in case he proved insolvent. See BANKRUPT.

CREDITOR, in *Book keeping*. See BOOK-KEEPING.

CREDO, *the grand*, in *Geography*, is the name given to the southern part of Mont blanc, between Gex and Bourg, in the department of the Ain.

CREDULITY denotes a weakness of mind, by reason of which a person yields his assent to propositions or facts, before he has considered their evidence. See EVIDENCE.

CRÉE, in *Geography*, a river of Scotland, which rises

rises in the S.E. part of Ayrshire, separates Kircudbright from Wigtownshire, and discharges itself into Wigtown bay. There is a small village on the E. side of Wigtown bay, near the mouth of the river Cree, which is navigable some miles higher to Carty port, near Newton-stewart, a considerable village, pleasantly situated in a fertile country, abounding with all the real necessaries of life, particularly extensive woods of full-grown trees, which overhang the banks of the Cree, and the waters which fall into it from the North.

CREE Indians, Indians of North America, who occupy the district W. of little lake Winnipeg, and fort Dauphin, in upper Canada.

CREECH, THOMAS, in *Biography*, chiefly celebrated for his poetical translations, was born in 1659 at Blandford in Dorsetshire. He was inducted into grammar learning at the free-school of Sherborne, and from thence he went to Wadham college, Oxford. In 1683 he took his degree of M.A., but he had already published his translation of Lucretius, by which he established his reputation as a scholar; and on account of which he was probably elected probationer-fellow of All-souls college. Creech translated many other pieces from the ancient writers; as parts of Ovid and Virgil; the greater portion of Horace, one of Juvenal's satires, and the Idylliums of Theocritus. This last he dedicated to his old master who had instructed him in the knowledge of the languages. In the year 1699 he was presented to the rectory of Welwyn in Hertfordshire, but put an end to his life before he took possession of it. It is not perfectly ascertained what led to this fatal catastrophe; some have thought it the effect of disappointed love, but others with more reason imputed it to certain pecuniary embarrassments, and the cold reception which he met with from a friend to whom he applied for assistance. He was found hanging in his study three days probably after he had committed the rash action. He is said to have been of a very morose temper, which engaged him in many disputes. *Biog. Brit.*

CREECH-Hill, in *Geography*, a remarkable eminence in the island of Purbeck in Dorsetshire. In the government trigonometrical survey in 1794 the situation of the ancient barrow on this hill was determined, by an observation from Nine Barrow down, distant 24,163 feet and bearing 83° 0' 57" S.E. from the parallel to the meridian of Dunnose, and another from Wingreen, distant 125,534 feet; whence is deduced its latitude 50° 38' 1".7 N., and its longitude 2° 6' 14".9, or 8" 25' W. of Greenwich.

CREED, CREDO, a short or summary account of the chief articles of the Christian faith; thus called from the first word thereof in Latin, *credo, I believe*. See *SYMBOL*.

The principal of these creeds are the *Apostles'*, the *Athanasian*, and the *Nicene*.

CREED, Apostles', is so called, because for many ages it was believed to have been framed by the apostles before they left Jerusalem. The first person who gave this account of its original was St. Ambrose, towards the latter end of the fourth century; in which he is followed by Rufinus, Jerom, and several others; and some have even asserted, that each apostle supplied his particular article; and according to the number of the Apostles, the creed was divided into 12 articles, one article being assigned to each Apostle. (See *SYMBOL*.) But there are many reasons why this account cannot be admitted: if a creed of such high authority had existed in the Christian church, it is reasonable to suppose that it would have been mentioned by St. Luke in the history of the Acts of the Apostles, or by

some of the earlier writers in the four first centuries, before the time of St. Ambrose; that it would have been referred to as a standard of doctrine by the more ancient councils; and that it would have superseded the necessity of composing new creeds, which was done on many occasions. Besides, the several copies of this creed, of which the principal are the vulgar or Roman, the Aquileian, and the Oriental, differ from one another in many articles; and this difference cannot easily be reconciled with the notion, that it was framed by the apostles, and transmitted from them to their successors. To which we may add, that some of the articles contained in it were inserted in opposition to errors that sprung up in the Christian church, long after the time of the apostles. However, this creed is a very ancient composition, and upon the whole an unexceptionable summary of the Christian doctrine, and much superior to compositions of a similar kind of later date. It might in part have been transmitted down from the apostles, and afterwards gradually enlarged in its present form as heresies arose and occasion required. Although the exact form of the present creed cannot pretend to be so ancient as the time of the apostles by 400 years; yet a form not very different from it was used long before, as we learn from Irenæus and Tertullian. It seems, however, that, in the first ages of Christianity, every church was at liberty to express the fundamental articles of the Christian faith in any manner, which was thought fit *pro re nata*, or as occasion offered. After its introduction, this creed was received in all ages with the greatest veneration and esteem, and for several centuries, such deference was paid to it, that it was not only used at the administration of baptism, but it was usually, if not always, read in every public assembly as the standard and basis of the Christian faith, to which the whole congregation testified assent by saying "Amen." The primitive Christians, however, affected an unaccountable secrecy in their faith and worship, and, therefore, did not in their assemblies publicly recite the creed, except at the times of baptism, which, unless cases of necessity occurred, were only at Easter and Whitsuntide; so that the constant repetition of the creed in the church was not introduced till a long time after our Saviour's incarnation. The repetition of a creed at every assembly was appointed in the eastern church by Timothy, archbishop of Constantinople in the reign of Anastasius, who died A.D. 521; but before this time the creed was only repeated on the day immediately preceding Good Friday, and its repetition on that day was first appointed by the 46th canon of the council of Laodicea. In the western churches the general and constant reading of the creed does not seem to have prevailed, till almost 590 years after Christ, when the third council of Toledo enjoined, that the creed should be repeated with a loud voice every Lord's day. The creed thus appointed to be read, both by archbishop Timothy and the council of Toledo, was the Nicene or Constantinopolitan creed, which, for reasons peculiar to that age, in some measure eclipsed the Apostles' creed, although in a little time this latter recovered its former value and estimation. Lord King's Crit. Hist. of the Apostles' Creed.

CREED, Athanasian, has been falsely attributed to ATHANASIVS, bishop of Alexandria, who lived and wrote in the fourth century, and who died A. D. 373: it is neither mentioned nor referred to in any of his genuine works; nor is it likely that he should himself compose a creed, as he and all the orthodox divines of those times constantly refer to the Nicene creed as the standard of their faith. No notice is taken of it by writers who immediately succeeded him; it was never

appealed to for the decision of the controversy relating to the procession of the Spirit between the Eastern and Western churches, in the seventh and ninth centuries; it condemns the Macedonian, Nestorian, and Eutychian heresies; but as it is never mentioned in those controversies, we may conclude that it did not then exist: nor is it quoted, say some, till one thousand years after Christ. Accordingly, the learned Dr. Cave says (Hist. Lit.) that it never was cited till about the year 800, above 400 years after the death of Athanasius, and that it was not received in the church till so very late as about the year 1000. Indeed Dr. Waterland, in his "History of the Creed," intimates, that it was written by some person about 60 years after the death of Athanasius; but he allows that it did not appear in the churches till a century or two after. It had never the sanction of any council, and it is doubtful whether it was ever admitted into the Eastern church. Fabricius is of opinion that it was first written in Latin long after the sixth century, and afterwards translated into Greek. It is appointed to be read in the service of the church of England thirteen times in the year. Vossii Diss. de Symbolis. Fabr. Bib. Græc. vol. v.

As to the uncharitable and damnable clauses of this creed, they seem to have been reprobated by the most eminent men in the church, and even by those who profess to believe the doctrines that are contained in it. It seems to have been one of the principal reasons of Mr. Chillingworth's long persisting in his refusal to subscribe the 39 articles; and he was one of the brightest ornaments and ablest defenders (says Dr. Clarke) the protestant cause ever had. Of the damning sentences in this creed he observes, that they are not only false, but in a high degree presumptuous and schismatical. "The account given of Athanasius's creed," says the excellent archbishop Tillotson, in a letter written from Lambeth, Oct. 23, 1694, to a right reverend prelate, "seems to me nowise satisfactory; I wish we were well rid of it." The learned bishop Taylor in his "Liberty of Prophecy," (Sect. ii. § 36.) has the following observation respecting it: "If it were considered concerning Athanasius's creed, how many people understand it not, how contrary to natural reason it seems, how little the scripture says of those curiosities of explication, and how tradition was not clear on his side for the article itself, much less for those forms and minutes: it had not been amiss if the final judgment had been left to Jesus Christ: and indeed to me it seems very hard to put uncharitableness into the creed, and so to make it become as an article of faith." "It certainly is to be lamented," says Dr. Tomline, the present bishop of Lincoln, in his "Elements of Christian Theology," (vol. ii. p. 220.) "that assertions of so peremptory a nature," referring to the damnable clauses, "unexplained and unqualified, should have been used in any human composition." "I am ready to acknowledge (p. 222.) that, in my judgment, notwithstanding the authority of former times, our church would have acted more wisely, and more consistently with its general principles of mildness and toleration, if it had not adopted the damnable clauses of the Athanasian creed. Though I firmly believe that the doctrines themselves of this creed are all founded on scripture, I cannot but conceive it to be both unnecessary and presumptuous to say that "except every one do keep them whole and undefiled, without doubt he shall perish everlastingly." Dr. Horsley, the late bishop of St. Asaph, avowed similar sentiments.

CREED, *Nicene*, was composed and established as a proper summary of the Christian faith by the council at Nice, A. D. 325, against the Arians. This is also called the *Constantinopolitan creed*, because it was confirmed with some few alterations by the council of Constantinople, A. D. 381. The greater

part of this creed, viz. as far as the words "Holy Ghost" was formed and settled by the council of Nice; which council also added the following clause: "The holy catholic and apostolic church anathematizes those who say there was a time when the Son of God was not, and that before he was begotten he was not, and that he was made out of nothing, or out of another substance or essence, and is created, or changeable, or alterable." (Socrat. Ecc. Hist. i. 8.) Our church hath dropped the anathematizing clauses at the end; and one cannot help wishing, says Dr. Jortin, that the Nicene fathers had done the same: the rest of this creed, after "Holy Ghost," was added at the council of Constantinople, except the words "and the Son," which follow the words "who proceedeth from the father;" and they were inserted A. D. 447. The addition made at Constantinople was occasioned by the denial of the divinity of the Holy Ghost by Macedonius and his followers; and the creed thus enlarged was immediately received by all orthodox Christians. The insertion of the words "and the Son" was made by the Spanish bishops, and they were soon after adopted by the Christians in France. The bishops of Rome for some time refused to admit these words into the creed; but at last, in the year 883, when Nicholas I. was pope, they were allowed, and from that time they have stood in the Nicene creed, in all the western churches, but the Greek church has never received them.

These three creeds are enjoined by the eighth article of the church of England, "thoroughly to be received and believed, for they may be proved by most certain warrants of Holy Scripture;" they are used in the public offices of the church; and subscription to them is required of the clergy, and as the law formerly stood of dissenting teachers properly qualified under the toleration act. See TOLERATION.

CREEK, a part of a haven where any thing is landed from the sea. So many landing places as there are in a harbour or port, so many creeks there are.

It is also said to be a shore or bank whereon the water beats, running in a small channel from any part of the sea; from the Latin *crepido*. This word is used in the Mat. 4 Hen. IV. c. 20. and 5 Eliz. c. 5.

CREEK *Moor*, in Dorsetshire, is a wharf at the northern extremity of Pool harbour, in the road between Pool and Lyones Mill. See CANAL.

CREEKS, or CREEK *Confederacy*, an Indian nation of America, so called from the creeks and rivulets with which their country abounds, and known also by the names of *Muskogulges*, and *Muskogees*, which inhabits the middle parts of Georgia. The country they claim is bounded N. by the 34th degree of latitude, and extends from the Tombigbee river to the Atlantic ocean, though they have by different treaties ceded a part of the tract on the sea-coast to the state of Georgia. The western line of their settlements and villages is formed by the Coosa river, and its main branches; but their hunting grounds extend 200 miles further to the Tombigbee, which separates their country from the Chactaws. Their territory is naturally divided into three districts, viz. the Upper Creeks, Lower and Middle Creeks, and Seminoles. The upper district includes all the waters of the Tallapoosie, Coosahatchee, and Alabama rivers, and is called the Abbaeoos. The lower or middle district includes all the waters of the Chatahoosie and Flint rivers, down to their junction; and although occupied by a great number of different tribes, they are altogether called Cowetauleas, or Coweta people, from the Cowetan town and tribe, the most ancient and warlike of any in the whole nation. The lower or southern district takes in the river Appalachicola, extends to the point of East Florida, and is called the country of the

C R E E K S.

the Seminoles. The Creeks or Muskogulges reckon 55 towns besides villages; and they have established a powerful empire upon the ruins of that of the Natchez. After their emigration from the west, beyond the Mississippi, their original native country, they first settled on the Oakmulge fields; and gradually subduing their surrounding enemies, they strengthened themselves by admitting into their confederacy the vanquished tribes; thus they rendered themselves victorious over the Chactaws, and formidable to all the nations around them. The smallest of their towns contain from 20 to 30 houses, and some from 150 to 200. These houses stand in clusters of 4, 5, 6, 7, and 8 together, irregularly distributed along the banks of the rivers or small streams. Each cluster of houses contains a clan, or family, of relatives, who eat and live in common. Each town has a public square, hot-house and yard near the centre of it, appropriate to various public uses. The principal towns of the upper and lower Creeks that have these public squares, beginning at the head of the Coosa, or Coosa Hacha river, are Upper Utalas, Abbacoochees, Natchez, Coosas, Oteetooheenas, Pinc Catches, Pocomtullahases, Weeokes, Little Talafsie, Tuskeegees, Coofadas, Alabamas, Tawafas, Pawactas, Autobas, Auhoba, Weelumpekes Big, Weelumpekes Little, Wacacoys, Wacksoy, and Ochees; the following towns are in the central, inland, and high country, between the Coosa and Tallapoosie rivers, in the district called the Hillabees, *viz.* Hillabees, Killeegko, Oakchoys, Slakagulgas, and Wacacoys. On the waters of the Tallapoosie, from the head of the river downward, are the following: *viz.* Tackabotchee, Tehassa, Totacaga, New-York, Chalaacpaulley, Loguspogus, Oakfuskee, Ufala Little, Ufala Big, Sogahatches, Tuckabatchees, Big Tallafsee, or half-way-house, Clewaleys, Coofahatchies, Coolamus, Shawansee or Savannas, Kenhalka, and Muckelefes. The towns of the Lower Creeks, beginning on the two waters of the Chattahoochee, and so downwards, are Chelu Nanny, Chattahoosee, Holitotoga, Cowetas, Cuffitahs, Chalagatcoor, Broken Arrow, Euchees Several, Hitchatees Several, Palachuolo, and Chewackala: besides 20 towns and villages of the little and big Chehaws, low down on Flint and Chattahoosee rivers: their country is hilly, but not mountainous, and the soil is very fertile and well watered, their agriculture is as far advanced as it well can be, without the proper implements of husbandry. They cultivate tobacco, rice, Indian corn, potatoes, beans, peas, cabbage, melons, and have plenty of peaches, plums, grapes, strawberries, and other fruits. A very large majority of the natives being devoted to hunting in the winter, and to war or idleness in the summer, they cultivate but small parcels of ground, barely sufficient for subsistence. But many individuals, particularly on Flint river, among the Chehaws, who possess a number of negroes, have fenced fields, tolerably well cultivated: but as they have no ploughs, they break the ground with hoes, and scatter the seed promiscuously over the ground, in hills, but not in rows: they rear horses, cattle, fowls, and hogs: the only articles they manufacture are earthen pots and pans, baskets, horse-ropes, or halters, smoked leather, black marble pipes, wooden spoons, and oil from acorus, hickory nuts, and chefnuts. Their land is a common stock, and any individual may remove from one part of it to another, and occupy vacant ground wherever he can find it. From their unsettled and roving disposition, their number cannot be easily or exactly ascertained. The fighting men are estimated at between 5 and 6000, exclusive of the Seminoles, who are of little account in war, except as small parties of marauders. The whole number of persons that compose the Creek nations may be reckoned at about 25 or 26,000.

Every town and village has one established white trader in it, and generally a family of whites, who have fled from some part of the frontier. The Creeks are a well-made, expert, hardy, sagacious, politic people, jealous of their rights, and averse from parting with their lands. They are badly armed, having few rifles, and being mostly armed with muskets. For about 40 years past, they have had little intercourse with any foreigners, except the English, to whom they are much attached, and whom they highly respect. Their language is soft and musical, and is spoken through the whole confederacy, though composed of many nations, who have a speech peculiar to themselves, and also by their friends and allies, the Natchez, the Chickasaw and Chactaw language is, say the Muskogulges, a dialect of theirs. These people are singularly laudable for prohibiting the use of spirituous liquors. One of the principal articles in their treaties with the white people is, that no kind of spirituous liquors shall be sold or brought into their towns. Most of their favourite songs and dances they derive from their enemies, the Chactaws, who are famous for poetry and music. Their music is both vocal and instrumental; but of the latter they have scarcely any thing that deserves the name; such are the tambour, rattle-gourd, and a kind of flute, made of a joint of reed, or the tibia of the deer's leg, which yields a hideous melancholy discord, rather than harmony; but the tambour and rattle, accompanied with their sweet low voices, produce a pathetic harmony, in which they keep time together; the countenance of the musician expressing, at proper intervals, the solemn elevated state of his mind; and the harmony touches the feelings of the attentive audience, and produces an universal sensation of delight and tranquillity throughout the assembly. Their music, both vocal and instrumental, united, keeps exact time with the performers or dancers. In dancing, their most admired and generally practised step is slow, shuffling, and alternate; both feet moving forward one after the other, first the right foot foremost, and next the left, moving one after the other, in opposite circles, *i. e.* first a circle of young men, and within a circle of young women, moving together opposite ways, the men with the course of the sun, and the females in a contrary direction; the men strike their arms with the open hand, and the girls clap hands, and raise their shrill sweet voices, answering an elevated shout of the men at stated times of termination of the stanzas; and the girls perform an interlude or chorus separately. In accompaniment with their dances, they have songs, martial, bacchanalian, and amorous,—and they have also moral songs, which seem to be the most esteemed and practised, and answering the purpose of religious lectures. Their doleful moral songs or elegies have a quick and sensible effect on their passions, and they manifest a lively affection and sensibility in their countenances. They have also a variety of games for exercise and pastime, some peculiar to the men, others to the female sex, and others in which both sexes are employed. The ball-play is esteemed the most noble and manly exercise. This game is exhibited in an extensive level plain usually contiguous to the town; and in this the inhabitants of one town play against those of another, in consequence of a challenge, where the youth of both sexes are often engaged, and sometimes stake their whole substance. Here they perform amazing feats of strength and agility. The game principally consists in taking and carrying off the ball from the opposite party, after being hurled in the air, between two high pillars, which are the goals, and the party which bear off the ball to their pillar win the game. Each person has a racket or hurl, which is an implement of curious construction, resembling a ladle or small hoop net, with a handle about three feet in length, the

hoop and handle of wood, and the netting of thongs of raw hide, or tendons of an animal. The foot-ball is likewise a favourite diversion. All their games are terminated with feasting and dancing in the public square. They have, besides, festivals almost for every month in the year, which are chiefly dedicated to hunting and agriculture. The principal of these is the bust, or feast of first-fruits, which seems to end the last, and begin the new year. There are three in August, when their new crops of corn are arrived at maturity, and every town celebrates it separately, when their new harvest is ready. If they have any religious rite or ceremony, this festival is its most solemn celebration. They begin with cleansing their houses, squares, and the whole town, of their filth, and consuming all their old vestments and provisions with fire. Then follows a fast of three days, during which the fire in the whole town is extinguished, and they abstain from the gratification of every appetite and passion. A general amnesty is proclaimed, and malefactors may return to their town, and they are absolved from their crimes, which are now forgotten, and they are restored to favour. On the fourth morning, the high priest, by rubbing dry wood together, produces new fire in the public square, whence every habitation in the town is supplied with the new and pure flame. The women then go forth into the harvest-field, and bring from thence new corn and fruits, which, being duly prepared, are solemnly brought, together with drink, into the square, where the people are assembled, in their new cloaths and decorations. The women and children place themselves in their separate families, and in the evening repair to the public square, where they dance, sing, and rejoice through the whole night, observing a proper and exemplary decorum: this continues three days, and during the four following days they receive visits, and rejoice with their friends from neighbouring towns, who have purified and prepared themselves. The Muskogulges allow of polygamy in the utmost latitude: for every man takes as many wives as he pleases; but the first is queen, and the others her handmaids and associates.

The youth of both sexes are fond of decorating themselves with external ornaments. The men shave the head, leaving a crest or comb, beginning at the crown, where it is frized and stands upright, covering the hinder part of the head and neck, and terminating behind in lank hair, ornamented with pendant silver quills, and jointed silver plates. Their ears are lacerated, and a piece of lead is fastened to the cartilage, which extends it to a great length, and which is then bound round with brass or silver wire in the form of a bow or crescent, decorated with soft white plumes of heron feathers. Their temples are encircled with a curious diadem or band, ingeniously wrought or woven, and decorated with stones, beads, porcupine quills, &c.; the front peak of it being embellished with a high waving plume of crane or heron feathers. Their clothing is simple and frugal. The head, neck, and breast are painted with vermilion; and some of the warriors have the skin of the breast, or muscular parts of the body, inscribed with hieroglyphic scrolls, flowers, figures or animals, stars, crescents, and the sun in the middle of the breast; which stains are given in youth, by pricking the skin with a needle, and rubbing in a blueish tinct. The decorations of dress are restricted to particular occasions; for the male youth are perfectly naked till they attain the age of twelve or fifteen years: but the females always wear a jacket, sash, and buskin, which reach to the middle of the leg. The junior priests or students constantly wear the mantle or robe, which is white; that of others being of a scarlet or blue colour; and they have a great owl skin

cased and stuffed, and so well executed as almost to represent the living bird, having large sparkling glass beads or buttons fixed in the head for eyes:—this ensign of wisdom and divination they sometimes wear as a crest on the top of the head: at other times it is borne on the arm, or on the hand. These bachelors are always distinguishable from other people by their taciturnity, grave and solemn countenance, dignified step, and by their singing to themselves songs or hymns, in a low sweet voice, as they stroll about the towns. For a farther account of the manners and customs of these people, see Bartram's Travels through North and South Carolina, Georgia, &c.

CREEKS' *Crossing-place*, lies on Tennessee river, about 40 miles E.S.E. of the mouth of Elk river, at the Muscle shoals, and 36 S.W. of Nickajack, in the Georgia Western territory.

CREEL, in *Rural Economy*, a name often provincially applied to signify a sort of stool contrived in different forms, for the purpose of performing different operations on sheep, and other small animals: such as smearing, clipping, slaughtering, &c. It is in much use in some districts, while in others it is almost wholly unknown.

CREENGLES, *Cringles*, probably derived from *krinckelen* (Beig.), to run into twigs, in *Naval Architecture*, are small ropes spliced into the bolt-ropes of the sails of the main-mast and fore-mast, into which the bowling bridles are made fast; and are also to hold by when a bonnet is shaken off.

CREEPER, in *Ornithology*, the English name of the *CERTHIA*; which see.

CREEPER, *New Zealand*. See *MEROPS Nova Islandia*.

CREEPER, *yellow throated*, and black and white *creeper*. See *MOTACILLA flavicollis* and *varia*.

CREEPER, in *Sea Language*, a sort of grapnel, having a shank, and four hooks or claws, but without flooks; used for recovering things that may be cast overboard.

CREEPING, *REPENS*. in *Botany*, is applied either to a root or stem, when either of them is extended horizontally, and throws out fibres for the absorption of nourishment as it goes. See *ROOT* and *RADICLE*. A creeping root, *radix repens*, is a kind of subterraneous stem, the fibres, which it sends forth here and there, being the only efficient part of the root. It serves powerfully for the increase of such plants as are furnished with it, whose vital principle is often so entirely devoted to the root, as not to have sufficient energy left to perfect the seeds. The Mints, the *Triticum repens*, or Couch-grass, and various others of the last-mentioned tribe, destined to inhabit and to bind down the sandy shores of the ocean, all exemplify this kind of root. In some other plants, particularly such as grow parasitically on the stems or branches of trees, the upper side of the root is frequently bare, witness the genus *Epidendrum*; and the same may be observed of some species of *Iris*.

A creeping stem, *caulis repens*, (see *CAULIS*), runs either along the ground, or over rocks, walls, or the trunks of trees; in every case throwing out radicles for the absorption of nourishment, as, in many species of Cinquefoil or *Potentilla*, several brambles, and other plants. When the fibres of the stem serve merely to attach it to other bodies for support, as in the ivy, such a stem is called *radicans*, clinging, a term by many botanists not sufficiently distinguished from the above. S.

CREGER'S TOWNS, in *Geography*, a town of America, in the state of Maryland, and Frederick county, on the W. side of Menococy river, between Owing's and Hunting creeks, which fall into that river; 9 miles S. of Emmitsburg,

burg, near the Pennsylvania line, and about 11 N. of Fredericktown.

CREGLINGEN, a small town of Franconia, on the Tauber, which formerly belonged to the king of Prussia, as margrave of Anspach.

CREICHAU, a canton of Germany, in Suabia, which formerly belonged to the free nobility of the German empire, and as such consisted of several lordships, under the immediate counts and barons of the empire. It is now part of the kingdom of Wurtemberg.

CREIL, in Latin *Creolium*, a small town of France, in the department of the Oise, on the river Oise, 6 miles N.W. of Senlis, and 36 miles N. of Paris. It is the chief place of a cañon in the district of Senlis. It has 1000, and the canton 12,402 inhabitants, living in 19 different communes, upon a territorial extent of 245 kilometres.

CREILSHEIM, a small town of Franconia, on the river Saxe, with an ancient citadel, and a grammar-school. It formerly belonged to the king of Prussia, as margrave of Anspach.

CREIOPOLUS, in *Ancient Geography*, a mountain of the Peloponnesus, in the Argolide, situated on the route from Tegæa to Argos, according to Strabo.

CRELLIUS, JOHN, in *Biography*, was born in Franconia, in the year 1590. He was indebted to his father for the early part of his school-learning, and afterwards pursued his studies at Nuremberg. At this place he was distinguished for great application, and excellent talents, and obtained the respect and favour of his superiors. He studied successively at some other German academies, and became an excellent linguist, and deeply versed in the Aristotelian philosophy. He next began to read with attention the works of the most celebrated divines, intending to make theology his principal pursuit. As, however, he meant to form his own opinions independently of the authority of great names, he previously formed the liberal determination of embracing no speculative doctrines concerning the truth of which he should not be perfectly satisfied from his own enquiries. He soon found reason to be dissatisfied with the Lutheran system, in which he had been brought up, and disavowed his belief in it. By this profession of his faith, or as his contemporaries would rate it, of his want of faith, he was prevented from rising to that eminence to which he would have otherwise attained: he resigned his pretensions to the office of inspector of youth, to which he was nominated in the year 1610. This was a great cause of mortification to his friends, who had anticipated for him the highest preferments in the church. Crellius, however, determined, according to the maxim of his great Master, to make every thing, even the attachment of friends, and the nearest relations, subservient to his sense of duty; he accordingly left his native country, and removed to Poland, where he had not a single friend; but the spirit of enquiry was cultivated and encouraged there, with singular advantages. At Racow, whither he arrived in 1612, he met with a considerable degree of patronage, joined the Unitarian church of that place, and determined to devote himself and his talents to the profession of the ministry. In the following year he was appointed Greek professor of the university; and in 1615 commenced the office of a public preacher with great acceptability. In the following session he was nominated rector of the university, a post which he filled with much usefulness, and honour, for the space of five years, when he resumed his ministerial functions, and was fixed on as one of the stated pastors of the church at Racow. The duties of this office he performed with great assiduity: he zealously defended and illustrated the opinions which he had em-

braced, as well from the pulpit, as from the press. He appeared as an advocate for Socinus against the celebrated Grotius, on the subject of the atonement. Crellius's answer was well received by his learned antagonist, who was from this, and other circumstances, suspected to lean, according to Moreri, too much to the Unitarian doctrines. Besides this answer to Grotius, the principal works of our author were, two books concerning the one God the Father, generally spoken of in catalogues as "*Crellius de Deo*;" "*A Treatise concerning God and his Attributes*;" one on "*The Holy Spirit*;" and another containing "*A Defence of Religious Liberty*." He wrote on "*Ethics*," and on various topics, which he discussed with learning, and great candour. He is reckoned one of the ablest among the *Fratres Poloni*, and his works make almost the half of the four volumes so well known in every theological library. He was intent upon planning other works, when he was attacked by a fever, which carried him off in the forty-second year of his age; highly revered for his integrity, learning, and ardent piety. Moreri. *Life of Socinus*.

CREMA, in *Geography*, a town of Italy, and capital of the Cremasco, situated on the river Serio, well built, fortified, populous, commercial, and rich: the see of a bishop, suffragan of Bologna. It contains 5 parish churches, and 16 convents. The name is said to be derived from *κρημα*, to burn, as being built on the ruins of a more ancient and beautiful town, burned by order of the archbishop of Milan, in the year 951; it has belonged to the Venetians from the year 1428: 22 miles E.S.E. of Milan. N. lat. 45° 22'. E. long. 6° 26'.

CREMASCO, a country of Italy, taking its name from the capital Crema, situated in the Milanese, and belonging to the Venetians. It is small, but fertile in corn, wine, flax, and hemp.

CREME, in *Ancient Geography*, a town of Asia, in the Pontus. Steph. Byz.

CREMAILLE, or **CREMAILLE'RE**. When the inside of the parapet of any work is notched or broken in such a manner as to resemble the teeth of a saw, it is said to be *en cremaille*, or *en cremailere*, whether it be in any part of a regular fortification, or in a field redoubt, in a line of circumvallation or countervallation, &c. This formation of the inside of a work by indenting it with small redans, having each of them one face perpendicular to the capital of the work, and the other parallel to it, is very useful for taking off the defects of salient angles, and furnishing defences in different directions from the same part. To whom this useful contrivance is justly attributable is not certainly known. Mr. Clairac says, that Mr. de la Fon, director of fortification of the maritime places in Flanders, shewed him at Duunkirk, in 1740, a project of this kind in tracing out a covert-way, and that Mr. De Verville, formerly chief engineer at Rocroi, to whom he had mentioned it, shewed him, in 1741, the plan of a redoubt at the army on the Lower Rhine, wherein he had proposed to defend the angles in this manner.

CREMASTA, in *Ancient Geography*, a place of Asia, situated, according to Xenophon, near the town of Antandra.

CREMASTER, in *Anatomy*, from *κρημα*, to suspend, is a muscle belonging to the testis. It arises from the inferior border of the internal oblique, and transversalis muscles; chiefly from the former. It becomes connected to the outer side of the spermatic chord, and passes, with that part, through the ring of the external oblique. Its fibres are in some degree separated as it descends, and they are ultimately scattered over the upper part of the tunica vaginalis testis. The fibres of this muscle pursue quite an opposite course in

the embryo; being reflected towards the abdomen. These muscles serve, as their name imports, to suspend the testes in their situation; and to bear the weight of these parts. They will draw the testes towards the abdominal ring; which effect may be observed in coughing; and particularly in the hooping cough. It is said to elevate the testis, and to produce some compression, or concussion of the part in the act of coition.

CREMATION is sometimes used for burning, particularly when applied to the ancient custom of burning the dead. This custom is well known to have prevailed among most eastern nations, and continued with their descendants after they had peopled the different parts of Europe. Hence we find it prevailing in Greece, Italy, Gaul, Britain, Germany, Sweden, Norway, and Denmark, till Christianity abolished it. Phil. Trans. N^o 458. sect. 3.

CREMAUX, in *Geography*, a small town of France, in the department of the Loire in the district, and 6 miles south of Rouanne.

CREMBS, a river of Carinthia, which runs into the Lyzer, about 6 miles N. of Milltatt.

CREMBSPERG, a town of Carinthia; 7 miles N. of Milltatt.

CREMERA, in *Ancient Geography*, a small river of Italy, in Etruria; it issues out of the lake of Baccano, and after a course of 3 miles, runs into the Tiber. It is at present called "La Varea," and is famous in ancient history for the surprize and slaughter of the Fabii by the Veientes. According to Livy, (l. ii. c. 50.) and other Roman historians, 306 of the Fabii fell into an ambuscade, and were cut to pieces near this river; one alone of the whole family surviving, who, by reason of his tender years, had been left at Rome. He, it is said, was the grandfather of Fabius Maximus, of whom Ennius says,

"Unus qui nobis cunctando restituit rem."

Virgil *Æn.* vi. 846.

"Whose wife delays retriev'd the Roman state."

CREMIEU, in Latin *Cremaicum*, in *Geography*, a small town of France, in the department of Isere, 18 miles E. of Lyons, at no very great distance from the Rhone. It is the chief place of a canton, in the district of La Tour du Pin, with a population of 2123 individuals. The canton itself has 29 communes, 13,823 inhabitants, and a territorial extent of 320 kilometres. Near Cremieu is the famous grotto of Notre Dame de la Balme.

CREMMEN, an ancient but small town of Prussia, in the middle mark of Brandenburg, containing about 300 houses, and remarkable for two battles which were fought in its vicinity, between the sovereigns of Brandenburg and Pomerania; one lost by the Margrave, Lewis of Brandenburg, against the duke of Pomerania in 1331, and the other won against another duke of Pomerania by the elector Frederic I. in 1413.

CREMNA, in *Ancient Geography*, a town of Asia, in Pisidia, according to Strabo and Ptolemy.—Also, an episcopal town of Asia, in Pamphylia Secunda.

CREMNI, a town of European Sarmatia, near the Patus Mæotis and Tanais, according to Herodotus, who says it was a commercial town. Ptolemy.

CREMNI SCOS, a town of European Sarmatia, placed by Ptolemy on the other side of the Ister.

CREMNITZ, KREMNITZA, Kermotz, in *Geography*, the principal mine-town of Hungary, about 40 miles to the south of the Carpathian mountains, in a deep valley famous for the nine rich gold and silver mines, which are in its neighbour-

hood. It has a mint which used to coin one hundred thousand ducats annually; but, at present, the mines yield the precious metals less abundantly.

Cremitz itself is an inconsiderable place; but the suburbs are large. It has three churches, an infirmary and a Franciscan convent. On a hill near the town is an old castle with a church.

In 1731, Cremitz was honoured with the visit of the emperor Francis I., who, in the garb of a miner, went down a very deep shaft.

Both the mines and the town of Cremitz suffered considerably during the disturbances raised by prince Rakotzy and count Tekely.

CREMONA, a town anciently of Gallia Transpadana, and now capital of the Cremonese, situated in a delightful plain, watered by the Oglio, about a quarter of a mile from the Po, over which is a bridge of boats, protected by a fort, as the town is by a castle: a canal, which passes through the town, forms a communication between the Oglio and the Po:—its circumference is about 5 miles. The principal streets are wide and straight, adorned with some small squares, and a few palaces, but the houses in general are not well built. An university was founded in this city by the emperor Sigismund; but it has long been in a declining condition. Cremona has 40 parish churches, from the tower of one of which is an extensive view over the fertile plains of Austrian Lombardy, 43 convents, and about 12,000 inhabitants. This is the see of a bishop, suffragan of Milan. This town is said to have been built 391 years B. C. When the country became subject to the Romans, they sent a colony into this city in the year of Rome 535, and a second in 562. In the war of Antony and Augustus, it took part against the latter; who surrendered the town and the adjacent territory to the plunder of the soldiers. After having recovered its former flourishing state, it was burnt by the soldiers of Vespasian. It was again laid waste by the Goths A. D. 630. In 1796, it surrendered to the French without resistance.

CREMONA STOP, on an organ, is a single reed stop, originally designed to imitate an ancient wind instrument, called a *Kneimborn*, (which see;) but time and the ignorance of organ-builders have corrupted this word into Cremona, which has led some of late to suppose, that this stop was at first intended as an imitation of the violin. See ORGAN.

CREMONAGE, in *Geography*, a country of Italy in the Milanese, deriving its name from its capital, Cremona; bounded on the E. by the duchy of Mantua, on the N. by the Bressan, on the W. by the Lodofan and Cremasco, and on the S. by the Parmesan, from which it is separated by the Po. It belonged for a long time to Spain till the famous war for the succession of Charles II., when it was ceded to the house of Austria, and made a fief of the empire. It is a fertile country, particularly in wine and fruit.

CREMONINI, GIO. BATISTA, in *Biography*, a painter, was a native of Cento, and flourished at Bologna in the 16th century. He had sufficient knowledge of perspective and architectural decorations, and was much employed at Bologna in painting in fresco the façades of the palaces and houses of persons of distinction, which he ornamented with the imitations of statues, basso-relievs, and friezes, representing combats of wild beasts, &c., which he executed with great spirit. He had the honour of numbering Guercino amongst his disciples. Cremonini died in 1610. Lanzi. Orlandi.

CREMPE, or KREMPE, in *Geography*, a town of Germany,

many, in the duchy of Holftein, feated on a brook or small river, which foon after runs into the Stoer: the inhabitants deal chiefly in cattle; 4 miles N. of Guuckftadt, and 27 N.W. of Hamburg.

CREMS, or KREMS, a town of Germany, in the arch-duchy of Austria, on the Danube: 32 miles W. N.W. of Vienna.—Also, a river of Austria, which runs into the Danube near Crems.

CREMSIER, KREMSIER, or *Kromerziz*, a small town of Moravia, in the circle of Prerau, on the river March, 24 miles S. of Olmutz, and the ufual refidence of the bifhops of Olmutz. It is well built, and has feveral churches and convents.

CREMSMUNSTER, or KREMSMUNSTER, a small town of Upper Austria, or the country above the Ens, 30 miles S. E. of Lintz on the river Krems, which, in the year 1490, obtained the rank of a market town, on account of the adjacent rich abbey of Benedictines, founded in the year 777. It has an academy for young noblemen.

CRENAN CRAIG, a cape of Scotland, on the coast of the county of Wigtown, in Luce bay: 13 miles S.S.E. of Stanraer.

CRENATUM, FOLIUM, in *Botany*, a notched or crenate leaf, has its margin cut into a number of notches, which are not directed towards either of its extremities; as in *Glechoma hederacea*, the Ground Ivy, and efppecially *Chrysofolium*, or Golden Saxifrage. The notches may be more or lefs acute, and in fome leaves they confift of a double ferief, for which the term *duplicato crenatum* is ufed. When the notches are very minute, the diminutive is adopted, *crenulatum*. All thefe terms are alfo occasionally applied to the *corolla*, *nectarium*, or any other expanded part of a vegetable. See SERRATUM. S.

CRENÆA, Schreb. gen. 807. Lam. Enc. Wild. 932. Juff. 332. Aubl. 523. Clafs and order, *dodecandria monogynia*. Nat. Ord. *Salicarie*, Juff.

Gen. Ch. *Cal.* Perianth one-leaved, top-shaped, permanent, four-cleft half way down; fegments egg-shaped, acute, equal, fpreading. *Cor.* Petals four, roundifh, longer than the calyx, and attached to it between its divifions. *Stam.* Filaments fourteen, capillary, white, inferted into the calyx below the petals, inclined to one fide; anthers roundifh. *Pift.* Germ fuperior, globular; ftyle long, incurved; ftigma oblong, thickifh. *Povic.* Capsule globular, five-celled, its lower part furrounded by the calyx. *Seeds* numerous, very fmall.

Eff. Ch. Calyx four-cleft, bearing the corolla. Petals four. Capsule five-celled, with many feeds.

Sp. C. *maritima* Aubl. tab. 209. *Stems* feveral, two or three feet high, knotty, quadrangular, winged. *Leaves* oppofite, oval-oblong, obtufe, narrowed near the bafe, almoft feffile, even-furfaced, entire, green. *Flowers* white, axillary; peduncles often two together, fflender, fhorter than the leaves, divided into two very fmall, one-flowered pedicels; bracts one at the bafe of each peduncle; two about the middle, oppofite. A native of Cayenne, growing in the falt water.

CRENDIREK, in *Geography*, a lake of America, in North Carolina; 30 miles N. N. E. of Newbern.

CRENEAUX, Fr. *Loop-holes*, are fmall openings made in the walls of a work for receiving the ends of mufkets or fmall fire-arms, and for firing through on thofe who advance to attack it. A creneau, or loop-hole, is for a mufket what an embrafure is for a cannon. It is alfo called *meurtriere*. Its opening on the outside is about three inches broad, and from 12 to 15 inches in height or depth, and on the infide it is from 8 to 10 inches wide.

VOL. X.

CRENELLE, in *Heraldry*. See EMBATTLED.

CRENI, in *Ancient Geography*, a place of Asia Minor, in Phrygia.

CRENIDES, a maritime place of Asia Minor, in Bithynia, fituated, according to Arrian, on the coast of the Euxine fea, between the port of Sandaraca and the town of Pfylla.

CRENO. *the Lake of*, in *Geography*, is a lake of confiderable extent at the top of mount Rotondo, in Corfica, in the department of Golo, out of which iffues the river Tovignano.

CRENOPHYLAX. The *crenophylaces* at Athens were magiftrates who had the infpection and management of fountains under their care.

CREODIBA, in the *Customs of the Middle Age*, a robbery and murder committed in a wood, where the body of the perfon killed was burnt, in order to prevent any difcovery of the crime. The word, fays Wendelinus, is compounded of *cray* and *diven*, that is, *wood-robbers*.

CREOLES, a name given to the families defcended from the Spaniards who firft fettled at Mexico in America. Thefe confitute the fecond clafs of fubjects in the Spanifh colonies; and they are diftinguifhed from the CHAPETONES, who are the firft in rank and power; from the mixed race, forming the third clafs of citizens, and comprehending the MULATTOS and MESTIZOS; from the NEGROES, who hold the fourth rank; and from the *Indians*, who form the laft and the moft depressed order of men in the country, which belonged to their anceftors. The character and ftate of the Creoles have enabled the Chapetones, or Spaniards arrived from Europe, to acquire various advantages, befides thofe which they derive from the partial favour of government. Although fome of the Creolian race are defcended from the conquerors of the New World; though others can trace up their pedigree to the nobleft families in Spain; though many are poffeffed of ample fortunes; yet, by the enervating influence of a fultry climate, by the rigour of a jealous government, and by their defpair of attaining that diftinction to which mankind naturally afpire, the vigour of their minds is fo entirely broken, that a great part of them wafte their life in luxurious indulgences, mingled with an illiberal fuperftition ftill more debafing. Languid and unenterprifing, the operations of an active extended commerce would be to them fo cumbersome and oppreffive, that almoft in every part of America they decline engaging in it. The interior traffic of every colony, as well as its trade with the neighbouring provinces, and with Spain itfelf, are carried on chiefly by the Chapetones; who, as the recompence of their induftry, amafs immenfe wealth; while the Creoles, funk in floth, are fatisfied with the revenues of their paternal eftates. From this ftated competition for power and wealth between thefe two orders of citizens, and the various paffions excited by a rivalfhip fo intereffing, their hatred is violent and implacable. The court of Spain, from a refinement of diftruftful policy, cherifhes thefe feeds of difcord, and foments this mutual jealousy, which not only prevents the two moft powerful claffes of its fubjects in the New World from combining againft the parent ftate, but prompts each, with the moft vigilant zeal, to obferve the motions, and to counteract the fchemes of the other. To the Creoles, or natives in the Weft Indies, fays Mr. B. Edwards, we muft look for the original and peculiar caft of character impreffed by the climate, if indeed the influence of climate be fuch as many writers imagine. (See CLIMATE.) This writer conceives that the climate of the Weft Indies difplays itfelf more ftroingly on the perfons of the natives, than on their manners, or on the faculties of their

their minds. They are obviously, he says, a taller race, on the whole, than the Europeans, but, in general, not proportionably robust. Many of them are six feet four inches in height; but they want bulk, corresponding to our ideas of masculine beauty. All of them, however, are distinguished by the suppleness of their joints, which enable them to move with great ease and agility, as well as gracefulness, in dancing. They also excel in penmanship, and the use of the small sword. It has been truly observed, he says, that the effect of climate is likewise obvious in the structure of the eye, the socket being considerably deeper than among the natives of Europe. By this conformation, they are guarded from the injurious effects of an almost continual strong glare of sun-shine; he also remarks, that their skin feels much colder than that of an European, a circumstance which, as he conceives, proves, that nature has contrived some peculiar means of protecting them from the heat, which she has denied to the nations of temperate regions, as unnecessary. Accordingly, though their mode of living differ in no respect from that of the European residents, they are rarely obnoxious to those inflammatory disorders, which frequently prove fatal to the latter. The Creole women, by their singularly abstemious diet, and the calm tenour of their lives, are peculiarly exempt from these disorders. Hence, however, their fibres are relaxed and their countenances wan. The Creole ladies, though destitute of that bloom which is more discernible in colder countries, surpass most others in their large, languishing, and expressive eyes; sometimes beaming with animation, and sometimes melting with tenderness; a sure index, says the writer now cited, to that native goodness of heart and gentleness of disposition for which they are eminently and deservedly applauded, and to which it is owing that no women on earth make better wives, or better mothers. The Creole ladies are also noted for very fine teeth, which they preserve beautifully white by a constant use of the juice of a withe called the "Chewstick," a species of rhamnus. This is cut into small pieces, and used as a tooth-brush. The juice is a strong bitter, and a powerful detergent. The circumstance most observable in the character of the West Indian Creoles is an early display of the mental powers. Hence it has been said that as the genius of the young West Indians attains sooner to maturity, it declines more rapidly than that of Europeans. The chief cause, however, according to De Ulloa, of the short duration of such promising beginnings seems to be the want of proper objects for exercising the faculties. The propensity also, which the climate undoubtedly encourages, to early and habitual licentiousness, induces a turn of mind unfriendly to mental improvement. Among such of the natives as have happily escaped the contagion and enervating effects of youthful excesses, men are found of capacities as strong and permanent as among any people whatever. Mr. Edwards cannot either admit that the Creoles in general possess less capacity and stability of mind than the natives of Europe, or allow that they fall short of them in those qualities of the heart which render man a blessing to all around him. Generosity to each other, and a high degree of compassion and kindness towards their inferiors and dependents, distinguish the Creoles in a very honourable manner. To this purpose, Mr. Ramsay observes, in his "Essay on the Treatment and Conversion of the Slaves," &c. that adventurers from Europe are universally more cruel and morose towards the slaves than the Creoles or native West Indians. "If they are proud," says Mr. Edwards, "their pride is allied to no meanness. Instructed from their infancy to entertain a very high opinion of their own consequence, they are cautious of doing any act which

may lessen the consciousness of their proper dignity. From the same cause they scorn every species of concealment. They have a frankness of disposition beyond any people on earth. Their confidence is unlimited and entire. Superior to falsehood themselves, they suspect it not in others." Indolence, this writer allows, is too predominant among them; but timidity constitutes no part of their character; and even the indolence, of which they are accused, is rather an aversion from serious and deep reflection than a sluggishness of nature. Both sexes, when the springs of the mind are set in motion, are remarkable for a warm imagination, and a high flow of spirits. Robertson's America, vol. iii. Edwards's West Indies, vol. ii. Voy. de Ulloa; and Voy. de Frezier.

CREON, in *Ancient Geography*, a mountain of the island of Lesbos.

CRE'ON, in *Geography*, a small town of France, in the department of the Gironde, chief place of a canton in the district of Bourdeaux. It has only 843, but the canton contains 13,394 inhabitants, dispersed in 28 communes, upon a territorial extent of 192 kilometres and a half.

CREONES, in *Ancient Geography*, a people who, according to Ptolemy, inhabited the northern part of Britain, on the western coast, N. of the Cerones.

CREONIUM, an ancient town of Macedonia, near the Lychnide lake. Polybius.

CREOPHAGI, a people of Ethiopia, near Egypt, placed by Strabo above the port of Antiphile. Both men and women practised a kind of circumcision.

CREOPHYLUS, in *Biography*, an excellent poet of Samos, contemporary with Homer, who presented him, as Strabo informs us, with a poem on the taking of the city Oechalia. This poem is also mentioned by Pausanias and Callimachus; but both these writers ascribe it to Creophylus, and not to Homer. Creophylus entertained Homer at his house, and is said by some to have been his master, and to have had great share in composing the divine work, as Cicero styles it, which passes under the name of that inimitable poet.

CREPANU, in the *Manege*, a chop in a horse's leg, made by the spunges of the shoes of one of the hinder feet, crossing and striking against the other.

CREPIDÆ, among the Romans, a kind of slippers or shoes, which were always worn with the *pallium*, as the *calcei* were with the *toga*.

CREPIS, in *Botany*, (the name of a plant in Pliny.) Linn. Gen. 914. Schreb. 1230. Willd. 1412. Gart. 915. Juss. 169. Vent. 2. 485. Class and order, *Syngensia polygamia aequalis*. Nat. Ord. *Compositæ semiseseuleæ*, Linn. *Cichoraceæ*, Juss.

Gen. Ch. Calyx common double; exterior one generally very short; scales generally spreading, deciduous; interior one egg-shaped, simple, furrowed, permanent, often swelling in the middle as the seeds ripen; scales linear. Cor. uniform; florets in several ranks, all ligulate, hermaphrodite, five-toothed. Stam. Filaments five, capillary, very short; anthers united in a hollow cylinder. Pist. Germ somewhat egg-shaped; style filiform, the length of the stamens; stigmas two, reflexed. Peric. none, except the permanent inner calyx. Seed solitary, oblong, spindle-shaped or columnar; down simple or feathery, sessile or stipitate. Recept. roughish.

Ess. Ch. Calyx calyced with deciduous scales. Florets in several ranks. Receptacle roughish.

Sp. 1. *C. burffolia*. Linn. Sp. Pl. 2. Mart. 2. Lam. 1. Willd. 1. (Hæracium ficulum, burse pastoris folio; Boec. Mas. 2. 147. tab. 106. and 112. Tourn. 471.) "Leaves pinnatifid,

pinnatifid, crenated; scape few-flowered." *Root* perennial. *Stems* six or seven inches high, naked, or furnished only with a few short lacinated leaves. *Root-leaves* spread on the ground, resembling those of *Thlaspi bursa pastoris*, or common shepherd's purse. *Flowers* rather small, on slender peduncles. A native of Italy and Sicily. 2. *C. nemausensis*. Willd. 2. Gouan. Illuf. 60. Allion. Ped. 309. tab. 75. fig. 1. (*Andryala nemausensis*; Vill. Delph. 3. 66. tab. 26.) "Leaves runcinate-lyrate, obtuse, toothed; scape many flowered, hispid; calyx-scales membranous at the edge." *Root* annual. Whole plant hispid. It has some resemblance to *hieracium sanctum* of Linnæus; but we have the authority of Dr. Smith for asserting, that Willdenow is wrong in supposing it to be the same plant. A native of the south of France, Italy, and Palestine. 3. *C. leontodontoides*. Willd. 3. Allion. Anc. Ad. Fl. Pedem. 13. "Leaves runcinate, toothed, smooth; scape many-flowered, ascending; calyxes tomentous; outer scales pressed close to the others." *Root* biennial. *Scape* a foot high, smooth, furnished at the base of the ramifications with a linear-awl-shaped bracte. *Leaves* acuminate, ciliated at the base and on the lower part of the mid-rib. *Doron* capillary, stipitate. A native of Piedmont. 4. *C. taraxacifolia* Willd. 4. Desf. Atl. 2. 231. "Leaves runcinate-pinnatifid, toothed, hispid; stems ascending, leafy at the base, many-flowered; calyxes tomentous; outer scales spreading." *Root* biennial. *Stems* one foot or two feet high, branched. *Peduncles* pubescent; bractes generally two at the base of each peduncle; inner scales of the calyx oblong-lanceolate; outer ones ovate-lanceolate, membranous at the edges. *Doron* capillary, stipitate. A native of Barbary. 5. *C. aparginoides*. Willd. 5. (*Hieracium stipitatum*; Jacq. Auth. 3. tab. 93.) "Leaves lanceolate-obovate, toothed, smooth; stem-ones linear-lanceolate; stem angular, scabrous near the bottom; peduncles and calyxes hispid." *Root* perennial. *Stem* a foot or a foot and half high, furrowed, hispid towards the top, sometimes leafless, two or three-flowered. *Stem-leaves*, when present, from one to three, sessile or somewhat decurrent, nearly entire at the base. *Flowers* yellow; calyx slightly calyced, blackish-green; inner scales lanceolate, smooth, hispid at the base; outer ones few, awl-shaped, hispid; down capillary, stipitate. A native of high meadows in Austria and Bivaria. 6. *C. vesicaria*. Linn. Sp. Pl. 5. Mart. 4. Lam. 3. Willd. 6. β . *Cichorium pratense hirsutum vesicarium*; Buxh. Pin. 126. *Cichorium sylvestricum*; Col. Ephr. 1. 238. tab. 237. "Involucres egg-shaped, concave, obtuse, spreading." Linn. Sp. Pl. "Involucres scarious, the length of the calyx; flowers in corymbs; bractes egg-shaped." Linn. Syst. Nat. *Root* annual, thick. *Stem* a foot and half high, striated, scabrous in its lower part, branched into a panicle, or corymb; longer branches two or three-flowered; the others only one-flowered. *Root-leaves* lyre-shaped, deeply cut at the base, enlarged upwards, entire and obtuse at the summit, runcinate, slightly rough; stem-leaves embracing the stem, acute, furnished with narrow teeth at the base. *Flowers* yellow, terminal; inner or proper calyx oval-conical, very hairy; scales of the outer calyx broad, concave, scarious, having the appearance of an involucre with respect to the other, and at least half its length; bractes at the divarications of the stem, panicle or corymb exactly similar to the scales of the outer calyx. β differs only in having rougher leaves. Dr. Smith, with his usual urbanity and zeal for the promotion of science, has obligingly informed us, that the specimen in the Linnæan Herbarium, from which the description in *Species Plantarum* was formed, was gathered by Hasselquist in the East; and that there appears

no authority for its ever having been found in Switzerland, as Linnæus has stated, from a misapprehension of *C. Bauhinii*'s *hieracium montanum rapifolium*, which Haller refers to *C. bicaris*. There is no specimen of β in the Herbarium, and it seems to have been taken up solely from Columna. Willdenow has considered it as a distinct species, and called it *scariosa*; he has also added another, under the name of *taurincensis*, giving as a synonym, *C. vesicaria*; Balbis; Taur. 93.; but Dr. Smith is inclined to think that he has made three species out of one. According to Willdenow, it differs in having the bractes and outer scales of the calyx, not lanceolate and scarious, but linear-awl-shaped, and only membranous at the edges. Both the varieties are natives of Italy. 7. *C. alpina*. Linn. Sp. Pl. 10. Mart. 5. Lam. 9. Willd. 9. Gært. t. 1. 158. tab. 8. Copied in Latr. Ill. Pl. 651. fig. 1. (*Hieracium alpinum scorzonerae folio*; Tourn. 472. *Leontodon*; Gmel. Siber. 2. 16. tab. 5.) "Leaves embracing the stem, oblong, acuminate; lower ones finely toothed above; upper ones, below." Linn. Sp. Pl. "Involucres scarious, the length of the calyx; flowers solitary." Linn. Syst. Nat. Somewhat resembling the preceding, but distinct. *Root* annual. *Stem* about a foot high, striated, leafy, with two or three simple branches. *Root-leaves* long, spatulate, toothed towards the summit, quite entire and narrowed towards the base; stem-leaves embracing the stem, toothed towards the base. *Flowers* pale-yellow; inner calyx hairy; scales of the outer one loose, smooth, according to Gærtner's figure, not a quarter the length of the other. *Receptacle* concave, deeply pitted; edges of the cavities ciliated. *Seed* very long, rugged, with numerous scabrous striæ, club-shaped at the base, gradually attenuated into a long point; down capillary, much shorter than the seed. Obs. The down of this and some other species may be styled semi-stipitate; it being difficult to determine whether it be seated on a real stipes, or only on the point of the lengthened seed. A native of Italy. 8. *C. albida*. Mart. 17. Lam. 5. Willd. 10. Jacq. Ic. Rar. 1. tab. 164. Allion. Ped. 800. tab. 32. fig. 3. Vill. Delph. 3. 139. tab. 33. "Leaves runcinate-toothed, somewhat hoary; peduncles naked, one-flowered; calyx-scales whitish at the edges." *Root* perennial. *Stems* several, from twelve to fifteen inches high, cylindrical, pubescent, divided into two or three simple branches, with a leaf at each division. *Root-leaves* oblong, runcinate, toothed, enlarged towards the summit, rather thick, clothed with short hairs, whitish; stem-leaves half embracing or sessile, sometimes a little narrowed at their insertion, acute, thinly and slightly toothed. *Flowers* pale-yellow, rather large; peduncles or branches long, one-flowered; outer calyx-scales oval, loose; inner ones lanceolate, pressed close to the flower. A native of the south of France, and of Italy. 9. *C. sinuata*. Lam. 6. "Leaves pinnate-lobed, somewhat scabrous; peduncles naked, one-flowered; outer calyx-scales widely spreading." *Root* perennial. *Stems* a foot high or more, furnished with two or three simple branches, leafy only at the divisions and near the base. *Root-leaves* oblong; stem-ones shorter and more deeply cut. *Flowers* pale-yellow, rather large; peduncles long, beset with some strap-shaped scales, one-flowered; outer calyx-scales green, not scarious. *Seeds* oblong, scabrous; down feathery. A native of the north coast of Africa, observed by Deffontaines, who sent seeds to Paris. 10. *C. rigida*. Willd. 11. Waldf. and Kitaib. Pl. Rar. Hung. 1. 18. tab. 19. "Leaves rigid, scabrous, toothed; root-ones inversely egg-shaped; stem-ones arrow-shaped, embracing the stem; flowers raceme-panicled; calyxes

pubescent." *Root* perennial. *Stem* four feet high, erect, rigid. *Raceme* terminal; long, peduncles two-flowered; outer calyx-scales brown at the tip. A native of the sunny side of mountains in Hungary and Tauria. 11. *C. rigens*. Mart. 18. Willd. 12. Hort. Kew. 3. 127. "Leaves oblong, doubly serrated, bristly; stem naked, branched; flowers panicled; calyxes cylindrical, smooth; down sessile." A native of the Azores, introduced into Kew garden by Masson. 12. *C. rubra*. Linn. Sp. Pl. 6. Mart. 6. Lam. 7. Willd. 13. (*Hieracium dentis leonis folio, flore suave rubente*; Bauh. pin. 127. Tourn. 469. *H. Apulum*; Col. Ecpbr. 1. 242, Moris. § 7, tab. 4 fig. 3. *Chondrilla purpurascens*; Bauh. Prod. tab. 68.) "Root-leaves runcinate-lyrate; stem-ones embracing, lanceolate; lower ones pinnatifid; calyxes hispid; outer scales scarious." Willd. *Root* annual. *Stems* scarcely a foot high, slender, striated, but little branched. *Flowers* of a delicate red colour, terminal, solitary; inner calyx hispid; scales lanceolate-linear; outer one smooth, rather short; scales oval-acute. *Down* semi-stipitate, as in *C. velicaria*. A native of Italy and the south of France. 13. *C. fatida*. Linn. Sp. Pl. 7. Mart. 7. Lam. 8. Willd. Eng. Bot. 405. (*Hieracium amygdalas anaras olens, five odore apuli suaviterubentis*; Tourn. 469. Moris. hist. 3. 63. § 7, tab. 4, fig. 4. *H. castorei* odore; Rai. hist. 232. Syn. 165.) "Leaves runcinate-pinnatifid, rough with hair; petioles toothed; stem hairy; calyx tomentous." *Root* biennial, small. *Stems* several, the central one erect, the others diffuse, branched, leafy, cylindrical, about a foot high. *Leaves* deeply pinnatifid, toothed; the lower stem-ones narrowed at the base into what Linnæus calls a toothed petiole, but which seems properly the termination of a sessile leaf. *Flowers* palish-yellow, terminal; peduncles one-flowered, elongated, thickened upwards, furnished with two or three scales, or small scattered bractæal leaves; calyx clothed more or less with soft hairy down, not glandular; inner scales nearly equal, keeled, finally embracing the marginal seeds; outer ones awl-shaped, loose, short; receptacle ciliate-pitted. *Seeds* slender, yellowish, furrowed, somewhat scabrous; down scabrous, not feathery; on the marginal seeds nearly sessile, on the others distinctly stipitate. The whole plant has the smell of bitter almonds, but stronger, and approaching to that of opium. A native of dry chalky pastures in England and other parts of Europe, but in England at least not of frequent occurrence. 14. *C. sprengeriiana*. Willd. 15. Allion. Ped. n. 810. (*Hieracium sprengeriianum*; Linn. Sp. Pl. Mart. Helminthia; Gart.) "Hispid-scabrous; leaves oblong, embracing the stem, remotely toothed; stem divaricated, branched; outer calyx-scales unequal, spreading." *Root* annual. *Stem* thinly beset with somewhat rigid hairs; branches alternate, short, simple. *Flowers* several, terminal, peduncled. *Down* of the seed stipitate, feathery. A native of Portugal and Italy. 15. *C. aspera*. Linn. Sp. Pl. 4. Mart. 8. Lam. 9. Willd. 16. (*Hieracioides sicula*; Vaill. act. 714.) "Leaves toothed; lower ones egg-shaped, auricled; upper ones arrow-shaped; stem beset with scattered stiff bristles." *Root* annual. *Stem* about a foot high, much branched, panicled, diffuse. *Leaves* rather small, lanceolate, sometimes entire, rough with short hairs. *Flowers* yellow, numerous, on short alternate peduncles; inner calyx oval-cylindrical, hispid, four or five lines long; outer one short, very loose, spreading or reflexed. *Down* of the seed sessile, feathery. 16. *C. rhagadioloides*. Linn. Mant. 16. Mart. 9. Willd. 18. Jacq. Hort. Schænb. 2. 9, tab. 144. "Leaves embracing the stem, oblong; inner calyx egg-shaped, angular, hispid with club-shaped hairs. *Root* annual. *Stem* half a foot high, erect, striated, scabrous, branched. *Leaves* entire

or recurved-toothed, even-sur-faced; lower ones narrowed a considerable way above the base; upper ones arrow-shaped, embracing the stem. *Flowers* yellow, purplish on the under side; peduncles elongated, scabrous, naked, one-flowered; outer scales of the calyx numerous, linear, obtuse, half the length of the others, unequally insert-d; inner ones about thirteen, parallel, boat-shaped, compressed. *Down* of all the seeds capillary. The lappacea of Willdenow seems only a slight variety of the preceding, distinguished by its tumid peduncles, and the simple not club-shaped hairs of its inner calyx. 17. *C. virgata*. Willd. 19. Desfont. act. hist. nat. par. 1. 37. tab. 8. Atl. 2. 230. "Leaves lanceolate, toothed, somewhat pubescent; upper ones linear, nearly entire, sessile; stem rod like; calyxes tomentous." *Root* annual. *Stem* erect, branched, furrowed, smooth. *Leaves* remotely toothed. *Flowers* somewhat umbelled, peduncled; lateral peduncles rising higher than the primary terminal one; calyx tomentous; down of the seed sessile, capillary. A native of Barbary. 18. *C. hieracioides*. Willd. 20. Waldf. and Kitaib. Hung. 1. 71. tab. 70. "Leaves smooth, toothed; root-ones ovate-spatulate, stem ones oblong, sessile; corymb terminal; calyxes glandular-hispid." *Root* perennial. A native of Hungary. 19. *C. hispida*. Willd. 21. Waldf. and Kitaib. Hung. 1. 42. tab. 43. "Bristly-hispid; leaves runcinate, auricled at the base; upper ones lanceolate, sagittate-hastate, pinnatifid at the base; calyxes extremely hispid." *Root* annual. A native of Aultria, Croatia, Slavonia, and the Banat. 20. *C. tectorum*. Smooth hawk's-beard. Smooth succory hawk-weed. Linn. Sp. Pl. 13. Mart. 11. Lam. 10. Willd. 22. Flor. dan. 501. Lam. Ill. Pl. 651. fig. 3. Curt. Lond. fasc. § 5. tab. 25. Eng. Bot. 111. (*Hedynois tectorum*; Huft. *Hieracium Chondrillæ folio, glabrum*; Bauh. Pin. 127. Tourn. 470. *H. luteum glabrum*; Rai. Syn. 165.) "Root-leaves runcinate, lanceolate, or somewhat lyrate, even-sur-faced; the rest embracing the stem, pinnate-toothed, somewhat hastate; stem smooth." A very common and very variable plant in different situations. *Root* annual, tapering. *Stem* often two feet high, erect, branched, furrowed, purplish sometimes, but rarely, a little hairy. *Leaves* smooth, bright green. *Flowers* small, bright yellow; panicle upright, terminal, somewhat corymbid, leafy, roughish; calyx rough. *Seeds* furrowed; down rough, sessile. *Receptacle* somewhat pitted, roughish. A native of England, and many other parts of Europe, on walls, dry banks, &c. flowering from June to the end of September. 21. *C. pinnatifida*. Willd. 26. (*C. virens*; Hoff. germ. 281. Roth. Germ. 1. 336. 2. 254. Allion. Ped. n. 805.) "Leaves smooth, sessile, lanceolate, pectinate-pinnatifid, quite entire towards the tip; stem erect, branched; calyxes pubescent." *Root* annual. Perfectly distinct from the next species, though it has a similar flower. A native of Germany and Italy. 22. *C. virens*. Linn. Sp. Pl. 9. Mart. 13. Lam. 11. Willd. 27. (*Hieracium minus glabrum, folis eleganter virentibus*; Bauh. Pin. 127. Tourn. 470. *Hedynois Plinii*; Lob. Ic. 229.) "Leaves runcinate, smooth, embracing the stem; calyxes somewhat tomentous." Linn. "Root-leaves toothed, somewhat lyrate, even-sur-faced; stem-ones half embracing the stem, narrow, toothed at the base; branches nearly naked, filiform." Lam. "Leaves smooth; lower ones remotely toothed; upper ones nearly entire, somewhat arrow-shaped; stem branched at the base, diffuse; calyxes pubescent." Willd. *Root* annual. *Stems* scarcely a foot high, slender, striated. *Root-leaves* about three inches long, six or eight lines broad. *Flowers* very small, yellow; peduncles almost capillary; outer scales of the calyx short, narrow, few;

CREPIS.

few; down of the feed capillary, sessile. A native of France and Italy, on walls, and by the sides of hedgcs. Nearly allied to *C. murorum*, but smaller in all its parts. 23. *C. Diaphoritis*. Linn. Sp. Pl. 8. Mart. 14. Willd. 28. (*C. virens* β; Lam.? *Hieracium majus erectum angustifolium*, caule laevi; Bauh. Pin. 127.) "Root-leaves runcinate; stem-ones hastate; calyxes somewhat tomentous." Lam. "Root-leaves lyrate-runcinate; stem-ones hastate, lanceolate; lower ones toothed; stem erect; branches divaricated; inner calyx roundish egg-shaped, angular." Willd. *Root* annual. *Stem* a foot high, somewhat angular, nearly even-surfaced. *Root-leaves* smooth, toothed, scarcely ciliated; stem-ones embracing the stem, purplish underneath, auricles at the base thickly toothed. *Flowers* yellow, purplish underneath; peduncles long, ascending, naked, one-flowered, scarcely thickened at the top; calyxes mealy, not nodding before the flower opens; calyx-scales tomentous, bristly at the back; outer ones filiform. A native of France, Siberia, and the Palatinate. Linnæus doubted whether this and the preceding are specifically distinct; Vailant, Haller, Gowan, and Vilars have actually united them. 24. *C. agrestis*. Willd. 23. Waldf. and Kitaib. Hung. "Root-leaves lanceolate-runcinate; stem-ones lanceolate, toothed at the base, arrow-shaped; flowers corymb-panicled; calyxes rough with hairs. *Root* annual. The wild plant is a foot and half high, and hispid; when cultivated it rises to the height of two feet, and becomes almost smooth. *Flowers* smaller than those of *C. tectorum*. A native of Hungary, on the borders of corn fields, and in dry meadows. 25. *C. biennis*. Linn. Sp. Pl. 14. Mart. 12. Lam. 13. Willd. 24. Hall. 30. Gært. tab. 158. fig. 2. Copied in Lam. Ill. Pl. 651. fig. 2. Eng. Bot. 149. (*Hedynnois biennis*; Hudf. 342. *Hieracium maximum*, *chondrilla folio*, *asperum*; Bauh. Pin. 127. Tourn. 470. Rai. Syn. 166.) "Leaves runcinate-pinnatifid, scabrous; lobes furnished with teeth, pointing upwards; calyx bristly, somewhat tomentous." *Root* biennial, spindle-shaped. *Stem* three or four feet high, erect, angular, leafy, rough with bristles, branched in the upper part, often purplish below. *Leaves* rough with whitish bristles; root and lower stem-ones petioled; upper ones lanceolate, pinnatifid at the base, embracing the stem; uppermost entire. *Flowers* large, yellow, in a kind of corymb; outer scales of the calyx loose, somewhat membranous at the edges, about half the length of the inner ones. *Receptacle* pitted; edges of the cavities ciliated. *Seeds* oblong, situated, smooth, more slender upwards, but not attenuated into a stipes; down sessile, capillary. A native of England, France, and other parts of Europe, chiefly in a chalky soil. 26. *C. scabra*. Willd. 25. "Leaves runcinate, hispid; stem-ones sessile; flowers in corymbs; calyx tomentous; outer scales pressed close to the others." *Stem* a foot high, striated, thinly clothed with very short hairs. *Root-leaves* two inches long, petioled, very rough with hairs, inversely egg-shaped; segments obtuse, somewhat toothed; stem-ones less hispid; lowest segments a little elongated; bracteal ones linear-awl-shaped, somewhat hastate at the base with linear auricles. *Flowers* yellow, about the size of those of *C. tectorum*, corymbed; peduncles white, with down; calyx downy, not bristly. A native of France. 27. *C. macrophylla*. Willd. 29. Desf. Atl. 2. 231. "Lower leaves ovate-oblong, hairy, unequally toothed; down stipitate, capillary." *Stem* a foot and a half or two feet high, erect, striated, branched, hairy, scabrous. *Leaves* clothed with short hairs; lower ones six or eight inches long; upper ones lanceolate, embracing the stem. *Flowers* numerous, yellow, the size of those of *C. biennis*, corymbed; outer calyx loose; scales

egg-shaped, smooth, membranous at the edges; inner one cylindrical; scales linear, acute, nearly equal, hirsute with short hairs. *Seed* elongated, slender, smooth. A native of Barbary about Algiers. 28. *C. pulchra*. Linn. Sp. Pl. 11. Mart. 15. Krok. Sues. 2. tab. 37. (*Chondrilla pulchra*; Lam. *Prenanthes hieracifolia*; Willd. *Chondrilla hieracii folio*, annua; Tourn. 238.) "Leaves arrow-shaped, toothed; stem panicled; calyxes pyramidal, smooth." *Root* annual. *Stem* three feet high, furrowed, leafy, smooth. *Leaves* roughish; root-ones six or seven inches long, and two broad, somewhat lyre-shaped, narrowed into a petiole; stem-ones embracing the stem, arrow-shaped acute, toothed towards the base. *Flowers* small, yellow, peduncled, in a loose terminal panicle; outer calyx-leaves very minute, close. *Down* of the feed capillary, sessile. A native of France, Italy, and Sicily. 29. *C. neglecta*. Linn. Mant. 15. Mart. 15. (*C. spatulata*; Lam.?) "Leaves embracing the stem, runcinate, somewhat hairy; stem panicled; inner calyxes with one or two weak spines on each scale." *Stem* a foot high, erect, somewhat hairy, branched. *Root-leaves* obovate-oblong, toothed, somewhat hairy; stem ones embracing the stem, runcinate, somewhat hairy, with elongated teeth even at the base; upper ones somewhat hastate. *Flowers* small, yellow; peduncles or flowering branches elongated, naked, even-surfaced, two-flowered or hispid; outer calyx-leaves very short, acute; inner ones eight or ten. *Root* annual. A native of Italy. Dr. Smith assures us that Willdenow has no good authority for asserting that, in the herbarium of Linnæus, a specimen of *C. nemausensis* is preserved under the name of *C. neglecta*. The latter is much more similar to *hieracium sanctum*, which Willdenow erroneously makes a synonym of *C. nemausensis*, but is quite distinct from both. 30. *C. succulenta* Hort. Kew. 13. (*C. coronopifolia*; Willd. 30. Desfont. act. soc. hist. nat. par. 1. 38. tab. 9. *Chondrilla hieracioides*; Roth. Cat. 1. 101. *Chondrilla tragopogonoides*; Bocc. mus. tab. 13.) "Leaves pinnatifid or toothed, somewhat fleshy; calyxes a little tomentous; down sessile." Hort. Kew. "Leaves pinnatifid; segments linear, root-ones toothed; stem-ones quite entire; stem panicled; calyxes tomentous; scales of the outer ones pressed close to the others." Willd. *Root* annual. A native of Madeira and the Canary Islands. 31. *C. tenuifolia*. Willd. 31. "Leaves pinnated; leaflets linear; root-ones toothed; stem panicled; calyxes pubescent; scales of the outer one reflexed." A native of Tauria? 32. *C. filiformis*. Willd. 32. Hort. Kew. 3. 1280. "Leaves linear-filiform, quite entire, smooth; down sessile." *Root* biennial. A native of Madeira.

CREPIS barbata; Linn. See *TOLPIS barbata*.

CREPIS pygmaea; Linn. See *HIERACIUM pumilum*.

CREPIS sibirica; Linn. See *HIERACIUM sibiricum*.

CREPIS, in *Gardening*, comprises plants of the herbaceous ornamental annual kind; of which the species mostly cultivated are; the Spanish bearded crepis, or purple eyed succory hawk-weed, (*C. barbata*;) and the purple crepis, (*C. rubra*.)

Method of Culture.—These, like other annual plants of the hardy kinds, must be raised by sowing the seed in either the autumn or spring, or both periods, where they are required to flower for a great length of time and in patches, in the clumps, borders, or other part where they are to remain, six or seven in each, covering them in lightly. When the plants have attained six or seven inches in growth, they should be thinned out, to three or four in each patch, and be kept free from weeds.

They are capable of succeeding in most soils and situations,

tions, having a pleasing effect in their flowers, in the fronts and other parts of the borders and clumps of ornamented grounds, as well as in many other places.

CREPITATION, that noise which some salts make over the fire in calcination; called also *detonation*.

CREPITATION is also used in *Surgery*, for the noise made by the ends or pieces of bones, when the surgeon moves a limb to assure himself by his ear of the existence of a fracture.

This is one of the evident indications of a fracture of bones; and to judge by it with the greater ease to the patient, it is necessary that the upper part of the limb be held fast, while the lower part is gently moved. The jar of the bones will likewise be sometimes felt by the hand, when nothing is heard.

CREPITUS LUPULI, in *Natural History*, a kind of fungus, popularly called *puff-ball*.

Mr Derham observes, that upon examining the powder thereof with a microscope, he found the seeds to be so many exceeding small puff-balls, with round heads, and long sharp-pointed stalks; as if made on purpose to prick into the ground.

The seeds become hurtful to the eyes, probably by their sharp stalks pricking and wounding them.

CREPON, in *Geography*, a town of France, in the department of the Caravos, and district of Bayeux; 2 leagues N E of Bayeux.

CREPSA, in *Ancient Geography*, an island of the Adriatic sea, according to Ptolemy; called *Cresa* by Pliny: now *Cherso*.

CREPSTINI, a people who inhabited the territory towards the mountains of the Rhine, according to the Pcutingerian table.

CREPUNDIA, in *Antiquity*, tokens left with exposed children, by which they might be afterwards known. These were of considerable value, if the child happened to be nobly born, in order to detract part of the expence of its education.

CREPUNDIA was also used, in a less proper sense, for the swaddling cloths in which children were exposed; because by them they might be known again. See *EXPOSING of children*.

CREPUSCULUM, in *Astronomy*, twilight; the time from the first dawn or appearance of the morning, to the rising of the sun: and again, between the setting of the sun, and the last remains of day.

Papius derives the word from *creperus*; which, he says, anciently signified *uncertain, doubtful, q. d. a dubious light*. "Res dubie creperæ vocantur," Censorinus. (Vid. Vossii Etymol.) It is called the *twilight* as being between or partaking of two lights, the light of the sun and that of the stars. (Skinneri Etymol.) The beginning of morning twilight is commonly called the day-break, day-spring, or dawning of the day. The crepusculum is usually computed to begin and end when the sun is about eighteen degrees below the horizon; for then stars of the sixth magnitude disappear in the morning, and appear in the evening. It is of longer duration in the solstices than in the equinoxes, and longer in an oblique than in a right sphere.

The crepuscula are occasioned by the sun's rays refracted in our atmosphere, and reflected from the particles thereof to the eye. For suppose an observer in O on the surface of the earth, O D F (*Plate V. Astronomy, fig. 38.*) B O A the sensible horizon, meeting in A the semicircle G A H I bounding that part of the atmosphere which is capa-

ble of refracting and reflecting light to the eye, and the sun under the horizon at S; and let the ray S E fall into the atmosphere below the horizon at E. Since it passes out of a rarer into a denser medium, it will be refracted towards the perpendicular, *i. e.* towards the semidiameter C E. It will not therefore proceed to T, but touching the sensible horizon; nor can any other ray b-fides A D, of all those refracted in E, arrive at A. But, since the particles of the atmosphere reflect the sun's rays; and since the angle D A C is equal to C A O, *i. e.* the angle of incidence equal to the angle of reflection, the rays reflected in A will be transmitted to O, the place of the spectator; who will therefore see the particle A shining in the sensible horizon, and consequently the beginning of the morning twilight. In the same manner might be shewn the refraction and reflection of the sun's rays in the atmosphere, in the evening twilight. The ray S E will be the first that reaches the eye in the morning, when the dawning begins, and the last that falls upon the eye at night, when the twilight ends; for when the sun is farther below the horizon the particles at A can be no longer illuminated. When the sun is not more than about 18° below our rational horizon, his rays in the morning first reach the eastern parts of the air within our visible horizon; as the time of his rising approaches, his light spreads farther round, and enlightens a larger portion of our air, and it becomes lighter and lighter, till sun-rise; in the same manner, after sun-set, the light gradually decreases, till the sun has descended so low that none of his rays can reach the western parts of the air within our visible horizon, or not in sufficient quantity to cause any sensible light there; and then the evening twilight ends: this happens when the sun's depression below the rational horizon is about 18°.

Kepler, indeed, assigns another cause of the crepusculum; *viz.* the luminous matter or atmosphere around the sun; which, arising near the horizon in a circular figure, exhibits the crepusculum; but it is in no respect, as he conceives, owing to the refraction of the atmosphere. The sun's luminous atmosphere, however, though neither the sole nor principal cause of twilight, may lengthen its duration, by illuminating our air, when the sun is too low to reach it with his own light. Greg. Ast. book ii. prop. 8.

The depth of the sun below the horizon at the beginning of the morning, or the end of the evening crepusculum, is determined in the same manner as the arch of vision; *viz.* by observing the moment wherein the air first begins to shine in the morning, and that wherein it ceases to shine in the evening; then finding the sun's place for that moment: and thence the time till his rising in the horizon, or from his setting in the evening.

Alhazen found it 19°; Tycho, 17°; Rothmannus, 24°; Stevinus, 18°; Cassini, 15°; Ricciolus, in the equinox in the morning 16°, in the evening 20° 30'; in the summer solstice in the morning 21° 25', in the winter solstice in the morning 17° 25'.

Nor need we wonder at this difference among astronomers; the cause of the crepusculum being inconstant: for, if the exhalations in the atmosphere be either more copious, or higher, than ordinary, the morning crepusculum will begin sooner, and the evening hold longer than ordinary: for the more copious the exhalations are, the more rays will they reflect, consequently the more will they shine; and the higher they are, the sooner they will be illumined

by

CREPUSCULUM.

by the sun. On this account, the evening twilight is longer than the morning, at the same time of the year in the same place. To this it may be added, that in a denser air, the refraction is greater: and that not only the brightness of the atmosphere is variable, but also its height from the earth: and therefore the twilight is longer in hot weather than in cold, in summer than in winter, and also in hot countries than in cold, other circumstances being the same. But the principal differences are owing to the different situations of places upon the earth, or to the difference of the sun's place in the heavens. Thus, the twilight is longest in a parallel sphere, and shortest in a right sphere, and longer to places in an oblique sphere in proportion to their nearness to one of the poles; a circumstance which affords relief to the inhabitants of the more northern countries in their long winter nights. And the twilights are longest in all places which have north latitude, when the sun is in the tropic of Cancer; and to those in south latitude, when he is in the tropic of Capricorn. The time of the shortest twilight is different in different latitudes; in England, it is about the beginning of October and of March, when the sun is in the signs \simeq and \times . Hence, when the difference between the sun's declination and the depth of the equator is less than 18° , so that the sun does not descend more than $18'$ below the horizon; the crepusculum will continue the whole night; which is the case in England from about the 22d of May to the 21st of July.

PROB. I. Given the Sun's declination, e. g. 10° N. and the latitude of the place, e. g. London, $51^\circ 32'$ N.; to find day-break, or the beginning of the twilight in the morning, and the end of twilight in the evening. In the oblique-angled spherical triangle, \odot Zenith N. (Plate V. Astronomy, fig. 39.) let $\odot N = 80^\circ$, the sun's distance from the north pole, i. e. $90^\circ - 10^\circ$; $\odot Z = 108^\circ$, the sun's distance from the zenith $= 18^\circ + 90^\circ$; $ZN = 38^\circ 28'$, the complement of the latitude; to find the angle Zenith N \odot , measured by the arc $a \text{ } \odot$ the time from noon. The solution of the problem by spherical trigonometry, will be as follows.

$\odot N = 80^\circ$	$\text{Co-sec. } ZN = 38^\circ 28'$	$.20617$	}	r indices.
$\odot Z = 108^\circ$	$\text{Co-sec. } \odot N = 80^\circ$	$.00665$		
$ZN = 38^\circ 28'$	Sine $113^\circ 14'$	996327		
2 226. 28	Sine $5^\circ 14'$	896005		
Half sum 113. 14	2 19. 13614			
$\odot Z = 108. 0$	Cofine $68^\circ 17'. 29''$	9.56807		
Remainder 5. 14	2			

Angle $\odot NZ = 136^\circ 34'. 58'' = 9^h. 6'. 20''$, time

from noon when the sun is 18° degrees below the horizon. Consequently the day breaks at $2^h. 53'. 40''$ in the morning, and twilight ends at $9^h. 6'. 20''$ in the evening, supposing the sun's declination to undergo no change between the beginning of twilight in the morning, and the ending thereof at night, being about 18 hours.

The same things might have been found from the triangle $\odot S$ Nadir, for $S\odot = 90^\circ + 10^\circ = 100^\circ$, Nadir $\odot = 180^\circ - 108^\circ = 72^\circ$, and Nadir $S = \text{comp. lat.} = 38^\circ 28'$. Then by the method above find the angle $\odot SN$ (measured by the arch $a Q$) $= 43^\circ 25'. 12'' = 2^h. 53'. 40''$ as before, the time from midnight, when the sun is 18° below the horizon.

Supposing that the sun's declination were 10° S, and the place the same, we shall have in the triangle $\odot S$ Nadir, the sun being on the south side of $\text{ } \odot Q$;

$\odot S = 90^\circ - 10^\circ = 80^\circ$	$\text{the sun's dist. from the south pole,}$		
\odot Nadir $= 180^\circ - 108^\circ = 72^\circ$	$\text{the sun's dist. from the Nadir.}$		
S Nadir $= \text{comp. lat.} = 38^\circ 28'$	$\text{Co-sec. } \odot S = 80^\circ$	$.00665$	
	$\text{Co-sec. } S$	$.20617$	
2 190. 28	Nad. } $= 38^\circ 28'$	$.20617$	
Half sum 95. 14	Sine $95^\circ 14'$	999819	
\odot Nadir $= 72. 0$	Sine $23^\circ 14'$	9.59602	
Rem. 23. 14	2 19. 80703		
	Cofine $36^\circ 47'. 47''$	9.90351	

Angle $\odot SN = 73. 35. 34 = 4^h. 54'. 22''$

the time from midnight when the sun is 18° below the horizon. Consequently day breaks at $4^h. 54'. 22''$ in the morning, and twilight ends at $7^h. 5'. 38''$ in the evening. Admitting the sun's declination constant for 1 day.

Again, if the sun's declination were $23^\circ 28'$ S, and the latitude of the place the same, we shall have in the triangle $\odot S$ Nadir, the sun being, as before, on the south side of $\text{ } \odot Q$;

$\odot S = 90^\circ - 23^\circ 28' = 66^\circ 32'$	$\text{the sun's distance from the south pole,}$		
\odot Nadir $= 180^\circ - 108^\circ = 72^\circ$	$\text{the sun's distance from the Nadir.}$		
S Nadir $= \text{comp. lat.} = 38^\circ 28'$			
	Half sum $88^\circ 30'$		
2 177. 0	\odot Nadir $= 72. 0$		
	Rem. 16. 30		
	Half sum 88. 30		
	Co-secant $\odot S = 66^\circ 32'$	$.03749$	
	Co-secant S Nadir $= 38^\circ 28'$	$.20617$	
	Sine 88. 30'	9.99985	
	Sine 16. 30'	9.45334	
	2 19. 69685		
	Cofine $45^\circ 8'$	9.84842	

Angle $\odot SN = 90^\circ 16' = 6^h. 1'. 4''$, the time

from midnight when the sun is 18° below the horizon. Consequently day breaks at $5^h. 58'. 56''$, and twilight ends at $6^h. 1'. 4''$ on the shortest day at London.

When the declination of the sun, the latitude and declination being of the same name, is greater than the difference between the complement of latitude and 18° , the parallel of declination (\odot SSS \odot) will not cut the parallel of 18° ($\text{ } \odot$ FW) below the horizon: consequently there will be no real night at these times, but constant day or twilight, as is the case at London from the 22d of May to the 21st of July.

Since the sun sets more obliquely at some times of the year than at others, it necessarily follows that he will be longer in descending 18° below the horizon at one season than another.

When the sun is on the same side of the equator as the visible pole, the duration of twilight will constantly increase as he approaches that pole, till he enters the tropic, at which time the duration of twilight will be the longest. It will then decrease till some time after the sun passes the equinox, but will increase again before he arrives at the other tropic; therefore, there must be a point between the tropics, where the duration of twilight is the shortest.

PROB.

PROB. II. To find the Sun's declination at the time of the twilight. Let *ab* (fig. 40.) be the parallel of the sun's declination at the time required; draw *ed* indefinitely near, and parallel to it, and *TW*, a parallel to the horizon, 18° below it; then *vPW*, *vPT* measure the twilight on each parallel of declination; and when the twilight is shortest, the increment of the hour angle being = 0, these must be equal; hence, *vPr* = *vz*, and therefore *vr* = *vz*; and as *rs* = *tz*, and the angles *r* and *z* are right angles, *rvs* = *zvt*; but *Pvr* = 90° = *Zvs*, and taking *Zvr* from each, *PvZ* = *rvs*: for the same reason, *PwZ* = *zvt*; hence *PvZ* = *PwZ*. Take *vce* = *vZ* = 90°, then as *Pv* = *Pw*, and the angle *Pve* = *PwZ*, therefore *Pe* = *PZ*; let fall the perpendicular *Py*, and it will bisect the base *eZ*. Then, by trigonometry, $\text{cof. } P y = \frac{\text{cof. } P v}{\text{cof. } v y} = \frac{\text{cof. } P v}{\text{fin. } e y}$; also, $\text{cof. } P y = \frac{\text{cof. } P e}{\text{cof. } e y} = \frac{\text{cof. } P Z}{\text{cof. } e y}$; hence $\frac{\text{cof. } P v}{\text{fin. } e y} = \frac{\text{cof. } P Z}{\text{cof. } e y}$; therefore $\text{cof. } P v$, or $\text{fin. } h v$, = $\text{cof. } P Z \times \frac{\text{fin. } e y}{\text{cof. } e y} = \text{cof. } P Z$

× $\text{tang. } e y$: hence $\text{rad.} : \text{cof. } P Z$, or $\text{fin. } \text{lat.} :: \text{tang. } e y = 9^\circ : \text{fin. } h v$, the sun's declination at the time of shortest twilight. Because *PZ* is always less than 90°, and *Zy* = 9°, therefore *Py* is always less than 90°, and therefore its cosine is positive; also *vy* is always greater than 90°, therefore its cosine is negative: hence $\text{cof. } P v$ (= $\text{cof. } P y \times \text{cof. } v y$) is negative; consequently, *Pv* is greater than 90°, and therefore the sun's declination is south. N. B. This is M. Cagnoli's investigation, cited by Vince. Astr. vol. i. p. 18.

To find the duration of the shortest twilight. As *vPZ* = *vPe*, therefore *ZPe* = *vPw*, measuring the shortest time. Now $\text{fin. } P Z$, or $\text{cof. } \text{lat.} : \text{rad.} :: \text{fin. } Z y = 9^\circ : \text{fin. } Z P y$, which doubled gives *ZPe*, or *vPw*, and this converted into time gives the length of the shortest twilight.

E. G. At London, N. lat. 51° 32', it is required to find the sun's declination, day of the month, and duration of twilight, when it is the shortest. For the declination:

Rad.	10 000000
Sin. 51° 32'	9.8937452
Tang. 9°	9.1997125
Sine of 7° 7' 25"	9.0934577
Cof. 51° 32'	9.7938317
Rad.	10.0000000
Sin. 9°	9.1943324
Sin. 14° 34'	9.4007007

This doubled gives 29° 8', which converted into time, gives 1^h 56' 32" for the duration of the shortest twilight, supposing it to end when the sun is 18° below the horizon. It may be also found by taking the difference between the time of sun-rise, and day-break, ascertained for the given declination.

PROB. III To find the Sun's declination, when it is just twilight all night. In this case, the sun at *a* (fig. 41.) must be 18° below the horizon; hence 18° + the declination *Qa* = *RQ* = *EH* = *comp. of lat. of place*; hence the sun's declination = *comp. lat.* - 18°. Find therefore in the "Nautical Almanac," or any good Ephemeris, on what

days the sun has this declination, and you have the time required. The sun's greatest declination being 23° 28', it follows that if the complement of the latitude be greater than 41° 28', or if the latitude be less than 48° 32', there can never be twilight all night. If the sun be on the other side of the equator, then its declination = 18° - *comp. lat.* "Gregory's Astron." b. ii. prob. 41. "Vince's Astronomy," vol. i. p. 18, 19. "Robertson's Nav." b. v. prob. 12. "Keith's Trigonometry," book iii. chap. 2.

To find the beginning and end of twilight by the artificial globe. Rectify the globe for the latitude of the place, bring the sun's place on the given day to the meridian; set the hour-index at 12, then turn the globe towards the east till the point of the ecliptic opposite to the sun's place is 18° above the west side of the horizon; the sun's place is then 18° below the east side, and the morning twilight begins, the index pointing at the hour. By a similar method the time of the ending of the evening twilight is found by turning the globe till the point of the ecliptic opposite to the sun's place on the given day be 18° above the east side of the horizon; the sun's place will then be 18° below the west side of the horizon, when the evening twilight ends, the hour-index shewing the time.

Supposing the depression of the sun at which twilight begins or ends to be 18°, it is easy to determine the height of the atmosphere. Let *A E F G* (Plate V. Astronomy, fig. 42.) be the earth, the pointed circle surrounding it the outward surface of the atmosphere, the height of which *DB* is to be found: let *A* be the place of an observer, *bo* his sensible horizon, *HO* his rational horizon; let *I K L M* be the sun, *E N G* the shadow of the earth, *l B* a ray from the upper edge of the sun, touching the earth in *E*, and falling upon the outward surface of the atmosphere at *B*, whence it is reflected to the eye of the observer at *A* in the line of his sensible horizon *B A*: since the sun is larger than the earth, he enlightens a little more than a hemisphere, or that part represented by the arc *E F G* = 180° 32', because, *E C F* + *E C N* = two right angles, and *E C N* is less than a right angle by the angle *E N C* = 16'; consequently, the half of *E F G* or the angle *E C S* = 90° 16'; and therefore taking away *O C S* the sun's depression = 18°, there will remain *E C O* = 72° 16'; and as *A C O* = 90°, *A C E* will be = 17° 44', and *D C A*, its half = 8° 52'. Then in the right-angled triangle *B A C*, the angles and one side *A C* are known, therefore the side *BC* may be found. *A C* being made radius, *BC* will be the secant of the angle *B C A* = 8° 52': therefore 10000000 : 10120948 :: 3967½ the miles in the earth's semidiameter : 4015½ the distance from the centre to the outward surface of the atmosphere, from which subtract the semidiameter, and the remainder, 48 miles, will be the height of the atmosphere. If allowance of 34' is made for the horizontal refraction, the angle *B C A* will be 8° 18', the secant of which is 10105851, whence the height of the atmosphere will be about 42 miles. "Long's Astr." vol. i. p. 260. See ATMOSPHERE.

CREPUSCULUM is sometimes used to denote a small circle drawn parallel to the horizon at 18° below it, where the twilight begins and ends.

CREPY EN LAONNOIS, in Geography, a town of France, in the department of the Aisne, and district of Lafen; 1½ league N.W. of Laon.

CRESCENCI, GIO. BATISTA, in Biography, a Roman marquis, born about the year 1597, who studied painting and architecture under the cavalier Pomerancio. He is said to have designed with much correctness; but he is principally distinguished as a patron of the fine arts, to the advancement of which he devoted his time and his fortune.

Pope Paul V. made him superintendant of the works then constructing in Rome. Crescenci afterwards went to Spain, where he was employed in forwarding the works of the Escorial; besides which he built the tomb of Philip III. He is said to have painted flowers with considerable ability. He died at Madrid in 1660. Lanzi.

CRESCENDO, *Ital.*, from *crefcere*, to increase, a term in *Musical*, unknown till about the middle of the last century. We had long before that time *piano* and *forte*, with their several shades of *piu piano*, and *pianissimo*, *piu forte* and *fortissimo* (which see); but it seems as if Jomelli, who had a good band to write for at Stutgard, introduced the terms *crefcendo* and *diminuendo* into Germany; and they were soon adopted by the symphonists of the Manheim school, such as the elder Hamitz, Holtzhamr, Canabich, Toefchi, Funzt, Filtz, &c. who tried experiments on the minute augmentation and diminution of an orchestra in the aggregate, and succeeded so well as to establish the practice throughout Europe.

The first time we recollect hearing it in England was in an air by J. Chr. Bach, composed for the celebrated tenor, Raaf, to sing at Manheim; but sung here by Ciprandi, an excellent tenor. The words were Metastasio's, in Ezio: "Non so donde vieni quel tenero affetto." This is the history of *crefcendo* and *diminuendo*, which have introduced as much chiar' oscuro in music as painting could boast. A keyed instrument, but above all an organ, by which the *crefcendo* could be obtained, is a grand desideratum in music. Grey has in some degree acquired this power, by a swell of the whole instrument.

CRESCENT, formed from *crefcere*, I grow, in *Astronomy*, the new moon, which, as it begins to recede from the sun, shews a little rim of light, terminating in points, or horns, which are still increasing, till it becomes full and round in the opposition.

The term is also used for the same figure of the moon in its wane, or decrease, but improperly; because the points or horns are then turned towards the west, whereas they look to the east in the just crescent, and because the figure is on the decrease.

CRESCENT, in *Geography*, an island of the South Sea, so called on account of its form, 6 or 7 miles in circumference, and lying in S. lat. 23° 22'. E. long. 225° 30'. The shore of this island is grey coral sand and stones, thrown up by the violence of the sea, forming a wall at the S.E. point, about 20 or 30 feet above the surface; and on this point were three piles of coral stones, two of which were built round and small, and one square, the sides of which might be about 12 feet and 6 in height, with a hole at one side, seemingly for the convenience of creeping into the hole. The natives seen by the missionary voyagers were 25, including three or four women carrying children at their backs; and these were probably all that inhabited the island. They are of a light copper colour and middling stature. The accent of their language is similar to that of the other islanders with whom these voyagers were acquainted. Some were quite naked, except a piece of cloth round their middle; others had a long piece of cloth thrown over their shoulders, and reaching half way down the leg: one, who was perhaps the chief, wore a piece of very white cloth round his head, in form of a turban. They did not seem to have any ornaments. It was difficult to imagine on what they subsisted, as they have neither bread-fruit, cocoa-nuts, nor any fruit-trees whatever: nor on the whole island could one canoe for fish be perceived; so that they must be either transient vi-

VOL. X.

sitors, or, if permanent settlers, miserably provided with means of subsistence. Mission. Voy. p. 116.

CRESCENT, in *Heraldry*, is a bearing in form of a half-moon. The Ottomans bear sinople, a crescent montant, argent.

The crescent is frequently used as a difference in coat-armour, to distinguish it for that of a second brother, or junior family.

The figure of the crescent is the Turkish symbol; or rather, is that of the city Byzantium, which bore this device from all antiquity; as appears from medals struck in honour of Augustus, Trajan, &c.

When the Tartars, to whom Muscovy was subject 200 years, converted any of the churches into mosques for the use of their own religion, they fixed the crescent, the badge of Mahometanism, upon them; and when the grand duke Ivan Basiovitch had delivered his country from the Tartar yoke, and restored these edifices to the Christian worship, he left the crescent remaining, and planted a cross upon it as a mark of its victory over its enemy. See King's Rites and Ceremonies of the Greek Church, p. 23.

The crescent is sometimes *montant*, i. e. its points look toward the top of the chief, which is its most ordinary representation; whence some contend, that the crescent, absolutely so called, implies that situation; though other authors blazon it *montant*, when the horns are toward the dexter side of the escutcheon, in which position others call it *incroissant*.

Crescents are said to be *adossed*, when their backs or thickest parts are turned toward each other; their points looking to the sides of the shield.

Crescent *inverted*, is that whose points look toward the bottom: *turned* crescents are placed like those *adossed*; the difference is, that all their points look to the dexter side of the shield: *conturned* crescents, on the contrary, look to the sinister side: *affronted* or *appointed* crescents are contrary to the *adossed*, the points looking toward each other.

CRESCENT is also the name of a military order, instituted by Charles I. king of Naples and Sicily, in 1268, who gave the knights a collar of fleurs-de-lis, and stars intermixed, and pendent to it a crescent with this motto, "Donec impleat orbem." The order was revived by Renatus of Anjou, &c. in 1464; the badge, or symbol thereof being a crescent of gold enamelled; on which was engraved, *lox, praise*: which, in the style of rebus, makes *lox in crescent*, q. d. *by advancing in virtue, one merits praise*.

CRESCENT, in *Military Language*, an order of battle among the Turks, in which they encamp as well as engage; similar to which was that called by Frontin, "lunata acies," in which a general keeps back his centre, in order to advance his two wings: an example of which occurs in the battle between P. Scipio Africanus and Asdrubal. In this order it appears to have been the aim of a general to avoid engaging in the centre, either because he had weakened it with a view of strengthening his wings, or because he had discovered that the enemy intended to open the action by attacking it. The Turks, in their crescent, propose to surround the enemy with their wings; but, at the same time, they wish to draw him to their centre, where they always place such of their troops as warrant their chief confidence. M. de Maizeroy observes, that the order of the crescent is fit for none but the large armies of rich and populous states; the object of it being to bring a great number of troops to bear against a small one, surround them, and then, as it were, trample them under foot. See TURKS. The Moors also, whose armies are very numerous, and consist chiefly of

Z z

cavalry,

cavalry, draw them up on the same principles with the Turks, and, like them, use the crescent. Of this we have a remarkable instance in the battle of Alcazar, between the Portuguese and the Moors, in which Don Sebastian, king of Portugal, perished with his whole army. The Moorish king, Muley-Moluc, though in a dying state, drew up his troops by his own special orders, and expecting to expire in battle, gave strict command that his death should be concealed, and that his aids-de-camp should ride up close to his litter, and appear to be receiving his orders as usual. He was then carried through all the ranks of his army, where, by his presence and the signs he made to them, he inspired his soldiers with a generous resolution to fight bravely for the defence of their country and religion. The Portuguese, unapprized of any extraordinary art or design in the disposition of the Moorish troops, advanced directly into the hollow of the crescent; and Moluc allowed them to approach, till he saw them near enough to be ferounded: he then gave a signal, upon which all the lines of cavalry, polled on his wings and in his rear, extended themselves, and formed an oval, in which they entirely pent up the Christian army. As soon as the two extremities of the crescent were thus joined, the Moors closed in, and contracted the circumference of their oval, according to a manœuvre to which they were accustomed; and at the same time their artillery began to do its duty. After a very severe engagement, in which great bravery was manifested on both sides, the Moors obtained a complete victory. See Maizeroy's System of Tactics by Maute, vol. ii.

CRESCENT-Shaped, lunatum, or more properly lunulatum folium, in Botany, is applied to that very unusual form of a leaf which resembles a half-moon, whether the points or horns be directed forwards, from the foot-stalk, as in Passiflora lunata, or backwards, towards that part, like some leaves of Sagittaria obtusifolia, and the leaflets, occasionally, of Osmunda Lunaria, or moonwort, a fern so denominated from this resemblance, which however is very slight and uncertain. S.

CRESCENTIA, (from Pietro Crescentio, an Italian writer on agriculture towards the end of the thirteenth century.) Linn. Gen. 762. Schreb. 1021. Willd. 1160. Juss. 127. Vent. 2. 378. Calabash tree. Calabassier, Couis; Fr. Class and order, *dialyspermia angiosperma*. Nat. Ord. *Putaminee*? Linn. *Solanis affinis*, Juss.

Gen. Ch. Cal. Perianth one-leaved, two-parted, short, deciduous; divisions oval, obtuse, concave, equal. Cor. monopetalous, somewhat campanulate, irregular; tube short, inflated on one side, curved or somewhat twisted; border five-cleft; divisions unequal, toothed, undulated. Stam. Filaments four, (sometimes five; Jacq.) the length of the corolla, two shorter than the others, a little curved; anthers incumbent, oblong, obtuse. Pist. Germ superior, egg-shaped, pedicelled; style long; stigma thick, capitate. Peric. Berry large, oval, hard, one-celled. Seeds numerous, two-celled, bedded in the pulp.

Ess. Ch. Calyx two-parted, equal. Corolla gibbous. Berry one-celled, pedicelled. Seeds numerous, two-celled.

Sp. 1. *C. cujete*. Linn. Sp. Pl. Mart. 1. Lam. 1. Willd. 1. "Leaves wedge-lanceolate; fruit obtuse; seeds heart-shaped." 2. *Cucurbitifera arbor, folio longo mucronata*; Pluk. Alm. 123. tab. 171. fig. 1. Comm. Hort. 1. 137. tab. 71. Jacq. Amer. 175. tab. 111. A tree about the height of our pear-tree, and nearly as thick as the human body. Trunk crooked, dividing at the top into numerous, very long, thick, nearly simple, almost horizontal branches. Leaves fascicled, nine or ten together at irre-

gular distances, from five to seven inches long, about an inch broad, narrowing very gradually towards the base, almost sessile, terminating in a long point, entire, smooth, rather shining. Flowers on the trunk and branches, pale white, solitary, of a disagreeable smell; peduncles thick, an inch long. Fruit varying in size and figure on different trees, roundish, from two inches to a foot in diameter, without a point or nipple at the summit, covered with a thin greenish-yellow skin, which encloses a thin, hard, almost woody shell, containing a pale yellow, soft, juicy pulp, of an unpleasant taste. The shell, stripped of the external skin, and emptied of its juice, is used in the West Indies, according to its size, for various kinds of domestic vessels, such as water-cans, goblets, coffee-cups, and, it is said, even for kettles to boil water in, it being so thin, hard, and close-grained, as to stand the fire several successive times before it is destroyed. In the Carolinas and Georgia, there is a vessel of water set in a cool part of every house, with a calabash, prepared for the purpose, swimming in it, for the family to drink out of, as often as they think fit. Its external surface is sometimes finely polished, and ornamented with engraved figures, which are variously coloured with indigo, and other pigments. The pulp is esteemed by the natives a sovereign remedy in several disorders: taken internally, it is supposed to cure dropics, diarrhœas, and inflammations of the chest; applied externally, it is thought serviceable in bruises, burns, and headaches. A native of the West Indies, New Spain, and Guiana. 3. *Cucurbitifera arbor, subrotundis foliis confertis*; Pluk. Alm. 124. tab. 171. fig. 2. Rai. Hist. 1667. Leaves shorter than those of the preceding variety, completely wedge shaped, ending in a very short obtuse point, sessile, fascicled. Fruit often larger than the human head. A native of the same countries. 4. *Cujete minima fructu duro*; Plum. Gen. 23. A middle-sized shrub, with stiff and widely spreading branches. Leaves constantly fascicled, linear-lanceolate, of unequal size, some in the same fascicle being scarcely half an inch long, and others an inch and half, not acuminate. Fruit resembling those of the preceding varieties, but scarcely larger than a pigeon's egg. A native of St. Domingo. According to Du Tour in Nouveau Dictionnaire, it is properly a distinct species. 5. *C. cucurbitina*. Linn. Mant. 250. Mart. 2. Willd. 2. (*C. cujete* 3; Linn. Sp. Pl. *C. latifolia*; Mill. Lam. 2. 111. Pl. 547.; but not the section of the fruit 2, nor the separate seeds *f*, which belong to *C. cujete*. *Cujete latifolia, fructu putamine fragili*; Plum. Gen. 23. Burm. Amer. tab. 109.) "Leaves egg-shaped, petioled, alternate; fruit egg-shaped, acuminate; seeds orbicular, compressed." A middle-sized tree, with a large umbrageous head, nearly upright branches, and a trunk considerably thicker than the human body. Leaves about six inches long and three broad, not fascicled, entire, quite smooth, shining, ending in a short point, on short petioles. Flowers whiter than those of the preceding species. Fruit nearly the shape of a citron, but larger, with a thin brittle shell and whitish pulp. Seeds brown, two-lobed, bitter. A native of St. Domingo. 6. *C. jasminoides*. Lam. 3. (*Arbor jasmini floribus albis*; Catf. Car. 1. 59.) "Leaves wedge-shaped, obtuse, emarginate; flowers funnel-shaped; border equal, five-cleft." A shrub, six or seven feet high, with a stem not thicker than the human finger. Leaves nearly the size of those of the common laurel, coriaceous, stiff, a little folded back at the edges. Flowers in terminal branches, resembling those of the common jasmine, white, with a mixture of red. Fruit yellowish-green, oval, obtuse, peduncled, about the consistence of a soft pear, and containing a pulp not unlike cassia in taste and

and colour. *Seeds* blackish, small, oval or rhomboid. A native of the Bahama Islands. La Marek and Jusſieu have both expreſſed a doubt whether this plant be really a creſcentia; and Ducour is of opinion that it ought to be referred to another genus.

Propagation and Culture.—The calabash tree, being a tropical plant, muſt be raiſed and conſtantly kept in the ſtove. It is eaſily raiſed from ſeed brought over in the ripe fruit. In winter it ſhould be placed in the tan-bed, and ſhould have but little water; in ſummer it requires to be watered two or three times a week, and in hot weather ſhould have a good deal of freſh air. The firſt two ſpecies have been long cultivated in England, but, we believe, have never yet flowered.

CRESCENTIA, in *Gardening*, comprises a plant of the exotic tree kind, the narrow-leaved calabash tree (*C. cujete*). There is alſo a broad-leaved variety, which may likewiſe be cultivated.

Method of Culture.—This ſpecies and variety of the calabash tree are capable of being increaſed by ſowing the ſeeds, procured from the places of their native growth, as ſoon as they are obtained, in pots of light, freſh, rich earth, plunging them into a bark hot-bed. When the plants have attained two or three inches in growth, they ſhould be removed into ſeparate pots of a ſmall ſize, replanting them in the hot-bed. They ſhould be kept in the hot-bed of the ſtove, and have the management of other tender plants of ſimilar growth. In this climate theſe plants have only a ſhrubby growth, being chiefly introduced for the purpoſe of varieties among ſtove-plants.

CRESCENTINO, in *Geography*, a ſmall town of France, in the department of Seſia, which was formerly a part of Piedmont in Italy. It is the chief place of a canton, in the diſtrict of Santhia, with a population of 3962 individuals. The canton itſelf has but 5 communes, and 8175 inhabitants. Creſcentino is ſituated on the river Po, 24 miles N.E. of Turin.

CRESCENZI, DEL BARTOLOMMEO, in *Biography*, fo called from his patron mentioned in a former article. His true name was *Cavarozzi*, and he was born in Viterbo. Bartolommeo was one of the beſt ſcholars of Pomerancio, whoſe ſtyle he ſtudied with great ſucceſs. His beſt works are at Viterbo, where his cabinet pictures are much eſteemed. He died young, in 1625. Baglione.

CRESELLA, a fair Grecian, who chifſelled ſeven ſtatues of Amazons for the temple of Diana at Ephelus. She was accounted the third in merit amongſt the numerous competitors who vied in decorating that famed edifice, being only inferior to Policletus and Phidias. Borghini.

CRESIUS MONS, in *Ancient Geography*, a mountain of Arcadia, N.E. of Megalopolis, and near Tegæa, upon which was a temple of Mars, mentioned by Pauſanias.

CRESPI, BENEDETTO, called *Il Buſtini*, in *Biography*, a painter who flouriſhed in the 17th century. He was a native of Como, and is ſaid to have poſſeſſed no mean abilities. He had a ſon, named Antonio Maria, to whom he taught the principles of his art. Orlandi.

CRESPI, GIO. BATISTA, an artiſt of conſiderable repute, called *Il Cerano* from the place of his birth, a ſmall town near Novara, in the ſtate of Milan. Creſpi was born in the year 1557, and at an early age was taught the art of deſign. His parents ſent him to Rome, and afterwards to Venice; at both which places he ſtaid ſome time to ſtudy the compositions of the moſt eminent maſters. Upon his return, he eſta bliſhed himſelf at Milan, where he acquired the favour of the reigning duke. This prince conferred on our artiſt a penſion and many honours, which were continued to him until the year of his death, 1633.

Gio. Batista Creſpi, was a ſkilful architect, and modelled with great ability. As a painter he poſſeſſed conſiderable talents, joined to great faults. His inventions are novel, his groups well diſpoſed, and his works poſſeſs great force of chiaro-ſcuro; but ſometimes from an affectation, either of grace or grandeur, the attitudes of his figures are extravagant, and the naked parts exaggerated and heavy. One of his beſt pictures is the Madonna del Roſario, in the church of St. Lazzaro at Milan. He was ſome time director of the academy of that city. Lanzi.

CRESPI, DANIELLO, a painter of whom the abbé Lanzi ſpeaks in the higheſt terms, though his works are little known out of the ſtate of Milan. He was born in that city about the year 1590, and at a proper age became the pupil of Gio. Batista Creſpi. He afterwards ſtudied under Camillo Procaccini, and is by many ſuppoſed to have equalled, if not to have excelled, that maſter. Creſpi and his whole family were ſwept away by the plague which raged at Milan in the year 1630.

One of his beſt pictures is the Taking down from the Croſs, in the church Della Paſſione at Milan; but even this is excelled by his laſt works, finiſhed in 1629, repreſenting ſtories of the life of St. Bruno, in the church of the Certosa in the ſame city. Lanzi.

CRESPI, GIUSEPPE MARIA, whom his companions called *Lo Spagnuolo*, from the ſtyle in which he affected to dreſs, a Bologneſe painter of conſiderable eminence, born in 1665. At a very early age he was placed under the tuition of Domenico Canuti, and afterwards became the pupil of Cignani. After having ſtudied the works of the Caracci, and other Bologneſe painters at Bologna, he travelled to Venice, and afterwards to Modena and Parma, where he contemplated thoſe of the divine Correggio. The compositions of Baroccio in Urbino and Pefaro next drew his attention; his deſign being to form a ſtyle of his own, by uniting, as far as he was able, the various excellencies of theſe different maſters.

Giuseppe returned to Bologna, where the fame of his abilities cauſed him to be employed by the principal nobility, for whom he executed many conſiderable performances. He ſpent in that city the remainder of a long life with undimiſhed reputation, and died in 1747.

The talents of this artiſt were of the moſt verſatile kind. His pencil poſſeſſed a facility which delighted to blend the comic even with his moſt ſerious ſubjects. He frequently deſigned caricatures, which he engraved with his own hand. A certain caprice and affectation of novelty diſtinguiſh his pictures, which are very numerous, and diſperſed into different parts of Europe. The gallery of Dresden contained ſome of the moſt eſteemed; amongſt which are the following: “the Seven Sacraments,” in ſeven pieces; “the Virgin, Chriſt, and St. John;” “an Ecce Homo, attended by two Soldiers.” Orlandi. Lanzi.

CRESPI, ANTONIO, and LUIGI, ſons of the laſt-mentioned artiſt, and named as ſome of the beſt of their father’s ſcholars; but though their works were much ſtudied, and compoſed with more ſobriety than thoſe of their father, they never attained his eminence in the art. Luigi, indeed, quitted the pencil for the pen, and wrote many conſiderable works relating to the arts; and amongſt others, the Supplement or 3d volume of the “*Felina Pittrice*.” He died in 1779, and Antonio ſurvived him only three years. Lanzi.

CRESPINI, DE’, MARIO, a painter of the Milanefe ſchool, who flouriſhed about the year 1720. He was a native of Como, and diſciple of Maderno, an artiſt of that city, who is known by his pictures of ſtill life. He, how-

ever, excelled his master in painting flowers, kitchen utensils, &c. after the manner of Bassan. His works are in some estimation in the state of Milan. Lanzi. Orlandi.

CRESPY, or CREPY, JEAN, and LOUIS, engravers and print merchants, who flourished in Paris at the commencement of the 18th century. We have many portraits by these hands, besides numerous plates from Albano, Le Brun, Guillot, &c. Amongst them are the following: "a Head of the Duke of Marlborough," a small upright plate; "a Ditto of Mahomet Effendi, the Turkish Ambassador in France." Heinecken.

CRESPY, in Latin *Crespitiacum*, in *Geography*, a small town of France, in the department of the Oise, 15 miles S. of Compiègne, and 45 N.E. of Paris. It is the chief place of a canton, in the district of Senlis, and contains 2305 inhabitants. The canton itself has 30 communes, and counts a population of 11,401 individuals, upon a territorial extent of 242 kilometres and a half.—Also, a commune in the department of Aisne, 6 miles N. of Laon. Crespy is famous for the peace concluded here, September 18th, 1544, between the emperor Charles V. and Francis I. king of France; for the articles of which, see Robertson's Hist. of Charles V., vol. iii. p. 301.

CRESS, in *Botany*, an English name given to various plants of the class tetradynamia, many of which are eaten in fallads.

CRESS, *Bastard*. See several species of THLASPI.

CRESS, *Bristol Rock*. See ARABIS *strigata*.

CRESS, *Early Winter*, or *Bellife*. See ERYSIMUM *pratense*.

CRESS, *Fine*. See LEPIDIUM *petraeum*.

CRESS, *Garden*. See LEPIDIUM *fativum*. This is the kind commonly used as an ingredient in spring fallads.

CRESS, *Hoary*. See THLASPI *hirtum*.

CRESS, *Indian*. See TROPÆOLUM.

CRESS, *Irish Rusb*. See SUBULARIA *aquatica*.

CRESS, *Narrow Wild*. See LEPIDIUM *sudemale*.

CRESS, *Penny*. See THLASPI *arvense*.

CRESS, *Rock and Shepherd's*. See IBERIS *nudicaulis*.

CRESS, *Speedwell*. See DRABA *muralis*.

CRESS, *Swine's*. See CORONOPUS *ruellii*.

CRESS, *Tower-wall*. See ARABIS *turrita*.

CRESS, *Wall*. See ARABIS *italiana*.

CRESS, *Water*. See SISYMBRIUM *nasturtium*.

CRESS, *Winter*. See ERYSIMUM *barbarea*.

CRESSA, (an adjective, denoting a native of Crete.) Linn. Gen. 313. Schreb. 439. Willd. 502. Juss. 134. Vent. 2. 397. Class, *pentandria digynia*. Nat. Ord. *Undetermined*, Linn. *Convulvuli*, Juss.

Gen. Ch. *Cal.* Perianth five-leaved; leaves egg-shaped, obtuse, incumbent, permanent. *Cor.* monopetalous, falver-shaped; tube the length of the calyx, bellied below; border with five egg-shaped, acute, spreading divisions. *Stam.* Filaments five, capillary, long, attached to the tube of the corolla; anthers roundish. *Pistl.* Germ superior, egg-shaped; styles two, filiform, the length of the stamens; stigmas simple. *Peric.* Capsule egg-shaped, one-celled, two-valved, a little longer than the permanent calyx. *Seeds* ovate-oblong, solitary, or four in each capsule.

Eff. Ch. Calyx five-leaved. Corolla falver-shaped. Filaments attached to the tube. Capsule two-valved.

Sp. 1. *C. cretica*. Linn. Sp. Pl. Mart. 1. Lam. Ill. 183. Willd. 1. (Anthyllis; Alp. Cent. 157. tab. 156. Rai. Hist. 215. Magn. Ch. 212. Quamoclit; Tourn. Cor. 4. Chamæpitys incana, exiguo folio; Bauh. Pin. 249. Lyfimachia spicatae purpure affinis; Pluk. Alm. 236. tab. 43. fig. 6.) "Corollas beardless; capsules with one seed."

A shrub, with a very slender stem, hard and somewhat woody at the base, dividing at the height of one or two inches into a great number of slender ramified branches, which form a close head, five or six inches high. *Leaves* alternate, sessile, very small, numerous, entire, villous, whitish. *Flowers* small, collected into a head at the end of each branch. La Marek suspects that there are naturally two seeds in each capsule, one of them constantly abortive. A native of salt marshes in the island of Candia, the south of France, and Italy. 2. *C. indica*. Mart. 2. Willd. 2. Retz. Obf. 4. 24. "Tips of the corollas bearded; capsules with four seeds." *Flowers* snow-white. It differs from the preceding only in this respect, and those exemplified in the specific character. A native of salt marshes in the East Indies.

CRESSA, in *Ancient Geography*, a port of Asia Minor, in the Doride. Pliny places it 11 miles from the island of Rhodes.—Also, a town of Asia Minor, in Paphlagonia. Steph. Byz.

CRESSANGES, in *Geography*, a town of France, in the department of the Allier; 10 miles S.W. of Moulins.

CRESSERELLE, in *Ornithology*, the name given by Buffon to the Kestrel; Stannel, or wind-hover of other authors; the *Falco tinnunculus* of Gmelin.

CRESETT, any great light on a beacon, in a light-house, or in a watch-tower.

CRESSEY, or CRESSY, HUGH PAULIN, or SERENUS, in *Biography*, an English Catholic divine, and celebrated writer among the Papists, who regard him as one of their ecclesiastical historians, was born at Wakefield in Yorkshire, in the year 1605. At the grammar-school in that town he received the early part of his education, and when he had laid in a sufficient store of classical literature, he was sent to Oxford. He was then only 14 years of age, but he applied with so much vigour to his studies, that in the year 1626 he was admitted Fellow of Merton college. After he had taken his degrees, he entered orders, became chaplain to lord Wentworth, with whom he continued some years, and, in 1638, he went to Ireland, as chaplain to lord Falkland, who, being raised himself to the office of secretary of state, caused Mr. Cressy to be made canon of Windsor in the year 1642, and also dean of Laughlin, but owing to the distracted state of the existing times, he never derived any profit from either of these preferments. After the death of his patron, who was killed in the battle of Newbury, he found himself almost destitute of the means of subsistence, and accepted the proposal of travelling with Charles Bertie, esq. who was afterwards created earl of Falmouth, a favourite of Charles II.; but who was killed in a naval battle with the Dutch soon after the restoration. He left England in the year 1644, and making the tour of Italy with his pupil, he there embraced the Romish religion, and made a public profession of his faith at Rome in the year 1646. At Paris, where he went shortly after, he published an account of the motives of his conversion, which was highly applauded by the devotees to that form of religion. From this period he began to think of devoting himself to a monastic course of life, from which he was dissuaded, but became a member of the Benedictine college of English monks, when he changed his name from Hugh-Paulin for that of Serenus de Cressy. He remained at this college seven years, during which he published a large work on theology, in two vols. 8vo. About the time of Charles the Second's restoration he was appointed to the mission in England, and upon the sovereign's marriage with Catharine the infant of Portugal, was nominated chaplain to the queen, and resided chiefly at Somerset-house in the Strand. He died at East-Grinstead

Grinstead in the year 1674, whither he had retired from his labours and from the controversies in which he had latterly engaged. Although a zealous advocate for the new system which he had adopted, he maintained the character of an open, candid, and good tempered opponent, and secured the respect and esteem not only of those who belonged to his own communion, but of his Protestant adversaries. His principal work was "The Church History of Britanny, from the beginning of the Norman conquest, under Roman Governors, British Kings, the English-Saxon Heptarchy, the English-Saxon, and Danish Monarchy, &c." in folio. The author had intended to have published another volume of this history, bringing it down to the dissolution of the monasteries by king Henry VIII. but his death already noticed prevented the accomplishment of his design. *Biog. Brit.*

CRESSY, in *Geography*. See CRECY.

CREST, in *Armoury*, the uppermost part of the defensive armour of the head; rising over the rest, in manner of the comb or tuft of a cock; to sustain the effort of very keen scimitars, &c. It has its name from *crisla*, *cock's comb*. It likewise denotes a tuft or plume of feathers on a helmet. Anciently those *aigrettes*, which the cavalry wore of a greater height than the infantry, were regarded as objects of luxury and ornament, and of terror to the army. They were originally of horse-hair. Herodotus ascribes the invention of them to the Ethiopians. They still use plumes of bird's feathers, and prefer those of a red colour, on account of its resemblance to that of blood. Sometimes the ancients put three on one helmet to distinguish perhaps different ranks or degrees, as the Turks use double and triple tails.

CREST, CUP, *Crete*, Fr. in *Fortification*, is employed to denote the earth thrown out of a ditch, trench, &c. It is also made use of to express the most elevated part of a parapet or glacis.

CREST, LE, in *Geography*, a town of France, in the department of the Drôme, situated on this river, which divides it north and south, 18 miles S.E. of Valence, 15 N. of Orange, 48 S. by E. of Grenoble, and 432 miles S. by E. of Paris. Its whole population comprises 4500 individuals, but each part of the town is the chief place of a canton, in the district of Die; the northern contains 3800, and its canton 11,307 inhabitants, dispersed in 16 communes, upon a territorial extent of 285 kilometres; the southern contains only 700, and its canton 7081 inhabitants in 12 communes, and upon an extent of 222 kilometres and a half.—Also, a commune in the department of the Puy-de-Dôme, 12 miles S. of Clermont.

CREST, a town of France, in the department of the Puy-de-Dôme, 2 leagues S. E. of Clermont-Ferrand.

CREST, in *Heraldry*, denotes the uppermost part of an armoury; or that part rising over the casq, or helmet.

NEXT to the mantle, says Guillim, the crest or *cognizance* claims the highest place, being seated on the most eminent part of the helmet; yet so, as to admit an interposition of some escrol, wreath, chapeau, crown, &c.

The ancient warriors wore crests to strike terror in their enemies, as the sight of the spoils of animals they had killed; or to give them the more formidable mien, by making them appear taller, &c.

In the ancient tournaments, the cavaliers had plumes of feathers, especially those of ostriches and herons, for their crests; these tufts they called *plumarts*; and they were placed in tubes, on the tops of high caps, or bonnets. Some had their crests of leather; others of parchment, pasteboard, &c. painted or varnished, to keep out the weather; others

of steel, wood, &c. on which were sometimes represented a member or ordinary of the coat; as, an eagle, fleur-de-lis, &c. but never any of those called honourable ordinaries, as pale, fesse, &c. The crests were changeable at pleasure; being reputed no other than as an arbitrary device, or ornament.

Herodotus attributes the rise of crests to the Carians, who first bore feathers on their casqs, and painted figures on their bucklers: whence the Persians called them *cocks*.

The crest is esteemed a greater mark of nobility than the armoury, as being born at Tournaments; to which none were admitted, till they had given proof of their nobility. Sometimes it serves to distinguish the several branches of a family. It has also served, on occasion, as the distinguishing badge of factions. Sometimes the crest is taken from the device; but more usually it is formed of some piece of the arms: thus, the emperor's crest is an eagle; that of Castile, a castle, &c. Families that exchange arms, as the houses of Brunswick and Cologne have done, do not change their crests; the first still retain the horse, and the latter the mermaid.

The crest of the arms of England is a lion passant guardant, crowned with an imperial crown; that of France, a fleur-de-lis.

CREST, among *Carvers*, an imagery, or carved work, to adorn the head, or top, of any thing: like our modern corniche.

CRESTED, in *Heraldry*, is a term applied to a cock, or other bird, whose crest is of a different tincture from other parts.

CRESTED *grass*. See GRASS.

CRESTED *stalk*. See STALK.

CREST-FALLEN, is spoken of a horse, when the upper part of the neck, on which the mane grows, does not stand upright, but hangs either to one side or the other.

CRESTI, DOMENICO, in *Biography*. See DA PASSIGNANO.

CRESTON, or CRESTONO, in *Ancient Geography*, a town of Thrace, and probably the capital of Crestonia, a province of that country.

CRETA, in *Natural History*, and in *Medicine*. See CHALK.

CRETE, in *Ancient Geography*, now called *Candia* from its capital, but known in very ancient times by the names of Aeria, Chthonia, Idæa, Curete, and Macaris, is one of the largest islands in the Mediterranean; and lies between the Archipelago to the north, the African sea to the south, the Carpathian to the east, and the Ionian to the west. Its name Crete is derived by some from the Curetes, who are said to have been its first inhabitants, by others from the nymph Crete, daughter of Hesperus, and by others from Cretus, the son of Jupiter, who is supposed to have reigned here. This island, in remote ages, was celebrated for its fertility; it abounded in all sorts of grain, as its plains were covered with a deep rich soil, and it was plentifully watered by small rivers. The fruits, according to Pliny's account, were much superior to those of any other countries; and its wines have been universally commended. The air was anciently deemed very pure and salubrious, and still retains the same property, though under the Mahometan yoke great part of the country lies uncultivated. From the fruitfulness of its soil, and the purity of its air, it obtained the appellation of Macaris, or the fortunate island. In former times 100 cities were reckoned in this island, 90 before the Trojan war, and 10 more after the Dorians settled here;

here; whence sprung the name of Hecatompolis. Of these 100 cities 40 remained in the time of Ptolemy, for he enumerates so many. The most noted of these were Gnofus, Cydonia, Gortyna, Lycus, Hierapytna, Eleuthera, Rithymna, now Retimo, Héraclea, Præfos, Opteron, and Arcadia. The principal mountain of this island is Ida, and next to this are Diète and Leuci. Its rivers are few and inconsiderable; but this defect is supplied by many creeks and bays, and some capacious and safe harbours. The labyrinth of Dædalus near mount Ida has been recorded among its ancient curiosities, but no traces of it were discoverable in the time of Pliny. The first inhabitants of Crete were, according to Diodorus Siculus, the Idæi Dactyli, 100 in number, who inhabited mount Ida. (See DACTYLI *Idæi*.) Next to these were the 9 Curetes. (See CURETES.) Contemporary with these were the *Titans*, which see. According to several ancient authors, the Curetes and Idæi Dactyli were the same people, and did not settle in Crete till the time of Minos. Bochart supposes, from a similarity between the appellation Curetes and that of Cerethites, a tribe among the Philistines, that they came from Palestine. But long before they settled in Crete a colony of Pelasgians had peopled the eastern coast of the island. After them, Teutamus, the grandfather of Minos, brought thither a colony of Dorians from Laconia, and the territory of Olympia, in Peloponnesus. These inhabitants occupied caves and huts, and subsisted on the spontaneous productions of the earth; but were at last reduced into one kingdom in the reign of Minos, who was their first law-giver, built many towns, and introduced the arts of ploughing and sowing. In the reign of Minos, Rhadamanthus his brother transported several colonies into the neighbouring islands, which he bestowed upon the commanders of his army. The Trojans, as the most ancient writers have said, were Cretans. The government of the Cretans was at first monarchical. The first king, who reigned in Crete, was, according to Eusebius, Cres or Cretes, of whom we have many discordant and fabulous accounts. In the list of sovereigns we find that Strabo and Pausanias distinguish two under the name of Rhadamanthus, and two under that of Minos. The famous Rhadamanthus, who, according to the poets, was judge of the infernal regions, was brother to Minos II. Minos, the famous law-giver of Crete, was the first of the Grecians who equipped a fleet, and gained the dominion of the sea; the father of Deucalion the Argonaut, and also of Androgeus, who was privately murdered by Ægeus king of Athens; in consequence of which outrage Minos denounced war against the Athenians. But finding all attempts to revenge the death of his son unsuccessful, he made his appeal to the gods, who are said to have afflicted the Athenians with pestilence and famine; upon which they consulted the oracle of Delphi, and were informed that they must not expect any relief, till they were reconciled to Minos. The Cretan king, as the condition of their deliverance, imposed upon them a yearly tribute of 7 boys and 7 girls, whom he condemned to be devoured by the Minotaur, during the space of 7 or 9 years. Minos, having for 3 succeeding years exacted this sanguinary tribute, Theseus, who had performed many glorious exploits, voluntarily offered himself to be one of the unhappy victims; and accordingly, sailing with his devoted companions to Crete, he there killed the Minotaur, and rescued his country from the bloody Cretan tribute. Minos was, according to Plato and Aristotle, the institutor of those laws, which they have highly commended. He first banished idleness and luxury from his dominions; and finding means of employment for all his subjects, either at home or abroad, he would not suffer any of them, what-

ever might be their rank, to lead an indolent life; but obliged them either to serve in the army, or apply to agriculture, which he raised into great reputation. In order to establish a kind of equality among his subjects, he decreed, that in each city the children should be educated together, in the same maxims, exercises, and arts; that they should be accustomed to bear hunger and thirst, heat and cold; to ensure themselves to labour and difficulty; to skirmish with each other in small parties, and to exercise themselves in a kind of dance with their armour, which was afterwards called the Pyrrhic. They were also accustomed to the use of the bow, in which they excelled. The poor and rich took their repasts together, and subsisted on the same diet; and the expence of their meals was defrayed by the public; one part of the revenues of the state being applied to the purposes of religion, and the salaries of the magistrates, and the rest allotted for the public feasts. After their repast, the old men discoursed of the actions and virtues of their ancestors, and of such as had distinguished themselves, either by their valour in war, or their wisdom in peace; and the youth, who were present at these entertainments, were exhorted to propose these great persons to themselves, as models for the forming of their manners, and for the regulation of their conduct. Another of the institutions of Minos, which Plato admires the most, was to inspire the youth sometimes with a high respect for the maxims, customs, and laws of their own country. He would not suffer them to question the wisdom of their constitution; but commanded them to consider the laws as dictated by the gods themselves. He paid the same regard to the magistrates and aged persons, whom he enjoined every one to treat with respect and honour: and that nothing might lessen the reverence due to age, he ordained, that if any defects were observed in them, they should never be mentioned in the presence of the youth. Slaves were also better treated at Crete than any where else; for here it was a custom, on occasion of the feasts of Mercury, for the masters to wait on their slaves at table, and to perform the same offices which they received from them during the rest of the year. This custom was designed to remind men of the primitive state of the world, in which all men were equal; and to signify to the masters, that their servants were of the same nature with themselves. The laws of Minos were anciently in such repute, that Lycurgus passed a considerable time in Crete, in order to study the Cretan constitution, that he might form his laws upon the model of those which then obtained in the island. Plato tells us, that Crete, under the government of so wise a prince, became the abode of virtue, probity, and justice; and that the laws which he established were so well founded in justice and equity, that they subsisted in their full vigour even in his time, that is, above 900 years after they had been first published. It is true, the Cretans afterwards degenerated from their ancient probity; and at length, by an entire change of manners, became the most vicious nation that was known either to the Greeks or Latins. Polybius (l. vi.) asserts, that the Cretans in his time were avaricious and selfish to such a degree, as to think no lucre forbid. Suidas and Callimachus (Hymn. in Jov. v. 8.) give them the character of liars and impostors; and justify the character given of them by St. Paul, on the testimony of one of their own poets, probably Epimenides, who paints them in very disgraceful colours. The impurity of their amours is too well known from the accounts given of them by Strabo (l. x.), Servius (*Æn.* l. x. v. 325.), and Athenæus (*Deipn.* l. xiii., &c.) Nevertheless, this change of manners does not affect the probity of the ancient Cretans, nor lessen the glory of their legislator. We cannot forbear mentioning, however,

however, that whilst by his institutions every citizen was obliged to marry, he contrived to prevent their having too many children by very unwarrantable means. Whether in Crete the fertility or extent of the lands did not correspond to the number of the inhabitants, or that the men were more robust, and the women more fruitful, Minos authorized, by his laws, a passion which nature disfavours, and permitted an excess which modesty can never make without horror. (See *Arist.* l. ii. c. 20. *Strabo*, l. x. *Athen.* l. xiii.)

We learn from *Suidas*, that the race of Minos possessed the sovereignty of Crete, till the abolition of a monarchical government. Upon the introduction of a republican form, the chief power was vested in the senate, composed of 30 members, called by *Aristotle* (*De Republ.* l. ii. c. 10.) the public council of the nation. The resolutions of this body, however, were of no force till the people had confirmed them by their suffrages. Next in authority to the senate were the "cosmi," magistrates, as their name imports, appointed for the maintaining of good order (*κοσμοι*) in the state. They were 10 in number, and resembled the Spartan ephori; they were chosen out of the whole body of the people, and were intended as a balance between the people and the senate, and a check upon both; for, without their approbation, no decree had any validity. They commanded the armies of the republic with absolute power, but were liable to be called to account; whereas the senators were not responsible for their administration. Out of this body the senators were chosen. In this condition the island of Crete continued for many years. But it was occasionally distracted by civil contests. In the time of Philip, the father of Perseus, the Gossians and Gortynians had reduced all the other cities of the island, and divided their conquests; so that the Cretans were no longer free, but subject to one of these cities, and obliged to acknowledge their subjection by an annual tribute. (*Polyb.* l. iv.) By these internal commotions the Cretans became skilled in the arts of war; and their reputation in this respect was so general among other nations, that most states and princes always maintained in their armies some bodies of Cretan bowmen and slingers; the Cretans having been, in all ages, as *Pausanias* observes (in *Attic.*), remarkable for their dexterity and experience in the use of the sling and bow. *Xenophon* informs us (*lib.* iv.) that they were of great service in the retreat of the 10,000. And if we credit *Arrian* (*De Exped. Alex.*), many of Alexander's victories were owing to the Cretan auxiliaries. *Livy* also mentions (*lib.* xxxvii. c. 41. *lib.* xxxviii. c. 21.) the advantages which the Romans derived from the archers and slingers of Crete, in the famous battle fought near mount Olympus. After the Romans became acquainted with Crete, they employed the inhabitants in all their expeditions, keeping constantly in their pay a numerous body of Cretan auxiliaries, who, in general, distinguished themselves by their gallantry. (*Livy*, *ubi supra.*) However, notwithstanding the alliance formed between them and the Romans, the Cretans entered into measures with other potentates, without consulting the Roman senate. This conduct furnished the Romans (B. C. 68.) with a specious pretext for enslaving an island, which, till that time, had been free from all foreign subjection. The Romans had formed a purpose of conquering Crete; and finding or feigning an occasion of quarrel, they employed means for this purpose. The Cretans endeavoured to conciliate their enemies; but their ambassadors returned from Rome without succeeding in their embassy. The conditions imposed upon them were so humiliating, that they chose rather to hazard a war, than to enjoy peace upon such terms. As soon as the ambassadors were dismissed, *Metellus* embarked with three legions, and arriving on the

coast of Crete, landed without opposition. Such was the progress of his arms, that the inhabitants of the island were compelled to submit to the Roman yoke (B. C. 66.) *Metellus* changed their form of government; obliged them to live according to the laws of Rome; imposed an annual tribute upon the whole island; and reduced it to a Roman province, after it had enjoyed its liberties for a series of ages. According to *Velleius Paterculus*, *Eutropius*, and other historians, the Romans spent three whole years in this work of subjugation, having to encounter with men no less brave than themselves. *Metellus* was honoured with a triumph, and the surname of *Creticus* or the *Cretan*, so important did the Romans deem this conquest. For the subsequent history and present state of this island, see *CANDIA*.

CRETE, *Sea of*, or *Cretan sea*, is properly that part of the *Ægean sea*, or *Archipelago*, which lies about Crete, and which contained the islands of *Claude*, *Dia*, *Letoa*, *Ægilia*, *Calymna*, *Αίτυπαῖα*, *Thera*, &c.

CRETEA, a country of the *Peloponnesus*, in *Arcadia*, where, and not in Crete, according to *Pausanias*, *Jupiter* was brought up.

CRETHOTE, a town of the *Thracian Chersonesus*, on the borders of the *Propontide*.

CRETI, **DONATO**, in *Biography*, a painter, who was born at *Cremona*, in 1671, and educated at *Bologna*, in the school of *Lorenzo Passinelli*; but, although he is considered one of the best disciples of that master, his style partakes more of that of *Simone da Pesaro*, whose beautiful etchings were the admiration of *Creti*. By studying these, he acquired that delicacy and facility of drawing with the pen, which have rendered his sketches so generally and so deservedly esteemed. As a painter, he is little known out of *Bologna*; but some of his pictures there exist, particularly an altar piece in the church of the *Padri Predicatori*, and the *Fest of Alexander*, in the *Palazzo Fava*, which possess great merit, although the colouring of them is somewhat crude and disagreeable. *Donato* died in 1749. *Lanzi*. *Orlandi*.

CRETIC, **CRETICUS**, in *Prosody*, a trisyllabic foot, consisting of one short syllable between two long ones; as in the words *ἰσχυρῶν*, *quōvō nūc*.

CRETIN, **GUILLAUME DUBOIS**, **DIT**, in *Biography*, an old French poet, was a native of *Lyons*, and died in the year 1525. He was historiographer to the king, under the reign of *Charles VIII.*, *Louis XII.*, and *Francis I.* of *France*. His works were reprinted at *Paris* in 1724. They are full of puns, conundrums, and equivocal expressions, as has justly been observed by *Rabelais* in his *Pantagruel*, where *Cretin* is designed by the name of old *Rominagrobis*. *Nouv. Dictionnaire Historique*.

CRETINS, is the name given in the republic of *Valais* in *Switzerland*, and in the department of *Mont Blanc* in *France*, formerly the duchy of *Savoy*, to helpless idiots, whose organization is so incomplete, that the most pressing wants of life scarcely draw from them any symptoms of sensation. They generally lie on couches, or on the ground, like senseless brutes. Sometimes, says *Mr. Coxe*, in his "Travels through *Switzerland*," they are seen basking in the sun, with staring eyes, open mouths, their tongues half out, and their heads hanging down, exhibiting the most affecting spectacle of intellectual imbecility that can possibly be conceived. *Mr. J. G. Le Maitre*, in his travels after the peace of *Amiens*, saw, at *Martigny* in the *Valais*, innumerable idiots with distorted forms, "grinning horribly a ghastly smile" in almost every window.

According to the author of the "*Recherches sur les Américains*," *Cretins* are deaf, mute, and almost insensible to blows; but they are neither furious nor malevolent; they have

have no other stimulus than their physical wants, are never contradicted or insulted by children, and are approached with veneration by old people.

Every humane attention is paid to these miserable objects, be their parents ever so poor. A fortunate prejudice preserves their excellence. The inhabitants of the countries where they are found imagine that it is a mark of divine favour to have an idiot of this kind born in their family. They esteem them "Blessings from Heaven," and call them "Souls of God without Sin;" because, as they are incapable of intentional criminality, they consider them as certain of happiness in a future state. Instead of neglecting these unhappy mortals, they treat them with the most affectionate kindness, and deprive themselves of common necessities in order to afford all the conveniences of life to these supposed favourites of heaven.

Mr. Coxe says, that these idiots are suffered to marry, as well among themselves as with others. However, Mr. F. J. Durand, in his "Statistique Elémentaire de la Suisse," published at Lausanne in 1795, assures us that they do not perpetuate their race. Their organization is incomplete from their birth, and often in a family of five or six children there is but one cretin. This monstrosity, therefore, cannot, as it has been asserted, arise from the disgusting filthiness of the parents, for the want of cleanliness in the inhabitants of those countries has been greatly exaggerated; and there are cretins in families of the utmost cleanliness and of the first opulence. Nor can it be owing to their physical education; for the idiots from the cradle are fed and brought up like their brothers and sisters, who labour under no intellectual imbecility. Neither can it be attributed to the excessive heat of the valleys, or to the unwholesomeness of the water, since these causes would operate equally on all the inhabitants.

These remarks are amply confirmed by the learned Ramond, in his "Observations sur les Pyrénées." He affirms, that the idiots of the Valais are inferior both in number and imbecility to those of the valley of Luchen, and other valleys in the Pyrenées. "On observing this sad conformity," says he, "who would not suppose that the causes of this degradation must be the same?" And yet the cretins of the Valais are found towards the south in confined valleys, on a moist soil, and having none but stagnant water; whilst, in the Pyrenées, they are mostly in spacious valleys to the north, in an open country, in a dry and temperate atmosphere, and surrounded by pure and limpid springs.

Besides, these idiots are not absolutely confined to the Alps and Pyrenées; they are also met with in other countries, yet not so frequently. Sir George Staunton informs us, in his "Embassy to China," that he found traces of cretinage in a very mountainous district of that country. Some years ago there was at Hull, a female cretin of the name of Southern, and another at Plymouth, a boy, son to Mr. Cowley, the inn-keeper. All that can be affirmed with truth is, that idiots are more abundant in some districts of the Valais, than perhaps in any other part of the globe.

A physician of Lyons, happening to be at Sion, the capital of the Valais, three days after the death of a cretin, solicited, in vain, permission to open the body, although the causes of this extraordinary appearance have not yet been satisfactorily explained. The abbé Richard, in his "Voyage d'Italie," has published several ingenious conjectures on this subject under the article SAVOYE. M. de Saussure ascribes this disorder to the concentrated heat and stagnant air; but for further particulars we refer to the article

GOITRE.

CRETIO, in *Antiquity*, a certain number of days allowed

the heir to consider whether he would act as heir to the deceased or not; after which time if he did not act, he was excluded from the estate.

CRETOPOLIS, in *Ancient Geography*, a town of Asia, in Carabala, a country of Pamphylia.

CREVACORE, in *Geography*, a small town of France, in the department of Sefia, which formerly constituted part of Piedmont in Italy. It is the chief place of a canton, in the district of Vercell. The town contains 919, and the canton 6792 inhabitants, dispersed in 18 communes. Before the revolution it was styled a marquissate, and had a very fine castle.

CREVALCORE, DA, ANTONIO, in *Biography*, a painter, whose family name was Leonelli, but who was called da Crevalcore, from the place of his birth, a town in the Bolognese state. This artist flourished at Bologna in the year 1490, and distinguished himself as a portrait painter. He also represented, with success, fruits, flowers, and animals, and was besides a celebrated musician. Orlandi.

CREVALCORE, DA, PIETRO MARIA, the scholar of Dionigio Calvaert, designed and painted with great bravura at Bologna. His pictures shew that he studied the works of the Caracci with some advantage. He flourished in the year 1580. Lanzi.

CREVASTA, in *Geography*, a town of European Turkey, in the province of Albania; 36 miles S.S.E. of Durazzo.—Also, a river of European Turkey, which runs into the Adriatic, 8 miles S. of Joannina, in the province of Albania.

CREVECOEUR, a small town of France, in the department of the Oise; 15 miles N. of Beauvais, which, before the revolution, conferred the title of marquis on the lords of the manor. It is the chief place of a canton, in the district of Clermont, and has some manufactures of woollen cloth. The town contains 2013, and the canton 11,207 inhabitants, in 20 communes, upon a territorial extent of 155 kilometres.

CREVECOEUR, a Dutch fort and factory in Africa at Acra, on the Gold Coast, situated within cannon-shot of the English fort James, on the extremity of a high rock; the beach for landing being under the fire of the artillery and musketry of the fort. It is a square building, flanked with batteries joined by long curtains, of such irregular construction that it cannot withstand a long attack.

CREVELT, a town of France, in the department of the Roer, which formerly constituted a part of the duchy of Juliers, in Westphalia. It is the chief place of a district, and very neatly built. It has a sub-prefect, a court of justice, a regiller-office, and 7443 inhabitants; several of whom are Memnonites, and whose manufactures of woollen and linen cloth, silk, velvet, ribbands, soap, and tobacco, are exceedingly flourishing. The district has besides excellent pastures, is famous for its good butter, and abounds with all sorts of corn, hemp, and flax. It contains 11 cantons, 192 communes, and 137,215 inhabitants, upon an extent of 1375 kilometres.

CREVIC, a town of France, in the department of the Meurthe, and district of Luneville; 1½ league N.W. of Luneville.

CREVIER, JOHN BAPTIST LEWIS, in *Biography*, was born at Paris in 1693, studied under the celebrated Rollin, was professor of rhetoric at the college of Beauvais; and, after the death of his master, completed his unfinished Roman History in 8 volumes. He also edited Livy, with notes, in 4to., wrote the History of the Roman Emperors, in 6 vols. in 4to., the History of the University of Paris, in 7 vols. 12mo., and a French Rhetoric, in 2 vols. 12mo., which has been reprinted at Liege in 1787. All his

works breathe the purest attachment to the cause of religion and virtue. His style, however, is inferior to that of Rollin. He died at Paris on the 11th of December, 1765, in his 74th year. His observations on Montesquieu's *Esprit des Loix* have sunk into merited oblivion. *Nouv. Dict. Historique.*

CREULLY, in *Geography*, a small town of France, in the department of Calvados; 12 miles N.W. of Caen, and 6 miles E. of Bayeux. It is the chief place of a canton, in the district of Caen, and has a population of 1060 individuals. The canton itself contains 31 communes, and 14,059 inhabitants, upon a territorial extent of 127 kilometres and a half.

CREUS, or CRUZ, *Cape*, a cape of Spain, on the coast of Catalonia in the Mediterranean. N. lat. 42° 29'. Long 19° 53' E. of the peak of Teneriffe.

CREUSE, a river of France, which gives its name to one of the nine central departments. It has its source in the south, in the mountains which border the department of Correze, flows to the north, and, passing by Aubusson, Argenton, Le Blanc, La Roche Pofay, and La Guerche, it throws itself into the river Vienne, below La Haye, at a place called *Le Bec des Eaux*. It takes up the Little Creuse and the Gartempe. The Creuse is navigable only in some places: its course is about 230 kilometres.

CREUSE, *the Department of the*, is the seventh central department of France. Its capital is Guéret. It consists of the province formerly called La Marche, and owes its name to the river Creuse.

To the northwest this department is bounded by that of the Indre; to the north-east by that of the Alier; to the east by that of the Puy-de-Dôme; to the south by that of the Correze; and to the west by that of the Upper Vienne. Its principal rivers are the Creuse, the Little Creuse, the Tardes, Thorion, Ardour, and Gartempe.

The climate is serene and salubrious, but rather cold. The soil is not favourable to wheat, but it produces rye, oats, garden-fruits, and the vine. There are good pastures for horses, cattle, and sheep; coal mines, marble quarries, and mineral springs. The principal trade is in cattle, wool, and cheese.

The department of the Creuse has some capital manufactures of tapestry, coarse woollens, and linen cloth. Its territorial extent is 5794 square kilometres and a half. The number of inhabitants amounts to 216,255, or 751 individuals to the square league. The average contribution of each individual annually is about 4s. 3d. sterling.

Besides the capital, Guéret, the principal towns are Aubusson, Bonnat, Evaux, Felletin, Bourgueuil, and Bouffac.

CREUSIS, in *Ancient Geography*, a maritime town of Bœotia, situated in the gulf of Corinth. It was the arsenal of the Thespians. *Pausanias*, l. ix. Bœotia, c. 32.

CREUSSEN, in *Geography*, a small town of Franconia, in Germany, 9 miles W. of Egra, with a flourishing manufacture of earthenware. It is also called *Crusen*, in Latin *Crusina*, and belonged to the king of Prussia as margrave of Anspach.

CREUTZBERG, or CREUTZBURG, a small town of Prussia, in the duchy of Silesia, on the little river Brinnitz, in the principality of Brieg, 39 miles E. of Brieg, famous for its very brisk trade in honey, bees' wax, leather, and linen cloth. Also, a small town of Saxony, in the principality of Saxe-Edenach, situated on the river Werra, over which there is a handsome stone bridge. The place contains 320 houses and about 1600 inhabitants, whose chief industry consists in agriculture.—Also, a small town of

Prussia, in the circle of Natangen in East Prussia, with an old ruined castle.

CREUTZFELDER, JOHAN GEORG, in *Biography*, a portrait painter, who died at Nuremberg in 1633. We have, amongst many others, the following portraits engraved after this artist: Gottlieb, count of Oettingen, a small plate, by L. Kilian; Philip Gottlieb, count of Hohenloe, a large oval ditto by Haunzelman. Heineken.

CREUTZNACH, in Latin *Cruciniacum*, in *Geography*, a small town of France, in the department of Rhine and Moselle, on the river Nahe, 24 miles S.W. of Mayence. It is the chief place of a canton, in the district of Simmern, and has 3187 inhabitants. The canton contains 17 communes, and a population of 9265 individuals. The salt-springs near Creutznach are very important, and produce annually to the value of from 220 to 230,000 French livres to the public revenue.

CREUTZOFF, a town of the duchy of Courland; 16 miles S.S.W. of Mittau.

CREUX, a term in *Sculpture*, much used by the French; though not yet, that we know of, naturalized among us; but the want of a word of equal import in English, as it has frequently put us under a necessity of using this in the course of the present work; so it pleads strongly for its admission into our language.

Creux originally signifies a hollow, cavity, or pit, out of which something has been scooped, or dug: hence it is used to denote that kind of sculpture, and graving, where the lines and figures are cut and formed within the face, or plane of the plate, or matter engraven on.

In which sense, it stands opposed to *relievo*; where the lines and figures are embossed, and appear prominent above the face of the matter.

CREUZBURG, in *Geography*, a town of Bohemia, in the circle of Czailau; 10 miles N.E. of Teutsch-Brod.

CREW, the company of sailors belonging to a ship, boat, or other vessel.

The sailors that are to work and manage a ship are regulated by the number of lasts it may carry; each last making two tun.

The crew of a Dutch ship, from 40 to 50 lasts, is seven sailors and a swabber; from 50 to 60 lasts, the crew consists of eight men and swabber; and thus increases at the rate of one man for every ten lasts; so that a ship of 100 lasts has twelve men, &c. English and French crews are usually stronger than Dutch; but always in about the same proportion.

In a ship of war there are several particular crews, or gangs, as the boatswain's crew, the carpenter's crew, the gunner's crew, &c.

CREW, NATHANIEL, in *Biography*, an English prelate who flourished in the seventeenth and eighteenth centuries, was born in 1633, and was the fifth son of lord Crew. In the year 1652 he was admitted commoner of Lincoln college in Oxford, where he took his degree in February 1655-6, and shortly after was chosen fellow of that college. At the restoration of Charles II. he became a zealous adherent of the royal cause, and was soon made one of the professors of the university. In the following year he took the degree of doctor of laws, and then went into holy orders. He was elected rector of Lincoln college, and in the following April he was installed dean of Chichester, with which he held the precentorship. He became a favourite of the king, and was appointed clerk of the closet, and in 1671 was raised to the see of Oxford. He had held this situation but three years, when he was elected to the more important bishopric of Durham, which was given him in

consequence of some services rendered by him to the duke of York, to whose measures he seems to have been but too subservient. In 1676 he was admitted to the rank of privy-counsellor; and on the accession of James II. to the throne, he obtained the appointment of dean of the chapel-royal in the room of Dr. Compton, bishop of London, who was rendered unfit by his honest and zealous opposition to popery. The principles of bishop Crew seem never to have stood in his way of preferment; he could change with the times, and join in any acts that his superiors might deem fit to be performed. He was accordingly selected as one of the ecclesiastical commissioners to carry into effect the determinations of James, which finally cost the ill-fated sovereign his crown. In this commission Crew was the abettor of many of the cruel projects which disgraced that age. He took an active part in the suspension of the bishop of London, and in the persecutions inflicted upon Mr. Samuel Johnson, an eminent divine; and he countenanced by his presence another prosecution carried on against Dr. Peachy. In the same year he offered to attend the pope's nuncio at his public entry into London, but it is said his coachman refused to drive him that way. He proceeded on in this course without any remorse, or apparent anxiety, till he found the prince of Orange's party likely to prevail; he then began to contrive means for escaping the punishment due to his misdeeds. When William ascended the throne, the name of Crew was omitted in the pardon granted to those who had been active for the fallen monarch. The bishop absconded, and offered to resign his office if he might be allowed a thousand a-year during life. By the intercession of Dr. Tillotson he was permitted to make his peace, and retain his dignity on very easy terms. In 1691 he succeeded to the title and estates of his late father, owing to the death of the last of his elder brothers, and from this time he passed through life without much notice, and spent his time in works of munificence, hospitality, and charity. He died in September, 1721, aged 88, having held the see of Durham 47 years, and his office as bishop full half a century, which, with the exception of Bourne, archbishop of Canterbury, was a longer period than any Englishman had ever enjoyed that distinguished honour. His lordship died without issue; nor did he leave any works as a literary character to render his name illustrious, and his conduct as a man and a courtier have no claim to the gratitude of posterity. They deserve, however, notice, in order that others may be deterred from acting so inglorious a part when temptations to wealth or to worldly honour are held out to draw them from the line of duty and strict integrity. Biog. Brit.

CREWKERNE, in *Geography*, a market town in Somersetshire, England, consists of five streets, and is situated in a pleasant well-wooded valley, remarkable for the salubrity of the air and the high cultivation of the surrounding lands. The Saxon name was *Crucerne*, derived, according to some topographers, from *Cruce*, a cross, and *Carne*, a cottage. Leland mentions his having seen the former when at Crewkerne, and describes it as then environed by small pillars. The church, with a body and transepts, and a handsome embattled tower, supported by masonry pillars, deserves the antiquary's attention, as it is decorated with many curious sculptures and has a confessional behind the altar. The door of entrance on one side is surmounted by the representation of two swine, intended as emblematic of the polluted soul of the penitent previous to confession and absolution, the purity conferred by which is denoted in the figures of two angels over another door. There are two almshouses, a large charity school endowed by Dr. Hody,

a free grammar school, a work-house, and a handsome town-house, though greatly out of repair. It has some manufactures of dowlas, sail-cloth, girt-web, and ilockings. By the return of the population act, 41 Geo. III., the number of inhabitants was 489, and of persons 2576, of whom 1154 are males and 1422 females, 406 employed in agriculture, and 551 in trade, manufactures, or handicraft. The market on Saturdays is well supplied with provisions and corn, and here is an annual fair in September. Crewkerne is 131½ miles W.S.W. of London. Collinson's History of Somersetshire, 3 vols. 4to.

CREX, in *Ornithology*, the daker-hen or rail of Ray, Willughby, and Albinus, the crane-gallinule of Pennant and Latham, and rallas with red-ferruginous wings of Linnaeus and Gmelin. See RALLUS *Crex*.

CREX is also the name given by Bellonius, Aldrovand, Willughby, and Ray, to the spotted red-shank of Pennant or spotted snipe of Latham, the *SCOLOPAX totanus* of Gmelin, which see.

CREXA, in *Ancient Geography*, an island of the Adriatic sea, on the coast of Illyria, according to Pliny; called by Ptolemy *Crepia*, and now Cherfo.

CRIB, in the English *Salt-Works*, the name given to a sort of case used in some places instead of the drab, to put the salt into as it is taken out of the boiling pan.

These cribs are like hay-racks, wide at the top, and tapering to a narrow bottom, with wooden tops on each side, placed so close, that the salt cannot easily fall through them. Through these apertures, however, the superfluous saline liquor drains out, and leaves the salt, after a few days, dry enough to be added to the heaps that stand ready for sale. At Lymington, and in some other places, they use, instead of these cribs, a sort of wooden troughs with holes in the bottom, through which the saline liquor drains from the salt, and falls into vessels placed underneath to receive it; and in other places they use barrows or wicker baskets, out of which the liquor runs with great ease on all sides at once.

CRIB-biting, a vice of horses; this term is of purely English origin, which is not frequent with the terms used in the management or diseases of the horse, which are for the most part French or Latin strangely corrupted.

The crib denotes, in more modern phrase, the manger, from *manger*, French, to eat; the crib being left for the fodder of the cows, to which the name is at present exclusively applied; the original crib, since oats have been introduced, being fixed to the wall of the stable for the horse, has obtained the name of *rack*, so that the term crib-biting to some would appear improper, to others too antique, or entirely obsolete. The crib-biting horse has generally a lean constricted appearance, the skin being contracted about the ribs, a sunken watery eye, or else too dry; the muscles of the face also, as well as the skin, drawn up with rigidity; when unemployed in eating, his almost constant amusement is to grasp the rail of the manger with his front teeth, then to draw himself up to it as to a fixed point, by a general contraction of all the muscles of the head, neck, and trunk: at the same time the effort is attended with a grunting sound, apparently from air expelled by the mouth; a relaxation succeeds, and then a new effort, flaving the manger very much with the tongue, as the mouth being held open, the saliva naturally takes this direction.

The horse that has contracted this unsightly habit grows lean, his digestion is sometimes impaired, and it is generally conceived he draws a r into his stomach, which is the cause of this; his temper becomes soured, and more or less weakness and unsuitness for service ensue, according to his natural strength;

strength; for some do not appear materially in this respect to be injured by it; while others are obviously rendered much weaker by it, and more incapable of a proper day's work; it appears indeed that horses of a fiery, hot, and unkind temper get the most easily into this vice.

How this extraordinary propensity is first created, has not been, we believe, much attended to; with some it appears to arise naturally, as though the sucking of air gave them pleasure, or a relief from some sort of suffering: at first we imagined pains of the stomach from acidity, or other causes might create it, as horses eat dirt, or gnaw the walls, to alleviate unpleasant feelings of this organ. The bad digestion and foul feeding are probably only a consequence and not a cause of this malady. That horses at all disposed to it may be easily led into it by the practices of the grooms in cleaning them, we have little doubt; if they clean them before the manger, and irritate them with too severe a comb, and in parts where they cannot endure it, they seize upon the manger for a counter action to their sufferings, and in doing this must first get a habit of it, and may extend it to the removing of other pains, or distressful feelings. By this means, especially if the grooms, and some have a happy knack of this, after every bite, put in a blow or stroke of the comb, till they follow each other in regular succession, they create a vice which may or may not continue afterwards, according to the situation and circumstances attending the individual. Some are said to get it by imitation of other horses; whether or not the same practices of the groom applied to several horses in the same stable, should not be rather apprehended to be the cause, we are not assured; in one instance, we think, we observed this satisfactorily enough to be the cause, though it passed for imitation.

To break horses of this vice is difficult; cutting off the end of the tongue has been resorted to by some as a cure for it; the soreness created by this means destroying the inclination to the trick for a time; when the habit once being interrupted, might or might not again return.

Another and more usual way with these horses is to buckle a strap tight about their neck, so tight as to prevent, by the constriction of the throat, the power of doing it, or at any rate, creating sufficient uneasiness to disincline them to it.

In preventing the habit, it appears but reasonable with regard to such horses as are inclined to it, always to turn them from the manger before they are cleaned, with their heads to the heel-posts, or to clean them in the open air, or by other means, to avoid as much as possible irritating those that have preternaturally thin and irritable skins, by too rough an iron comb, and to break through any regular habit of inducing biting after each stroke of the comb, for they learn to do this at first only in the most sensible parts, as the flanks, the inside of the thighs, the belly, &c. and afterwards in every part on the slightest touch of the comb, or even the sight of it. Some horses, it must be admitted, are truly difficult to clean; many also are rendered more so than they need be by inconsiderate rashness, and ill applied severity, to prevent these associations and mischief. Proper precautions cannot be taken too early against a habit of this kind, for once formed, it is not easily afterwards to be subdued, even by great patience and well-judged measures.

In concluding these remarks, we may observe, that in the purchase and sale of horses this vice is not unfrequently a subject of litigation: should we venture to interpose an opinion on the question usually agitated on those occasions, whether a horse be unsound or not, or, in other words, returnable or not with this defect, we should say if the warranty extended to soundness only, the horse is not returnable, as horses are often found with it as to their going; but if vice is stated in the

warranty, the horse is unquestionably returnable, as it may be ranked among the worst of them.

CRIBBAGE, a game at cards, wherein no cards are thrown out, and the set makes sixty-one: it being an advantage to deal, by reason of the crib, it is proper to lift for it; and he who has the least card deals.

CRIBBATH *Lime-works*, in the south-west corner of Brecon county, in South Wales, are the property of Matthew Gwyn, esq. leased to Shearby and Co. who have made a rail-way extension of the line of the Swansea canal, of three-quarters of a mile in length, to reach these quarries, which are situate on the northern edge of the mineral basin or coal district of South Wales. (Phil. Transf. 1806, p. 342.) See SWANSEA CANAL.

CRIBBLE, in *Rural Economy*, a term sometimes employed provincially to signify a coarse sort of meal, which is but very little finer than bran.

CRIBRARIA, in *Botany*, a genus in the class *cryptogamia*, and the order of fungi, formed by Schrader out of the spherocarpi of Bulliard. It has for its essential character a pericarp, the upper part of which has numerous apertures, through which the seeds are ejected in the form of a powder. It contains spherocarpus trichioides, and semi-trichioides of Bulliard, and several other species, all which are found in autumn on rotten wood.

CRIBRATION, in *Pharmacy*, *sifting*; the act of separating the finer parts of a medicine, whether dry or humid, from the grosser; the latter by means of a pulping sieve, the former by a fine sifter.

With respect to cribration, Quincy makes the following remark, in order to obviate the mischiefs and inconveniences which, through inadvertency or haste, frequently happen in the practical shops: which is, that whatsoever is to be powdered, the whole ingredient or ingredients, with all their parts, to be used, should pass the sieve, and be all mixed equally together before any be used. For though neglect of this caution, several medicines which come under this kind of management, will, in their different parts, be of different efficacies, according as that part of most virtue, being more or less friable, may pass through first, which will make that much too strong, or remain behind to the same prejudice. In composition likewise of ingredients of different textures or cohesions, some run through much sooner than others; so that there is an absolute necessity of mixing the whole carefully after all is passed.

CRIBRIFORME, or *Cribrosum os*, in *Anatomy*, appellations which are sometimes given to the ethmoid bone.

CRICELASIA, formed of *κρικος*, ring, and *ελαινω*, I drive, among the Greeks, the exercise of rolling the circle, or trochus. This was a species of exercise in use among the ancients; and is, though not very distinctly, observed by Oribanius, in his Medicinal collections, lib. vi. cap. 26. from Antyllus. It should seem to be little more than driving the hoop, as is now practised by boys. The hoop was so large as to reach as high as the breast of the person who used it: the instrument by which it was driven along was of iron, with a wooden handle; and small rings, *κρικαι*, were fastened to the hoop, to jingle and divert the person who exercised himself with it; which Oribanius considers of importance. This exercise was recommended for rendering the limbs pliable, and strengthening weak nerves.

CRICETUS, in *Zoology*, the name of an animal of the mouse kind; the hamster of Buffon, the German marmot of Pennant, and *Mus Cricetus* of Gmelin, which see.

CRICH, in *Geography*, a vicarage in the hundred of Morleston, in the county of Derby.

The church stands on an eminence, and has a spire of considerable height, which makes it a conspicuous object towards

every quarter but the N.W., in which direction the hill rises, to that high and remarkable isolated mass of lime-stone, on which the round tower or monument was erected some years ago, as a prospect-house. To the geologist, Crich-hill presents one of the most curious and stupendous dislocations of the strata which Derbyshire perhaps any where furnishes; the mineral lime-stone here seen, forming the summit of the hill, is lifted and supported, at not less, perhaps, than 1000 yards above the level of the same stratum surrounding it at a distance on every side. On the N.W. N. and E. sides of the monument-hill or cliff, the lime-stone rock dips in an angle of 30 or 40 degrees, and is soon covered by the shale, grit-stone, and coal-measures, dipping almost equally fast. The town stands upon a considerable tract of the elevated lime-stone, lying nearly in an horizontal position, a fissure passing on its S.W. side, across which we pass in going towards Wirksworth, at once from the surface of the lime-stone stratum to the surface of the second grit-stone stratum, without being at first sensible of any dislocation, although the grit is naturally situate so far above the lime. A new fongle for the draining of the Crich-cliff lead-mines is now driving from Fritchley Brook. To the southward of the town the great lime-works are situate, and kilns, from which the country S. and E. for a great way is supplied with lime, by means of the Cromford canal, from whence a rail-way branch extends up into the works. The stone here burns to a very white lime, and is highly esteemed for agricultural purposes as a manure for building and also as a flux at the several iron smelting furnaces in the neighbourhood. The chase, and a common in this parish of about 200 acres, were inclosed by act of parliament in the year 1786. Here also is a large poor-house, whose plan is worthy perhaps of imitation in other districts; several of the surrounding parishes are joined for its support, and send their paupers hither to work and be maintained, paying a settled sum per week for each to the general fund which is managed by trustees on the spot, who superintend the establishment, and account annually to a general meeting of the parish officers and chief inhabitants of the parishes interested. It is impossible for each small parish to have its *work-house*, as the law presumes, but such are almost sure, for want of proper management, to degenerate into haunts of idleness, vice, and misery: in larger establishments persons of sufficient abilities and of character can be retained as governors and masters, &c. and order, and useful labours by such as are able, may be enforced. There are other similar establishments in Derbyshire.

CRICHTON, JAMES, in *Biography*, who, on account of his very extraordinary talents, obtained the epithet of "The Admirable," was descended from a good family in Scotland, where he was born about the year 1551. He was educated at Perth and St. Andrew's, and made a most rapid progress in the whole circle of sciences, as they were then taught and understood. Mr. Rutherford was, at that time, professor at St. Andrew's, but Crichton was not indebted to him alone for his knowledge. He was educated with James I., and had the advantage of instructions from Buchanan and other celebrated professors: to them, as well as to his own natural powers, he must have owed much, for it appears that before he was 20 years of age he had made himself master of all the sciences, and could speak and write to perfection in ten different languages. He had likewise improved himself to the highest degree in the arts of riding, dancing, and singing, and likewise in that of playing upon almost all sorts of instruments. Thus accomplished, Crichton went on his travels, and we find him first at Paris, where he gave the most splendid proofs of his talents. He invited, by public advertisement, all those who

were versed in any art or science, to dispute with him in the college of Navarre, that day six weeks, by nine of the clock in the forenoon, where he would attend, and be ready to answer whatever should be proposed to him in any art and science, and in any of the twelve languages; Hebrew, Syriac, Arabic, Greek, Latin, Spanish, French, Italian, English, Dutch, Flemish, and Slavonian; and this either in verse or prose, at the discretion of the several disputants. During this time, while the whole strength of the learned was preparing for the contest, Crichton regarded nothing but his amusements; nevertheless, when the appointed day arrived, he acquitted himself beyond all expectation, though the dispute was carried on from nine in the morning till six in the evening. The president, at length, after extolling him very highly, on account of the rare and excellent endowments bestowed on him, rose from the chair, and accompanied by four of the most eminent professors of the university, gave him a diamond ring, and a handsome present of money, as a testimony of respect and esteem. Henceforward he was denominated the "admirable Crichton." A display of a similar kind is attributed to him next at Rome, where he appeared, in the presence of the pope, many cardinals, bishops, and professors of science, and displayed such wonderful proofs of his universal knowledge, that he excited no less surprise than he had done at Paris. At Venice he conciliated the public favour by a Latin poem in praise of the city, and contracted an intimate acquaintance with several eminent literary characters. Among these was Aldus Manutius, who has borne his testimony to the extraordinary powers of Crichton, and who has asserted, that he possessed the knowledge of ten languages, as well as of all kinds of science, and all gymnastic exercises; that he had spoken with the greatest applause before the doge and senate of Venice, and in many assemblies of learned men, who flocked from all parts to behold him, and that, in particular, he had held a solemn disputation before the university of Padua, with the most eminent professors, on a variety of topics, especially the Aristotelian philosophy. He afterwards sustained a scholastic conflict for three days, against all opposers, in any form which they chose. His great reputation caused him to be chosen by the duke of Mantua, preceptor to his son Vincenzo, a dissolute youth, who was suspected of having contrived the death of his tutor. The story has been related very differently; but the following seems to be as near the truth as any: One night, during the time of the Carnival, as Crichton was walking along the streets of Mantua, and playing upon his guitar, he was attacked by half a dozen people in masks: the assailants were unable to maintain their ground against him, and the leader, who proved to be his pupil, being disarmed, pulled off his mask, and besought his own life. Crichton fell on his knees, and expressed his concern for what had happened; alleging, that he had only engaged in self-defence, and that if Gonzaga had any design upon his life, he might be always master of it. Then taking his own sword by the point, he presented it to the prince, who immediately seized it, and with savage fury ran him through the heart. This fatal catastrophe happened in June 1583, and excited the greatest affliction among those who were the friends and associates of the deceased. The high pretensions of Crichton have been accurately and candidly examined by the late excellent biographer Dr. Kippis, who has stated the question with impartiality, but who denies upon good authority, we think, that he has any thing like the claims to celebrity that have been ascribed to him. There is no doubt that he possessed uncommon dexterity of body and quickness of understanding, with a considerable degree of confidence.

"One method," says the candid doctor, "yet remains, by which

which we may be enabled to form a judgment of Crichton's genius, and that is, from the perusal of the four poems of his which are still extant." These, by the fair rules of criticism, will be found possessed of a very moderate degree of merit: they are faulty in language and prosody, and must, according to another valuable writer, ever exclude him from the rank of the eminent and cultivated scholars of that age. These poems are to be found in the notes to the article in the *Biographia Britannica*. And the author of that article concludes with saying, that "it is evident that he was a youth of such lively parts as excited great present admiration, and high expectations with regard to his future attainments. He appears to have had a fine person, to have possessed a peculiar facility in learning languages, to have enjoyed a remarkably quick and retentive memory, and to have excelled in a power of declamation, a fluency of speech, and a readiness of reply. His knowledge was likewise uncommon for his years, and this, in conjunction with his other qualities, enabled him to shine in public disputation. But whether his knowledge and learning were accurate or profound may justly be questioned, and it may equally be doubted whether he would have arisen to any extraordinary degree of eminence in the literary world." *Biog. Brit.*

CRICKEITH, or **CRICAETH**, in *Geography*, a poor borough-town of North Wales, in the county of Caernarvon, situated near the coast of the Irish sea, with a weekly market on Wednesday. It is chiefly distinguished by the ruins of a castle, placed on an eminence projecting into the sea, and presenting a fine view across the bay towards Harlech, and its once magnificent castle: 21 miles S. of Caernarvon, and 236½ N.W. of London.

CRICKET, in *Entomology*. See **GRYLLUS**.

CRICKET is also the name of an exercise, or game, with bats and a ball.

CRICKHOWEL, in *Geography*, a small town, or rather village, of South Wales, in the county of Brecon, situated in a beautiful vale near the river Usk, and the line of the *Brecknock* and *Abergavenny* CANAL, and principally distinguished by an ancient castle, now in ruins. The keep seems to have been a very secure building, seated upon a lofty artificial elevation: 6 miles W.N.W. from Abergavenny, 13 E. S. E. from Brecknock, and 149 W.N.W. from London.

CRICKLADE, a town of England, in the county of Wilts and hundred of Highworth; situated on the river Isis, and near to the line of the Thames and Severn Canal, and also in the line formerly marked out for the intended Thames and Avon canal. (See **CANAL**.) Cricklade is a borough-town, but the inhabitants having been convicted of corruption before a committee of the house of commons in 1782, an act of parliament was passed to disqualify those electors who had accepted bribes, and to extend the right of voting for the future to the freeholders of the several hundreds of Highworth, Staple, Cricklade, King's-bridge, and Malmesbury. It has a weekly market on Saturday; 30 miles W. of Oxford, and 83½ W.N.W. of London. By the last return (41 Geo. III.) Highworth, Cricklade, and Staple contain 1722 inhabited houses, occupied by 1999 families, and the total of inhabitants is 9587, of whom 4539 are males, and 5048 females; 6245 employed in agriculture, and 650 in trade, manufacture, or handicraft.

CRICO-ARYTENOIDEI MUSCULI, in *Anatomy*, muscles of the larynx. See **LARYNX**.

CRICOIDEA CARTILAGO; from *κρίκος*, a ring, or circle, and *ἴδος*, form; a cartilage of a circular form, belonging to the larynx. See **LARYNX**.

CRICO-PHARYNGEUS MUSCULUS. Under this name are described those fibres of the inferior constrictor of the pharynx, which have their origin from the cricoid cartilage.

CRICO-THYREOIDEUS MUSCULUS; a muscle of the larynx. See **LARYNX**.

CRÍ DES ARMES, or *Cri d'Armes*, or *Cri de Guerre*, Fr. the cry or shout of arms, or war-hoop: an ancient custom, which is still preserved by the Turks and other uncivilized nations whenever they go into action. The French, Spaniards, English, and every nation in Europe formerly practised it. The national acclamations were Montjoie and St. Denys for the French, St. James for Spain, St. George for England, St. Malo or St. Yves for the dukes of Brittany, St. Lambert for the principality of Liege, St. Andrew for Scotland, St. Patrick for Ireland, &c. The war-hoop of the savages in America may be considered as of this nature.

Every sort of noise however is now exploded among the nations of Europe, the Turks excepted. When two armies are ready to engage, the soldiers, on both sides, are attentive to the word of command, and a profound silence, till it is given, prevails. And when the action once commences, nothing is heard but the noise of drums, trumpets, and cymbals, of cannon and musquetry.

The French soldiers sometimes call out *tué, tué*, in making any desperate attack, or in charging with the bayonet, or when one battalion or squadron is directly opposed to another. And the Spaniards sometimes bawl out *amal*. Such effusions or exclamations, however, are apt to lead to confusion and disorder.

CRIEFF, in *Geography*, a town of Scotland, in the county of Perth; 17 miles N. of Sterling, and 16 W. of Perth.

CRIEL, a small town of France, in the department of the Lower Seine; 6 miles S.W. of Eu.

CRIER, **COMMON**, an officer in the city of London, to whom, and to the serjeant at arms, it belongs to summon all executors and administrators of freemen to appear, and to bring in inventories of the personal estates of freemen, within two months after their decease; who is also to have notice of the appraisements. He is also to attend the lord-mayor on set days, and at the courts held weekly by the mayor and aldermen.

CRILLON, **LEWIS DE BERTHON DE**, in *Biography*, distinguished as a military character, was born in 1541. He served at the siege of Calais at the age of 15, and afterwards signalized himself in many battles against the Huguenots. In 1571, at the battle of Lepanto, he was wounded, but fixed upon as a knight of Malta to carry the news of the victory to the pope and the king of France. He was a great favourite with Henry III., yet scorned to do a base act at his desire. When Henry urged him to assassinate the duke of Guise, his own, as well as his sovereign's foe, the soldier scorned to be concerned in so foul a deed. By Henry IV., whom he served with fidelity, he was regarded as a brother in arms, and the monarch ever designated him as the brave Crillon, and treated him with the familiarity of a friend; but never rewarded him according to his merits. Ill health obliged Crillon to retire from service, and he spent his latter days in exercises of piety and penitence. He died in his 75th year at Avignon. Many amusing and interesting anecdotes have been told of this warrior; of these we shall mention but one. Being awakened in the dead of night by the young duke of Guise, and informed that the enemy was in possession of the town, he was urged to escape, rather than to become prisoner. Crillon quietly took his arms, and declared

clared he had rather die at his post. When he was apprized that it was a mere trick to try the preference of his mind; he looked sternly at the youth, and seizing him, said, "Young man, never amuse yourself with founding the courage of a man of character. Had I in this instance betrayed any weakness, I would have run you through."

CRILLON, in *Geography*, a small town of France, in the department of Vaucluse, formerly called the Comtat Venaissin; 6 miles N.E. of Carpentras.

CRIM, *ESKI CRIM*, *Crim Staroi*, or *Old Crim*, a small town of the Crimea, from which the whole peninsula has probably derived its name, is situated in a fertile plain on the slope of a mountain, and was doubtless the *Cimmerium* of the ancients. It is remarkable for numerous and extensive ruins. The first that strike the eye on coming from Burunduk are those of two Tartar mosques near the road, a fountain, and the remains of a large Armenian church. Beyond the town are some vineyards of the tockay plant. Its modern name is *Leucopolis*.

The ancient palace of the Chans who resided in this place before they removed to Baktshifarai is in a tolerable state of preservation, and until the year 1800 the Russian bishop of the Taurida inhabited here a very handsome and extensive palace, which had been built for the empress Catharine II. when she made her famous tour through the Crimea.

The beautiful orchards which surrounded Eski Crim are almost destroyed, and few are left of those numerous mulberry trees which induced prince Potemkin to establish a nursery for rearing silk-worms and a silk manufactory near this place. Both establishments have dwindled into nothing. Professor Pallas observes that if ever the Crimea were peopled with colonies of Georgians and Armenians, they would soon increase the commerce of Russia by several hundred poods of silk and promote other useful branches of trade.

All the environs of Eski Crim contain traces of a formerly considerable population. It was considered as the capital of the country by the Genoese when they were in possession of the peninsula. "Pallas's Travels through the Southern Provinces of the Russian Empire," vol. iii.

CRIM *Steppe*. See *NOGAI*.

CRIM *Tartars*, or *Crimskoi Tartars*, a race of Tartars inhabiting the Crimea, who, like the genuine unmingled Tartars from whom they spring, are of a middling stature and lean, the mouth and eyes small, the hair dark brown and the teeth firm and white. Temperance and cleanliness form a law of their religion, which is that of Mohammed. They are extremely hospitable. Their manners are mild and generous. Their *Kaima* Chan, or commandant, is supreme judge of all litigious matters and offences, except cases of murder; and he pronounces without appeal on the sole authority of the Koran. They have some difficulty to accustom themselves to European manners and to the domination of the Russians. Their *murzas*, chiefs, or nobles, generally reside in the country.

The houses in the towns, as well as in the villages, are for the most part of square timbers, having the interstices filled with brick-work or with turf. The chimneys and crannies are made tight with clay and then plastered within and without. Only the mosques, minarets, and baths are of stone, and a few of marble. They have chimnies in the rooms, but no stoves. Their custom is to sit upon low sofas with Turkish coverings and cushions, or upon a clay seat raised a little above the ground and spread with a carpet.

The residence of the chans was at Baktshifarai, which is still the principal Tartar town of the Crimea.

The Tartar mountaineers of Kikensis Limena and Simaus in the south have a particular physiognomy. Their faces are uncommonly long, their noses aquiline and out of all proportion, their heads high and flat at the sides, their beards and hair of a clear brown, reddish, or white colour, which is so very rare in the Crimea. Their feet are admirably light, and they jump from stone to stone like dancers. Their huts are, like those of almost all the inhabitants of the south of the peninsula from Balaklava to Ajushta, built in general against the terraces of the rock and partly excavated in the rock itself, having but two oblique and transverse walls in front; the roof, which is flat, is covered with turf, and is commonly on a level with the terrace of the mountain, so that they can pass from the rock to the roof. The interior of these huts contains a spacious fire place and a tunnel for the smoke. The stony nature of the soil in their vicinity will not admit of their using the great Tartarian wheeled plough; they employ a pole with a ploughshare. To bring their wood for building and fuel down from the mountains they make use of a particular kind of truck called *kafak*, to which they fix two oxen; and these animals, which are generally small, are of the same advantage to them as mules, in ascending or descending the mountains.

The mountain Tartars keep a few horses, which are likewise small, but uncommonly hardy and very surefooted; they have numerous herds of goats, and their sheep, like the goats, are of a small size with a little fat tail, but covered with a very fine wool which might be brought to the greatest perfection by means of Spanish rams.

These mountain Tartars are of an entirely different race, and even their dialect differs considerably from that of the Tartars who inhabit the valleys to the north. They must be the descendants of other nations who had been driven to the peninsula or who came from the sea coast. For this reason those who are properly called the Tartars of the Crimea consider them as foreigners, and give them the contemptuous name of *Tat*. "Tooke's View of the Russian Empire," vol. ii. "P. S. Pallas's Travels through the Southern Provinces of the Russian Empire," vol. iii.

CRIME, a breach or transgression of a law, or an action contrary to the purport of a law, either natural or divine, civil or ecclesiastical: to which a penalty is annexed.

The term crime includes in it the idea of a determination and design formed to do an injury. It is derived from the Latin *crimen*, of *crimare, judico, I judge*.

The Romans distinguished two kinds of crimes; *viz. private*, which only affected particular persons; the prosecution whereof was not allowed by the laws to any but those interested therein; as adultery, &c. and *public* crimes; the prosecution whereof was permitted to all persons, though in no-wise immediately interested.

A *crime*, considered as an act committed, or omitted, in violation of a public law, either forbidding or commanding it, is a term synonymous with *misdemeanor*; and both may be comprehended under this general definition; though, in common usage, the word "crimes" is made to denote such offences as are of a deeper and more atrocious dye; while smaller faults, and omissions of less consequence, are comprised under the gentler name of "misdemeanors" only. The distinction of public wrongs from private, of crimes and misdemeanors from civil injuries, seems principally to consist in this; that private wrongs, or civil injuries, are an infringement or privation of the civil rights which belong to individuals, considered merely as such; whereas public wrongs, or crimes and misdemeanors, are a breach and violation of the public

public rights and duties, due to the whole community, considered as a community, in its social aggregate capacity. In all cases the crime includes an injury; every public offence is also a private wrong, and somewhat more; it affects the individual, and it likewise affects the community. Accordingly, in taking cognizance of all wrongs, or unlawful acts, the law has a double view; *viz.* not only to redress the party injured by either restoring to him his right, if possible; or by giving him an equivalent; but also to secure to the public the benefit of society, by preventing or punishing every breach and violation of those laws, which the sovereign has thought proper to establish for the government and tranquillity of the whole. See PUNISHMENT.

Military crimes and offences are, strictly speaking, those crimes and offences that are cognizable by courts martial, and are described in the articles of WAR, which see.

CRIME, *Quasi*. See QUASI.

CRIMEA, or CRIM TARTARY, anciently the *Chersonesus Taurica*, a southern province of Russia, in Europe, in the government of Taurida, between the 44° 44' and 45° 63' of northern latitude; bounded to the south-west and north-west by the Black Sea, to the east and north-east by the sea of Azoph; and joined to the continent on the north by a narrow isthmus or neck of land; whence it is also called the Crim Peninsula, or Peninsula of the Crimea. This isthmus is not above six miles in breadth from the sea of Azoph, or rather an arm of it called the Sivash, to the Black Sea. The moat which separates the peninsula from the main land is not very wide; in the middle of it is a handsome bridge adorned with the arms of Russia. This moat is only two miles distant from the fortress of Perecop, called by the Tartars *Or-Capi*, which is but an insignificant village. See PERECOP.

As the whole peninsula of the Crimea is connected with the continent by the isthmus of Perecop only; professor Pallas conjectures that the Crimea was formerly detached from it and constituted a complete island; but this must have been at a time when the Black Sea had a much higher bed; and that its bed was higher is sufficiently attested by passages of the ancients. Pliny, in the fourth book of his Natural History, chap. xxvi., says: "Sed a Carcinite Taurica incipit quondam mari circumfusa et ipsa, quo nunc jacent campi; deinde vallis attollitur jugis."

At a very ancient period this isthmus had been fortified in order to protect the peninsula from the irruptions of the Tauro-Scythians. The means of defence consisted of a wall furnished with turrets, from which the place received the Greek name of *Neon Teichos*, or the new wall.

The first known inhabitants of the Crim were *Cimmerians*, a great and martial people of the race of the Thracians. Of all their extensive possessions, which were ravished from them by the Scythians, they retained the Crim the longest. Six hundred and sixty-five years before the Christian æra, they were, it seems, driven from the plain by these their stronger neighbours; but maintained their station in the mountains under the name of Taurians or mountaineers. From them the whole peninsula obtained the appellation *Taurica*.

In the former half of the sixth century Greeks began to settle in the Crim. The Milesians built Panticapæum or Bosphorus, at present called Kertsch, and Theodosia, now called Cassa; and an uncommonly flourishing commerce was carried on here by the Greeks.

About a hundred years afterwards, the Scythians were for the most part exterminated by the Sarmates. The Taurians then extended their dominion over nearly the whole peninsula. They pressed so hard upon the empire of Bos-

phorus, that it submitted 112 years before the birth of Christ to the great Mithridates, king of Pontus, who, subduing the Taurians, made himself master of the whole peninsula.

In the beginning of the Christian æra, the Alans forced the Bosphorian kings to pay them tribute, and drove away the Taurians. They maintained their power about one hundred and fifty years, and were succeeded by the Goths, during whose dominion Christianity was first introduced into the Crimea, in the time of Diocletian and Constantine the Great. But the Goths in their turn were obliged to submit to the Huns, and to take refuge in the mountains, where they had their own sovereigns, who were Christians; and the kingdom of Bosphorus was entirely extinct towards the close of the fourth century.

The Hungarians who, with the Bulgarians, had conquered all the country between the Don and the Dniester, entered the Crimea in 464. The Goths and Alans went to Taman.

The descendants of the Hungarians took the name of Aoulziagrians, and led a wandering life in the Crimea, but were obliged to submit to the Khatyars, who made likewise the Goths in the mountains, and the Grecian towns on the coast, their tributaries.

In the year 840, the emperor Theophilus erected a government at Cherson, to which he subjected all the other towns of the Crimea and Cuban; for though these countries were tributary to the Khatyars, they yet acknowledged the supremacy of the Byzantine court. However, from the time that the Khatyars had first conquered the Crimea, that peninsula had taken the name of Khat or Gatyaria, except the mountainous part, which was called Gothia from the Goths, and Tfikia from the remaining Alans. Jews were then numerous in the Crimea.

The Petschenegers, or Kangleians, in 882, drove the Hungarians from the Crimea, and about the middle of the eleventh century were forced in their turn to fly before the Komanes, otherwise called Uzes, Butyes, Polostzes or Polouzes, who also extorted a tribute from the Greeks and Goths that were left in the Crimea. About this time the town of Sougdaia or Sugdaya, now Sudak, rose into such consideration by its commerce, that all the Grecian possessions in the Crim received the name of Sugdania; and, in 1204, the Greeks no longer acknowledged the supremacy of the Byzantine empire. They submitted to different princes. When the Ottomans made themselves masters of the empire, there existed two principalities in the Crimea, one called Theodor, now Inkerman; and the other Gothia, now called Mangoutc.

At length the Komanes were subdued by the Mongoles or Tartars, in 1237, and from that time the Crim formed a province of the Kaptschakian Tartar empire. The people were governed in clans by their own princes, to whom the name or title of ulutz-bey, or ough-beigh, was given, and who roamed about the plain with their hordes. The Greeks and Goths paid tribute to the Mongoles, as they had before done to the Komanes.

In the beginning of the Tartar dominion, a number of Tcher, Caffes, or Circassians, established themselves in the Crimea in 1333, and Kertsch was governed by a prince of that nation.

While they were masters of Constantinople, the Latins, and especially the Venetians, carried on a very important commerce with the Crim and Taman. But, in later times, the Genoese appropriated it exclusively to themselves, and, in the bloody wars which ensued in consequence, they often gained the superiority. By permission of the Mongoles they

rebuild

rebuilt Caffa, and made that to be the centre of their commerce. They conquered Sudak and Cenibalo, now called Balaklava. They paid duties and imposts to the Mongoles, when they were in full force: but when the hordes were agitated by intestine commotions, they bid them defiance, and even the princes of the Tartars were frequently elected and deposed at the discretion of the Genoese. It was at this period that the trade from India to the Crimea was divided into two branches; one over the Amoor, the Caspian Sea, and through Astrakan to Tana; the other by the way of Bagdad and Tauris to Trebizond and Sevastopolis. Tana belonged to both the Genoese and the Venetians, but under Mongolian supremacy.

In 1441, the Crim was formed into a separate Chanate, under the dominion of the Tartars; and the Chans were descendants from the house of Tschinghis-Khan. The proper founder of the Tartar Crimean state was Mengly Gheray, a descendant of the Tschingises. While yet very young, he had been taken prisoner in an engagement by the Genoese, who caused him to be well educated, and in all respects treated like a prince. On being driven to extremities by the Tartars, young Mengly was sent with some of the principal Genoese to Constantinople, for the purpose of moving Mohammed II. to take them under his protection. The sultan shewed great affection to Mengly, and when the Tartars petitioned Mohammed to give them a Chan of their own, he appointed this young prince, who, in return, acknowledged the supremacy of the Porte. This state of dependence not proving agreeable to the Tartars, Mengly, not long after his arrival in the Crim, was obliged to apply for assistance to the Turks, with which he not only reduced the Tartars to obedience in 1475, but even annihilated the Genoese authority in the peninsula. Elated with his conquests, Mengly was thinking of withdrawing himself entirely from the supremacy of the Porte, when the Turks sent garrisons to the principal towns of the Crimea, and reduced the Chan to a dependence, which, particularly from the year 1584, sunk into a complete subjection. Not contented with keeping strong garrisons in the forts of the Crimea, and setting up and deposing the Chans at pleasure, the Turks shut up the entrance of the Black Sea, to other nations, and completely ruined the commerce of the peninsula.

Under the austere despotism of the Turks, the Crim continued till the year 1774, when the empress of Russia, Catharine II., by the peace of Kutschuk Kainardgi, procured the independence of the Chan of Crim Tartary; and obtained for the Russian empire some strong places on the frontiers as a safeguard against the predatory incursions of the Tartars.

But this pretended independency of the Crimea created new troubles. Sahim Gheray, the Chan who had been placed over the Tartars of that peninsula by the power and influence of Russia, made a more ostentatious display of his attachment and even vassalage, than was suited either to his character as Chan, or to that of the people whom he governed. They had always considered liberty as the most invaluable of human blessings, and preferred a connection with the Ottomans with whom they had been so long united, who were of the same religion, and in conjunction with whom they had shared so much glory and spoil in war, to their new alliance with a Christian nation which they had been in the habit of regarding either with enmity or with contempt. Their discontents broke out in 1781. They elected a new Chan. A civil war ensued. Sahim Gheray was worsted. Russia sent her forces into the Crimea to support him against the rebels. The Russians defeated the usurper, and obliged him to abandon the peninsula. His

adherents were either dispersed or subdued. In 1783, Sahim Gheray abdicated his power and transferred it to Russia, and in the beginning of the year 1784, by a treaty signed at Constantinople between the Russian plenipotentiary Bulgakoff, and the ministers of the Grand Signior, Russia retained the sovereignty of the Crimea, of the isle of Taman, and a great part of the Cuban. In 1787, the empress visited her new provinces, where she was met by the emperor Joseph II. of Germany. But the unfortunate Sahim Gheray was no longer in the Crimea. He had been dragged from the place of his retreat in Moldavia to the island of Rhodes, and was assassinated by the Turks in the house of the French consul, where he had taken refuge.

The principal remains of antique monuments are found in the south-west angle of the peninsula around Sevastopol, or Atkiar, which is true classic ground. The whole of this angle, which is intersected on one side by the port of Atkiar, and on the other by that of Balaklava, was formerly called the *Heracleotic Chersonesus*, from some Greek colonists that came from the town of Heraclea, in Asia Minor. It forms exactly, as Strabo observes, a large cape or promontory. "In littore, præter quod navigatur, meridiem versus expositum est magnum promontorium, continenter porrectum, portio totius peninsulae; inque eo sita est urbs Heracleotarum, colonia eorum qui sunt in Ponto, nomine Cherronesus." And farther, is (portus Symbolon, the port of Balaklava;) "cum alio portu, Ctenuntem appellant," (which can be no other than that of Atkiar), "isthmum constituit, stadiorum quadraginta; is est isthmus, qui parvam peninsulam claudit, quam magnam peninsulae partem esse diximus, et in se habere cognominem sibi urbem Cherronesum." Between the great port of Atkiar and the point of Fanary are four bays, which might form as many ports; "inter urbem," (Cherronesum, adds Strabo,) "et promontorium (Parthenium), portus sunt tres." He, probably, does not reckon the round bay, which is not so convenient for a port. The next to that of Atkiar, and at the same time the smallest of these bays, to the east of which is the town of Korfun, or Cherronesus, is also, at the present time, called by the Tartars Tshortshun, and by the Russians Karantinnaya Bukta, on account of quarantine being performed at this place.

Vestiges of antiquity are scattered in every direction over the whole Heracleotic Cherronesus: but there are no traces of old buildings, except in the vicinity of the monastery of St. George, along the southern coast, where are three remains of a wall and some square and round towers, which probably indicate the place on which stood the wall that, according to Strabo, formerly inclosed the Cherronesus from the port of Balaklava to that of Atkiar to the extent of forty furlongs, or eight versts. "Cum autem hi (Scythæ) et murum quo interclusus erat isthmus ad Ctenuntem aggredierentur, ingestisque calamis fossam impleverit; regii quantum ab his interdium quasi ponte factio fratum fuerat, noctu incenderunt." There is, however, no longer any vestige of a ditch.

Not far from thence are the remains of a singular building which professor Pallas supposes to have been the *Fanum Damonis Virginis* mentioned by Strabo. There are also several frames of stone, in a circular form, which Mr. Pallas takes for the ancient tombs of the Cherronesites.

The most remarkable district, however, of the Cherronesus, in point of antiquity, is the remotest part of the tongue of land called Fanary, which, in some maps, is erroneously denominated Cape Famar; and there is every reason for supposing it to be the ancient Cherronesus of Strabo. "Inter urbem,

ubem, (the new Cherronefus) et promontorium (Parthenium) portus sunt tres; fequitur vetufta Cherronefus, diruta, et poft hanc portus angufto introitu; portus fymbolorum dicitur." Therefore, the fituation of the ancient town muft have been betw. en the latter bay and Balaklava, the port of which was Symbolon, which the Genoefe called Cembalo. Ruins of fortifications, and foundations of large buildings are numerous here. But the light-houfe, at the corner of the moft advanced western point, appears to have been a modern building, and either the work of the Genoefe or the new Cherfonites. The name of Fanary (lanthorn), fufficiently indicates that this tower was ufed as a pharos, from whence the whole cape has derived its name.

The ruins of the new town of Cherronefus, which flourifhed in the time of Strabo, are feen near Atkiar. Mr. Pallas found a fine infcription on white marble, relating to the repairs which the fortrefs underwent in the reign of the emperor Zeno. Broken columns, fculptured marble, and copper and filver coins of the reigns of Gordianus, Aurelian, Aurelius, Conftantine, and even Auguftus, are frequently found, together with remains of enamel and common glafs; but gold coins are fcarce.

Another very remarkable piece of antiquity, but of a later date, is the ancient fortrefs of Inkerman, fituated at the extremity of the bay of Atkiar, with fome very curious caverns; which town Formafioni in his "Philofophical and Political Hiftory of the Commerce and Navigation of the ancient Colonies in the Black Sea," publifhed at Venice in 1789, fuppofes to have been the *Ctenus* of the ancients. But the caverns appear to be the work of the monks, under the emperors of the middle age. Similar cells are obferved in other parts of the Crimea.

When Ruffia obtained poffeffion of the Crimea, the following countries were confidered as forming part of the peninfula, viz.: the eaft and weft Nogaik Tartary between the Dnieper and the Berda, which the Ruffians call the Crim Steppe; an extenfive traft of Bessarabia between the Dnicfter and the Danube, the Black Sea, and Moldavia, called the Budgiak; the Cuban or eafternmoft part of the continent, and the ifle of Taman. But the Crimea itfelf has only 225 Englifh miles in circuit, and its extent does not exceed 1242 Englifh fquare miles. Its climate is mild. Its temperature unequal, but falubrious, the fummer's heat being tempered by frequent winds, and the winter having rarely more than three consecutive days of fevere froft, which never exceeds the tenth degree of Reaumur's thermometer.

Three fourths of the peninfula to the north form an undulated plain, the foil of which varies very much. At its fuperficies, and in its greateft extent, but particularly at the angle between Perecop and Koflof, it confifts of fand combined with clay. In the vicinity of the falt lakes it is of an argillaceous quality.

The whole country from Perecop to the river Salgir abounds with falt marfhes and lakes, from whence the neighbouring Ruffian governments, as well as the Crim itfelf, Anatolia, and Bessarabia, are fupplied with falt. Caffa alone ufed to export 200 cargoes annually.

The Crimea may be divided into the flat country and the mountainous. The former, which extends from Perecop to Koflof, and from the river Bulganak to Karafubazar, Caffa, and Yenikaly, is fprinkled with a number of fmall Tartar villages; which, however, have been greatly deferted fince Ruffia acquired the country. The care which the Tartars take in their towns and villages, to procure water from the heights at a diftance, cannot be too highly commended. They employ tunnels of clay, which run under ground into

ftone refervoirs; the water of which feives to irrigate their gardens, and to fupply the ditches, which carry off the impurities of the ftreets. The Tartarian police carefully watches over this canal fyftem, which, in the Ruffian towns, is fuffered to go to deftruction by careleffnefs and neglect. The mountainous part of the Crimea is towards the fouth, along the Black Sea. The oldeft and higheft mountains extend from Balaklava to the vicinity of Theodofia or Caffa. Their elevated platforms are covered with fnow to the end of May. The Tartars, who feed their flocks on them in hot fummers, call thefe Alps Yaila. The Tibatyrdagh, or mountain of the Tent, near the village of Shuma, or Shumai, is reckoned the higheft of the mountains of the Crimea: its perpendicular elevation is nearly 1200 feet above the level of the fea. No traces of metals have yet been difcovered; but among the calcareous rocks is an excellent marl, of the nature of fuller's earth, of a greyifh colour, and poffeffing the property of foap. The mountains are covered with forefts, which yield excellent fhip timber. The vallies produce all forts of corn, chiefly wheat, barley, and millet; fine garden fruits, and excellent wine, particularly in the neighbourhood of Sudak, where it refembles champaign both in colour and in ftrength.

Elevated plains and agreeable vallies, covered with the fineft verdure, and fituated between perpendicular calcareous mountains, efpecially on the fouth fide of the peninfula, form a moft enchanting fcenery. The valley of Baidari, fo extolled by all travellers, but particularly by the margrave of Anfpach (lady Craven), on account of its charming fituation, was given to prince Potemkin, and is really enchantingly interefting. The fine and rich wood of this valley, which is only interrupted by open and well cultivated lands, confifts of every leafy kind; among which there are fome large oaks and walnut trees. One of the latter, in a garden of the village of Urkuffa, affords in fome feafons from 80 to 100,000 nuts. Mr. Pallas himfelf had one in his garden at Stulu, which was not much fmall; and in the grounds of admiral de Rebas, near the Belbek, was an oak of a monftrous fize, meafuring, at the height of a man, 30 feet in circumference. The valley of Sudak is thickly planted with vines.

From the number of plants mentioned by profeflor Pallas, it appears that the vegetation of the Crimea is extremely luxuriant. The wild horfe-radifh, or *crambe orientalis*, is in particular very abundant between the rivers Salgir and Suga, and often thicker than a man's arm. The margrave of Anfpach affirms, that it is the ftrongeft and beft flavoured horfe-radifh fhe ever tafte; and that the root is as long and as big as the ftouteft leg ever feen by the late margrave of Anfpach.

The two moft confiderable rivers of the Crimea are the Salgir and the Karafu; befides which the peninfula is interfefted by numerous other rivers, as the Alma, Belbek or Kabarta, Byuk or Kafiky Ufen, Aithodor, Bulganack, Badrak, Katfha, Daffafu, Burultfha, which in other mountainous countries would only be confidered as rivulets, but which after a ftorm are really rapid and dangerous torrents.

The prefent capital of the Crimea, for the choice of which prince Potemkin tiffed up with his generals, is Akmetfhet, or Sympheropol. The latter is its modern Greek name. The other towns of the Crimea are Perecop, Baktfiferay, Karafubazar, Mangup, Koflof or Eupatoria, Leucopolis, Inkerman, Baluklava, Aljuchta, Sudak, and Ynikale.

The maritime town of Sevaftopol, or Atkiar, was founded immediately after the occupation of the Crimea by the

the Russians, on account of its excellent harbour. Caffa or Theodosia and Kertsch are reckoned the next best ports.

The peninsula of the Crimea was formerly extremely populous; but the long troubles which preceded its subjection to the Russian empire, have caused numbers of Turks, Jews, Greeks, and Armenians, to emigrate; and the Tartars have since fled in such numbers, that Mr. Tooke rates the population of the Crim, in 1782, at only 50,000 individuals, whose numbers, as it appears from later accounts, have not been considerably increased. Tooke's *View of the Russian Empire*, vol. ii. *Life of Catharine II.*, 2d edition, 1798, vol. ii. *Voyage en Crimée*, Paris, 1802. P. S. Pallas's *Travels through the southern Provinces of the Russian Empire*, vol. iii. *Marguerite of Aspach's* (Lady Craven's) *Journey through the Crimea to Constantinople*, 1789.

CRIMELN, a town of Germany, in the circle of Upper Saxony, and territory of Neudorf: 2 miles N. of Weyda.

CRIMEN FALSI, in *Law*. See **FALSI**.

CRIMHALL, or **CRIMBLE** *P-fing.*, in *Geography*, the extremity of a point of land in Plymouth-dock, in Cornwall. The exact situation of the obelisk was determined, in the government trigonometrical survey in 1795, by an observation from Butterton station, distant 69,376 feet, and bearing $74^{\circ} 7' 9''$ N.E. from the parallel to the meridian of Butterton; and another from Kitt's-hill, distant 63,803 feet: whence is deduced its latitude $50^{\circ} 21' 38''.6$, and longitude $4^{\circ} 0' 53''.3$, or $16^{\circ} 39'.5$ W. of Greenwich.

CRIMINAL CONVERSATION, in *Law*, is used as synonymous with *adultery*.

CRIMINAL Law, is that which discusses the nature of crimes, and inflicts suitable penalties; or, as it is more usually denominated in England, the doctrine of the *PLEAS of the crown*; which see. For the method of pronouncing capital sentence on criminals in the canton of Bern, see **BERN**.

From an account, just now printed, of the number of criminals executed in the city of London and county of Middlesex, from the year 1749 to the year 1806 inclusive, shewing the proportion in each seven years, and distinguishing years of war from years of peace, it appears, that during the seven years of peace which preceded the war of 1756, the number of criminals, executed in the city of London and county of Middlesex, was very considerable, being on an average 43 a year:—in the seven years of war which succeeded, they were reduced to about 15 a year:—in the seven years which followed the peace of 1763, the number again increased, but not to more than 26 a year upon an average:—in the seven years which followed, from the year 1770 to 1776 inclusive, which was likewise a period of peace, the number further increased to 38 a year:—from the year 1776 to the year 1783, a period of war, first with America, and afterwards successively with France, Spain, and Holland, the number, instead of decreasing as in the former war, still further increased, the average being, during these seven years, about 39 a year:—from the year 1783 to the year 1790, a period of peace, the average continued increasing to 54 a year, and the years 1785 and 1787 were great beyond all former example: from 1793, the year in which the existing police establishment was first instituted, to the present period, the numbers appear to have progressively diminished; till within the last seven years the average has not been 12 a-year. This period has, with the exception of one intervening year of peace, been a period of war; but during that year, though the militia was disbanded, some part of the army, and a considerable part of the navy,

reduced, the number of capital convicts does not appear to have increased. The example of the American war, and of the year 1802, are sufficient to prove that the increase of capital offences cannot be traced exclusively or even principally to the different operations of war or peace; though it is natural to suppose that the first may have some effect in diminishing, and the latter in increasing, the number of them.

From an account of the number of criminals executed in the city of London and county of Middlesex, between January 1, 1749, and December 31, 1806, shewing the various crimes of which they were convicted, it appears, that the whole number amounted, within this period, to 1788:—that the number of murders, from the year 1771 to the present period (1808), have remained nearly the same; but that they were considerably more upon an average, in the 20 years preceding:—and that a most important change has taken place respecting the crimes of burglary and highway robbery; these offences in their aggravated character, in which it is found necessary to apply capital punishment to them, having nearly disappeared, within the county of Middlesex. From other statements it appears, that the number of prisoners committed to Newgate during the last six years (from 1802 to 1807 inclusive), charged with criminal offences of various kinds in the cities of London and Westminster, and county of Middlesex, amounted to 6254, of whom 4284 were males, and 1970 females: the total of persons executed in these six years includes 61 males, 7 for murder and 16 for forgery, and 3 females.

From an account of the number of criminal offenders, committed to the several gaols of England and Wales for trial, in the years 1805 and 1806, it appears that in the former year were committed 3267 males and 1338 females, and in the latter year 3120 males and 1226 females; and in the former year 350 received sentence of death, and 68 were executed; and in the latter, 325 were sentenced to die, of whom 57 were executed. From an account distinguishing the commitments in each county, it appears that the number of offenders in the county of Middlesex amounts to more than one-fourth of the whole; and that the number, in proportion to the population, in the counties most contiguous to London, is nearly double the number of the same population in the more remote counties.

It appears likewise, that the northern counties possess a very great advantage, both with respect to the small number of offenders and paupers, when compared with the rest of England. This observation applies, not only to the counties within the northern circuit, but likewise as far as relates to paupers generally, to all the more northern counties. The counties of Lincoln, Nottingham, Derby, and Rutland, the most northern counties in the midland circuit, and those of Staffordshire and Shropshire, the most northern in the Oxford circuit, appear to be, in this respect, in the same comparatively favourable situation as the counties within the northern circuit, when compared with the other more southern counties of England, Middlesex, Monmouth, and Cornwall alone excepted.

CRIMISA, or **CRIMISSA**, in *Ancient Geography*, a promontory of Italy, in the country of the Bruttii.—Also, a town of Italy, in the same country, situated on the fore-mentioned promontory, before Crotona and Thurium, and said to have been founded by Philoctetes. It is now *Ciro*.

CRIMISUS, or **CRIMISSUS**, a river of Italy, in the country of the Salentini, whose mouth was in the gulf of Crotona.—Also, a river of Sicily, which discharged itself into the Hyphas. This river was famous among the ancients for its god, who, in the shape of a dog, found tra-

our in the eyes of Ségesta, and is represented in that form on the Segestan coins. Some have supposed that this was the present San Bartolomeo; but Cluvier thinks that the Belici was, by its size and depth, better adapted to the description given us of the victory obtained on its banks by Timoleon over the Carthaginians.

CRIMMITZSCHAU, in *Geography*, a small town of Saxony, on the river Pleisse, in the circle of the Ertzgebirge, famous for its woollen and cotton manufactures, conducted on the English plan, and provided with excellent machinery. The chief sale of these manufactures is at Leipzig, but great quantities are also exported immediately from Crimnitzschau to Russia, Poland, Turkey, Italy, Spain, and Portugal.

CRIMNOIDES, or **CRIMOIDES**, formed of *crimus*, *bran*, in *Medical Writers*, is used for urine with thick sediments at the bottom, like bran.

CRIMSON, in *Dyeing*, is produced by various processes according to the nature of the substance employed, and the kind of stuff destined to receive the colour. Wool and silk are dyed either with cochineal or Brazil; with the former the colour is more fixed and permanent, and is called the true or fine crimson; Brazil gives a fine colour, but does not resist the action of the sun and air so well.

All the processes for dyeing wool crimson with cochineal may be reduced to two. Either the shade desired is given to cloth previously dyed scarlet, or the cloth is dyed crimson at once.

The natural colour of cochineal is crimson, and it affords this colour both with alum and the solution of tin, when its effects are not modified by the action of tartar, as has been shewn by Bancroft. When cloth therefore that has been dyed scarlet in the usual way is boiled in a solution of alum, the natural hue of the cochineal is restored, and the cloth becomes crimson. Alum, salts with earthy bases in general, the fixed and volatile alkalies all effect this change; the quantity necessary to produce any determinate shade, varies considerably with the nature of the water employed. Some which is loaded with earthy salts will answer the purpose without the addition of alum, or any other substance whatever.

Hellot tried soap, soda, and potash; all these substances produced the colour desired, but saddened it and gave it less lustre than when alum was employed. Ammonia, on the contrary, produced a very good effect; but it evaporates quickly from the bath and requires a considerable quantity. Hellot replaced the use of it, by adding equal quantities of muriate of ammonia, or common sal ammoniac, and potash; the ammonia was disengaged in the bath, and in this way the cloth instantly took a very bright colour. He asserts that the colour is so much heightened as to render less cochineal necessary. Mr. Poerner has given nearly the same process. He directs the cloth to be boiled an hour in a solution of common salt in the proportion of 2½ ounces to 1 lb. of wool, and to let the cloth remain in it 24 hours after it is become cool. A bath is prepared with 1 ounce of cochineal, 2 drams (gros) of tartar, and 2 ounces of solution of tin for every pound of cloth, and in this it is boiled one hour. When washed it is steeped in a vat, in which equal quantities of sal ammoniac and potash, in the proportion of 6 drams of each to a pound of cloth, have been previously dissolved; it is suffered to remain here 24 hours, frequently turning and moving it in the liquor. It is afterwards taken out and washed. The colour is a reddish crimson inclining to blue.

This mode of producing crimson by the action of alkalies or alum, is generally resorted to when cloth dyed scarlet

has been stained or spotted by accident. These defects are thus remedied or rendered less glaring. Muriate of soda, or common salt, has also the property of converting scarlet to crimson, and has long been used for this purpose in Languedoc, according to the testimony of Hellot.

To dye crimson at once, a solution of two ounces and a half of alum, and an ounce and a half of tartar to every pound of cloth, is used for the boiling; the cloth is afterwards dyed with 1 ounce of cochineal. Solution of tin is commonly added, but in less proportion than for scarlet. The processes employed vary greatly according as the shade required is deeper or lighter, or more or less removed from scarlet. Some use common salt for the boiling.

Mr. Poerner directs the boiling to be made with 3 ounces of common salt and 3 of alum, to 1 pound of cloth, and after suffering it to remain 24 hours in the solution after cooling, to boil one hour in a bath composed of 1 ounce of cochineal, 2 drams of tartar, and 2 ounces of solution of tin. The cloth takes a reddish crimson.

A bright reddish crimson of very agreeable hue may be obtained by boiling 1 lb. of cloth a full hour in a bath prepared with 3½ ounces of alum and 2½ ounces of tartar, suffering it to remain 24 hours in the liquor after cooling. Then boil an hour and a half in a bath composed of 1 ounce of cochineal only, without any other ingredient. If this cloth be steeped 24 hours in a cold solution of 1½ ounce of sal ammoniac, and 1½ ounce of potash in 20 lbs. of water, the colour becomes deeper, and another shade of crimson is by this means obtained.

Archil and potash are frequently used for saddening crimsons and giving them more bloom, but the hue thus imparted soon vanishes.

The boiling for crimson is sometimes made after a scarlet dyeing, by adding alum and tartar to the bath, and some particular shades of crimson are said to possess more bloom when dyed this way, than when fresh baths are used.

Crimsons in half grain are sometimes dyed by substituting madder for half the quantity of the cochineal, following in general the same processes as for the grain crimson. Other proportions of madder may be used instead of half, according to the effect required.

The colour produced by Brazil is not so permanent on wool as cochineal, it is nevertheless employed. The cloth is boiled in a solution of alum, to which a fourth of its weight, or even less of tartar is added. A greater proportion of tartar inclines the colour too much to the scarlet or yellow hue.

The cloth thus impregnated should remain several days in a cool place; after which it is dyed by boiling gently in Brazil liquor. The colouring matter which is not deposited does not yield so fine a colour, the coarsest goods should therefore be passed through the bath first, and afterwards the finer ones. In this way a colour is obtained which stands the action of the air tolerably well.

Mr. Poerner directs 1 lb. of cloth prepared with 5 ounces of alum, and 1 ounce of tartar, to be boiled one hour in a bath containing 6 ounces of Brazil, and 6 ounces of alum. The cloth acquires a deep brick red. When steeped 24 hours in a cold solution of potash, it becomes a fine reddish crimson. By preparing the cloth with alum and tartar, Mr. Poerner observes that very good and useful colours may be obtained from Brazil, which are deeper and richer than those obtained on cloth prepared with alum, tartar, and solution of tin, or with tartar and solution of tin without alum. By varying the proportion of the ingredients, and still more by the action of potash and sal ammoniac, these shades of crimson may be greatly modified. Colours obtain-

ed from Brazil may thus be rendered tolerably permanent, yet they are not comparable in this respect with those obtained from cochineal or madder. A bloom is sometimes given to madder colours by passing them through a decoction of Brazil, but this slight tinge soon fades and perishes.

Mr. Gahlische gives a process, by which he pretends that fine and more permanent colours are obtained than by those in general use. He directs pure vinegar, or aceto-citric acid, or aqua regia, to be poured on Brazil rasped or chipped, till it is covered with the liquor; the mixture to be well shaken, then left to settle for 24 hours, after which it must be decanted, filtered, and kept for use. On the residuum, fresh water or vegetable acid is to be poured, and this to be repeated till all the colouring matter is extracted, when the wood will be found to be black. All these liquors are then to be mixed together for use.

The stuff having been prepared with a slight galling of sumac, or white galls, is slightly alumed. After rinsing, it is entered wet into a bath prepared as follows: Some of the acid solution of Brazil is diluted with water proportionate to the quantity of stuff, or the shade of colour to be given. When this is so hot that the hand will just bear it, solution of tin is poured in till it is of a fire colour: it is then stirred and the stuff entered. In half an hour it is taken out and washed. The remainder of the bath may be used for lighter shades, but those stuffs only must be galled that are for deep ones. The aceto-citric acid, as it is called by Berthollet, is a liquor of which Mr. Gahlische makes great use in dyeing under the name of vegetable acid spirit, which he prepares in the following manner: He takes any quantity of lemons; those of which the rind is rotten will do, remove the peel and the skin that adheres to it, and slices them into a vessel, which should not be made of wood. He sprinkles them with a quantity of good vinegar, and then squeezes out the liquor through a flannel by means of a press, and filters the expressed liquor through paper. It may be used with success in this state, but it is apt to grow mouldy and the acid is watery. In order therefore that it may keep, and not dilute the baths into which is put, he directs it to be purified and concentrated as follows: The liquor is to be exposed to the sun till a sediment forms and it becomes clear, it is then to be filtered and distilled on the sand bath. The receiver is to be changed when the liquor that drops becomes acid, and the distillation continued till oily streaks are perceptible in the neck of the retort.

The acid found in the receiver is to be kept for use.

On the foregoing process for obtaining aceto-citric acid, we shall observe that if the acid be used in its recent state, as expressed from the lemons, it is indeed a mixture of citric and acetous acid, but the rectified and concentrated spirit of Mr. Gahlische is, after all, nothing but distilled vinegar. Citric acid will not rise in distillation; it may be decomposed by heat, but cannot be driven on like acetous acid; this process of rectification is therefore a separation of the acid of the lemons from the vinegar they were sprinkled with, and proves the inutilty of one of the ingredients at least of this composition. Of the efficacy of galls in rendering the colouring matter of Brazil more permanent there can be little doubt, but it has a tendency to debase the colour, and it is with reason, that Mr. Gahlische observes that the galling should be employed only for the deeper shades.

Silk acquires from cochineal a colour which is distinguished from the false crimson obtained by means of Brazil.

Silk intended for cochineal crimson ought not to be boiled with more than 2elb. of soap to 100 of silk, as the yellow cast which silk has when imperfectly scoured is favourable to this colour. It is sometimes imparted to it

by a slight tinge of annotto, when white silk is to be dyed crimson.

When the silk is well cleaned from the soap by washing, it is soaked in a strong solution of alum, in which it is generally left all night, and next day is wrung, washed, and twice beetled at the river.

The bath is prepared as follows: Into the dyeing vessel, half, or two thirds filled with boiling water, from one to two ounces of pounded white galls are thrown in for every pound of silk. After boiling a few minutes, two ounces of cochineal or more, according to the strength and fulness of the shade required, are added for every pound of silk, and for every pound of cochineal, one ounce of tartar. When this is dissolved, an equal weight of the solution of tin is added; the ingredients are all well stirred, and the bath filled up with cold water. The proportion is generally about eight or ten quarts to every pound of silk. In this the silk is entered and worked till it appears quite uniform in colour; the fire is then increased, and the bath made to boil two hours, turning the silk from time to time. The fire is then withdrawn, and the silk left in the bath a few hours longer. It is then washed at the river, twice beetled, wrung, and dried. The solution of tin for this process ought to contain more tin than is used in the composition for scarlet, otherwise the colour is too bright, and not sufficiently full and deep. Macquer directs the solution to be made with one pound of nitric acid, two ounces of sal ammoniac, two ounces of tin, and twelve of water.

If the colour is to be faddened, the silk after washing is passed through a solution of sulphate of iron, more or less strong, according to the shade required: if the crimson should have a tinge of yellow, a greater or less proportion of the decoction of fustic must be added to the solution.

White galls are preferred, because the black or blue galls debase the colour of the cochineal; and even white, when used in too great a quantity, dull the crimson very much. Macquer pretends that the galls serve only to increase the weight of the silk; their general effect, however, is that of giving greater permanency to the colours, and in crimsons of the deeper shades their use is indispensable.

The quantity of solution of tin employed in the foregoing process is very small. If used in the bath in the same proportion as for dyeing wool scarlet, the silk would lose its lustre, and acquire but a faint colour. Macquer and Scheffer have however each published processes for dyeing silk rose or poppy colour, which differ only in a few particulars from the ordinary mode of dyeing scarlet, the solution of tin being employed cold to avoid its strong action on the silk.

In the process which Macquer published in 1768, the solution is prepared by adding three ounces of tin by little at a time, to a mixture of four ounces of nitric, and two of muriatic acids. When the solution is finished, 6 lbs. of silk that have already had a slight ground of annotto, are immersed, and remain in it half an hour. It is then wrung and washed till it no longer renders the water turbid. It is dyed with four ounces of cochineal, and one ounce of tartar, for every pound of silk. These are boiled up in water, and afterward cooled down till the hand can bear the heat. The silk is then entered, and the fire increased; after boiling one minute it is withdrawn and washed. By this process the silk has acquired an increase of one fourth of its weight. Its colour resists soap, and is much more permanent than that which Carthamus affords.

In 1751, Scheffer published a description of the following process. He dissolved one ounce of tin in a mixture of

four ounces of nitric acid, and one of common salt. The solution was diluted with twice its quantity of water, and the silk steeped in it 24 hours. When withdrawn it was washed till the water no longer appeared milky, and dyed with four fifths of its weight of cochineal in a small quantity of water. The bath retains a considerable portion of colouring matter which may serve for dyeing silk a lighter shade, or even for dyeing crimson by the ordinary process. It may be used also for dyeing wool.

Scheffer describes the following varieties of his process for obtaining different shades. If the silk be wrung out of the solution of tin, left all night in a cold solution of one ounce of alum in a quart of water, wrung, dried, washed, and afterwards dyed with cochineal, it will take only a pale poppy colour. If the silk be steeped twelve hours in the solution of tin diluted with eight parts of water, and then left all night in the solution of alum, washed, dried, and passed through two baths of cochineal as before, adding to the second bath a little sulphuric acid, the colour will be a fine poppy red.

In the experiments made by Berthollet on this subject, the solution of tin, which answered best for dyeing silk, is that which he has directed for the scarlet dye, and is made by dissolving slowly in one pound of nitric acid, two ounces of tin, and two ounces of sal ammoniac; the salt to be dissolved first, and the tin added afterwards in small portions at a time, stirring it frequently to incorporate the solution fully. When finished and decanted from the black sediment which is deposited, it is diluted with one fourth of its weight of water. The nitric acid employed should be of the strength of 30° of the hydrometer of Beaumé, which corresponds with a specific gravity of about 1.26.

Solutions containing a greater proportion of tin gave deeper shades. The colour obtained by the above, was a fine cherry colour sufficiently bright.

Brazil wood is used for dyeing silk what is called *falfe* crimson, to distinguish it from that produced by means of cochineal, or *grain* crimson, which is much more permanent. Vinegar is used to distinguish the true colour from the false, but this proof is fallacious, since the Brazil crimson dyed with the solution of tin, resists the action of vinegar like cochineal, though that dyed with alum does not.

Silk intended for this crimson, should be boiled with soap in the proportion of twenty pounds to a hundred of silk, and afterwards alumed. Less alum is required for this than for grain crimson. After rinsing in the river, it is passed through a bath more or less charged with the decoction of Brazil according to the shade required. If water, free from earthy salts, be used, the colour is too red for crimson; the proper hue is given to it by passing the silk through a slight alkaline solution, or by adding a little alkali to the bath.

Working the silk in hard water till it has acquired the proper shade, will answer the same purpose.

Logwood liquor may be added to the Brazil, to deepen the shade of crimson, and a little alkali used with it also when the shade desired requires it.

There is the same objection to the use of the solution of tin in dyeing silk crimson with Brazil as with cochineal; silk has not that powerful attraction for the colouring matter combined with tin that wool has; the greater part therefore separates and contracts no union with the stuff. Bergman, however, remarks that the colours imparted to silk by different dye woods, may be much improved by steeping the silk in a cold solution of tin. A strong decoction of Brazil, says he, gives to yellow silk prepared in this way a scarlet colour inferior indeed to that of cochineal, but finer and more permanent than if it be steeped in alum only, and as

capable of standing the proof by vinegar as crimson or poppy in grain. Mr. Guldiche describes a process, in which he uses solution of tin in the bath to give silk a fire colour. He directs the silk to be galled with a solution of galls in white wine, asserting that an astringent solution thus made preserves the brightness required in silks much better than one prepared with water. With this solution he mixes water till it has acquired a yellow colour, and impregnates the silk well with it, leaving it to steep cold for several hours. He then presses out the liquor strongly, but without rinsing the silk which he dries, and afterwards soaks for twelve hours in a solution of alum, containing four ounces for every pound of silk. The silk taken out of the alum water is wrung, and entered wet into a bath of Brazil, after adding to it an ounce of solution of tin. The remainder of the bath may be exhausted for lighter shades. If the colour be required more approaching to orange, the silk is not to be galled, but to be alumed cold with two ounces of alum to the pound of silk, after which it must be dyed orange with annotto, without boiling, and before it dries dyed in the Brazil bath. The author confesses that these colours, particularly the latter, are not very permanent. For rose colours he omits the galling, and for the aluming uses only two ounces of alum to the pound of silk. For light shades he recommends the solution of alum to be decanted from the sediment that may have been deposited, and prefers dyeing them cold, using a bath richer in colour. The silk is to be taken out as soon as it has acquired the proper tint, and the bath may be exhausted for other shades. With these precautions he assures us, that fine colours of tolerable permanency may be obtained.

The crimson imparted to cotton or linen by cochineal and Brazil, has little solidity, and is on that account but little used, more especially as madder imparts to these substances, properly prepared, one of the most beautiful and permanent colours which the art of dyeing can produce.

As this however is not the place in which to enter into a detail of the operations of the Turkey or Adrianople red, which we purpose to treat at large under another head, we shall give some account of the processes that have been proposed and practised with more or less success for producing a fine crimson colour upon cotton by means of cochineal and Brazil.

Mr. Poerner has made many experiments with different mordants, as alum, solution of tin, sal ammoniac, potash &c. for dyeing cotton with Brazil, used either in the bath or in the preparation of the cotton. He could not produce a colour, however, that would stand washing with soap, though some would stand the action of the air and washing with simple water very well. He recommends cotton thus dyed, to be dried in the shade.

Mr. Berthollet received from Mr. Brown the following process for dyeing cotton a crimson colour, which is used by some manufacturers.

A solution of tin is prepared in the proportion of nitric acid two pounds, muriatic acid one pound, tin eight ounces and water one pound. The liquids being well mixed, the tin is added by little and little. For a piece of cotton velvet weighing fifteen or sixteen pounds, a bath is prepared consisting of boiling water four parts, strong decoctions of galls two parts. Having raked up the bath, the piece is entered and worked for half an hour, and left to soak two hours, when it is taken out and left to drain. Another bath prepared with three buckets of boiling water, and one of decoction of Brazil wood, also boiling, is to be raked up and the piece worked in it an hour. This bath is to be thrown away, the vessel washed out and then filled with a pure decoction

of the wood, in which the piece is to be worked half an hour, and then raised on the winch. A bath of very clear river water, with a quart of solution of tin, being prepared and raised, the piece is to be worked in it a quarter of an hour. It is then wound on the winch, and let on the vessel containing the decoction of Brazil, one sixteenth of which is to be taken out and replaced by an equal quantity of boiling decoction. This being raked, the piece is worked in it half an hour, wound on the winch and carried back to the vessel containing the solution of tin. These operations are performed alternately six or eight times, observing each time to take out a sixteenth of the bath of Brazil wood, and replace it with an equal quantity of boiling decoction of the same wood, to rake the bath of composition each time, and to finish the dyeing with the latter. The piece is to be washed in the river, and dried in a dark place.

With the aluminous mordant cotton takes a full and tolerably bright crimson from Brazil, the permanency of which is considerably increased by previously subjecting the cloth to the operation of galling. The printer's mordant prepared with acetite of lead and alum, is best for this purpose. When used diluted, the shades of crimson and rose colour are very delicate, but so fugacious as not to support the action of the sun and air unimpaired a single day. Sumac used in the bath along with Brazil contributes greatly to its fixity; the stronger shades dyed this way support the action of the air tolerably well, and have greatly the appearance of a madder red.

Cochineal is little used for dyeing cotton and linen, since the colour is much less permanent than that obtained from madder. Scheffer however has described a process which may be employed. The cotton is to be steeped 24 hours in a cold solution of tin, it is then wrung, washed, and boiled a quarter of an hour with four-sixths of its weight of cochineal. It takes a light red, and resists the sun and air for a time, but not soap. Little use appears to have been made of this process of Scheffer, though it is probable that Dr. Berkenhout availed himself of it some years afterwards, when he pretended to have discovered the means of dyeing scarlet crimson, and other colours upon cotton and linen; and though his process was not materially different from Scheffer's, nor in any respect preferable, he obtained 5000 *l.* from the British government, as a reward for making it public.

As it excited considerable interest and some contention at the time, we shall present our readers with the following detail of the process, as it was communicated by order of the lords of the treasury to the company of dyers in the city of London, Aug. 16th. 1779. *viz*

"Cotton or linen, either in yarn or piece, should be perfectly wet with hot water, and then wrung out, as is the common practice.

"This being done, it must be perfectly soaked in a solution of tin diluted with an equal quantity of clear soft water.

"The cotton or linen being so far prepared, must be wrung out, but not forcibly; it is then to be nearly dried, lying horizontally upon a hurdle with a double linen sheet between them, and covered with the same.

"The solution of tin being for scarlet, must be made of vitriolic acid, and rest of aquafortis; but for crimson, aqua is more to be used, and the alum is to be given after it comes out of the tin, by a small quantity of sal ammoniac and sulphuric acid; the bath is warm water, but this is not to be used in red or crimson yarn.

"The bath being put for the scarlet or crimson is simply

cochineal in water no hotter than the hand will bear, and as vegetable matter receives only the small particles of the colour from the nature of its pores, two ounces to a pound of the materials dyed may be necessary: but cotton or linen fresh prepared, will draw from the same vat, treated as before, all the inferior shades from scarlet and crimson, and if any colour still remains in the vat, it may be taken out entirely, by wool prepared in the usual manner.

"The same preparation of tin serves for the green and yellows, with the same materials only that are employed by dyers, except the best yellow, which is produced from turmeric.

"It is necessary to observe, that after the preparation has been made use of for scarlet or crimson, the residue continues sufficiently strong for greens or yellows, even after it has been kept a considerable time.

"N. B. To make the best solution of tin with nitrous acid, it is necessary to have the strong fuming spirit, to which an equal quantity of the purest river water must be added, and the proportions of the following ingredients are to the weight of spirits $\frac{1}{2}$ sal ammoniac, $\frac{1}{2}$ refined nitre, dissolved by little at a time. In this aqua regia, dissolve $\frac{1}{2}$ of granulated tin also by small quantities, to prevent too great an ebullition which would weaken the solution considerably. The ingredients and proportions are the same when a solution is to be made with aquafortis, but that spirit in general will not bear any water when a perfect solution is intended."

Besides the fugitive nature of the colour dyed by the above process, it was found that the texture of the cloth was considerably injured, and it was soon laid aside, or rather was never adopted. If, notwithstanding the want of sufficient permanency, however, the colour which cochineal affords, should still be required; the best way of producing it, according to Dr. Bancroft, is to soak the cotton (previously moistened) about half an hour in a diluted solution of murio-sulphate of tin; then wring or press out the superfluous part of the solution, and plunge the cotton into water, in which as much, or nearly as much clean potash has been dissolved as will neutralize the acid still adhering to the cotton, so as to precipitate the oxyd of tin, and cause it to be more copiously deposited or fixed in the cloth, which being afterwards rinsed in clean water may be dyed with cochineal in the usual way. A full bright colour may be given to cotton in this way, which will bear a few slight washings with soap, and a considerable degree of exposure to air. The murio-sulphate of tin, on which Dr. Bancroft lays great stress, as well for the above process as for dyeing silk crimson, is prepared by dissolving 14 ounces of tin in a mixture of two pounds of oil of vitriol with three of muriatic acid. The muriatic acid should be first poured upon the granulated tin in a large glass vessel, and the oil of vitriol afterwards added slowly; and these acids mixed should be left to saturate themselves with tin, which they will do in time without artificial heat; but the solution will be rapidly promoted by a sand heat.

Under the head of cochineal we have given a short account of its use in calico-printing in dyeing crimson, to which we must refer our readers as well as to the article COLOURS for other details connected with the subject. The colours produced from madder with the aluminous mordant in the ordinary processes of this art, strictly speaking, belong not to the class of crimson, yet by repeated branning, boiling in soap or alkalis, the yellow or fawn coloured principle which this root contains, may be nearly extracted, and tolerable crimsons obtained. The addition of a small quantity of solution of copper to the acetite of alumine, gives the colour

colour a crimson hue of no great lustre, but very permanent.

The following process by Mr. Grouse, affords a colour of less intensity indeed, and solidity, but scarcely inferior in beauty, to the Adrianople red.

Prepare a mordant by dissolving 4 lbs. of acetite of lead, and 4 lbs. of alum in a gallon of pure water, and after decanting the supernatant clear solution from the precipitate which forms, thicken it with gum to the consistency required. If the work requires the mordant to be *lightened*, add a little infusion of cochineal till it is sufficiently tinged to enable the printer to observe the progress of his work. Keep the goods from four to six days after printing, in a warm place, to facilitate the liberation of the acid; rinse them five minutes in a copper of water at 120°, with two good spade-fulls of cow dung, after which wash and rinse them in clean water several hours, alternately winching, washing, and suffering them to steep in the river. Lastly, winch five minutes in a clean hot water copper at 120°, and after rinsing and washing again in the river, dye them as follows. Into a dye copper of 300 gallons capacity three parts filled with clean water, free from all accidental impurities, and not discoloured either by rain or floods, put 20 lbs. of the best crop madder, and 60 lbs. of good sweet bran. Mix well, and bring them up quickly to a boil, and keep them in a state of ebullition 20 minutes. Add cold water sufficient to take the copper off the boil, then enter two pieces, winching them briskly and keeping them down with the copper stick the whole time they are in. Bring the copper up to a boil again, and in 8 or 10 minutes, according as the shade required, the goods will have acquired their full colour. Enter two more pieces after these are withdrawn, and keep them in a few minutes longer; they will be scarcely inferior to the former, but as the copper becomes exhausted, every succeeding set will acquire less colouring matter than the preceding, and if the operation be continued upon several sets without refreshing the copper, the last will acquire only a pale but delicate rose colour. If the whole are required to be full deep colours, the copper must be supplied with a regular charge of bran and madder after every second set, but to exhaust the bath fully, and proceed with due regard to economy, the strong colours should be dyed first, and the pale and more delicate shades afterwards.

Wash them well after dyeing, and bran them at a boil. The colour improves much by this last operation, which may be repeated on the stronger shades till the colour has acquired its proper hue, and the whites are good. See **MADDER**.

CRIMSON-Grass Vetch, in *Botany*. See **LATHYRUS Nissolia**.

CRINAN LOCH, in *Geography*, is a branch from the fount of Jura, in Argyleshire, in Scotland, connecting with Craigness loch, and terminating at the west end of the Crinan canal; the town of Glasre is situate not far from its southern shore.

CRINAN Canal, a short canal of very large dimensions, for the passage of ships between loch Crinan and loch Fine, when coming or going northward to or from the Clyde river, by which a very circuitous navigation round the mall of Cantire is avoided. See **CANAL**.

CRINED, in *Heraldry*, a term denoting that the hair of the head of a man or woman, or the mane of a horse, unicorn, &c. is represented.

CRINGLE, in *Rural Economy*, a term which is provincially applied to signify a withe or twilled wooden rope which is employed in fastening a gate, from whence to

“cringle up” implies to fasten with a wooden rope or withe.

CRINGLES, in *Sail-making*, small holes formed on the bolt-ropes of sails by intertwisting the strand of a rope alternately round itself and through the strands of the bolt-rope, till it assumes the shape of a ring. To the cringles the end of a rope is fastened, to haul the sail up to the yard, &c. They should be made of the strands of new bolt-rope, half an inch smaller than the bolt-rope on the sail.

CRINIÈRE, Fr. The mane of a horse, literally speaking. This name is also given to a tuft of horse hair fixed in the crest of a dragoon's helmet, and flowing or waving down to the lower part of the same, on the side thereof, like a garland.

CRINITA, in *Botany*, capensis; Hoult. See **PAVETTA castra**.

CRINITUS applies to any plant, or part of a plant, that resembles a tuft or head of hair, as the inflorescence of *Hedysarum crinitum* of Linæus, and *Pbleum crinitum* of Schreber. It differs from *comosus* in being more precisely and necessarily composed of hair or bristles, and not restricted to a flowing or pendulous form or posture. In some cases it is equivalent to *capillatus*. The roots of *Mrum abumantium* and *Trichochin bulbosum* are *radices capillate, vel crinitæ*, being each crowned with a dense tuft of upright hairs or bristles, originating from the fibres of decayed leaves or leaf-stalks, and serving to protect the root, or young plant, from cold, or other injuries, in a remarkable manner. S.

CRINITZ, in *Geography*, a town of Germany, in the circle of Lower Saxony, and territory of Erzgebirg; 6 miles S. of Zwickau.

CRINODENDRUM, in *Botany*, (from *κρινος*, a lily, and *δενδρον*, a tree) Schreb. Gen. 1114. Willd. 1267. (Patagua; Enc.) Class and order, *monadelphica decandria*. Nat. Ord. *Undetermined*, Juss. 431.

Gen. Ch. *Cal.* none. *Cor.* bell-shaped; petals six, oblong, erect, spreading at the top. *Stam.* Filaments ten, united at the base into a tube; anthers egg-shaped, erect. *Pist.* Germ superior, egg-shaped; style simple, awl shaped, a little longer than the stamens. *Peric.* Capsule coriaceous, obtusely three-cornered, one-celled, opening elastically at the top with three valves. *Seeds* three, roundish, nearly the size of a pea.

Ess. Ch. Calyx none. Corolla bell-shaped. Petals six. Capsule with three seeds, one-celled, trigonous, opening classically at the top.

Sp. C. *patagua*. Mart. Poir. Willd. Molin. Chil. 179. Cavan. Dif. 5. 300. tab. 158. fig. 1. A superb evergreen tree, with a trunk often seven feet in diameter. *Leaves* bright green, opposite, lanceolate, acute, serrated, without stipules; petioles short. *Flowers* solitary, axillary, peduncled, smelling like a lily. A native of Chili. Jussieu suspected that the capsules sent to Europe by Dombey, under the name of Patagua, might belong to a plant of this genus; but Ruiz and Pavon assert that Dombey's plant, which produces the true Patagua of Chili, constitutes a distinct genus, which they call *Tricuspidaria*. The trivial name given to the present plant is therefore erroneous and tends to mislead. See **TRICUSPIDARIA**.

CRINONES, from *crinis*, hair, in *Medicine*, a sort of worms, sometimes found under the skin, in children; resembling short thick hairs, or bristles.

They are called *dracunculæ*, and *comedones*, from the Latin *comedere*, to eat; from their preying upon the substance of the

the child, or consuming its nourishment. See DRÆVEN-
CILI.

The common way of getting out these worms is by the point of a needle; and to prevent their forming there again, the usual custom is to wash the parts with wine or vinegar, with alum, nitre, or common salt, or with a strong lixivium of oak ashes, and afterwards anointing them with an ointment of the common kind, used for scorbutic eruptions, with a small mixture of quicksilver.

CRINONIA, a kind of cap, worn by the emperors of Constantinople on solemn occasions.

CRINUM, in *Botany*, (*crinum*; Theophr. a name given by the Greeks to the lily, and some other plants with showy flowers.) Linn. Gen. 425. Schreb. 533. Willd. 618. Clais and order, *hexandria monogynia*. Nat. Ord. *Spathaceæ*, Linn. *Narcissi*, Juss.

Gen. Ch. *Cal.* Involucre spathe-shaped, of two or more oblong leaves, umbelliferous, reflexed after it has opened. *Cor.* monopetalous, funnel-shaped; tube oblong, cylindrical; border half six-cleft; segments lanceolate-linear, obtuse, channelled, reflexed; three alternate ones, in most species, distinguished by a hooked appendicle. *Stam.* Filaments six, awl-shaped, the length of the border and inserted in its base, converging; anthers oblong, linear, rising upwards, incumbent. *Pist.* Germ inferior; style filiform, the length of the flower; stigma simple, or three-cleft. *Peric.* Capsule somewhat egg-shaped, three-celled. *Seeds* numerous.

Ess. Ch. Corolla funnel-shaped, half six-cleft; tube filiform; border spreading, recurved; segments lanceolate-linear, channelled. Filaments inserted in the base of the border, distinct. Germ inferior.

Obs. It differs from *pancratium* in the want of a nectary. The *crinum* of Gærtner and La Marck has a superior germ, and is formed for the *crinum Africanum* of the Species Plantarum, which has that character, and on that account has been made by Schrader a distinct genus under the name of *Agapanthus*. La Marck, however, has included in his *crinum*, *C. americanum* and *C. tenellum*, because he thinks their germ is not decidedly inferior. Such as are so he has removed to *anaryllis*.

Sp. 1. *C. asiaticum*. Linn. Sp. Pl. 2. Mart. 1. Willd. 1. Lour. Cochinch. 197. "Leaves keeled." Linn. "Leaves linear, acuminate, keeled; flowers sessile; tube longer than the border; spathe two-leaved." Willd. *Root* solid, top-shaped, surmounted with long branching fibres. *Stem* short, thick, coated, white, single. *Leaves* three feet long, three inches broad, subulate-linear, erect, striated, thick, imbricated. *Scapes* axillary, cylindrical, the length of the leaves. *Flowers* white, large, in a single flat umbel; common involucre oblong; segments of the corolla equal, not hooked; stamens distant. *Capsule* roundish, irregularly lobed. Lour. There has been some confusion with respect to this species. Osbeck, a pupil of Linnæus, observed it in 1751, embellishing the sandy shores of the island of Java; and in the year following, brought into Europe, not only bulbs preserved in sand, but also the plant itself in a flower-pot, which arrived perfectly alive in Sweden. About the same time Mr. Miller received from Panama and Carthæna two distinct plants, the smaller of which he supposed not to differ from the Asiatic species, and accordingly figured it under that name in his coloured plates. Linnæus, misled by Miller, quoted that figure as really belonging to his *C. asiaticum*. In this error he was probably confirmed by observing in Miller's figure no appearance of a hooked appendicle at the summit of the

alternate segments of the corolla; and hence seems to have considered that appendicle itself as a sufficient specific distinction of the larger American plant. We apprehend, however, that it was left out in Miller's plate by the negligence of the engraver; for we have now before us a dried specimen of a plant cultivated many years since by Mr. Salisbury at Chapel Allerton, under the name of *crinum asiaticum*, in which that particular character is distinctly visible. The real *C. asiaticum* does not appear ever to have been seen by Miller; nor was it known at Kew when the *Hortus Kewensis* was published; but the author of the specific characters in that work had discovered Miller's mistake, and removed the reference to the new species *crubifens*, *C. americanum* β of Linnæus. Gærtner quotes the *C. asiaticum* of Linnæus, as his *bulbine asiatica*; Mr. Salisbury, however, assures us that the bulbine is certainly a plant not in our collections, and that he is yet ignorant what it is, but that if he should guess at any one in particular, it would be the *cæpa sylvestris* of Rumphius, quoted by L'Heritier, as a synonym of his *crinum nervosum*. See *Parad. Lond.* 52. *C. americanum*. Linn. Sp. Pl. 3. Mart. 2. Willd. 2. Hort. Kew. 413. (*Lilio-asphodelus americanus maximus*; *Comm. Rar.* 14. tab. 14. Dill. *Elth.* 194. tab. 161. fig. 195.) "Leaves oblong-lanceolate, quite smooth at the edge, contracted and hooked at the end; flowers pedicelled; tube shorter than the border." *Scape* a foot and half high, the thickness of a finger, slightly compressed, coming out from the root on one side of the leaves. *Leaves* two feet long or more, three inches broad, furrowed on the upper surface, keeled on the lower, smooth, stiff, light green, slightly undulated at the edge, thickish, sharp-pointed, punctured with numerous and rather large pores. *Flowers* milk-white, opening successively, and each lasting only one or two days; tube about two inches long; segments of the border keeled; stamens long, bending in, white at the bottom, purple at the top; style shorter than the stamens, of a deeper purple colour. Some very slender threads adhere to the involucre, and to the pedicels of the flowers. A native of South America; cultivated at Eltham by Dr. Sherard in 1732. 3. *C. erubescens*. Hort. Kew. 413. Mart. 3. Willd. 3. (*C. americanum* β ; Linn. Sp. Pl. *C. asiaticum*; Mill. tab. 110. *Lilio-asphodelus minor*; *Com. Rar.* tab. 15.) "Leaves lanceolate, cartilaginously-crenulate, drawn out and unfolded at the end; flowers sessile; tube longer than the border." *Scape* rising from the root at the outside of the leaves. *Flowers* eight or ten, forming an umbel, closely joined at their base, but spreading above; petals delicate, not continuing in beauty more than four or five days. A native of the Spanish West Indies. 4. *C. brazeatum*. Willd. 4. "Leaves oblong-lanceolate, attenuated at the base, cartilaginous and smooth at the edges, somewhat callous at the tip; flowers pedicelled; tube shorter than the border; spathes numerous, longer than the tube." *Flowers* white; segments of the border narrow, reflexed, channelled, hooked at the tip; bractes or spathes oblong-lanceolate. Described by Willdenow from a living plant; native country unknown. 5. *C. nervosum*. Mart. 6. Willd. 5. L'Herit. fert. angl. 8. (*Cæpa sylvestris*; Rumph. Amb. 6. p. 160. tab. 70. fig. 1.) "Leaves roundish, nerved; filaments dilated at the base." *Leaves* cordate-rounded, entire, acuminate, with concentric nerves. *Scape* many-flowered, with a many-leaved involucre. *Flowers* on rather long peduncles; tube of the corolla filiform; segments of the border lanceolate, acute, spreading; filaments shorter than the segments of the corolla, straight, not declining. A native of the Philippine islands, observed by Monf. Poivre.

CRINUM africanum; Linn. See *AGAPANTHUS umbellatus*.

CRINUM angustifolium; Linn. jun. See *CYRTANTHUS angustifolius*.

CRINUM caspium; Pall. See *AMARYLLIS caspia*.

CRINUM falcatum; Jacq. See *AMARYLLIS falcata*.

CRINUM latifolium; Linn. See *AMARYLLIS latifolia*.

CRINUM lineare; Linn. jun. See *AMARYLLIS linearis*.

CRINUM longifolium; Thunb. See *AMARYLLIS longifolia*.

CRINUM obliquum; Linn. jun. See *CYRTANTHUS obliquus*.

CRINUM speciosum; Linn. jun. See *AMARYLLIS purpurea*.

CRINUM tenellum; Linn. jun. See *STRUMARIA filifolia*.

CRINUM zeylanicum; Muir. See *AMARYLLIS zeylanica*, under which genus it was originally placed by Linnæus. Mr. Gawler Kerr declares (*Bot. Mag.* 923.*) that after a diligent research, he is assured of the specific identity of the Indian *amaryllis zeylanica*, and the African *ornata*, and has published the *crinum giganteum* of the Botanical Repository, tab. 169, as an obvious variety. Mr. Salisbury thinks the *A. ornata* and *crinum giganteum* distinct, and is inclined to refer both to the genus *crinum*. His *C. yuccæ-florum*, figured in *Paradisus Londinensis*, Pl. 52, is, as he himself acknowledges, so similar to *A. ornata*, cultivated in the stoves about London, that he cannot find a satisfactory specific distinction. It differs so much, however, in the structure of its anthers, that he thinks it safest for the present to separate it. He says that these plants and the *C. longifolius* of Thunbery, since removed to *amaryllis*, may be distinguished from that genus by the herb alone, as well as by the fruit. See *Par. Lond.* 52.

CRINUM, in *Gardening*, comprehends plants of the flowery tuberous and bulbous-rooted perennial kinds; of which the sorts mostly cultivated are, the keel-leaved Asiatic *crinum*, (*C. asiaticum*); the great American *crinum*, (*C. americanum*); and the small American *crinum*, or *asphodel lily*, (*C. crubescens*).

Method of Culture.—All these three sorts are capable of being increased, by planting the off-sets of their roots in pots filled with good fresh earth, plunging them in the bark-bed of the stove, where they should be continued until they begin to show flowers. After this they may be removed, when necessary, to the shelves or other parts of the hot-house where they must be kept.

It is necessary that the roots of all the different sorts should be shifted every two years, at the period when the stems decay, in order to separate the off-sets for the purpose of increase, and to refresh the plants with fresh mould.

The succulent stalks and beautiful flowers of these plants afford a good effect among other stove plants, when properly placed in mixture with them.

CRIO, CAPE, in *Geography*, a cape on the W. coast of Asiatic Turkey. N. lat. 36° 40'. E. long. 27° 8'.—Also, a cape of the island of Candia; 7 miles S.W. of Canea.

CRIQUE, Fr. in *Fortification*, small ditches, which are made in different parts of the ground for the purpose of inundating the country in the environs of a place, to render the enemy's approach to it either difficult or impracticable.

CRIQUETOT LESNEVAL, in *Geography*, a small town of France, in the department of the Lower Seine, 9 miles south of Fecamp. It is the chief place of a canton in the district of Havre, and contains 1650 inhabitants. The canton has 26 communes, upon a territorial extent of 140 kilometres, with a population of 14,748 individuals.

CRISCUOLO, GIO FILIPPO, and GIO ANGILOLO, in

Biography, two brothers, natives of Gaeta, who enjoyed considerable reputation at Naples in the 16th century, as historical painters. Gio Angiolo was the scholar of Marco di Siena. Gio Filippo was a disciple of Andrea da Salerno, and afterwards travelled to Rome, where he studied the compositions of Raffaele with great profit. The works of these two artists are described by Dominici in his lives of the Neapolitan painters. Gio Angiolo died in 1572; Gio Filippo survived him 12 years, and died at the age of 75. Lanzi. *Storia Pitt.*

CRISIS of diseases, a sudden change for the better, in the symptoms of acute diseases, preceded by a considerable disturbance of the functions, and accompanied by some evacuation.

This appears to be the sense in which the term was generally understood by Hippocrates and Galen, and the other ancient physicians, who adopted the doctrine of *crises*. It is, however, not only a sudden alteration towards recovery, which they have denominated a crisis; but a rapid change for the worse, or to death itself, also received the same denomination; but the epithet *bad* was in that case added. And those disturbances, which only make some considerable change, without entirely removing the disease, or which are followed by an exacerbation or return of the symptoms, were called *imperfect crises*. The word *crisis*, *κρίσις*, literally signifies *judgment*, from *κρίνω*, *I judge*; and Galen is of opinion that the term was originally the contrivance of vulgar and uninformed persons, rather than of physicians. The change being always preceded by great disturbance of the body, and alarming symptoms, the friends and attendants, affrighted by the violence of the disease, pronounced that a decisive *judgment*, as to the death or recovery of the patient, might speedily be formed; hence they called the change of the symptoms themselves, the *crisis*, or *judgment*. The disturbances, the violent symptoms, the discharges, which ensue, were hence also denominated *critical discharges*, *critical perturbations*, and *critical symptoms*.

It is a curious fact in pathology, that the vital powers, after being worn down, and apparently almost exhausted, by the continued violence, or successive exacerbations, of fever, often suddenly and spontaneously become recruited, the alarming symptoms disappearing, and leaving the patient with little more complaint than extreme general weakness. This sort of change takes place most commonly in continued fevers, more especially in those which are violent from the beginning. For these crises happen most frequently within the first ten or eleven days of the disease, and if they occur at a later period than the fourteenth, are less decisively beneficial, and less distinctly marked. Crises, indeed, do not happen so frequently in this climate, or in modern times, as anciently; in so much that it has been disputed whether the maxims, which have been handed down to us, have any application to the diseases which we now observe. It is probable, that the frequent vicissitudes of our climate, the greater activity of our practice, and the less regular mode of life among the moderns, is the cause of the comparative rarity of the occurrence of violent crises: they occur, nevertheless, sufficiently often, to render the study of them important, especially with a view to the prognosis of the event.

The doctrine of crises, although originating, no doubt, in the careful observation of facts, for which the physicians of the Hippocratic school were remarkably distinguished, was nevertheless much connected with their speculative opinions respecting the humoral pathology; and especially with the doctrine of concoction. (See *CONCOCTION*.) They observed that those sudden or critical changes were always preceded

preceded or accompanied by some evacuation; as by copious sweat, or a great deposition of sediment in the urine, or by a discharge from the bowels, by hæmorrhages, &c.; in pulmonary fevers, by a free and copious expectoration; and so on. Hence they were led to suppose, that the disease was the effect of the presence of some morbid matter in the humours, and was itself an effort of the constitution to expel this matter, after due concoction, from the body. These discharges were, therefore, considered as proofs at once of the existence of morbid humours, and of the successful struggle of the system in expelling them; and the violent perturbations which preceded the expulsion, were deemed to be signs of the conflict between the powers of the constitution, struggling to expel the humours, and the noxious influence of these humours upon the constitution. The hypothesis was plausible, and has been the ground-work of the reasoning of medical writers, from the time of Hippocrates, down to the age of Hoffmann and Cullen; and it is still the favourite theme with the ill-informed part of the profession, and with the public at large. But the distinguished professors, just mentioned, taught us to attend to the operations and excitability of the nervous or living power in the solids, by the action of which the fluids are principally modified in their qualities. Thus in respect to the progress of common inflammation, which is the prototype of the humoral theory, the swelling, tension, pain, &c. were considered by those pathologists as the effect of obstruction, occasioned by the presence of morbid humours: and when the inflammation was not gradually cured by resolution, but went on, it was only finally removed by a discharge of the morbid humours, when concocted in the shape of *pus*. Now the modern doctrine, which is deduced from a more complete generalization of the facts, teaches us that these phenomena are not the result of morbid humours circulating in the vessels; but that the morbid humours are the result of certain disordered actions of the vessels, by which the secretions of those vessels are altered. In the healthy condition of the body, there is no urine, no bile, no saliva, in the blood; these fluids are produced in the kidneys, the liver, and the salivary glands, by the peculiar action of the vessels of those organs, which gives new combinations to the elementary parts of the blood. This action is called *secretion*. Similar actions in inflamed parts produce the variety of humours which appear in the progress of the inflammation; as particularly obvious in the inflammation of surfaces. Take *Coryza* for example. The natural secretion of the membranes lining the nose is a simple moisture. But if an inflammatory action is excited in these membranes, the vessels, at the commencement, either do not secrete at all, or they pour out a thin and acrid humour, which the ancients call *crude*; as the inflammation goes on, the action of the vessels changes, and they produce a thick, whitish mucus; and when the inflammatory action is beginning to subside, the secretion from the blood is again altered, it has the appearance of *pus*, and is said by the humoralists to be concocted. The inflammation from this time declines and ceases. In this case there is no morbid humour in the blood of the inflamed membrane; but the action of the vessels being changed, in various progressive degrees, by an external cause, *viz.* cold, they produce new combinations in the blood, which circulates through them, and at once generate and eject the morbid humour. The morbid humour is not a cause, therefore, but an effect, and a sign of a morbid condition of the living power, and the consequent morbid action of the part.

And thus it is, also, with respect to those discharges which are deemed *critical* in the more general deranged action of fevers. It will not be difficult to shew, as we enu-

merate them, that they are oftener the effects of a favourable change in the system, than the causes of it. A profuse sweat is a symptom which very commonly attends those sudden changes from fever to health. It accompanies the crisis in intermittent fevers, and frequently that of the synocha, or inflammatory fever: indeed, continued fever in general is seldom terminated favourably, without some degree of moisture appearing on the skin. But physicians were long misled into a most pernicious practice, (the employment of the hot regimen, and alexipharmics,) by the conclusion, that the solution of the fever was to be attributed to the flow of sweat, and that could this discharge by any means be produced, it would always prove equally beneficial. But a proof of their error, and also of the position that such salutary sweats were the result of a favourable change in the constitution, is this, that sweats, forced by artificial means, never affect the solution of the fever, but most frequently increase its violence, prolong its duration, and, by greatly debilitating the patient, endanger his life. Nor is every spontaneous sweat salutary: unless it be universal and thin, it is seldom beneficial.

The same observation may be made as to the deposition of the sediment in the urine, which commonly appears at the crisis, and was deemed a proof of the concoction being completed. Now this deposited matter is not in the blood, but secreted by the kidneys, and it exists in some proportion almost constantly in the urine of persons in health. Its production in larger quantity is much connected with a soft and moist state of the skin, and invariably accompanies much sweating, from whatever cause produced. It occurs with the spontaneous sweats of fever, whether critical or even prejudicial; it is found after all night sweats, as from those of hectic fever, where no relief is brought by it, and even when there is no fever at all; and, farther, it may be produced in any one at pleasure in a state of health, by promoting the perspiration by small doses of tartar emetic or Dover's powder. (See Wilson on Febrile Diseases, vol. i. p. 398.) Therefore all that can be inferred from the appearance of the lateritious sediment in the urine in fevers is, that the relaxation of the skin has taken place, and its secretion is restored; or in other words, where the deposition is spontaneous, that it is the consequence of a favourable change in the constitution. The changes in the urine, however, although affording no particular indication of cure, merit our attention, as they sometimes anticipate the other phenomena which mark a solution of the fever.

Among the critical discharges, diarrhœa occurs less frequently than the two preceding ones: Hoffmann, however, remarks, that in the petechial fever he has more frequently observed a diarrhœa critical, than either sweat or hæmorrhage. This crisis is generally for some time preceded by flatulence, gripes, and pains of the loins: it has been said to be prefiged by an intermitting pulse; (Nihell on the Pulse,) but the pulse has often been observed to intermit, when no diarrhœa succeeded. We believe, however, that diarrhœa, in the fevers of this country, is more frequently detrimental than critical; and where it is attended with much loss of strength, it is among the worst and most unmanageable symptoms of the disease. It is frequently, we believe, the consequence of a neglect to clear the bowels in the commencement of the disease.

The crisis, which is next in degree of importance and frequency, is hæmorrhagy or discharge of blood. It is curious to observe, that hæmorrhages, even to a considerable extent, are sometimes followed by immediate relief to the symptoms; even in typhous fevers, *i. e.* in those fevers which are characterized by great debility. The most frequent critical hæmorr-

hæmorrhages are those from the nose, and the quantity is generally small. These have been said, by the same whimsical author above quoted, to be presaged by a rebounding pulse, whose stroke seems double: (Nihell.) There is generally some heat, pain, or tension in the part whence the blood is about to flow. It may here be observed, that the relief which a trifling hæmorrhage from the nose sometimes affords to the patient, cannot be explained upon the notion of any morbid matter being evacuated with it. If there be a morbid humour in the circulating mass, it is quite absurd to suppose that a very trifling and partial abstraction of the blood can free the system of much of that humour, or that it can leave the remaining blood in the circulation less impregnated than before.

Other discharges have been mentioned as occasionally critical, such as vomiting, flow of saliva, cutaneous eruptions, abscesses, &c.; but these are comparatively rare.

Although the diseases which we are accustomed to see in this climate, and in persons using a mode of life altogether different from that of the ancients, are by no means the same with those recorded by the physicians of Greece and Rome, and differ especially in the rarity of well-marked crises; yet the observation of those imperfect crises, those perceptible changes for the better or worse, which are frequently accompanied by some evacuation, occurring in modern diseases, is important. In the first place it will aid us in forming a correct prognosis of the termination of diseases; and secondly, which is of greater consequence, it will assist us in the choice of proper measures in their cure. It will enable us, for instance, to judge of the propriety of suppressing, or of allowing to proceed those evacuations which obviously tend to augment or to alleviate the original disorder, and will point out to us when we may aid or imitate the processes of nature in the constitution. The speedy relief, or the continuance and even increase of the symptoms of the disease, is the best criterion of the beneficial or injurious nature of such evacuations. The ancients, however, had two sorts of tests by which their prognosis and practice were guided. The first and most important point was, according to Galen, the observation of the *concoctions* of the urine, excrement, and the sputa. I have been present, he says, a thousand times during the occurrence of crises, and I never saw one person die, whose crisis was preceded by concocted discharges. (De Crisibus, lib. iii.) The second point in importance, according to the same writer, was the observation of the *day* on which the crisis took place. For it had been remarked from the time of Hippocrates, that these sudden crises occurred more frequently on certain days, reckoned from the commencement of the disease, than on others; and those were hence termed *critical days*. See *CRITICAL DAYS*. The crisis was considered as most likely to prove curative if it had been *indicated*, i. e. if an amendment had taken place on the previous critical day; and especially if it occurred on a critical day of great power. The observation of the species and type of the disease, also aided the ancient prognosis; as, whether it was quotidian, tertian, ardent fever, pleurisy, &c.; or whether moderate, mild, malignant, and so forth. And farther, they did not omit to note, whether the sort of discharge was correspondent with the nature of the disorder. Some of their observations on this head are fanciful, and purely hypothetical. Thus Galen asserts, that when the convex part of the liver is diseased, a crisis takes place in three ways; namely, by hæmorrhage from the right nostril, by free sweats, and copious discharge of urine. When the concave parts of the liver are affected, the crisis is completed by means of bilious stools, and sweat, and sometimes by vomiting. It is un-

cessary to detail the various observations of this sort which have been transmitted to us by the ancient physicians. The reader who is curious on the subject, will find an ample collection of them in Galen's three books, *De Crisibus*, particularly in the third; and also in his book, *De Diebus Decretoriis*. See also Van Swieten's Commentaries, Aph. 587.

CRISNA, or KRISHNA, in *Geography*, a river of India; called also KISTNAH; which see.

CRISNEZ, CAPE, a cape on the coast of France, in the English channel, between Boulogne and Calais. N. lat. 50° 50'. E. long. 1° 35'.

CRISP, TOBIAS, in *Biography*, a divine of the church of England, was born at London in the year 1600. He was educated at Eton, and from thence he removed to Cambridge, and afterwards to Balliol college, Oxford. In the year 1627 he was appointed rector of Brinkworth in Wiltshire, and shortly after he took his degree of doctor in divinity. In early life he was the favourer of the doctrines of Arminianism, but as he advanced in life he stood forth as the champion of Antinomianism. During his life-time he published nothing in justification of his tenets; but after death sermons in three volumes 8vo. were printed, which were afterwards published in one volume 4to. He died in 1642-3; and though the tenets which he embraced seem to be a plea for licentiousness, yet Dr. Crisp was himself remarkable for the chasteness of his piety, the purity and sanctity of his manners, and the humility and modesty of his deportment. His income being ample, he devoted a considerable part of it to works of hospitality and kindness.

CRISPELT, in *Geography*, a mountain of Switzerland, in the canton of Uri, 10 miles S.E. of Altroff.

CRISPELLO, a town of Naples, in the province of Abruzzo Citra; 25 miles E. of Civita Borella.

CRISPI, SCIPIONE, in *Biography*, a painter of the 16th century, a native of Tortona, in the state of Piedmont. In the church of that place is a picture of the Madonna, with St. Francis and St. Dominic, bearing his name, and the date 1592, and in Voghera, the meeting of Mary and Elizabeth, in the church of St. Lorenzo, both evincing him an artist of no small abilities. Lanzi.

CRISPIANA, in *Ancient Geography*, a place of Pannonia, in the route from Sirmium to Carnuntum, between Ulmi and Mursa, according to the Itinerary of Antonine.

CRISPUM FOLIUM, in *Botany*, a curled leaf, has its border considerably more dilated than the disk, in consequence of which the former part becomes elegantly curled and twisted. Linnæus thought this a morbid luxuriance, and with great probability. It is the characteristic mark of *Malva crispa*, the curled mallow, a plant cultivated chiefly for ornamenting the table in deserts, and which seems most likely to be a variety of *Malva verticillata*; yet it retains its peculiar character when propagated by seed, at least in the rich soil of a garden. The above term is also applicable to the margin of the cup or nectary in several species of *Narcissus*, even in their natural state. With respect to leaves, the reverse of this character is *folium concavum*, a concave leaf, whose margin is more tight than the disk, like *Cyamus Nelumbo*. Sm. Exot. Bot. t. 32. S.

CRISPUS, ANTHONY, in *Biography*, born June 11th. 1600, at Trepani, a town in Sicily, received the early part of his medical education under his father, whom he succeeded in his practice, in which he became so famed, that persons resorted to him for his advice, not only from the most distant parts of the island, but from many parts of Italy also. Towards the latter end of his life, which was extended to the year 1688, he united the office of priest to that of physician, and a few years before his death, he retired altogether

from business. The following are the titles to a few of his numerous publications: "In lethargum fabri supervenientem acutæ, Commentarii duo." Panorini, 1668, 4to. "De sputo sanguinis a partibus corporis infirmis, supervenientis cum Tussi, &c." 1682, 4to. The practice here recommended has been very little altered since his time; also a treatise on the cure of infectious fever by venesection and cathartics, the mode now recommended in the yellow fever, and on the most celebrated mineral waters of the island, with an examination of their constituent parts. Haller Bib. Med. Eloy. Diæt. Hist.

CRISSA, in *Ancient Geography*, a town of the Locrian Ozoli, near the gulf Crisæus, formed by a part of the gulf of Corinth, and now called "Golfo di Salona."

CRISSE, or KREESE, in *Military Language*, a kind of dagger used by the Malays, particularly in the island of Ceylon; the blade of which is of the best tempered steel, and often in a serpentine form, so as to inflict a most dreadful wound; the handle is of ivory or wood, carved into the figure of a man's body and arms, with a head representing something between that of a man and a bird: this they call their "swaming," or god; and to this figure they make their "salam," or obeisance, before they draw the kreefe to execute any bloody purpose on which they have determined. After they have ratified their vow by this ceremony, they draw their kreefe, and never again sheath it till they have drenched it in blood. So resolute is their ferocious disposition, that if their adversary is placed beyond the reach of their vengeance, sooner than not indulge it they will plunge the dagger into the body of a pig, dog, chicken, or any other living animal which happens to come in their way. The scabbard is made of wood, frequently ornamented with gold or silver wire; and the whole appearance of the weapon, as well as the mode of wearing it, on the right side, greatly resembles that found in the ancient dress of the Celtic nations. This terrible instrument is rendered still more so by its being always poisoned, commonly by the juices of some poisonous herbs, and among those who can procure it, with poison from the Upa tree. These daggers, in the use of which the Malays are peculiarly dextrous, are regarded by them with veneration, and they descend as sacred relics from father to son, and from generation to generation. No money is accounted sufficient to purchase them, and no violence can compel their owners to give them up. When a Malay is pressed in battle, he will sooner be slain, or kill himself, than surrender his kreefe to the enemy.

CRISTA, a *Crest*, in *Botany*, applies to several accessory parts, or appendages, chiefly belonging to the *antheræ* of plants, thence said to be *crislata*, as in the genus *Erica* and that of *Pinus*, in both which instances the crest of the *antheræ* is of great use in furnishing specific characters. The same term is used for an elegant double tuft or fringe, attached to the keel of the flower in many species of *Polygala*, milkwort, whence such species are denominated *crislata*, and they form a section in the genus by themselves. The pod of *Hedysarum Caput galli*, and *H. Crista-galli*, has a curious crest, running along its upper edge, which has given occasion to the names of these two species. In the former of them its segments are awl-shaped and simple; in the latter flat, dilated, and toothed; which marks afford a good specific difference. See HEDYSARUM. S.

CRISTA-Galli, in *Anatomy*, a process standing out from the middle of the upper surface of the cribriform lamella of the ethmoid bone. See SKELTON.

CRISTA-Galli, in *Botany*, Ger. Lob. See RHINANTHUS *Crista Galli*.

CRISTA Galli, in *Conchyliology*, the name of a peculiar

species of muscle, called also by some *auris porci*, or the hog's ear shell. See MYTILUS.

CRISTÆ is also a term used in *Surgery*, for certain preternatural excrescences arising about the fundament, resembling cock's combs.

These, M. Dionis says, are taken off either by ligature, cauterization, or amputation. When they have other figures they have other names, as *ficus*, &c. See CONDYLOMA.

CRISTA is also used for a crooked, twisted, spiral eminence, in the middle of the spine of the *omoplata*.

CRISTA pavonis, in *Botany*, a name by which some authors have called the poinciana.

CRISTA pavonis is also a name given to the tree, the wood of which is usually denominated logwood.

CRISTARIA, *coccinea*; Sonn. See COMPRETUM *decandrum*.

CRISTIANA, or CRISTINA, in *Geography*, a small island of the Grecian Archipelago, in the Cretan Sea; the ancient Letoa. N. lat. 36° 20' E. lon. 25° 16'.

CRISTOFORI, or CRISTOLANI, FABIO, in *Biography*, an artist of the 17th century, who carried the art of painting in Mosaic to the greatest perfection. The St. Petronilla, from the large picture by Guercino, St. Girolamo, from Domenichino, and the baptism of Christ from Carlo Maratta, in the church of St. Peter at Rome, are sufficient proofs of his extraordinary abilities. He had a son, named Pietro Paolo, who assisted him in the work. The latter died after 1736. Lanzi.

CRISTOFORO, a painter of the 14th century, who is said by some to have been a native of Ferrara, by others of Modera. These cities dispute the honour of having given birth to this early artist. The abbé Lanzi does not pretend to decide the question, but he informs us that he painted many works both in fresco and distemper at Bologna, in a style evidently not derived from the school of Florence. Some of Cristoforo's pictures bear the date 1382. Lanzi.

CRISTONÆI, in *Ancient Geography*, a people placed in the vicinity of Scythia by Stobæus, who says that the women burnt themselves on the bodies of their deceased husbands.

CRITALÆ, or CRITALI, a town of Asia, in Cappadocia. Herodotus.

CRITERIUM, or CRIFERION, formed of κρινω, *I determine*, a rule or standard whereby to compare propositions and opinions, in order to discover their truth or falsehood.

The doctrine of criteria, and the characters and rules thereof, make the first part of the Epicurean philosophy. Evidence is the grand criterion of truth.

CRITH, or CORATH, in *Ancient Geography*, a torrent of Palestine, which commenced in Acrabaterra, near Silo, ran by the north-west, passed S.E. of Phasæis, and emptied itself into Jordan.

CRITHE, κριθη, in *Surgery*, a small tubercle, hard, red, and immoveable, seated upon the eye-lid, above the cilia, or range of hairs. It is always included in a kind of cysta, and by inflammation degenerates into a thickish matter, from whence frequently proceed intense pains, and various disorders of the sight. It is sometimes seated immediately under the skin of the eye-lid: sometimes it is within, under the muscle. When this tubercle is moveable, it is generally called *chalazion*, or in English *stye*, or *stibbe*.

CRITHMUM, in *Botany*, (κριθμων, Diosc.) Linn. Gen. 340. Schreb. 473. Willd. 537. Tourn. Cl. 7. § 4. gen. 7. Juss. 223. Vent. 3. 27. Cl. and order, *pentandria digynia*. Nat. Ord. *Umbelata*, Linn. *Umbellifera*, Juss.

Gen. Ch. *Cal. involucre universal*, many-leaved β; leaflets lanceolate,

lanceolate, obtuse, reflexed; *partial* lanceolate-linear. Perianth proper, scarcely discernible. *Cor.* Universal and *partial* umbels uniform; florets all fertile; petals five, egg-shaped, inflexed, equal. *Stam.* Filaments five, longer than the corolla; anthers roundish. *Pist.* Germ inferior; styles two, reflexed; stigmas obtuse. *Peric.* none; fruit oval, compressed, striated, dividing into two elliptical flattish seeds.

Ess. Ch. Fruit oval, compressed, striated. Flowers equal; calyx entire.

Sp. 1. *C. maritimum.* Linn. Sp. Pl. 1. Mart. 1. Lam. Willd. 1. Jac. Hort. tab. 187. Eng. Bot. 819. (*Crithmum* five *feniculum maritimum* minus; Bauh. pin. 288. Tourn. 377.) Rock samfire, from the French St. Pierre, often coarsely pronounced, and spelt samphire. "Leaflets lanceolate, fleshy." *Root* perennial, branched. *Stems* about a foot high, hard and somewhat woody at the base, nearly erect, cylindrical, leafy, moderately branched. *Leaves* twice or thrice ternate; leaflets acute, quite entire, smooth, rather glaucous, recurved-ascending. *Flowers* in dense umbels, greenish white; petals incurved, broad at the base, not furnished with claws. *Fruit* somewhat spongy, smooth. A native of rocks on the sea-coast of Italy, Spain, France, and the south of England. On the continent the leaves pickled in vinegar are in common use at the table; but in England the much more common *falicornia* has generally usurped its name and place, though a very inferior substitute, and entirely destitute of its aromatic flavour. That it grows on Dover cliff is known to every reader of Shakspeare. We have met with it in Cardiganshire, but in no part of the north of England. 2. *C. latifolium.* Mart. 3. Willd. 2. Linn. jun. Supp. 180. Hort. Kew. 1. 342. "Leaflets wedge shaped, cleft." A very smooth plant, a foot and half high." *Root* biennial. *Stem* erect, cylindrical, furrowed. *Leaves* petioled, pinnated; leaflets in two or three pairs, sessile, decurrent at the outer edge, gradually dilated; lobed, toothed; petioles dilated at the base, embracing the stem. Universal and *partial* involucre of six or seven leaves. *Flowers* yellow. *Seeds* smooth, furrowed, even and elevated at the edges. A native of Teneriffe.

CRITHMUM maritimum spinosum; Bauh. Pin. See *ECHINOPHORA spinosa*.

CRITHMUM pyrenaicum; Linn. See *ATHAMANTIS libanotis*.

CRITHMUM, in *Gardening*, comprises a plant of the herbaceous succulent, perennial, esculent kind; the sea or rock samfire (*C. maritimum*.)

Method of Culture.—This is a plant which, from its being a native of the sea-coasts, is raised in the garden with some difficulty. In order to its successful culture, it should have a rather moist, sandy, or gravelly situation, and be duly supplied with moisture.

It may be propagated either by sowing the seeds in the places where the plants are to remain, in the early spring months, to the depth of about half an inch, or by parting the roots, and planting them out where they are to remain, in the beginning of autumn.

When the plants have been introduced in either of these methods, they will continue for a number of years.

The leaves constitute an admirable pickle, and are sometimes used in fallads, as well as for other culinary purposes.

CRITHOMANCY, a kind of divination, performed by considering the dough, or matter of the cakes offered in sacrifice; and the meal strewed over the victims to be killed. Hence, as they ordinarily used barley-meal in these ceremonies, this kind of divination was called *cribhomancy*, from κριθα, *barley*, and μαντικη, *divination*.

CRITICAL DAYS, in *Medicine*, are those days on which the crises of diseases occur most frequently.

The observation of those sudden changes in febrile disorders, which have been denominated crises, originated with Hippocrates; and the same acute observer remarked, that these crises occurred, in a great number of patients, on particular days of the fever: whence he termed these days *critical* or *judicial* days. It is not, indeed, stated that crises never occur, except on these particular days; on the contrary, there is no day on which a crisis has not been observed to take place: but the crises which occur on the non-critical days are much more rare, and less complete, seldom putting a final termination to the fever.

As the doctrine of critical days was denied and derided by some of the ancients, who had an opportunity of observing diseases under the same common circumstances, we cannot be surprised that many modern physicians should have disputed its truth; especially those who reside in northern climates. For in those climates diseases are less acute, and less disposed to become periodical; crises, therefore, are less frequent, and slighter, and critical days consequently less obvious: not to mention the difference occasioned by the more active modern practice. On the shores of the Mediterranean sea, Dr. Cleghorn observes, that "both these classes of fevers (*viz.* those of summer and winter), and indeed almost all others which happen in that climate, whether primary or symptomatical diseases, may be termed periodical; having remissions and intervals more or less considerable." (On the Diseases of Minorca, chap. vi. p. 259.) This is very far from being the case in the diseases of more northern latitudes. There is still, however, a presumptive evidence, in favour of the disposition to periodical exacerbation and remission in our diseases, sufficiently strong to have satisfied Dr. Cullen, and other distinguished moderns, of the truth of the doctrine of critical days.

This evidence, *a priori*, consists in the obvious disposition of the constitution, in a state of health, to periodical motions. Thus, the appetite for food, which would seem to depend altogether upon the evacuation of the stomach, and the secretion of the gastric juice, returns rather at the habitual period of eating; and, if not then gratified, frequently ceases to be urgent, although the emptiness of the stomach and the production of the digestive liquor continue. The same is in a great degree true with respect to the return of drowsiness, at the usual period of sleep, whether the body is exhausted or not; and the discharges from the bowels are much regulated by this habitual recurrence of time. The disposition to periodical actions is also obvious in many disorders. We need not particularize the quotidian, tertian, and quartan periods of intermitting fevers; the regular return of the paroxysms of intermitting headache, &c. It is frequently evident also in the returns of epileptic and maniacal paroxysms, of the attacks of hæmorrhoids or piles, of gout, of abortion, and so forth. In the eruptive fevers, there are certain regular periods of the appearance and cessation of the fever and eruption, inclining to the tertian interval. Thus Dr. Cullen describes the small-pox: "*Tertio die incipit, et quinto finitur eruptio,*" &c. There is obviously a diurnal revolution in the body, produced by the irritations of the day, and the suspension of them in the night: thus, the pulse is quicker in the evening than in the morning, in health; and hence, perhaps, the general evening paroxysm of hætic and other fevers. But having, in addition to these facts, the testimony of Dr. Cleghorn, Dr. Jackson, and many other respectable physicians, of the general tendency of all fevers to intermissions, in warm climates,

CRITICAL DAYS.

we can have little doubt that the observations of Hippocrates are founded in truth.

The doctrine of critical days, however, as delivered by Hippocrates, and his great commentator, Galen, is involved in some confusion, and not a little inconsistency. This has been attributed to the circumstance, that the works, to which the name of Hippocrates is attached, were not all written by one person; and also to the errors of transcribers. From whatever cause, the doctrine is obscured by such inconsistency, and has been made open to dispute from early times.

The substance of the doctrine is found in the books on Prognostics, and in the Aphorisms of Hippocrates; and the facts, on which it is founded, are related in the treatise on Epidemics. Galen believes that the latter was first written, and the former deduced, by induction, from the facts which it contains. In one of his aphorisms Hippocrates states, that "sweats in febrile patients are salutary, if they begin on the third, fifth, seventh, ninth, eleventh, fourteenth, seventeenth, twenty-first, twenty-seventh, thirty-first, or thirty-fourth days; for these sweats terminate the disease. But the sweats which happen not on these days, denote that the disease will be long, difficult of cure, and liable to relapse." (Aph. 36. sect. 4.) It will be observed, that the twenty-first day is here enumerated among the *critical days*. This is considered by Van Swieten and Cullen as an error of transcription, or an interpolation. But the twenty-first day is mentioned in other places in the works of Hippocrates; and Galen admits it to be critical, although less frequently than the twentieth day. Archigenes, he observes, considered the twenty-first day as more frequently critical than the twentieth; and Diocles deemed it next after the twentieth in critical power. (Galen de Dieb. Decretoriis, lib. i. cap. 10. and lib. iii. cap. 9.) Dr. Cullen's reason for denying the critical quality of the twenty-first day is somewhat hypothetical. From the universal tendency to tertian and quartan periods in intermittent fevers, he presumes such a tendency to exist in the animal economy in all fevers: and hence he believes the critical days to occur at tertian periods to the eleventh day, and afterwards at quartan periods to the twentieth, or perhaps longer. The critical days, according to his notion, are therefore the third, fifth, seventh, ninth, eleventh, fourteenth, seventeenth, and twentieth. (First lines, par. exi. *et seq.*) After this he marks no critical day; because, though fevers are sometimes protracted beyond this period, it is more rarely, so that there are not a sufficient number of observations to ascertain the course of them; and because it is probable that, in fevers long protracted, the movements become less exact and regular, and therefore less easily observed. He believes also that this is the series of critical days, from comparing the facts, which are related in the writings of Hippocrates. From these facts, as collected by M. de Haen, it appears, that of 163 instances of the termination of fevers, which happened on one or other of the first twenty days of the disease, there are 107, or more than two-thirds of the whole number, which happened on one or other of this series of days; that none happened on the second or thirteenth day; and upon the eighth, tenth, twelfth, fifteenth, sixteenth, eighteenth, and nineteenth, there were but 13 instances of termination, or one-ninth of the whole. And, he adds, the many terminations which happened on the seventh, fourteenth, and twentieth days, afford a proof both of critical days in general, and that these are the chief of them.

But the majority of the observations of Hippocrates and Galen applies to a different series of days from those above stated, in which some days are included as frequently cri-

tical, which are altogether omitted in the preceding list. Whether altogether from the induction of experience, or whether under the influence of some Pythagorean hypothesis, as to the power of number, Hippocrates considered the septenary period as the most important, and the quaternary, or division of the former, the second in critical power. Thus the fourth, seventh, eleventh, fourteenth, seventeenth, and twentieth, are deemed the most frequently critical; but not in the order here stated. The seventh, the fourteenth, and the twentieth, were the most powerfully critical; the fourth, eleventh, and seventeenth, less critical, but connected with the former as indices; so that any change taking place on the fourth day of each week, indicated a similar and more complete change on the seventh. The third, fifth, sixth, and ninth, which are occasionally critical, but of feeble power, *i. e.* seldom finally and salutarily critical, were called by Galen *incidental or coincidental* critical days. Thus Galen observes, (lib. ii. cap. 8. De Diebus Decretoriis,) "the most powerful of all is the seventh day: the fourth presages it, having these two qualities, being a minor critical day, and an index to the seventh. Then come the fourteenth and eleventh, bearing the same proportion, and being of the same reciprocal nature to each other as the seventh and fourth: then the seventeenth as allied to the twentieth, rarely the eighteenth, as connected with the twenty-first. The ninth, fifth, and third days are coincidental with these; the ninth being most frequently critical; the fifth second in critical power; and after it, the third. The sixth is elsewhere mentioned as a bad critical day. The thirteenth is the weakest of all critical days; but the most powerful of all non-critical days, inasmuch as it stands in a sort of medium between the two, &c."

In book i. chap. 2. Galen remarks, "on the twelfth and sixteenth I never saw a crisis occur; but I am unable to number the crises which I have witnessed on the seventh day. On the sixth day crises do take place, but with symptoms of difficult concoction, and no small danger, and they are not to be relied on, being imperfect, obscure, and prejudicial." Of the critical terminations happening on the sixth day, among the histories related by Hippocrates, there is not one which proves finally salutary; the greater number are fatal; and all the rest are imperfect, and followed by a relapse. Hence Galen calls the sixth a *bad* critical day; and he compares the seventh and sixth days to a king and a tyrant: the former, like a good prince, judging in mercy and clemency, and mitigating the punishment or favouring the acquittal of his subjects; the latter, gratified with their sufferings, and prolonging the infliction of punishment to the uttermost.

With respect to the fourth, which is omitted to be mentioned in the list of critical days, in the aphorism, much importance is given to it in other places. Hippocrates observes, in his prognostics: "But the physician must attend to all the appearances from the very first day of the disease, and consider the sum of his observations on every *fourth* day; by which means he will not be unacquainted with the course that the disease is about to take." Again, he says, in Aphorism 71, sect. 4, "when a crisis happens on the seventh day, there is a small red cloud in the urine on the fourth day, and other things are proportionate to this appearance." The fourth day, therefore, is, in general, only an *indicating* day to the seventh, and never proves finally critical, except in slight fevers, or in some which are extremely acute and rapid. (De Prognost.) It is obvious, then, that each critical day, in the quaternary and septenary periods, is considered as related to the succeeding critical day, in the quality of an *indicator*; the fourth as an index

to the seventh, the seventh to the eleventh, and so on. Thus, if on a critical day, the patient finds himself better, although on the following day he relapses into his former state, the physician may expect a more remarkable remission on the subsequent critical day. On the contrary, if the patient find himself worse on a critical day, a still more unfavourable change is to be looked for on that which follows, although during the intermediate days the symptoms become milder.

This doctrine had an extensive influence over the practice of the ancients, who watched these days with particular attention, and almost suspended medical assistance, lest they interrupt or derange the processes of nature in the constitution. Galen is minute in the detail of circumstances, by which such a prejudicial interruption or derangement may be occasioned. (*De Deib. Decret. lib. i. cap. 2.*) The crises, which occur on the *coincidental* critical days, *viz.* the third, fifth, sixth, and ninth, and which are imperfect, and not to be depended on, were attributed to some pernicious interference of this sort, or to a fresh paroxysm of the disease, and were considered as anticipations of the proper critical days, on which the regular unexcited operations of nature would have terminated the disease. For the process of concoction requires a certain time to be completed, says Van Swieten, pursuing the humoral hypothesis. But as it is improper to open an inflamed part before the matter is completely formed; so likewise evacuations made in fevers, before nature has subdued and separated the morbid from the healthy humours, can hardly be of any service, because they remove only part of the morbid matter, whence a return may be expected from what remains, &c. (*Commentaries, Aph. 741.*) The coincidental critical days are most numerous in the first septenary, or week, because, according to the ancients, the violence of fevers which run their course in so short a time as one week, often disturbs the crisis which ought to happen only on the 4th or 7th day. In the second septenary, the ninth is esteemed almost the only coincidental critical day; and after the fourteenth day, the coincidental days are of little consequence, the crises generally occurring on the true critical days. We shall say nothing respecting the critical days after the twentieth and twenty-first, although much is said by the ancients, even beyond the hundredth day; as it is confessed that they are few, and not easily assigned to a particular day.

Although this doctrine of critical days was generally adopted among the ancients, it was rejected by some. Herophilus, as Galen informs us, denied its truth; and Aesculapiades deemed it idle and nugatory. Celsus coincides with them, and derides it, on account of its inconsistency in itself; intimating also that it is a doctrine taken up by those physicians, who, for the sake of gain, wish to visit a great number of patients; since it is much easier to count days, even without seeing the patient, than to sit by him, and watch the symptoms as they change. (*De Medicina, lib. iii. cap. 4.*) The inconsistency, observed by Celsus, is this. Hippocrates considers the *fourth* day in each septenary as critical; hence the fourth, and the eleventh (taking the 8th as the first of the second septenary) are critical. But he assimilates the seventeenth with these as a fourth; whereas the 17th is only the *third* of the 3d septenary; for the eleventh is the 5th from the seventh; but the seventeenth is only the 4th from the fourteenth. This also makes the twentieth the last of the 3d septenary, instead of the twenty-first.

Various conjectures were entertained respecting the causes of these periodical movements in fevers. Some attributed them to the harmony of numbers, according to the Pytha-

gorean philosophy, and Celsus and others have conceived that Hippocrates was swayed by this absurd doctrine. But Van Swieten states the irregularity, just related, as a proof that Hippocrates deduced his numbers from a faithful observation of diseases. Galen imagined that the crises of fevers were caused by the changes of the moon; and this notion has been also entertained by Dr. Jackson and some other modern physicians.

Such is the doctrine of critical days delivered by the ancients, as observed in Greece and Asia Minor. The diseases of those climates being very different from those of our own, we cannot expect the doctrine to apply here. Although changes for the better or worse are often well marked, yet they are rarely preceded by those perturbations of the constitution which belong to a complete crisis. The following list of well marked terminations, in a hundred and twenty cases of the contagious malignant fever of this country, is given by Dr. Willan in his "Reports on the Diseases of London," p. 233.

Days of Fever.	Number of Cases.
4th.	Six.
5th or 6th.	Three.
7th.	Ten; one case fatal.
8th and 9th.	Five; two cases fatal.
10th and 11th.	Ten; two cases fatal on the 10th night; three on the 11th day.
12th.	Twelve; one case fatal.
13th.	Five; one case fatal.
14th.	Thirty; one case fatal.
15th.	Two.
16th.	None.
17th.	Fourteen.
18th.	One, fatal.
19th.	One, fatal.
20th.	None.
21st.	Twelve.
22d.	Three.
28th.	Two.
29th.	Three.
30th to 40th.	Two.

Here we find the two septenaries, and the 17th the most complete critical days, and the proper third septenary, or 21st, also critical; but no crises on the 20th, or third septenary of Hippocrates. On one of the days, in which Galen never saw a crisis, *viz.* the 16th, none occurred; but the other, the 12th, was here the third in critical quality. If the regular crises are as easily deranged as the ancients affirm, this list will rather tend to confirm the doctrine than otherwise; and the 12th and 21st may perhaps be the 11th and 20th postponed. But it must be remembered that, in the fevers of this country, the time of commencement is frequently obscure, and not to be ascertained; and that true crises are rare. A mere list of terminations of fever, therefore, such as that published in the second Report of the House of Recovery at Dublin, are of no value, as illustrations or refutations of the ancient doctrine. See CRISIS and CONCOCTION.

CRITICISM, the art of judging concerning discourse and writings. See JUDGMENT.

Some define criticism, more amply, the art of judging of a history, or a work of genius, with the various incidents there met with, their style and authors.

On which footing, M. le Clerc seems to have given a defective idea of criticism, when he defines it simply the art of entering into the meaning of ancient authors, and of making

ing a just discernment of their genuine works. True criticism, says Dr. Blair, (*Lect. on Rhet.* vol. i. p. 36, &c.) is the application of taste and of good sense to the several fine arts. The object which it proposes is to distinguish what is beautiful and what is faulty in every performance; from particular instances to ascend to general principles; and so to form rules or conclusions concerning the several kinds of beauty in works of genius.

The rules of criticism are not formed by any induction *à priori*; that is, by a train of abstract reasoning, independent of facts and observations. Criticism is an art founded wholly on experience; on the observation of such beauties as have been found to please mankind most generally, *e. g.* Aristotle's rules concerning the unity of action in dramatic and epic compositions, were not rules first discovered by logical reasoning, and then applied to poetry; but they were drawn from the practice of Homer and Sophocles; they were founded upon observing the superior pleasure which we receive from the relation of an action which is one and entire, beyond what we receive from the relation of scattered and unconnected facts. Such observations, taking their rise at first from feeling and experience, were found on examination to be so consonant to reason, and to the principles of human nature, as to pass into established rules, and to be conveniently applied for judging of the excellency of any performance. This, as Dr. Blair conceives, is the most natural account of the origin of criticism. To the same purpose Mr. Harris observes, (*Philological Inquiries*, ch. i.) that they were authors who made the first good critics, and not critics who made the first good authors; however writers of later date may have profited by critical precepts. Accordingly, criticism in its beginning was "a deep and philosophical search into the primary laws and elements of good writing, as far as they could be collected from the most approved performances." No observations or rules of criticism can supply the defect of genius, or inspire it where it is wanting; but they may often direct it into its proper channel, correct its extravagancies, and point out to it the most just and proper imitation of nature. Critical rules are designed chiefly to shew the faults that ought to be avoided; to nature we owe the production of eminent beauties. In tracing the history of criticism, we must begin with Aristotle, who may be justly regarded, notwithstanding some general principles suggested by Plato, as the inventor or father of the art, both from the age in which he lived, and from his truly transcendent genius. The criticism which he taught, has so intimate a correspondence and alliance with philosophy, that it may be called "philosophical criticism." To Aristotle succeeded Theophrastus, who followed his master's example in the study of criticism, as may be seen in the catalogue of his writings preserved by Diogenes Laertius, (*lib. v. § 46, 47, &c.*) But all the critical works of Theophrastus are now lost, as well as those of many others. The principal authors of the kind now remaining in Greek, are Demetrius of Phalera, who was the earliest, and appears to follow the precepts and even the text of Aristotle more closely than any of the rest; Dionysius of Halicarnassus, who has written with judgment upon the force of numerous composition, besides other tracts on rhetoric, both critical and historical; Longinus, who seems to have principally had in view the passions and imagination, in the treating of which he has acquired just applause; and also Hermogenes, Aphthonius, and a few others. Among the Romans, the first critic of note was Cicero, who, though far inferior to Aristotle in depth of philosophy, may be said, like him, to have exceeded all his countrymen. Next to Cicero came Horace, whose art of poetry is a standard

of its kind, and too well known to need any encomium. After Horace arose Quintilian, Cicero's admirer and follower, who appears, by his works, not only learned and ingenious, but an honest and worthy man. The latter Latin rhetoricians need not be mentioned, as they have not contributed much towards the illustration of the subject of philosophical criticism. Among the cultivators of "historical criticism," we find a tribe of scholiasts, commentators, and explainers. These naturally attached themselves to particular authors; Arriarchus, Didymus, Eustathius, and many others bestowed their labours upon Homer; Proclus and Tzetzes upon Hesiod; the same Proclus and Olympiodorus upon Plato; Simplicius, Ammonius, and Philoponus upon Aristotle; Ulpian upon Demosthenes; Macrobius and Arrianus upon Cicero; Calliergus upon Theocritus; Donatus upon Terence; Servius upon Virgil; Acro and Porphyrio upon Horace; and so with respect to others, as well philosphers, as poets and orators. To these scholiasts may be added the several compilers of Lexicons; such as Hesychius, Philoxenus, Suidas, &c. and also the writers upon grammar, such as Apollonius, Priscian, Sossipater, Charisius, &c. All these have completed, by their assiduity and labour, another species of criticism, which, by way of distinction from the former, may be denominated "historical criticism." When the Roman empire sunk through the west of Europe, an age succeeded of legends and crusades. At length, after a long and barbarous period, when the shades of monkery began to retire, and the light of humanity once again to dawn, about the time of Charlemagne and his sons, the art also of criticism insensibly revived. The authors of the philosophical part were not, indeed, many in number. Of this rank, however, among the Italians were Vida, and the elder Scaliger; among the French were Rapin, Bonhours, Boileau, and Bossu, the most methodical and accurate of them all. In our own country, the nobility may be said to have distinguished themselves, among whom we may mention lord Roscommon, in his "Essay upon translated Verse," the duke of Buckingham in his "Essay on Poetry," and lord Shaftesbury in his treatise entitled "Advice to an Author;" and to these we may add Pope in his "Essay upon Criticism." Although the number of philosophical critics among the moderns may be comparatively small, the writers of historical or explanatory criticism have been in a manner innumerable. Such were in Italy, Bernoldus, Ficinus, Victorius, and Robertellus; in the Higher and Lower Germany, Erasmus, Sylburgius, Le Clerc, and Fabricius; in France, Lambin, Du Vall, Harduin, Capperonierus; in England, Stanly, editor of Æschylus, Gataker, Davis, Clarke, Bentley, &c. &c. Among the compilers of Lexicons or Dictionaries we may mention Charles and Henry Stephens, Favorinus, Constantine, Budæus, Cooper, Faber, Vossius, &c. &c. To these we might add the authors on grammar, in which subject the learned Greeks, when they quitted the East, led the way: Moschopulus, Cryfoloras, Lascaris, Theodore, Gaza; then in Italy, Laurentius Valla; in England, Grocin, and Linacer; in Spain, Sanctius, professor of rhetoric and of the Greek tongue in the university of Salamanca, towards the end of the 16th century; in the Low Countries, Vossius; in France, Cæsar Scaliger, by his residence, though a native of Italy, and the Messrs. de Port Royal. Among modern critics of the explanatory kind, are lexicographers, grammarians, and translators; among whom Mr. Harris (*ubi supra*) has mentioned Mr. T. Warton, Mr. Tyrwhit, Mr. Upton, Mr. Addison, Dr. Warton, and Mrs. Montague. The dictionaries, says the same writer, of Minshew, Skinner, Spelman, Sumner, Junius, and Johnson, are well known and justly esteemed.

teemed. Dr. Lowth, and his admirable tract on grammar, are noticed with distinguished commendation. Among translators, our author enumerates Meric Casaubon, Mrs. Carter, and Mr. Sydenham. To these, he says, may be added the respectable names of Melmoth and of Hampton, of Franklin and of Potter; others might have been added if the author had not recollected the trite, though elegant admiration,

“ ——— Fugit irreparabile tempus,
Singula dum capti circumvectamur amore.”

Virgil.

The critics of our own times have been innumerable; but it might appear invidious to select names of recent, and more especially of living authors, out of the numerous class that must present itself to every one's own recollection.

Upon the whole, it must appear that criticism does, indeed, suppose an uncommon stock of knowledge of the subject whereon it is employed; but that criticism itself is nothing else but good sense perfected by grammar and logic.

We may distinguish divers sorts, or branches, of this art: as,

CRITICISM, *philosophical*, or the art of judging of opinions and hypotheses in philosophy.

CRITICISM, *theological*, the art of judging of explications, of doctrines, of faith, &c.

CRITICISM, *political*, the art of judging of the means of governing, acquiring, and preserving states.

But the ordinary use of the word is restrained to

CRITICISM, *literary*, which, however, is of great extent, as it takes in the art of judging of facts; a branch of criticism, which regards not only history, but also the discernment of the real works of an author, the real author of a work, the genuine reading of a text, and the art of discovering supposititious monuments, charters, interpolated passages, &c.

The other parts of *literary criticism* comprehend the art of judging of works of genius, their excellencies and defects.

Mr. Harris (*ubi supra*) divides this kind of criticism into three species, the *philosophical*, treating of the principles, and primary causes of good writing in general; the *historical*, being conversant in particular facts, customs, phrases, &c.; and the *corrective*, subdivided into the *authoritative*, which depends on the collation of MSS. and the best editions, and *conjectural*, depending on the sagacity and erudition of editors. We have also

CRITICISM, *grammatical*, or the art of interpreting and discovering the words and meanings of an author.

CRITICISM of *Antiques*, consists in distinguishing genuine medals, and the different taste and spirit found among them, according to the different people, the different country, and the different times wherein they were struck; the distinguishing between what is cast, and what struck; what has been retouched, and repaired or added, from what is really antique; the genuine from the spurious, &c; and to decypher and explain them, &c.

CRITICISM, *Sacred*, in general, is that employed in ecclesiastical matters, the history of the church, the works of the fathers, councils, lives of the saints, &c. but more particularly what concerns the books of the Holy Scriptures, and the canon thereof.

To this head we may refer *Conjectural Criticism*, for which see the article CONJECTURE. In connection with this part of the subject, we may mention that species of criticism which the ingenious Mr. Harris (*ubi supra*) called the *corrective*. All ancient books, having been preserved by trans-

cription, or fraud, to be corrupted in three different ways, *viz.* by retrenchments, by additions, and by alterations. As a remedy to these evils, *corrective* criticism was introduced. The business of this, at first, was carefully to collate all the various copies of authority, and then, from the variety of readings thus collected, to establish by good reason the *true*, or the *most probable*. In this sense such criticism may be denominated not only *corrective*, but *authoritative*. In ancient times various readings have been noted, in the text of Homer, and in that of Aristotle; which latter has been examined by his commentators, Ammonius and Philoponus; and Aulus Gellius has noticed the same as to Roman authors: but since the revival of literature, correction has been a more extensive business, and has employed, for 2½ centuries, the pains of the most laborious, and the wits of the most acute critics. Many of the learned men already enumerated were not only famous as historical critics, but also as correctives. Such were the two Scaligers, the two Casaubons, Salmasius, the Heinsii, Grævius, the Gronovii, Burman, Kuster, Wasse, Bentley, Pearce, and Markland; to whom we may add Toupe, Taylor, and Upton. This latter kind of criticism has been too often abused, and extended by conjecture to an undue extreme (see CONJECTURE); and authors have been treated, like anatomical subjects, with a view to the display of the skill and abilities of the artist; so that the design of various editions seems to have been merely the exhibition of the wonderful sagacity and erudition of an editor. The joy of the task has been the honour of mending, while corruptions were sought with a more than common attention, as each of them afforded a testimony to the editor and his art. “Critics,” says Mr. Harris, (if I may be allowed the metaphor,) “are a sort of *masters of the ceremony* in the court of letters, through whose assistance we are introduced into some of the first and best company. Shall we even, therefore, by idle prejudices against pedantry, verbal accuracies, and we know not what, come to slight their art, and reject them from our favour? 'tis well we do not slight also those classics, with whom criticism converses, becoming content to read them in translations, or (what is still worse) in translations of translations, or (what is worse even than that) not to read them at all. And I will be bold to assert, if that should ever happen, we shall speedily return into those days of darkness, out of which we happily emerged upon the revival of ancient literature.”

CRITICISM, *Musical*. As music may be defined the art of pleasing by the succession and combination of agreeable sounds, every hearer has a right to give way to his feeling, and be pleased or dissatisfied without knowledge, experience, or the fiat of critics; but then he has certainly no right to insist on others being pleased or dissatisfied in the same degree. We can very readily forgive the man who admires a different music from that with which we are pleased, provided he does not extend his hatred or contempt of our favourite music to ourselves, and imagine that on the exclusive admiration of any one style of music, and a close adherence to it, all wisdom, taste, and virtue depend.

Criticism in this art would be better taught by specimens of good composition and performance than by reasoning and speculation. But there is a certain portion of enthusiasm connected with a love of the fine arts, which bids defiance to every curb of criticism; and the poetry, painting, or music, that leaves us on the ground, and does not transport us into the regions of imagination beyond the reach of cold criticism, may be correct, but is devoid of genius and passion. There is, however, a tranquil pleasure, short of rapture, to be acquired from music, in which intellect and

fevation are equally concerned; the analysis of this pleasure is, therefore, the subject of the present short essay; which, it is hoped, will explain and apologize for the critical remarks which have been made in the course of this history, on the works of great masters, and prevent their being confounded into pedantry and arrogance.

Indeed, musical criticism has been so little cultivated in our country, that its first elements are hardly known. In justice to the late Mr. Avison, it must be owned, that he was the first, and almost the only writer, who attempted it. But his judgment was warped by many prejudices. He exalted Rameau and Geminiani at the expense of Handel, and was a declared foe to modern German symphonies. There have been many treatises published on the art of musical composition and performance, but none to instruct ignorant lovers of music how to listen, or to judge for themselves. So various are musical styles, that it requires not only extensive knowledge, and long experience, but a liberal, enlarged, and candid mind, to discriminate and allow to each its due praise:

“ Nullius in verba magistri.”

A critic should have none of the contractions and narrow partialities of such as can see but a small angle of the art; of whom there are some to bewilder in tangles and complicated contrivances, that they can receive pleasure from nothing but canonical answers, imitations, inversions, and counter-subjects; while others are equally partial to light, simple, frivolous melody, regarding every species of artificial composition as mere pedantry and jargon. A chorus of Handel and a graceful opera song should not preclude each other: each has its peculiar merit; and no one musical production can comprise the beauties of every species of composition. It is not unusual for disputants, in all the arts, to reason without principles; but this, we believe, happens more frequently in musical debates than any other. By principles, we mean the having a clear and precise idea of the constituent parts of a good composition, and of the principal excellencies of perfect execution. And it seems, as if the merit of musical productions, both as to composition and performance, might be estimated according to De Piles' steel-yard, or test of merit among painters. If a complete musical composition of different movements were analysed, it would perhaps be found to consist of some of the following ingredients: melody, harmony, modulation, invention, grandeur, fire, pathos, taste, grace, and expression; while the executive part would require neatness, accent, energy, spirit, and feeling; and, in a vocal performer, or instrumental, where the tone depends on the player, power, clearness, sweetness; brilliancy of execution in quick movements, and touching expression in slow.

But as all these qualities are seldom united in one composer or player, the piece or performer that comprises the greatest number of these excellencies, and in the most perfect degree, is entitled to pre-eminence: though the production or performer that can boast of any of these constituent qualities cannot be pronounced totally devoid of merit. In this manner, a composition, by a kind of chemical process, may be decomposed as well as any other production of art or nature.

Prudent critics, without science, seldom venture to pronounce their opinion of a composition, decisively, till they have heard the name of the master, or discovered the sentiments of a professor; but here the poor author is often at the mercy of prejudice, or envy. For the opinion of professors of the greatest integrity is not equally infallible concerning every species of musical merit. To judge minutely

of *singing*, for instance, requires study and experience in that particular art. Indeed, we have long suspected some very great instrumental performers of not sufficiently feeling or respecting real good singing. Rapid passages neatly executed seem to please them infinitely more than the finest *mezza di voce*, or tender expression of slow notes, which the sweetest voice, the greatest art, and most exquisite sensibility, can produce. They frequently refer all excellence so much to their own performance and perfections, that the adventitious qualities of singers who imitate a hautbois, a flute, or violin, are rated higher than the colouring and refinements that are peculiar to vocal expression; which instrumental performers ought to feel, respect, and try to imitate, however impossible it may be to equal them: approximation would be something, when more cannot be obtained. Of *composition*, and the genius of particular instruments, whose opinion, but that of composers and performers, who are likewise possessed of probity and candour, can be trusted? There are, alas! but too many professors who approve of nothing which they themselves have not produced or performed. Old musicians complain of the extravagance of the young; and these again of the dryness and inelegance of the old.

And yet, among the various styles of composition and performance, the partial and capricious tastes of lovers of music, and the different sects into which they are divided, it seems as if the following *criteria* would admit of little dispute.

In *church music*, whether jubilation, humility, sorrow, or contrition are to be expressed, the words will enable the critic to judge; but of the degree of dignity, gravity, force, and originality of the composition, few but professors can judge in detail, though all of the general effect.

In hearing *dramatic music*, little attention is paid by the audience to any thing but the airs and powers of the principal singers; and yet, if the character, passion, and importance of each personage in the piece are not distinctly marked and supported; if the airs are not contrasted with each other, and the part of every singer in the same scene specifically different in measure, compass, time, and style, the composer is not a complete master of his profession.

Good singing requires a clear, sweet, even, and flexible voice, equally free from nasal and guttural defects. It is but by the tone of voice and articulation of words that a vocal performer is superior to an instrumental. If in swelling a note the voice trembles or varies its pitch, or the intonations are false, ignorance and science are equally offended; and if a perfect shake, good taste in embellishment, and a touching expression be wanting, the singer's reputation will make no great progress among true judges. If in rapid divisions the passages are not executed with neatness and articulation; or in adagios, if light and shade, pathos, and variety of colouring and expression are wanting, the singer may have merit of certain kinds, but is still distant from perfection.

Of *perfect performance on an instrument*, who can judge accurately but those who know its genius and powers, defects and difficulties? What is natural and easy on one instrument, is often not only difficult but impracticable on another. *Arpeggios*, for instance, which are so easy on the violin and harpsichord, are almost impossible on the hautbois and flute. And the rapid iteration of notes which give the violin player such little trouble, are impracticable on the harpsichord with the same finger. Those instruments of which the tone and intonation depend on the player, as the violin, flute, hautbois, &c. are more difficult than harps and keyed-instruments, where the player is neither answerable
for

for the goodness of the tone nor truth of intonation. However, there are difficulties on the harpsichord of another kind, to balance the account, such as the two hands playing two different parts in dissimilar motion at once, and often three or four parts with each hand. Of a good shake, a sweet tone, and neat execution, almost every hearer can judge; but whether the music is good or bad, the passages hard or easy, too much or too little embellished by the player, science and experience can only determine.

In *chamber music*, such as cantatas, single songs, solos, trios, quartets, concertos, and symphonics of few parts, the composer has less exercise for reflection and intellect, and the power of pleasing in detached pieces by melody, harmony, natural modulation, and ingenuity of contrivance, with fewer restraints, and fewer occasions for grand and striking effects, and expression of the passions, than in a connected composition for the church or the stage. Many an agreeable lesson, solo, sonata, and concerto, has been produced by musicians who would be unable to compose a *Te Deum* for voices and instruments, or to interest and satisfy an audience during a single act of an opera. We never have heard of Corelli, Geminiani, or Tartini attempting vocal melody, and the music merely instrumental of the greatest vocal composers is often meagre, common, and insipid. There are limits set to the powers of every artist, and however universal his genius, life is too short for universal application.

It was formerly more easy to compose than play an adagio, which generally consisted of a few notes that were left to the taste and abilities of the performer; but as the composer seldom found his ideas fulfilled by the player, adagios are now made more chantant and interesting in themselves, and the performer is less put to the torture for embellishments.

In 1752, Quantz classed quartettes at the head of instrumental music, calling them the touch-stone of an able composer; adding, that they had not yet been much in fashion. The divine Haydn, however, has since that time removed all kind of complaint on that account, having produced such quartets for number and excellence, as have never been equalled in any species of composition at any other period of time.

In composing and playing a solo, the least complicated of all music in parts, much knowledge, selection, invention, and refinement are necessary. Besides consulting the genius of the instrument and power of the performer, new, interesting, and shining passages must be invented, which will at once please and surprise the hearer, and do honour to the composer and performer. And who can judge of the originality of the composition, its fitness for the instrument, or degree of praise due to the performer, but those who have either studied composition, practised the same instrument, or heard an infinite variety of music and great performers of the same kind?

The famous question, therefore, of Fontenelle: "sonate, que veux tu?" to which all such recur as have not ears capable of vibrating to the sweetness of well-modulated sounds, would never have been asked by a real lover or judge of music. But men of wit of all countries being accustomed to admiration and reverence in speaking upon subjects within their competence, forget, or hope the world forgets, that a good poet, painter, physician, or philosopher, is no more likely to be a good musician without study, practice, and good ears, than another man. But if a lover and judge of music had asked the same question as Fontenelle; the Sonata should answer: "I would have you listen with attention and delight to the ingenuity of the composition, the neatness of the execution, sweetness

of the melody, and the richness of the harmony, as well as to the charms of refined tones, lengthened and polished into passion."

There is a degree of refinement, delicacy, and invention which lovers of simple and common music can no more comprehend than the Asiatics harmony. It is only understood and felt by such as can quit the plains of simplicity, penetrate the mazes of art and contrivance, climb mountains, dive into depths, or cross the seas in search of extraneous and exotic beauties, with which the monotonous melody of popular music has not yet been embellished. What judgment and good taste admire at first hearing, makes no impression on the public in general, but by dint of repetition and habitude. A syllogism that is very plain to a logician, is incomprehensible to a mind unexercised in associating and combining abstract ideas. The extraneous, and seemingly forced and affected modulation of the German composers of the present age, is only too much for us, because we have heard too little. Novelty has been acquired, and attention excited, more by learned modulation in Germany, than by new and difficult melody in Italy. We dislike both, perhaps, only because we are not gradually arrived at them; and difficult and easy, new and old, depend on the reading, hearing, and knowledge of the critic. The most easy, simple, and natural is new to youth and inexperience, and we grow nice and fastidious by frequently hearing compositions of the first class, exquisitely performed.

CRITONIA, in *Botany*, Gært. See KURNIA.

CRIVELLARI, BARTOLOMEO, in *Biography*, an engraver, born at Venice about the year 1725. He was much employed in that city by Wagner, for whom he engraved several plates. Some of the prints for the work entitled, "Istituto di Bologna," are likewise by him, particularly those four beautiful conversation-pieces from Niccolò del Abbati. Huber. *Manuel des Arts*.

CRIVELLI, ANGELO MARIA, a Milanese painter, celebrated for his skill in painting cattle. He was called Il Crivellone to distinguish him from his son Jacopo, who was a painter of birds and fishes. Angelo Maria died in 1730, Jacopo about the year 1760. Oriandi. Lanzi.

CRIVELLI, CARLO, a Venetian painter of the 15th century, who was the disciple of Jacobello del Fiore. He travelled many years, working wherever he came, and at length fixed his residence at Ascoli. His compositions are numerous, but the best of them are his small historical pictures, in which he introduces landscapes touched with great delicacy; nor are his figures void of grace or expression, though he was less correct as a designer than excellent as a colourist. Some of his pieces bear his name at length, and their respective dates from 1450 to 1474.

In the church of St. Sebastiano at Venice, is a figure of pope St. Fabiano in his pontifical habit, and the marriage of St. Catharine by the hand of this artist. Lanzi. Storia Pitt.

CRIVITZ, or KRIEWITZ, in *Geography*, a small town of Mecklenburgh Schwerin, in the ancient county of Schwerin, which in 1573 and 1660 suffered very much by conflagrations, the houses being mostly built with wooden frames, the interstices of which are filled with brick work.

CRIUMETOPON, in *Ancient Geography*, Asia, a promontory of the Tauric Chersonesus, and the most southern point of that peninsula.—Also, a promontory of the island of Crete.

CRIUS, a river of the Peloponnesus, in Achaia, which had its source in the mountains above Pallene, and discharged itself into the sea, before the town of Egyres, according to Pausanias.

CRIXIA, a town of Italy, in Liguria, situated between

Aquæ and Canalicum, according to the Itinerary of Antonine.

CRIZZELLING, in the *Glass Trade*, a kind of roughness arising on the surface of some kinds of glass. This was the fault of a peculiar sort of glass made in Oxfordshire, and some other places, of black flints, a crystallized sand, and a large quantity of nitre, tartar, and borax. The glass thus made is very beautiful, but, from the too great quantities of the salts in the mixture, is subject to *crizel*; that is, the salts in the mixture, from their too great proportion, are subject, either from the adventitious nitre of the air from without, or from warm liquors put in them, to be either increased in quantity, or dissolved, and thereby induce a scabiness, or roughness, irrecoverably clouding the transparency of the glass. This is what was called *crizzelling*; but by using an Italian white pebble, and abating the proportions of the salts, the manufacture is now carried on with advantage, and the glass made with these salts is whiter than the finest Venetian, and is subject to no faults. Plott's Oxfordshire, p. 258.

CROAGAN-KINSHELLY, in *Geography*, a mountain in the barony of Arklow, Ireland, elevated 1850 feet above the level of the sea.

CROAGH-PATRICK, or **CROW-PATRICK**, a mountain of the county of Mayo, Ireland, situated on the south of Clew-bay. This is by many esteemed the highest mountain in Ireland, rising in a conical form 2666 feet above the level of the sea. This mountain is celebrated by the natives as that from which St. Patrick drove all venomous beasts into the sea. On the summit there is an altar much frequented by Catholic pilgrims. Latocnaye's Rambles, &c.

CROAGHMORE, a mountain of Antrim county, Ireland, elevated 600 feet above the level of the sea.

CROARA, a town of Italy, in the duchy of Modena, 18 miles S.W. of Modena.

CROATIA, a country of Europe, situated between the 15th and 17th degree of E. longitude, and the 45th and 47th of N. latitude, belonging to the empire of Austria. It is a part of the ancient Illyricum. In the middle ages, Croatia, together with Dalmatia, formed a kingdom subject to the emperors of the East. This kingdom, in the eleventh century, devolved to Hungary. The Hungarians call it Horvath Orsozag. Zagrab or Angram on the river Save is the capital. An Austrian viceroy governs Croatia jointly with Slavonia and Hungarian Dalmatia.

Croatia extends from the river Drave to the Adriatic, about 80 miles in length, and 70 in breadth. It is bounded to the north by Slavonia, to the east by Bosnia, to the south by Dalmatia and the Adriatic, and to the west by the Austrian provinces of Stiria and Carniola. Its principal rivers are the Save and the Unna.

The whole country is divided into two parts: Croatia on this side of the Save, *Croatia Cissavana*, which is also called Upper Slavonia, and subdivided into five counties, and Croatia beyond the Save, *Croatia Transavana*, or Croatia Proper, which is subdivided into Hungarian or Military Croatia, and the Banat, *Banalis Croatia*, and Turkish Croatia, on the other side of the river Unna.

Military Croatia is one of the five principal divisions of the military frontiers of Austria in Hungary. This district commences at the most western corner of Dalmatia on the Adriatic, and runs through Croatia, Slavonia, the Banat of Temeswar, and Transylvania, into the Buccovina. This long tract of land, which surrounds Hungary on the south and on the east, has about 420,000 inhabitants, the fifth part of which is military. Keresyturi in his "Introductio," &c. Vienna, 1788, divides it into six districts, *viz.* Carlstadt,

which has four regiments; Banat, which has two; Warasdin, which has two; Slavonia, which has three; Banat of Temeswar, which has two; and Transylvania, which has three; in all sixteen regiments of infantry, of 3825 men, with 480 hussars attached to each regiment. The whole military frontier was formerly without any civil magistrates; but its military constitution has been abolished by the emperor Joseph II., and the Croats are now drafted into the regular regiments, like the rest of the subjects of Austria.

Croatia, according to Mr. de Lucca's Statistical Tables of 1793, contains 267,000 inhabitants, or 500 individuals per square mile.

CROATS, or **CROATIANS**, the inhabitants of Croatia, derive their origin from the Slavonians and Slavi, and settled in Croatia under the reign of the emperor Heraclius. Their ancient name was Hruatæ, or Hrouatæ, of which the Greeks made Chrobatæ. Of all the Illyrian nations they have the greatest affinity in their language with the Poles. Their manners, religion, and customs, are similar to those of the Slavonians and Transylvanians their neighbours. They are the successors of those *Daci*, or *Dacians*, who were at first the terror, and afterwards the strength, of the Roman armies; and have maintained their reputation for bravery in modern warfare, particularly in the seven years' war between Austria and Prussia, which terminated in 1763. The best general officers of the Austrian army, as Laudon, de Wied, and Kleefeldt, were formed in the Croatian regiments. Although the Croats have lost their ancient military constitution, they are still excellent soldiers, generally employed in the van and rear guards. They are also known by the name of **PAKDOURS**; which see.

CROBIALUS, or **CROBIALUM**, in *Ancient Geography*, a small town of Asia, situated near the Euxine sea, towards Paphlagonia.

CROBYZI, a people who occupied the district beyond the river Axius, according to Pliny, and the banks of the Ister, according to Steph. Byz. They were a people of Thrace, between mount Hæmus and the Euxine sea, according to Athenæus, and Ptolemy refers them to Lower Mœsia.

CROCALA, an island of sand, which Pliny and Arrian places near the mouth of the river Indus.

CROCALLIS, in *Natural History*, the name given by the ancients to a stone famous for its virtues against poisons, and venomous bites. All the description Pliny gives of it is, that it was of the size and shape of a cherry.

CROCARDS, an old name given by the Irish to a certain kind of money brought over into that kingdom from France, and other parts beyond the seas, and uttered there for pennies, though not really worth so much as a halfpenny. They were a small sort of coin, made of a mixture of copper, sulphur, and a small quantity of silver, and were called by several other names, as *mitris*, *lionines*, *rosaries*, and the like, from the figures they were impressed with. They were current in Ireland, and in some parts of England, a great many years; but were afterwards denied, and prohibited importation, both in England and Ireland, under the penalty of the forfeiture of life and effects. At this time, mints were set up in Dublin, for the coining of good money, and, in a few years, the whole quantity of the *crocards* was destroyed. See **POLLARDS**.

CROCE, **BALDASSARE**, in *Biography*, a Bolognese painter, born in the year 1553. He is generally said to have been the scholar of Annibale Caracci; but this is disputed by Baglione, who informs us, that so early as the pontificate of Gregory XIII, he was employed in several public works at Rome. The cupola of the church of Gesu

was painted by this artist; and in the church of S. Sufanna are several large stories in fresco by him, which are of a style natural and facile. Although he can scarcely be called the scholar of Caracci, it is probable that he benefitted by his example during the long sojourn of that great master at Rome. Croce died in 1628. Baglione.

CROCE, S. GIROLAMO DI, a painter of some eminence, of the Venetian school, who flourished at the commencement of the 16th century. He was one of the best imitators of the manner of Giorgione and of Titian. Many of his works are at Venice, amongst which, "The Last Supper," in the church of S. Martino, and "The Martyrdom of S. Lorenzo," a composition of many small figures, in the church of S. Francesco della Vigna, are worthy of notice. His works bear date from 1520 to 1549. Lanzi, Storia Pitt.

CROCE, S. PIETRO PAOLO DA, a painter who flourished at Padua, about the year 1591. Several of his pictures, evincing no small abilities, are to be seen in the churches of that city. Lanzi. Storia Pitt.

CROCEFISSAJO, DEL. See MACCHIETTI.

CROCHE, in *Geography*, a lake of N. America, in New South Wales, which is crossed in proceeding from Portage la Loche in a westerly direction of 6 miles, though its whole length may be twice that distance; after which it contracts to a river that runs westerly for 10 miles; when it forms a bend, which is left to the south, and entering a portion of its waters called the "Grass-river," whose meandering course is about 6 miles, but in a direct line not more than half that length, where it receives its waters from the Great river, which then runs westerly 11 miles before it forms the "Knee-lake," whose direction is to the north of west. It is full of islands for 18 miles, and its greatest apparent breadth is not more than 5 miles. The Portage of the same name is several hundred yards long, and over large stones. Its latitude is 55° 50' N. and longitude 106° 30' W. Two miles farther north is the commencement of the Croche Rapid, which is a succession of cascades for about 3 miles, making a bend due south to the lake du Primeau; which see.

CROCHE, Fr. the character in *Musick* which we call a *quaver*; which see.

CROCHES, among *Hunters*, the little buds about the top of a deer's horns.

CROCI, among *Botanists*, the apices, or small knobs, on the tops of flowers.

CROCIA, a bishop's or abbot's crozier, or pastoral staff. See CROSIER.

CROCIAS LAPIS, in *Natural History* a name given by some of the old authors to a species of agate, of a yellow colour, but deeper than the cerachates, or wax-coloured agate, and approaching to what is called a saffron colour.

CROCIATONUM PORTUS, in *Ancient Geography*, the capital of a people called *Uelli*, situated in the maritime part of Lyonnese Gaul, according to the table of Ptolemy. Ptolemy mentions it; and it is generally supposed to be the present Carantan.

CROCINUM, a name given by the ancient physicians to a sort of oil of saffron, which is thus described by Dioscorides.

Eight drams of saffron are to be put into three pints of inspissated oil, and they are to be stirred together several times in a day, for five days together; then the oil is to be separated from the saffron, and a like quantity is to be added to the same saffron, and stirred about at times for three days; then this oil is to be cleansed off, and to it are to be added fifty ounces of powdered myrrh. These having been well stirred together, are then to be set by for use.

Some used an oil, impreguated with aromatics, in the composition of the *crocinum*; but that was usually esteemed best, which smelt the most strongly of saffron, or else of myrrh.

The *crocinum* was esteemed heating and narcotic; whence it was frequently prescribed by way of embrocation, or else held in the nose in frenzies. It was also esteemed useful as a suppurative, and to cleanse old ulcers: it was much esteemed also in hardnesses, obstructions, and other disorders of the uterus, being used with wax, marrow, and double the quantity of oil; for a *glaucoma* it was also used with success, when mixt with water, and the eyes anointed frequently with it.

CROCKET, (from *croc*, French, a *hook* or *fork*;) one of the small ornaments which are usually placed all along the angles of pinnacles, and on the outside of pediments, canopies, tabernacles, and cupolas, in the pointed style of architecture. The first idea of these ornaments seems to have been taken from the buds seen upon the boughs of trees and plants in the spring season, which, in many early instances, they resemble. In their subsequent and more perfect form, they evidently represent the opening leaves of the oak or vine, or of some other tree or plant. Beautiful specimens of them may be seen in the works of Carter, Halfpenny, &c. See *GOTHIC* and *POINTED Architecture*.

CROCOCOLANA, in *Ancient Geography*, a town of the isle of Albion, on the route, according to Antonine's Itinerary, from Londinium to Lindum, or London to Lincoln, between Ad Pontem, near Southwell, and Lindum or Lincoln; 7 miles from the former, and 12 from the latter. The vestiges of this station, which are very faint, are described by Dr. Stukeley in his Itinerary. It is supposed to have been Brugh near Colingham.

CROCODILE, in *Zoology*, a species of lizard, being the largest of that kind; for a description and account of which, see *LACERTA Crocodilus*. *Crocodili* forms, in the arrangement of Gmelin, one of the general divisions of *lacerta*, characterised by a two-edged tail divided into segments, and a very short tongue.

CROCODILE, *fossile*. One of the greatest curiosities in the fossil world, which the late ages have produced, is the skeleton of a large *crocodile*, almost entire, found at a great depth under ground, bedded in stone. This was in the possession of Linkius, who wrote many pieces in natural history, and particularly an accurate description of this curious fossil. It was found in the side of a large mountain, in the midland part of Germany, and in a stratum of a black fossil stone, somewhat like our common slate, but of a coarser texture, the same with that in which the fossil fish of many parts of the world are found. This skeleton had the back and ribs very plain, and was of a much deeper black than the rest of the stone, as is also the case in the fossil fishes, which are preserved in this manner. The part of the stone where the head lay was not found, this being broken off just at the shoulders, but that irregularly, so that, in one place, a part of the back of the head was visible in its natural form. The two shoulder-bones were very fair, and three of the feet were well preserved; the legs were of their natural shape and size, and the feet preserved, even to the extremities of the five toes of each.

CROCODILE, CROCODILUS, in *Rhetoric*, a captious and sophistical kind of argumentation, contrived to seduce the unwary, and draw them speciously into a snare.

It has its name, *crocodile*, from the following occasion, invented by the poets. A poor woman, begging a *crocodile* that had caught her son walking by the river side, to spare and restore him, was answered that he would restore him, provided

provided she should give a true answer to a question he should propose: the question was, *Will I restore thy son or not?* To this the poor woman suspending a deceit, sorrowfully answered, *Thou wilt not:* and demanded to have him restored, because she had answered truly. Thou liest, says the crocodile: for if I restore him, thou hast not answered truly: I cannot therefore restore him, without making thy answer false. Under this head may be reduced the propositions called *mentiments*, or *insolubiles*; which destroy themselves. Such is that of the Cretan poet: *Omnes ad unum Cretenses semper mentiuntur: All the Cretans to a man, always lye.* Either then the poet lyes, when he asserts that the Cretans all lye, or the Cretans do not all lye.

CROCODILE Town, or *Meegheoun-yay*, in *Geography*, a town of Asia in the Buman empire, represented by lieutenant-colonel Symes, who visited it, as a place of considerable trade and importance. Its harbour contained no less than 100 large boats, and several smaller ones, lying at different stairs which took in rice, onions, garlic, and oil, for the consumption of the capita'. It stands on a very high bank, and has fewer religious buildings than any town which the colonel had seen of equal magnitude. In its vicinity are some neat farms, each containing 4 or 5 cottages, better built than houses in towns generally are, and fenced round with wide inclosures to receive the cattle, of which there was great abundance. The fields are divided by thorn-hedges; the low grounds prepared for rice; and the higher planted with leguminous shrubs, or left for pasture.

CROCODILIOIDES, in *Botany*, Vaill. See *ATRAC-TYLIS gummifera*.

CROCODILIVM, Juss. Vaill. See *CENTAUREA*.

CROCODILOPOLIS, in *Ancient Geography*, a town of Egypt, S.E. of the lake Moeris; the Greeks called it *Arsinoe*; and it is succeeded by the modern Faioum, built at the distance of about a league N. E. of its dilapidated walls. It derived its first name from the crocodiles which were fed and worshipped there. The prefecture of Arsinoe, says Strabo, reveres the crocodile, and looks upon it as sacred. The priests preserve one of them in a particular lake, and they nourish it with bread, flesh, and wine. Whilst the crocodile is reposeing himself on the banks of the lakes, the priests approach him; and whilst one opens his mouth, another puts cakes, flesh, and wine into it. After this repast the monster descends quietly into the water, and swims away. The Egyptians are said to have honoured the crocodile, because it was consecrated to Typhon, an evil genius whose fury they dreaded. They thought to calm his indignation, and avert the calamities with which he afflicted them, by honouring an animal which was his symbolical image. According to Diodorus (lib. i.) the crocodile was revered by the Egyptians upon account of their king, Menes, sometimes called Menes, and Manes. This prince, it is said, had been in great danger of being drowned; but was wafted through the waters to land by a crocodile. In memorial of this he built a city, which from this event was denominated the "city of the crocodile." This writer supposes that Menes really reigned over the Egyptians, because he stood at the head of their genealogical list; and he further imagines that the story was local, and that the event happened in the lake Moeris. The learned Bryant, (*Anal. Mythol.* vol. ii. p. 396.) supposes that Menes, the king of Egypt, was the Deus Lunus, and called also Mean, Men, and Man; and the legend about a crocodile was taken from some symbolical representation in the city of the same name; and hence it was supposed to have happened in Egypt. The crocodile had many names, one of which was Campsa, which signified an ark or receptacle; whence the purport of the hieroglyphic

is sufficiently manifest. The crocodile, according to Plutarch (Ius et Osiris) was equally a symbol of Typhon, and the deluge. See *LACERTA Crocodilus*.

CROCODILOPOLIS, another town of Egypt, in the Aphroditopolite nome, upon the left of the Nile, in the Thebaïd.—Also, a town of Asia, in Phœnicia, situated near, and to the south of, the town of Doræ, according to Strabo and Pliny.

CROCODILORUM LACUS, a lake of Palestine, or rather on the coast of Phœnicia, S. of Cæsarea, near which probably existed the town of the same name. This lake received the river Canz, which ran from mount Garizin.

CROCODILUS, a mountain of Asia, in Cilicia.

CROCODYLIUM, in *Botany*, Dalech. See *ECHINOPS Ritro*.

CROCOMAGMA, in *Pharmacy*, a name given by some to troches composed of saffron, myrrh, red roses, starch, and gum Arabic; thus called from *κροκος*, saffron, and *μαγμα*, a mass of any thing.

CROCOTTA, in *Natural History*, a name given by the ancients to a very fierce and terrible animal, produced by copulation between the large hyæna and the lioness. See *LEOCROCOTTA*.

CROCQ, in *Geography*, a small town of France, in the department of the Creule, chief place of a canton, in the district of Aubusson. It contains but 521, and the canton itself 920 inhabitants, dispersed in fifteen communes, upon a territorial extent of 260 kilometres.

CROCUS, in *Botany*, (from *כרוס*, or rather, as Kircher conjectures, it was originally read *כרכוס*, which occurs only in Solomon's Song, iv. 14. and is retained in the Septuagint with no variation, except in the form of the letters, *κροκος*; rendered in our English version saffron. As Solomon enumerates with it spikenard, calamus, and cinnamon, trees of frankincense, myrrh, and aloe, he probably intended by it one of the precious aromatics then imported into Judea from Arabia, and the remotest regions of the East, to furnish the toilets of the ladies in his splendid court. But Theophrastus and all the subsequent Greek and Latin writers clearly describe the crocus of Linnæus, and of modern gardeners.) Linn. Gen. 55. Schreb. 75. Willd. 92. Tourn. Cl. 9. § 2. gen. 1. Juss. 59. Vent. 2. 194. Class and order, *triandria monogynia*. Nat. Ord. *Enfataz*, Linn. *Irides*, Juss.

Gen. Ch. *Cal.* Spathe transparently membranous, one or two-leaved. *Cor.* Monopetalous, superior, funnel-shaped; tube very long, partly beneath the surface of the ground; border with six ovate oblong, nearly equal divisions. *Stam.* Filaments three, awl-shaped, shorter than the corolla, inserted into the tube. *Pist.* Germ inferior, roundish; style filiform; stigmas three, convolute, ferrate-crested. *Peric.* Capsule egg-shaped, trigonous, three-celled, three-valved. *Seeds* several, roundish.

Ess. Ch. Corolla tubular, six-parted, superior; stigmas three, convoluted.

Sp. 1. *C. sativus*, Linn. Sp. Pl. α officinalis. Poir. 3. Smith Fl. Brit. 39. Eng. Bot. 343. Wood. Med. Bot. tab. 176. Lam. Ill. tab. 30. fig. 1. Poir. 3. Willd. 1. Bauh. Pin. 65. Tourn. 350. (*C. officinalis*; Mart. Saffron.) "Stamens shorter than the pistil; style deeply trifid." Lam. "Stigma inserted, three-parted; segments linear." Smith. "Stigma three-parted, the length of the corolla, reflexed; leaves linear, revolute at the edges." Willd. *Root* bulbous, depressed. *Flower* very nearly or entirely sessile on the root; tube very long, white; segments of the border rich purple, elliptical, concave, regular. *Leaves* radical, invested with membranous sheaths, emerging after the flowers open, linear, slightly revolute, dark green above, with a white longitudinal furrow,

farrow; pale underneath, with a very prominent flattened mid-rib; style hanging out on one side between two of the segments of the corolla; stigmas deep orange, long, rolled in at the edges, notched at the summit. A native of Greece and Asia Minor. Its odorous aromatic stigmas are the saffron of the shops, for the sake of which it has been cultivated in its native countries from the earliest antiquity, and has long since been introduced into the western parts of Europe. In England it has given a distinguishing name to Saffron-Walden. See SAFFRON. 2. *C. scrotinus*. Salisb. Par. Lond. tab. 30. (*C. autumnalis*; Poir. 4. *C. alpinus autumnalis*; Bauh. Pin. 65. Tourn. 350. *C. montanum primum*; Cluf. Hist. 209. with a figure.) "Bractes two under the pericarp; (or in the language of Linnæus, spathe two-leaved;) border of the corolla slightly bearded; closed and pitcher shaped at the base; stigmas deeply multilobed." Salisb. *Root* bulbous, small, much depressed. *Leaves* radical, narrow, linear-awl-shaped, scarcely rolled in at the edges, appearing at the same time with the flower. *Flower* purple, or deep blue; tube rather short, a little enlarged towards the summit; divisions of the border lanceolate, deep; stamens little more than half the length of the border; anthers yellow, narrow, long, lanceolate, not arrow-shaped; stigmas very long, rising above the stamens, gradually enlarging upwards, crenulate or toothed at the summit. It is the latest of the autumnal crocuses, and in a mild season, and sheltered sunny situation, continues in flower till the beginning of December. A native of Spain, Portugal, Switzerland, and the south of France. 3. *C. nudiflorus*. Smith Flor. Brit. 41. Eng. Bot. 491. (*C. multifidus*; Poir. 5. *C. speciosus*; Von Bieberstein in Ann. Bot. 2. 404. *C. pyrenæum autumnale*; Cluf. Cur. Poët. 23. and Appen. alter. *C. autumnalis flore minore*; Bauh. Pin. 65.) "Stigma included in the flower, trifid; lobes multifid-laciniate, pencil-shaped; flower without leaves." Smith. *Root* bulbous, very small. *Flowers* purple-violet, opening early in October, and fading before the end of the month; stamens shorter than the divisions of the corolla; style longer than the stamens; stigmas orange-coloured, scentless. *Leaves* not appearing before December, more erect than those of the other species, paler, scarcely revolute at the edges. A native of the Pyrenées, and of Georgia, between the Terck and the Kur. In England it occurs sparingly in some old pastures and meadows, near Halifax, and in great profusion between Nottingham castle and the Trent, in a meadow annually overflowed by the river. In consequence of a negligent observation, it was at first mistaken by the writer of the article for *C. fativus*, and thence that plant was erroneously supposed to be a native of England. 4. *C. vernus*. Mart. 2. Poir. 1. Lam. Ill. Pl. 30. fig. 2. Willd. 2. Smith Fl. Brit. 40. Eng. Bot. Pl. 344. Jacq. Aust. App. tab. 36. β . Neapolitanus; Bot. Mag. 860. (*C. fativus* β ; Linn. Sp. Pl.) "Stigma included in the flower, trifid; lobes wedge-shaped, notched." Smith. *Root* bulbous, globular. *Scape* an inch or two high, almost triangular. *Flowers* generally purple, sometimes yellow or white; tube slender, very long, gradually enlarged towards the top; closed at the mouth by a ring of glandular entangled hairs; border campanulate; segments elliptic-lanceolate, much shorter than the tube; three inner ones smaller; anthers yellow, arrow-shaped. According to La Marck the stamens are longer than the pistils; but they are not so in his own figure to which he directly refers. A native of the Alps, Pyrenées, Italy, Spain, and Mount Atlas. In England it has been found only in the meadows between Nottingham castle and the Trent, growing with the preceding species, but always flowering in the spring. 5.

C. luteus. Lam. Ill. 2. Poir. 2. (*C. vernus*; Bot. Mag. 45. *C. vernus, latifolius, flavo flore*; Cluf. hist. 205. with a figure. *C. vernus, latifolius, flavus, flore majore*; Bauh. Pin. 66. Tourn. 352.) "Stamens longer than the pistil; border large, almost the length of the tube" *Roots* bulbous, roundish, a little depressed; enclosed in smooth, scarious, shell-like membranes, closely ribbed with fine parallel fibres, but not netted. *Leaves* radical, flat, narrow, linear, awl-shaped at the summit, longer than the corolla, with a white, rather large longitudinal rib. *Flowers* always yellow; tube slender, enlarged towards the summit; segments of the border oval-lanceolate, obtuse, erect; stamens shorter than the corolla; stigmas short, unequal, striated, thickened at the top, plaited and curled. A native of Switzerland, flowering in March, a little earlier than the preceding species. 6. *C. aureus*. Smith Prod. 85. Fl. Græc. tab. 35. (*C. vernus mæfiacus primum*; Cluf. Pann. 228.) "Stigma included in the flower, trifid; lobes nearly linear, finely toothed; tunic of the root membranous." A native of Thrace, found by Dr. Sibthorp near Scelus. 7. *C. fusianus*. Bot. Mag. Pl. 652. (*C. vernus latifolius flavo-vario flore*; Cluf. hist. 206. Bauh. Pin. 66.) "Few-flowered; bulb coarsely netted, with large irregular meshes; outer segments of the corolla constantly revolute near the tip; stigmas rising far above the anthers." A smaller plant than *C. luteus*, flowering earlier, and opening its flowers in all states of the weather. Received by Clusius from Constantinople, about the year 1587. 8. *C. biflorus*. improperly called the Scotch crocus by the English gardeners. Bot. Mag. Pl. 845. Bot. rep. Pl. 362. "Tunics of the bulb even surfaced, hard, circinate-imbriated; mouth of the tube naked." *Flowers* whitish; outer segments of the border marked on the outside with longitudinal purple streaks. Supposed to be a native of the East. 9. *C. sulphureus*. Bot. Mag. Pl. 938. (*C. vernus flavus striatus*; Park. par. 163. fig. 10. *C. vernus latifolius, flavo-vario flore*; Rai. hist. 1174. n. 8.) "Tunics of the bulb membranous, brown, thin, finely fibrous-striated; segments of the corolla spreading equally; anthers small, arrow-shaped, pale; stigmas unequal, rising far above the anthers." *Flowers* pale yellow; three outer segments of the corolla narrower, marked with three broadish dusky streaks which throw out lateral veins of the same colour; three inner ones broader, dark purple on the outside near the bottom; but marked with similar streaks. *Leaves* narrow, long, appearing before the flower. It never produces seeds in our climate, but propagates itself most profusely by off-sets. There is a permanent variety, in which the whole of the flower is of a uniform colour.

Obs. The crocus has been so long and so extensively cultivated, that it is not easy to distinguish the original species from the accidental varieties. The old botanists strove to make as many sorts as possible. C. Bauhin reckons twenty-nine; Tournefort, forty-six. Linnæus, on the other hand, reduces them all to one, and supposes the vernal and the autumnal, or officinal crocus, to be only varieties, notwithstanding the manifest difference in the form of their stigmas, leaves, and bulbs, as well as in the time of their flowering; very differently, as professor Martyn justly observes, from what he has done with respect to *Hemerocallis*, which he has divided into two species, though they differ only in their size, the colour of their flowers, and a little in the time of their flowering. Most modern botanists have thought the vernal and autumnal kinds specifically different, and several other species, apparently distinct, have gradually been added. Mr. Salisbury of Mill-hill, whose accuracy of observation, and acuteness of discernment, are well known, thinks he has ascertained

C R O C U S.

ascertained twelve well-ascertained species, but has not yet communicated his ideas concerning them to the public. See *Annals of Botany*, vol. i. p. 120.

CROCUS flore fructui imposito, tubo brevi; Roy. See *IXIA bulbocodium*.

CROCUS foliis & radice scorzonerae; Plum. See *HYPOXIS decumbens*.

CROCUS spatula diphylla; Linn. Sp. Ed. 1. See *IXIA bulbocodium*.

CROCUS sylvestris zeylanicus; Herm. Burm. See *MECYLON capitellatum*.

CROCUS vernus angustifolius quartus; Claf. See *IXIA bulbocodium*.

CROCUS, in *Gardening*, comprehends plants of the low flowering ornamental bulbous-rooted perennial kinds; of which, the sorts mostly cultivated, are the autumnal or common officinal *crocus*, and the spring *crocus*.

The first sort has a roundish bulbous root, as large as a small nutmeg, being a little compressed at the bottom, and covered with a coarse, brown, netted skin; having many long fibres sent out from the bottom of the bulb, which strike pretty deep into the ground; the flowers come out from the upper part of the root, which, with the young leaves, whose tops just appear, are closely wrapped about by a thin spathe or sheath, that parts within the ground, and opens on one side: the tube of the flower is very long, arising directly from the bulb without any foot-stalk, being divided at top into six segments which are equal, and of a purple blue colour. A roundish germ is situated in the bottom of the tube, which supports a slender style not more than half the length of the petal, being crowned with three oblong golden stigmas, spreading asunder each way, which constitutes the saffron. It flowers in October, and the leaves continue to grow all winter; but it never affords seeds in this climate.

Of this sort the varieties are chiefly the sweet-smelling, with a smaller and more compressed root, having a deep blue colour, but varying to a sky-blue;—the mountain, which has a flower of a pale blue colour;—the many-flowering blueish, with numerous sky-blue flowers; and the small-flowering, having a small deep blue flower.

The second kind has a pretty large compressed bulb, covered by a light brown netted skin, from which proceed four or five leaves of a purple colour on their lower parts, from among which issue one or two flowers, sitting close between the young leaves, and never rising above two inches in height, but having an agreeable odour. From the centre of the tube a slender style proceeds, which is crowned by a broad flat stigma of a golden colour. When the flower is past, the germ pushes out of the ground. The flower in the wild state is mostly white, with a purple base.

And of this kind, the varieties are; the broad-leaved purple variegated, which has a flower of a deep blue colour and striped;—the broad-leaved plain purple;—the broad-leaved violet-coloured, or large deep blue;—the white with a purple bottom;—the broad-leaved white variegated;—the broad-leaved, with many violet purple flowers, striped with white;—the broad-leaved ash-coloured;—the broad-leaved large yellow;—the broad-leaved small pale yellow;—the broad-leaved small yellow striped with black; the narrow-leaved small brimstone;—and the narrow-leaved small white. But in modern catalogues, there are many other varieties of different colours introduced, as blue and purple, yellow and white, or striped. New ones are also continually imported from Holland. The usual varieties at present in gardens are 1.—the beautifully striped Scotch;—the blue;

—the blue striped;—the white;—the yellow of several shades, larger and smaller;—the yellow striped with black;—the cloth of gold, &c.

Method of Culture.—The culture in both these sorts, and all the varieties, is easily effected, by planting the bulbs or off-sets taken from the roots; the first sort in July, or the beginning of the following month; and the latter any time when the weather is open, from September to the beginning of April in the following year; but the more early it is performed, the stronger they flower; it may be performed by means of a dibble or trowel, to the depth of about two inches, the ground being previously well dug over, and left some time to settle. They may be set either in beds by themselves in rows, at the distance of eight or nine inches, and six or eight inches apart, or in patches of five or six roots in each, on the fronts of the clumps, borders, or other parts of gardens and pleasure-grounds, putting them in, in a varied manner, both in respect to the sorts, and the order in which they are planted.

Where the soils are tolerably dry, they may remain two or three years without being disturbed; but should then be taken up at the time the leaves decay, in order to separate the new bulbs or off-sets for further increase, as well as new dig the ground. The larger bulbs should be separated from the small ones, and put up, each by themselves, in order to be planted out at the proper season; the former in the above manner, and the latter in beds, in rows six inches distant, to remain till they are of a proper size. See *BULBOUS ROOTS*.

As the bulbs increase fast, a large stock may, with care, soon be provided in this way. But when this is not practised, bulbs of the different species and varieties may easily be procured from the nursery and seeds-men.

It may be observed, that in the culture of these plants, great injury is frequently done by trimming off the green leaves at the time the flowers decline, in order to prevent litter; as by such means the future blow is rendered more weak and less beautiful.

Where new varieties are wanted recourse must be had to the seed, which must be sown in the spring season, either where the plants are to remain, in a bed of light mellow earth, or in pots filled with the same sort of earth.

The first species is the plant, which is cultivated in fields, and from the stigma of which the preparation known, under the title of English saffron, is made.

CROCUS, or *Saffron*, in the *Materia Medica*. The substance called saffron, is sold in the shops in the form of thin tough cakes, formed of the pistils of the flower, which are carefully picked by hand, pressed together, and gently dried in kilns. No other preparation whatever is employed. Saffron used to be cultivated pretty largely in England, and the neighbourhood of Saffron-Walden, in Essex, was celebrated for this substance, which was employed very largely in cookery and confectionary as well as in medicine; but, at present, it is scarcely used for the table, and but little as an article of the *Materia Medica*. In various parts of the continent it is still largely employed.

Saffron has a high orange red colour, readily staining the fingers when a little moist. The cakes should not be above a year old, close and tough in texture, neither so dry as to be pulverizable, nor so moist as to feel sensibly damp. The smell is very strong, fragrant, and penetrating, and the taste aromatic and bitter, but both are much injured by long or careless keeping. The fine yellow colour is readily imparted to almost any menstruum, to water, vinegar, alcohol, &c. and the intensity of tinging power is very great. The colour,

hour, however, is completely fugitive on exposure to air for some time, and is not permanently detained on cloth of any kind by any of the usual mordants, so that as a dye it is nearly useless, except to give a false and superficial finishing gloss to yellow or orange stuffs. Both the watery and acetous infusions lose most of their colour by keeping, but the spirituous tincture preserves its rich hue for a great length of time.

Saffron was formerly reckoned one of the most valuable and potent cordials which the *Materia Medica* possessed, raising the strength, spirits, and animal powers in a very high degree, when given in doses of no more than a few grains. These virtues, however, have been excessively exaggerated, nor does this medicine appear to have higher powers than many other of the aromatic bitters. This circumstance, added to the great and necessary costliness of a substance which requires so much manual employment in its preparation, has caused saffron to fall nearly into disuse, though it is still retained in a few of the compounds of the pharmacopœia. A syrup and tincture of saffron are often employed as grateful and elegant medicines.

Saffron yields, by distillation, a very pungent essential oil, and the residue is a bitter ungrateful extract.

Crocus of Antimony, is a perfect oxyd of this metal, formed by deflagration with nitre, and is called a crocus from its yellow colour. See *ANTIMONY*.

Crocus Martis. Several oxyds of iron have had this name given to them. Stahl's *aperient crocus of Mars* is formed by deflagrating with nitre the scorix of the martial regulus of antimony, which consists of sulphuret of iron retaining a small portion of antimony; and hence the crocus, or washed orange-powder, left after deflagration, consists of oxyd of iron mixed with a minute portion of oxyd of antimony. It is now disused.

The common *crocus martis*, or *colcothar*, is the deep orange red oxyd of iron left by calcination of the sulphat of iron, in a heat strong enough to expel all its acid.

CROCUTA, in *Zoology*, the quumberigo of Barbot, (Guin. p. 486.), and spotted hyæna of Pennant, is a species of *CANIS*, with a straight tail, four toes on the feet, and the body spotted with black. It inhabits Guinea, Ethiopia, Abyssinia, the Cape of Good Hope, and all the intermediate countries of Africa; living in holes of the ground and clefts of rocks. It preys by night on cattle, sheep, and horses, attacks men, and digs up graves to feed on dead bodies. It has a dreadful howling voice. The upper parts of the head and face are black; the mane short and black; the body and limbs covered with short soft hair, of a reddish-brown colour, marked with round black spots; the tail short and curly. This species is of such size, strength, and ferocity, that it can carry off, with great speed, a full-grown man. The head is large and flat, having fine long hairs above each eye, and very large whiskers on each side of the nose.

CROCYLEA, in *Ancient Geography*, a town and district which belonged, as some have supposed, to the island of Ithaca, but which really pertained to Etolia.

CROEKER, JOHN, in *Biography*, an artist, who was employed in England under queen Anne, and its two succeeding monarchs, to execute many medals upon public occasions. Amongst his works we may enumerate the following: A medal in commemoration of the Union of England and Scotland in 1707. Another medal, representing George II. and his family. A print of his own portrait exists, engraved by his own hand. Heinecken.

CROESUS, the fifth and last king of Lydia. He succeeded his father at about the age of thirty-five, which is dated B. C. 537. Almost immediately after he ascended

the throne, he gave himself up to plans of war and ambition, and by his great successes over the Grecian states and the kingdoms of Asia Minor, which he not only subdued but plundered, he became the richest and most powerful prince of his time. Wealth and power are, however, no security for happiness; in the midst of his glory, and when he had attained nearly the summit of his expectations, he lost his son Atys, who was killed in hunting. To wear off, if possible, the uneasiness which this misfortune excited in his mind, he determined to make war upon Cyrus; but before he engaged in so important an enterprise, in compliance with the customs of the age, he modestly consulted the most celebrated oracles. From that of Delphos, he obtained an answer, like others of the same kind, which admitted of two interpretations: "If Croesus crosses the Halys, he will put an end to a great empire." Croesus, depending on his own good fortune, expected from this to destroy the Persian monarchy, but Cyrus, its king, was destined for more important purposes. (See *CYRUS*.) He obtained a complete victory over the Lydian monarch, and Croesus was made prisoner, and would, probably, have lost his life, but from the extraordinary circumstance of his own son, who till then had been perfectly dumb, but who, on seeing a soldier about to kill his father, exclaimed, as if it were by divine inspiration, "Soldier, spare the King." We are told that the young man from this time had the use of his tongue. The fortune of Croesus, after this event, was various, and he had full leisure to reflect on the folly of trusting to wealth. In his prosperity, "the wealth of Croesus" was proverbial, and the king once invited Solon the wise to witness a display of his riches, hoping that the philosopher would deem him, as he concluded himself to be, the most fortunate man living; but Solon, to various interrogatories, replied, that "he deemed no man happy before his death." The prince was disconcerted, and dismissed the philosopher from his presence. When fortune had turned the scale, and he was about to be put to death at the command of Cyrus the conqueror, he recollected the saying of Solon, and thrice loudly called upon his name. Cyrus inquired into the cause, and when he had heard the relation, he pardoned the fallen monarch, took him into his favour, and made him his companion and counsellor in his several expeditions. Croesus survived his friend, who, in his last moments, recommended him to the particular care of his son Cambyfes, as one in whom he might place the most unlimited confidence. Cambyfes, however, treated him ill, and condemned him to death; from this cruel sentence he escaped, and history furnishes us with no clue whence his subsequent fortunes can be traced. *Univer. Hist. Plutarch's Life of Solon.*

CROEVER REICH, or *CROEFER Reiet*, in *Geography*, a small district of Germany, in the circle of the Upper Rhine, on the N. side of the Moselle, sold by the counts of Sponheim, in 1274, to the archbishop of Treves.

CROFT, in *Agriculture*, is a name often applied in the more northern districts to a small field or inclosure, mostly that in which the cottage, or house and garden are situated. It is, however, sometimes employed to signify a common field in particular districts. "Possunt etiam dicti monachi de eisdem mariscis versus occidentem jacentibus pro se, & hominibus suis, includere *croftos*, five pratum juxta pontem, specialiter, quantum illius placuerit." Ingulf. In some ancient deeds, *crofta* occurs as the Latin word for a croft; but *cum tofts & crofts* is more frequent. Croft is translated in *Abbo Floriacensis*, by *pradium*, a farm.

CROFT, HERBERT, in *Biography*, a prelate of the church of England, who flourished in the 17th century, was third

son of Sir Herbert Croft, and born in 1603, at Great Milton, Oxfordshire. In 1616, he was entered, it is believed, at Christ college, Oxford, from whence, on account of his father's conversion to the tenets of popery, he was sent to the English college of Jesuits at St. Omers, and entered into the order. Upon the death of his father, he had occasion to visit his native country, and was, by means of Dr. Morton, bishop of Durham, brought back to the religion in which he was originally educated. He went a second time to Oxford, and the time which he had spent at Douay was allowed to him, as if he had continued wholly at the English university. This was in 1635, when he went through the appointed exercises with applause, and in the following year was admitted to the degree of bachelor of divinity. He now rose rapidly in the church, and in 1641, was promoted to a canonry of Windsor. Three years after this he was appointed dean of Hereford, in which city he chiefly resided, until his zeal for royalty, and his attachment to the interests of the church, rendered him obnoxious to the existing government. His exertions in these services, which were attended with hazard, occasioned him to expend much of his own small fortune, as well the little which he derived from his preferments. His circumstances became embarrassed, but in 1659 he succeeded to the family estate, and was delivered from the pressure of want; he thought it prudent, however, to live in the most retired manner at a friend's house in Worcestershire, till the restoration, when he was re-instated in his several preferments, and in the year 1661 was promoted to the see of Hereford. From this time, he refused offers of more valuable bishoprics; and being disgusted with the profligate manners and intolerant practices of the court, he confined himself to the conscientious discharge of his duties as a bishop, which he performed with honour to his own character, and for the benefit of the church of which he was a member. Though zealously attached to his own opinions, he was the determined enemy of all persecution, wrote in defence of toleration, to be extended to dissenters, and pleaded the cause of humanity and Christian forbearance, with a zeal and manliness that reflect high honour on his principles, and the excellence of his temper. This work, which was intitled "Naked Truth; or the true State of the Church," excited much controversy. The bishop, shortly after, had formed a determination to quit his office and resign the bishopric, but was prevailed on to abandon the resolution, and to continue his episcopal labours till his death, which happened in 1691. He was author of several other pieces, among which were "Animadversions on a Book intitled the Theory of the Earth;" "The Legacy, &c. or a short Determination of all Controversies which we have with Papists, by God's Holy Word;" and "A Discourse concerning the reading his Majesty's Declaration in Churches." The learned prelate deserves higher applause as a man and a Christian than as a writer, though his pieces were respectable, considering the times in which he lived: but in his clerical character he was an admirable pattern, both with regard to the sanctity and amiableness of his manners, and the diligence with which he instructed his people, and visited the aged and the sick. His memory, however, claims particular respect on account of the moderation and candour which he exhibited towards those whose consciences would not permit them to conform to the established church, and his avowed abhorrence of every measure of the legislature which wore the least appearance of persecution. *Biog. Brit.*

CROFTING SYSTEM, in *Agriculture*, is that practice of grazing-farming in which the bullocks is conducted in small inclosures at no great distance from the farmer's house.

It has been lately recommended by Mr. Brown as an advantageous method to be adopted in some of the highland districts of Scotland; and might, probably, be pursued with benefit and success in particular situations in Wales.

CROFTON, ZACHARY, in *Biography*, a non-conformist preacher in the 7th century, was born at Dublin, where he received the principal part of his education. During the civil wars he came to England, but so destitute, that he is said to have arrived at Chelster with only four-pence in his pocket. He soon after obtained the living of Wrensbury in Cheshire; here, on account of his attachment to the cause of royalty, for refusing to subscribe "The Engagement," an instrument of the existing government, and exciting others to do the same, he was persecuted. He thought it right to seek a new course of life in the metropolis. Shortly after this he was presented with the living of St. Botolph, Aldgate, in which he continued till he was ejected under the act of uniformity. Soon after the restoration, he engaged in a controversy respecting the obligation of the "solemn league and covenant," for which he pleaded with so much zeal and freedom, that he provoked the indignation of the court, and was committed prisoner to the Tower, where he was detained, to the detriment of his fortune, which was very scanty, and to the injury of his family, which was numerous. He, at length, was liberated, and retired into Cheshire, where he was again imprisoned; but on his release, he first endeavoured to maintain his family by going into trade, and afterwards by becoming a farmer in the county of Bedford. In 1667, he came again to London, and opened a school at Aldgate, where he died, in 1672. He was author of many tracts on controversial subjects, and of sermons. *Calamy's Ejected Ministers.*

CROJA, in *Geography*, a town of European Turkey, in the province of Albania; anciently the capital and residence of the Albanian kings. The famous Scanderberg used this place as a fortress, from whence he continually harassed the Turks; but when the Turks became masters of Albania, they destroyed the fortifications. It is the see of a bishop, suffragan of the archbishop of Durazzo; 20 miles N.E. of Durazzo.

CROIDIT, and **CERVETTO** *the Younger*; for a parallel between thesetwo admirable performers, see **VIOLONCELLO**.

CROISADE, CRUSADE, or CRUSADO, a *holy war*, or an expedition against infidels and heretics; particularly against the Turks, for the recovery of Palestine. This expedition was distinguished, in the French language, by the name of a *croisade*, and all who embarked in it were called *croises*, because the end of this holy war was to arrest the cross of Christ out of the hands of the infidels, and also on account of the consecrated crosses of various colours, which the soldiers wore upon the right shoulder. They were ordered, as it is said, by the council of Clermont. The English wore them white; the French, red; the Flemish, green; the Germans, black; and the Italians, yellow.

People anciently flocked on these croisades out of devotion; the pope's bulls, and the preaching of the priests of those days, making it appear a point of conscience. Hence several orders of knighthood took their rise.

Many circumstances contributed to give rise to these expeditions. The desire of visiting a country which had been the scene of very important transactions, and in which the Son of God had accomplished the redemption of mankind, together with the idea of peculiar merit, acquired by a particular pilgrimage of this kind, and of its serving as a general expiation for almost every crime, had no small influence on this occasion. Besides, an opinion prevailed,

vailed, about the close of the 10th and beginning of the 11th century, that the thousand years mentioned by St. John, (Rev. xx. 2, 3, 4.) were accomplished, and that the end of the world approached; many thus hurried into the Holy Land, where they imagined that Christ would quickly appear to judge the world. Christians also thought it reproachful to suffer a country, which had been so signally distinguished, and whence they derived the most valuable benefits, to be abandoned to the enemies of the Christian name; and they thought it meritorious to avenge the calamities and injuries which its professors had suffered under the Mahometan yoke. Moreover, pilgrims were encouraged in their resort to Jerusalem, whilst Palestine continued subject to the caliphs; but when the Turks conquered Syria, about the middle of the eleventh century, they were exposed to every kind of outrage from these barbarians, and returned with exaggerated accounts of the dangers they had encountered in visiting the Holy City, and the cruelties and vexations they had endured. Accordingly, the first signal was given by Silvester II. towards the close of the tenth century, in an epistle wrote in the name of the church of Jerusalem to the church universal throughout the world, in which all the European powers are intreated and exhorted to succour and rescue the Christians in Palestine. This effort of zeal, however, produced no immediate effect. Gregory VII., in the beginning of the 11th century, revived an attention to this undertaking, proposed in person to invade the Holy Land, and upwards of 50,000 men were already mustered to follow him in this bold expedition. Although he was prevented by his quarrel with the emperor Henry IV. from executing this design, the spirit of the people was inflamed; and Peter the Hermit, returning from a voyage which he had made through Palestine, A. D. 1093, complained of the extreme sufferings of the Christians, applied to Urban II. for succour, and ran from province to province with a crucifix in his hand, exciting princes and people to this holy war, and pretending a divine commission for this purpose. At length, Urban II. finding a general ardour for the cause, assembled a grand and numerous council at Placentia, A. D. 1095, and warmly recommended this expedition. Soon after, in the same year, the proposal was renewed with success at the council of Clermont; at which were present, besides the papal court and council of Roman cardinals, 13 archbishops, 25 bishops, 400 mitred prelates, a great number, some say 4000, of ecclesiastics, and three hundred thousand laymen. In the market place of Clermont, the pope (Urban II.) ascended a lofty scaffold and addressed his eloquence to a well-prepared and impatient audience. Such was the success with which he addressed a numerous multitude, that he was interrupted by the clamorous shouts of thousands who with one voice exclaimed, "*Deus vult; Deus vult!*" "God wills it; God wills it!" "It is indeed the will of God," replied the pope; "and let this memorable word, the inspiration surely of the Holy Spirit, be for ever adopted as your cry of battle, to animate the devotion and courage of the champions of Christ. His cross is the symbol of your salvation; wear it; a red, a bloody cross, as an external mark on your breasts or shoulders, as a pledge of your sacred and irrevocable engagement." The proposal was joyfully accepted; and if we may believe the concurring testimony of contemporary authors, six millions of persons assumed the cross, as the distinguishing badge of those who devoted themselves to this holy warfare. The fumes of this enthusiastic zeal did not evaporate at once; the frenzy was as lasting as it was extravagant. During two centuries Europe seems to have

had no object but to recover or keep possession of the Holy Land, and through that period vast armies combined to march thither.

The number need not astonish us, if we consider that it was a motley assemblage of monks, prostitutes, artists, labourers, lazy tradesmen, merchants, boys, girls, slaves, malefactors, and profligate debauchees; and that it was principally composed of the lower dregs of the multitude, who were animated solely by the prospect of spoil and plunder, and hoped to make their fortunes by this holy campaign.

Besides, we shall have no reason to wonder at the multitude who flocked to the standard of the cross, if we advert to the natural operation of frantic zeal and the numberless privileges which the Crusaders acquired. Many or perhaps the greatest number of the chiefs and soldiers we may naturally suppose were prompted by the spirit of enthusiasm; the belief of merit, the hope of reward, and the assurance of divine aid. But it is equally certain that with many this was not the sole, and that with some it was not the leading, principle of action. In the council of Clermont, pope Urban had proclaimed a plenary indulgence to those who should enlist under the banner of the cross; the absolution of all their sins, and a full receipt for all that might be due of canonical penance. Moreover, the extensive privileges and immunities, granted to those who assumed the cross, will serve to account for the first ardour and long continuance of the Crusading spirit in Europe. The Crusaders were exempted from prosecutions on account of debt, during the time of their being engaged in this holy service.—They were exempted from paying interest for the money which they had borrowed.—They were exempted either entirely, or at least during a certain time from the payment of taxes.—They might alienate their lands without the consent of the superior lord of whom they held.—Their persons and effects were taken under the protection of St. Peter, and the anathemas of the church were denounced against all who should molest them, or carry on any quarrel or hostility against them, during their absence, on account of the holy war.—They enjoyed all the privileges of ecclesiastics, and were not bound to plead in any civil court, but were declared subject to the spiritual jurisdiction alone.—And as we have already observed, they were promised a plenary remission of all their sins, and the gates of heaven were set open to them, without requiring any proof of their penitence by their engaging in this expedition, and thus gratifying their favourite passion, the love of war. (Du-Cange.) Besides, the civil and ecclesiastical powers vied with one another, and strained their invention to devise expedients for encouraging and strengthening the spirit of superstition, and in setting a mark of cowardice and infamy on those who declined engaging in the holy war. In a letter addressed from Stephen, the earl of Chartres and Blois, to Adela his wife, in which he gives an account of the progress of the crusaders, he describes them as the chosen army of Christ; as the servants and soldiers of God; as men who marched under the immediate protection of the Almighty, being conducted by his hand to victory and glory. He speaks of the Turks, on the other hand, as accursed, sacrilegious, and devoted by heaven to destruction; and when he mentions the soldiers in the Christian army who had died or were killed, he is confident that their souls were admitted directly into the joys of paradise. Actuated and animated by such views, the crusaders embarked in this frantic expedition with singular ardour, and submitted without reluctance to the inconvenience and enormous expence that attended it. That the expence of conducting

CROISADE.

Mustering numerous bodies of men from Europe to Asia must have been excessive, and that the difficulty of raising the necessary sums for this purpose must have been proportionably great, we may infer from the expedients to which the leaders of this expedition were obliged to recur, during ages when the public revenues in every nation of Europe were extremely small. Hubert II. dauphin of Vienne, was obliged to furnish himself with money towards defraying the expense of the crusade. A. D. 1346, by very extraordinary sacrifices and concessions. He exposed to sale part of his domains; and the French king, in this sacred service, gave his consent and ratified the alienation. Moreover, he issued a proclamation, in which he promised to grant new privileges to the nobles, as well as new immunities to the cities and towns, in his territories, for certain sums which they were instantly to pay on that account; and, in this manner, many charters of community were obtained. He exacted also a contribution towards defraying the charges of the expedition from all his subjects, both ecclesiastics and laymen, who did not personally accompany him to the East. He appropriated a considerable part of his usual revenues for the support of the troops to be employed in this service: and he exacted considerable sums, not only of the Jews settled in his dominions, but also of the Lombards and other bankers who had fixed their residence there. Notwithstanding all these resources, he was involved in difficulties, which, on his return, required fresh exactions and demands. When the count de Fois engaged in the first crusade, he raised the money necessary for that expedition, by alienating part of his territories. In like manner, Baldwin, count of Hainaut, mortgaged or sold part of his dominions, to the bishop of Liege, A. D. 1096. And, at a later period, A. D. 1239, Baldwin, count of Namur, sold part of his estate to a monastery, when he intended to assume the cross.

Early in the spring of the year 1096 above 60,000 of the populace of both sexes from the confines of France and Lorraine assembled and put themselves under the conduct of Peter the Hermit, and followed him along the banks of the Rhine and Danube. The example and footsteps of Peter were closely pursued by another fanatic, the monk Godefcal, whose sermons had swept away 15 or 20 thousand peasants from the villages of Germany. Their rear was again pressed by an herd of 200,000, the most stupid and savage refuse of the people, who mingled with their devotion a brutal licence of rapine, prostitution, and drunkenness. Some counts and gentlemen joined the motley multitude with a view of sharing in the spoil. The first attacks of these enthusiasts were directed against the Jews, who were numerous and rich in the trading cities of the Moselle and Rhine, and who enjoyed, under the protection of the emperor and the bishops, the free exercise of their religion. At Verdun, Treves, Mentz, Spire, and Worms, many thousands of these unhappy people were pillaged and massacred. As these crusaders advanced to the wild and desolate countries of Hungary and Bulgaria, and traversed an interval of 600 miles, they endured incredible hardships. About a third of the naked fugitives, and among them the hermit Peter, escaped from the attacks of the Hungarians to the Thracian mountains; and the emperor, who respected the pilgrimage and succour of the Latins, conducted them by secure and easy journies to Constantinople, advising them to await the arrival of their brethren. Here, however, regardless of the kindness of their benefactor, neither gardens, nor palaces, nor churches, were safe from their depredations. Alexius, therefore, for his own security, allured them to pass over to the Asiatic side of the Bosphorus; but their blind impetuosity urged them to rush precipitately against the Turks;

who occupied the road of Jerusalem. Soliman, by spreading a rumour that some of their companions were rioting on the spoils of his capital, tempted the main body to descend into the plain of Nice, where they were overwhelmed by the Turkish arrows; and where a pyramid of bones informed their companions of the place of their defeat. Of the first crusaders 300,000 had already perished, before a single city was rescued from the infidels, and before their graver and more noble brethren had completed the preparations of their enterprise. None of the great sovereigns of Europe embarked their persons in the first crusade; but the religious ardour more strongly operated on the princes of the second order, who held an important place in the feudal system. The first rank both in war and council is justly due to Godfrey of Bouillon, a descendant of Charlemagne in the female line. He was accompanied by his two brothers, Eustace, the elder, and Baldwin, the younger; the duke of Lorraine, and the barons of France, Germany, and Lorraine, who assembled their vassals. The confederate force that marched under the banner of Godfrey was composed of 80,000 foot, and about 10,000 horse. Among the heads of the early crusaders we may also mention Hugh of Vermandois, Robert duke of Normandy, the eldest son of William the Conqueror, Robert count of Flanders, surnamed the Sword and Lance of the Christians, and Stephen, count of Chartres, Blois and Troyes, one of the richest princes of the age, the number of whose castles is said to have amounted to the 365 days of the year. These four were the principal leaders of the French, the Normans, and the pilgrims of the British isles: but the list of the barons, who were possessed of 3 or 4 towns, would exceed, says a contemporary, the catalogue of the Trojan war. Raymond of Toulouse, and Adhemar, bishop of Puy, and legate of the pope, assumed the command in the south of France; and the united force consisted of 100,000 horse and foot. Bohemond, the son of Robert Guiscard, at the head of 10,000 horse, and 20,000 foot, was accompanied by several princes of the Roman race, and also by his cousin Tancred.

The difficulty of procuring subsistence for such an incalculable multitude of men and horses, induced these several leaders to separate their forces; and they agreed to meet at last in the neighbourhood of Constantinople, and thence to begin their military operations against the Turks. Godfrey of Bouillon, departing from the banks of the Meuse and Moselle, pursued the direct way of Germany, Hungary, and Bulgaria. From Austria to Belgrade, they traversed the plains of Hungary without enduring or offering any injury; with the same conduct and discipline, he pervaded the woods of Bulgaria and the frontiers of Thrace; and he almost reached the first term of his pilgrimage, without drawing his sword against a Christian adversary. After an easy and pleasant journey through Lombardy, from Turin to Aquileia, Raymond and his provincials marched 40 days through the savage country of Dalmatia and Scythia; and his march between Durazzo and Constantinople was somewhat harassed, without being stopped, by the peasants and soldiers of the Greek emperor. From the Alps to Apulia the march of Hugh the Great, of the two Roberts, and of Stephen of Chartres, through a wealthy country, and amidst the applauding catholics, was a devout and triumphant progress; they kissed the feet of the Roman pontiff; and the golden standard of St. Peter was delivered to the brother of the French monarch. All separately accomplished their passage, regardless of safety or dignity, and within 9 months from the feast of the Assumption, August the 15th, 1096, the day appointed by Urban, all the Latin princes had reached Constantinople.

The

C R O I S A D E.

The principal force of the crusaders consisted in their cavalry; and when that force was mustered in the plains of Bithynia, the knights and their martial attendants on horseback amounted to 100,000 fighting men, completely armed with the helmet and coat of mail. The whole number, that formed the infantry and promiscuous crowd, was composed of 600,000 pilgrims, able to bear arms, and priests, monks, women, and children. It is farther said, that if all who took the cross had accomplished their vow, above *six millions* would have emigrated from Europe to Asia. Of these religious volunteers great numbers never beheld Constantinople and Nice. Some declined the enterprise in consequence of the transitory duration of their enthusiasm; others through cowardice, and others again on account of their poverty or weakness. Many fell in the savage countries of Hungary and Bulgaria; their vanguard was cut in pieces by the Turkish sultan; and we have stated the loss of the first adventure by the sword, or climate, or fatigue, at 300,000 men.

The first efforts of these adventurers were irresistible, and they gained considerable advantages. From their first station in Nicomedia, they advanced, from May 14th, to June 20, A. D. 1097, in successive divisions; passed the contracted limit of the Greek empire; opened a road through the hills; and commenced their pious warfare against Soliman, the Turkish sultan, by the siege and capture of Nice, his capital. Soliman, provoked rather than dismayed by the loss of his capital, collected his Turkman horde, constituting a force which is stated by the Christians at 200, or even 300, thousand horse. A severe engagement took place at Dorylaeum, in Phrygia, July 4th, A. D. 1097, which terminated in victory on the part of the crusaders, and the hasty retreat of the sultan, who evacuated the kingdom of Roum. In a march of 500 miles, from July to September, the crusaders traversed the Lesser Asia, through a desolate land, and deserted towns, without finding either a friend or an enemy, encountering in every step of their progress a great variety of difficulties and hardships. A detachment from the main army over-ran in a rapid career the hills and sea-coast of Cilicia, from Cogni to the Syrian gates; the Norman standard was first planted on the walls of Tarsus and Malmistra; and after a private conflict between Baldwin and Tancred, the former took possession of Edessa, and founded the first principality of the Franks or Latins, which subsisted 54 years beyond the Euphrates. During the ensuing winter the siege of Antioch, the capital of Syria, was commenced, and after an attack and defence equally obstinate, the city was surprisèd in the night; the army rushed in through the gates; and the Moslems soon found that resistance would be impotent and unavailing. The citadel still refused to surrender; and the victors were encompassed and besieged by the innumerable forces of Kerboga, prince of Mosul. In this extremity they collected the relics of their strength, sallied from the town, and in a single memorable day (June 28th, A. D. 1098), annihilated or dispersed the host of Turks and Arabians, consisting of 600,000 men. The attack of Jerusalem was suspended above ten months after the defeat of Kerboga; for the crusaders, after the victory they had obtained, hastily disordered to enjoy the luxury of Syria. By the siege of Antioch, and subsequent battle, as well as by famine and sickness, their numbers had been greatly diminished, and their strength enfeebled; however, in the month of May, A. D. 1099, the relics of their mighty host proceeded from Antioch to Laodicea; about 40,000 Latins, of whom no more than 1500 horse, and 20,000 foot, were capable of immediate service. Their easy march was continued be-

tween mount Libanus and the sea-shore; their wants were liberally supplied by the coasting traders of Genoa and Pisa; and they drew large contributions from the cities of Tripoli, Tyre, Sidon, Acre, and Caesarea, which granted a free passage, and promised to follow the example of Jerusalem. From Caesarea they advanced into the midland country, recognising in their progress Lydda, Ramla, Emmaes, and Bethlehem; and as soon as they descried the Holy City, the crusaders forgot their toils, and claimed their reward. The garrison is said to have consisted of 40,000 Turks and Arabians, under the command of Aladin or Istikhar, the lieutenant of the caliph, with whom the defence of the city was entrusted. The siege commenced on the 7th of June, A. D. 1099, and was directed against the northern and western sides of the city. Godfrey of Bouillon erected his standard on the first swell of mount Calvary; to the left, as far as St. Stephen's gate, the line of attack was continued by Tancred, and the two Roberts; and count Raymond established his quarters from the citadel to the foot of mount Sion, which was no longer included within the precincts of the city. On the 5th day, the crusaders made a general assault, with the fanatic hope of battering down the walls without engines, and of scaling them without ladders. By dint of brutal force, they burst the first barrier; but they were driven back with shame and slaughter to the camp. The siege was prolonged for 40 days; and they were 40 days of calamity and anguish, during which they endured distressing privations of food and water. Having constructed two turrets, they were rolled to the most accessible, and most neglected, parts of the fortification. One of them was unfortunately reduced to ashes by the fire of the besieged; but by means of the other, the enemies were driven by archers from the rampart; the drawbridge was let down; and on Friday at three in the afternoon, the day and hour, as it is said, of the passion, Godfrey of Bouillon stood victorious on the walls of Jerusalem. His example was followed on every side by the emulation of valour; and about 460 years after the conquest of Omar, the Holy City was rescued from the Mahometan yoke. The victors, to their everlasting disgrace, indulged themselves three days in a promiscuous massacre; so that the infection of the dead bodies occasioned an epidemical disease. After 70,000 Moslems had been put to the sword, and the harmless Jews had been burned in their synagogue, they reserved a multitude of captives; and Raymond granted a capitulation and safe-conduct to the garrison of the citadel.

"The holy sepulchre was now free; and the bloody victors prepared to accomplish their vow. Bare-headed and bare-foot, with countenances, and in an humble posture, they ascended the hill of Calvary, amidst the loud anthems of the clergy; kissed the stone which had covered the Saviour of the world; and bedewed, with tears of joy and penitence, the monument of their redemption."

Eight days after this memorable event (July 23, A. D. 1099), the Latin chiefs proceeded to the election of a king, to guard and govern their conquests in Palestine; when the free, just, and unanimous voice of the army proclaimed Godfrey of Bouillon the first and most worthy of the champions of Christendom. His magnanimity accepted a trust as full of danger as of glory; but in a city where his Saviour had been crowned with thorns, the devout pilgrim rejected the name and ensigns of royalty; and the founder of the kingdom of Jerusalem contented himself with the modest title of "Defender and Baron of the Holy Sepulchre." Within a fortnight after his acceptance of this honour, he was called to the field of battle by the approach of the vizir or sultan of Egypt, who was totally vanquished in the battle of Ascalon,

CROISADE.

Ascalon, Aug. 12, A. D. 1099. This victory sealed the establishment of the Latins in Syria, and signalized the valour of the French princes, who in this action bade a long farewell to the holy wars. Godfrey could retain, after this battle, only with the gallant Tancred 300 knights, and 2000 foot soldiers, for the defence of Palestine. Soon after this, a new enemy attacked his sovereignty, who sprung out of the bosom of the church. The seditious clamours of the ecclesiastics were urgent for the choice of a bishop, which, in their opinion, should have preceded that of a king. At this time Daimbert, archbishop of Pisa, seasonably arrived, with a fleet of his countrymen, for the service of the Holy Land; and he was immediately installed, without a competitor, the spiritual and temporal head of the church. The new patriarch instantly grasped the sceptre which had been acquired by the toil and blood of the victorious pilgrims; and both Godfrey, and Bohemond, who had claimed the sovereignty of Antioch as the recompence of his services during its siege, and in obtaining its surrender, submitted to receive of the hands of Daimbert the investiture of their feudal possessions. Daimbert further claimed the immediate property of Jerusalem and Jaffa; and a quarter of either city was ceded to the church; and the modest bishop was satisfied with an eventual reversion of the rest, on the death of Godfrey without children, or on the future acquisition of a new seat at Cairo or Damascus. This infant kingdom consisted only of Jerusalem and Jaffa, with about 20 villages and towns of the adjacent country. By the arms of Godfrey himself, and of the two Baldwins, his brother and cousin, who succeeded to the throne, the boundaries of this kingdom were enlarged. After the reduction of the maritime cities of Laodicea, Tripoli, Tyre, and Ascalon, the range of seacoast from Scanderoon to the borders of Egypt, was possessed by the Christian pilgrims. The counts of Edessa and Tripoli owned themselves the vassals of the king of Jerusalem. The Latins reigned beyond the Euphrates; and the four cities of Hems, Hamah, Damascus, and Aleppo, were the only relics of the Mahometan conquests in Syria. The new government was framed, and the laws and language, the manners and titles, of the French nation, and Latin church, were introduced into these transmarine colonies. However, the firmest bulwark of Jerusalem was founded on the knights of the hospital of St. John, and of the temple of Solomon. These knights maintained their fearless and fanatic character; and the spirit of chivalry, which was both the parent and offspring of the crusades, was transplanted by this institution from the holy sepulchre to the isle of Malta. As soon as Godfrey of Bouillon was seated in the office of supreme magistrate, he solicited the advice of the Latin pilgrims, who were best skilled in the statutes and customs of Europe, and from the materials which they furnished, with the counsel and approbation of the patriarch and barons, of the clergy and laity, Godfrey composed the "Assise of Jerusalem," which is a precious monument of feudal jurisprudence. The final revision of this code was accomplished in the year 1369, for the use of the Latin kingdom of Cyprus. The justice and freedom of the constitution were maintained by two tribunals of unequal dignity, instituted by Godfrey of Bouillon, after the conquest of Jerusalem. The king presided in person in the upper court, the court of the barons; the nobles, who held their lands immediately of the crown, were entitled and bound to attend the king's court; and each baron exercised a similar jurisdiction in the subordinate assemblies of his own feudatories. The connection of lord and vassal was voluntary and honourable. The cognizance of marriage and testaments was blended with religion, and

usurped by the clergy; but the civil and criminal causes of the nobles, the inheritance and tenure of their fiefs, formed the proper occupation of the supreme court. Each member was the judge and guardian of both public and private rights. The Assise of Jerusalem admits, in many cases, the barbarous institution of judicial combat. The trial by battle was established in all criminal cases, which affected the life, or limb, or honour, of any person; and in all civil transactions, of or above the value of one mark of silver. Champions were only allowed to women, and to men maimed, or past the age of 60. In the Assise of Jerusalem it is expressly declared, that after instituting, for his knights and barons, the court of peers, in which he presided himself, Godfrey established a second tribunal, in which his person was represented by his viscount. This court extended its jurisdiction over the burgesses of the kingdom; and it was composed of a select number of the most discreet and worthy citizens, who were sworn to judge, according to the laws, of the actions and fortunes of their equals. In the conquest and settlement of new cities, the example of Jerusalem was imitated by the kings and their great vassals; and above 30 similar corporations were founded before the loss of the Holy Land. These cities and corporations, if those of Palestine were coeval with the first crusade, may be ranked with the most ancient of the Latin world. (See CITY and CHARTERS of Community.) A third court was established for the use of those Syrians and oriental Christians who were oppressed by the zeal of the clergy, and who wished to be judged by their own national laws. Its jurisdiction was limited and domestic; its sworn members were Syrians, in blood, language, and religion; but the office of the president was sometimes exercised by the viscount of the city. At an unmeasurable distance below the nobles, the burgesses, and the strangers, the Assise of Jerusalem condescends to mention the villeins and slaves, the peasants of the land, and the captives of war. The relief or protection of these unhappy men was not esteemed worthy of the care of the legislator; but he diligently provides for the recovery, though not indeed for the punishment, of the fugitives.

In the 12th century, there were considerable bodies of emigrants who marched by land from the West to the relief of Palestine. The soldiers and pilgrims of Lombardy, France, and Germany, were excited by the example and success of the first crusade. Forty-eight years after the deliverance of the holy sepulchre, the emperor Conrad III. and the French king, Louis VII., undertook the second crusade to support the falling fortunes of the Latins. This expedition was undertaken at the instigation of Bernard, abbot of Clairval, and under the pontificate of Eugenius III.; A. D. 1147. Conrad and Louis met at Nice, and proceeded to Jerusalem, A. D. 1148, from whence they led back into Europe the miserable remains of those troops which had survived the disaster that had occurred in this expedition. Its unhappy issue has been ascribed principally to the jealousies and divisions that prevailed among the Christian chiefs in Palestine. Nor was it more ineffectual in Palestine than detrimental to Europe, by draining the wealth of its fairest provinces, and destroying such a prodigious number of its inhabitants. The third crusade was undertaken, A. D. 1189, by Frederic I., surnamed Barbarossa, emperor of Germany, whose example was followed, A. D. 1190, by Philip Augustus, king of France, and Richard Cœur-de-lion, king of England. These two monarchs arrived in Palestine in the year 1191, and succeeded in their first encounters with the infidels. After the reduction of Acre or Ptolemais, the French monarch returned to Europe; and the king of England, who remained, pushed the war with

great

C R O I S A D E.

great vigour, and not only defeated Saladin in several engagements, but made himself master of Jaffa and Cæsarea. Deserted, however, by the French and Italians, and influenced by other weighty considerations, he concluded, A.D. 1192, with Saladin a truce of 3 years, 3 months, and 3 days, and soon evacuated Palestine with his whole army. A *fourth* crusade, if it may be so called, was undertaken by the Teutonic knights, in consequence of the miseries which the besiegers suffered at the siege of Acre, and at the intimation, or at least with the marked approbation of pope Celestin III., who confirmed the above-mentioned order by a bull issued on the 23d of February, A.D. 1192. The support of Christianity, the defence of the Holy Land, and the relief of the poor and needy, were the important duties and services to which the Teutonic knights devoted themselves by a solemn vow. The *fifth* crusade, A.D. 1198, was excited by an illiterate priest of the neighbourhood of Paris, Fulk of Neuilly, who deserted his parochial duty, in order to assume the more flattering character of a popular and itinerant missionary. No sooner did Innocent III. ascend the chair of St. Peter, than he proclaimed in Italy, Germany, and France, the obligation of this new crusade. The eloquent pontiff described the ruin of Jerusalem, the triumph of the Pagans, and the shame of Christendom: his liberality proposed the remission of sins, a plenary indulgence to all who should serve in Palestine, either a year in person, or two years by a substitute; and among his legates and orators who blew the sacred trumpet, Fulk of Neuilly was the loudest and the most successful. Although the principal monarchs of that period, the emperor Frederick, Philip Augustus of France, and Richard of England, were on account of their peculiar circumstances not much inclined to engage in this expedition; nevertheless the preacher was heard and obeyed by the great vassals, the princes of the second order; and the foremost in the holy race was Theobald, or Thibaut the young count of Champagne. His companion in arms was Louis, count of Blois and Chartres; and they were joined by a crowd of prelates and barons, who imitated their zeal, and whose names it is needless to mention. The operations of the war were debated in full and frequent assemblies; and it was resolved to seek the deliverance of Palestine in Egypt, a country, which, since Saladin's death, was almost ruined by famine and civil war. But as the French barons who took the lead in this business were destitute of ships and ignorant of navigation, they dispatched 6 deputies to Venice, to solicit, on motives of piety or interest, the aid of that powerful republic. The deputies were hospitably received; and after much deliberation and debate, they were authoritatively informed that they would assist them on certain conditions, which they proposed. They offered a considerable number of flat-bottomed boats and ships for the use of their horses and foot-soldiers, to supply them with provisions for nine months, and to join the armament with a squadron of 50 galleys. But they required, that the pilgrims should pay, before their departure, a sum of 85,000 marks of silver; and that all conquests by sea and land, should be equally divided between the confederates. The treaty was ratified and preparations were made for the departure of the crusade. About the festival of Pentecost, A.D. 1203, Boniface, marquis of Montserrat, to whom the conduct of the enterprise was committed, displayed his banner and marched towards Venice at the head of the Italians; he was attended and followed by the counts of Flanders and Blois, and the most respectable barons of France; and their numbers were swelled by the pilgrims of Germany, who were actuated by views and motives similar to their own. The Ve-

netians fulfilled their engagements. After obviating some difficulties that occurred in their negotiation, the fleet and army directed their first hostilities against Zara, a strong city in Scлавonia, which had renounced its allegiance to Venice, and implored the protection of the king of Hungary. This city was soon compelled to surrender; but this commencement of their military career occasioned great disgust and complaint. The pope excommunicated the false crusaders, who had pillaged and massacred their brethren, the Hungarians, actually enlisted under the banner of the cross; and none but the marquis Boniface and Simon of Montfort, who were absent, escaped these spiritual thunders. The crusaders formed an alliance with young Alexius, the Greek prince; who promised in his own and his father's name, that as soon as they should be seated on the throne of Constantinople, they would terminate the long schism of the Greeks, submit to the lawful supremacy of the Roman church, pay the crusaders, for their services, 200,000 marks of silver, and accompany through Egypt, or maintain during a year 10,000 men, and during his life, 500 knights, for the service of the Holy Land. The alliance was ratified by mutual oaths and seals. They then proceeded towards Constantinople with all possible speed, which they besieged and captured. Thus was this crusade diverted from Syria to Constantinople, and the conquest of the Greek or Roman empire by the Latins.

The *sixth* crusade was undertaken A.D. 1217, under the pontificate of Honorius III. by the confederate army of Italy and Germany. The allied army was commanded by Andrew, king of Hungary, who was joined by Leopold, duke of Austria, Lewis of Bavaria, and several other princes. In this crusade 200,000 Franks were landed at the eastern mouth of the Nile, and it was expected that Palestine might be subdued in Egypt, the seat and storehouse of the sultan. After a few months absence Andrew returned into Europe. The remaining chiefs carried on the war with vigour, and in the year 1220 made themselves masters of Damietta, the strongest city in Egypt; but their prosperity was of short duration; for in the following year their fleet was totally ruined by that of the Saracens, their provisions cut off, and their army reduced by sickness and other causes to the greatest distress. This irreparable loss was followed by that of Damietta, and their expectations were completely frustrated. By the evacuation of Damietta they obtained a safe retreat, some concessions for the pilgrims, and the tardy restitution of the doubtful relic of the true cross. The failure has been ascribed, in some measure, to the abuse and multiplication of the crusades, which were preached at the same time against the Pagans of Livonia, the Moors of Spain, the Albigeois of France, and the kings of Sicily of the imperial family.

A *seventh* crusade was undertaken by the emperor Frederick II., who set out A.D. 1228, after having been excommunicated for his delay by the incensed pontiff Gregory IX. As soon as he landed in Palestine, he turned all his thoughts towards peace, and without consulting the other princes and chiefs of the crusade, concluded, A.D. 1229, a treaty of peace, or rather a truce of 10 years, with Melic-Camel, sultan of Egypt. He stipulated, among other things, that he should be put in possession of the city and kingdom of Jerusalem; which condition was immediately executed, and the emperor, entering into the city with great pomp, placed the crown upon his head with his own hands; and he then returned without delay into Italy, to appease the discords and commotions which the vindictive and ambitious pontiff had excited in his absence. The expeditions that followed were less important and less successful.

ful. In 1239 Theobald VI., count of Champagne and king of Navarre, set out from Marseilles for the Holy Land, accompanied by several French and German princes; and in the following year another expedition was undertaken by Richard, earl of Cornwall, brother to Henry III., king of England. The former of these expeditions failed through the influence of the emperor's ambassadors in Palestine, who renewed the truce with the Mahometans; while, on the other hand, a considerable body of Christians was defeated at Gaza, and such as escaped the carnage returned to Europe. This fatal event was chiefly owing to the discords that subsisted between the Templars and the knights of St. John of Jerusalem. Hence it happened, that the arrival of Richard, indulgently retarded by Gregory IX., and which had somewhat revived the hopes of the vanquished, was ineffectual to repair their loss. The utmost which he could accomplish was to conclude a truce with the sultan of Egypt, in the year 1241, after which he immediately set sail for Europe.

The *eighth* crusade was undertaken by Louis IX. king of France, in consequence of a vow which he had made in the year 1248, on occasion of a very dangerous illness: his first attempts, after he had arrived in Egypt with a formidable army and a numerous fleet, were crowned with success; for Damietta yielded to his arms; but the progress of the war presented one uniform scene of calamity and desolation. Famine and pestilence overwhelmed the royal army in 1250; Robert, earl of Artois, the king's brother, was slain in an engagement with the Saracen army; and, a few days after, the king himself, with two other brothers, and the greatest part of his army, were taken prisoners in a bloody action after a bold and obstinate resistance. The ransom of this prince, together with the restoration of Damietta, cost a sum, which in our days would amount to about 190,000 pounds sterling. After having remained four years in Palestine, he returned to France in 1254, with the small remnant of his formidable army.

The *ninth*, and last, crusade was renewed by the same valiant, but unfortunate monarch; who, with a formidable fleet and a splendid train of princes and nobles, arrived upon the African coast, and made himself master of the fort of Carthage. But a pestilential disease broke out in the fleet, in the harbour of Tunis, carried off the greatest part of his army, and seized at last the sovereign himself, who fell a victim to its rage on the 25th of August, A.D. 1270. Louis was the last of the European princes that embarked in the holy war; the dangers and difficulties, the calamities and disasters, and the enormous expences that accompanied each crusade, dispirited the most zealous, and discouraged the most intrepid promoters of these fanatical expeditions.

Towards the beginning of the 14th century, several attempts were made by the monarchs and princes of the west, incited by the Roman pontiffs, to renew the war in Palestine against the Turks and Saracens. But their success was not answerable to their zeal. Clement V. urged this business with the greatest ardour in the years 1307, 1308, and appropriated an immense sum of money for carrying it on with alacrity and vigour. John XXII. ordered a fleet of 10 ships to be fitted out in the year 1319 to transport an army of adventurers into Palestine, and had recourse to the influence of indulgences for raising the funds necessary to the support of this great enterprise. But it was a ground of complaints against their pontiff, that he made use of the holy war as a pretext to disguise his avarice and ambition. Under the pontificate of Benedict XII., a formidable army was raised in the year 1330, by Philip de Valois, king of France, with a view of attempting the deliverance of Chris-

tians in Palestine; but when he was ready to embark his troops, the apprehension of an invasion from England obliged him to lay aside the enterprise. In the year 1335, Clement V., at the request of the Venetians, engaged, by the persuasive power of indulgences, a prodigious number of adventurers to embark for Smyrna; but the want of provisions obliged them soon to return. Another formidable army was raised, A.D. 1363, in consequence of the zealous exhortations of Urban V., and it was to be employed, under John, king of France, in an expedition against the infidels; but the unexpected death of that prince disappointed the expectations formed from this grand project, and occasioned the dispersion of the numerous body which had repaired to his standard.

Although the crusades, which wasted the population of Europe, and squandered away immense sums of money, will ever remain in the records of history, as a singular monument of human folly; yet from these expeditions, extravagant as they were, beneficial consequences followed, which had neither been foreseen nor expected. In their progress towards the Holy Land, the crusaders marched through countries better cultivated and more civilized than their own. Constantinople, in particular, was the greatest, as well as the most beautiful, city in Europe, and the only one in which there remained any image of the ancient elegance in manners and arts. The naval power of the eastern empire was considerable. Manufactures of the most curious fabric were carried on in its dominions. Constantinople was the only mart in Europe for the commodities of the East Indies. Great wealth flowed into the capital from these various sources; which not only cherished such a taste for magnificence, but kept alive such a relish for the sciences as appear considerable when compared with what was known in other parts of Europe. Even in Asia, the European crusaders found the remains of the knowledge and arts, which the example and encouragement of the caliphs had diffused throughout their empire. It was not possible for the crusaders to travel through so many countries, and to behold their various customs and institutions, without acquiring information and improvement. Their views gradually enlarged; their prejudices subsided; new ideas crowded into their minds; and they must be sensible, on many occasions, of the rudicity of their own manners compared with those of a more polished people. These impressions would remain when they returned to their own countries. A close intercourse subsisted between the east and west for two centuries; new armies were continually marching from Europe to Asia, while former adventurers returned home and imported many customs to which they had been familiarized by a long residence abroad. Accordingly we discover, soon after the commencement of the crusades, greater splendour in the courts of princes, greater pomp in public ceremonies, a more refined taste in pleasure and amusements, together with a more romantic spirit of enterprise spreading gradually over Europe; and to these wild expeditions, the effect of superstition and folly, we owe the first gleams of light which tended to dispel barbarity and ignorance. These effects, however, would be slowly produced; but the influence of the crusades upon the state of property, and consequently of power, in the different kingdoms of Europe, was more immediate and more discernible. The nobles, who assumed the cross, found it necessary to raise large sums for these expeditions; but the genius of the feudal system did not admit of the imposition of extraordinary taxes; and therefore large sums could be raised only by the sale of their possessions. The ardour of their zeal disposed them to alienate their ancient inheritances at a low price; and thus the monarchs

varchs of different kingdoms, nine of whom engaged in the first crusade, seized this opportunity of annexing considerable territories to their crowns at a small expence. The fiefs likewise of those great barons who perished in the holy war and left no heirs, reverted to their respective sovereigns; and by this accession of property and power, the regal authority increased in proportion as the aristocracy declined. The prerogative of sovereigns was also extended in consequence of the departure of those powerful vassals, who were accustomed to limit and controul it; and thus they acquired a degree of weight in the constitution which they had not formerly possessed. Those who followed the cross were taken under the special protection of the church, and it denounced its anathemas against such as should disgust and wrong them; hence hostilities would be for a time suspended, and extinguished; and a more general and steady administration of justice would be introduced, and some advances would be made towards the establishment of a more regular government in the several kingdoms of Europe. The commercial effects of the crusades were not less considerable than those that have been already recited. Venice, Genoa, and Pisa furnished the transports in which the crusaders embarked; and these cities received immense sums for freight on account of numerous armies. The crusaders also contracted with them for provisions and military stores; and whilst the fleets kept on their coasts as the armies advanced by land, these states engrossed all the profits of that lucrative branch of commerce. Besides, they obtained grants of the most extensive immunities in the several settlements which the Christians made in Asia. When the crusaders seized Constantinople, and placed one of their leaders on the imperial throne, the Italian states were considerable gainers by that event. Many valuable branches of the commerce, which formerly centered in that city, were transferred to Venice, Genoa, or Pisa. The wealth which thus flowed into these cities served to establish and to maintain their liberty and independence. By the increase of wealth, which was owing to the commerce resulting from the crusades, a spirit of activity and a passion for liberty and independence were excited; so that before the conclusion of the last crusade all the considerable cities of Italy had either purchased or had extorted large immunities from the emperors. See *CITY and CHARTERS of Community*.

In tracing the consequences and effects of the crusades, Mr. Gibbon states, that the intercourse between Constantinople and Italy diffused the knowledge of the Latin tongue; and several of the fathers and classics were at length honoured with a Greek version. If we compare, he says, at the era of the crusades, the Latins of Europe with the Greeks and Arabians, their respective degrees of knowledge, industry, and art, our rude ancestors must be content with the third rank in the scale of nations. Their successive improvement and present superiority may be ascribed to a peculiar energy of character, to an active and imitative spirit, unknown to their more polished rivals, who, at that time, were in a stationary or retrograde state. With such a disposition, the Latins might have derived essential benefits from events which opened to them a long and frequent intercourse with the more cultivated regions of the East. Their first and most obvious progress was in trade and manufactures, in the arts, which are strongly prompted by the thirst of wealth, the calls of necessity, and the gratification of the sense or of vanity. But the intellectual wants of the Latins were more slowly felt and supplied; and in the age of the crusades, they viewed with careless indifference the literature of the Greeks and Arabians; nor did they derive any substantial advantage from it. The principle of the crusades was a savage fanati-

cism; and the most important effects were analogous to the cause. Each pilgrim was ambitious to return with his sacred spoils, the relics of Greece and Palestine; and each relic was preceded and followed by a train of miracles and visions. The active spirit of the Latins preyed on the vitals of their reason and religion; and if the 9th and 10th centuries were the times of darkness, the 13th and 14th were the ages of absurdity and folly. The embers of the arts of antiquity, as Mr. Gibbon conceives, were rekindled by the northern conquerors of the Roman empire; and after a long interval, from the reign of Charlemagne forward, the tide of civilization began to flow, about the 11th century, with a steady and accelerated course. During the two centuries of the crusades, its increase was great, and its progress rapid; and some philosophers, as we have already stated, have applauded the propitious influence of these holy wars; but Mr. Gibbon thinks, that they checked rather than forwarded the maturity of Europe. The lives and labours of millions, which were buried in the East, would have been more profitably employed in the improvement of their native country; the accumulated stock of industry and wealth would have overflowed in navigation and trade; and the Latins would have been enriched and enlightened by a free and friendly correspondence with the climates of the East. In one respect Mr. Gibbon perceives the accidental operation of the crusades, not so much in producing a benefit as in removing an evil. "The larger portion of the inhabitants of Europe was chained to the soil, without freedom, or property, or knowledge; and the two orders of ecclesiastics and nobles, whose numbers were comparatively small, alone deserved the name of citizens and men. This oppressive system was supported by the acts of the clergy and the swords of the barons. The authority of the priests operated, in the darker ages, as a salutary antidote:—they prevented the total extinction of letters, mitigated the fierceness of the times, sheltered the poor and defenceless, and preserved or revived the peace and order of civil society. But the independence, rapine, and discord, of the feudal lords were unmingled with any semblance of good; and every hope of industry and improvement was crushed by the iron weight of the martial aristocracy. Among the causes that undermined that Gothic edifice, a conspicuous place must be allowed to the crusades. The estates of the barons were dissipated, and their race was often extinguished, in these costly and perilous expeditions. Their poverty extorted from their pride these charters of freedom which unlocked the fetters of the slave, secured the farm of the peasant, and the shop of the artificer, and gradually restored a substance and a soul to the most numerous and useful part of the community. The conflagration which destroyed the tall and barren trees of the forest gave air and scope to the vegetation of the smaller and nutritive plants of the soil." Gibbon's *Hist. Rom. Emp.* vol. ii. Robertson's *Hist.* ch. v. vol. i. *Hist. Diss.* concerning India, p. 131, &c. Smith's *Wealth of Nations*, vol. i. ch. 3. Mosheim's *Eccle. Hist.* vol. ii. and iii. Hume's *Hist.* vol. i. and ii.

Towards the middle of the 12th century, A. D. 1143. there was also a crusade of the Saxons, against the pagans of the north, whom they determined either to convert or to extirpate. The attempt produced the usual effects, ravages and murders, and then was dropped. In this crusade the archbishop of Magdeburg, the bishops of Halberstadt, Munster, Meriburgh, Brandenburg, &c. with several lay-lords, embarked. And towards the beginning of the same century, under the pontificate of Innocent, there was also a crusade undertaken against the Albigenses; who were become powerful in Languedoc, &c. and who had no other

crime but that of rejecting the tyranny, idolatry, and superstitions of the church of Rome. See ALBIGENSES.

When the opinions of Wickliffe were disseminated in Bohemia, as well as in England, the court of Rome was much alarmed; and pope Martin V. published a bull, A. D. 1428, which he sent into England, as well as into other countries, commanding solemn processions to be made, on the first Sunday of every month, in all churches and churchyards, in order to draw down the vengeance of heaven on the heretical Bohemians; and promising 60 days' indulgence to all who attended these processions, or who said 25 paternosters, with the same pious intention. His holiness, not trusting entirely to supernatural interposition for the destruction of the enemies of the church, proclaimed a crusade against the Bohemians, granting the pardon of all their sins, and the happiness of heaven, to all who contributed to its success, in proportion to the value of the contribution. Many of the English engaged in this crusade, which was conducted by the cardinal of Winchester.

The capture of Constantinople, May 29, A. D. 1453, by Mahomet II., emperor of the Turks, alarmed all the Christian princes and states of Europe. But these princes and states were so much engaged in war, that they could not unite against the common enemy, but left it to the clergy to wield their spiritual weapons against those adversaries of the Christian faith. Archbishop Kemp published in England March 2, A. D. 1453, an order for processions to be made for a whole year, and he was followed in this course by his successor; processions being then regarded as the most effectual means of obtaining the divine favour and assistance. At length pope Pius II. (Æneas Silvius), published a long, eloquent, and pathetic bull, A. D. 1463, engaging to march in person, at the head of a Christian army, against the Turks, and most earnestly exhorting all Christians to take the cross, or to contribute by their money to the success of the expedition; promising the pardon of sin, and the happiness of heaven to all who complied with his desire: at the same time the pope sent bulls into every Christian country, imposing a tax of one-tenth on the benefices of all the clergy. Edward IV., then king of England, not willing to acknowledge the pope's right to tax his clergy, and yet desirous that they should, on this occasion, contribute liberally, wrote to the primate to raise a handsome sum by voluntary assessment, which would satisfy the pope, and prevent the publication of his bull. This plan was adopted; but it was with great difficulty that the primate could prevail on the clergy to grant six-pence in the pound.

CROISE, LAKE *of, Isle a la Croise.* See CROSSE.

CROISES, or CROIZES, in our *Ancient Customs*, pilgrims bound for the Holy Land, or who had already been there; so called from a badge which they wore on their garments, representing a cross. See CROISADE.

The word croises is also extended to the knights of St. John of Jerusalem, created for the defence and protection of pilgrims; and all those of the nobility, gentry, &c. who, in the reigns of king Henry II., Richard I., Henry III., and Edw. I. were *cruce signati*, i. e. dedicated themselves to the wars for the recovery of the Holy Land.

CROISIE, Lt, in *Geography*, a small town of France, in the department of the Lower Loire; 9 miles N. of the mouth of the Loire, with a good harbour, and 306 miles S.W. of Paris. E. long. 15° 8' 18", and N. lat. 47° 17' 40", according to the French computation. It is the chief place of a canton, in the district of Savenay, and one of the 84 maritime quarters into which all the principal sea-port towns of France are divided, with a judge of admiralty, to whom the maritime syndics of St. Nazaire, Montoir, Mes-

quer, and Redon are subordinate, and who, in his turn, is subordinate to the admiralty court of L'Orient. Le Croisic contains 2310, and the canton itself 5564 inhabitants in two communes, and on a territorial extent of 52½ kilometres.

CROISIERS, CRUCIGERI, or *Cross-Bearers*, a religious order, or congregation of regular canons, so called.

There are three orders which have, or do still bear this name; one in Italy; another in the Low Countries, and a third in Bohemia.

The first pretend to be derived from St. Clet; and add, that St. Quiriacus the Jew, who slew S. Helena the place of the true cross, and was afterwards converted, reformed them. All we know for certain is, that they subsisted in Italy before Alexander III. mounted the throne; for that pontiff, flying from Frederic Barbarossa, found an asylum in the monasteries of the croisiers, which he afterwards, in 1169, took under his protection, giving them the rule of St. Augustine, &c.

They were confirmed by Pius V.; but the discipline being much relaxed, they were suppressed, in 1656, by Alexander VII.

Matt. Paris says, that the croisiers, bearing staves with crosses at the end, came into England in 1244, and presented themselves before a synod held by the bishop of Rochester, demanding to be admitted. They were here called *crouched friars*.

Dodsworth and Dugdale mention two monasteries of this order in England, the one at London, the other at Ryegate; the first founded in 1245, the latter in 1298; some add a third at Oxford, where they were received in 1349. M. Allemand says, there were fourteen monasteries of cross-bearers in England; adding, that they came from Italy; those of the Low Countries disowning them.

The croisiers of the Low Countries and France were founded in 1211, by Theodore de Celles, son of Bofon, who, having served in a crusade in Palestine, in 1188, and there found some of the croisiers instituted by St. Clet, conceived a design of instituting another congregation in his own country. This is certain, that Theodore, in his return from Palestine, engaged himself in the ecclesiastical state; and went in quality of missionary to the crusade against the Albigenes: and that at his return, in 1211, the bishop of Liege gave him the church of St. Thibault near Huy; where, with four companions, he laid the foundation of his order; which was confirmed by Innocent III. and Honorius III. Theodore sent his religious to Tholouse, to join those of St. Dominic, and combat the Albigenes; and the congregation multiplied in France. The popes have endeavoured to bring the croisiers of Italy under those of Flanders. The croisiers, or port croix with a star, in Bohemia, derive their origin from St. Quiriacus, and say they came from Palestine into Europe, where they embraced the rule of St. Augustine, and built monasteries. They add, that St. Agnes of Bohemia, to distinguish them from other croisiers, obtained of Innocent IV. to add a star to their habit. But the story of St. Quiriacus has no foundation; and it was Agnes herself, daughter of Premislaus, king of Bohemia, who instituted the order at Prague, in 1234. They are very numerous, and have now two generals.

CROISILLES, in *Geography*, a small town of France, in the department of Pas-de-Calais, chief place of a canton, in the district of Arras, with a population of 972 individuals. The canton has 28 communes, and 14,487 inhabitants, upon a territorial extent of 185 kilometres.

CROISSANT CONTOURNE', in *Heraldry*, denotes the half moon, looking to the left side of the shield.

CROISSANTE',

CROISSANTE, **CROIX**, is a cross crescented; that is, having a crescent, or half-moon, fixed on each end thereof.

CROISSILLE, in *Geography*, a town of Savoy, in the duchy of Geneva; 11 miles N.N.W. of Annecy.

CROISSY, a small town of France, in the department of Seine and Marne; 15 miles E. of Paris, and 3 miles from the left shore of the Marne. Before the French revolution of 1789, it conferred the title of marquis on the lords of the manor.

CROITES ROMOS, in *Ancient Geography*, the name given to the territory of the town of *Cros*, situated in Egypt. Steph. Byz.

CROIUS, **JOHN**, in *Biography*, a French Protestant minister, who flourished in the 17th century, was born at Uzeze, where he officiated as a minister. He was a considerable writer on controversial subjects; but his principal work was in Latin, intitled, "Observationes sacræ et historicæ in Novum Testamentum," 1644. In early life he was reckoned a high Calvinist, but afterwards embraced the sentiments of the Universalists. He died in the year 1659.

CROIX-DU-MAINE, **FRANCIS GRUDÉ DE LA**, a writer frequently referred to by the French literati, was born in the province of Maine in 1552. He was educated at Paris, and discovered, at an early age, a great passion for collecting books. In 1584, he published a general catalogue of all French writers, intitled, "Bibliothèque Française." He was author also of a plan of a complete library, addressed to Henry III. He was assassinated at Tours in 1592. A new edition of his Bibliothèque was published with that of Verdier, in 5 vols. 4to. 1772, 1773.

CROIX, DE LA, **G.** a French landscape-painter of some eminence, the scholar of Vernet, whose style he adopted. Several prints have been engraved from the pictures of this master. We shall only mention the following: "Le Tybre, paysage & les orientaux au bord du Tybre," 2 large pieces, lengthways, engraved by Aliamet. "La Cascade de Tivoli," by de Flumet. "Vue de Mont Vefuve," as it appeared in 1757, lengthways, 1762, by Le Miré. Heineken.

CROIX, DE LA, **P. F.** a portrait painter, a native of Holland, from whose pictures we have the following plates: "William V. Prince of Orange, and the Princess Caroline of Orange," two standing figures, a pair, engraved by Tanjé, 1755. "Portraits of the fame," a pair, by Houbraken. "Wolf Dietrich, Count of Beuchling," by Bodenehr. "J. Van Span," by J. Houbraken. "Eg. Buys," by the same. "Sebast. le Clerc, the Engraver," by Dupin. Heineken.

CROIX, La, en Bric, in *Geography*, a small town of France, in the department of Seine and Marne; 6 miles W. of Provins, formerly a commandery of the order of Malta.—Also, a small town of France, in the department of Eure; 6 miles N.E. of Evreux, properly called *La Croix Saint Leufroy*.

CROIX, La, a mountain of Piedmont, in the district of the Four Vallies; 13 miles W. of Pignerol.

CROIX, Cape, a cape on the W. coast of Africa, in the Mediterranean. N. lat. 3° 38'. W. long. 9° 55'.

CROIX, Sainte, Santa Cruz, one of the three Caribbee islands of the Virgin Group which the Danes possessed in the West Indies, until the latter end of December, 1807, when the three Danish islands surrendered by capitulation to the English. Denmark had purchased St. Croix from France in 1733. It is situated about five leagues east of St. Thomas, in the 64th degree of western longitude, and the 18th of north latitude, ten or twelve leagues long, three or four broad, and intersected by several small rivers. The air is

rather unhealthy at certain times of the year, the whole island being almost level. The soil is uncommonly fertile.

St. Croix has many valuable sugar and cotton plantations. It used to export annually from 20 to 24,000 hogheads of sugar, from 7 to 8000 puncheons of rum, and 150 cwt. of cotton. Christianstadt was the residence of the Danish governor. The population of this town exceeds 5000 individuals, and it has a good harbour.

In 1796 this island had a population of 2223 white, 1164 free negroes, and 25,425 negro slaves; but the importation of slaves into the Danish islands has ceased since 1803. There were in St. Croix 160 sugar plantations, each of which gave 150 hogheads of 100wt.

The other two Danish West India islands, which are likewise in possession of the English at present (1808), are St. Thomas and St. John. The three islands had been taken by the English in 1801, during the short war between Great Britain and Denmark, on account of the revived convention of armed neutrality; but they had been restored after the memorable battle of Copenhagen of the 27th of April, 1801. (Oxholm's Danish Account of the Danish West India Islands.)—Also, a small town of France, in the department of the Upper Rhine, 12 miles north of Ensisheim, in the district of Colmar.

CROIX, St., or *Santa Cruz*, a town of Luconia, one of the Philippine islands, which is separated from Manilla by a river that flows under the walls of this city, and serves as a harbour for merchant ships. St. Croix is in part equally well built with the capital; peopled with Indians and Spaniards in considerable numbers, and surrounded by three villages of the natives, which may be regarded as suburbs.

CROIX, St. a small navigable river in Nova Scotia, which runs into the Avon or Pigiguit.—Also, a river which forms part of the boundary-line between the United States of America, and the British province of New Brunswick, and discharges itself into Passamaquoddy bay.—Also, a river in the north-west territory, which runs into the Mississippi from the N.N.E. about 50 miles below the falls of St. Anthony.

CROLIES, a small town of France, in the department of the Isere, 12 miles N.E. of Grenoble.

CROMA, Ital. in *Music*, the character which in English is called a quaver. It is the eighth part of a semibreve; has a black head, like a crotchet, and a hook at the

tail: thus, when single, ; but when united with other

quavers, it has a single tie; thus, . See **CROTCHET**, and **TIME-TABLE**.

CROMACH CRAIG, in *Geography*, a mountain of Scotland, in the county of Perth; 5 miles N. of Crieff.

CROMACK HEAD, a cape of Scotland, on the N. coast of the county of Bamff; 3 miles N.W. of Cullen.

CROMARTY HARBOUR, in Cromartyshire, in Scotland, is a spacious and safe retreat for ships, at the entrance of Murray Firth, about 18 miles to the eastward of the commencement of the Inverness and Fort William, or Caledonian canal; see **CANAL**. This harbour was surveyed in 1801 by Mr. Thomas Telford, with a view to some improvements therein for the better accommodation of ships, intending to pass or having passed the Caledonian canal, connecting the east and west British seas.

CROMARY, a town of France, in the department of the Saône, and district of Vezoul; 2½ leagues N. of Besançon.

CROMATIC French Horns, in *Music*, were instruments manufactured

manufactured by Charles Clagget, of Greek-street, Soho, which, we are told, were capable of producing the full chromatic scale of the organ, without the aid of crooks, or the instrument undergoing any part of change. On the 15th of April 1791, a trial of two of these instruments was made in a concert in the New Rooms at Bath, in the presence of a full company, when the performers are said to have performed their parts in several airs of Haydn's, Giardini's, &c. and to have modulated as far as seven flats, in perfect harmony with the violins, violincellos, &c. every intonation being pointed, clear, quick, and in the natural tone of the instrument.

CROMAU, CRMAU, or KRUMLOW, in Latin *Cromena*, in *Geography*, a small but well built town of Bohemia, in the circle of Bechin, or Bechynsko, on the river Mulda. It has a good citadel, and a college of Jesuits, and confers the title of dukes on the princes of Schwartzenberg, to whom it belongs. There are some silver mines in its neighbourhood.

CROMBACH, a town of Germany, 7 miles N.E. of Siegen.

CROME, or CROOM, in *Agriculture*, a name provincially applied to an implement of the fork kind, with crooked or hooked prongs. Thus we have muck croome, turnip crooms, &c.

CROMER, GIULIO, called *IL ROMA*, in *Biography*, a painter of some reputation in his time, who was born in Ferrara, about the year 1572. He was the scholar of Domenico Mona, but his style more resembles that of Jacopo Bambini, another Ferrarese painter of that period. The pictures of this artist evince much study, and considerable correctness of design; but they are characterised by the reddish tint which pervades his carnations, and a too ostentatious introduction of architectural decoration. In the church of S. Andrea in Ferrara are several large compositions by this master, representing the actions of that saint, besides some small altar-pictures. Cromer died in 1632.

CROMER, in *Geography*, a town of England, situated on the N.E. coast of the county of Norfolk, having a harbour for fishing vessels, and chiefly inhabited by fishermen. Attempts have been made for erecting a pier, but hitherto without success, the sea washing it away. This town appears to have been formerly much larger than it is now: as it had two churches, one of which has been demolished by the inundation of the sea. It is now a place of resort for sea-bathing; and has a weekly market on Saturday; 23 miles N. of Norwich, and 127 N.N.E. of London. N. lat. 52° 55'. E. long. 0° 50'.

This place has no harbour for ships, but vessels of 60 to 100 tons burthen are laid upon the sandy beach, where carts can be drawn to them when the tide retires, and thus, coals, tiles, oil-cakes, and other commodities are imported for the use of the inhabitants, and some corn is exported. A lighthouse stands about three-quarters of a mile eastward of the town, lighted by 15 argand lamps, each with a large plated copper reflector behind it, arranged round an upright axis, which, by means of a large clock-movement, is made to revolve once in a minute, constantly presenting to the mariner off the coast, a series of moving lights, so different from any other, as to be immediately distinguished in the night.

CROMFORD CANAL. This is the parliamentary name of a navigable canal in the counties of Nottingham and Derby, of about 18 miles in length, cut about 15 years ago, for carrying coals, corn, &c. up into the mining district of Derbyshire, and bringing down lead, mill-stones, grind-stone, lime-stone, marble, &c. for exportation, by means of the Erewash and Nottingham canals with which

it connects; see our article **CANAL**, wherein we omitted to mention a short collateral cut to Lea bridge stone-sawing mill and wharf; it is near half a mile in length from the Derwent aqueduct bridge, and is level with the line, except in time of floods, when a lock is used for turning the same over the weir at its top, into Lea brook. Messrs. Dadford, Shaveby, Benjamin Outram, and Edward Fletcher, were employed as engineers with Mr. Jessop, on different parts of the works of this canal.

CROMFORD, a town in the parish of Wirksworth, Derbyshire; within 35 years past this place has increased in population, so as to have become a considerable town: the *Cromford Canal* terminates at this town (which see). Cromford fough, a subterraneous drain or passage of near two miles in length cut in the solid lime-stone rock, for freeing the lead mines near Winstar of water, at an expence exceeding 30,000 *l.*, gave rise to the subsequent prosperity of this place, by furnishing an opportunity to Mr., afterwards sir, Richard Arkwright, to erect his first cotton spinning mill, to which another similar establishment has since been added. The late sir Richard Arkwright erected a spacious and convenient chapel of ease for this town, of the salmon-coloured grit stone, which is dug on the S. E. side of the town, above the lime-stone Shale stratum. The same patriotic individual contributed much to the ornament of the environs of this town, by his plantations and other improvements. Stocking-weaving and lace-weaving are carried on to some extent in this town, whose inhabitants, the girls in particular, are much subject to a disease called the thick neck, from a tumour which forms in that part, which is said by some to be hereditary.

CROMIS, in *Ichthyology*, the *coracinus brasiliensis* of Ray, the *guaticupa* of Marcgrave, and the *LABRUS cromis* of Gmelin; which see.

CROM-LECHE, in *British Antiquity*, derived, according to the conjecture of Mr. Rowlands, from the Hebrew *carem-luach*, a devoted stone or altar, are huge, broad, flat stones, raised upon other stones set up on end for that purpose. They are common in Angleley; and Mr. Rowlands (*Mona Antiqua Restaurata*), supposes, that they are the remains of altars erected there by the first colonists.

Mr. Gough, in his "*Sepulchral Monuments of Great Britain*," supposes, that these cromleche were Danish monuments. Mr. King, in his "*Monumenta Antiqua*," vol. i. inclines to think, that they were altars for idolatrous sacrifices. Mr. Toland also, in his "*History of the Druids*," mentions, that the cromleche were altars of a larger size than those denominated "carns," or "cairns," and consisting of a greater number of stones; some of them serving to support the others, on account of their enormous bulk. They were placed in the centre of the circular temples of the Druids, and near them has been found, occasionally, a prodigious stone, which served as a pedestal to some deity. He says, that they were places of worship, and so called from *bowing*, the word being derived from *crom* or *crum*, which, in Armoric, Irish, or Welsh, signifies "bent," and *lech*, or *leac*, "a broad stone," and signifying the "bowing-stone." Mr. Toland mentions a cromlech in Nevers parish in Pembrokeshire, South Wales, having the middle stone 18 feet high, and 9 broad towards the base, but narrowing upwards: and by it there lay a broken piece 10 feet in length, which seemed to be of a weight heavier than 20 oxen could draw. But at Poitiers in France, there is one supported by 5 lesser stones, much exceeding all in the British islands, as it is 50 feet in circumference. This he conceives to have been a "Rocking-stone." At Bodouyr, in Anglesea, there is a noble cromlech; many of them are 30 ton in weight; but they differ in size, as all pillars

pillars do; and the altars are always larger than the "Kistieu-vaen." In some parts of Wales these stones are called "Meincuguyr," importing the same with "cromleche." In Caithness, and other remote parts of Scotland, these cromlechs are very numerous, some of them pretty entire, and others, not so much consumed by time and overturned by storms, as disordered and demolished by the hands of men. But no such altars were ever found by Olaus Wormius, the great northern antiquary, nor by any others, in the temples of the Gothic nations, or of those who speak the several dialects of Gothic original, from Ireland to Swiflerland, and from the Bril in Holland, to Presburg in Hungary, the Bohemians and Polanders excepted. Among the Germans there were no Druids, and they had no sacrifices; and therefore to the former altars were as useless as they were necessary to the latter. In Jersey likewise, as well as in the other neighbouring islands, there are many altars and cromlechs. The principal cromlech in Ireland was "Crum-cruch," which stood in the midst of a circle of 12 obelisks, on a hill in Bresin, a district of the county of Cavan, formerly belonging to Leitrim. It was wholly covered with gold and silver; the lesser figures on the 12 stones about it being only of brass; which metals, both of the stones and statues they bore, became every where the prey of the Christian priests, upon the conversion of that kingdom. The druidical altars of a smaller size were called "carns," or "cairns." These cairns consisted of stones of all sorts, from one pound to a hundred: they are round in form, and somewhat tapering or decreasing in size upwards; but on the summit was always a flat stone: some of them contain at least 100 cart-loads of stone: and if any of them be grown over with earth, it is by accident, in the long course of time during which they have been neglected; for this was not intended when they were first constructed, as was the case with regard to the sepulchral barrows of the Gothic nations, which are generally of earth. Such a place is in the ancient Celtic language, and in every dialect of it, called "Carn," and every carn was so disposed as to be within view of some other. On the carn, called "Crig-y-dyon," in the parish of Trelech, in Carmarthenshire, the flat stone on the top is 3 yards in length, 5 feet over, and from 10 to 12 inches thick. The circumference of this carn at the base is about 60 yards, and its height about 6 yards; the ascent being very easy: though perhaps a ladder was originally used for this purpose. In process of time, the cairns served every where for beacons; though they were originally designed for fires of another nature. See BELENUS and BEL-TEIN.

Of the altars called cairns, many are to be seen entire in Wales, particularly two in a parish of Denbighshire, hence called "Kerig-y-Druidion," or Druid's stones, and one in Llan-Hammwlch parish, in Brecknockshire. These Druids' altars were commonly placed in the middle of the temples, near the great stone or colossus, which we have already mentioned; such as that at Carn Llechart, in the parish of Llan-gvvelach, near Swansea, in Glamorganshire, and others in Scotland. These are called by the Welsh, in the singular number, "Kist-vaen," that is, a stone-chest; and in the plural, "Kistieu-vaen," stone-chests. But they denote things quite different from those real stone-chests or coffins, commonly of one block and the lid, that are in many places found under ground. Wherever a circle occurs without an altar, it is certain that there was one formerly; as altars are found where the circular obelisks are mostly or all taken away for other uses, or from an aversion to this superstition, or because time has destroyed them. Those who adopt the opinion, now commonly received, from the bones which are

often found near these altars or circles, though seldom within them, that they were burying-places, forget what Cæsar, Pliny, Tacitus, and other authors affirm, concerning the human sacrifices offered by the Druids; and in mistaking the ashes found in these cairns, they betray an ignorance of those anniversary fires and sacrifices for which they were reared. The huge coping-stones of these cairns were to serve as altars, and altars of the lesser form are frequently found near them; as in the large Latin and Greek churches, there are, besides the high altar, several smaller ones.

CROMMYON, or CROMYN ACRIIS, in *Ancient Geography*, a promontory of the isle of Cyprus, at the extremity of the peninsula, towards the north, between Soloë to the south-west, and Lapathus to the south-east. It is now Cape Cormachitti.—Also, a village of Greece, in the territory of Corinth.

CROMMYONESUS, the name given by Pliny to a small island of Asia Minor, which he places in the vicinity of Smyrna.

CROMNA, a town situated on the coast of Paphlagonia, near the river Parthenius. Steph. Byz. supposes this place to have been the ancient Amaltris; but Arrian states that they were at the distance of 120 stadia from one another. The destruction of Cromna, however, contributed to the aggrandizement of Amaltris.

CROMNUM, a town of Greece, in the Peloponnesus, situated near Megalopolis.

CROMONT, in *Geography*, a small town of France, in the department of the Somme, 9 miles E. of Abbeville.

CROMORNE, *Fr.* in *Musie*, a reed-stop in most of our old organs, built by Father Smith, and other Germans. And we believe that the word is of German origin: as KRUMON is crooked, and the name of this stop should be written KRUMHORN. Whether it was at first intended that the tone of this stop should imitate a cornet, a shawn, or a bassoon, is not settled. Menage, in his *Dct. Etym.* thinks the latter; and the tone certainly resembles a bassoon more than any other instrument.

CROMPTON POINT, in *Geography*, the N.E. point of the island of Dominica. N. lat. 15° 42'. W. long. 61° 21'.

CROMWELL, THOMAS, earl of Essex, in *Biography*, was the son of a blacksmith at Putney, in Surrey, but who became invested with great authority, and at length was sacrificed by the prince whom he had long and faithfully served. In what manner Thomas Cromwell was educated, and for what profession he was particularly intended does not appear, but we find him early in life situated as clerk to the English factory at Antwerp. In the year 1510 he visited Rome; and it has been thought he served as a soldier in the duke of Bourbon's army, and that he was present when that city was plundered. See ROME. As, however, this happened in the year 1527, and it is known that Cromwell was actively employed in England sooner than this period; the conjecture is probably without foundation. He was patronised by cardinal Wolsey, and assisted him in founding the two colleges at Oxford and Ipswich, and in procuring, in 1525, the suppression of some monasteries for their endowment. When the cardinal was disgraced, Cromwell used his utmost efforts to restore him to his sovereign's favour; and by his exertions in the house of commons, of which he was a member, he prevented the passing of the articles of treason exhibited there against him. For his intrepidity on this occasion, he obtained the king's favour, and was taken into his service, in which he engaged with more zeal than honesty. He suggested to Henry a project for raising a supply of money of his clergy, who through fear gave up, as a gift, about 120,000*l.* For this and other services he obtained

obtained the honour of knighthood, which was in higher estimation at that period, than it is now; he was also appointed one of the privy-council; and in 1534 rose to the posts of principal secretary of state and master of the rolls. In the following year he took an active part in the suppression of the monasteries, for which purpose he was made visitor-general, and is said to have exercised the office without any regard to the principles of justice or humanity. His services were, however, rewarded by the king, who advanced him to the post of lord-keeper of the privy-seal, and to a seat in the house of peers, by the title of lord Cromwell of Okeham. After the abolition of the pope's supremacy, lord Cromwell, under the title of king's-vicar-general, was placed at the head of the whole ecclesiastical power in the kingdom. His influence in this situation he employed in favour of the reformation, to which he was apparently much inclined from conviction, having in early life committed to memory Erasmus's translation of the New Testament, and having been prepossessed in favour of the principles of the reformers during his residence in the Low Countries. Without referring to the minuter acts by which he promoted the cause which he had espoused, we may observe that he encouraged an English translation of the Bible, of which, when finished, he directed a copy to be provided for every parish church. This in those times was the most important and truly valuable gift that could have been made to a parish. Honours were still increased on the head of lord Cromwell; he was appointed chief justice itinerant of the forests beyond Trent, and in 1539 was advanced to the dignity of earl of Essex, and lord high chamberlain of England. His fortune and his property in land were augmented in full proportion to his rank in life; he obtained many noble manors and estates out of the wrecks of the religious foundations. Envy and ill-will were, however, the constant companions of his good-fortune; he had in various instances laid himself open to his enemies, who never failed to take every advantage of his failings. The clergy hated him for his exactions on their body; the ancient nobility despised him on account of the meanness of his origin, and his sudden elevation to the highest distinctions of the state. To the friends of law and justice, his arbitrary proceedings against the innocent, or at least against those who were not permitted to defend themselves, rendered him justly obnoxious. He had been chiefly instrumental in procuring the condemnation of the countess of Salisbury and the marchioness of Exeter, on charges of high treason. Under such circumstances he could scarcely hope to finish his course without some reverse, especially since his only security was the will of a prince who was guided by no principle but that of gratifying his own passions at any price. Cromwell had recommended Anne of Cleves to Henry as a wife; from her he hoped for support in the cause of the reformation, being a Lutheran. Her person did not answer the expectations of the king; he determined to dismiss her, and to avenge himself on Cromwell, who had been the means of uniting them. He was accordingly arrested at the council table by the duke of Norfolk, a zealous catholic, on the charge of high treason; and, in conformity to the wicked precedent which he had given, he was condemned without being permitted to justify himself. He pleaded by an humble petition with the king; thrice was the prayer of the supplicant read to his majesty, but he was inexorable; the great men of the earth rarely forgive, and Henry VIII. was not an exception to this rule. Cranmer, whose character we have already discussed and appreciated, was the only friend who ventured to acknowledge Cromwell in his misfortune: he wrote to the king, attesting from his own knowledge, the loyal attachment of his faithful

servant, and affirming, that "he loved his majesty no less than his God." The decree was however passed, and Cromwell was beheaded on Tower-hill, July 28, 1540, declaring with his latest breath that he died in the catholic faith; which is scarcely to be accounted for on any principles of human action. Thus fell Thomas Cromwell, earl of Essex, under the weight of a tyrant's displeasure, whom he had served with fidelity, courage, and resolution, in the most hazardous, difficult, and important undertakings. Mr. Hume denies that there were any grounds for the impeachment of lord Cromwell of treason, but admits that he justly merited his fate, for suffering himself to be the instrument of the king's tyranny in the case of the countess of Salisbury and others. "He was," adds the same historian, "a man of prudence, industry, and ability, worthy of a better master, and of a better fate." Mr. Gilpin, speaking of his condemnation, remarks, that "among all the arts of expediency, laid up in the cabinets of princes, the readiest is to sacrifice a minister. The death of Cromwell was represented to the king as the best mean of composing the people. But though prudential reasons may oblige a prince to discard a minister, yet guilt only, and that nicely examined, can authorize an act of blood; the hand of a tyrant, however, generally throws aside the balance. It is a nice machine, and requires pains and temper to adjust it. The sword is an instrument more decisive, and of easier dispatch. Henry's was always stained with blood—often with innocent blood—but never with blood more innocent than that of Essex." *Biog. Brit.*

CROMWELL, OLIVER, one of the most distinguished characters in English history, who raised himself to supreme power, from an obscure situation, was son of Robert Cromwell and Elizabeth Stuart, his wife, and born at Huntingdon, on the 24th of April, 1599. At the free-school in this town he received the early part of his education, which he completed at Sidney college, Cambridge. His attainments in literature were by no means considerable; and he has been charged with exhibiting, in his youth, all the turbulence of temper which was compatible with a system of scholastic restraint. The death of his father called him home from Cambridge, and in a short time after he was entered at Lincoln's-Inn, but, in the interval, the want of employment afforded him scope for indulgence in certain irregularities which gave his mother much uneasiness. In London he paid but little attention to the law, for the study of which he was intended, but giving into the vices of the town, he involved himself in expences, which the smallness of his fortune would ill support, and reduced him to difficulties. Still, however, he has the apology usually made, in like circumstances, for youth; as he married before he had attained to the age of twenty-one, the daughter of sir James Bouchier, and from this period he began to lead a grave and sober life. By the death of his uncle, a few years after his marriage, he came in for an estate of nearly 500*l. per annum*, which he had endeavoured to obtain before, by applying for a statute of lunacy against his relation. Previously to this, he had been returned member of parliament for the borough of Huntingdon; but, on coming to his fortune, he removed to the Isle of Wight, neglected the church, in which he had been educated, and openly joined himself to the Puritans. In 1628, he was elected member of parliament, and was shortly after appointed on the committee of religion, in which he distinguished himself by his zeal against popery, and by complaining of the bishop of Winchester's licensing books of a very dangerous tendency. During the recess from public business, he associated much with the ministers who had been silenced, and

invited

invited them to perform religious services at his own house. By the support which he gave to their cause, and by his retribution to persons of property, of that which he had formerly gained by gambling, his affairs became again very much embarrassed. In the hope of adding to his income by honest industry, he took a farm at St. Ives, which he held about five years, without experiencing those gains which he had anticipated. Uneasy at his present embarrassed situation, he formed the project of embarking for the Western world, which he would probably have put into execution, had he not been prevented by a proclamation against emigration. He now appeared in various useful concerns as a man of business, and was regarded by his friends as one designed for matters of higher import than fall to the lot of the generality of mankind. Oliver was elected member of the Long Parliament, for Cambridge, in the year 1640. From this event his future greatness is to be dated. In the house he was zealous and assiduous, and a very frequent speaker, which gave him a considerable degree of influence, though he was deemed inelegant in his manners, and in his person he was remarkable slovenly and careless as to his dress. In 1641, he was the most active person in carrying the Remonstrance, which was, in fact, the basis of the civil war, and which was gained by a majority of nine only. This remonstrance, of which we shall have occasion to speak more at large under the article ENGLAND, contained a concise history of the enormities of Charles's government, the evil counsellors who had guided and did guide him, and the mischiefs which they had been meditating against the house itself, for their opposition to, and correction of, abuses. It occasioned a debate that lasted from noon, till ten o'clock the next morning, which has led some historians to compare the decision to the verdict of a half-starved jury: it was, however, of so much importance to the cause of the opposition, that many from this time, who had been wavering in their politics, gave a decided voice against the measures of the court, and it dispirited such as adhered to the king so powerfully, that, from this period, they ventured to make no resistance. Cromwell's firmness on the occasion, contrary to the wishes of many leading men on the same side, who were willing to put off the discussion, was the principal cause of success, and it so recommended him to Hampden, Pym, and others of the same party, that, from henceforward, they admitted him into all their councils. Naturally of a clear and penetrating mind, he soon obtained an insight into every subject that was deemed of importance at the time, and so perfect a knowledge of his contemporaries, and of all their designs, that he was not only able to manage when they were removed, but even to contrive the means of dismissing some, who, at this crisis, looked upon themselves as his superiors.

In the beginning of 1642, when parliament had determined upon the levy of forces, he went to Cambridge, where he raised a troop of horse, of which he took the command by a commission from the earl of Essex. Though subject to a higher authority, he engaged, of his own accord, in some spirited enterprises, which were very beneficial to his party. The celebrity that he acquired as a soldier laid the foundation of the greatness to which he afterwards attained as the ruler of the country. His successes enabled him to increase his force, and he found himself in a very short time colonel at the head of a thousand well-disciplined horse-soldiers. Cromwell uniformly selected persons of religious principle, who felt a zeal for the business in which they engaged, rightly judging that men of abandoned characters are never, on trying occasions, to be trusted. His levies consisted of his countrymen, substantial yeomanry,

and their sons, whom he trained in excellent discipline, and rendered valiant by example and instruction. Cromwell has often been charged with hypocrisy, and where dissimulation answered his ends, he doubtless made no hesitation in calling it in to his aid; but in this business he adopted the line of manliness and true courage: in addressing his men, he said, "he did not mean to deceive them, by pretending to fight for king and parliament, for should the king himself be found in the opposite army, he would as soon fire his pistol upon him as upon another man."

Without attempting to trace the detail of Cromwell's military transactions, which will be given hereafter, we may observe that by various important services he acquired the complete confidence of parliament, and was in the year 1643-4 made lieutenant-general of the horse in the army of the duke of Manchester, and in the battle of Marston-moor, July 3, 1644, his cavalry turned the fortune of the day, and gave the first severe blow to the royal party. He next distinguished himself at the battle of Newbury, in which his valour was so conspicuous, and the effects arising from it so very important, that he was styled by his party "The Saviour of the Nation." By the discerning and the wise, his motives were suspected; and his conduct was impeached in the house of lords as worthy of particular notice. He, on the other hand, exhibited charges of considerable moment against some members of the upper house. These accusations led to the carrying of the "self-denying ordinance," the professed object of which was to exclude the members of both houses from commands in the army. By this measure the earl of Manchester, the principal enemy to Cromwell, and other persons of rank and consequence, were excluded from offices in the army: from which, however, on the score of his extraordinary merit, that set him above all ordinances, Cromwell was at first occasionally, and at length absolutely exempted. The chief command of the army was now committed to sir Thomas Fairfax, a man of undoubted bravery, and unimpeachable integrity, but unfit to cope with Cromwell, who was lieutenant-general of the army. On the 15th of June, 1645, he distinguished himself by the most brilliant exploits in the battle of Naseby. On that occasion he had the command of the right wing, and after Ireton had been beaten, and rashly pursued out of the field by prince Rupert, it was Cromwell's charge which broke the king's infantry, and secured a complete victory. He followed up the success of the day with other actions of high merit, and was rewarded by parliament with 2500*l.* *per ann.* and when he resumed his seat in the house, thanks were returned to him in the warmest expressions, which he received with an affected humility, and declarations of profound submission to the will of that assembly. Those who, in parliament, had excited the war, for the sake of redressing grievances, and to set some bounds to the prerogative, were now desirous of peace, to which they conceived nothing would so much contribute, as having the king's person in their hands. For this purpose sir Thomas Fairfax was ordered to besiege Oxford: the king however contrived to escape, and put himself into the hands of the Scots, who, at length, scandalously gave him up on condition of receiving a stipulated sum of money. Parliament, having thus attained their object, was desirous of disbanding a part of the army. Cromwell, whose overgrown authority this measure was meant to check, contrived to turn it to his own advantage; and procured from the general regulation an exception for Fairfax's army, which was in fact his own. From this period, the ways of Cromwell were directed by a policy very difficult to unravel. Ambition was doubtless the passion that had fastened on his mind: he fought for power, and

CROMWELL.

was careless as to the means of attaining his object. He professed principles of deference and respect for the parliament, which he probably held in contempt: under the mask of friendship for the fallen monarch he was plotting against his life. By his instigation, the king's person was seized by Cornet Joyce, who had no orders but the verbal instructions of Cromwell for what he did. When Charles was taken to head-quarters, the behaviour of the lieutenant-general was so respectful, that it was thought he meant to restore him to his lost crown: he obtained a letter from the army to parliament to declare that their cause and that of the king was the same. By the arts of Cromwell, the king left Hampton Court, where he seemed to be gaining importance, and put himself into the hands of the governor of the Isle of Wight, a person devoted to the interests of Cromwell. A second civil war in defence of monarchy called him again into the field: he marched into Wales, quelled an insurrection there; from thence he marched into Scotland, put the power into the hands of the other party, and made arrangements conformably to his own wishes, and then returned to London. In the mean time parliament opened a treaty with the king, which might have been concluded, had not Cromwell interfered: a detachment of the army seized the king's person, and lodged him in Hurst castle, which was at first resented by the parliament, who commanded the general to recal his orders; but instead of this a part of the army marched directly to London, took possession of it, purged the house of commons of the best part of its members, and obliged the remainder to do what they pleased. The fate of the king was now drawing near, and it must be admitted that Oliver Cromwell was the prime mover in the cruel and bloody deed. He acted the hypocrite, and would willingly have kept through the whole business, in the back ground; but finding that his own energy was requisite to accomplish it, he came forward in the most public manner: he sat in the court, signed the warrant, and probably procured not only the execution, but the executioner, whose name and character have never yet been fully ascertained.

The constitution of the country was now destroyed, and in the stead of one sovereign, there were nominally many, under the name of a Council of State, but Cromwell, who formed it, was the principal member. The spirit of the army, which he had fostered for his own purposes, seemed to rise against him; a mutiny broke out, which, however, by his vigilance and resolution, was quelled without much serious mischief. He was next called to Ireland, where three parties were opposed to each other, *viz.* the native catholics, the royalists, and the friends to the parliament. He went out in 1649 in quality of lord lieutenant, with ample powers, and with a full determination of reducing all to order. Here he practised the utmost rigour of the law of arms, and murdered a multitude of people who opposed his projects, under the milder title of military execution, a phrase, which by others, as well as Cromwell, has been used to justify the most savage outrages against humanity. At Drogheda he is said to have given up to the sword more than 2000 veteran troops; and at Wexford, women and children did not escape his fury. By these means he reduced Ireland to obedience, and returned to London in the following spring, where he was received by the thoughtless multitude with the most triumphant exultation.

Soon after his return, it was discovered that the Scotch had invited Charles II., and were preparing an army in his support. Cromwell recommended a previous invasion of Scotland, and was himself appointed general commander in chief of all the forces of the commonwealth, still keeping

the lieutenancy of Ireland. Cromwell marched to Scotland at the head of 20,000 chosen troops, a still larger army was raised to oppose him, which in the first contest were proved to be unequal to contend with the invaders. The battle of Dunbar, fought Sept. 3, 1658, terminated in a complete victory over the Scots, with great slaughter. Edinburgh castle fell in consequence of this decisive blow, and Cromwell reaped various other important successes. In the mean time, Charles determined upon trying the strength and attachment of his friends in England. Cromwell followed him, and at Worcester on the 3d of September 1651, he obtained over the royal army what he denominated his "crowning victory," attended with the total destruction of his opponents. He now proceeded to London, where he was hailed with all the honours due to a conqueror and deliverer of his country. He was met by the parliament and its speaker, the council of state, and the magistrates of the city, who were assembled to render him the praise due to his successful labours. A day of thanksgiving was appointed, and Cromwell himself was rewarded with 4000*l.* a year, taken from the forfeited estates. From this period he began to concert measures for securing to himself the supreme power. The Long Parliament had become exceedingly unpopular in the country; they had long talked of dissolving themselves, but had always found pretexts for putting off the time to a more convenient opportunity. Cromwell took advantage of the odium which attached to an assembly that appeared determined to maintain the powers originally delegated to them for their country's good, with a view to the sordid purposes of self-interest. He resolved upon a decisive measure: he founded his friends, and talked to them of "*stabilising the kingdom*," a phrase made use of to cover his real designs. He was well acquainted with human nature, and in every instance, he contrived to make persons of different views, and almost opposite habits, suppose that their intentions, as to the remedy of evils, coincided with his own. To the sober and religious, he complained of the scandalous lives, and dissolute manners, of certain leading republican members. He exposed the pride of some, the fraud of others, and the interestedness of all, except those to whom he was immediately addressing himself. With the fifth-monarchy men, he conversed in their own style, professing a desire that the saints should reign; but his real design he kept profoundly locked in his own bosom; so that all who were desirous of a change, were willing to aid him in his efforts, upon the full persuasion that it would be such a change as they themselves wished. Having thus prepared the way, on the 19th of April 1653, he called a council of officers, explained his designs, took a party of 300 soldiers, whom he placed about the avenues to the parliament-house, and entered himself, as a spectator of their proceedings. They were debating the necessity of continuing as a house till the November of the following year. Displeased with their arguments, he called major general Harrison, and told him that he thought this was the proper moment for a dissolution. Harrison urged upon him the danger of the business: as if satisfied with his reasons, he remained quiet a few minutes, till the very moment when the speaker was about to put the question for passing the act of continuing their duration, he then started up, and bade the speaker to proceed at his peril: he commanded him to leave the chair, and told the house in a vehement tone that they had existed long enough, for the good they had performed. He then addressed individuals, charging them with vices which they probably could not deny, and for which they had no expectation of being called to account. A few of them attempted to reply; but his object was not de-

bate,

bate, but decision. "Come, come," said he, "I will put an end to your prating.—You are no longer a parliament; I say you are not a parliament;" and stamping with his foot, he bade them for shame begone, and give place to honest men. The soldiers instantly entered the house, one of whom he commanded to "take away the bauble," meaning the mace. An officer, at the same time, took the speaker by the arm, and led him down from his seat. After which, with a degree of canting hypocrisy that never was surpassed, he addressed the house, saying, "It is you that have forced me upon this business, for I fought the Lord night and day, that he would rather slay me than put me upon the doing this work." To conclude the scene, he seized the books and papers, turned the members out of the house, and locked the doors. His next step was to dissolve the council of state, after which for a few days he governed by his own authority, calling to his aid a council of officers. Shortly after a new representative body was summoned consisting of 142 members, who from their numbers were styled the *Little*, from their manners the *Godly*, and from the name of one of its members, "Barebon's parliament." This body were found unequal to the charge which they had undertaken; the greater part from a sense of weakness resigned their power into the hands of Cromwell, and the rest he forcibly dismissed. The supreme power again devolved upon the officers, who conferred upon Cromwell the office of PROTECTOR OF THE COMMONWEALTH OF ENGLAND, SCOTLAND, and IRELAND. This happened Dec. 16, 1653, and he was solemnly invested with the high trust in Westminster-hall, and from this time he must be considered as the sovereign of a great nation; his power was almost boundless, but he exercised it with prudence and dignity. He applied himself to state affairs, made peace with Holland, and entered into treaties with Denmark, Sweden, and Portugal. France and Spain appeared ambitious of his friendship, and the general state of Europe was such as to give to England a large share of consequence among surrounding nations. In his domestic administration, he was an enemy to religious persecution; and shewed a respect for the rights of conscience. He displayed a zeal for justice, but was extremely severe in punishing conspiracies against the state, as he denominated those which were levelled against himself. He summoned a parliament, in which Scotland and Ireland were united in sending representatives, and obtained by this method a supply of money necessary for the carrying on of government. This body was not sufficiently obsequious to his will, and he dissolved it in about five or six months. In 1655 an insurrection broke out in the west of England, but Cromwell was too well informed of all the proceedings to feel any anxiety on this head; his numerous spies, and no monarch had more, gave him constant intelligence of every thing that passed, and he suffered the mal-contents to proceed far enough to involve themselves in the penalties of treason, and then crushed them with a blow. Economy and frugality were not characteristics of Cromwell's reign, and the want of money led him to the seizure of property belonging to the king of Spain, which excited a war chiefly carried on in the West Indies. In that quarter the result was not highly favourable to the English, unless in the subjection of Jamaica, which has continued ever since attached to this country. But the successes of admiral Blake in the Mediterranean gave great importance to the protector's government, and raised him high in the opinion of foreigners. France was glad of an alliance, upon the condition of banishing the Stuart family from her realms, and giving up Dunkirk to England; and a splendid embassy from Sweden was sent and received with great parade.

After the dissolution of parliament, Cromwell's government

VOL. X.

might fairly be denominated a despotism, for the money was raised by his own decrees without the intervention of the people. He issued, among other mandates, one for inflicting the penalty of the tenth of the annual income upon all those who had borne arms for the king, and commissioners were sent into the several counties to levy the same, who were empowered to compound for the same on the terms of a three years' purchase. Such in those days were the penalties of high treason.

In the year 1656, Cromwell had recourse to another parliament in order to obtain the necessary pecuniary supplies; after he had obtained these he aimed at extorting from them the title of king, but his expectations not being answered, he contented himself with that of protector; he then attempted to form a new house of peers, but the ancient nobility refused to associate with the sons of the protector, and others whom he was anxious to raise to a similar rank. About this period a pamphlet was written and circulated, entitled "Killing no Murder," insisting upon the right of tyrannicide; this work, which was the production of Titus, an officer in the army, made so deep an impression on the mind of Cromwell, that he probably never enjoyed one hour's solid peace after the refusal. New conspirators were discovered, and many suffered, some in consequence of projects discovered before they could be attempted, and others to allay the fears of the usurper. Among these were sir Henry Slingsby, and Dr. Hewett, a clergyman of the church of England; for the latter every interest was made, particularly by the protector's favourite daughter, but the irrevocable sentence was passed and carried into execution. She fell sick, and with almost her last breath execrated the cruel policy that took away the life of her friend. From this time the health of the protector began visibly to decline; and the cares and the fears, connected with his greatness, were doomed to bring him to a speedy end. A slow fever terminated his existence September 3, 1658. He does not appear to have expected this termination of the disease; he maintained, in opposition to the opinions of his physicians, the certainty of his recovery; but took the precaution to make his will, in which he bequeathed the reins of government to his son Richard, and to Henry his other son he left the governorship of Ireland. He was interred with great pomp in Westminster Abbey. He died at a period when, according to the opinion of bishop Burnet, "his life and his arts were exhausted together, so that if he had survived any longer, he would scarcely have been able to preserve his power." The fabric of his greatness was false and unsound. By cunning and deceit he had attained his high situation; these seemed to render him the less assistance the longer he lived, and it is probable that in a very few years, or even months, they might have served him no more. His own children are said to have been all foes to his government, either royalists or republicans from principle; and, perhaps, says one of his biographers, "there was not a person in the nation sincerely attached to, and a well-wisher of his government." It were in vain to look for a disinterested account of the character of this great man, for great, in the common acceptation of the word, he unquestionably was, among those who were the witnesses of his life and conduct. No two writers in the present age seem agreed as to the degree of merit or demerit to which he is entitled. We shall, however, quote the opinion of Mr. Granger, who has indeed drawn different sketches of him. "Oliver Cromwell," says he, "united in a very high degree, the characters of the politician and general, and occasionally assumed those of the buffoon and the preacher. He broke forth from his obscurity, at an age when others think themselves doomed to it for ever; and

J G

when

when many begin to entertain thoughts of retiring from the world, he began to make the most conspicuous part in it. He availed himself of the virtues and vices, the talents and weaknesses, of mankind; and such obstacles as would have been insurmountable to an inferior genius, helped greatly to carry him on in his career."—"He is," says the same writer, "an amazing instance of what ambition, heated by enthusiasm, restrained by judgment, disguised by hypocrisy, and aided by natural vigour of mind, can do. He was never oppressed with the weight, or perplexed with the intricacy of affairs; but his deep penetration, indefatigable activity, and invincible resolution, seemed to render him master of all events. He persuaded without eloquence; and exacted obedience, more from the terror of his name, than the vigour of his administration. He appeared as a powerful instrument in the hand of Providence, and dared to appeal to the decisions of heaven for the justice of his cause. He knew every man in the three kingdoms, and endeavoured to avail himself of their respective talents. He has always been regarded by foreigners, and of late by the generality of his countrymen, as the greatest man this nation ever produced. It has been disputed which he most deserved, a halter or a crown, and there is no less disparity betwixt the characters drawn of him, and the reports propagated by his enemies and his friends." *Biog. Brit. Harris's Life of Cromwell, &c.*

CROMWELL, RICHARD, eldest son of the protector, was born at Huntingdon, in 1626, where he received his grammar learning. When he was about 20 years of age, he was entered at Lincoln's Inn, being probably intended for the bar, but he was too much attached to his pleasures to make any considerable progress in his legal studies. Neither in this, nor in any period of life, had he the ambition to distinguish himself. His political opinions were opposite to those of his father, and he had not the smallest taste for military distinction. It is said that he pleaded, on his knees, for the life of Charles, and it is well ascertained that he joined the party who wished success to the cause to which his father was the most formidable enemy. By the protector he was raised to some offices of distinction, and was one of his new peers. Richard rather acquiesced in his fate, than felt proud of the honour which he then enjoyed, and which, as the heir of Oliver, he might reasonably anticipate. Upon the death of his father, he succeeded to the government, and received the accustomed homage, with addresses from all parts of the nation. His title and claim were acknowledged by continental powers, and, for a few months, every thing went on very smoothly. A parliament was then necessary, which, though called in the usual manner, exhibited some alarming symptoms of opposition; disaffection appeared also in the army. In this exigence, Richard advised with his privy council, who recommended a dissolution of the parliament, with which he complied, and this act may be considered as the real termination of his power. He retained, indeed, the name and the appearance of protector a few days longer, though without any degree of authority, and his reign was finally ended by the resolution of the council of officers to invite the surviving members of the Long Parliament, to return to the exercise and discharge of their trust. By some of his friends Richard was advised to retain his power by force, and to cut off those men who were aiming to deprive him of sovereignty. But he despised their council, and spurned the thought of retaining power at the expence of blood. He quietly submitted to all the sacrifices that were required, and was particularly anxious that he might be freed from the debts which the splendour of his father's funeral seemed to fix upon him. Parliament

gave him security for this purpose, and promised a liberal provision for himself and family. At the restoration he thought it right to retire to the continent, though there seems to have been no intention on the part of the king or his ministers to molest him; and so completely was he forgotten, that his name was not once mentioned in either house. For some years he resided at Paris, under a feigned name, and in great obscurity; from thence he went to Geneva, and about the year 1680 he returned to England, and fixed his residence at Theobald in Hertfordshire, under the name of Clark, where he lived much respected by those who enjoyed his acquaintance. He died in the year 1712, in his 86th year, a happier and a better man than his father, but possessed of none of those qualities that attract notice or lead to celebrity. He is described as an excellent character, possessing in his latter years great gravity and real piety. He was endowed with many amiable qualifications, and was much beloved by his friends, with some of whom he kept up a correspondence to his death. He had been married, and left three daughters, who some years before their father's death had attempted to deprive him of his property; by an appeal to the law, he obtained his right, and was afterwards reconciled to his children, whom in his last moments he recommended to "live in love, as he was going to the God of love." *Biog. Brit.*

CROMWELL, HENRY, the youngest surviving son of Oliver, was born in January 1627-8, and at the age of 16 was introduced to military service. In 1649, he accompanied his father to Ireland, where he attained the rank of colonel. He returned, and was elected member of the "Barebone's Parliament," but was afterwards sent to Ireland in a political capacity, and at length was lord-lieutenant of that kingdom. In every situation he acted his part with honour, and was generally respected. Such indeed was the integrity of his character, that in a letter to his brother, he said, "I will rather submit to any sufferings with a good name, than be the greatest man upon earth without it." Upon the restoration of Charles, he lived quietly as a private gentleman, and took no part in the various changes of the state. It is thought that he rejoiced in the succession of the king to his crown, and he was not only included in the act of indemnity, but received some marks of favour from the king, of which he expressed a very grateful sense, in a letter to lord Clarendon, through whose interposition the benefit was obtained. He died in the 47th year of his age, and was buried near his mother. After the restoration he conformed to the church of England, and died in that communion. Many are the testimonies to the excellence of his character: we shall only notice that of Mr. Neal, who says, "that he was a wise and discreet governor: that by his prudent conduct he kept the Irish in awe; that he brought that nation into a flourishing condition; and that he behaved with such generous impartiality, as gained him the esteem even of the Royalists themselves." *Biog. Brit.*

CROMYON, in *Ancient Geography*, a burgh of Corinth, situated on the gulf to the east of Sclærus. It is pretended that it took its name from Cromus, the son of Neptune. In the first times of Greece, this was the place where the monster of cruelty, called *Sinis*, fastened the limbs and arms of travellers whom he apprehended to branches of the pine-tree, which he bent to the ground; and then giving them liberty to restore themselves, they thus tore to pieces the unfortunate wretches, whom the savage monster doomed to this kind of death. Tuceus is said to have destroyed him in the same manner. Pausanias mentions the fact, and says that these cruelties were practised towards the point of the

the Isthmus. Here was an altar of Melicertes. When Ino's mother plunged herself with him into the sea, in order to preserve him from the cruelty of his father, the fable says that a dolphin brought her to the shore, and that Sisyphus finding the body, interred it in this place, and instituted in honour of her the *Isthmian* games.

CRONACA, SIMONE, in *Biography*, a Florentine architect, born in the year 1454. He travelled to Rome and other cities of Italy to study and take exact measurement of the antique edifices. Returning to Florence he acquired considerable reputation, and was employed to finish the Palazzo Strozzi, begun by Benedetto da Maiano. Amongst his other works at Florence are the "Sagresty of the Church of Santo Spirito, and the Church of S. Francesco del Osservanza," at S. Miniato, in the suburbs of that city. He died in 1509, and was buried in the church of St. Ambrogio. *Vafari*.

CRONACH, in *Geography*. See **CRANACH**.

CRONBERG. See **CRONENBURG**.

CRONE, in *Rural Economy*, a term applied to sheep, which denotes an old ewe. Thus in speaking of the aged stock of this sort, they are usually denominated crones.

It is stated by the author of the Farmer's Calendar as a common system of management in inclosed districts, to buy in old crones in the month of September, to put the ram to them in the following month, and to dispose of the lambs as they become fat in the ensuing summer and autumn, so as to clear the whole within, or at most in about a year from the period of buying them in.

And this is supposed a tolerable method of management in cases where the fences are in a perfectly secure condition, and the food in great abundance, though in general inferior to the system of wether lambs. See **SHEEP**.

Crone stock is, however, considered by the author of the Minutes of Agriculture as a very unprofitable sort, especially where the chief spring food is turnips, as they are not, from their want of teeth, capable of breaking them in a manner so as to go on well with such kinds of food.

CRONE, or **KORONOW**, in *Geography*, a town of Prussia, in Pomerania; 56 miles south of Dantzick.

CRONEBANE, a mountain in the county of Wicklow, Ireland, rising about 1000 feet above the level of the sea, which, with Ballymucktagh, is noted for its copper mines. The chief line of the metalliferous vein extends from the hill of Cronebane to that of Croaghan, nearly ten miles in length. The former of these mines is wrought by a chartered company with much scientific art. The species of ore which is found here is the most common of copper ores, called copper pyrites. Copper water, or water in which sulphate of copper is dissolved, is found in these mines, and it is accounted one of the strongest in Europe. Its strength however depends upon the quality of the copper. The attention of the traveller will be repaid by an investigation of the process by which this water deposits almost pure copper ore. The ore is fused at Aiklow, but afterwards farther refined at Swansea or Neath, in South Wales. The ground around these mines was lately bog and rock, but by the exertions of captain Mills and Mr. Weaver, its appearance is now altered, and it produces excellent crops. These mines are situated between Rothdum and Aiklow, about 28 miles south from Dublin. *Robertson's Guide*.

CRONEBORG, or **TAWASTEHUS**, in Latin *Cronenburgum*, a small town of Swedish Finland, chief place of the province of Tavastland, on a river which empties itself into the lake of Wana, 63 miles north-west of Borgo, 75 north-east of Abo. It was built in the year 1650, in a pleasant situation, by count Peter Brahe, and favoured with consi-

derable privileges. In 1717, it was taken by the Russians, and has always suffered considerably during the wars between the Russians and the Swedes. Croneborg has the hundredth vote in the Swedish diet. The castle, which is very strong, ought to be exclusively denominated Tawastehus or Tawasteborg. It is used as an arsenal and military magazine. When the Russians invaded Finland in the latter end of February 1808, the Swedes retired under the walls of this castle, and took a concentrated position in its neighbourhood.

CRONENBURG, a small town of France, in the department of the Oulle, chief place of a canton, in the district of Malmédy, with a population of 639 individuals. The canton has five communes, and 2454 inhabitants, upon a territorial extent of 135 kilometres.

CRONENBURG, or **CRONBERG**, a strong castle of Denmark, in the island of Zealand, on the west coast of the Sound, near the town of Ellsineur, built by Frederick II. in 1756, for the purpose of defending the entrance of the Sound, which is only 1331 fathoms wide opposite the castle. It is constructed with large blocks of hewn stone, and adorned with several turrets. The fortifications are reckoned excellent. However, the guns of this castle could not prevent the passage of the English fleet under admirals Parker and Nelson, in March 1801. Every vessel in passing lowers her top-sails, and pays a toll at Ellsineur. This fortress, it is generally said, guards the Sound; and all ships are obliged, on account of shoals and currents, to steer so near the batteries as to be exposed to their fire, in case of refusal. This notion, however, is erroneous: although the safest passage lies near the fortress, the water in any part is sufficiently deep for vessels to keep at a distance from the batteries, and the largest ships can sail even close to the coast of Sweden. The constant discharge of the toll is owing, not so much to the strength of the fortress as to a compliance with the public law of Europe. Many disputes have arisen concerning the right which the crown of Denmark has to impose this duty. The Swedes were for some time exempted by treaty; but, in 1720, Frederick I. agreed that Swedish vessels should be subject to the usual imposts. All vessels, besides a small duty, are rated at 1½ per cent. of their cargoes, except the English, French, Dutch, and Swedish, which pay only one per cent.; in return, the crown takes the charge of constructing light-houses, and erecting signals to mark the shoals and rocks, from the Cattegat to the entrance of the Baltic. The tolls of the Sound, and of the two Belts, supply an annual revenue of above 100,000*l*.

It was in the palace which stands in this fortress that the unfortunate queen Carolina Matilda of Denmark, sister to king George III. of England, was confined in 1772; from hence she was removed to Zell, where she died of a scarlet fever. This palace is a square Gothic building of free-stone. From an inscription over the gate, it appears that it was begun by Frederick II. and has been repaired and augmented by succeeding sovereigns. It contains two good portraits of Frederick II. and Christian IV. and several battle-pieces representing the wars of Christian V.

Adjoining to another royal palace, about half a mile from Cronenburg, is "Hamlet's garden," which tradition reports to be the identical spot where the murder of his father was perpetrated.

CRONICAL, in *Astronomy*. See **ACRONICAL**.

CRONIUM, in *Ancient Geography*. See **CROMYON**.

CRONIUM Mare, a northern sea, which, according to Pliny, was one day's sail beyond Thulé. It is called "Mare Pigrum"

Pigrum" by Tacitus; and is now denominated the Icy or Frozen sea.

CRONIUS, in *Chronology*, the ancient name of the Athenian month Hecatombæon, which was the first of their year, and answered to the latter part of our June, and beginning of July.

There were feasts called *croniones*, celebrated at Athens in this month, in honour of Saturn, answering to the *Saturalia* of the Romans.

CRONIUS *Mons.* in *Ancient Geography*, a mountain of Greece, in the Peloponneseus. Dionysius of Halicarnassus places it before Alphæus, in the territory of the town of Pylæ.

CRONBERG, in *Geography*, a small town of Sweden, in the province of Smoland, on an inconsiderable island in the Helge lake, which formerly had a very fine castle, the ruins of which are still seen. It was built in 1002, by St. Siegfried, the first preacher of the gospel in those parts, and given to the bishop of Wexie, for which reason it was called Bishop's-berg or Bishop's hill. But in the year 1545, it was enlarged and walled in by king Gustavus I., when its name was changed into that of Cronberg, Crown's hill.

CRONSWITZ, a town of Germany, in the circle of Upper Saxony, and territory of Neustadt; two miles north-east of Weyda.

CRONSLÖT, or KRONSCHLOSS, *Crown Castle*, is a fort built in the year 1703 by Peter the Great of Russia, on a small island in the gulf of Cronstadt opposite the fort of St. Alexander. It defends the only passage through which ships of burthen can sail from the gulf of Finland to Peterburg; its fortifications project into the water; it mounts several batteries, and generally has a garrison of 100 men.

CRONSTADT, or KRONSTADT, a sea port town in the northern division of Russia, in the government of Peterburg, built by Peter the Great in 1710, on the island *Retufari*, called by the Russians *Kotloi*, or *Kotlinnoi Ostraf*, the kettle island, but since the year 1723 better known by the name of Cronstadt. It lies 39 versts west-north-west of Peterburg, at the eastern extremity of the gulf of Finland, which, from this isle to Peterburg, is denominated the gulf of Cronstadt. It is not more than eight fathoms above the level of the water, rather flat, about seven versts long and one broad; has some wood, chiefly birch; and its soil is clay, sand, and limestone. At the eastern extremity of the island is the town of Cronstadt. Near it on the south side are two small fortified islands called St. Alexander and Cronslot. There is a third island on the northern side of the channel smaller than either, named St. John.

Ships of war, frigates, and merchant vessels, whose masts exhibit a huge impervious forest; fortifications of granite projecting into the water, and spacious and lofty magazines give to the harbour of Cronstadt a magnificent appearance at a distance: but the town itself answers not the expectations which this appearance excites. There are but few good houses. It is a straggling place, and like all Russian towns, occupies a larger space of ground than the number of habitations, which are mean and mostly of wood, seems to require.

There are three different harbours. That to the east, in which the greatest part of the Russian Baltic fleet is laid up, holds 25 large ships of war, but its issue is difficult, and the water being rather fresh, accelerates the wear of the vessels, and causes them to rot. The middle harbour is for frigates, sloops of war, and yachts belonging to the crown. The harbour to the west is appropriated to merchant ships, and may hold six hundred vessels. Close to it

is the Peter's canal, which derives its name and its origin from Peter the Great, the immortal founder of Cronstadt. Two fine obelisks bear inscriptions commemorative of this great undertaking.

Dry-docks for the refitting of men of war were begun by Peter at Cronstadt, in the year 1719, but neglected under his successors, and not completed before the reign of his daughter Elizabeth. Ten ships may be put upon the blocks at the same time. The docks are provided with flood-gates for admitting and letting out the vessels, and the water is emptied into a vast basin of granite, from whence it is pumped into the docks by means of a large steam engine erected by the Carron company of Scotland in the year 1772. The length of these works from the beginning of Peter's canal to the last dock is 4231 feet. The docks are lined with stone and paved with granite. They are 40 feet deep, and 105 broad. There is also a foundery for casting cannon balls, and a rope-walk for cables of all sizes.

Another canal was completed soon after the death of Catharine II., by means of which vessels of all sizes are enabled to take in their stores at the very gates of the magazines built on both sides of the canal, which, like the Peter's canal, is lined with brick-work.

The marine hospital at Cronstadt is on a very extensive scale. In 1788 it had at different times 25,007 patients; in 1789, 16,809; of the former 20,924 were cured, of the latter 12,974.

The academy for cadets of the marine was removed towards the latter end of the reign of Catharine II. from Cronstadt to Oranienbaum, from whence the emperor Paul transferred it to the Vassili Ostrof quarter at Petersburg.

The population of Cronstadt is estimated at 30,000 individuals; most of whom belong to the fleet, and to the garrison.

The number of registered burghers does not exceed 300. The streets are thronged with mariners from all the ports of Europe. There is an English chapel, and a Lutheran church for the Germans.

Cronstadt, being seated on a small island, has no other communication with the adjacent country than by water. Boats are continually passing between Cronstadt and Oranienbaum, a distance of seven versts, which in still weather is crossed in one hour's rowing. Oranienbaum is only 23 versts W. of Petersburg. In winter there is a common carriage road from Petersburg to Cronstadt on the ice, down the river Neva in a direct line over the gulf of Cronstadt, marked out with fir branches, and by the side of it are several guard-houses and a half-way or baiting booth. "Tooke's View of the Russian Empire." "Storch's Picture of St. Petersburg."—Also, a handsome and populous town of Austria, in Transylvania, near the frontiers of Moldavia, 60 miles E. of Hermannstadt, and next in rank to that place. It has three large suburbs, and was anciently called *Brassau*, *Brasso*, *Brassovia*.—Also, a castle in Sweden, erected in the year 1710, near the small town of Frosan in the southern part of the province of Jamtland.

CRONSTADT, *the gulf of*, is that part of the gulf of Finland in the Baltic sea which stretches from the island and town of Cronstadt to the mouth of the river Neva, or rather to St. Petersburg itself. See the preceding article.

CRONSTEDT, AXEL FREDERICK, in *Biography*, a celebrated mineralogist, was born at Sudermania in 1722. From a very early period he shewed a great attachment to the studies of natural history; and as he advanced in life he received several appointments from the government of Sweden, connected with the mines of that country. In 1753 he was elected a member of the royal academy of sciences at

Stock-

Stockholm; and in 1755 made a tour to Norway, to inspect the mines there. The greater part of his life was spent among the mines, the management of which fell chiefly on him. He died Aug. 1765. His principal work was entitled "An attempt towards an Arrangement of Minerals, or of the different Substances of the Mineral Kingdom." He published many papers on metallurgy, economy, &c. He was the first scientific writer on mineralogy, and was the inventor of most of those terms which have been since applied to the distinction of the external characters of mineral bodies. Gen. Biog.

CROOK, in *Rural Economy*, a term often provincially employed to signify a sort of strong iron hook, such as is in use for hanging field and other gates with. It is also sometimes applied to the crooked staff formerly made use of by the shepherd.

CROOKS, a name applied in some districts, as Devonshire, to a sort of pack-horse furniture, by which various articles of the farm kind are conveyed on the back of the horse. It is a sort of contrivance which, according to the author of the rural economy of the above county, varies with the nature of the load.

And it is remarked by the same writer that "hay, corn, straw, faggots, and other comparatively light articles of burden, are loaded between "crooks" formed of willow poles about the thickness of scythe-handles, and seven or eight feet long, bent as ox-bows, but with one end much longer than the other. These are joined in pairs with light cross-bars, eighteen inches to two feet long; and each horse is furnished with two pair of these crooks, slung together, so as that the shorter and stronger ends shall lie easy and firmly against the pack-saddle; the longer and lighter ends rising, perhaps, fifteen or more inches above the horse's back, and standing four or five inches from each other. Within and between these crooks the load is piled, and bound fast together, with that simplicity and dispatch which long practice seldom fails of striking out.

"Cord-wood, large stones, and other heavy articles, are carried between short crooks, made of four natural bends or knees, both ends being nearly of the same length; and in use the points standing nearly level with the ridge of the pack-saddle.

"Dung, sand, materials of buildings, roads, &c. are carried in "pots," or strong coarse panniers, slung together like the crooks; and, as panniers are usually slung, the dung, especially if long and light, being ridged up over the saddle.

"The bottom of each pot is a falling door, on a strong and simple construction. The place of delivery, being reached, the trap is unlatched, and the load released."

These are rude methods of conveying such sorts of materials which have continued in use long after the causes which introduced them have ceased to exist; better modes are now beginning to be practised.

CROOKS, are short tubes of brass of different lengths, adapted to fit into the upper end of the tubes of French-horns, trumpets, and trombones, and into their mouth-pieces, by which the instrument is lengthened or shortened at pleasure, in order to tune it to the pitch of the organ, or other instrument, with which it is to be used in concert, or for adapting it to perform in different keys.

CROOKED HAVEN, in *Geography*, a bay of Scotland, on the N. coast of the county of Banff, $2\frac{1}{2}$ miles N.W. of Cullen.

CROOKED Island, one of the Bahama islands, in the West Indies. In this island is a singular excavation of the rocks, resembling a dilapidated structure, and formed by the violent agitation and continued action of the breakers from the sea.

For a minute description we refer to McKinnen's West Indies, p. 21.

CROOKED Lake, a lake of America, in the Genessee country, communicating in an E. by N. direction with Seneca lake.—Also, one of the small chain of lakes which connects the lake of the Woods with lake Superior, on the boundary line between the United States and Upper Canada, remarkable for its rugged cliffs, in the cracks of which are a number of arrows sticking.

CROOKED River, a river of America, in the state of Georgia, and county of Camden, which discharges itself into the sea opposite to Cumberland island, 12 or 14 miles N. from the mouth of St. Mary's. Its banks are well timbered, and its course is E. by N.

CROOKEDNESS. See DISTORTION.

CROOKHAVEN, in *Geography*, a small town, or rather village, of the county of Cork, Ireland, on a harbour of the same name. It is at the western extremity of the county, a few miles N.W. from Cape Clear. The harbour is narrow, but all good ground, well-sheltered, and has water sufficient for large ships. It is a commodious place for vessels bound to the eastward. It is about 180 Irish miles S.W. from Dublin, and 3 east from Mizen-Head. N. lat. $51^{\circ} 25'$. W. long. $9^{\circ} 38'$. McKenzie.

CROOKKNEL, in *Mineralogy*, a miner's term in Derbyshire, for a belly or wide place of ore in a vein. See LUM, KIDNEY, NEST.

CROOM, in *Geography*, a small post-town of the county of Limerick, Ireland, on the river Maig, 142 miles S.W. from Dublin, and 10 S. from Limerick.

CROONE, WILLIAM, in *Biography*, a native of London, received his education at Emanuel college at Cambridge, of which he was admitted a fellow in the year 1654. His inclination leading to the practice of medicine, he soon after settled in London. In 1659 he was chosen rhetoric professor of Gresham college, and the following year register of the royal society, which held their meetings there. In 1662, he was created doctor in medicine, by mandate of the king, and the same year he was elected a fellow of the royal society, and of the college of physicians. In 1670 he was appointed lecturer in anatomy to the company of surgeons, in the place and on the recommendation of sir Charles Scarborough. Dr. Croone had travelled some years over France, and other parts of Europe, and kept up a correspondence with many of the foreign literati. On his death, which happened on the 12th of October 1684, he left one hundred pounds to the company of surgeons. His books on medicine he gave to the college of physicians, those treating on mathematics to Emanuel college, to which college, and to six other colleges, he left the sum of 20*l.* annually to each of them, to found lectures in mathematics, and to the college of physicians, and to the royal society, the profits to be derived from a house in Old Fish-street, the King's-head tavern, for lectures to be read annually before those learned bodies, on muscular motion. The only publication by Dr. Croone is a small tract, "De ratione motus musculorum," printed in London, 1664, 4*to.*, though several papers were left on philosophical subjects. Ward's Professors of Gresham college.

CROOTES, in *Mineralogy*, a substance found about the ore in the lead-mines at Meudip, being a mealy, white, soft stone, matted with ore.

CROP, in *Agriculture*, a term signifying the quantity or produce of any sort of field crop, as of grain, pulse, roots, plants, grass, or any similar kinds, raised by the farmer on any portion of ground at one time. And from this diversity, they are likewise further distinguished into corn, root, and green crops, according to the circumstances of the case.

The

The culture and utility of the two last sorts have been greatly increased within these last few years, in consequence of their application, as cattle food, being more perfectly understood. It is indeed to this circumstance that much of the modern improvement in husbandry is owing, and from which a great deal of the increased profit of the farmer has been derived.

The nature of the different sorts of crops, and the methods of distributing them on different sorts of farms, will be fully considered in speaking of the courses of crops. See *CROPS, Course of*.

CROP, in *Gardening*, a term denoting the produce or kind of any sort of vegetable, plant, fruit, seed, or root, which is raised or cultivated upon any bed, border, or other compartment of the kitchen garden. They are distinguished in many different ways, as into autumnal, winter, and spring crops, into early and late crops, and into seed or root crops, generally, as well as small seed crops. And there are likewise various sorts of fruit crops, both of large and small kinds, as well as various descriptions of forcing or frame crops. The proper management of these different kinds of crops constitutes a principal part of the art of gardening.

CROP, in *Mining*, denotes the upper part or covering of a stratum; thus, the roof of a coal-mine is sometimes called its crop.

CROPALATE, in *Geography*, a town of Naples, in the province of Calabria, 11 miles S.E. of Rossano.

CROPANI, a town of Naples, in the province of Calabria Ultra: 9 miles E.N.E. of St. Severina.

CROPASSIA, a town of Naples, in the province of Calabria Citra: 7 miles W. of Umbriatico.

CROPERDY, a village in Oxfordshire, in the hundred of Banbury, 3 miles N. of Banbury, and 7 S N.W. of London; is situate on the Charwell river, and on the line of the Oxford canal, at a place where it was once proposed that the Stratford and Croperdy canal should join this. (See *CANAL*.) In the year 1644, a battle was fought here between the forces of the king and those of the parliament, in which the latter were defeated.

CROPHI, in *Ancient Geography*, a mountain of Egypt, between Elephantina and Syené. The sources of the Nile, according to Herodotus, were between this mountain and that of Mophi.

CROPPER, or *Dutch Cropper*, in *Ornithology*, the name of a particular species of pigeon, called the *columba gutturosa Bataviae*, by Moore: the *gutturosa*, a variety of the *COLUMBA DOMESTICA*, which see. It is naturally thick, and has its name from its large crop, or bag of wind, which it carries under its beak, and can at pleasure either raise or depress. These are thick bodied, and short; their legs are also thick and short, and are feathered down to the feet; the crop is large and hangs low; the feathers on the thighs hang loose; and their legs stand wide; they are gravel-eyed, and are generally very bad feeders.

There are of these pigeons of all colours, and those who are careful of them, generally take them away from their proper parent, while young, and breed them under the females of other species.

CROPS, Course of, in *Agriculture*, denotes the means or methods of adapting and sowing them in such a manner to the particular nature of the land or soil, as that they may render it the most abundant and productive, with the least possible degree of deterioration or exhaustion of its fertile properties. It has been well observed by a late writer that "the proper cropping of arable land is a matter of the utmost importance to the interests of the farmer, as upon it in a great measure must depend the profits and advantages

which he is to derive from his labour and industry." It is conceived by Mr. Billingsley, an experienced agriculturalist in the western part of the kingdom, to be "the most prominent feature in good farming, and that by which the produce of the soil may be increased in a threefold proportion: and by another writer in a more southern district, as one of the most important subjects that can occupy the attention or exercise the ingenuity and skill of the agriculturalist." And Mr. Young, in his valuable calendar of husbandry, conceives it to be the most important subject that has been treated of by the modern writers of husbandry, and that on which they have thrown far more light than upon any other circumstance in agriculture. It is a very singular and remarkable circumstance, he says, that before the reign of his present majesty, notwithstanding the multitude of books on agriculture, there is not one author who had any tolerable ideas upon this subject, or even annexed to it any importance. They recite, he observes, courses good, bad, and execrable in the same tone, as matters not open to praise or censure, and unconnected with any principles that could throw light on the arrangement of field-crops. But that "when once the idea was properly started, its importance, continues he, presently became obvious, so that thirty years have carried to great perfection the precepts which practice has afforded in this branch of rural economy."

And that it demands much regard by the cultivator is fully evinced, says a late writer, by the great advantages that have been gained by it since its principles have become more perfectly understood and more extensively applied. It has indeed been well remarked by the editor of the "Annals of Agriculture," that "wherever either very good or very bad husbandry is found on arable land, it results more from the right or wrong arrangement of the crops than from any other circumstance." And that "no district is well cultivated under bad rotations, while it is exceedingly rare to see any badly managed under good ones."

It may be observed farther that, in the arrangement of this business, as different sorts of plants or crops not only require different kinds and proportions of nutritious materials to be drawn from the earth for their increase and perfect growth, but also different situations and conditions of soil, it must be necessary to adapt them as much as possible to the peculiar qualities of the soil, as well as the state of the land, and the nature of the climate, in which it is placed; and as on the same principles some sorts of crops may exhaust or deteriorate the soils on which they grow, in much less proportions than others, which is well known to be the case with many kinds of what are termed *green crops*, when compared with those of the *wheat* or *corn* kind; it will be requisite to alternate or interpose them in such a manner as that the ground may sustain the least possible injury in that way. In addition to the above observations and directions; it may likewise be of great utility to attend to other circumstances, as those of introducing such sorts of green crops as are most suited by the shade of their leaves and the kind of culture which they require while growing, for keeping the ground clean from weeds, and in a mellow and suitable state for the reception of the more valuable kinds of grain crops, as in this way the necessity of having recourse to the uneconomical process of fallowing, may be considerably lessened, if not wholly obviated. It has been shewn by experience that all the culmiferous class of plants injure the soil in a very high degree, which probably depends upon their having but few, and those small leaves; consequently being necessitated to draw their nourishment chiefly from the soil at all periods of their growth, but especially during the time of their maturing their seeds, when, from the dry withered state of their

C R O P S.

their leaves, it is impossible that any thing can be drawn from the atmosphere. But they may be prejudicial in other ways, the seeds of their plants ripening all at the same time; on their beginning to ripen the plants become stationary, the roots ceasing to push or penetrate into the ground, and of course to move or loosen it; and the withered leaves and sapless stems being cut down, leave the land fully exposed to the action of the sun and winds, by which it becomes dry, hard, and compact, being greatly exhausted by the dissipation of its moisture and other properties, while opportunities are given for its being filled with weeds before the winter sets in. Of all the various sorts of this class of plants, wheat, from its being the heaviest in its grain, is probably the most deteriorating in its effects on the soil, while the difference between barley and oats is but trifling in this respect; and rye is well known to be less prejudicial in this way than any of the other kinds.

In regard to the green, or what are frequently termed leguminous crops, and those of the root kind, it may be remarked that the former, from their seeds being formed in a successive manner, their flowers, with green and ripe fruit presenting themselves at the same time on different parts of the same plant, they continue, of course, in a state of growth, pushing their numerous fibrous or other roots deeply into the ground, while at the same time they derive much of their nourishment from the surrounding air, by means of their green leaves, till the very period at which they are cut down. It is probably on this account that the straw of some of the plants of this class is so much superior to that of the grain kind, as well as the great difference in the state and condition of the land, the leguminous plants keeping the mould not only loose, friable, and mellow for the plough in the way noticed above, but by their close thick shade, they preserve the moisture in the land in an effectual manner, and produce a fermentative process, by which means the vegetable matters which are covered, are speedily reduced, and the soil left in a rich, moist friable state.

Red or broad clover is very beneficial in this way, and when cut readily shoots again, keeping the soil loose by its deep tap root, and when ultimately turned in, affords a large portion of vegetable matter to the soil; and besides it admits wheat to be sown on a single furrow, by which the great labour and expence of summer fallow is saved. This probably deserves the first place as an ameliorating plant in cropping land.

And tares or vetches are in general considered as deserving the next place in the scale of improving crops. They have much similarity to the pea and bean in their habits of growth, but of less size. There are different varieties or sorts of them, which serve the purpose of green cattle food at different seasons of the year, but in some cases are made into hay in the summer kind. They consequently contribute largely in this way, as well as by the closeness of the shade which they afford, and the preservation of moisture to improve the soil.

Pease, when cultivated for the purpose of being cut green, as fodder, have similar effects to those of vetches in meliorating the soil as well as most of the properties of clover upon it. But when they are suffered to ripen their seed, they become exhausting in a high degree, perhaps not very much less than grain.

The bean plant is found highly beneficial on the more stiff, heavy, clayey soils, as bringing such sorts of land into a state of preparation for wheat; but though, like other plants of the same class, they exhaust little, they do not shade the ground so perfectly as the crops which have been just mentioned, consequently do not preserve the moisture so com-

pletely. Besides, from their being mostly suffered to ripen their seeds, they require manure. They are in general found more useful in breaking down and reducing stubborn soils, and preventing the growth of weeds, than in improving the land on which they are raised.

Turnips and cabbages are plants which afford considerable shade by the number and size of their leaves, and their roots penetrate to some depth in the soil. By the preparation of the ground, and the after culture which they require, the land is also rendered fine, and kept free from weeds, by which it becomes in excellent condition for barley. When not consumed upon the ground, some deterioration is probably produced by them, as they require rich soils and manure, to raise them with success. They are, however, crops which afford large supplies of food for cattle stock in the latter part of the autumn, the winter, and the early spring.

The culture of the potatoe is had recourse to with similar intentions in reducing the soils which, from the nature and size of the root, is perhaps performed with more effect, and of course renders them in excellent order for barley, which is usually found to succeed better after them than wheat. They cause great closeness and shade by which the moisture of the land is well preserved; but from the nature and size of the roots, they are found to exhaust the ground in an equal degree even to wheat crops, and they require a large supply of manure.

Where the soils are suitable the carrot and parsnip may be grown with vast advantage, as affording an abundant supply of the most nutritious sorts of food for domestic animals. From the nature of their top roots and their size, they prepare the land well for the crops which are to follow them. Under these crops, and those of clover, tares, cabbages, and potatoes, the same quantity of land has been found to produce twice as much cattle food as when in the state of grass. There are several other plants that may be introduced in the courses of cropping, under particular circumstances with much propriety and advantage, but it is not necessary to notice them here.

It has been remarked by Mr. Middleton, in his Agricultural Report of Middlesex, in speaking of green crops as a substitute for fallows, that "the aggregate benefits that may be derived to the country from this measure are not to be estimated, but among the first of these will stand the abolition of fallows, and the introduction of green crops to supply their place over an extent of about three millions of acres of arable land, which have hitherto under the fallow system, produced nothing useful during the fallow year." Further that, "so far as tares and turnips or potatoes, or pease and turnips, or potatoes, or any two good crops, can be raised in one year, in place of a fallow, the produce will be double in quantity what it has been under the former system." And he adds that "there are about nine millions of acres in England and Wales in the course of two crops and a fallow; that is, six in crop and three in fallow. Hence it follows that by procuring one crop in lieu of the fallow, fifty per cent. is added to the former produce. But so far as two crops can be obtained in place of a fallow, it adds 100 per cent., or double the former number of acres of produce."

And that "as most sorts of soils when continued for any great length of time either under grain or grass are liable, it is remarked by another writer on this subject, to fall in injury, and become less capable of producing full crops; in the first case, probably from the carbonaceous principle being too greatly exhausted, and in the latter from the occurrence of mofs or other noxious vegetable productions that establish themselves in consequence of the weak and imperfect growth of the grass plants; it may be proper to occasionally alter and change

C R O P S.

change the nature of their crops by keeping them for a while after being broken up from grafs under the plough, and then restoring them again to the state of grafs, as in this way the deficient principles may probably be the most readily supplied where manure in sufficient quantities cannot be procured, and the injurious vegetable products be the most effectually removed." And it is further necessary "to be constantly kept in view in directing the modes of cropping lands that such an intermixture of green root, pea, bean, and grain crops be grown, as will not only be best adapted to keep the soil in the most perfect order, but suit the demands of the cultivator, for the purposes of sale as well as the keeping of such numbers of different sorts of live-stock, as may be proportionate to the supplying of those quantities of manure that may be requisite for the preserving the farm in the most perfect condition, or state of heart."

It is likewise stated by the author of "Practical Agriculture" that, "in regulating the courses of crops on all descriptions of land with the view of preventing their exhausting the soil, it will be necessary to guard against the occurrence of grain, potatoe, or other crops of a similar kind, in succession, as the result of experiments attentively made, as well as the experience of the most correct agricultors in different districts have decidedly shewn their effects to be very powerful when employed in such a manner, in deteriorating and lessening the productive powers of the ground."

In the trials of Mr. Arthur Young, in respect to the effects of different sorts of crops on land, "which appear to have been conducted with a considerable degree of accuracy and attention, on a soil of the sandy loam kind, incumbent on a wet clay marle bottom, rendered dry by means of previous hollow draining, and of the annual value of about fifteen shillings the acre, broken up from the state of grafs under which it had been for a great length of time, and ploughed into ridges in contrary directions each succeeding year, no manure being applied except on particular lands or ridges in the fourth, though two or three white crops in succession were found to exhaust in a high degree, potatoes had a still greater effect in the same way, much more than barley in most cases, and in some courses even more than wheat." These experiments are fully recorded in the twenty third volume of the Annals of Agriculture; and more concisely below.

And it is added, that, "the results are equally curious and interesting, as they not only demonstrate the advantages that may arise from the alternation of different sorts of crops in different ways, but the effects of various rotations, both good and bad, upon the soil and produce derived from it. They would, however, it is observed, have been more satisfactory, if the nature of the land had admitted the turnip and cabbage crops to have been consumed upon the ground, as no certain conclusions can probably be drawn where this is not the case; for though a proportionate quantity of manure may be afterwards returned to the land, its application in that way does not seem to afford such beneficial effects as when gradually incorporated with the soil during the time the animals are feeding on it, upon such luxuriant vegetable substances. Besides the effects of the urine and perspiration, which are known to be of considerable utility in ameliorating the earth, are wholly lost." It is further suggested by this able writer, that tares, clover, and other grasses of the artificial kinds, should likewise have been introduced, as by such kinds of crops, the courses would not only have been more varied, but the effects of different combinations more fully shewn.

And the able experimenter further remarks, that, "all the work of tillage was performed by the common imple-

ments of the farm, and that the crops in the whole of the thirty-six courses were reaped and threshed directly, distinct from each other, to obviate the danger of mixing and errors, and that they are numbered accurately to save the trouble of calculation. In the valuation all the straw is rated at 10s. an acre, and the crops are likewise estimated, that the fluctuations of price may not affect the general conclusions; the turnips at 4s. a ton carted off, cabbages at 5s., wheat 5s. a bushel, barley 2s. 6d., oats 2s. 3d., beans 3s., potatoes 6d., any other value may however, he says, be put upon them according to circumstances."

It is, however, added that, in order to afford a full and complete view of the effects of different courses of crops, it would be necessary to compare them on soils of different qualities, and which vary much in respect to their nature, climate, situation, and other circumstances. But even as they stand, the intelligent farmer may draw many useful deductions from them.

Upon these courses it is remarked, that their effects lead to different conclusions: in the first course, in which there are four green fallow crops, to two of the white or grain kind, little advantage is shewn except in the leaving of the

C R O P S.

the land in fine tilth, and perfectly clean. Nothing of superiority is shewn by the quantities of produce for lands newly broken up. But it is observed, that the turnips, by being drawn and removed from the land, were not favourable, as wheat or turnip ground is not generally good, except well trodden by feeding. Potatoes appear to exhaust, and the experimenter suggests that estimating thirty tons of yard compost, the proportion employed at any imaginable rate, the course cannot be advisable; the loss on the potatoe crop, would not, he thinks, be less than five pounds, nor would the turnips pay so as to leave a profit equal to the expences of newly broken up lands for the first six years.

He however states the second as a more profitable course from the great charge of the potatoes not being incurred, and it shews that though cabbages cannot be grown to any great advantage on such soils, without manure, they may be of much utility by the pulverization and cleanness which they afford. The goodness of the grain crops, evinces, it is supposed, that they exhaust but little, and that it is of great importance to have few white crops in rotations. And the third he considers as explaining the necessity of manuring for potatoes on all soils except such as are rich and dry. With only two white crops in six years, the land seems rather, it is observed, to improve, notwithstanding the potatoe crop. The goodness of the last crop of wheat, in comparison with the first, proves, he says, the superiority of cabbage and bean crops, over those of beans and potatoes, in cleaning and rendering the ground fine and fit for the growth of wheat crops, in a perfect manner.

The experimenter says, that the results of these courses shew, in the first, the utility of repeated bean crops in cleaning land; and, when combined with cabbages, in preserving the fertility of such as is newly broken up. When compared with the first course, which ends in the same way, its advantages also appears, he thinks, great in different other respects. By the two last, the disadvantages attending successive crops of corn are particularly brought forward. And it is well remarked, that they also shew that any sort of corn crops will succeed, to a certain extent, on lands recently broken up, from the state of old grass or sward; and that, for the first two or three years, they may afford a produce proportionate to the sort of crop that is sown or cultivated on them. But that the three last years, on being compared with the three first, the whole still in corn, the product was in the ratio of 9*l.* 14*s.* 5*d.* to 14*l.* 18*s.* 7*d.* or a decrease of more than 5*l.* While, in the preceding courses, with better rotations, the products have somewhat increased. The difference, he says, is therefore enormous. The decline in the barley, and even the wheat crops, notwithstanding the intervention of beans in the latter case, is very great. Besides, they leave the land in a bad condition, being in the fourth and sixth years such a bed of weeds, as could not be half destroyed by the hoeing of the beans. In these instances, the land not being left worth eleven shillings an acre, while in some of the preceding it was left of the value of sixteen. These, he well remarks, are the prejudicial effects of adopting bad courses of cropping, from the circumstances of old grass lands being capable of affording a good produce for a time. The same consequences may, likewise, he thinks, take place, even upon soils of a much better quality by such methods of cropping. It is evident that they should, therefore, be avoided as much as possible on all descriptions of soil by the correct farmer. The last of these courses not only exhibits the badness of the practice of taking successive grain crops, but that beans, by the aid of the hoeing culture, cannot afford a produce, even on newly broken up land, that will sufficiently repay the great trouble and expence of the farmer.

On these courses, it is noticed, that the produce of the first of them, though there is only one grain crop in the six years, is so considerable, as to prove the disadvantage of deteriorating courses, especially as the circumstances under which they are put in are supposed by some to be unfavourable, on account of the land, after turnips and potatoes, from the repeated tillage which is required for such crops, being left in too light and porous a state for the growth of beans. It has the advantage, however, of leaving the land perfectly clean, and in a fertile condition. And likewise proves, in the opinion of the experimenter, that great attention may be had to the keeping of land clean and in heart, by gentle modes of cropping, without the danger of immediate injury being sustained by it. And it is further supposed, that, if beans or wheat had been the crop of the fourth year upon the manure, in place of the potatoes, the profit, on the whole, would have been more, without the ground being left in a less rich condition. In regard to the two last courses, they show, from there being but one grain crop in six years, that though cabbages, by being removed from the land, exhaust, three crops of beans are sufficient to preserve the land for a good wheat crop, besides leaving it in a good situation. They are, consequently, profitable courses, and such as are suited to the obtaining of perfect cleanness of culture. In the latter course, the profit is, however, less, from the circumstance of potatoes being had recourse to as a crop.

The experimenter on these courses suggests, that it is evident, from the first, that successive crops of beans have a considerable ameliorating property, as both the cabbages and beans after them were very good. Their effects in preserving the fertility arising from the old turf is likewise obvious, as well as that of keeping the land perfectly free from weeds, at the same time that a good profit is afforded. It also, he supposes, affords a strong proof of the advantage of a careful method of cropping newly broken up lands. Such courses should, consequently, he says, be more frequently employed on all those stiff and retentive descriptions of land on which beans can be grown, both with the view of immediate profit, and the benefits that may ensue from the land being kept clear and free from noxious weeds.

In respect to the second, it affords, in his opinion, an example of a good and correct mode of practice, without much exhaustion: though, if compared with the preceding course, there appears to be, he says, a slight degree of deterioration from the wheat, in that being a quarter more. It may, however, be adopted as a very profitable course. The last of these courses is well known to be a very profitable one on all the richer sorts of heavy soils; and it is here shewn, he thinks, to answer well on such as are of an inferior quality, even without the application of manure. The power of bean crops, in preserving the fertility of lands newly broken up from sward, is likewise here evinced by the sixth crop, though inferior to others. This course should not, however, in general, he thinks, be attempted, except on the richest sort of heavy-soiled kinds of land.

The experimenter remarks on these courses, that the first exhibits the utility of repeated turnip crops in the preparation of this kind of soil for grain crops, the produce of the oats from the pulverization they effected being very great. It is added, that oats are molly sown on newly broken up-lands, but never with much success on such as are wet. The exhaustion of the soil in this course seems not to have been great; though the oats were followed by potatoes, which are known to exhaust, as the succeeding bean and wheat crops were both good, but more especially the latter. It is obvious, however, he says, that as turnips and cabbages cannot be produced to advantage on such cold, wet soils, without much manure; that such rotations must be the most beneficial and proper on the drier sorts of land, where such crops can be grown and fed on the grounds by live stock. And, he adds, that the gross product in the second course is not to be compared with the first, as the potatoes affording six guineas left no profit. The largeness of the produce of oats seems to shew, he says, the beneficial effects of cabbage crops in preparing the soil. The inferiority of the wheat crop, when compared with that in the first of these courses, is supposed to depend on the want of manure. Notwithstanding there are two crops of cabbages and one of turnips in this course, it appears, he says, to be

profitable. It would seem, however, to be the most suited to the more dry kinds of soil.

He states farther, that in comparing the third course with the two that precede it, the deteriorating properties of potatoes are evidently much greater than those of either turnips or cabbages, from the inferiority of the oat crop that followed them. And it is suggested that, "wherever potatoes enter with a small produce, the expenses more than absorb the value."

On these courses he hints that the result of the first displays the advantage of beans over potatoes in respect to profit. In the second, the land being left foul and in a bad condition, shews by the lightness of the wheat crop, when compared with those in other courses, that great deterioration had been produced by it. The last course exhibits a still worse practice, and that the land is left in a more deteriorated and foul situation by three wheat crops. Such courses can of course never be had recourse to with either the view of profit, or that of keeping the land in proper condition in respect to cleanness.

On theſe courſes it is ſtated, that the deteriorating effects of potatoe crops are fully demonſtrated. With manure in the proportion already explained in the fourth courſe, the beans which ſucceeded were, he ſays, a very poor produce, and the wheat, though the only white crop in ſix years, a miſerable produce in a very good year. He adds, that in the fourth courſe, where there were two crops of wheat, with three of beans, the concluding wheat crop afforded three quarters one buſhel, without any manure, a difference that is highly ſtriking. And that in the eighth, three crops of beans, and two crops of cabbages, were followed with very good wheat, though cabbages removed from the ground exhauiſt; but in theſe courſes there are ſcarcely any except ſucceſſive wheat crops, that exhauiſt the land ſo greatly as potatoe crops are found to do.

With reſpect to the ſecond courſe, it diſplays little elſe, he thinks, but a continued loſs; and the third affords a proof of the loweſt decrease of produce that can be ſuppoſed on newly broken up-land; beſides, the ſoil is left ſo foul and deteriorated, that the whole of its fertility from improve-

ment, and the decay of the old turf, appears removed. It makes ſtrongly, he thinks, againſt potatoes; which can probably only be introduced with advantage as a cleaning crop, and where manure is readily procured, and in great abundance.

The experimenter has remarked, that the firſt of theſe courſes ſhews the exhauiſting effects of potatoes in a ſtill more evident manner; but the effects of the beans are ſomewhat different than in the other caſes noticed above.

It is ſuppoſed evident from the ſecond, that barley ſucceeds better after potatoes than wheat; while the inferiority of the ſecond crop proves that the preparation they afford is not perfectly ſuitable, and that the wheat that ſucceeds is affected by their deteriorating property. The third courſe not only confirms the different reſults that have been ſtated, but affords, by a compariſon with the twelfth, proofs of the utility of having beans and wheat in alternate courſes.

The writer remarks, that in the first of these courses, though the potatoes of the fourth crop were manured for as above, the poorness of the wheat crop, which was the only one of the grain kind in six years, shews the exhausting effects of cabbage and turnip crops, when removed from the ground in combination with potatoes, to be considerable; and from the second it is evident, that cabbages, when not consumed upon the land, are so prejudicial as not to permit the ameliorating powers of beans to secure a favourable crop of wheat. Neither this nor the preceding course is therefore profitable. The last is stated to be a course of nothing but loss, and which shews, in addition, the exhausting effects of potatoes and cabbages to be great, when removed from the ground to be consumed in other situations.

Here the writer suggests, that the profit of these courses is too trifling to recommend them; and the products of the fifth and sixth years' crops are supposed to be less than they ought to be, from the circumstance of manure being applied in the fourth, and there being only one grain crop in the course: of course, that potatoes, even when manured for, leave the soil in no very advantageous situation for the growth of wheat, though assisted by the cleaning and improving qualities of bean crops.

And that the second and third courses are equally decisive in shewing the exhausting effects both of potatoe and cabbage crops, when not consumed on the land, as well as that they are courses that should seldom be employed, where they cannot be manured for, and be fed off upon the land by live stock.

On these three courses it is observed, that the first shews still more fully the effects of potatoes and cabbages. The second also shews, that while the turf of newly broke-up grounds is in a state of decay, spring corn succeeds well after potatoe crops. It likewise proves that three grain crops may be grown in six years, without the soil being greatly exhausted, where proper care and attention is paid to the nature of the crops that are interposed between them in the different courses.

From the numerous facts and observations which have been stated above, we may be enabled to comprehend more clearly the nature and principles of the modern system of cropping land, or the art of properly regulating the courses of crops; by which, long experience has now satisfactorily demonstrated, that ground may be preserved in a tolerable state of heart with a considerably less supply of manure, than under other circumstances; the great expence of the naked fallow process be avoided; and where a proper plan is pursued in the consumption of the different green and other crops, an abundant supply of dung be provided for the further improvement of the land.

It has been stated by a late writer in his "System of Practical Husbandry," that the injurious consequences of cropping land with grain, and other kinds of crops, which deteriorate and exhaust in a high degree, may probably be prevented in the best manner on the more stiff and retentive sorts of land, whether of the clayey or loamy kinds, by the interposing of bean and clover or tare crops between them; as the experiments detailed above have shewn the former to possess the power of ameliorating the condition of such soils, and the latter seems not less calculated for the same purpose, as it is known to grow well on these sorts of land; and on those of a more light and dry quality, whether sandy, or of a gravelly nature, the intermixing of turnip, pea, and other crops of the same sort with those of corn may be equally successful. In many cases, especially on the more heavy kinds of soil, it may be necessary and highly beneficial to take two green crops for one of grain. This, it is remarked, is a practice that the results of the trials, just detailed, place in an advantageous point of view, and which has extended itself over a considerable tract of land, with great success, in

C R O P S.

in the county of Middlesex, and by which, from the cleanliness of the cultivation, and the great vigour of the land, in consequence of the few corn crops, the grain is found of a superior quality. It is indeed remarked by Mr. Middleton, a writer of considerable experience, that "land under common circumstances will not even bear without injury a corn crop every two years." This is fully shewn, he conceives, "by the turnip crops in Norfolk being uniformly found to be not only less certain, but much lighter than formerly, as well as from the same remark being applicable to the clover, and probably to the corn crops. Such diminutions in the quantity of produce, he supposes, demonstrate that the valuable and favourite rotation of that district, as turnips, barley, clover, wheat, is somewhat more than the ground can sustain, as it appears to be gradually sinking under too much exhaustion." With the aid of extensive sheep-walks, he conceives the soil not even capable of supporting the depressing consequences of the present courses of crops, particularly, when a five years' course, by introducing barley after wheat, is improperly employed.

Various rules have been laid down by writers on husbandry for regulating and proportioning the different sorts of crops to different kinds of soil. In the "Agricultural Survey of the County of Middlesex," the following are advised as the most suitable under the different circumstances and cases of soils:

For the *best* sorts of land, alternate green and white crops.

For those of a *full medium* quality, three green crops for two of the grain or white kind.

For *ordinary* land, two of the green for one of the corn kind. And,

For the worst or most exhausted, as downs and sheep-walks, three green crops for one of the white or grain kind.

These may be arranged as below to a still greater number of green crops.

COURSE I.

Alternate Green and White Crops.

- 1 Turnips.
- 2 Barley.
- 3 Clover.
- 4 Wheat.

COURSE II.

Two Green Crops to one of Grain.

- 1 Corn, or Pease.
- 2 Clover, Beans.
- 3 Pease, Corn.

COURSE III.

Three Green Crops to one of Grain.

- 1 Corn— or— 1 Corn.
- 2 Clover, 2 Clover.
- 3 Tares, 3 Pease.
- 4 Turnips, 4 Beans.

Which affords four crops in three years.

COURSE IV.

Four Green Crops to one of Grain.

- 1 Tares.
- 2 Potatoes, or cole for sheep feed.
- 3 Turnips.
- 4 Corn.
- 5 Clover.

Which affords five crops in four years.

COURSE V.

Five Green Crops to one of Grain.

- 1 Pease.
- 2 Beans.
- 3 Corn.
- 4 Clover.
- 5 Tares.
- 6 Turnips.

Which affords six crops in five years.

It is suggested, that by cropping in these ways and proportions, the land may be kept perfectly clean from weeds, and in a high state of cultivation; and that under such a system it might be continued in a perpetual state of tillage, "with a constant succession of large products." And that in addition, the farmer would be more certain of obtaining plentiful returns for his labour, expence, and exertion.

The able writer of the Survey mentioned above, wishes also to draw the attention of farmers, particularly where the soil is proper for barley, to the crops stated below, in the view of affording a continued successional *abundant supply* of the best kinds of *green food*, the whole year round.

Water meadows,

Rye-grass,

Rye, cut green,

Winter tares,

Clover, the first crop,

Spring tares,

Clover, the second crop,

After grass of meadows, clover, and seeds of all sorts.

Turnips,

Potatoes,

Cabbages, common sorts, favoys,

Cole, green boor-cole, and purple boor-cole,

Swedish turnips,

Turnip-rooted cabbage,

Kohlrabi.

Where these different crops are raised on a sufficient scale to the extent of the farm, and the quantity of *live stock*, there can be no inconvenience sustained, it is supposed, for the want of food for them, at any period or season of the year. "Water meadows, says the writer, afford a vast deal of food from the middle of March; rye-grass from the first of April; rye from the beginning of May; winter tares soon follow; then comes clover the first crop; spring tares; clover the second crop; and the after-grass of natural meadows, clover, &c. which will continue in perfection for heavy cattle till early sown turnips are ready. Late sown turnips and cabbages will be sufficient till the end of February, without storing; about which time the cole, Swedish turnip, and turnip-rooted cabbage will come in, and continue good through March, April, and even May, if needful." All which, he thinks, more than complete the circle of the year.

The variations of courses which are capable of being made use of under different states and situations of land are very numerous, but the following may be sufficient for the present purpose:

I. On strong wet soil, where a fallow is intended.

Course.

Course.

- | | | |
|-----------|----|-------------|
| 1 Fallow, | or | 1 Fallow. |
| 2 Barley, | | 2 Barley. |
| 3 Beans, | | 3 Clover. |
| 4 Wheat, | | 4 Beans. |
| 5 Tares, | | 5 Wheat. |
| 6 Barley, | | 6 Cabbages. |

7 Clover,

C R O P S.

- | | |
|-----------|-----------|
| 7 Clover, | 7 Oats. |
| 8 Beans | 8 Tares. |
| 9 Wheat | 9 Barley. |

It is the most improved practice in these cases to let the fallow be the preparation for the first corn crop, depending on some kind of green crop for those that follow, without any repetition of it.

Other courses in this case may be as below:

Course.

- 1 Fallow.
- 2 Barley.
- 3 Clover.
- 4 Wheat.

Or in cases where manure is in plenty, it may be better thus:

Course.

- 1 Fallow,
- 2 Wheat
- 3 Beans
- 4 Barley
- 5 Clover
- 6 Wheat.

or

Course.

- 1 Cabbage, beans, or pease.
- 2 Barley or oats.
- 3 Clover.
- 4 Wheat.

Also,

Course.

- 1 Cabbage,
- 2 Oats
- 3 Beans
- 4 Wheat

or

Course.

- 1 Beans.
- 2 Wheat.
- 3 Cabbages.
- 4 Barley.
- 5 Clover.
- 6 Wheat.

And in some cases where the culture is well executed, the course may run in this way:

Course.

- 1 Turnips.
- 2 Oats.
- 3 Vetches.
- 4 Wheat.

In converting lands of these kinds to the state of tillage from that of grass or sward, by means of paring and burning, the proper course may be:

Course.

- 1 Cole.
- 2 Beans.
- 3 Wheat.
- 4 Beans.
- 5 Wheat.

It is the remark of the Rev. Mr. Cartwright, in an able Essay in the fourth volume of "Communications to the Board of Agriculture," that tares, though by some objected to with propriety, as coming too late in the spring season on such sorts of land, may be occasionally introduced with advantage, in the view of being eaten off by sheep, or mown green for horses, milch cows, young flock, and hogs. By these methods of cropping, with proper regard to the eating off the green crops on the ground, where it can be effected without injury; or to the removing them to be consumed in the fold yards, or other places, in order to the manure being afterwards applied; the ground may not only be ameliorated, by being rendered more rich and friable, but be preserved perfectly free from all descriptions of weeds.

In the generality of the heavier kinds of land of this description, when brought into tillage from the state of old

sward, it would seem that beans would be the most suitable crop to begin with, notwithstanding the most usual practice has been to have recourse to oats in such cases; as from the gradual decay of the turfy and grassy materials, the growth of the beans may be greatly promoted, and large crops thus produced. Besides, the roots of the bean plants, by their penetrating deeply, render the land more mellow, and at the same time improve it, bringing it more expeditiously to the proper state for wheat.

Where, however, the quality of the land is more light and mellow, pease are often capable of being introduced with greater benefit as a first crop after breaking up. However, in very old sward, from worms, grubs, and slugs being often prevalent in them, great injury may be sustained by the first crops from these causes: consequently the process of paring and burning should be adopted, or the use of the trench plough, that these and the grassy material may be got quit of as much as possible. And in this view it has likewise been advised, as of much advantage, to have such lands kept as closely sown as possible before the time of breaking them up; as by such a practice less *ova* may be deposited by the fly, and consequently fewer of such injurious animals generated. But in all such cases, beans are considerably less liable to suffer injury in this way than pease.

II. On Soils of the Sound loamy kinds where Fallows are excluded.

Course.

- 1 Turnips,
- 2 Barley,
- 3 Clover,
- 4 Wheat,
- 5 Cabbages,
- 6 Oats,
- 7 Tares,
- 8 Barley,
- 9 Beans.
- 10 Wheat.

Course.

- 1 Turnips.
- 2 Ruta baga.
- 3 Barley.
- 4 Clover.
- 5 Beans.
- 6 Wheat.
- 7 Beans.
- 8 Wheat.

or

On these courses it may be observed, that the soil must be in a high state of fertility to support the frequent recurrence of these exhausting grain crops; and that more green crops will frequently be required.

III. On the rich Kinds of sandy Soils.

Course.

- 1 Turnips.
- 2 Barley.
- 3 Carrots.
- 4 Barley.
- 5 Clover.
- 6 Wheat.

It would appear to be the practice of the best arable districts, on these two last sorts of soils, to have recourse to turnips as a preparation for barley, and clover that for wheat, in this way.

Course.

- 1 Turnips.
- 2 Barley.
- 3 Clover.
- 4 Wheat.

But in this course it may sometimes be proper to substitute oats in the place of the barley, as well as tares, chicory, or some other kind of artificial grass seed, in the room of the clover.

In bringing lands of these kinds into a state of tillage from that of grass or sward, where the practice of paring

ing and burning is employed, the proper course may be this :

- Course.*
 1 Turnips.
 2 Barley.
 3 Clover.
 4 Wheat.
 5 Turnips.
 6 Barley.
 7 Clover.
 8 Wheat.
 9 Turnips.
 10 Barley with feeds.

But where the land is only to be kept a short time under the tillage system, a more proper course may be :

- Course.*
 1 Turnips.
 2 Barley.
 3 Clover.
 4 Wheat.
 5 Turnips.
 6 Barley with grafs feeds.

In cases where paring and burning are not practised, which is not so common, it may be the best plan to begin with beans or pease dibbled, and then go on as above. But in cases of this kind, the turnip and clover crops are constantly to be eaten off, upon the land, by sheep, or some other kind of live stock. In the more dry and light soils of this description, pea crops may likewise be had recourse to as a first crop, especially the white sort under the dibbling practice ; then going on with the other crops in the above manner. In cases where potatoes are begun with, it will be requisite to have more of the ameliorating crops, in consequence of their greater effect in exhausting and injuring the land, as has been shewn by the experiments stated above.

In particular districts, on some soils, merely of the sandy sort, it is also the practice to make turnips the preparation for both grafs and grain ; and experience has shewn that there are few of these soils so light as not to afford such a crop. In cases of this kind, the course is usually thi :

- Course.*
 1 Turnips.
 2 Barley.
 3 Grafs feeds.

Here the grasses, being raised in the view of sheep feed, should of course be such as will stand for some time, as it is not by any means a good method to break up the land again too soon ; for the flocks fed upon the turnips in the winter season, are not provided with a due quantity of food on such *new layers* for their summer support.

In the county of Suffolk, as appears from the Agricultural Report of that district, on the better kinds of sandy soils, the layers are frequently planted with pease by dibbling, to much advantage, after being broken up, without being fed with sheep during the summer season : the succeeding crop of wheat being, in such methods, much larger. The following is considered as an excellent course on such sorts of soil :

- | | | |
|---|--|--|
| <p><i>Course.</i>
 1 Turnips.
 2 Barley.
 3 Trefoil and ray grafs.
 4 Pease dibbled.
 5 Barley.</p> | } Or, where the soils are poor, or of the nature of heath or sheep walk, to bring them into cultivation. | <p><i>Course.</i>
 1 Pare and burn for turnips.
 2 Turnips.
 3 Barley, with grafs feeds.</p> |
|---|--|--|

Where they are intended to be kept in tillage longer than this course, the turnip, barley, and grafs crops may be al-

ternately had recourse to, until the fifth or seventh year, or even longer, where it is supposed necessary. And here likewise, when potatoes are employed as the first crop after breaking up, from their deteriorating property being considerable, they must be succeeded by more numerous improving crops, as turnips and grasses, as shewn in the above courses.

In soils of this nature, which are of the poor, light, blowing kind, their want of tenacity must be corrected by the use of earthy substances of the clayey kind in suitable proportions, and the consuming of the crops upon the land by sheep. But where these means cannot be had recourse to, the course given above will be found highly proper and beneficial.

IV. *On the more dry Sorts of Soils, as the Limestone or calcareous Kinds, and those of the gravelly and stony Descriptions.*

- Course.*
 1 Turnips.
 2 Turnips.
 3 Barley.
 4 Saintfoin for ten years or more, then pared and burned for.
 5 Turnips.
 6 Barley.
 7 Pease.
 8 Wheat.

The dry, gravelly, and stony soils, where of the lighter descriptions, should be cropped in such a way as that their moisture may be preserved in them in the most perfect manner, and their fertility be impaired in the least possible degree. In this situation, two or more of the green sort of crops for one of grain may often be proper, as in the above courses ; or, in the following manner :

- Course.*
 1 Turnips.
 2 Barley.
 3 Clover.
 4 Wheat.
 5 Turnips.
 6 Barley, with grafs feeds.

And in many situations and circumstances of such lands, pease, tares, and cole may be had recourse to in the courses with great propriety and benefit. And where flints are abundant, from having been supposed incapable of being performed with facility, it has been suggested that the turnips should be sown thin, and a portion of cole feed be blended with them, by which an abundant supply of sheep food may be afforded. It has been also advised in these sorts of soils, that the corn crops, particularly those of the spring kind, should be constantly sown early, where the land is sufficiently dry, that they may be so forward as to cover the ground well before the hot season sets in, and thereby prevent the injury that must be sustained by too much dissipation of their moisture.

But that, on the heavier sorts of soils of this nature, beans or pease may often be made the preparation for barley, or even occasionally for wheat, in this way :

- Course.*
 1 Beans or pease.
 2 Barley.
 3 Clover.
 4 Wheat.

And the course may be further varied, by having recourse to tares and turnips, according as the state of the land may be suitable.

In regard to the thinner description of chalky soils, and such old down lands as are become so unproductive of

C R O P S.

herbage, as to be incapable of being continued any longer in the state of sheep walk or pasture, it has been proposed, as the best method of cropping them when brought under the plough, to make turnips or some other luxuriant green crop, which, while it keeps the land clean, and affords a large supply of green food for the support of sheep or other sort of live stock, is highly beneficial by preserving the humidity, which in such sorts of land is liable to be too rapidly carried off, the preparation for corn. The course in this view may stand thus:

Course.

- 1 Turnips.
- 2 Barley.
- 3 Clover.
- 4 Wheat.

Or in particular instances, as where feed weeds are apt to prevail in a high degree, two crops of turnips may be grown before any grain crop with much benefit. And in cases where such lands are designed to be kept for a greater length of time in the state of tillage, two crops of turnips may be again taken after the wheat, which will leave the land in a perfect state of preparation for barley; after which saintfoin may be introduced, as affording an excellent sheep pasture for a number of years. But in these cases the turnip and clover crops must always be fed off by sheep, which ought not to be removed from the land during the whole of the time the crops are in consumption; such other sorts of food as may be necessary being conveyed to them on the ground. In this way, it is imagined, the land will be left in the best state possible for the growth of barley, without the great trouble and expence which must otherwise be incurred for manure.

In cases where the soil is sufficiently friable and mellow in its nature, the method of cropping may be in this way:

Course.

- 1 Pease.
- 2 Oats.
- 3 Turnips.
- 4 Barley with grafs seeds.

Or where it is intended to continue the course, it may be done by going on with turnips or pease as before; concluding the course with saintfoin, as supplying a pasture for sheep for a number of years.

By properly attending to these directions in the courses of cropping, and the modes of managing such sorts of land, very considerable improvement may be made, both in rendering them capable of producing excellent crops of the grain kind, and in affording a much larger supply of green food for the support of sheep, and other sorts of live stock, than is commonly the case under other modes of cropping and consuming their produce.

V. *On the peaty kinds of soil, and such as have been long under the system of grain crops.*

Course.

- 1 Cole-seed, or turnips.
- 2 Cole-seed, or turnips.
- 3 Oats.
- 4 Ruta baga, or Swedish turnips.
- 5 Barley.
- 6 Grasses.
- 7 Grasses.
- 8 Grasses.
- 9 Grasses.
- 10 Potatoes.

- 11 Barley.
- 12 Tares, or pease.
- 13 Barley with grafs seeds.

In the business of cropping soils of the peaty, moory, and fenny kinds, it has been recommended by some writers, after freeing them by suitable draining from injurious moisture and wetness, that a difference should be made according as they are deep, or the contrary, in the superficial peaty covering. It is suggested that, in the former kind, the most suitable method may be that of making turnips, potatoes, cabbages, cole, or any of such sorts of crops, the plants of which produce much shade; and which, by preserving the moisture in the more superficial parts of the land, may promote their decomposition and decay, the preparation for corn; in which intention the course may be:

Course.

- 1 Turnips, cabbages or cole.
- 2 Oats.
- 3 Turnips, cabbages or cole.
- 4 Oats.
- 5 Clover.
- 6 Wheat.
- 7 Turnips, &c.
- 8 Oats with grafs-seeds, to remain some years.

It may be remarked here that potatoe crops, though they have been considered objectionable by some farmers from their great exhausting quality in this kind of land, have been shewn by experience to be highly beneficial and proper. Where this sort of crop is in use the course may be:

Course.

- 1 Potatoes.
- 2 Oats.
- 3 Turnips, cole or cabbages.
- 4 Turnips, cole or cabbages.
- 5 Oats with grafs seeds.

On this description of soil in the northern parts of Scotland, the use of potatoes, as a first crop, has been found, the author of Modern Agriculture says, by much the most certain and beneficial mode, the succeeding oat crops being not only in most cases more certain, but greatly more abundant and productive.

But on the thinner kinds of soils of this nature, as those of the moory and fenny sorts, with the subsoil of a stiff and retentive quality, it may be the most advisable to commence with cole, making it the preparation for corn, in this manner:

Course.

- 1 Cole,
- 2 Oats,
- 3 Cole,
- 4 Oats,

Course.

- 1 Cole.
- 2 Oats.
- 3 Beans with dung.
- 4 Potatoes.
- 5 Wheat.
- 6 Cole.
- 7 Oats.

But in the latter of these courses, in consequence of potatoes and wheat coming together, it is probable they may be too much for the land, as the experiments stated above have shewn them to be highly exhausting crops: a better plan may be, therefore, that of substituting beans in the place of the potatoes, in this manner:

Course.

- 1 Cole.
- 2 Oats with manure.

3 Beans.

C R O P S.

- 3 Beans.
- 4 Wheat.
- 5 Cole.
- 6 Oats.

And it is not improbable but that, in some cases of this nature, clover crops may be introduced as a preparation for the wheat. In this description of soils immense benefits and improvements may be produced by attention to proper modes of cropping.

In those circumstances where the dry quality of such soils, and their disposition to the production of a good turf or sward, is such as to admit of their being cultivated under the convertible system, or that of alternate grain and grass, which is often a most advantageous method; it will be proper, in directing the course of cropping, not only to consider the particular quality of the soil, but the growth of such sorts of roots and plants, or other crops, as may, while they tend to clean, improve, and prepare the ground for the production of abundant crops of grain and grass, be the most suited to the feeding, rearing, and maintaining of those descriptions of live stock which are capable of affording the most regular and abundant supplies of human food, at the different seasons or periods when they are the most wanted.

This is a system of practice which may often be carried on to great advantage and profit upon the loamy, gravelly, and fenny, as well as the thianer sorts of peaty soils; as in consequence of their having a great number of different green crops fed off upon the grounds, a degree of amelioration and improvement is effected, while they are under the tillage system, which must be highly beneficial for the production of grass; and by being occasionally laid down to grass for a short interval, and thickly stocked with sheep or other animals, they must become in an excellent state for being again brought under the plough. This is in short a sort of husbandry which has been found extremely beneficial in many districts. It is practised with vast advantage in the county of Northumberland; it having been there found that, on the sandy and dry light loamy soils, excellent grain crops, especially oats, may be grown by the lands remaining three years under grass, closely eaten with sheep, which could never be done while they were managed according to their old method of practice."

Under this system of management, on the more wet and stiff kinds of loam, where there is considerable fertility, the course of cropping may be as below, after first breaking up:

Course.

- 1 Beans or oats.
- 2 Turnips.
- 3 Barley.
- 4 Clover, or winter tares.
- 5 Wheat.
- 6 Turnips.
- 7 Barley.
- 8 Grass seeds for three, four, or more years.

Or,

Course.

- 1 Oats.
- 2 Beans.
- 3 Wheat.
- 4 Fallow and grass for four or five years.

On the dryer kinds of these sorts of soil, it is supposed better to begin in a somewhat different way.

Course.

- 1 Pease or turnips.
- 2 Barley.
- 3 Clover.
- 4 Wheat.
- 5 Turnips.
- 6 Barley with grass seeds for not less than three years.

Or,

Course.

- 1 Oats.
- 2 Turnips.
- 3 Barley with seeds to remain three or four years.

But in cases where large supplies of green food are in demand, or danger is apprehended from the wire worm grub, &c., the course may be commenced with more propriety by turnips or cabbages.

In Cumberland, where different plans of cropping, in this view, are stated to have been attempted, the course of:

Course.

- 1 Turnips,
- 2 Barley,
- 3 Clover,
- 4 Wheat,

is said to have been made use of till there was an evident falling off in the crops, especially in those of the green sort; in which circumstances the only means of restoring the lands has been found to be that of permitting them to remain, after they have been three years under the plough, the same length of time in the state of grass; it being discovered that "by this mode nature has time to prepare a sufficient lea clod, which being turned up for the turnip fallow, will insure a vigorous crop of turnips, as it is well known they always flourish upon fresh land, or where they find the remains of a lea clod to vegetate in."

These, and various other facts of the same kind, fully shew that great advantage may be gained by cultivating lands under this alternate system of tillage and grass, especially when, with the proper knowledge of the nature and modes of managing different kinds of live stock, that of the best means of connecting them with this sort of tillage husbandry, is fully comprehended.

Where the land, after some time, is to be restored to the condition of sward, and the practice of horse hoeing had recourse to for preserving the different crops in a perfectly clean state; and the various green crops, as turnips, pease, and beans, are at the same time cultivated in double rows, on ridges of three feet in breadth, and those of the cabbage kind in single rows on the same ridges; the courses given below have been stated to answer well, by the Rev. Mr. Close, for any length of time, in all the different kinds of soils.

COURSE.

On Clays.

- 1 Turnips or cabbages.
- 2 Oats.
- 3 Beans and clover.
- 4 Wheat.
- 5 Turnips or cabbages.
- 6 Oats.
- 7 Beans and vetches.
- 8 Wheat.

COURSE.

On clayey Loams.

- 1 Turnips or cabbages.
- 3 1 2

Oats.

C R O P S.

- 2 Oats.
- 3 Clover.
- 4 Wheat.
- 5 Turnips or cabbages.
- 6 Barley.
- 7 Beans.
- 8 Wheat.

COURSE.

On rich or sandy Loams.

COURSE.

On a chalky Subsoil

- 1 Turnips.
- 2 Barley.
- 3 Clover.
- 4 Wheat.
- 5 Potatoes.
- 6 Barley.
- 7 Pease.
- 8 Wheat.

In cases of this kind it is suggested that ten acres in each hundred should be laid down with saintfoin for eight or ten years.

COURSE.

On Gravels.

- 1 Turnips.
- 2 Barley.
- 3 Clover.
- 4 Wheat.
- 5 Potatoes.
- 6 Barley.
- 7 Pease.

COURSE.

On light Lands.

- 1 Turnips,
- 2 Barley.
- 3 Clover and rye-grafs.
- 4 Clover and rye-grafs.
- 5 Clover and rye-grafs.
- 6 Pease.
- 7 Wheat or rye.
- 8 Wheat.

The nature and principles on which the system of cropping ground should be founded, with the courses which have been found most beneficial in the most improved practice, on soils of different sorts and qualities, being thus pointed out, it may be proper to take a concise view of the modes which are actually followed in the best grain districts of the country; as this may serve to guide the tillage farmer in many points and circumstances, which could not be otherwise noticed.

It is remarked by the secretary to the board of agriculture, in his excellent Survey of the County of Norfolk, that in that great corn district, the principles of cropping, which have been constantly attended to for a long time, are those of avoiding the taking of two corn crops in succession, and of making turnips the preparation for barley, and grasses that for wheat and other sorts of grain.

The courses usually had recourse to on sandy lands and turnip loams, are the following. But the writer previously states, that the finest rye he met with in 1802 was on the farm of Mr. Bevan, which was raised after the culture of colc for two successive years, which was eaten off by sheep. The rye was put in on one earth to the extent of thirty acres, fourteen of which were upon a black sand: and Mr. Bradfield, his tenant, is stated to regularly pursue the course given below.

Course.

- 1 Turnips,
- 2 Barley,
- 3 Seeds,
- 4 Seeds,
- 5 Wheat,
- 6 Turnips,

} But if the seeds
} fail, changed to

Course.

- 1 Turnips.
- 2 Barley.
- 3 Vetches.
- 4 Turnips.
- 5 Barley.
- 6 Turnips.

By which in the sixth year, "the variation ceases, and it comes, as in the former, to turnips again. It is however added that to this system there are two great objections; in the fourth year the farmer has no summer food for sheep, and what is as had, he doubles his quantity of turnips; he also loses wheat in the course. To have two successive years of vetches, appears to be a better system, and a much less interruption, or rather none at all. If the first vetches are to be fed, grass-seeds might be sown with them for the second year, and this would save the expence of feed, vetches, and tillage, for that year. At Snetterton the course given below is employed by Mr. Fowel.

- 1 Turnips, drilled at 18 inches.
- 2 Barley ditto at nine.
- 3 Seeds.
- 4 Seeds.
- 5 Pease, drilled at twelve inches, or wheat at nine, &c., and this is the course of the whole neighbourhood.

Wheat, pease, oats, or rye, the fifth year; if rye, a bastard fallow for it: the second year, seeds.

About Hingham the course is in general

- | | |
|--|--|
| <ol style="list-style-type: none"> 1 Turnips, 2 Barley, 3 Clover, 4 Wheat, | <ol style="list-style-type: none"> 1 Turnips. 2 Barley. 3 Clover. 4 Pease. 5 Wheat. |
|--|--|

And about Watton it is

- 1 Turnips.
- 2 Barley.
- 3 Clover.
- 4 Wheat.

In one field near his farm yard, Mr. Blomfield, at Billingford, had

- 1 Winter tares, and then turnips.
- 2 Barley.

And

C R O P S.

And the crop always good; and Mr. Drake gets better turnips after wheat, the stubble ploughed in, than after pease." However, Mr. Wright of Stanhow never takes barley or pease after wheat, though his soil is a good loamy sand; he thinks that no district where this is the practice deserves the reputation of having the true Norfolk husbandry;" while Mr. Drozier remarked, that upon the sandy land of Rudham, and that vicinity, the greatest improvement perhaps would be, to lay down for eight or ten years, to repose the land from turnips and corn, which would so freshen it as to render it productive perhaps in the style of the first breaking up; but common grasses wear out, and will not pay the present rents after two years; they sow trefoil and ray."

Sir Mordaunt Martin's course is a five shift:

- 1 Turnips.
- 2 Barley.
- 3 Clover.
- 4 Wheat.
- 5 Potatoes, mangel wurgel, or vetches, &c.
- 6 Turnips.
- 7 Barley.
- 8 Trefoil and ray.
- 9 Pease.
- 10 Potatoes, mangel wurgel, vetches, &c.

It is added that "Mr. Overman of Burnham has found, from many observations, that pease do not succeed well if sown oftener than once in twelve years: where he has known them return in six or eight years, they have never done well. He ploughed up a layer of four years, and drilled wheat upon it—then ploughed for winter tares; ploughed the stubble once for a second crop of wheat, which the writer viewed; a very fine produce, and as clean as a garden. Three crops of great profit, on only three ploughings, and yet the land kept perfectly clean. Not a little resulting from four years sheep feeding without folding from it.

His common course is

- 1 Turnips.
- 2 Barley.
- 3 Seeds.
- 4 Ditto.
- 5 Ditto.
- 6 Wheat.
- 7 Turnips.
- 8 Barley.
- 9 Seeds.
- 10 Ditto.
- 11 Pease.
- 12 Wheat.

But with the variation of having part of the twelfth under pease on the three years layer, and also some tares. This course is partly founded on the experience of pease not doing well, if sown oftener than once in twelve years."

And by Mr. Coke;

- 1 Turnips.
- 2 Barley, drilled at $6\frac{3}{4}$ inches.
- 3 Seeds.
- 4 Ditto.
- 5 Wheat, drilled at 9 inches.
- 6 Turnips.
- 7 Barley, drilled at $6\frac{1}{4}$ inches.
- 8 Seeds.
- 9 Ditto.
- 10 Pease, drilled at 9 inches, or tares at 6 inches.
- 11 Wheat, drilled at 9 inches.

Mr. Purdis of Eggmore has a very uncommon variation from the general husbandry:

- 1 Turnips.
- 2 Barley.
- 3 Seeds.
- 4 Ditto.
- 5 Tares.
- 6 Wheat.

It is added, that "upon a large part of this fine farm the former course or rotation included a summer fallow, which afforded (broken at whatever time) little food for live-stock; tares now occupy the place, and support immense herds of cattle and sheep. What a noble spectacle, says the author, is this farm; 300 acres of turnips, 300 of barley, 600 of seeds, 300 of tares, and 300 of wheat; 1,800 acres arable, the crops luxuriant, much the greater part of the farm very clean, all of it except the layers, on which, however, are some thistles, too difficult to extirpate."

"But Mr. Thurtell, near Yarmouth, is in the four-shift, returning to turnips always after the wheat, for he thinks that nothing is so bad as taking a fifth crop." And at Caistor in Fleg, the land excellent, they are in the five-shift of East Norfolk; that is,

- 1 Turnips,
- 2 Barley,
- 3 Clover,
- 4 Wheat,
- 5 Barley;

with two variations practised sometimes by Mr. Evorit at the Hall farm:

- 1 Cole seed instead of turnips and barley.
- 2 Ditto.
- 3 Wheat.
- 4 Barley, but not a great crop, and then turnips again.

"The other is to substitute pease instead of clover, followed by wheat, and then in the four shift, to come again to turnips." But a remarkable circumstance in the rotation of crops here is, that spring corn will not succeed well after wheat, which follows cole seed; they will give an excellent summer fallow for this crop; spread 14 loads of fine dung *per* acre, and sowing wheat after the cole get the finest crops; yet if barley or oats follow, the produce is seldom tolerable; oats better than barley, but neither good.

By some farmers at Hemefby, the courses or rotations are,

- 1 Turnips.
- 2 Barley.
- 3 Seeds, (clover once in 10 or 12 years.)
- 4 Wheat.
- 5 Pease, or oats.
- 6 Wheat.

"It may easily, says the author, be supposed that the wheat of the fourth year is much better than that of the sixth. The course cannot be defended even on Hemefby land, and the wheat stubbles were some of them not so clean as they ought to be."

And "at Thrigby, Mr. Brown, &c. is, he says, in the Fleg five-shift; barley after the wheat, with the variation, to avoid clover every other round, of sowing half the barley with other seeds, and dibbling pease on the other half.

But at South Walsham, Mr. Syble and others:

- | | | |
|---|---|---------------------------|
| Unworthy of Norfolk in any case whatever. | } | 1 Turnips. |
| | | 2 Barley. |
| | | 3 Seeds, one or two years |
| | | 4 Wheat. |
| | | 5 Barley or oats. |
| | | 6 Pease. |
| | | 7 Wheat. |

The variation of the seeds is to prevent clover coming two rounds

C R O P S.

rounds together, as the land here, as elsewhere, is sick of it. Upon a part white clover, trefoil, and ray, are substituted, and left two years; about one third of the wheat is on a two years layer. If the clover be a good crop, the wheat is better than after the other seeds. The barley after wheat (if that followed a two year's lay) is better than after turnips. But Mr. Syble, if the land is foul after the first wheat, is sure then to take turnips. Sometimes pease on a two years lay, and then wheat; but he does not like pease, from their being so liable to failure. He is of opinion, the reporter says, that the husbandry of Fleg and Blonfeld wants variation, from having been kept too long in a regular course. One, which has succeeded with him, is to sow barley after pease or vetches, in which way he has had great crops. It is added that at Repps and Martha the common Fleg five-shift husbandry, that is, barley follows wheat, clover and other feeds alternately, and the wheat is as good after the one as the other; and at Ludham, the common five-shift. "But that at Catfield he found a variation; there the course is a six-shift husbandry:

- 1 Turnips.
- 2 Barley.
- 3 Clover, &c.
- 4 Clover, &c.
- 5 Wheat.
- 6 Barley.

"It is also stated, that Mr. Cubit practises this in common with his neighbours: the seeds sowed the second year before harvest, that is, rice-banked, raftered, half ploughed: some sealed: a clean earth as thin as possible: this management Mr. Thurtell reprobated for his soil: and what is singular, they seem to do it with equal reference to dibbling and broad-casting."

And Mr. Repton, at Oxnead, has been, from the year 1773, regularly in the six-shift husbandry of,

- 1 Turnips,
- 2 Barley,
- 3 Seeds-hay,
- 4 Seeds-ollond,
- 5 Wheat,
- 6 Barley;

which is common throughout the county.

But Mr. Reeve, of Heveringland, is in the five-shift; the seeds two years: and with Mr. Bircham, at Hackford:

- 1 Turnips.
- 2 Barley.
- 3 Clover and other feeds alternately.
- 4 Clover and other feeds alternately.
- 5 Wheat.
- 6 Barley, oats, or pease.

"But, if the land be out of condition, the method to recover it is, to take,"

- 1 Turnips.
- 2 Barley.
- 3 Turnips.
- 4 Barley.

But Mr. Johnson, of Thurning, thinks, that the common course of

- 1 Turnips,
- 2 Barley,
- 3 Seeds two years,
- 4 Seeds,
- 5 Wheat,
- 6 Barley;

which is the usual system about him, would be improved by the following variation:

- 1 Turnips,

- 2 Barley,
- 3 Seeds,
- 4 Seeds,
- 5 Seeds,
- 6 Pease,
- 7 Wheat,
- 8 Barley;

"in which the land would have rest for feeding, three years in eight, instead of two in six, as in the other."

With Mr. England, at Bingham:

- 1 Turnips,
- 2 Barley,
- 3 Seeds,
- 4 Seeds,
- 5 Wheat;

"never adding barley after the wheat. Sometimes, on tender land, not equal to wheat, drills pease on the ollond; and then, if the land be clean, takes barley, or even wheat; but not without rape-cake."

And Mr. Reeve of Wighton:

- 1 Turnips.
- 2 Barley.
- 3 Trefoil, white clover, and ray.
- 4 Ditto.
- 5 Wheat, drilled.
- 6 Turnips.
- 7 Barley.
- 8 Clover.
- 9 Wheat.

It is observed, that "every idea of this most accurate farmer merits much attention; and this course among the rest: whenever red clover is left a second year, it disappears, and the land is principally covered with ray-grass: query if it is not much better when red clover is the object, never to leave it two years: this is an improvement in Mr. Reeve's intention; but it has not been his general practice." He mucked a barley-stubble for vetches; ploughed once for that crop; and then drilled wheat on one other ploughing. The stubble clean as a garden.

Mr. M. Hill has

- 1 Turnips.
- 2 Barley.
- 3 Seeds.
- 4 Seeds.
- 5 Wheat.
- 6 Turnips.
- 7 Barley.
- 8 Seeds.
- 9 Pease, or tares.
- 10 Wheat.

It is likewise observed, that he has now (1801) on his farm, a very fine field of wheat, drilled on a flag of a four years layer: he remarked it, the reporter says, as an instance of confidence in his landlord (Mr. Coke), not to have broken it up sooner at the end of a lease. The same farmer sows cole after winter vetches fed off; eats it off at Michaelmas; sows rye for spring feed; eats that off, and tills for turnips, getting four green crops, to feed, on the land in two years. This is excellent husbandry, says the writer of the report.

There are many other courses, or modes of cropping, detailed, but it is unnecessary to notice more of them in the present view.

In the county of Essex, as in most other tillage districts, the courses of crops are extremely various, according to soil and circumstances; there is, however, in some cases, a disposition in the farmers to too much fallowing, which, probably, proceeds from the great desire which they have to keep

C R O P S.

keep the land clean, a fallow, or fallow crop, being consequently generally interposed between every two of white corn

In the district about Felstead, Great Waltham, and the Roodings, &c., on their cold strong loams, and poor loams on white clay, the course commonly pursued is that of crop and fallow, with some variations, by means of tares, clovers, pease, beans. The crop and fallow thus :

1 Fallow,	or	1 Fallow.
2 Wheat,	—	2 Barley.
3 Fallow,	—	3 Clover pease, or beans.
4 Barley,	—	4 Wheat.

But the following course is suggested as more proper :

- 1 Fallow,
- 2 Barley,
- 3 Clover,
- 4 Beans,
- 5 Wheat,
- 6 Tares,
- 7 Wheat,

applying the dung for beans.

On this, it is remarked, in the Agricultural Report of the county, that the fallow for barley is their own practice ; that the clover is near enough to receive what benefit it has to give ; that the clover and manure would secure beans, and afford an ample season for mucking, which is of much consequence on such soil ; that the wheat prepared for by the double fallow of clover and beans would be good ; while winter tares sowed would leave sufficient time for the most valuable fallow season, July, August, and September ; of course, little reasonable doubt could be entertained of the seventh year.

In the coast district, on the fine impalpable loams and clays of Bradfield and Wicks, the course with Mr. Hardy is :

- 1 Fallow.
- 2 Barley.
- 3 Clover, red or white ; generally red.
- 4 Wheat.
- 5 Beans.

When the clover misses, beans are substituted in its stead. And on the turnip loams of the same sort, turnips are substituted instead of the fallow, except on about one-fifth, which is under pease. On suggesting the propriety of wheat for a sixth year after beans, it was objected to from the danger of the black grass, or mouse-tail, choking it, as had often happened.

It is general, in all this part, never to put wheat in on a fallow, but always barley or oats, as the wheat never succeeded in this way. Beans have been tried on clover, and the wheat after the beans, but not with much success, merely from the bad effects of the black grass.

On land which is too heavy for the turnip culture, this mode of cropping is pursued by Mr. Woodrooffe at Ramsay.

1 Fallow,	or	
2 Barley,	—	
3 Clover,	—	3 Beans or pease.
4 Wheat,	—	4 Wheat.
5 Beans,	—	5 Beans.

These fifth crops are only had recourse to in cases where the ground is in a good condition, from the use of manure. The beans being well hoed and cleaned, it is considered good husbandry to fallow after them, as a double cleaning is thus given to the land, for though much is done by hoeing, it does not fully destroy either thistles or black grass ; while hand-weeding extirpates the latter completely.

This old five-course shift is thus varied, with good effect by Mr. Blythe :

- 1 Fallow.
- 2 Barley.
- 3 Clover, white ; and ray-grass for two or three years.
- 4 Wheat.
- 5 Beans.
- 6 Wheat.
- 7 Beans.
- 8 Wheat.

This is done, without injury, from the black grass. The laying down two or three years, or as long as may suit the object of live stock, is such a check to black grass, that much of the success may depend upon it ; but besides this, it lessens the great expence incurred in the tillage in such cases, and leaves the land greatly improved.

On remarkably fine mould, on a gravelly bottom, on the level vale-land of Gold Hanger, close to the sea wall, the course followed by Mr. Lee of Maldon, is this :

- 1 Turnips manured with 20 to 25 loads of dung, and ploughed for eight times.
- 2 Oats, some barley.
- 3 Clover, red and trefoil : both mown and fed crops very great.
- 4 Wheat ; average four quarters.
- 5 Beans dibbled, six rows on an eight-furrow ridge, hoed three times ; produce four quarters and a half.
- 6 Wheat, 4 quarters.

Oats here much more advantageous than barley after the turnips.

On fine sandy loam, Mr. Pattison of Maldon, on Spital farm, follows this course :

- 1 Fallow.
- 2 Oats, six quarters, or barley five quarters.
- 3 Clover, red and mown.
- 4 Wheat, four quarters.
- 5 Beans, four quarters.
- 6 Wheat, three quarters and three-fourths.

And at Burnham, on light land, Mr. Wakefield follows :

- 1 Turnips, fed by sheep.
- 2 Oats, or barley.
- 3 Clover.
- 4 Wheat.
- 5 Mazagan beans, or pease, well hoed three times.

And on his medium marsh-land, on which turnips cannot be fed,

- 1 Coleseed feed.
- 2 Oats, (never barley).
- 3 Clover.
- 4 Wheat.
- 5 Beans of any sort, (pease never).

On a field of good land, Mr. Spurgeon's practice was as below, which is suggested, as removing "some steps the necessity of repeated fallows."

- 1 Fallow : soon after 70 loads an acre of chalk and earth compost.
- 2 Oats.
- 3 Clover manured, and none after.
- 4 Wheat.
- 5 Mazagan beans ; the stubble well *cased* for.
- 6 Wheat.
- 7 Pease ; the stubble well *cased* for.
- 8 Wheat.
- 9 Tares, well *cased* for.
- 10 Wheat ; the stubble quite clean.

C R O P S.

And on land fit for turnips, near Rochford, Mr. Barrington pursues ;

- 1 Turnips.
- 2 Oats, very little barley.
- 3 Clover ; tares, pease, or beans, if a failure.
- 4 Wheat.
- 5 Oats.

But if good land,

- 5 Beans.
- And when very good,
- 6 Wheat.

About Yieldham, where the soil is too heavy for turnips, the usual course is ;

- 1 Fallow,
- 2 Barley,
- 3 Clover,
- 4 Wheat ;

and when the clover land is mucked for wheat, sometimes

- 5 Oats.

Clover sown once in four or five years is, however, apt to fail ; consequently, variations are formed by pease, beans, or tares, and clover does well once in eight years.

In some cases the course of,

- 1 Fallow,
- 2 Coleseed,
- 3 Wheat,

is pursued with success.

On turnip land at Layer de la Haye,

- 1 Turnips.
- 2 Barley or oats.
- 3 Clover.
- 4 Wheat.
- 5 Pease or oats.

At Chesterford, on loamy soils or gravel, while open field, the flock farms are thus cropped.

- 1 Turnips.
- 2 Barley.
- 3 Pease or oats, if pease.
- 4 Wheat.

When enclosed, changed to,

- 1 Turnips.
- 2 Barley.
- 3 Clover, by some trefoil.
- 4 Wheat, and by some
- 5 Tares.

At Boreley, the course pursued by Mr. Coker on different sorts of land, are these,

<i>On Strong Land.</i>	<i>On Dry Land.</i>
1 Fallow,	1 Turnips.
2 Barley,	2 Barley.
3 Clover,	3 Clover.
4 Wheat,	4 Wheat.
5 Beans or pease,	5 Pease.
6 Tares.	
7 Oats.	

But by changing red for white clover or trefoil one round, clover will then stand well.

In the practice of Mr. Sewell, at Maplestead, in the view of banishing fallows from strong as well as light lands, the following courses in one field have been successful for some years.

- 1791 Turnips mucked for and drawn,
- 1792 One ploughing for carrots for seed ; crop $3\frac{1}{2}$ cwt. *per acre*, at 63s.
- 1793 One ploughing for wheat, 18 bushels *per acre*.
- 1794 One ploughing for winter tares, mown green for soiling.

1795 Three ploughings for barley ; six quarters and a half.
1796 Clover, half-fed, half-mown ; then all seeded ; 4 bushels *per acre*.

1797 Mucked for wheat, the fed and mown equal $3\frac{1}{2}$ quarters.

1798 Windfor beans dibbled at 18 inches ; three quarters.

1799 Wheat ; twenty bushels.

1800 Pease ; four quarters and a half.

1801 One ploughing for oats ; six quarters.

1802 Trefoil seeded : badly got in ; nine bushels at 20s.

1803 Wheat ; twenty-two bushels.

1804 So much trefoil came up, that it was dunged and seeded, but failed ; only four bushels *per acre*.

1805 Windfor beans, oats and pease, fair crop.

Next year summer fallow.

And Mr. Sperling follows.

1 Turnips, half drawn, half fed, in alternate ridges on dry land-fallow.

2 Barley, or oats, alternately.

3 Clover, red, white, or trefoil.

4 Wheat.

And when the land is in good order adds

5 Beans.

6 Wheat.

Wheat never sown on fallow, which is bad husbandry.

At Bocking, Mr. Saville follows.

1 Fallow or turnips, according to soil.

2 Barley.

3 Clover, the dung on the barley stubble.

4 Wheat.

5 Oats, by some, but here not allowed.

The variation where clover fails, is tares or pease.

He is stated as commencing an interesting variation, in that of the alternate system of corn and grass. In which view, white clover, and ray grass, have been sown for two or three years past, in one field each year, with coleseed for feeding by sheep, having twelve acres in the whole ; the cole being a good crop, with a beautiful plant of the grasses amongst it, even where the thickest and highest. It is intended to feed or mow this grass, for three, four, or five years, as circumstances may direct, and then to break it up with the expectation of good corn crops. It is suggested that he will not be disappointed, but that "the success with ray demands close feeding and no mowing."

And the same gentleman is stated as having another idea which has a tendency to lessen the expences of fallows, and which promises in certain cases to be beneficial ; it is that of ploughing the intended fallows as early as possible, and to harrow in cole, to be used as spring feed for sheep.

At Barking, with Mr. T. Pittman a common course is,

1 Potatoes,

2 Wheat,

3 Clover sown in April,

5 Wheat ;

and then potatoes again, but with some variation, as that of putting them in on the clover, which is found to afford better crops than corn stubbles.

These are some of the courses which are practised in this extensive district, but various others are met with.

In the county of Hertford, where, on the clays and strong loams, the fallow system is still in practice, the following courses, Mr. Young says, are commonly in use about Sawbridgeworth.

1 Fallow.

2 Barley.

3 Clover.

4 Wheat.

C R O P S.

- Also, 1 Fallow,
2 Barley,
3 Peafe.
4 Wheat.

- And 1 Fallow.
2 Wheat.
3 Fallow.
4 Barley.

Many farmers pursuing,

- 1 Fallow.
2 Wheat.
3 Fallow.
4 Barley.
5 Clover.
6 Oats.

“ It is however observed, that whatever fault may be found and perhaps justly, with so much fallowing, it must be admitted that their crops are good.”

On the authority of Mr. Byde of Ware Park, all the turnip land he knows in the country is stated to be managed in this manner.

- 1 Turnips.
2 Barley.
3 Clover, the first crop mown, the second fed.
4 Wheat, good farmers stopping here, and bad ones adding
5 Oats.

“ And the turnips may be reckoned at 50s. an acre ; the barley three quarters, and the wheat 17 to 20 bushels.”

But the strong heavy soils are thus cropped :

- 1 Fallow.
2 Wheat.
3 Fallow.
4 Barley.
5 Clover.
6 Oats.

Varying the course thus :

- 1 Fallow.
2 Wheat.
3 Clover.
4 Barley.
5 Fallow.
6 Wheat.
7 Oats, peafe, or beans.

An acre of wheat yields 25 bushels.

And on the same authority it is stated that about Watford there is a peculiar course of,

- 1 Fallow.
2 Beans, on which they put all the dressing.
3 Wheat.

And at little Hodham they have a course of,

- 1 Fallow, ploughed four times,
2 Wheat,
3 Fallow, four or five times ploughed,
4 Barley :

the only variation being, sometimes

- 5 Clover,
6 Oats.

But Mr. Jones is, it is observed, decidedly of opinion, that the crop and fallow course is the most profitable. He asserts that beans will not succeed on this soil. The writer, however, says he knows they will on land exactly such in Suffolk, and give four quarters *per* acre.

About Westmill the course is :

- 1 Fallow, ploughed four times.
2 Wheat.
3 Clover.

- 4 Barley on three earths.
5 Peafe.

But Mr. Whittington on light land cultivates,

- 1 Turnips.
2 Barley.
3 Clover.
4 Wheat ; and if the land is in good order he adds,
5 Peafe, or oats.

On clay land his course is,

- 1 Fallow,
2 Wheat,
3 Peafe ;
or, 1 Fallow,
2 Barley,
3 Peafe ;
or, 1 Fallow,
2 Wheat,
3 Clover,
4 Oats ;

and this he reckons better than either of his former.

On proposing barley on a fallow with clover, and then beans and wheat he objected, that if clover is sown at the time of sowing barley, it gets so forward as to spoil the crop ; and if sown at rolling, it is apt to fail. This the writer, however, cannot admit to be fair reasoning in a country where it is common to sow clover on wheat in the spring, and even so late as May and July.

On much of the poor hungry gravel in the open fields near Hatfield, let at 7s. *per* acre, the course is,

- 1 Fallow.
2 Wheat, producing two or three loads (five bushels).
3 Oats, producing 4½ or three quarters.

On better land they cultivate,

- 1 Turnips, sheep fed.
2 Barley ; four quarters are produced on an average.
3 Clover twice mown, two loads are grown.
4 Wheat, 22 bushels are reaped.
5 Oats, or peafe.

This is the course of Mr Cassmajor, at North Mimms :

But his course on wet land is,

- 1 Summer fallow.
2 Barley, four quarters are grown.
3 Clover, twice mown, and 2½ loads at the two are grown.
4 Wheat, four or five loads are reaped.
5 Oats, peafe, or beans ; three to four quarters of either are the amount of the produce.

“ But the last crop in either case is only taken when the land is in high order.” It is stated, that in this “ there is a proof of the impropriety of the question, whether clover may safely be sown with barley on land in high order ; the point on which the objection to clover sown with barley on land summer fallowed is founded.” It is observed that Mr. Leach follows the under mentioned course.

- 1 Turnips.
2 Barley.
3 Clover.
4 Wheat.
5 Oats, or peafe.

Then they return to turnips on some land ; but on about 40 acres of gravel, he sows,

- 1 Turnips.
2 Barley.
3 Trefoil, white clover, ray grass, common clover fed.
4 Ditto. fed.
5 Ditto. fed.

C R O P S.

6 Oats, on one earth.

7 Three earths are given immediately after oats, and then wheat is sown.

8 Winter fallow for barley.

9 Grasses, as before, for three years :

and then the land is cultivated as above. "Thus, says the writer, these 40 acres neither want nor have any manure more than they receive from the feeding of the sheep on them, and from 60 bushels of ashes *per* acre, spread the first year on the grasses only, and 30 bushels of foot *per* acre on the wheat. It has answered greatly for 18 years to his full satisfaction. He made it a rule to feed his land as bare as possible, and always wishes not to let the ray run to bent."

And it is observed, that lady Melbourne has a field, which has been thus managed.

1 Potatoes were planted on it and well manured, and the produce amounted to 400 bushels per acre.

2 Wheat was drilled on it, at the distance of nine inches. The crop amounted to seven loads, or 35 bushels, an acre.

3 Winter tares were next sown, for which 12*l.* an acre were this year (1803) offered; but they were mown for soiling; and at present the turnips after them are good.

4 Barley will be drilled next spring, as the fourth crop.

"Mr. Young of Hurrall, who farms on a large scale, with much intelligence, pursues the common course of taking oats or pease after wheat. It is extraordinary, says the author, to see how general this practice is; but if the clover is at all foul, he passes over this crop and sows turnips. The same course holds to St. Albans, and he found it steady on the fine farm of 483 acres, of Mr. Clarke, at Sandrigbury." But Mr. Biggs, near that town, omits the oats after wheat, returning to fallow for turnips, instead of an after crop, except on 20 acres nearly in a year, which he sows with pease.

Tares he sows on the wheat stubble, and grows good turnips the same year. On his heavier strong land, of which he has not much, his course of crops is :

- 1 Fallow.
- 2 Barley.
- 3 Pease.
- 4 Fallow.
- 5 Wheat.
- 6 Beans.

And that "the common Hertfordshire course of 1 turnips, 2 barley, 3 clover, 4 wheat, 5 oats, continues about Watford, Rickmansworth, and all around Berkhemsted and Hempsted." But Mr. Jennings of the latter place, has a course,

- 1 Fallow.
- 2 Wheat.
- 3 Pease, drilled.
- 4 Barley.
- 5 Clover.

6 Wheat, but not in general, only as a variation from his common course.

It is noted, that "Mr. Cotton, of the same place, observed, in defence of the common practice of taking oats after wheat, that they are the black oat, which, according to his opinion, succeeds best in land held together by roots, though of weeds which will yield better than land in tilth, though clean; and this makes a bad manager in many cases, obtain a better crop of black oats than a good farmer would produce on the same land."

"The old course continues to Beechwood and Market-Street; where, if clover fails, they sow pease, followed either

by turnips or summer fallow. They sow winter tares after wheat, three bushels *per* acre. They use them for feeding and soiling, and then fallow for turnips, or give a bastard fallow for wheat; but the crop is not so good as on clover." Round Hitchin, in every direction, the old course of five shifts is continued: it is, however, varied by a few, by,

- 1 Turnips.
- 2 Barley.
- 3 Barley.
- 4 Clover.
- 5 Wheat.

And by some a sixth shift of oats is added.

In the open land they follow a course of

- 1 Fallow.
- 2 Wheat or barley.
- 3 Oats or pease.

But sometimes sow turnips, by agreement, on the fallow.

"Mr. Sedgwick, of Rickmansworth, on stony land, pursues a course of,

- 1 Fallow.
- 2 Wheat.
- 3 Oats or pease.

On dry land this is the common course, but often turnips are sown after wheat. If a field grows so tired of clover as to want a change, their course is then;

- 1 Turnips.
- 2 Wheat.
- 3 Barley, or pease, or oats.
- 4 Turnips.
- 5 Barley.
- 6 Clover.
- 7 Wheat.
- 8 Oats.

And Mr. Parker, at Munden, sows

- 1 Turnips.
- 2 Barley.
- 3 Clover.
- 4 Wheat.

Upon which "he remarks, that by this course the land is favoured, as oats never follow wheat. If dung should run short, and a farmer not have it in his power to manure all his turnips, he may venture to sow a field of turnips without dunging, and succeed; a practice by no means to be depended on in the common rotation of taking oats after wheat. In order to favour the land, he has occasionally omitted sowing the clover, and taken pease for one round; but he suffered in his wheat; so that he scarcely knows what to do in the awkward circumstance of the failure of clover." "And when clover fails at King's Langley, some farmers sow pease, others (but this is not common) fallow for wheat, and then take oats:" and the earl of Essex sows, near his farm-yard,

- 1 Tares, and then turnips.
- 2 Barley.
- 3 Clover.
- 4 Wheat.

And Mr. Young "saw at Cashiobury very fine turnips after tares used in soiling, though sown twice and three times. This course affords, he says, much provender for the yard, in tares and clover for soiling, and turnips for staling. In other parts of the farm, oats follow wheat:"

But at Chesshant they sow

- 1 Turnips.
- 2 Wheat.
- 3 Clover.
- 4 Wheat.

C R O P S.

Also,

- 1 Fallow.
- 2 Wheat.
- 3 Oats, pease, or beans.

On the clays of Albury, Pelham, &c. their course of crops is,

- | | |
|-----------|-----------|
| 1 Fallow, | 1 Fallow. |
| 2 Wheat, | 2 Barley. |
| 3 Oats. | 3 Pease. |

Some courses consist of, 1 fallow, 2 wheat, 3 fallow, 4 barley; clover is also added with wheat; and oats and barley sometimes. They feed their clover in the spring, and then give a bastard fallow for wheat or barley. In the extensive open fields about Darkway, the writer finds the rotations to be,

- 1 Fallow.
- 2 Wheat.
- 3 Oats.
- 4 Fallow.
- 5 Barley.
- 6 Pease.

The same in the open fields (and all are open) about Roylton. There are no inclosures, he says, in the parish, except small patches, quite in or near the town. And "Mr. Foster, of Roylton, practises a husbandry which long ago the writer publicly recommended; not that he took it from that recommendation, but his practice has confirmed it."

Common Course.

- 1 Fallow,
- 2 Wheat,
- 3 Oats,
- 4 Fallow,
- 5 Wheat,

Mr. Foster's Course.

- 1 Fallow.
- 2 Wheat.
- 3 Clover and trefoil.
- 4 Ditto.
- 5 Wheat.

It is noted that the "feeds are sown on the wheat in March. The first year he tops them in May, and then mows the ground for hay or feed. The second year, the flock-master feeds them with the rest of the fields; but the grass entices the sheep to the spot, and dresses it consequently better than other parts, and his following wheat has always been much superior to, that fallowed; even to the degree of beating that on which *3l. 4s. per acre* have been bestowed in dressing: a clear proof that so much fallowing is a real injury to the land. Besides this, he keeps two horses in eight fewer than before he practised this husbandry." But Mr. Doo of Bygrave is in the Norfolk four-shift course, leaving out the oats taken so commonly in Hertfordshire. If clover fails, he sows turnips; and if turnips fail, carries on the fallow for barley. This is excellent husbandry, the writer says.

However, round Baldock, generally, but with some exceptions, oats are taken after the wheat. And Mr. Smith of Cloth-hall, has a course of,

- 1 Fallow.
- 2 Wheat.
- 3 Clover.
- 4 Oats or barley.

And the four shift turnip course.

In the open field he finds,

- 1 Fallow.
- 2 Barley.
- 3 Pease.
- 4 Fallow.
- 5 Wheat.
- 6 Oats: this by agreement.

And in the open field near Baldock, he finds another course by a singular agreement.

- 1 Turnips.
- 2 Barley.
- 3 Barley.
- 4 Clover; which the parish flock-master eats till the last Thursday in May; then removes his sheep, and the farmer lets it stand for feed.
- 5 Wheat.
- 6 Oats.

It is suggested by the writer, that the practice in these courses, of commonly taking a crop of oats after the clover land wheat, is incorrect in a very high degree. "It is, says he, putting in a corn crop the fourth from the fallow, for though clover is certainly to be esteemed a fallow respecting amelioration, yet, in that of cleaning land, it is by no means powerful. If there is any couch in land, it is sure to increase very considerably while the land rests from tillage. This circumstance makes it such ill husbandry to leave broad clover a second year. To sow wheat on one ploughing, which can destroy no root-weeds, and then to put in a second crop of corn, must, in the nature of things, he supposes, be injurious by encouraging weeds. But what is the motive, he asks, for this conduct? Those who say that the land will bear it, simply assert that profit is thus to be gained, provided the land be kept in heart. He could never, he says, understand this, nor upon what principles the idea can be founded; and in order to place the question in the clearest light, it appears to him that nothing more can be necessary than to contrast the two courses for any given number of years."

And upon the courses in the clay district, where the fallow system is found, he remarks, that "great crops are gained in favourable years, is, an undeniable fact. But great as these exertions are, these exertions are little or no security against bad seasons, which form a very material deduction from their profit. That husbandry, upon the long run, will be most beneficial which is calculated by a variation of crops to be advantageous with a moderate produce. When a year's fallow and manuring are given to one crop, a moderate produce will not be a profitable return: if the farmer has not a great success, he has loss, and consequently his hazard is considerable. The course he wishes to see tried effectually is this:

- 1 Fallow, in partial compliance, not with his, but with the opinion of others.
- 2 Barley.
- 3 Clover.
- 4 Beans.
- 5 Wheat.

"All the manure should, he says, be laid for the beans. The fallow will secure barley. The clover will give good beans; and the beans, if well cultivated, are sure to give good wheat." He adds, that "in answer to this, he has been told, that beans will not do in this county; that they have been tried, &c. The trials made have, he says, been broadcast, and therefore no rule whatever. They should be dibbled in double rows; that is, two furrows dibbled, a row on each, and then two or three furrows (according to soil and circumstances) should be missed, and two others dibbled, and so on; the intervals should also be well horse-hoed; the rows must be hand-hoed and weeded, and the whole kept clean like a garden. The soil is, he says, unquestionably well calculated for this crop; for similar land produces great beans in other counties, and therefore if well managed would do the same here. When beans are compared with fallow, let the consumption of the straw be considered, which yields excellent dung; let that dung be carried to the field, in addition to the quantity the land receives in the

present system; a condition absolutely necessary, if the comparison be made fairly. Let these circumstances be duly attended to, and he has little doubt what the result will be. But when random assertions are ventured, and the propriety of the recommendation questioned, he admits the fairness of all, if the proposal could be applied at once to a whole farm. But how very easy is it, says he, to try the experiment on three or four acres in perfect management not merely for one season good or bad, but to try such a quantity every year. It would then be soon ascertained, by a truly practical man, free from prejudices, whether the husbandry be really adapted to the land or not." And he advises that "in the tillage preparatory to the beans, the Middlesex management should be adopted, of ploughing while the land is dry in autumn, to throw the field into the destined form, it having been previously well gripped. Spring tillage should also be avoided, as it is pernicious on wet, stiff soils, and nothing should require to be done then except the planting of the field, when the weather would permit the work to proceed, without the land being injured."

In the district of East Lothian in Scotland, where the tillage husbandry is extensive, and in general well executed, the methods of cropping pursued by the best farmers on the different sorts of soil, are the following:

On the coast lands, where the soils are of the dry gravelly loamy description, they are under a four course shift, in this way:

- 1 Turnips, sometimes with, and sometimes without dung.
- 2 Barley, or spring wheat, with grafs-seeds.
- 3 Clover, which is generally cut for hay, or given green to farm-stock in the house, and sometimes pastured with ewes and lambs.
- 4 Wheat, or oats, if wheat was taken before, dunged upon the clover ley.

It is stated in the Report of the District, that, "after this the course again returns;" and that, "upon this description of land, the turnips are for the most part consumed upon the ground with sheep confined, by flakes, a mode by which the soil is greatly enriched. Of late years, however, an improvement has been made in the way of using turnips upon these lands, that deserves attention. In place of eating the whole upon the field where they grow, a certain proportion is drawn, and either carried home and used for cattle in the house, or given to sheep upon an adjoining stubble or grafs field: by this mode a double quantity of land is manured, and if the winter is wet, the turnip field is less injured than it would otherwise be, if the whole were consumed where they grow. The quantity drawn and carried off in this manner is from a half to a third of the crop; in some cases five or six drills are taken out; and the same number left. Taking out alternate drills is certainly a preferable mode, and is now pretty generally practised."

But that on the deeper loams with a dry bottom:

- 1 Turnips.
- 2 Barley, or spring wheat.
- 3 Pasture.
- 4 Oats.
- 5 Beans, drilled and horsehoed.
- 6 Wheat.

It is suggested, that, "this rotation requires land of the best quality. Dung is only once applied during the rotation, and is uniformly given to the turnips."

On the heavy loams on a retentive bottom:

- 1 Fallow, with dung.
- 2 Wheat.
- 3 Beans, drilled and horsehoed.

- 4 Barley.
- 5 Clover, which is dunged on the stubble.
- 6 Oats.
- 7 Beans drilled.
- 8 Wheat.

It is added, that, in "this course, the land is dunged twice, though not very heavily, a practice that is found to be very beneficial. Beans and wheat alternately are sometimes taken on such soils, but much manure is necessary, where a system of this kind is executed."

And another course on this sort of soil is:

- 1 Fallow, dunged.
- 2 Wheat with grafs-seeds.
- 3 Pasture, eaten by sheep.
- 4 Oats.
- 5 Beans, or a mixture of beans and pease drilled.
- 6 Wheat or oats.

It is stated "that the above is a rotation of six, with only one manuring, but the quantity applied is generally greater than in the foregoing rotation, and the pasture being the second after the fallow, and fed off with sheep, compensates in some degree, for the want of dung."

A rotation is sometimes followed on the best clays, such as is marked in the first class of the above.

And on thin clays,

- 1 Fallow without dung.
- 2 Oats with grafs-seeds, or if the fallow was dunged, wheat.
- 3 Pasture.
- 4 Oats.
- 5 Beans, dunged.
- 6 Wheat.

After which the fallow is repeated, and the course returns.

On the poorest of these clays, the course commonly followed, is,

- 1 Fallow, dunged.
- 2 Barley, sometimes oats, with grafs-seeds.
- 3 Clover.
- 4 Oats.

It is here suggested, that, "on the coast, a considerable portion of what was formerly *link* grounds, covered with bents and other herbage of small value, is now brought under the plough, and profitably employed in raising useful crops." That description of soil is for the most part under a rotation of four, as follows:

- 1 Turnips with dung, or sea ware.
- 2 Rye or barley, with grafs-seeds.
- 3 Clover cut for hay, or pastured.
- 4 Oats, manure on the clover ley.

It is noticed, that the "great bar to the improvement of these sandy soils, arises from the risk to which they are exposed of being blown by high winds, a circumstance which frequently happens, and by which the crops, both of turnips and barley, are often greatly injured, and sometimes entirely lost." A remedy, the writer says, "has lately been suggested and put in practice, for that evil which bids fair to be attended with benefit. The season during which the greatest mischief happens from blowing, is the latter part of the spring, and beginning of summer, and the winds by which the blowing is occasioned, are generally from the west and south; to prevent the mischief, to barley and turnips crops, it is proposed to keep barley out of the rotation, and substitute rye in its place, that the ridges of the field shall run in a direction from north to south, and that the three westernmost ridges shall be sown with rye before winter, leaving the three ridges immediately adjoining for turnips, sowing again the

C R O P S.

the three next ridges with rye, and so on, having alternately three ridges of each over the whole field. Where this is practised, the rye, by the time the turnips are sown, has made considerable progress, and from the circumstance of the sides of the ridges being opposed to the wind, breaks its force so much, as to prevent it from hurting the turnips. Perhaps alternate ridges of rye and turnips would answer the purpose of shelter more completely, but as some loss would arise from treading the rye in the working of the turnips, and as the latter, if the rye grew to any great height, would suffer from the want of a due proportion of the light and air, two or three ridges appear to be the proper breadth."

The above is considered as the rotation or course generally followed, on the different soils in the middle districts, and coast lands; upon the deep and well sheltered soils in the uplands, it is not materially different, except that winter wheat is seldom sown, and spring wheat not at all; for the generality of that district, however, which is a dry gravelly loam, the rotation principally followed is one of four shifts:

- 1 Turnips with dung.
- 2 Barley or oats.
- 3 Clover.
- 4 Oats.

"But upon heath lands, broken up by a two years fallow, the rotation is generally different from any of the above. Where the soil of these lands is, however, deep, the above rotation is followed; but when the situation is elevated, and the soil thin, as is often the case, the most common rotation is as under."

- 1 Oats.
- 2 Clover.
- 3 Pasture.

It is suggested, that, "in this last, the land is permitted to remain for a number of years." But that, "in some cases the system is different; the second year of the fallow, and after the lime is wrought in, turnips are sown, and eaten off with sheep, oats are sown in the spring with grass, and the land afterwards pastured. The last is unquestionably the most profitable rotation, as along with the value of the turnip crop, which in some cases may be considerable, the land is manured and has its parts consolidated, by the treading of sheep; this last is a circumstance of great importance to soils of a loose texture, as these frequently are."

And it is supposed by "some good farmers, that the rotation upon these new broken uplands, may be lengthened by taking a second crop of oats, after the clover, and again sowing down with grass-seeds. It is believed that on some of the best of these lands, that may be done with advantage; but if the soil be thin, and contain few useful principles, the experiment is dangerous, as there is a risk of rendering it useless for the future."

These details of the courses, which are pursued in cropping lands in these great grain districts, clearly prove that much remains still to be done in this way, before the greatest possible advantages can be derived from the cultivation of the soil.

Having thus explained the principles on which the business of cropping land should be conducted, the courses of crops which are best suited to different circumstances and sorts of soil, and shewn the systems of cropping, which are commonly pursued in the best corn districts of the kingdom, it may be proper to state the usual distribution of crops on farms of different descriptions. It is not however an easy matter to state with exactness the proportions of crops of different sorts, that

may be the most suitable and advantageous on farms of different sorts and sizes under the arable or other systems, as much must always depend on soil, climate, and situation in so far as markets are concerned, as well as the sort of cultivation which is practised, and other circumstances which relate to the peculiar nature of the farm itself.

It has been stated that the governing principles in this sort of arrangements should be "that the extent of land, in the state of natural and artificial grass, be fully adequate to the support of such a number of live stock of different kinds, as may be sufficient to supply such a proportion of manure as is necessary for keeping the portion of ground under grain root, green, or other crops, in the most perfect heart and order. Hence the space of ground to be conducted under grain, root green, and other arable crops, must constantly be proportioned to the quantity of manure that can be raised by the keeping of different sorts of domestic animals, while the number of the last must be regulated by the amount of the food that can be procured from the grass and green cattle crops which can be cultivated and preserved for their use during the winter season. As without considerable attention to these different circumstances, it must be impossible, it is supposed, except near large towns, where manures can be obtained at a reasonable rate, to cultivate land to the greatest advantage."

The proportionate distribution of crops on a farm of 150 acres, 60 of which were dry turnip land, and the other part a mixture of clay with gravel lying on a wet bottom; being situated on the best cultivated portion of the West-Riding of Yorkshire.

Distribution of Crops.

Wheat	-	-	30 acres.
Barley	-	-	20
Oats	-	-	14
Meadow grass	-	-	7
Red clover	-	-	14
Pasture	-	-	45
Summer fallow and turnips			20
			150

On another farm in the western part of the same district; of the extent of 80 acres, customary measure of 7840 square yards, under the grazing and dairying systems.

Annual Distribution of the Crops.

- 3½ acres of oats.
- 1½ acre of barley.
- 21 acres of meadow, cut for hay.
- 20 acres pastured with feeding cattle.
- 30 acres pastured with milch cows, young cattle and horses.

But it is suggested, that the proportion of grain is here much too small, even under such systems of management.

And upon a farm in the centre of the Riding; the soil of which is red gret and water shaken, incumbent on clay. The extent 200 statute acres, under the arable system.

Annual Distribution of the Crops.

43 acres wheat being	{	15 acres after fallow. 15 acres after clover ley. 13 acres after oats.
-------------------------	---	--

C R O P S.

The quantity of seed sown from 2½, to 3 bushels per acre.

15 acres barley, after fallow, 3½ to four bushels sown per acre.
 18 acres after oats, 5 bushels seed per acre.
 14 acres beans and pease, 3 to 4 bushels seed per acre.
 70 acres pasture and meadow.
 16 acres clover.
 31 acres summer fallow.

200

On a farm on a dry gravelly soil, the extent 78 statute acres, restricted to ploughing more than 40 acres.

Annual distribution of the Crops.

18 acres wheat.
 8 acres potatoes.
 6 acres oats.
 8 acres pease, cabbages, &c.
 27 acres pasture grafs.
 11 meadow land.

78

And on a farm where the soil was limestone, clay and moor, the extent of which was 139 statute acres.

Annual distribution of the Crops.

Wheat	-	-	23 acres.
Barley	-	-	9
Oats	-	-	23
Beans	-	-	7
Meadow	-	-	12
Fallow	-	-	20
Pasture	-	-	47

139

On a farm of the extent of 116 statute-acres, the soil limestone and clay :

Annual distribution of the Crops.

Wheat	-	-	22 acres.
Barley	-	-	9
Oats	-	-	8
Beans	-	-	5
Meadow	-	-	10
Fallow	-	-	13
Pasture	-	-	49

116

The distributions of crops on different sorts of land in the northern part of the same county, are in this way :

On a farm of 100 acres of light soil.

Annually.

	Acres.	Roods.	Perches.
In corn	40	0	0
In turnips	20	0	0
In temporary grafs ley	30	0	0
In clover	10	0	0
Total	100	0	0

And on another farm of 120 acres of heavy soil.

Annually.

	Acres.	Roods.	Perches.
In white corn	30	0	0
In Beans	10	0	0
In clover or pease	10	0	0
In green fallow crops	10	0	0
In grafs	60	0	0

Total 120 0 0

For a farm of 200 acres, managed under the convertible system, or that of alternately grain and grafs, being continued only three years under the plough, and then laid down to grafs, one, two, or a greater number of years, according to circumstances.

Distribution of the Crops.

Under different states of grafs 110 acres.
 Under fallow crops - - 30
 Under grain crops - - 60

200

Or, Annually thus ;

Under the state of old turf or sward 20 acres.
 Under different artificial grasses, as clover, lucern, saintfoin, &c. 10
 Under irrigation, or the state of preserved grafs. - 5
 Under different sorts of fallow crops 30
 Under wheat and barley after different fallow crops - 30
 Crops of different grasses 1st year 25
 Crops of ditto. 2d year 25
 Crops of ditto. 3d year 25
 Under oat and other grain crops, after breaking up the grafs - 30

200

CROPS, *Course of*, in Gardening, is the method of putting in or cultivating culinary vegetables, so as that the soil and state of the ground may be the most suitable to the nature of the plant, herb, or root, and at the same time be the best preserved from being injured by the exhaulting properties of the crops.

From the general richness of garden-ground, and much manure being constantly employed in the raising of crops on them, much less attention has perhaps been paid to the courses of cropping in the garden than in the field. It is, however, equally necessary in this case as in that and the same principles are equally applicable.

A variety of circumstances, however, conspire to prevent its being so effectually accomplished in the garden as in the farm ; as the smallness of the portions of ground generally allotted to this use, the vast number of articles which are to be grown, and their great similarity and relation to each other. It has, notwithstanding, been suggested by Mr. Nicol that they may be classed in the following manner, with much propriety and advantage.

- 1 Brocoli, cabbage, cauliflower, and favoys.
- 2 Common beans, French beans, and pease.
- 3 Carrots, beets, and parsnips.
- 4 Turnips, early potatoes, onions, leeks, shallots, &c.
- 5 Cellery, endive, lettuce, &c. &c.

It is found in practice that cellery constitutes an excellent preparation for asparagus, onions, and cauliflowers.

Turnips or potatoes are a good preparation for cabbages or greens.

Brocoli or cabbages, are a proper preparation for beans or peas.

Cauliflowers prepare well, for onions, leeks, or turnips.

Old asparagus land affords a good preparation for potatoes or carrots.

The strawberry, currant, gooseberry, and raspberry for the same.

Turnips give a suitable preparation for cellery, or endive.

And pease, when well manured for, are a good preparation for spinach, &c.

It is recommended by the writer mentioned above, that in all cases a studied course should be had recourse to, so that no crops of the same class or kind may immediately follow each other. In order to accomplish which in the most perfect manner, the garden should be divided with regularity into quarters, and numbered, a journal being kept for the purpose of entering every thing which regards the manner of cropping, manuring, trenching, digging, ridging up, and fallowing of each of them, in the manner below.

No. 1.

1793. Subtrenched after asparagus without manure for carrots.

1794. Winter fallowed, planted with early cauliflowers with moderate dunging, 2d May.

1794. Winter fallowed sowed with yellow turnips, with compost dressing, 20th July.

1795. Dug over lightly for sowing onions without manure, 8th February.

1795. Dug over deeply for planting cabbages with light dunging, 5th October.

1796. Dug over lightly for setting Charleton pease without manure, for a late crop, 20th June.

1796. Trenched three spits deep in December, winter fallowed.

1797. Dug deep, to be set with early potatoes, with moderate dunging, 20th March.

1797. Dug common depth, for German greens, without manure, 10th September.

1797. Dug common depth, intended for leeks in June next.

The other numbers of the different compartments or divisions should be managed in the same way.

It is likewise remarked that it is becoming a practice with market gardeners to crop a portion of their ground every season with some sort of grain or grass, which, besides being found highly useful for their cattle, is of vast benefit to their ground. After being laid down a year or two with some sort of the latter kind of crop, the ground is found to be capable of again growing good esculent or kitchen vegetables.

CROPPING, in *Agriculture*, the operation or process of putting different sorts of field crops into the ground. In performing this business to the most advantage, various circumstances are necessary to be taken into consideration, such as the season, and the nature, state, and preparation of the land, as well as the nature, quality, and quantity of the seed. By properly attending to all these different points of management, crops of almost all descriptions may be put into the soil, so as to succeed with much greater certainty, and in a much more perfect manner than is usual in the ordinary methods of putting them into the ground.

CROPPING, in *Gardening*, the practice of committing the various culinary and other garden crops to the soil. In this

business much attention is necessary to the season, as well as the particular habits and economy of the different sorts of plants, roots, or other kinds of crops which are to be raised; and also to the proper preparation of the ground on which they are to be grown, both in respect to the manner and depth of stirring it. There are likewise many other circumstances which require the notice of the careful gardener in this important department of his art.

CROPPING, in *Rural Economy*, a term often employed to signify the cutting off the ears or other parts of different sorts of animals, such as sheep, goats, horses, dogs, &c. either with the view of ornament or as a mark by which they may be distinguished from others of the same kind.

CROP-OUT, in *Mining*, signifies to *lasset*, *out-go*, or burst upon the surface. (See those articles.) Since the discoveries of Mr. William Smith have been promulgated respecting the stratification, a large portion of these appearances of the edges of strata, on the surface of the ground, has been denominated *ENDINGS of the strata* (which see.) These are generally on the west or north-west sides of hills and mountains, and are generally very irregular or fingered; but the dislocations, depressions, and elevations of different parts of the strata, with the denudation and excavation of other parts, have occasioned the strata frequently to crop-out, especially in mountainous districts, in every possible direction. See the above articles.

CROQUANT, *Fr.*; the name of a faction that committed great ravages towards the end of the sixteenth century in several provinces beyond the Loire. In 1593 the peasants of Perigord, Limosin, and Poitou, assembled, and appointing for themselves leaders and officers, refused to pay the imposts, over-ran the country, and gave no quarter to gentlemen who fell into their hands. They were called *croquans*, because they eat voraciously, and helped themselves plentifully wherever they went.

CROQUE-NOTE, *Fr.* in *Music*, a title given in derision by the French, to such unskilful and unfeeling musicians as are called in England mere fiddlers and scrapers.

CROQUIS, a sketch made in haste, of any design to be completed afterwards.

CRORE, in *Commerce*, the term used in the East Indies for a sum of money, equal to ten millions of rupees or 100 lacks; each lack comprehending one hundred thousand rupees, or in a round sum, 10,000*l.* sterling.

CROS, in *Geography*, a town of Egypt, according to Steph. Byz.

CROSATO, GIO. BATISTA, in *Biography*, a Venetian painter of the 18th century, who died in the year 1756. He was the tutor of Bernardino Galliani. From the design of this artist Zucchi engraved a design of God the Father and the Saviour, for the Italian translation of Milton's *Paradise Lost*. A picture, by him, representing the scourging of Christ, is in the church of St. Ermagora at Venice. Great part of his life was spent in Piedmont, where he is better known as an ornamental painter (*quadraturista*) in which line he acquired great reputation. Lanzi. Heineken.

CROSE, or *Drawing-board*, in *Heraldry*, an instrument of the coopers, used as part of their armorial enign.

CROSETTES, in *Architecture*, the returns in the corners of chambranes, or door-cales, or window-frames; called also *ears*, *elbows*, *ancones*, *prothyrides*, &c.

CROSLICIN, in *Geography*, a town of Poland, in the palatinate of Lemberg; 52 miles W.S.W. of Lemberg.

CROSIER, or *CROZIER*, (from *Crocus*, low Latin, *à similitudine crucis*; called also *Cambuta*, *Pelum*, and *Baculus Pastoralis*), the pastoral staff of archbishops, bishops, abbots, abbesses, as also of certain priors and priorities. In the testament

tament of St. Remigius, archbishop of Rheims, who died in the year of Christ 533, mention is made of an ornamented silver crozier, which he bequeathed to his cathedral church. The crozier originally was not longer than a common walking stick, and was used as such by bishops and abbots, at the same time that it was an emblem of their authority. In process of time it became longer and more ornamented, until it reached the height, richness, and exquisite workmanship which is seen in that of William of Wykeham, bishop of Winchester, bequeathed by him to his college at Oxford, called New College, and still preserved there. The crozier of ordinary bishops, and of abbots and abbesses, resembles a shepherd's crook, being curved at the upper end, and shod at the bottom with a sharp ferule, to denote its two-fold purpose, expressed in the following well-known verse:

“Curva trahit mites, pars pungit acuta rebelles.”

The crozier of an archbishop consists of a lofty, processional cross, with a single bar to it; that of a patriarch of such a cross with two bars to it; and that of the pope of a triple-barred cross.

The crozier being an ensign of spiritual jurisdiction, it was the privilege of all ecclesiastical persons, who had been canonically invested with it, to have it carried before them within the limits of their jurisdiction; that is to say, an abbot within the walls of his convent, a bishop within his diocese, a metropolitan within his province; but by no means out of it. The archbishop of Canterbury might display his crozier throughout all England, Wales, and, previously to the year 1150, throughout all Ireland; but the archbishop of York could not exhibit his on the south side of the Humber. Hence when Richard I. was crowned a second time, which ceremony took place at Winchester in the year 1194, by way of effacing the ignominy of his captivity at Trivallis, his brother Geoffrey Plantagenet, archbishop of York, finding that he was not permitted to have his crozier carried before him in the province of Canterbury, refused to be present at the coronation, as we are informed by Roger Hoveden. In conformity with this principle, abbots and abbesses were required to have a veil affixed to their croziers; which veil, however, was fashioned in the nature of a pendant, or flag, to signify that their authority was of a private nature, and confined to their respective communities. For the same reason, they were accustomed to hold the crooked head of the crozier inwards, namely, turned towards their own persons; whereas bishops held them outwards, that is to say, turned from themselves. These remarks, however trivial they may appear of themselves, are of great use in ascertaining the personage, character, and authority of many figures in our ancient sculpture and painting. M.

CROSIER, in *Astronomy*, four stars in form of a cross; by help whereof, those who sail in the southern hemisphere find the antarctic pole.

CROSNE, in *Geography*, a town of Poland, in the palatinate of Lemberg; 80 miles W.S.W. of Lemberg.

CROSNIERE, a small island in the Atlantic Ocean, on the coast of France, of about six miles in circuit, near the island of Noir Montier, which is considered as a part of the department of the Vendée. It was gained from the ocean, in 1767, by means of dikes, which on a small scale represent the famous dikes of Holland. The soil is uncommonly fertile, and well cultivated. There is but one commune or parish in the whole island.

CROSNO, **KROSNO**, or **KROSNA**, a small town of Austria, in Galicia or Austrian Poland, which carries on a good trade, chiefly in wine and other commodities of Hungary.

CROSS, **THOMAS**, in *Biography*, an English engraver of the 17th century, by whom we have, amongst others, the following portraits, executed in a poor, laboured style: Jeremiah Burroughs, 1646. James Burroughs, theol. 1648. John Richardson, bishop of Armagh, 1654. He also engraved the frontispiece to White's Rich Cabinet, 1684. Walpole. Heineken.

CROSS, —, an English painter, who flourished in the reigns of Charles I. and II. He is said to have been so excellent a copyist, that being employed by the former monarch to copy some of the finest pictures in Italy, he brought away from the church of St. Mark at Venice, a fine Madonna by Raffaele, substituting the imitation for the original. So excellent was the deception, that the cheat was not discovered until too late to regain it. This picture is now said to be in the Escorial in Spain. Pilkington.

CROSS, **CRUX**, a sort of instrument, composed of two pieces of wood, traversing and cutting each other, ordinarily at right angles. Such being the form of the cross, the body of the criminal was fastened by nailing the feet to the upright part, and the hands on each side to the transverse piece.

Pezron derives the word *crux* from the Celtic *croug*, and *croas*; though, perhaps, *croug* and *croas* might with as much justice be derived from *crux*.

The cross was used amongst the ancients as an instrument of punishment for malefactors, and particularly slaves; and was planted at several places, *in terrorem*, as our gallows, &c.

The death of the cross was, both on account of the shame and pain of it, the most dreadful of any; so that it was inflicted on the vilest criminals.

Sozomen observes, that it was Constantine who by law first abolished the punishment of the cross, which had obtained among the Romans till his time. It had also been in use among the Assyrians, Egyptians, Persians, Carthaginians, and even the Greeks. The Jews pretend that they inflicted the punishment of crucifixion upon no person whilst he was alive; but that, having first put them to death in some other way, they then fastened them to the cross either by the hands or neck. But instances occur of their frequently crucifying persons that were alive. See 2 Sam. xxi. 9.

Constantine was induced to abolish crucifixion by his respect for the cross of Christ. He would not suffer the instrument of our salvation to be thus dishonoured, and rendered an object of aversion and horror, and he thought it indecent and irreligious, that the cross should be used for the punishment of the vilest offenders, whilst he himself erected it as a trophy, and esteemed it the noblest ornament of his diadem and military standards. Although the text of this law is not preserved, the fact is asserted both by Pagan and Christian writers. (*Vid.* Aurel. Victor. and Sozomen.) Influenced by the same religious sentiment, he prohibited the breaking of the legs of criminals, which was a punishment often annexed to that of the cross, as appears from the example of the two thieves crucified with Christ. The circumstance in which Constantine's peculiar veneration for the cross originated is related by Eusebius (*De Vita Const. lib. i. c. 27, 28, 29, 30.*) in the following manner.—This writer represents the emperor as deliberating, and determining what God he should worship when he was undertaking the war with Maxentius, or, however, before he had finished it; which was begun in 311, when Constantine was considerably above 30 years of age. Weighing, says Eusebius, in his mind the misfortunes of those who had worshipped idols, he made choice of the Christian religion; and considering

dering with himself that he wanted some better assistance than military forces, he sought for a God that might be his helper. In consequence of his deliberation on this subject, he was convinced, that it was the utmost folly so far to trifle as to pay honour to such gods as were mere nullities; and he therefore resolved to worship only the God of his father. Eusebius proceeds in the following words: "He therefore called upon this God in his prayers, earnestly intreating and beseeching him, that he would make himself known to him, and afford him his powerful aid in the difficult affairs before him. Whilst the emperor was putting up these earnest prayers and supplications, a divine sign (*θεοσημεία*) of a most wonderful nature appeared; which thing, possibly, if related by another, would not be easily credited. But the victorious emperor himself having told it to us, who wrote this history a long time after, when we had the honour of his acquaintance and conversation, and having likewise confirmed it with an oath, who can refuse his assent to it, especially when following events have borne testimony to the truth of it? He said then, that about noon, when the day was declining, he saw with his own eyes in the heavens, the trophy of the cross, placed above the sun, consisting of light, with an inscription annexed, *τῷ ὄντι*. BY THIS CONQUER; that at the sight of it, astonishment seized him and his whole army, which then followed him in a certain march, and beheld that wonderful sight." "In the mean time," as he said, "he began to doubt with himself, what the meaning of this should be; but whilst he was revolving in his mind, and continued meditating upon it, at length night came on. As he slept, the Christ of God appeared to him with that sign which had appeared in the heavens; and commanded him to make a standard resembling the sign, which he had seen in the heavens, and to use it as a defence, in the battle with his enemies."—"As soon as it was day, he arose, and communicated this wonderful thing to his friends. And then sending for such as worked in gold and precious stones, he seated himself in the midst of them, and gave them a description of the sign, and commanded them to make one like it in gold and precious stones, which we have also seen." Eusebius afterwards describes the standard. In a crown of gold at the top of the cross was a figure, consisting of the two first letters of the name of Christ, according to the Greek orthography.

This figure on some medals, is formed thus , in others

thus , and the standard thus marked is called *labarum*, which see. When the troops in any part of the army began to give way, the emperor caused the standard with the cross to be conveyed thither; and his faith, says Eusebius, was rewarded with victory, which began on that side where the greatest danger was apprehended.

The appearance of the luminous cross in the heavens is altogether denied by some, who call it a fiction, a stratagem, a political device of Constantine, to animate his soldiers, and to engage the Christians firmly on his side. By some it was regarded as a pious fraud. This opinion, as Fabricius assures us (*Apud Bib. Græc. l. v. c. 3. t. vi. p. 8., &c.*) has been fully considered and confuted by Jo. Chr. Wolfius. By others, more generally, the cross, which is said to have been seen by Constantine in the heavens, is reckoned not only a reality, but a miracle. Fabricius (*ubi supra*) allows and contends for the reality of it, but does not think it properly miraculous. He suggests that it was a solar halo, which is a well known phenomenon; and in order to account for the inscription, *τῷ ὄντι*, he suggests,

that *ὄντι*, in Eusebius's relation, means a *picture*, as well as a *writing*, and that *λέγειν*, when applied to a picture or image, means to *denote* or *imply*, and that the words of Constantine and Eusebius may be thus interpreted: to the cross was adjoined a picture or image, intimating that by this he should conquer; which image was a lucid crown, a representation or symbol of victory. In confirmation of this solution, it has been alleged, that Eusebius, by not using the words *σοῦμα*, or *ἑσθημεντα*, nor mentioning in what language it was written, seems to speak rather of an emblem or picture, than of a writing. Besides, in the standard which Constantine ordered to be made in form of a cross, in memory of this omen, he placed a crown of gold and jewels on the top of it, and a cypher denoting the name of Christ, but not the words *τῷ ὄντι*. We shall here subjoin some pertinent and judicious remarks that have been made on this history of Eusebius by Dr. Lardner. (*Works, vol. iv. p. 152, &c.*) 1. This relation is delivered by Eusebius upon the sole credit of Constantine; whereas a thing of so public a nature could not have rested upon his credit and authority only, if it had been true. Other witnesses might have been called to vouch for the truth of an event, so surprising, and so recent; *i. e.* 20 years before Eusebius wrote the life of Constantine; and the historian, from dutiful affection for the emperor, and from a just concern for his own honour, would not have failed to add something to this purpose. 2. The oath or oaths of Constantine upon this occasion, rather bring his relation into suspicion. 3. Eusebius renders this whole account suspicious, by not mentioning the place of this wonderful sight; and this defect renders it probable, in Dr. Lardner's judgment, that Eusebius himself did not believe this story, nor intend to vouch for the truth of it. 4. There are other things concerning the standard related by Eusebius, which he also had from Constantine, and which are very unlikely, if not altogether incredible. Wherever the standard was, says the historian, the enemies fled; and this is not improbable, because it might animate Constantine's soldiers, and terrify the enemy. But it is added, that the salutary trophy was a safeguard to him who bore it, and there never was any one wounded in this service. This relation, for which Eusebius does not make himself answerable, surpasses all credible accounts of miracles; that when many darts were thrown, none should strike the bearer, nor yet light upon the upper part of the standard, where were the cross and the motto, but only, and always, upon the narrow circumference of the spear, or pole of the standard. 5. Lactantius, or the author of the book "Of the deaths of Persecutors," who wrote a few years after this appearance in the heavens is supposed to have happened, says nothing of it, but only mentions Constantine's dream or vision in his sleep. But the truth of this vision rests solely upon the emperor's own word; and if the appearance of the cross in the heavens be denied, which Constantine confirmed to Eusebius with an oath, the credit of the emperor, as to the whole matter, is so weakened, that nothing concerning it can be taken upon the authority of his testimony only. It is further added by Lardner, that since several ecclesiastical historians, who wrote after Eusebius, particularly Rufinus and Sozomen, insist not upon the appearance of the cross in the heavens, there were at that time Christians, as well as others, who either were totally ignorant of it, or else did not credit the account, as related by Eusebius from Constantine. Indeed, it does not seem reasonable to believe the relation of any one man, concerning a public appearance, which is attested by no others; nor did Eusebius himself believe it, much as Constantine endeavoured to impose upon his learned friend. In order to account for the difference in

the relation of this fight in the heavens, and the silence of historians respecting it, Dr. Lardner conjectures, that when Constantine first informed people of the reason that induced him to use the sign of the cross in his armies, he alleged nothing but a dream; but in the latter part of his life, when he became acquainted with Eusebius, he added the other particular of a luminous cross seen somewhere by him and his army in the day-time; and the emperor having related this in the most solemn manner, Eusebius thought himself obliged to mention it. But the first account had been so long and so often told, that it was generally known, and the only one that was so known. Whence it came to pass, that historians a good while afterwards related the vision in the dream as the original cause of Constantine's using the cross; that being the common and prevailing tradition concerning it.

As to the time when the appearance of the cross in the heavens and the dream of Constantine are said to have happened, authors are not agreed; but these events have generally been referred to the 26th of October, A. D. 312. But this opinion is far from being satisfactory, as it is liable to many objections. Dr. Lardner supposes, that the sign of the cross began to be made use of by Constantine in his armies on occasion of his last battle with Maxentius; some short time at least before this battle; and the day of it, the thought of employing this sign must have come into Constantine's mind; whether by divine revelation and admonition, or his own politic contrivance, let the inquisitive judge, says Lardner, after mature consideration. Constantine was a politician as well as a Christian, and he might have adopted the standard of the cross, and the mark of it upon the shields of his soldiers, with a view of reconciling them to his change of religion, and also as a means of success in his designs, and of victory over his enemies.

After this digression, we shall return to the more immediate subject of this article. As to crucifixion, or the manner wherein the punishment of the cross was effected, the critics, both ancient and modern, are exceedingly divided; the points in dispute are, whether the criminal was fastened with three nails, or with four; whether the feet were immediately fastened to the cross, or whether they rested on a little piece of wood, in manner of a step, or rest, called *σκαμνίον*; whether the cross was planted in the earth before the person was nailed on, fastening him afterwards by means of a scaffold raised to the height of the place where the feet were to be nailed; or whether he was nailed before the cross was raised or planted, as the painters represent it: or lastly, whether the patient was fastened quite naked, or covered: questions that have all been occasioned by the crucifixion of Jesus Christ.

In reference to this event, we may here add, that our Saviour was scourged before he was delivered to be crucified (Matth. xxvii. 26. Mark, xv. 15.), agreeably to the usual custom among the Romans, who scourged persons condemned to capital punishment before execution. He also bore his cross. (John, xix. 16, 17.) It was the constant practice among the Romans for criminals to carry their own cross. Thus Plutarch (*De iis qui ferro puniuntur*), alleges this circumstance as an illustration of the misery of vice; "that every kind of wickedness produces its own particular torment, just as every malefactor, when he is brought forth to execution, carries his own cross." We are also told by the evangelist, that our Lord was crucified without the city.

This is conformable to the Jewish law, and to examples mentioned in the Old Testament. Among the Romans also this custom was very common, at least in the provinces. The robbers at Ephesus, mentioned by Petronius Arbitr

(Satyr. c. 71.), were crucified by order of the governor of the province, without the city. This was the custom likewise in Sicily, as appears from Cicero (in *Verr. l. x. c. 66.*) Persons devoted to this kind of death often lingered for a long while before their pain terminated in dissolution. Sometimes they remained suspended till they died of hunger; and in some cases they were suffered to remain on the cross till their bodies were devoured by birds of prey; nor were their relations allowed to take them down and bury them. The law of Moses, however, forbade the bodies to remain on the cross after sun-set. See John, xix. 31, 32, 33.

Cross, in *Antiquity*, was under one form or other of it, a kind of monument of art, which very long and very generally subsisted, which was constructed of various materials, but most commonly of stone, and which was intended to answer a variety of purposes, civil and religious. Under the article *CROMLECH*, we have already mentioned several stone structures, which were erected in the British islands by the Druids, Saxons, or Danes, and which served as temples or altars, or burying-places. The stones that formed them were sometimes placed across one another, probably more from necessity or convenience, than from any particular view to the figure of a cross. After the introduction of Christianity, and more especially after the age of Constantine, the cross became an object of very general veneration, and traces of it are discernible in many of our churches and monuments, as well as in our civil and religious customs and ceremonies. Those monuments of stone, which served as instruments of Druidical superstition before the plantation of the gospel in the British isles, were afterwards appropriated to the use of Christian memorials, by being formed in the figure of a cross, or marked with this emblem of sanctity and object of veneration. Structures of the kind now mentioned were appropriated to various purposes; and we find them subsisting in several places, as memorials of the demarcation or boundary of property, parishes, and sanctuaries; as sepulchral monuments; as public records of battles, murder, and other disastrous events; as places of public prayer, preaching, and proclamation: and others were placed by the road-side, in market-places, at the junction of three or four streets or roads, and on the spot where the corpse of any person of rank and eminence was set down for the rest of the attendants, in its way to interment; so that "a transfentibus pro ejus animo deprecetur." It was a common practice for mendicants to station themselves near some of these crosses, and beg alms in the name of Jesus; and to this custom the provincial proverb, still retained in the north of England, seems to allude, when applied to a person very urgent in his intreaties; "He begs like a cripple at a cross." Crosses were also in former times erected on the tops of houses, by which tenants pretended to claim the privileges of the templars-hospitallers, of defending themselves against their rightful lords. This was condemned by the statute Will. II. c. 37. These stone-crosses were anciently incitements to superstition, and even objects of worship. See *Exaltation of the Cross, infra.*

Such was the veneration with which crosses were formerly regarded, that when St. Augustine first came to preach the Christian faith to the Saxons, he had a cross borne before him with a banner, on which was the image of our Saviour. Crosses were also erected by many Christian kings, before a battle, or great enterprize, with prayers and supplications, for the assistance of Almighty God. Oswald caused a cross of wood to be erected before he fought with Cadwallo, holding it till the earth was rammed in round about it, while all his soldiers kneeled down devoutly. Many instances occur of crosses that were placed to mark the bound-

aries of districts, of church-property, and of sanctuary. Of the former class are "Stump-crosses," being the boundary-stone between Frisby and Ashfordby, in the county of Leicester; another of the same name on the summit of a high hill at Townley, in the parish of Whalley, and county of Lancaster; the shire cross-stone, on the mountain called Wry-nose, near the river Dudding, dividing Cumberland from Westmoreland; the cross yet remaining on Stainmore, which is the boundary-stone between Yorkshire and Cumberland; and the stone-cross, called "Mugdrum cross," near Lundorfs in Fifeshire, which, according to Camden, marked the boundary between the districts of Fife and Strathern, which was also a place of sanctuary.

At Ripon, in Yorkshire, the boundaries of sanctuary of the collegiate church were distinguished by crosses. Among the monumental crosses, those at Penrith church-yard, in Cumberland, are somewhat singular and curious. Such are those in the church-yard of Glames in Scotland, and that in the church-yard of Bewcastle in Cumberland, the latter of which is ascribed by many antiquarians to the Danes. These monumental stones are very numerous in Wales, Scotland, Ireland, and the north of England. There were two of this kind in the monks' cemetery at Glastonbury; and such was also the monument of St. Dunstan at Canterbury. Crosses were usually erected in the way leading to parochial churches and cemeteries. Cornwall abounds with stone-crosses. In church-yards, by the sides of roads, and on the open downs, they remain solitary and neglected, though among the lower classes of the people a sort of superstitious reverence is still paid to these monuments. The preaching-cross, stone-pulpit, or oratory, was probably first erected for the purpose of sheltering and accommodating the minister when he preached to a large concourse of people in the open air, or for his convenience in reading the funeral service. Of this kind are the crosses near the monastic house of the Black-friars in the city of Hereford; that in the church-yard of Iron-Aeton in Gloucestershire; that at Holbeach in Lincolnshire; and that on the south side of the abbey at Shrewsbury, commonly called "St. Winifrid's pulpit." But the most noted of this class was "St. Paul's cross" in London, which was probably at first of the monumental kind. This was the most celebrated place in London for public sermons, though it was often abused by the agents of the predominant party. This cross appears to have been standing at the time when Dugdale wrote his history of St. Paul's. There was another public preaching cross in Spitalfields, near London, where the lord-mayor, and principal officers of the city, &c. regularly attended to hear sermons in Easter-week. Those discourses, called the Spital-sermons, originated at this cross; but they are now preached at St. Bride's.

Crosses not only marked civil and ecclesiastical limits, but probably served for stations, when the bounds were visited in processions; a station denoting a church-oratory, or other resting place, where a prayer was said or a short verse sung. In the isle of Iona were 360 crosses, of which one only now remains. Crosses also on the road, or without the limits of the cemetery, seem to have been endowed with a privilege of sanctuary.

The market-crosses are of various shapes and sizes. Their general design was to excite public homage to the religion of Christ crucified, and to inspire men with a sense of morality and piety amidst the ordinary transactions of life. In almost every town that had an abbey, or any other religious foundation, there was one of these structures. At most markets and fairs it was then, as it is now, customary to pay certain tolls on articles that were sold. Many of these tolls belonged to monasteries, and in populous places they must have produced considerable revenues. To promote these, as well

the doctrines of their religion, the monks frequently harangued the populace from these crosses; and it is reasonable to suppose that they strongly urged the necessity of a strict adherence to religion, honesty, and industry. Previously to the dissolution of the monasteries, there was hardly a market town in England without one or more of these structures; and many of them still remain, exhibiting beautiful specimens of the architecture and sculpture of the times. To this class we may refer the "White Friar's cross" in the road, about one mile W. of Hertford; the crosses at Coventry, Gloucester, Cheddar, Malmesbury, Chichester, Stourhead in Wiltshire removed from Bristol, Winchester, Leighton-Buzzard in Bedfordshire, and Glastonbury. Crosses of memorial are those which were erected in places where the bodies of eminent persons halted in their way to interment. Of these a series formerly stood by the side of the road which communicated between Paris and St. Denis, where the kings of France were usually interred. The most memorable and interesting objects of this kind were those which king Edward I. of England erected at the different stages where the corpse of queen Eleanor rested, in its progress from Nottinghamshire to London. Mr. Gough (*Vetusta Monumenta*, vol. iii.) states, that there were originally 15 of these elegant structures; but only three are now remaining, which, by their peculiar beauty, as specimens of architecture and productions of art, serve to excite regret at the destruction of the others. Historians, however, differ, not only as to the place and time of queen Eleanor's death, but also concerning the number of crosses erected. The most probable account is that she died at Hereby in the county of Nottingham, in November, A. D. 1290. At the place, probably near a religious house, where the corpse halted for a night, the king afterwards ordered a sumptuous cross to be erected. The first of the three above-mentioned is the *Cross at Geddington*, about four miles from Kettering, in Northamptonshire, which is of a triangular shape, elevated on eight steps, and divided into three compartments; the first, or lower one, is solid, covered with ornamental sculpture, each face divided into six pannels, attached to which are six shields, charged with the arms of England, Castile, Leon, and Ponthien. Above this is an embattled turret, from which rise six pillars, supporting as many decorated canopies. Beneath these are placed three statues of the queen, disposed in so absurd a manner, that the pillars at the angles directly intersect the front of each figure. The second is the *Queen's cross* near Northampton, the most perfect of the three, and very similar in shape and ornaments to that at Waltham, though the latter is of an hexangular form, and the former is octangular. Standing on eight steps, in an open country, and on elevated ground, it assumes a very imposing appearance. Like the others, it is divided into three stories, the lower of which has eight faces, separated by buttresses at the angles. Each face is ornamented with a pointed arch, having a central mullion, with tracery, and the whole crowned with a purfled pediment. Two shields are also attached to each face, charged with the arms of England and Ponthieu singly, and those of Castile and Leon quarterly. A carved book is also affixed to four of the sides. On the western face has been inserted the arms of Great Britain, in a garter, under a crown, beneath which is a Latin inscription; and on another tablet is another inscription, the former importing that it was repaired in the year 1713, and the latter in 1762.

The third is the *Cross at Waltham* in Hertfordshire, which, though more dilapidated than either of the former, is more enriched in its architecture, and more elegant in its sculpture. This formerly stood on steps, but the ground hav-

ing been raised round it, the steps are covered and it appears shorter than the others. This has six faces. For a further account of these crosses, illustrated with appropriate and excellent engravings, see the valuable work of Mr. Britton, entitled "Architectural Antiquities of Great Britain," parts iv. and v.

Crosses, &c. are forbid to be brought into England, by 13 Eliz. c. 2, on pain of a *præmunire*, &c.

Cross, *Invention of the, inventio crucis*, an ancient feast, solemnized on the third of May, in memory of St. Helena's (the mother of Constantine) finding the true cross of Christ deep in the ground, on mount Calvary; where she erected a church for the preservation of part of it: the rest being brought to Rome, and reposed in the church of the Holy Cross of Jerusalem.

Theodoret mentions the finding of three crosses, that of Jesus Christ, and those of the two thieves; and that they distinguished between them by means of a sick woman, who was immediately healed by touching the true cross. The place is said to have been pointed out to her by St. Quiriacus, then a Jew, afterwards converted and canonized.

Nothing, says Tillemont, is more certain than this discovery of the true cross in the days of Constantine; for it is attested by Rufinus, Sulpitius Severus, Theodoret, Socrates, Sozomen, Ambrose, Paulinus, and Chrysostom. The account he gives of this wonderful discovery is as follows: "When St. Helena, the mother of Constantine, was arrived at Jerusalem, and had begun to visit the sacred places, the Holy Ghost inflamed her with a desire to find the wood of the cross. But no person had ever seen it, or could tell where it had been hid. She then inquired for the place where Christ was crucified, and found it out by the help of the Jews and Christians; or, as Rufinus says, by some revelation; and being moved by the Holy Spirit, she ordered the buildings to be pulled down, and the rubbish to be removed. The faith of this female saint was recompensed beyond expectation; and upon digging very deep, they found the holy sepulchre, and near it three crosses, with the title which had been affixed to the cross of Christ, and the nails which had pierced his sacred body. But a difficulty still remained, which was to distinguish the cross of Christ. St. Macarius, bishop of Jerusalem, proposed the method. He was a prelate illustrious for his wisdom, truly worthy of God, and had just overthrown the heresy of Arius at the great council of Nice. This holy man, knowing that one of the principal ladies of the city lay extremely ill, told Helena, that they must carry the three crosses to the sick person, and beg of God that he would cure her by the application of the true cross. The empress, and all the people being present, he touched the woman with two of the crosses ineffectually; but as soon as he had made use of the third, she arose in perfect health, and stronger than she had ever been. It is believed, says Sozomen, that they applied the cross to a dead body, which instantly revived. St. Paulinus and St. Sulpitius Severus mention only this last miracle. Helena, full of joy, adored not the wood itself, says St. Ambrose, which would have been a Pagan folly, but the king of heaven who suffered upon it. She took part of this treasure to carry to her son, and inclosing the rest in a silver box, she committed it to the bishop of Jerusalem. It was carefully kept in the church, which was built there, and the bishop alone had the power to give little pieces of it, which were considered as a singular favour and blessing. St. Paulinus relates a *very singular thing* concerning that part of the cross which was at Jerusalem. This cross, says he, having a vital virtue in an insensible and inanimate substance, hath yielded, and continues to yield, almost daily, its precious wood to the desires of an infinite number of

persons, without suffering any diminution, continuing all the while as if it had been untouched. It permits itself every day to be divided into several parts, and yet remains exposed entire to the veneration of the people. St. Cyril of Jerusalem says only, that the pieces of the cross were brought away from Jerusalem, and were spread all over the earth twenty-five years after." (H. E. vii. 5.) In the review of this relation a difficulty occurs, whether the discovery of the cross was a fiction formed some years after the death of Helena and of Constantine, or whether Helena really found a cross. Upon the whole, it seems most probable, that the story was invented by the Christians at Jerusalem, after the emperor and his mother were dead. The discovery in the time of Constantine rests principally upon the authority of Cyril of Jerusalem, the only witness who lived at that time, and who speaks of no miracles attending the discovery; and the question is, whether the epistle of Cyril, which mentions it, be genuine or spurious, or interpolated; and also whether Cyril, supposing it genuine, made up that part of the story himself, and dated the discovery at too early a period. If Helena found a cross, it is impossible now to know how the fraud was conducted, on the part of those who were actors, both hid and finders, in this transaction. Eusebius, who lived at the time, and was bishop of Cæsarea, in the neighbourhood, says not a word of the cross, though he relates the discovery of the sepulchre of Christ, and mentions the magnificent church which was erected there, and names Macarius as the person to whom the care of the building was committed. (Vit. Const. iii. 25, &c.) It is, therefore, to be concluded, either that he knew nothing, or believed nothing of it. One would hope that the letter ascribed to St. Cyril is spurious or interpolated. Helena was fourscore years old when she took this journey to Jerusalem; and it is more probable that she should have been imposed upon, than that she should have had any share in the contrivance. After her death she was faint and highly honoured: her body is said to be in an abbey in France, and also at Rome; but there is no great inconvenience in supposing it to be in two places at once. The multiplication of the cross attested by Paulinus, leads us to this opinion. (See Tillemont, H. E. vii. 18.) The ecclesiastics of Jerusalem, at whatever time they contrived the discovery of the cross, knew their own interest very well. It must have drawn a swarm of pious vagrants to their city, and have brought in great revenues to the church and to the bishop, if they gave only *6d.* a-piece, to see the box in which the cross was locked up. The finding of the cross hath also been ascribed to one Judas, a Jew, by Gregory of Tours. See the remarks of J. Basnage, *Hist. des Juifs*, vi. 14. § 10. Jortin's Remarks on E. H. vol. iii. Gibbon's *Hist.* vol. iv.

Cross, *Exaltation of the*, an ancient feast, held on the 14th of September, in memory of this, that Heraclius restored to mount Calvary the true cross in 628, which had been carried off fourteen years before, by Chosroes, king of Persia, upon his taking Jerusalem from the emperor Phocas.

The adoration of the cross appears to have been practised in the ancient church, in as much as the heathens, particularly Julian, reproach the primitive Christians with it. And we do not find that their apologists disclaimed the charge. Mornay, indeed, asserted, that this had been done by St. Cyril, but could not support his allegation at the conference of Fontainebleau. St. Helena is said to have reduced the adoration of the cross to its just principle, since she adored in the wood, not the wood itself, which had been direct idolatry and heathenism, but him who had been nailed to this wood. With such modifications, some protestants have been induced to admit the adoration of the

C R O S S .

crosses. John Hufs allowed of the phrase, provided it were expressly added, that the adoration was relative to the person of Christ. The Roman catholics have been charged, in our opinion unjustly, with the adoration of the cross. To this purpose, it has been said, that Imbert, the good prior of Gascony, was severely prosecuted in 1683, for telling the people, that in the ceremony of adoring the cross, practised in that church on Good Friday, they were not to adore the wood, but Christ who was crucified on it: the curate of the parish told them the contrary: it was the wood! the wood! they were to adore. Imbert replied, it was Christ, not the wood: for which, it is said, that he was cited before the archbishop of Bourdeaux, suspended from his functions, and even threatened with chains and perpetual imprisonment. It little availed him to cite the bishop of Meaux's distinction; it was answered, that the church allowed it not. This story we have cited, as it has been related by various authors, in order to have an opportunity of contradicting the allegation implied in it, considered as a charge against the Catholics. We are well assured by a Catholic priest, of unquestionable veracity and honour, that as Bossuet's exposition was solemnly approved of at its first publication, by the whole prelatial body of France, and by the reigning pontiff, Innocent XI., so it will be formally subscribed to, should the occasion require it, by every Catholic bishop in the three kingdoms, and by Pius VII. himself. But it is unnecessary to add any thing further on this subject, besides appealing to the very words of the council of Trent on the subject in question; *viz.* of a council from the doctrinal decrees of which the Catholics are never permitted to swerve, and which was specially held to determine the sense of their church upon all modern controversies. "Imagines porro Christi, Deiparæ Virginis, & aliorum sanctorum in templis præsertim habendas, & retinendas, eisque debitum honorem, & venerationem impertiendam: non quod credatur inesse aliqua in iis divinitas vel virtus propter quam sint colendæ; vel quod ab eis sit aliquid petendum; vel quod fiducia in imaginibus sit figenda: velut olim fiebat à gentibus quæ in idolis spem suam collocabant: sed quoniam honores quæ eis exhibetur refertur ad prototypa quæ illæ representant: ita ut per imagines quas oculamur, & coram quibus caput aperimus & procumbimus Christum adoremus & sanctos, quorum illæ similitudinem gerunt, veneremur." Concil. Trid. sess. xxiv. cap. 21.

CROSS-bearer, port-crois, cruciger, in the Romish Church, the chaplain of an archbishop, or a primate, who bears a cross before him on solemn occasions.

The pope has the cross borne before him every where; a patriarch any where out of Rome: and primates, metropolitans, and those who have a right to the pallium, throughout their respective jurisdictions.

Gregory XI. forbid all patriarchs and prelates to have it borne in presence of cardinals. A prelate bears a single cross, a patriarch a double cross, and the pope a triple one on their arms.

CROSS-bearers, also denote certain officers in the Inquisition, who make a vow before the inquisitors, or their vicars, to defend the catholic faith, though with the loss of fortune and life. Their business is to provide the inquisitors with necessaries. They were formerly of great use; but in process of time, some of their constitutions were changed, and they were called, of the penance of St. Dominic. Limborch's Hist. Inq. by Chandler, ch. x. See **FAMILIARS,** and **INQUISITION.** See also **ALBIGENSES.**

CROSS-birth, in *Midwifery.* When in labour, the arm, shoulder, or any other part of the child than the head, presents to the mouth of the uterus, it is usually called a cross-birth.

CROSS, pectoral, is a cross of gold or silver, or other precious materials, often enriched with diamonds, which the bishops, archbishops, &c. and regular abbesses, wear hanging from the neck.

CROSS of Jesus Christ, order of, was instituted, in 1217, by St. Dominic, and confirmed by pope Innocent VI. in 1220. The badge of this order was a cross potence per cross counter-changed, argent and sable, in pale the letter P, surmounted with the letter X, or.

CROSS, order of the starry, or Croisade, an order for ladies instituted in 1668, by the empress Eleonora de Gonzaga, wife of the emperor Leopold; on occasion of the miraculous recovery of a little golden cross, wherein were enclosed two pieces of the true cross, out of the ashes of part of the palace. It seems the fire had burnt the case wherein it was inclosed, and melted the crystal; yet the wood remained untouched. The ensign of the order is a medal of gold chased and pierced; in the centre the imperial eagle; over all a cross surmounted with the letters I. H. S., and a small cross over the letter H, with a motto, "*Salus et Gloria:*" worn pendent at the breast by a small black ribbon.

CROSS of St. Louis, a French order, which was purely of a military nature. It was instituted by Louis XIV. in addition to that of *Christian Charity*, which had been founded by Henry III., king of France, in favour of maimed officers and soldiers in 1693. This order consisted of eight great crosses and 24 commanders, besides the king, who was grand master, the dauphin always invested with it, the treasurer, recorder, and usher. Land and sea officers wore it promiscuously. The cross consisted of eight points enamelled, white, edged with gold, having in the angles four *flurs-de-lis*, and on the middle a circle, within which is the image of St. Louis in armour, holding in his right hand a crown of laurel, and in his left a crown of thorns, &c. The cross of the knights was attached to the button hole of the coat by means of a small ribbon crimson coloured and watered.

On one side was this inscription, *Ludovicus magnus instituit 1693;* and on the reverse there was a blazing sword with the following words, *Bellicæ virtutis præmium.*

CROSS, Maids of the, a community of young women instituted in 1265, at Roye, in Picardy, and since dispersed to Paris and other towns. They instruct young persons of their own sex; some take the three vows of poverty, chastity, and obedience; others retain their liberty. They are under the direction of a superior.

CROSS, judgment of the, a custom in France and other parts of Europe, in the middle ages, of giving judgment in favour of one of two contending parties, who held his arms for the longest time lifted up to a cross.

Charlemagne ordered, that if any difference should arise between his children, they should be terminated by the judgment of the cross. In a placitum or trial in the presence of this emperor, we have such an account of it as sufficiently shews the imperfect manner in which justice was administered even during his reign. In the year 775, a contest arose between the bishop of Paris and the abbot of St. Denis, concerning the property of a small abbey. Each of them exhibited deeds and records in order to prove the right to be in them. Instead of trying the authenticity, or considering the import of these, the point was referred to the *judicium crucis*, in the manner stated in the sequel of this article. The person employed by the bishop on this occasion, had less strength, or less spirit than his adversary, and the question was decided in favour of the abbot. If a prince so enlightened as Charlemagne countenanced such an absurd mode of decision, it is no wonder that other monarchs should tolerate it so long. Lewis the Pious confined this judgment

judgment to ecclesiastical affairs: his son Lotharius abolished it in all cases; and he abolished even the trial by cold water. When we consider how much the cross was an object of superstitious veneration at the period to which we now refer, we cannot be surprised that it was employed as an ordeal. It was used to this purpose in a variety of ways. In criminal trials, the judgment of the cross was commonly thus conducted: When the prisoner had declared his innocence upon oath, and appealed to the judgment of the cross, two sticks were prepared exactly like one another; the figure of the cross was cut on one of these sticks, and nothing on the other; each of them was then wrapped up in a quantity of fine white wool, and laid on the altar, or on the relics of the saints; after which, a solemn prayer was put up to God, that he would be pleased to discover, by evident signs, whether the prisoner was innocent or guilty. These solemnities being finished, a priest approached the altar, and took up one of the sticks, which was uncovered with much anxiety. If it was the stick marked with the cross, the prisoner was pronounced innocent: if it was the other, he was declared guilty. (Spelm. Gloss.) When the judgment of the cross was appealed to in civil causes, the trial was conducted in this manner: the judges, parties, and all concerned, being assembled in a church, each of the parties chose a priest, the youngest and stoutest that he could find, to be his representative in the trial. These representatives were then placed one on each side of some famous crucifix; and at a signal given, they both at once stretched their arms at full length, so as to form a cross with their body. In this painful posture they remained while divine service was performing; and the party whose representative dropped his arm first, lost the cause. (Murator. Antiqu. t. 111.)

CROSS, in *Baptism*. In the administration of this Christian ordinance, a practice, though not enjoined by any express command, or sanctioned by any known example in Scripture, was adopted at an early period, of signing the forehead of the person baptized with the sign of the cross. The use of the cross indeed was very frequent in the primitive times. Such was the respect paid to it, that it formed, in one mode or other, a distinguishing part of their civil and religious ceremonies. The first Christian writer who mentions it in connection with baptism, is Tertullian, after the middle of the 2d century; and he also says (De Cov. Mil. c. 2.) "that at every setting out, or entry upon business, whenever we come in, or go out from, any place, when we dress for a journey, when we go into a bath, when we go to meat, when the candles are brought in, when we lie down or sit down, and whatever business we have, we make on our foreheads the sign of the cross:" and speaking of baptism, in his treatise, ("De Carn. Resur.") he says, "the flesh is signed, that the soul may be fortified." This signation was performed with the oil used in the attendant ceremony of unction, with which the priest touched the head or forehead in the form of a cross. Tertullian, however, on other occasions, describes the custom of baptizing without mentioning signing with the cross. This father also speaks (De Præscript. adv. Hæret.) of priests, who, imitating the service of God in the idolatrous rites of Mithras, baptized some as his believing and faithful servants, and signed them in their foreheads as his soldiers. Cyprian, who lived in the third century, observes (De Unit. Eccles. § 16.) that this sign was made in the forehead; and hence (De Lapsis, § 1.) he calls a Christian's forehead, "a signed forehead." In succeeding ages, the same practice of signing with the sign of the cross is mentioned as used whenever a person was baptized; and it was done, as the

form of baptism in the service of the church of England expresses it, "in token that hereafter he shall not be ashamed to confess the faith of Christ crucified, and manfully to fight under his banner against sin, the world, and the devil, and to continue Christ's faithful soldier and servant unto his life's end." It has been said, however, that this ceremony does not appear to have been used in baptism till the latter end of the fourth or fifth century. See BAPTISM. To this ceremony, as well as some others, enjoined by the service of the church, and by the injunctions of queen Elizabeth, the puritans scrupled conformity, A. D. 1567; alleging that the sign of the cross in baptism is no part of the institution as recorded in Scripture; and that, although it was usual for Christians, in the earlier ages, to cross themselves, or make a cross in the air upon some occasions, yet there is no express mention of its being used in baptism till about the 5th century. They also alleged, that it had been abused to superstition by the church of Rome, and regarded with such veneration by some protestants, that baptism itself was thought to be imperfect without it; and that for those reasons it ought to be laid aside. On occasion of a debate upon the cross in baptism in the upper house of convocation, A. D. 1603, Bancroft, bishop of London, and some others warmly vindicated it; but Dr. Rudd, bishop of St. David's, pleaded, with singular candour and considerable eloquence, but without much effect, for charity and moderation. He was answered by other prelates, and forbidden by the president to reply. The puritans, and also the protestant dissenters of modern times, object to the imposition of any rite, the observance of which, as a religious act, is not authorized by precept or pattern in the Christian code of their faith and practice.

CROSS, in *Botany*, is used to express the arrangement of the petals of certain flowers; called *planta flore cruciformi*. See CRUCIFORM.

CROSS, in *Coins*, a name given to the face, or right side, the other being called the pile, or reverse. It has been a common error that the reverse was meant by the cross, because at this time with us marked with figures disposed in that form; but the stamping of the head of the prince in these kingdoms, on the right side of the coin, was preceded by a general custom of striking on that part the figure of a cross, while the other, called the pile, contained the arms, or some other device.

CROSS, in *Dialling*. See DIAL.

CROSS, in *Heraldry*, is defined by Guillim, an ordinary composed of fourfold lines; whereof two are perpendicular, and the other two transverse; for so we must conceive of them, though they be not drawn throughout, but meet by couples, in four right angles, near the fess-point of the escutcheon. See ORDINARY.

The content of a cross is not always the same: for when it is not charged, cantoned, nor accompanied, it has only the fifth part of the field; but if it be charged, it must contain the third part thereof.

This bearing was first bestowed on such as had performed, or at least undertaken, some service for Christ, and the Christian profession; and is held, by divers, the most honourable charge in all heraldry. What brought it into such frequent use was the ancient expeditions into the Holy Land; and the holy war pilgrims, after their pilgrimage, taking the cross for their cognizance; and the ensign of that war being the cross.

In those wars, says Mackenzy, the Scots carried St Andrew's cross; the French a cross argent; the English a cross or; the Germans, sable; the Italians, azure; the Spaniards, gules.

C R O S S .

St. George's cross, or the red cross, in a field argent, is now the standard of England; that faint being the reputed patron of this nation.

Guillim enumerates thirty-nine different sorts of crosses used in heraldry, the several names of which here follow; and the descriptions of them are to be sought for under their proper articles. A cross voided, a cross wavy voided, a cross patée fimbriated, a cross patée fitché on the foot, a cross patée on three parts and fitché on the fourth, a cross engrailed, a cross patonée, a cross flory, a cross patonée voided, a cross avelane, a cross patée lambeaux, a cross furchée, a cross croiset, a cross croiset fitchée at the point, a cross bottonée, a cross pommée, a cross urdée, a cross dégradé fitchée, a cross potent, a cross potent fitché, a cross calvary, a cross croiset set in degrees, a cross patriarchal, a cross anchored, a cross molinée, a cross clechée, a cross flory or fleur-de-lis, a cross double fitchée, a cross a-feize points, a cross milrinée, a cross raguled, a cross pointed voided, a cross pall, a tau or St. Antony's cross, a cross voided and coupé, a cross coupé pierced, a cross molinée pierced lozenge-ways, a cross molinée quarter-pierced, a saltire or St. Andrew's cross, which will be distinctly spoken of under that denomination; and so all the other may be found more particularly described under the names of their several differences.

Colombiere makes seventy-two distinct sorts of crosses, of which we shall only mention those that differ from such as have been mentioned above; as a cross remply, which is only one cross charged with another; a cross party, that is, one half of one colour, and the other of another; a cross quartered, that is, the opposite quarters of several colours; a cross of five pieces, that is, of so many colours; a cross mouffue, and abaissée; a cross barbée; a cross croissanante, or crescented, that is, having a crescent at each end; a cross forked of three points; a cross pometée of three pieces; a cross ressercelée; a cross pointed; a cross ankered, and sur-ankeré; a cross ankered with snakes heads; a cross orlé; a high cross; a cross rayonnant, or casting out rays of glory; a cross of Malta; a cross of the Holy Ghost; a cross forked like the ancient rests for musquets; a cross with eight points; a cross bourdonnée; a cross cramponnée and tournée; a cross cablée; a cross inclining; a cross pater-nostre, that is, made of beads; a cross tresse; a cross fleuronée; a cross vuidee, glechée, and pometée; a cross crenellée and bailliée; a cross with four steps to every arm; a cross rounded; a cross and an half; a cross estoilée, or starways; a cross corded; a cross doubled of six pieces set together; a double cross split in pale; a long cross cut in pieces and dismembered; a cross coupé or cut through in fesse, of the two contrary colours to the field; a chevron surmounted by an half cross; four tails of ermine in a cross, the tops of the ermines opposite to each other in the middle; four pieces of vair placed cross-ways, and counterpointing in the centre; the cross or sword of St. James; a cross potence cramponnée on the dexter upper arm, and a potence about the middle of the shaft.

These are the various crosses we find in the aforesaid authors; which some may think too many, as not being all used in England: but heraldry extends to all countries; and all terms used require to be explained.

Nor is it only in crosses that the variety is so great; the like is found in many other bearings, and particularly in lions, and the parts of them; whereof the same Colombiere gives us no less than ninety-six varieties. Leigh mentions but forty-six several crosses; Sylvanus Morgan, twenty-six; Upton, thirty; Johannes de Bado Aureo, twelve; and so others, whom it is needless to mention. Upton owns he dares not presume to ascertain all the various crosses used in

arms, for that they are at present almost innumerable: and therefore he only takes notice of such as he had seen used in his own time.

Cross, in the *Manege*, a figure which horses describe in making curvets. To teach a horse to describe this figure, he should first be made to walk upon a straight line, about four times the space of his own length; then go backward upon the same line; afterwards advance to the middle of it, then go side ways to the right hand about twice the measure of his own length; the same on the left, and then return to the middle of the line, where he should stop and be caressed. When he can tread these lines equally, advance, go backward, and to either side, flying the heel, it will be right to put him to make a curvet at the beginning, the middle, and the end of each line; and if, upon repeated trials, he is found ready and obedient, he may be called upon to make the entire cross in curvets.

Cross, in *Mining*, are two nicks cut on the superficies of the earth, thus \pm , which the miners make when they take the ground, to dig for ore. This cross gives the miners three days liberty to make, and set on stones.

As many of these crosses as the miner makes, so many mears of ground he may have in the vein, if he set on stones within three days after the making his cross or crosses. But if he makes but one cross, and a stander-by makes the second, and a stranger makes the third, every one is served with the next mear, according as they have, first or last, sooner or later, made their cross, or crosses, upon the ground.

Cross, in *Surveying*, is a mathematical instrument of great utility to a land surveyor, as it enables him, while going about his survey with his chain, to measure the length of the station lines, at the same time to take offsets, or perpendicular directions to the corners of a field, or irregular boundaries; so as to get the exact figure of the boundaries of one or more fields. When a theodolite is dispensed with, the use of this instrument is absolutely necessary. The principle of this instrument consists in two lines of sight, placed at perfect right angles to each other, and about 4 inches apart, either on wood or brass. *Fig. 1, Plate III. (Surveying)* represents one usually made of brass by mathematical instrument makers; it consists of four sights fixed on a cross, at right angles to each other, and when in use is screwed to a wooden staff about 6 feet long, with an iron pointed ferril at the bottom, to go easily into the ground.

For portability, the sights are made to take away from the cross, by unscrewing four screws, *a, a, a, a*, and the staff by brass sockets to unscrew into three parts, each two feet in length.

Another kind of cross, (and rather more used by surveyors,) is made of a brass cylindrical tube, about two or three inches in diameter, with four sight-slits pierced out of it's circumference at perfectly equal distances, which cause any two of the opposite sights to be at right angles to the other two. (See *fig. 2.*)

The correctness of the sights of any cross may be easily proved, by looking at one object through two of the sights, and without moving the instrument, observing an object through the other two sights; then turning the cross on its staff, look at the same object through the opposite sights; if they are accurately in the direction of the sights before, the instrument is correct.

To survey a field by the cross, (suppose of the form of *A B C D E*, (*fig. 3.*)): place marks at the several angles. Measure the line *A C*, and also the perpendiculars from the angles, to that line as determined by the cross. To find a perpendicular, such as at *F*, place marks at pleasure on the line *A C*, and set the cross at the same time, in such a place,

so that through two of the sights you can observe two of the staves placed on that line, and the staff at E. If at this station E be not visible, remove the instrument backwards or forwards, till the lines, A F, E F, make a right angle in F, by which means the triangle, A F E, will be had. After the same manner is the point, H, found, where the perpendicular D H falls, whose length, together with that of H F, is measured to have the plot of the trapezium E F H D.

Again, measure H C, making a right angle with H D, and the figure of the triangle, D H C, will be had. Lastly, find the point G, where the perpendicular, B G, falls after the same manner, and the whole figure of the plot, A B C D E, will be given; the area of which is obtained by adding those of the triangles and trapezium together.

The determination of a very irregular boundary of a river, hedge, &c. by the cross, is as follows: Let A b i k l m n, *fig. 4*, be the irregular boundary, measure a straight line, as A B, along the side of the foregoing line, and while measuring, observe when you are opposite to any corner or bend of the hedge, as at *c d e*, &c. From thence measure the perpendicular offsets as at *e h*, *d i*, with the offsets staff; but if they are long ones, with the chain. The situations of these offsets are readily found by the cross as above directed.

Fig. 2, represents the cylindrical cross with the additional improvements by Mr. W. Jones. A small compass and needle are applied at its upper part, as at A, and a moveable graduated base at B, turning by rack and pinion. A nonius, C, is engraved at the bottom of the cylinder, so adapted to the graduations of the moveable limb, as to subdivide them into 5 minutes of a degree. Where no great accuracy is required, this small pocket instrument unites the advantages of a cross, circumferentor, and small theodolite.

A useful surveying cross by reflexion, (*fig. 5*.) was contrived many years ago by the father of the late Mr. George Adams. It consists of the index and horizon glasses of the Hadley's quadrant, placed together with the inclination of 45 degrees. The small mirror, A, is left half unsilvered, so that an object seen reflected first from the large glass, and then from the small one, will appear to coincide with another object, seen by direct vision through the unsilvered part of the glass, whenever the two objects subtend a right angle from the centre of the instrument. Thus, in *fig. 6*, suppose a person at C looking into the silvered part of the small mirror, sees the windmill, B, after two reflections, upon, or coincident with a tree, A, visible through the unsilvered part of the glass; he is certain that the windmill, C, is perfectly at right angles with the tree A, at the point where the centre of this optical square is held. Upon this principle, the reader may readily conceive how, with its assistance in the field, a perpendicular may be found to any given point, or from any particular point to raise a perpendicular. For the objects, by direct vision, through the transparent part of the glass, will always coincide with the objects seen by reflection, when they are at right angles to each other from the centre of the instrument. *Fig. 5*, represents the glasses uncovered; when complete, it has a small brass box cover, with an opening behind the glass A, and a slight hole for the eye, as shewn at C, *fig. 6*.

This small pocket instrument has been found useful to military officers for determining the perpendicular positions of men or marks in the field. See Jones's edition of Adams's Geometrical, &c. Essays, 1803. page 200.

CROSS, as a signature to a deed, is derived from the Saxon practice of affixing the sign of the cross, whether they could write or not. Several charters still remain, to which

kings and persons of great eminence affix "signum crucis manu propria pro ignoratione literarum." Hence is derived the expression of *signing* instead of *subscribing* a paper. In the 9th century, Herbaud Comes Palatu, though supreme judge of the empire by virtue of his office, could not subscribe his name. So late as the 14th century, Du Guesclin, constable of France, the greatest man in the state, and one of the greatest men of his age, could neither read nor write. The greater number of the clergy were not much less ignorant than the laymen. Many dignified ecclesiastics could not subscribe the canons of those councils in which they sat as members.

CROSS-Bars. See CARRIAGE.

CROSS-Bar Shot, are shot with iron bars crossing through them, sometimes standing six or eight inches out at both sides. They are used at sea, for injuring the enemy's rigging; and at sieges, for destroying the palisades in the covert-way, ditches, &c.

CROSS-Battery, in War. See BATTERY.

CROSS-Bill, in Chancery, is an original bill, by which the defendant prays relief against the plaintiff.

CROSS-Bill, in Ornithology, the English name of the *LOXIA CURVIROSTRA*, which see.

CROSS-Bow, a species of bow made use of before, and for a considerable time after, the invention of gunpowder, for throwing arrows, &c. See BOW, and ARCHERY.

CROSS, Cape, in Geography, a cape of Upper Canada, which projects from the N.E. side of St. Mary's river, at the outlet of Lake Superior, opposite the Falls. N. lat. 46° 30'. W. long. 84° 50'.—Also, a cape on the western coast of North America. N. lat. 57° 57'. E. long. 223° 21'.

CROSS-Creek, a township of America, in Washington county, Pennsylvania.

CROSS Causes, in Chancery, are such as occur on a cross-bill filed by the defendant against the plaintiff in the original cause: these are generally contrived to be brought in together, that the same hearing and the same decree may serve for both of them.

CROSS-Fell, in Geography, a mountain of England, in Cumberland, which, in Dr. Garnett's opinion, is the highest mountain in England. In Mr. Houseman's Description of Cumberland, its height above the level of the sea is stated to be 3390 feet; according to Pennant, 3839 feet. The summit presents a large heap of loose whitish free-stone, or, more probably, argillaceous grit.

CROSS-Fire, in the Art of War, is when the lines of fire from two or more parts of a work cross one another. It is frequently made use of, to prevent an enemy's passing through a defile. The flanks as well as the faces of two adjoining bastions afford cross-fires. The faces of two adjoining redoubts furnish a cross-fire.

CROSS-Furrow, in Agriculture, a term signifying the oblique or cross grip, or gutter, which is formed in tillage lands, for the purpose of receiving the superabundant rain, or other water, from the outer and other furrows, in order to convey it away from them into a side ditch, or other proper outlet. See FURROW.

CROSS-Furrowing, the process or operation of forming or constructing cross gutters or furrows. It is a business which requires considerable care and attention to perform it well; but which is capable of being executed either by the spade or the plough, when properly constructed for the purpose. Some attentive farmers are likewise in the habit of having recourse to the spade after the plough, in performing this sort of field work. It should always be executed in a perfect and complete manner, as much of the success of the crop depends upon it. See FURROW, and FURROWING.

Cross-grained Stuff, in *Joinery*. Wood is said to be cross-grained, when a bough or branch has shot out of it: for the grain of the branch, shooting forward, runs athwart that of the trunk.

In wood well grown this defect is scarce perceivable, except in working; but in deal-boards these boughs make knots. If the bough grew up with the young trunk, instead of a knot is found a *curling in the stuff*; very sensible under the plane.

Cross-Haven, in *Geography*, a small town of the county of Cork, Ireland, situated at the mouth of the river Oonbuy, which flows into the west of Cork harbour. Sir Francis Drake, in 1589, having a small squadron of five ships of war, was chased into this harbour by a superior fleet of Spaniards, and moored his ships in a safe basin behind a hill, whilst the Spaniards failed up the harbour of Cork in pursuit of him, and returned without discovering his retreat. A little up this river Oonbuy, near the spot where the castle of Corigoline was built, the first earl of Cork intended to have founded a town, which should rival Cork in trade; but the rebellion of 1641 ruined the design. Cross-haven has about 50 houses, placed one above another on the side of a hill, the permanent inhabitants of which are chiefly fishermen; but it is much frequented in the summer for sea-bathing. It is about 9 miles from Cork. Smith.

Cross-Headings, in *Canal-making*, are small culverts or foughs, branching from the main heading or drain, where a tunnel or subterraneous arch is to be formed, for more effectually collecting the springs out of the strata, without which it is often impossible to proceed with the work. See CANAL, and TUNNEL.

Cross-Jack, or *Square-Sail* of a sloop, in *Nautical Language*, is a quadrilateral sail, square on the head and leeches; the head is bent to the cross-jack yard, and it hangs at right angles with the ship's length, and parallel to the deck, extending within six inches of the cleats on the yard-arms. The depth of this sail is four-fifths of the depth of the fore-leech of the main-sail. This sail has two reef-bands, four inches broad; the lower one, at one-sixth of the depth of the sail from, and parallel to, the foot; and the upper one at the same distance from the head. A reef-criingle is made at each end of the upper reef-band; and three bow-line-criingles are made on each leech; the upper bow-line-criingle is on the middle of the leech, and the others are equally distant from that and the clue. The clues are sometimes marled on; and for this purpose, ten marling-holes are made each way from the clues. The bolt-rope, on the foot and leeches, should be $1\frac{1}{2}$ inch or 2 inches in circumference; and, on the head, 1 or $1\frac{1}{2}$ inch. The clue-rope, when there is one, should be $2\frac{1}{2}$ inches. When sewing on the bolt-rope, one inch of slack-cloth should be taken up in every cloth in the head and foot. To find the quantity of canvas in this sail; multiply the number of cloths by the depth, and add the quantity in the foot-gores, bands, and pieces.

Cross Island, in *Geography*, an island in the Atlantic ocean, near the coast of Mann, at the entrance into Machias bay. N. lat. $44^{\circ} 30'$. W. long. $67^{\circ} 15'$.—Also, one of the smaller Shetland islands of Scotland; 35 miles S. of Lerwick.

Cross Multiplication, a method of multiplying feet and inches, by feet and inches, or the like; so called, because the members are multiplied *cross-wise*. See MULTIPLICATION.

Cross-Piece, in *Ship-Building*, a rail of timber extended over the windlafs of a merchant-ship, from the knight-heads

to the belfry. It is stuck full of wooden-pins, which are used to fasten the running-rigging as occasion requires.

Cross Sound, in *Geography*, a bay of the North Pacific ocean, on the west coast of North America, discovered by captain Cook on the 3d of May, 1778, and so called from the name given in the English calendar to the day of discovery. This inlet appeared to branch into several arms, the largest of which turned to the northward. The S.E. point of this sound is a high promontory, to which was given the name of *Cross Cape*. It lies in N. lat. $57^{\circ} 57'$. E. long. $223^{\circ} 2'$. The most advanced point of land to the N.W. lies under a very high peaked mountain, to which was given the name of "Mount Fair-weather." M. la Pérouse, in his "Voyage round the World," (vol. i. Eng. edit.) observes, that the entrance into Cross Sound appears to form two very deep bays, where it is probable ships might find very good anchorage. At this Sound the high mountains covered with snow terminate: their summits are from 13 to 1400 toises high. The lands that form the coast to the S.E. of Cross Sound, though 8 or 900 toises high, are covered with trees to the top; and the chain of primary mountains seems to go very far into the interior of the continent. To the northward of Cross Sound is Mount Crillon, which is almost as high as Mount Fair-weather, which lies to the northward of the bay des Français. These points serve as land-marks to the harbour which they surround; and as their latitude does not differ 15 minutes, one of them, in coming from the southward, may be easily mistaken for the other. Mount Fair-weather is accompanied with two less elevated mountains; and Mount Crillon, which is more isolated, inclines its point to the southward. In the vicinity of Cape Cross there is a great number of small islands very thickly wooded, between which are several channels that must have formed good roads. Captain Cook has called this part of the coast the "Bay of Islands." From Cross Sound to Cape Enganno (the Cape Edgecumbe of Cook) lies an extent of coast of 25 leagues, in which are 25 different harbours; and Perouse says, that three months would scarcely suffice to explore this labyrinth of navigation. Cape Enganno is a low land covered with trees, and stretching far out to sea. Mount St. Hyacinth (Mount Edgecumbe of Cook) rests upon it and forms the frustum of a cone, but rounded off at the top, and is at least two toises high. To the eastward of this mount is an extensive bay, so open to the S. and S.E. winds, which are the most dangerous, that navigators ought to dread anchoring there. Captain Dixon anchored there to trade for furs, and gave it the name of "Norfolk Sound." Its latitude was $53^{\circ} 5'$ N., and its longitude $138^{\circ} 16'$ W. from the meridian of Paris. Captain Cook perceived the mouth of this creek May 2d, 1778, but did not anchor there. Its shores are covered with trees, of an equal height with those to the southward of Cross Sound. The summits of the hills are somewhat covered with snow; and they are so pointed and numerous, that their appearance is altered by the least change of situation. These hills are some leagues within the land. Smaller hills lie against their sides, and are connected with a low and undulating base, extending as far as the sea. Before the shore lie a great number of islands; for to the northward and southward of Cape Enganno the coast is bordered with islands for the space of 10 leagues. From the extremity of these islands to the cape, called by Perouse "Cape Tschirikow," in honour of the celebrated Russian navigator who landed on this part of America in 1741, are two large bays, appearing to stretch far into the land, and called by La Pérouse "Port Necker" and "Port Guibert." Dixon anchored

chored in one of them, which he called "Port Banks." N. lat. $56^{\circ} 35'$. W. long. from Paris $137^{\circ} 20'$. At a small distance lies a cluster of five islands, separated from the continent by a channel four or five leagues wide, which neither captain Cook nor the pilot Maurelle has noticed. La Perouse called them "Iles de la Croÿere." from the celebrated French geographer, Delisle de la Croÿere, who accompanied captain Tschirikow, and who died during that voyage, and whose place of interment was discovered by captain Clerke in Kamtschatka. La Perouse, during his stay at Petropawlowka, had an opportunity of retaliating this act of kindness with similar liberality; for finding that the inscription on captain Clerke's tomb had been destroyed by the Kamtschadales, he took pains to re-establish it, as it occurs in the account of Cook's third voyage, and in order to prolong its duration, he caused it to be engraved on copper. Dixon has distinguished these five islands by the name of "Foggy islands." La Perouse has placed them in $55^{\circ} 50'$ N. lat. and $137^{\circ} 11'$ W. long.; Dixon in $55^{\circ} 50'$ N. lat. and $137^{\circ} 3' 45''$, reduced to the meridian of Paris. La Perouse, being in $55^{\circ} 39' 31''$ N. lat. and $137^{\circ} 5' 23''$ W. long., according to his time-keepers, perceived great openings between considerable islands, at a distance from the continent; which Archipelago commences four leagues to the S.E. of Cape Tschirikow, and apparently extends as far as Cape Hector. Port Bucarelli of Maurelle is in this part. (See BUCARELLI.) La Perouse suggests, that from Cross Sound he had coasted only along islands; and Dixon confirms his opinion. La Perouse, sailing along the coast at a distance of 3 leagues, saw the isles of "San Carlos," the principal of which lies S.E. and N.W., and may be 2 leagues in circumference. A long chain connects it with other little islands, stretching far out into a channel of considerable breadth. The place of the island farthest from the continent, at the distance of half a league, was ascertained to be $54^{\circ} 48'$ N. lat. and $136^{\circ} 19'$ W. long. Ranging for a considerable distance along the coast, La Perouse discovered a bay, which he called "La Touche bay," N. lat. $52^{\circ} 39'$, W. long. $134^{\circ} 49'$, affording, as he had no doubt, very good anchorage. Advancing farther, he saw a cape, which apparently terminated the coast of America; and he also perceived four or five small islands near it, which he named "Islets Kerouart," and the point "Cape Hector," the cape "St James" of Dixon; which, according to La Perouse, is in N. lat. $51^{\circ} 57' 20''$, and W. long. $133^{\circ} 37'$, and according to Dixon in $51^{\circ} 46'$ N. lat. and $132^{\circ} 20'$ W. long., reduced to the meridian of Paris. The opposite coast of "La Touche bay" was named by La Perouse "Cape Butache;" and the breadth of the channel or gulf, from east to west, was ascertained to be 30 leagues between Cape Hector and Cape Fleurieu (Cape Cos of Dixon). The situation of this cape is $51^{\circ} 45'$ N. lat. $131^{\circ} 15'$ W. long. according to La Perouse; and N. lat. $51^{\circ} 30'$, W. long. from Paris $130^{\circ} 32'$, according to Dixon. This cape forms the point of a very high island. Along the coast lie several clusters of islands, called by La Perouse "Isles Sartine," and by Dixon "the Islands of Beresford;" situated, according to the former, in N. lat. $50^{\circ} 56'$, W. long. $131^{\circ} 38'$; and, according to the latter, in N. lat. $50^{\circ} 52'$, and W. long. from Paris $132^{\circ} 3'$. A passage may possibly lie between these islands, but it would be dangerous to attempt it. The "Woody Point" of captain Cook, forming a continuation of the coast from mount St. Elias to Nootka, is situated in N. lat. $50^{\circ} 4'$, W. long. from Paris $130^{\circ} 25'$. For other observations on this celebrated navigator on the west coast of America, we refer to *Port des FRANCAIS*, and the account of his voyage; and also to *NOOTKA*.

Cross-staff, a mathematical instrument, otherwise called the *FORE-staff*.

Cross-tining, in *Agriculture*, a term applied to a method of harrowing land, in which the harrow is made to pass up the interval it went down before, and down that which it previously passed up. See *HARROWING*.

Cross-trees, in a ship, cross-pieces of timber set on the head of the mast, and bolted, and let into one another very strongly. They are four in number, and are generally called cross-trees, but strictly speaking, only those which go thwart ships are called cross-trees; the other, in the largest ships, are called treffel-trees. Their use is to keep and bear the top-masts up; for the foot of the top-mast is always fastened into them, so that they bear all the stress. They also bear the tops, and are necessary to all masts which carry any other top, or flag-staff, at the head.

Cross-tree-yard, is a yard standing square, just under the mizen-top, and to it the mizen top is fastened below. See *CROSS-jack* and *YARD*.

Cross-veins, in *Mining*, are such mineral veins as branch from or cross the principal or rake-veins; if small, these are in Derbyshire denominated *STRINGS*, or *SCRINS*, which see. These cross-veins, according to Jameson, the translator of Werner, take place usually on the over-hanging or upper side of the vein, and less frequently on the lower or lying side.

Cross, Winter, in *Botany*. See *ERYSIMUM*.

Cross-wort. See *GALIUM cruciatum*.

CROSSÆA, in *Ancient Geography*, a country of Europe, which was a part of Thrace, before the kings of Macedonia united it to their kingdom. It was in a peninsula between the Thermaic gulf to the west, and the gulf of Strymon to the east. It contained the towns of LIPAXOS, COMBREA, LISÆ, GIGONOS, CAMPSA, IMILA, and GENIA. Steph. Byz. and Thucydides call it *Cronsis*, and the former makes it a part of Macedonia.

CROSSANDRA (from *κροσσος*, *frimbria*, and *ωνος*, *vir*, alluding to the fringed anthers), Salisb. Parad. Lond. t. 2. (*Ruellia infundibuliformis*; Roxb. MSS.) Clafs and order, *didynamia angiospermia*. Nat. Ord. *Acanthi*; Juss.

Gen. Char. *Cal.* five-leaved; leaves convolute-imbricated; inner ones gradually smaller. *Cor.* monopetalous; tube slender, enlarged at the base, swelling a little at the insertion of the stamens, open at the mouth; border one-lipped, trifid; segments emarginate. *Stam.* Anthers four, nearly sessile, fringed at the edges of the valves. *Pistl.* Stigma bifid. *Pericarp.* with two-seeded cells.

Sp. C. *undulata*. A pretty large upright shrub, flowering all the year round. *Stem* cylindrical, jointed; branches opposite. *Leaves* opposite, ovate-lanceolate, entire, undulated; petioles jointed at the base. *Flowers* in a dense terminal spike, of a dull orange colour; bracts three under each flower, ending in a sharp brittle; the middle one the largest. *Pericarp* swelled at the base into a round nut. Common in the pagoda gardens at Bengal.

CROSSE, a name given by the people of Guinea, and some other parts of Africa, to a kind of fruit very common among them. It very much resembles our common hazel-nut, but that the shell is not so hard. Phil. Transf. N^o 108.

CROSSE, Isle a la, in *Geography*, the name of a fort in North America, near Beaver river, situated on a low isthmus, in N. lat. $55^{\circ} 25'$. W. long. $107^{\circ} 48'$.—Also, a lake into which the Shagoina strait and rapid lead, in which the course is S. 20 miles, and S.S.W. 14 miles, to the Point au Sable; opposite to which is the direction S. of the Beaver river, bearing S. 6 miles; the lake in the distance

distance run does not exceed 12 miles in its greatest breadth. It now turns W.S.W., the isle a la Croise being on the south, and the main land on the north; and it clears the one and the other in the distance of 3 miles, the water presenting an open horizon to right and left; that on the left formed by a deep narrow bay, about 10 leagues in depth; and that to the right by what is called "la Riviere Creuse," or Deep-river, being a canal of still water, which is here 4 miles wide.

This lake and fort take their names from the island just mentioned, which received its denomination from the game of the crofs, that forms a principal amusement among the natives. The situation of this lake, the abundance of the finest fish in the world found in its waters, the richness of its surrounding banks and forests, in moose and fallow deer, with the vast number of smaller animals whose skins are precious, and the numerous flocks of wild fowl that frequent it in the spring and fall, make it a most desirable spot for the constant residence of some, and the occasional rendezvous of others, of the inhabitants of the country, particularly of the Knisteneaux. Who were the original people that were driven from it when conquered by the Knisteneaux, is not now known, as not a single vestige remains of them. The latter and the Chépewians are the only people that have been known here; and the last mentioned evidently consider themselves as strangers, and seldom remain longer than three or four years without visiting their relations and friends in the barren grounds, which they term their native country. The Knisteneaux, who for some time treated them as enemies, now allow them to hunt to the north of the track from Fort du Train upwards; but when they occasionally meet them, they demand contributions, and punish resistance with their arms. When the Europeans first penetrated into the country, in 1777, the people of both tribes were numerous; but the small pox was so fatal, that there does not exist of the one, at present, more than 40 resident families, and the other has been from about 30 to 200 families. Since traders have spread themselves over this country, it is no more the rendezvous of the errant Knisteneaux, some of whom used annually to return thither from the country of the Beaver river, which they had explored to its source in their hunting and war excursions, and as far as the Salkatchwine, where they sometimes met people of their own nation, who had prosecuted similar conquests up that river. From thence they returned in the spring to the friends they had left; and met with others, who had penetrated, with the same designs, into the Athabasca country. When they met, they occupied their time in feasting, dancing, and other pastimes, which were occasionally suspended for sacrifice and religious solemnity; while the narratives of their travels, and the history of their wars, amused and animated their festival. After a short interval spent in this manner, they prepared for their annual journey to Churchill, to exchange their furs for such European articles as they wanted. The length of the way, and shortness of the season, demanded dispatch; and in this business the most active men of their tribes, and some young women, engaged; remaining at Churchill factory but a little while for bartering their commodities, and indulging themselves with spirituous liquors.

From isle a la Croise fort it is not more than two miles to a point of land which forms a check of that part of the lake called the "Riviere Creuse," which preserves the breadth already mentioned for upwards of 20 miles; then contracting to about two, for the distance of 10 miles more, it opens to "lake Clear." Mackenzie's Voyages from Montreal, &c. Introduction.

CROSSELET, *little cross*, a diminutive of cross, used in *Heraldry*, where we frequently see the shield covered with crosselets; also fesses, or other honourable ordinaries charged or accompanied with crosselets.

Crosses themselves frequently terminate in crosselets.

CROSSEN, in Latin *Crossia*, in *Geography*, a small but handsome town of Prussia, in the duchy of Silesia, on the confluence of the river Bober with the Oder, 26 miles S.E. of Frankfort on the Oder; E. long. 15° 20'. N. lat. 51° 5'. The country about Crossen is uncommonly fertile, and famous for its orchards and vineyards, the latter of which yield a very good sort of white wine.—Also, a small town of Saxony, in the circle of Naumburg Zeitz, on a small river called the white Elster. It has about 600 inhabitants, who derive their principal maintenance from agriculture, and excellent fish ponds.

CROSSIN, a town of Poland, in the palatinate of Lublin; 24 miles S.W. of Lublin.

CROSSMALINA, a small post town of the county of Mayo, Ireland, on the river Deel, near the northern extremity of Lough Conn. It is on the road from Castlebar to Killalla, and is 134 miles N.W. from Dublin, and 15 miles N. from Castlebar.

CROSSOPETALUM, in *Botany*, Brown. See *MYGINDA rhabcoma*.

CROSSOSTYLIS, (from *κροστος*, *fimbria*, and *στυλις*, *columella*, alluding to the fringed style.) Schreb. 1149. Willd. 1307. Juss. 432. Forst. gen. tab. 44. Class and order, *monadelphia polyandria*. Nat. Ord. *Salicarie*? Juss.

Gen. Ch. *Cal.* top-shaped, quadrangular, attached by its lower part to the germ, permanent, with four egg-shaped spreading divisions. *Cor.* Petals four, elliptical; claws narrow; inserted into the calyx; nectaries twenty, filiform, ciliated, alternating with the filaments. *Stam.* Filaments twenty, almost the length of the calyx, united at the bottom into a short cup; anthers small, roundish. *Pist.* Germ superior, convex; style the length of the stamens, cylindrical; stigmas four, spreading, lacinated, or fringed. *Peric.* Berry? hemispherical, striated, enveloped in its lower part by the calyx, one-celled. *Seeds* numerous, globular, attached to a central column.

Esf. Ch. Calyx four-parted. Petals four, inserted into the calyx. Nectaries twenty, alternating with the stamens after they become separate. Stigmas four, fringed.

Sp. C. *biflora*. A native of the Society islands.

CROSSWICKS, in *Geography*, a village of America, in the state of Jersey, and county of Burlington, through which the stages pass from New York to Philadelphia. It has a respectable Quaker meeting-house; 4 miles S.W. of Allen town, 8 S.E. of Trenton, and 14 S.W. of Burlington.

CROSTIGAL, a small town of Saxony, in the circle of Leipzig, with 284 inhabitants, which is so close to the gates of the ancient town of Wurtzen, that it is considered as one of its suburbs.

CROSTILO, a river of Italy, which runs into the Po, about a mile N.W. from Lazzara, in the duchy of Mantua.

CROTALARIA, in *Botany*, (from *κροταλον*, the name of an ancient noisy brazen instrument; alluding, according to Linnæus, to the form of the legume; but, according to others, because the seeds in the ripe legumes make a rattling noise when shaken.) Linn. gen. 862. Schreb. 1172. Willd. 1343. Gært. 859. Juss. 354. Vent. 3. 390. Class and order, *diadelphia decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* often with three deep divisions; the two upper ones lanceolate, pressing on the standard, lower one lanceolate,

CROTALARIA.

lanceolate, concave, three-cleft, supporting the keel; sometimes with five deep, nearly equal divisions. *Cor.* papilionaceous; standard generally large, somewhat heart-shaped, acute, depressed on the sides; wings egg-shaped, often about half the length of the standard; keel acuminate, recurved, most commonly about the length of the wings. *Stam.* Filaments all united towards the base into a membranous sheath, with a fissure at the back; anthers simple. *Pist.* Germ superior, oblong, often hirsute; style simple, bent inwards, ascending; stigma obtuse. *Peric.* Legume often pedicelled, most commonly short and turgid, one-celled. *Seeds* generally few, roundish-kidney-shaped.

Est Ch. Legume turgid, inflated; filaments connate, with a dorsal fissure.

* *Leaves simple.*

Sp. 1. *C. perfoliata*. Linn. Sp. Pl. 2. Mart. 2. Lam. 1. Dill. elth. tab. 102. (*Rafnia perfoliata*; Willd.) "Leaves perfoliate, cordate-egg-shaped." *Stem* apparently shrubby, but the branches perish every year, two feet high or more, branches cylindrical, smooth, leafy. *Leaves* alternate, smooth, stiff, veined. *Flowers* yellow, axillary, solitary, on very short peduncles. *Legumes* smooth, rather short, inflated. A native of open woods in the back part of Carolina. 2. *C. amplexicaulis*. Linn. Sp. Pl. 3. Mart. 3. Lam. 2. (*Rafnia amplexicaulis*; Willd. Thunb. Geniita perfoliata; Seb. thes. 1. tab. 24. fig. 5.) "Leaves all heart-shaped, embracing the stem, reticularly veined, alternate; floral ones opposite, coloured; flowers solitary, axillary." A perfectly smooth shrub. *Stem* a foot and half high, slender, leafy; branches alternate, very slender. *Leaves* entire. *Flowers* yellow, almost sessile; two upper divisions of the calyx large, truncated with an oblique point; standard roundish, raised. A native of the Cape of Good Hope. 3. *C. reniformis*. Lam. 3. "Leaves cordate-kidney-shaped, embracing the stem, reticulated, smooth; floral ones orbicular, legumes compressed, solitary, nearly sessile." *Branches* smooth, woody. *Leaves* larger and rounder than those of the preceding species, entire. *Legumes* from nine lines to an inch long, smooth. *Calyx* as in the preceding species. A native of Africa. 4. *C. cuneiformis*. Lam. 4. "Smooth; leaves ovate-wedge shaped; lower ones reflex; uppermost inversely egg-shaped, mucronate; floral ones nearly opposite." *Stems* somewhat woody, full of pith, not so thick as a goose-quill, smooth, leafy; branches simple, with one or two leaves at the summit. *Stem leaves* alternate, almost sessile, not reticulated, from eight to ten lines long, and seven or eight broad. *Flowers* yellow, axillary, solitary; peduncles shorter than the leaves; calyx smooth, short. A native of Africa. 5. *C. capitata*. Lam. 5. "Villous; leaves lanceolate, scattered, crowded, sessile; flowers in heads." *Stem* woody, cylindrical, leafless; marked with scattered, somewhat callous scars; branched near the top; flowers fasciated, ascending, leafy their whole length. *Leaves* slightly convex above, entire, six or seven lines long. *Flowers* variegated with purple-violet and white; calyx rather short, with five divisions, obtuse at its base; filaments diadelphous; germ thickly set with reddish hairs. A native of the Cape of Good Hope. 6. *C. chinensis*. Linn. Sp. Pl. 5. Mart. 5. Lam. 6. Willd. 4. and 21. "Leaves egg-shaped, somewhat petioled; stipules very minute." Linn. "Villous-silky; leaves ovate, oblong, obtuse, somewhat petioled; stipules awl-shaped; style curved and twisted at the base, reflexed." Lam. *Stems* and branches pubescent, cylindrical. *Leaves* rather obtuse, quite entire, a little hairy on both sides. *Racemes* few-flowered, rough with hairs; bractes lanceolate, the length of the peduncles; calyxes hairy, the

length of the corolla; corolla yellow, with a striated banner; stipules awl-shaped. Linn. Whole plant clothed with reddish hairs, which are silky on the young shoots. *Stem* woody, full of pith, with numerous simple branches. *Leaves* alternate, numerous; lower ones near two inches long; upper ones very small; stipules four or five lines long, commonly several together in a kind of fascicle. *Flowers* in short racemes, which form a terminal panicle; bractes lanceolate, three or four lines long. *Legumes* scarcely five lines long, small, oval, inflated, villous. A native of China and the island of Java. Obs. La Marck states his plant to be the chinensis of Linnæus. Willdenow thinks it distinct, and has taken it up separately as such, and called it paniculata. Their respective descriptions do not appear to us to be absolutely inconsistent with each other, though the resemblance is not striking. The last five species were communicated by Sonnerat to La Marck, who described them from dried specimens. 7. *C. sagittalis*. Linn. Sp. Pl. 4. Mart. 4. Lam. 7. Willd. 1. (*C. americana*, caule alato; Mart. Cent. tab. 43. *C. hirsuta minor*; Herm. Lugdb. tab. 203. Pluk. Alm. 122. tab. 169. fig. 6. *Sagittaria cordialis*. Marg. hist. 1. 55. β . *C. Sagittalis glabra*; Pluk. Alm. 122. tab. 169. fig. 6.) "Leaves lanceolate; stipules decurrent, solitary, two-toothed." Linn. *Root* annual. *Stem* about a foot high, herbaceous, erect, stiff, pubescent, branched. *Leaves* alternate, entire, rounded at the base, on short petioles, hoary underneath, and somewhat hirsute, but sometimes smooth; stipules at the sides of the petioles, bifid, with two open teeth, so as to appear sagittate. *Flowers* pedicelled from three to five, in short peduncled racemes, at the top of the stem and branches; calyx nearly or quite as long as the corolla, clothed with reddish hairs, divided into five ovate-lanceolate segments. *Legumes* from twelve to fifteen lines long, almost sessile in the calyx, inflated, vesicular, smooth. A native of Virginia, the West Indies, and Brazil. 8. *C. parviflora*. Willd. 2. Roth. Cat. 1. 83. and 2. 84. "Leaves lanceolate; upper stipules decurrent, very slightly two-toothed." *Root* annual, very similar to the preceding, but smaller in all its parts. A native of Virginia and Carolina. 9. *C. rubiginosa*. Willd. 3. "Leaves lanceolate, villous; upper stipules lanceolate, decurrent; calyxes villous." *Root* annual. A plant the length of a finger, branched, villous. *Stem* and branches, especially the younger ones, beset with numerous, spreading, ferruginous hairs. *Leaves* an inch long, oblong-lanceolate, on short petioles; stipules on the upper part of the stem towards the flower oblong-lanceolate, decurrent. *Flowers* about four in a raceme, yellow; calyx the length of the corolla or longer, covered with ferruginous hairs. *Legume* turgid, obtuse, mucronate with the permanent style. A native of the East Indies. 10. *C. anthylloides*. Lam. 8. "Leaves linear, acute, villous underneath; corollas and legumes included in the very hirsute ferruginous calyx." *Stem* a foot high, or a little more, simple, cylindrical, rather slender, full of pith, naked towards the base, leafy, and clothed with reddish hairs on the upper part. *Leaves* two or three inches long, alternate, narrow; stipules small, narrow, villous. *Flowers* sessile, drooping, in a terminal raceme; calyx oval-campanulate, completely concealing both the flower and the legume, with five erect, obtuse segments. *Legumes* oval, inflated, terminated by a style similar to that of *C. chinensis*. Found by Commerçon in the island of Java. 11. *C. glauca*. Willd. 5. "Leaves linear lanceolate, smooth, peduncles axillary, about three-flowered." *Stem* a foot high, erect, branched from the base; branches erect. *Leaves* an inch and half long, nearly sessile, glaucous; stipules scarcely apparent. *Peduncles* twice

CROTALARIA.

the length of the leaves; corolla larger than the calyx. A native of Guinea. 12. *C. fruticosa*. Mart. 28. Mill. Houft. MSS. "Leaves linear-lanceolate, hirtute; petioles decurrent; stem shrubby." Stem four feet high, taper, with numerous slender branches. Flowers small, dirty yellow, alternate, three or four in a loose spike. Legumes about an inch long, very turgid, dark blue when ripe. A native of Jamaica; cultivated by Miller. 13. *C. juncea*. Linn. Sp. Pl. 6. Mart. 6. Willd. 6. Hort. Kew. 3. Bot. Mag. 490. (*C. benghalensis*; Lam. 9. Pluk. alm. 122. tab. 169. fig. 5.) "Leaves lanceolate, nearly sessile; stem striated." Linn. "Stem rod-like, simple; leaves lanceolate, nearly sessile; lower lip of the calyx three-parted beyond the middle." Lam. The habit of a spartium. Root annual. Stem three or four feet high, angular, stiff, rather slender, leafy, branched. Leaves alternate, covered in native specimens with soft silvery hairs, but only slightly pubescent when cultivated in the European stoves. Flowers in terminal racemes, large, deep yellow, resembling those of the Spanish broom; calyx villous, almost silky; standard large; keel much bent, acute, two-leaved, paler than the standard; filaments scarcely united at the base; five of the anthers erect, long, linear; five short, oval, incumbent; germ sessile, oblong-conical, hairy; style bent, pubescent. A native of the East Indies. La Marck observes that Linnæus has confounded two plants under his *juncea*, and has restored to that now before us the name given it by Plukenet: but as it is known and cultivated in this country under the Linnæan name, we have given a new one to the next species, to which the other synonyms of Linnæus and the description in Richard's edition belong. 14. *C. tridentata*. (*C. juncea*; Lam. Tandel-cotti; Rheed. Mal. 9. 47. tab. 26. Rai. Hist. 3. 464. n. 9.) "Stem branched at the base; leaves wedge-lance-shaped, somewhat petioled; lower lip of the calyx three-toothed." Lam. β. *C. fericea*; Burm. Ind. 156. tab. 48. fig. 1. Stems slightly striated, branched. Leaves near together, enlarged towards the summit, terminated by a sharp point, smooth and dark-green above, pubescent and a little silky underneath. Flowers in short terminal racemes, which are more leafy than those of the preceding species; germ smooth. A native of the East Indies. La Marck observes that it more resembles *C. retusa* than *C. juncea*. 15. *C. fericea*. Willd. 7. Retz. Obs. 5. 26. "Leaves lanceolate, silky underneath; legumes silky; raceme terminal; stem furrowed." Root annual. Leaves acute; stipules semi-cordate. Flowers much larger than those of Burman's *fericea*, which La Marck supposes a variety of the preceding. A native of the East Indies. 16. *C. limifolia*. Linn. jun. Supp. 322. Mart. 14. Lam. 18. Willd. 8. "Leaves linear, silky, obtuse, mucronate; raceme terminal; legumes smooth, scarcely longer than the calyx; stem somewhat striated." Nearly allied to *C. juncea*. Stem varying from half a foot to a foot and half high, erect, filiform, rush-like, simple, hirtute, hoary. Leaves rather short, on short petioles. Flowers yellow, drooping, in a long raceme. Legumes short, obtuse. A native of the East Indies. La Marck suspects that it does not materially differ from Burman's *fericea*. 17. *C. retusa*. Linn. Sp. Pl. 8. Mart. 8. Lam. 11. Willd. 13. Gært. tab. 148. fig. 2. (*C. asiatica folio singulari cordiformi*; Herm. Lugdb. 200. tab. 201. Tourn. 644. *C. major*; Rumph. Amb. 5. 278. tab. 96. fig. 1. *Dolichos cuneifolius*; Forsk. Ægypt. 134. Tandel-cotti; Rheed. Mal. 9. 44. tab. 25. Rai. Supp. 464.) "Leaves oblong, wedge-shaped, retuse." Root annual. Stem from two to four feet high, striated, leafy, branched. Leaves alternate, quite obtuse, smooth on both sides; stipules small, awl-shaped. Flowers yellow, in a ter-

minal raceme; calyx nearly smooth; upper lip with two ovate-lanceolate divisions; lower one with three acute teeth. Legume smooth, wider upwards, inflated, turgid at the sides, depressed along the feminiferous suture, gradually attenuated into the peduncle. Seeds from fifteen to twenty. A native of the East Indies. 18. *C. gerifloides*. Lam. 12. "Leaves linear-lanceolate, smooth, scattered, sessile; racemes short, few-flowered; calyxes and legumes hirtute." A shrub with the habit of a broom. Branches slender, cylindrical, smooth and slightly tubercled towards the base, leafy almost their whole length, a little villous towards the summit. Leaves scarcely an inch long, mucronate. Flowers in axillary racemes; calyx flat or concave at the base, with five oval-lanceolate divisions, particularly villous at the edges; keel much bent. Legumes covered with reddish hairs. A native of the Cape of Good Hope. 19. *C. imbricata*. Linn. 7. Mart. 7. Willd. 9. (*Borbonia axillaris*; Lam. Cytiso affinis; Pluk. Mant. 63. tab. 388. fig. 3.) "Leaves oblong, silky, shining; flowers axillary, sessile, near the top of the branches." A small shrub. Leaves acute, scattered, somewhat imbricated, without stipules. Flowers purple, solitary; calyx clothed with red silky down; divisions very acute. A native of the Cape of Good Hope. 20. *C. villosa*. Mart. 29. Mill. Linn. Hort. Clif. 357. Herm. Lugdb. 170. "Leaves egg-shaped, villous; petioles entirely simple; branches cylindrical." A shrub about five feet high, with several taper, smooth branches. Leaves fitting close to the branches, roundish, hoary, green, soft to the touch. Flowers fine blue, in loose racemes. A native of the Cape of Good Hope. 21. *C. parviflora*. Willd. 10. Thunb. Prod. 124. "Leaves egg-shaped, acute, tomentous; flowers axillary, nearly sessile; legumes egg-shaped." 22. *C. lanata*. Willd. 11. Thunb. 124. "Leaves egg-shaped, acute, woolly; flowers axillary, nearly sessile." 23. *C. reflexa*. Willd. 12. Thunb. 125. "Leaves egg-shaped, acute, tomentous, reflexed; flowers in heads; branches retroflexed." The last three are natives of the Cape of Good Hope. 24. *C. sessiliflora*. Linn. Sp. Pl. 9. Mart. 9. Lam. 13. Willd. 14. "Leaves lanceolate, nearly sessile; flowers sessile, lateral; stem equal." Root annual. Stem scarcely a foot high, erect, cylindrical, striate-furrowed, but little branched. Leaves smooth above, hairy underneath; stipules scarcely visible. Flowers blue, axillary, with two oblong bractes. A native of China. 24. *C. triflora*. Linn. 10. Mart. 10. Lam. 14. Bot. Mag. 482. (*Rafnia triflora*; Willd.) "Leaves egg-shaped, sessile, smooth; branches angular; peduncles growing by threes, lateral, one-flowered." Root biennial. Whole plant smooth. Stem three or four feet high, strong, often unbranched. Leaves three inches long, large, numerous, very handsome when young, becoming glaucous as the plant advances. Flowers bright yellow; bractes like the leaves, but smaller, one to each flower, about the length of the peduncle. Legumes generally containing only one seed. A native of the Cape of Good Hope; introduced into Kew garden by Masson, in 1786. It is a green-house plant, readily propagated by seeds, which will ripen in the open air in our climate, if the weather be favourable. 25. *C. verrucosa*. Linn. Sp. Pl. 11. Mart. 11. Willd. 15. (*C. angulata*; Lam. 16. *C. asiatica, folio singulari verrucoso*; Herm. Lugdb. 199. Tourn. 644. Rai. Hist. 1893. *C. cærulea*; Jacq. Ic. Rar. tab. 144. *C. foliis solitariis*; Burm. Zeyl. 81. tab. 34. Pee-tand-li-cotti; Rheed. Mal. 9. 53. tab. 29.) "Leaves somewhat egg-shaped; stipules crescent-shaped, embracing the stem; stems quadrangular, furrowed." α. "Leaves egg-shaped." Root annual. Stem a foot and half or two feet high, erect, zig-zag, branched,

CROTALARIA.

branched, with four very remarkable acute angles. *Leaves* near two inches long, alternate, somewhat petioled, green, almost smooth, warty, (but La Marek thinks it probable that this is rather accidental than constant.) *Flowers* light blue, drooping, in peduncled terminal racemes; standard striated on the outside; calyx smooth, with lanceolate segments. *Legumes* an inch long, turgid, almost cylindrical, sessile in the calyx, villous only when young. A native of the East Indies, on the coasts of Malabar and Coromandel. The natives call it Vatti quilliquel-pé, the plant that rattles, in allusion to the noise which the ripe pods make when shaken. β "Leaves hastate-lanceolate, very acute." Found by Commerçon in the Isles de France and Bourbon. γ . "Leaves ovate-lanceolate, larger." *Leaves* near five inches long, and two broad. *Flowers* in racemes from six to eight inches long, yellow; standard with purple streaks above; keel reddish-brown at the point. Found by Commerçon in the island of Java. La Marek thinks that these three plants, though differing so much in their foliage, are nothing more than varieties. 26. *C. semperflorens*. Willd. 16. Vent. Pl. Jard. Cels. Pl. 17. "Leaves oval, emarginate, mucronate; stipules crescent-shaped, embracing the stem; stem somewhat shrubby, cylindrical, striated." *Root* perennial. *Stipules* narrower than those of the preceding species. *Flowers* yellow. A native of the East Indies. 27. *C. hirsuti*. Willd. 17. "Leaves egg-shaped, acute; stipules awl-shaped, reflexed; raceme nearly terminal; legumes hirsute; stem hairy. *Root* annual. *Stem* two feet high, erect, nearly cylindrical, branched. *Leaves* two inches long, on short petioles, smooth above, slightly pubescent underneath. *Raceme* few-flowered. *Legumes* an inch long. A native of the East Indies, near Hyderabad. 28. *C. scandens*. Mart. 32. Lour. Cochinch. 433. "Leaves oblong; peduncles many-flowered, axillary; stem shrubby, climbing." A large shrub, with long, woody, climbing branches. *Leaves* acuminate, quite entire, alternate, smooth, petioled. *Flowers* white; calyx smooth; petals nearly equal, spreading. *Legume* turgid, acuminate at both ends, containing a few seeds. A native of Cochinchina. 29. *C. biflora*. Linn. Mant. 560. 570. Mart. 12. Willd. 18. (*C. nana*; Burm. Ind. 156. tab. 48. fig. 2. Lam. 15. *C. maderaspatana*; Pet. Gaz. tab. 30. f. 10. *Astragalus biflorus*; Mant. Alt. 273.) "Leaves oblong, obtuse, hairy; stems prostrate, herbaceous; peduncles two or three-flowered, axillary." Willd. *Stem* about three inches high, erect, cylindrical, hairy, terminated by the peduncle; branches, from the base of the stem, several, alternate, decumbent, simple, much longer than the stem. *Leaves* an inch long, alternate, obtuse, veinless, slightly hairy, on very short petioles. *Flowers* yellow; peduncles terminal, but on the branches they finally become lateral, by the branch extending itself beyond the flower; calyx with lanceolate segments; upper one bifid; banner egg-shaped, ascending, the length of the calyx; wings oblong, adpressed; keel bellied, beaked, gibbous downwards at the base; filaments all connate, alternately shorter; anthers five, rather oblong; five round, barren; stigma villous. *Legume* didymous-globular, inflated, becoming rather cylindrical in the cultivated plants. Found by Koenig in the island of Johanna. La Marek suspects that the *biflora* of Linnæus, or at least the *astragalus biflorus*, quoted as a synonym, is his *cicer nummularifolium* (see *CICER*), and altogether distinct from Burman's *C. nana*; but, if the fructification of his *nummularifolium* be, as he asserts, entirely that of *cicer*, its filaments must be diadelphous, and therefore it cannot be the plant now described. 30. *C. nummularia*. Willd. 19. "Leaves roundish-ovate, or lanceolate, hairy underneath; peduncles axillary, one or two-

flowered; stem procumbent." *Stems* several, a foot long, hairy, branched. *Leaves*, on most of the branches, orbicular, egg-shaped, half an inch long; on some lanceolate, almost an inch long. *Peduncles* four times the length of the leaves, hairy. *Legumes* four lines long, roundish-egg-shaped, obtuse, pubescent. A native of the East Indies. 31. *C. bifaria*. Linn. jun. Supp. 322. Mart. 15. Lam. 19. Willd. 20. "Lower leaves roundish; upper ones ovate-lanceolate; stipules reflexed; peduncle terminal, one-flowered." *Stems* diffuse, cylindrical, pubescent. *Leaves* in two opposite rows, on short petioles, widely spreading; stipules egg-shaped, tubular. *Flowers* bluish, rather large; peduncles erect, long, filiform; bractes two on the peduncle, near the flower, resembling the stipules. *Legumes* oblong, with a point hispid. Observed by Koenig in shady parts of the garden of the queen of Tanjour. 32. *C. opposita*. Linn. jun. Supp. 322. Mart. 13. Lam. 17. (*Spartium capense*; Linn. Sp. Pl. Liparia; Syst. Veg. ed. 13. *Cytisus capensis*; Berg. cap. 217. *Rafnia opposita*; Willd. 950. *Genista*; Herm. Afr. 11.) "Smooth, without stipules; leaves oblong, sessile; peduncles axillary, two-leaved." A shrub. *Stems* simple, (branched, Berg.) quite smooth. *Leaves* obtuse, erect, (two inches long or more, linear-lanceolate, Berg.) *Flowers* yellow, drooping, axillary towards the top of the stem; peduncles long, with two opposite bractes near the flower, which resemble the leaves of the stem; stamens diadelphous. A native of the Cape of Good Hope. Authors have been much at a loss what to do with this plant. It has already had several names; and La Marek presumes that it cannot be suffered to remain long in this genus, where the younger Linnæus has placed it. Willdenow has accordingly removed it to *rafnia*, taken up from Thunberg; but as we have not yet been able to make up our mind, with respect to that new genus, we have let it rest here for the present.

** *Leaves compound.*

33. *C. lotifolia*. Linn. Sp. Pl. 12. (misprinted *latifolia*.) Mart. 16. Lam. 20. Willd. 22. Dill. Elth. 121. tab. 102. fig. 121. (*C. trifolia fruticosa*; Sloan. Jam. 114. Hist. 2. 33. tab. 176. figs. 1, 2.) "Leaves ternate; leaflets inversedly egg-shaped, smooth; racemes lateral, few-flowered; legumes sessile in the calyx." *Stems* a foot or a foot and half high, slender, weak, cylindrical, hard and woody towards the base, tender, and herbaceous above; branches numerous. *Leaves* petioled; leaflets smooth, egg-shaped; stipules two at the base of each petiole, small, narrow. *Flowers* yellow; standard streaked with purple above; peduncles axillary, commonly shorter than the leaves, three or four flowered. *Legumes* inflated, slightly hairy. A native of Jamaica and South America. 34. *C. pubera*. Willd. 23. Vahl. Eclog. 2. 55. "Leaves ternate; leaflets oblong, obtuse, villous underneath; legumes in racemes, villous." *Root* perennial. *Branches* woody, cylindrical. *Leaves* petioled; petioles half an inch long, cylindrical; leaflets on very short petioles, acute at the base, without veins or nerves, pale green, mucronate; stipules awl-shaped, minute, deciduous. *Flowers* small, remote; racemes axillary and terminal, longer than the leaves; bractes minute, bristle-shaped; segments of the calyx lanceolate. *Legumes* scarcely half an inch long, oblong, pendulous. A native of the island of St. Martha. 35. *C. argentea*. Willd. 24. Jacq. Hort. Schoenb. 2. 50. tab. 220. "Leaves ternate; leaflets lanceolate, hoary; peduncles one-flowered, solitary; calyxes three-parted." A shrub, three feet high, with the habit of a coronilla, and zig-zag hoary branches. *Leaves* hoary; leaflets rather obtuse, shorter than the petiole. *Flowers* yellow, opposite to the leaves at the tops of the branches; calyx the length

CROTALARIA.

of the corolla. *Legumes* lanceolate, somewhat compressed. A native of the Cape of Good Hope. 36. *C. lunaris*. Linn. Sp. Pl. 13. Mart. 17. Lam. 22. Willd. 25. "Leaves ternate; leaflets egg-shaped, acute; stipules semi-sordate, crescent-shaped." *Stem* erect, filiform, branched, woody, zig-zag. *Leaflets* green, and smooth above; villous, whitish, and shining underneath, equal; sessile on the common petiole; stipules with the point directed to the leaf. *Flowers* towards the summit of the branches; peduncles one-flowered, opposite to the leaves, solitary; bractes three, awl-shaped, shorter than the calyx, forming a kind of involucre to each flower. A native of Africa. 37. *C. laburnifolia*. Linn. Sp. Pl. 14. Mart. 18. Lam. 23. Willd. 26. (*C. asiatica frutescens*; Herm. Lugb. 196. tab. 197. Rai. Hist. 1893. *C. arborefcens*; Burm. Zeyl. 82. tab. 35. Nella tandale-cotti; Rheed. Mal. 9. 49. tab. 27.) "Leaves ternate; leaflets egg-shaped, acuminate, smooth; stipules none; raceme terminal; legumes pedicelled." A shrub, three feet high or more, quite smooth, branched; branches slender, cylindrical, even-surfaced, leafy. *Leaves* on long petioles; leaflets green on both sides, slightly petioled. *Flowers* large, yellow, in long lateral racemes, a little below the summit of the branches; calyx rather short, especially the upper lip; keel larger than the other petals, compressed, much bent, with a reversed beak. *Legumes* smooth, inflated, hanging out of the calyx, by a pedicel at least an inch long, terminated by the curved style. A native of the East Indies. 38. *C. macrophylla*. Willd. 27. "Leaves ternate; leaflets oblong-ovate, pubescent underneath; racemes axillary, aggregate, shorter than the petiole." *Root* perennial. *Branches* cylindrical. *Leaves* alternate, on petioles two inches long; leaflets four inches long, three-nerved, veined, smoothish above, pubescent underneath; middle one narrowed at the base; the others oblique. *Racemes* an inch long, somewhat compound, numerous; calyx two-lipped; corolla falcate. *Legumes* half an inch long, oblong, acute, turgid, generally with one small, roundish seed. A native of the East Indies. A plant, with the habit of hedyfarum; but the flower and fruit of crotalaria. 39. *C. levigata*. Lam. 21. Willd. 28. "Shrubby, smooth; leaves ternate; leaflets oblong-elliptical, smooth; racemes lateral, few flowered; legumes pedicelled in the calyx." *Branches* woody, slender, cylindrical. *Leaves* small, alternate; leaflets only three or four lines broad. *Flowers* yellow, from two to four on an axillary peduncle, a little longer than the leaves, with an awl-shaped bracte. *Legumes* half an inch long, oval, inflated, terminated by the twisted reflexed style. Found by Commerfon in the island of Madagascar. 40. *C. trifolialstrum*. Willd. 29. "Leaves ternate; leaflets wedge-shaped, emarginate, shorter than the common petiole; racemes terminal." A plant with the habit of melilot. *Branches* two feet long, simple, cylindrical, erect. *Leaflets* an inch long, smooth above, clothed with adpressed hairs, when seen under a lens underneath; stipules bristle-awl-shaped. *Racemes* three or four inches long, terminal; sometimes with one or two-flowered axillary peduncles. *Flowers* yellow. *Legume* roundish, turgid, pubescent. A native of the East Indies. 41. *C. cordata*. Linn. Mant. 266. Mart. 19. Lam. 25. Willd. 30. (*Spartium sopheroides*; Berg. cap. 198. *Hypocalyptus obcordatus*; Thunb. Prod. 124.) "Leaves ternate; leaflets inversely heart-shaped, mucronate; flowers in corymbs; item shrubby." A shrub eight feet high; branches purple, somewhat angular, rugged with truncated scars. *Leaves* petioled; leaflets smooth, almost equal, petioled, nerved, plaited lengthwise, purplish above, glaucous underneath, the size of a finger nail; stipules bristle-shaped, minute. *Flowers* purple-violet; corymbs terminal, solitary. A native of the Cape of Good Hope. 42. *C. pilosa*. Willd. 31. Thunb. Prod. 125. "Leaves ternate, hairy; leaflets mucronate; flowers terminal." A native of the Cape of Good Hope. 43. *C. spicata*. (*C. villosa*; Willd. 32. Thunb. 125.) "Leaves ternate, villos; leaflets obtuse; spikes terminal." A native of the Cape of Good Hope. Another plant from the Cape of Good Hope, cultivated by Miller, having been previously called *C. villosa*. (See n. 20.) We have given a new name to the present. 44. *C. axillaris*. Willd. 33. Hort. Kew. 3. 20. "Leaves ternate; leaflets ovate-elliptical, hairy underneath; stipules awl-shaped, minute; peduncles axillary, in pairs, one-flowered." *Root* annual. *Branches* furrowed. *Leaves* alternate; leaflets acute, mucronate; stipules hairy. *Flowers* yellow. *Legumes* hairy. A native of Guinea. 45. *C. incanescens*. Linn. jun. Supp. 323. Mart. 21. Willd. 34. Hort. Kew. 3. 20. (*C. arborefcens*; Lam. 24. *C. capensis*; Thunb. 127. Jacq. Hort. 3. 36. tab. 64.) "Leaves ternate; leaflets inversely egg-shaped; stipules resembling the leaves petioled; racemes terminal; legumes pedicelled." A handsome shrub, five or six feet high, with the habit of a cytissus. *Stem* arborescent, with a greyish bark, much branched towards the top; branches short, leafy, cylindrical; covered with a fine, very short, whitish down. *Leaves* petioled; leaflets obtuse, green, on whitish petioles; stipules two, opposite, heart-shaped, deciduous, much smaller than the leaves. *Flowers* large; standard larger than the keel, recurved towards the peduncle, bright yellow, striped at the base, on the inside; spotted with purple brown on the back; wings bright yellow; keel pale, raised and greenish at the beak; filaments connate, but almost diadelphous; anthers oblong, saffron-coloured. A native of the Cape of Good Hope, and of the Isles of France and Bourbon. La Marek observes that as it is called in the Isle of France Baguenaudier, the French name for the bladder fenna (*Colutea*) of our English nursery-men, the legumes are probably much inflated. 46. *C. incana*. Linn. Sp. Pl. 15. Mart. 20. Lam. 26. Willd. 35. Jacq. Obf. 44. tab. 82. Swartz. Obf. 278. Cav. Ic. 4. 11. tab. 322. (*Anonis americana*, folio latiore subrotundo; Tourn. 409. *Crotalaria folis rotundis incanis*; Sloan. Jam. Hist. 2. 34. tab. 179. fig. 1.) "Leaves ternate, leaflets oval, villous underneath; racemes spike-shaped; keel tomentous at the edge; legumes sessile, hirsute." *Root* annual. *Stem* from two to five feet high, erect, almost simple, pubescent. *Leaves* petioled; leaflets obtuse with a small point; petioles pubescent; stipules bristle-shaped, solitary, deciduous. *Flowers* yellow, rather large, pedicelled; bractes filiform; one at the base and two at the top of each pedicle under the calyx; calyx pubescent, with lanceolate divisions. *Legumes* inflated, villos, pendant, sessile in the calyx. A native of the West Indies. Dombey sent from Peru in 1779, what appears to be a variety, with longer leaves, rather larger flowers, and a denser spike. 47. *C. purpurascens*. Lam. 27. (*C. indigofera*; Sounerat. Herb.) "Villos; leaves ternate; leaflets ovate-wedge-shaped, retuse, terminated with a minute point; standard of the corolla purplish above." *Root* annual. *Stem* from one to three feet high, erect, often simple, hard, cylindrical, covered with loose woolly hairs. *Leaves* green, nearly smooth on both sides; petioles villos like the stem; partial ones half a line long; stipules bristle-shaped, villos. *Flowers* small, yellow, drooping, in loose lateral racemes just below the top of the stem; calyx nearly as long as the corolla, villos, with narrow-lanceolate divisions; standard not reflexed; bractes villos. *Legumes* from twelve to fifteen lines long, inflated, villos, pendant, sessile in the calyx. A native of Madagascar and the Isle of France; cultivated at Paris. 48. *C. coluteoides*.

CROTALARIA.

scabres. Lam. 28. (Geniſæ ſimilis; Pluk. tab. 185. fig. 3. without the fruſtification.) "Leaves ternate; leaflets inverſely egg ſhaped; racemes looſe, terminal; legumes veſiculous, ſmooth, pedicelled, deſtitute of the ſtyle." *Branches* cylindrical, full of pith, ſmooth, leafy. *Leaflets* obtuſe, with a ſcarcely perceptible point, ſmooth above, thinly ſet with hairs underneath; petioles ſhorter than the leaflets. *Flowers* in looſe terminal racemes from one to three inches long; calyx ſhort; upper leaf truncated, biſid; lower one with three ſhort diſtant teeth; filaments connate in a cylinder more than two-thirds of their length. *Legumes* an inch long, ſmooth. Communicated by Sonnerat, it is ſuppoſed, from Africa. Cultivated at Paris. 49. *C. glycinea*. Lam. 29. (*C. aſiatica* hirſuta; Herm. Lugbd. App. 663. from the herbarium of Juſſieu; Rai. Hiſt. 1893.) "Villous; leaves ternate; leaflets oval, lateral ones gibbous outward." *Root* annual. *Branches* cylindrical. *Leaves* petioled; middle leaflet petioled, nearly inverſely heart-ſhaped, often obtuſe, with a very ſmall point; ſtipules ſmall, oval-acute. *Flowers* apparently red, drooping, in terminal racemes; calyx villous, with narrow-lanceolate diviſions; germ covered with woolly hairs. A native of the Eaſt Indies. 50. *C. uncinella*. Lam. 30. "Leaves ternate; leaflets egg-ſhaped; ſtipules none; legumes ſerotiform, ſilky, ſcarcely longer than their terminal hooked ſtyle." A very branching ſhrub, about a foot and half high. *Branches* ſlender, cylindrical, pubeſcent. *Leaves* alternate, petioled; leaflets ſmooth above, clothed with fine and cloſe preſſ'd hairs underneath; middle one as long as the common petiole. *Flowers* ſmall, in lateral and terminal racemes; calyx villous; peduncles almoſt filiform. *Legumes* about the ſize of a pea, clothed with a fine ruſſet down. A native of the iſland of Bourbon, preſerved in the herbarium of Commerſon. There is a variety in the herbarium of Juſſieu ſmooth in all its parts, with ſmaller leaves and yellow flowers, the ſtandard ſlightly ſtriated behind, the keel bent and terminated by a ſtraight beak as in the next ſpecies. There is another variety from Madagaſcar, preſerved in the herbarium of Commerſon, with much larger ſmooth fruit. And a third in Adanſon's herbarium of Senegal, now poſſeſſed by Juſſieu, with villous ſmaller leaves, and villous ſomewhat larger legumes. 51. *C. medicaginea*. Lam. 31. "Leaves ternate; leaflets cordate-wedge-ſhaped; keel horned; legumes ſerotiform, ſhorter than their terminal reflexed ſtyle." A plant with the habit of medicago polymorpha. Linn. *Branches* ſomewhat woody at the baſe, very ſlender, cylindrical, compound, clothed with ſhort hairs, cottony near the ſummit. *Leaves* alternate, very ſmall; leaflets clothed with ſhort depressed hairs underneath, a little longer than the common petiole; ſtipules very ſmall, awl ſhaped. *Flowers* very ſmall, from three to five together; peduncles lateral, filiform, oppoſite to, and longer than the leaves; calyx villous, with five lanceolate diviſions; keel bent nearly at a right angle, terminated by a long, conical, ſtraight horn, a little twisted at the top; ſtandard ſhorter than the keel, and reſting upon it, pubeſcent and ſtriated on the back. *Legumes* ſcarcely the diameter of a lentil, pubeſcent. A native of the Eaſt Indies, communicated by Sonnerat. 52. *C. ſforaloides*. Lam. 32. "Leaves ternate; leaflets oblong, obtuſe, longer than the petiole; ſpikes axillary, ſlender, elongated." *Stem* apparently a foot and half or two feet high, ſomewhat zig-zag, obtuſely angular, full of pith, tomentous towards the top. *Leaves* alternate, on very ſhort petioles; ſtipules lanceolate, the length of the petioles. *Flowers* ſmall, ſeſſile; bractes bristle-ſhaped. *Legumes* oval-rhomboidal, ſlightly inflated, villous, terminated by the recurved ſtyle. Found by Commerſon in the iſland of Madagaſcar. 53. *C. pallida*. Mart. 26. Willd. 30. Hort. Kew. 3. 20. "Leaves ternate; leaflets lanceolate, ſmooth; racemes terminal, reſembling ſpikes." *Root* annual. *Flowers* pale-coloured. A native of Africa, found by Bruce. 54. *C. longifolia*. Lam. 33. Willd. 37. (*C. guianenſis*; Aubl. guian. 2. 761. tab. 305.) "Leaves ternate; leaflets lanceolate, ſmooth; p. duncies axillary, aggregate, one-flowered; legumes tetragonal." *Root* perennial. *Stems* a foot high or more, angular, leafy, with ſhort branches. *Leaves* alternate, on very ſhort petioles; leaflets four or five inches long, near an inch broad, nerved, veined, middle one longer, ſlightly petioled; ſtipules, two at the baſe of each common petiole, lanceolate; two at the baſe of each leaflet, rather long, very acute. *Flowers* purple, from two to four together, on very ſhort peduncles; calyx long, enveloped at its baſe by two bracteal ſcales. *Legumes* ſmooth, inflated, oblong, acute. A native of Guiana. 55. *C. anguſtifolia*. Willd. 38. Jacq. Hort. Schoen. 2. 49. tab. 219. (*C. elongata*; Thunb. prod.?) "Leaves ternate; leaflets lanceolate, hoary, ſilky, ſhorter than the petiole; raceme terminal." *Root* perennial. *Raceme* three inches long. *Flowers* dull white. A native of the Cape of Good Hope. 56. *C. lineata*. Lam. 34. Willd. 39. Thunb. prod.?" "Leaves ternate; leaflets linear-lanceolate, on ſhort petioles, villous, marked with lines; legumes ſhort, hirſute, in racemes." Lam. "Leaves ternate, tomentous underneath; nerved; ſtem decumbent." Thunb. A ſhrub. *Branches* cylindrical, ſtriated, cottony towards the ſummit. *Leaves* alternate; petioles ſcarcely a line long, villous; leaflets from one to two inches long, about four lines broad, villous, with numerous lateral nerves; middle one a little longer, ſomewhat petioled; ſtipules two, lanceolate. *Flowers* from five to nine in a raceme, alternate, ſeſſile. *Legumes* four or five lines long, inflated. Communicated to La Marek by Juſſieu. Thunberg's plant is a native of the Cape of Good Hope. 57. *C. tomentosa*. (*C. geniſtoides*; Willd. 40.) "Leaves ternate; leaflets linear-wedge-ſhaped, emarginate; raceme terminal." Whole plant pubeſcent. *Branches* ſomewhat woody, compound. *Leaves* on a very ſhort common peduncle; ſtipules awl-ſhaped. *Flowers* ſmall, yellow. *Legumes* half an inch long, roundiſh egg-ſhaped, acuminate. The habit of a geniſta. A native of the Eaſt Indies. Willdenow ought to have obſerved that the trivial name *geniſtoides* was pre-occupied by La Marek, whoſe work was certainly before him, though he did not chuſe to take up many of its peculiar ſpecies, even ſome which are deſcribed from living plants by ſo eminent a botaniſt. 58. *C. floribunda*. Mart. 24. Hort. Kew. 3. 19. "Leaves ternate; leaflets wedge-ſhaped; branches pubeſcent; legumes pedicelled, ſmooth, wrinkled, keeled." *Root* perennial. A native of the Cape of Good Hope. 59. *C. microphylla*. Willd. 41. Vahl. Symb. 1. 52. "Leaves ternate; leaflets oblong; peduncles lateral, two-flowered; ſtem decumbent." *Stem* a foot long, woody, filiform, cylindrical, ſmooth, branched. *Leaves* petioled, remote; leaflets two lines long, nearly ſeſſile, ſmooth, thickiſh; common petiole the length of the leaves; ſtipules bristle-ſhaped, ſpreading, half the length of the petiole. *Flowers* pedicelled. *Legume* oblong, ſmooth, on a very ſhort pedicel. A native of Arabia Felix. 60. *C. volubilis*. Willd. 42. Thunb. prod. 125. "Leaves ternate; leaflets ſmooth, inverſely egg-ſhaped, obtuſe; flowers axillary, ſolitary." A native of the Cape of Good Hope. 61. *C. heterophylla*. Linn. jun. Supp. 323. Mart. 22. Lam. 35. Willd. 43. "Leaves ternate; leaflets elliptical, emarginate; lower leaves ſimple." *Root* annual. *Stem* a foot high, erect, ſmooth, a little branched near the top. *Leaves* ſmooth, nerved, on very ſhort channelled petioles; ſtipules ſmall, awl-ſhaped, ſpreading. *Flowers* yellow, ſtriated, in a terminal

a terminal raceme, which becomes lateral as the fruit ripens. *Legumes* smooth. A native of the East Indies. 62. *C. appalahoïdes*. Lam. 36. "Leaves ternate, petioled; leaflets wedge-linear, hirsute; stipules none; racemes peduncled, terminal." A shrub, scarcely a foot high." *Stem* woody, twisted, stiff, rugged, branched; smaller branches slender, cylindrical, leafy, pubescent, whitish. *Leaves* small, narrow, hairy. *Flowers* pedicelled, from three to six in a raceme, on a very slender peduncle; calyx villous; keel crescent-shaped; filaments at first entirely connate; but afterwards dividing at the top; germ very villous; style at first hooked, afterwards curved and ascending; stigma simple. A native of the Cape of Good Hope. 63. *C. quinquefolia*. Linn. Sp. Pl. 17. Mart. 23. Lam. 37. Willd. 44. (*C. pentaphylloides*; Pluk. alm. 122. Welha-tandall-cotti; Rheed. Mal. 9. tab. 28. Rai. Supp. 465.) "Leaves digitate-quinuate; flowers in racemes." A plant with the habit of a lupin. *Root* annual. *Stem* about two feet high, erect, rather thick, striated, slightly villous. *Leaves* alternate, petioled; leaflets five, oblong, obtuse, rather narrow, the side ones the shortest; upper surface sprinkled with very small black points, clothed with short fine hairs underneath; stipules narrow, nearly awl-shaped, reflexed. *Flowers* yellow. *Legumes* two inches long, much inflated, vesicular, smooth, pedicelled in the calyx, terminated by the recurved reflexed style. A native of the East Indies, and the Isle of France, described by La Marek from specimens gathered by Commerçon. 64. *C. heptaphylla*. Mart. 31. Lour. Cochinch. 443. "Leaves pinnated with seven leaflets; spikes long; stem arborescent." A tree, ten feet high, with diffuse branches. *Leaflets* ovate-oblong, veined, slightly tomentous; petioles short. *Flowers* white, axillary, and terminal, in simple solitary spikes; calyx five-toothed, villous, short; standard emarginate, rising; rings oblong, half the length of the standard. *Legume* turgid, villous, unequal, pedicelled. *Seeds* few, roundish. A native of Cochinchina.

CROTALARIA asarina; Berg. See *GLYCINE monophylla*.

CROTALARIA perforata; Linn. See *BORBO니아 perforata*.

CROTALARIA zeylanica argentea totia; Herm. See *SOPHORA tomentosa*.

Oof. From only a cursory survey of the descriptions in the above numerous list, it is but too evident, not only that some of the species do not correspond with the genuine character as it now stands, even after the very liberal modifications which we have given it; but also that it would not be easy, perhaps not possible, to include them all in any precise generic character whatever. Jussieu has observed that this genus wants revival, and that some of the present species ought to be removed. La Marek has accordingly removed *imbricata* (n. 19.), to *borbonia*, and thinks that *perfoliata*, *amplexicaulis*, and *reniformis* (n. 1, 2, 3.), might with propriety follow it. Willdenow has arranged the three former of these, and some others, under Thunberg's new genus, *rasnia*. But were we to admit the propriety of this disposition, so much would still remain to be done, that we have been induced to leave the genus as we found it. In the course of our labours we often painfully feel the truth of La Marek's observation, that those who write general botany in an alphabetical order, cannot have entire natural families before them at once, and that, therefore, they can seldom do more than suggest their doubts, without being able positively to determine what station should be assigned to a plant which seems to be improperly placed. A complete reformation of the genera in all the great universally acknowledged natural families, adapted to the multitude of species, which, within a few years, have poured in upon us from every quar-

ter of the world, is indeed a task to which the unremitted attention of a whole life would scarcely be equal.

Propagation and Culture.—Most of these plants are cultivated by seeds, sown in a hot-bed in the spring, and afterwards treated in the usual manner. Those which are natives of the Cape will be sufficiently protected by the conservatory or dry stove; but such as come from the East Indies and West Indies, and the hotter parts of Africa, must be kept in the bark stove. *C. laburnifolia* (n. 37.) is easily propagated by cuttings.

CROTALARIA, in *Gardening*, comprehends plants of the herbaceous and shrubby exotic kinds, of which the species cultivated are, the channel-stalked *crotalaria* (*C. juncea*), and the laburnum leaved *crotalaria* (*C. laburnifolia*.)

Method of Culture.—The first kind of these plants may be increased by sowing the seeds in pots of light mellow fresh mould in the spring, plunging them in the hot bed of the stove; and when the plants are of sufficient growth, removing them into separate pots.

The second sort may be raised either by seeds in the above manner, or by planting cuttings of the young branches in the later spring months, in pots of the same sort of earth, and plunging them in the bark-beds of the stove, giving them water frequently, and removing them when well rooted into separate pots, of proper sizes.

These plants are capable of being exposed to the open air during a little of the heat of the summer season, but at other times stand in need of the protection of the hot-house or stove.

CROTALO, an instrument of military music. (See *CROTALUM*.) The Turks are the first, among the moderns, who introduced the use of it for their troops. It is now common in Flanders and Florence, and other territories on the continent. It has only one tone; but its effect in marking time may be distinctly heard through the noise of forty drums. This is the same instrument with the ancient *cymbalum*.

CROTALOPHORUS ANGUIS, in *Zoology*, the name used by the generality of authors for the *rattle snake*. See *CROTALUS*.

CROTALOPHORUS anguis, is also the name of a very remarkable species of serpent, more usually known by the name of *cobra de capello*.

CROTALUM, an ancient kind of castagnetta, or musical instrument, found on medals, in the hands of the priests of Cybele.

The *crotalum* differed from the *xylyrum*; though authors frequently confound the two. It consisted of two little brass plates, or rods, which were shaken in the hand, and in striking against each other made a noise.

It was sometimes also made of a reed split lengthwise half-way down; one part whereof they struck against the other; and as this made a noise something like that of a crane's bill, they called that bird *crotalifris*, a player on the *crotale*; and Aristophanes calls a great talker a *crotalum*.

Clemens Alexandrinus attributes the invention to the Sicilians; and forbids the use thereof to the Christians, because of the indecent motions and gestures that accompany it.

Pausanias relates, that Hercules did not kill the Stymphalides with his arrows, but that he frightened and drove them away with the noise of the *crotala*, which shews, admitting the truth of the relation, that the *crotalum* must have been a very ancient instrument. Ovid joins the *crotalum* with the *cymbals*.

"Cymbala cum crotalis prurientiaque arma Priapo
Ponit, et adducit tympana pulsa manu."

CROTALUS.

CROTALUS, in *Zoology*, a genus of serpents, having plates on the belly, both plates and scales under the tail, and the tail itself terminated by a rattle.

These are the rattle-snakes of the English, and serpens à sonnettes of the French, or, as some writers among the latter call them, *crotalophores*. The whole genus is furnished with poisonous fangs. Their head is large, somewhat triangular, rather flat on the upper part, and, like the body, covered with carinated scales, but which in general are of a larger size; the eyes are very brilliant, and protected by a nictitant membrane; the mouth large, and capable of great distension; the tongue long, furcated at the extremity, and susceptible of a brisk vibratory motion. The venomous fangs are placed in two longitudinal rows, in the upper part or roof of the mouth: the largest of those fangs stand foremost, from whence they progressively become smaller as they recede further back in the mouth, and are usually fourteen in number altogether, seven being disposed in each series. Each of those have two small fissures, one at the base, the other a little above the tip, through which the venom is discharged into the wound, by pressing on the poison bags at the base of the fangs. This poison is of a greenish colour, and the larger fangs in rattle-snakes of considerable size about half an inch long.

The rattle is a peculiar instrument ordained by nature to announce the approach of this formidable serpent to other animals, and warn them of their danger. Till the discovery of America, such extraordinary powers in the reptile race were unknown to the inhabitants of our hemisphere; and from that period to the present they have attracted the particular attention of naturalists. The rattle is a moveable apparatus of a horny texture, and consisting of a greater or smaller number of joints, which, as the creature moves, sends forth a peculiar jarring sound, not very unlike that of a child's rattle. The number of its joints vary not only in different species, but in individuals of the same species; and seem, if any dependance can be placed on the veracity of travellers, to be governed in a great measure by the age and health of the animal. Some believe the age of these snakes may be constantly ascertained by the number of those joints, one being added annually; and hence they are supposed to attain to a great age, as rattle-snakes have been found with no less than forty or even fifty joints in this part. Some of the Indians deny this, and assert that the amount of those joints in the rattle determines the number of human beings that have fallen victims to the deadly fangs of those hideous creatures. A particular account of the structure of the poisonous fangs of the rattle-snake is given in the *Philosophical Transactions* by Dr. Grey; and a copious description of the rattles of different species has lately appeared by La Cèpede.

The noise of the rattle-snake is said to be rather feeble in general, and of course not very distinctly heard till the creature approaches pretty near. This we suspect from what we have observed of the rattle-snakes brought over to Europe. Those, indeed, having endured the want of proper subsistence for months, and being in a state of captivity, cannot be supposed to afford any absolute criterion; but from these we may presume that the noise is not so loud as some travellers represent. Once we had an opportunity of hearing the noise of three rattle-snakes of the striped or durissus species, confined in the same cage: it was an incessant rattling hum, distinct enough in any part of the room, which was moderately large, but not so strong or piercing as to be heard at a much greater distance.

Almost every animal becomes panic struck at the sight of the rattle-snake, and seems at once deprived of the power of

motion, or the exercise of its usual instinct of self-preservation. Horses and dogs are momentarily arrested in their progress, and wait, without attempting to move, the nearer approach of the terrific creature, unless driven by man with force from the immediate danger. From what cause this torpor in animals may arise, when the serpent advances and threatens destruction, is difficult to say, except it be the effect of terror. The fascinating power attributed to serpents does not admit of much credit: we should suspect rather that they become stupefied with horror at their danger, and are unable through fear to attempt escaping till the snake inflicts its wound, when escape is too late. The snake remains quiet till his victim expires, and then proceeds in security to devour it. That this does not depend on the power of fascination, as it is expressed, in snakes may be in some measure inferred, from considering that the most stupid of all animals are more likely to get out of their power than those whose instinctive penetration, on other occasions, might most readily enable them to avoid difficulties. Thus we see that horses and dogs fall a prey to the rattle-snake, through their acute sense of danger; while the hog, stupid and indifferent, and scarcely possessing the instinct to turn a few paces aside to avoid almost certain destruction, approaches the rattle-snake with impunity, or seeks him in his covert, attacks him, tramples on him, and devours him.

Man or animals bitten by the rattle-snake expire in extreme agony: the tongue swells to an enormous size; the blood turns black; and all the extremities becoming cold, gangrene ensues, and is speedily succeeded by death. The remedies in common use are the polygala feneca, or aristolochia serpentaria, employed as a decoction, and applied in fomentation as hot as can be possibly borne; or sometimes scarification, or cauterising the wound with a burning iron, if immediate in their application, is attended with success: and in either case, if the situation of the wound will allow, it is necessary to retard the circulation of the venom through the system, by means of ligatures. The rattle-snakes have an offensive smell, notwithstanding which the negroes eat the flesh like that of other serpents; and they have a superstitious idea, that the rattles, as a *charm*, are of sovereign efficacy to women in child-birth.

The different kinds of rattle-snakes seem to have been confounded with each other till of late years. Gmelin makes five distinct species, in which he is followed by the writers of this country. To these, however, Latreille adds three more, which he describes from specimens in the National Museum at Paris. These are his *crotale à losange*, *crotale à queue noire*, and *crotale camard*: the two first of these are natives of America, the other is from the East Indies. It is believed that two of the above number have been previously noticed by Seba, but whose description, if it be really so, is much less explicit than the account rendered from the specimens in the French Museum by Latreille.

Species.

HORRIDUS. Fuscous, with blackish transverse bands. Plates of the belly 167, of the tail 23.

This species is found from three to four or five feet in length, some say even six feet, and the thickness of a man's arm. We once saw the skin of a rattle-snake, which, when perfect, measured, as it was affirmed, eleven feet six inches, and in the girth appeared to be about the thickness of a man's thigh; it was, therefore, in dimensions, equal to some of the largest box. The general colour of the rattle-snake is yellowish-brown, marked throughout its length with a number of transverse, and somewhat irregular, bands

of deep brown; and from the head to some distance down the neck run two or three longitudinal stripes of the same colour. The under parts are of a dingy yellowish-brown colour, with dusky spots and freckles; the rattle at the end of the tail brownish.

The largest rattle-snake which Catesby ever saw (and he travelled over those parts of America in which they most abound) was about eight feet in length, and weighed between eight and nine pounds. "This monster," says he, "was sliding into the house of colonel Blake of Carolina, and had certainly taken up his abode there undisturbed, had not the domestic animals alarmed the family with their repeated outcries. The dogs and poultry united in their hatred to him, shewing the greatest consternation, by erecting their bristles and feathers, and expressing their wrath and indignation, surrounded him, but carefully kept their distance; while he, regardless of their threats, glided slowly along." "It is not uncommon," adds Mr. Catesby, "to have come into houses: a very extraordinary instance of which happened to myself in the same gentleman's house, in the month of February, 1723. The servant, in making the bed in the ground-room (but few minutes after I left it), on turning down the sheets, discovered a rattle-snake coiled between the sheets in the middle of the bed." "They are the most inactive and slow moving snake," adds this author, "of all others, and are never the aggressors, except in what they prey upon; for unless they are disturbed, they will not bite; and when provoked, they give warning by shaking their rattles. These are commonly believed to be the most deadly serpent of any in these parts of America. I believe they are so, as being generally the largest, and making a deeper wound, and injecting a greater quantity of poison. The most successful remedy the Indians seem to have is to suck the wound, which, in a slight bite, has sometimes a good effect. They have likewise some roots, which they pretend will effect a cure, particularly a kind of asarum, commonly called heart-snake-root; a kind of chrysanthemum, called St. Anthony's cross; and some others: but that which they rely on the most, and which most of the Virginian and Carolina Indians carry dry in their pockets, is a small tuberous root, which they procure from the remote parts of the country. This they chew, and swallow the juice, applying some to the wound." Mr. Catesby having, by travelling much among the Indians, had frequent opportunities of seeing the direful effects of the bite inflicted by these snakes, seems to consider that the good results attributed in common to these remedies is owing more to the force of nature, or the slightness of the bite, than to any other cause. He has known persons bitten to survive, without any assistance, for many hours: but where a rattle-snake with full force penetrates with his deadly fangs into a vein or artery, inevitable death ensues, and that, as he has often seen, in less than two minutes. The Indians, for this reason, know their destiny directly they are bit; and when they perceive it is mortal, apply no remedy, concluding all efforts in vain: if, however, it happens in a fleshy part, they cut it out to stop the current of the poison.

The charming, as it is commonly called, or attractive power this snake is said to have of drawing to it small animals, and devouring them, Mr. Catesby says, is generally believed in America. He allows that he never witnessed the fact; but that a great number of persons, by whom the circumstance had been related, agreed exactly in the manner in which the effect is produced. Little birds, and quadrupeds of a small size, particularly squirrels, (on which these snakes chiefly prey,) no sooner perceive their mortal enemy than they skip from spray to spray, hovering and approach-

ing gradually nearer to him, regardless of any other danger, and with distracted gestures and outcries descend, though from the top of the loftiest trees, to the mouth of the snake, who opens his jaws, takes them in, and in an instant swallows them. In a memoir on the supposed fascinating power of the rattle-snake, by Dr. Barton, professor of natural history in the university of Pennsylvania, it is however contended to be nothing more than the fluttering of old birds in defence of their young, when they perceive the snake lying in wait for prey, and which are themselves caught, as well as their young, by the rattle-snake, unless they save themselves by a timely retreat.

Rattle-snakes are said to swarm in the less inhabited parts of America, but are now almost extirpated in the neighbourhood of populous places. None are found further north than the mountains near lake Champlain, but they infect South America even as far as Brazil. They love woods and lofty hills, especially where the strata are rocky or chalky. The pass near Niagara abounds with them. Being slow of motion, they frequent the sides of hills to seize on frogs, or such animals as resort there to quench their thirst. During summer they are generally found in pairs; in winter, assembled together in multitudes, and lurking under ground, where they remain till the return of fine weather, when they creep out of their hiding-places in a weak and languid state. A person has seen a piece of ground covered with them, and killed with a long rod between sixty and seventy, till overpowered with the stench, which is dreadfully offensive, he was obliged to retire.

The rattle-snake is a viviparous animal; producing its young in the month of June, generally about twelve in number, and which by September acquire the length of twelve inches. It is said to protect its young in the same manner as the common viper, namely, by receiving them into its mouth, and swallowing them. This is asserted by M. de Beauvois, who saw a large rattle-snake, which he happened to disturb in his walks, coil itself up, open its jaws, and instantly receive five small ones, which were lying by it, and instinctively rushed into its mouth. M. de Beauvois retired, and watched the snake, and in about a quarter of an hour after saw her again discharge them. He then approached a second time, when the young retired into its mouth with greater celerity than before; and the snake immediately moved off among the grass, and escaped. This happened at a place called Pine-Log, where the writer staid some time with the Indians, during an illness with which he was seized. This circumstance is related in the American Philosophical Transactions.

From experiments made in Carolina by captain Hall, and related in the Philosophical Transactions, it appears that a rattle-snake of about four feet long, being fastened to a stake fixed in the ground, bit three dogs: the first of which died in less than a quarter of a minute; the second, which was bitten a short time afterwards, in about two hours, in convulsions: and the third, which was bitten about half an hour afterwards, shewed the visible effects of the poison in about three hours, and died likewise. Four days after this, another dog was bitten, which died in half a minute; and then another, which died in four minutes. A cat, which was bitten, was found dead the next day. Eight days after this, a frog was bitten, which died in two minutes; and a chicken of three months old in three minutes. The experiments having been discontinued some time, from want of subjects, a common black snake was procured, which was healthy and vigorous, and about three feet long. It was brought to the rattle-snake, when they bit each other: the black snake biting the rattle-snake so as to make it bleed.

They were then separated, and in less than eight minutes the black snake died; while the rattle-snake, on the contrary, shewed no signs of indisposition, appearing as well as before. Lastly, in order to try whether the rattle-snake could poison itself, it was provoked to bite itself: the experiment succeeded, and the animal expired in less than twelve hours. According to the experiments of Vossnaer at the Hague, with a lively young rattle-snake, which he received from Surinam, small birds, such as sparrows, finches, &c. died sometimes in four, sometimes ten, and sometimes twenty minutes after being bitten; and a mouse in a minute and a half.

The peculiar apparatus, called the rattle, in this kind of snake, is minutely described by Grew; who observes, that it consists of hollow, hard, dry, and semi-transparent bones, nearly of the same size and figure; resembling, in some degree, the shape of the human os sacrum; for although only the last or terminal one seems to have a rigid epiphysis joined to it, yet have every one of them the like, so that the tip of every uppermost bone runs within two bones below it; by which artifice they have not only a moveable coherence, but also make a more multiplied sound: each bone hitting against two others at the same time. The rattle is placed with the broad part perpendicular to the body, and not horizontal; and the first joint is fastened to the last vertebra of the tail by means of a thick muscle under it, as well as by the membranes, which unite it to the skin. All the remaining joints are so many extraneous bodies, as it were, or perfectly unconnected to the tail by any other means than their curious interfections into each other.

DURISSUS. Brown, with yellowish rhomboid stripes. Abdominal plates 172, subcaudal scales 21. *Crotalus durissus*, Linn.

This species is distinguished from the former by the different disposition of its colours. The lighter colour is pale yellow, marked along the back with a series of large black rhombic spots, and on each side with another series, similar in size and form, but not so deep in colour; and most of these have the disc white. The lower surface is dusky yellowish-brown, with numerous small dark spots and patches.

The general size of this snake agrees with that of the species horridus, with which it has been oftentimes confounded; more especially as it inhabits the same parts of America, and much resembles it in colours, though not in the disposition of its pattern. Its bite is equally fatal with that of the first-mentioned kind. Three varieties of this snake are mentioned by writers, which differ in the number of abdominal plates and caudal scales.

MILIARIUS. Cinereous, with a triple row of black spots, and a red spot between each of the dorsal ones. Abdominal plates 132, subcaudal scales 32. *Crotalus miliarius*, Linn. Small rattle-snake, Catesby.

Described by Catesby as a probable variety of the common rattle-snake. It is, however, now considered as a distinct species. In its general habits it resembles the preceding kinds, but is the smallest of the rattle-snakes known, rarely exceeding the length of two feet.

DRYINAS. Greyish variegated with yellow. Abdominal plates 105, subcaudal scales 50. *Crotalus dryinas*, Linn. *Vipera caudifona ceilanica*, Seba.

Seba describes this species as a native of America, but erroneously, as it is supposed; the whole genus appearing to be confined to the American continent. There is a specimen of this in the Parisian Museum.

MUROS. Back with black rhombic concatenate spots; tail terminated in a quadruple row of very minute sharp scales. Gmel.

This is a native of Surinam, is very large, and armed with fangs of vast size. It can scarcely be considered with propriety as belonging to this genus.

LE CROTALE A QUEUE NOIRE. Tail black. Abdominal plates 116, subcaudal scales 36.

Described by Latreille, who observes that it measures from three to four feet in length. The back is reddish-grey, speckled with brown, and marked with brown irregular angular bands; and a streak of fawn colour down the back. The species is a native of Carolina.

LE CROTALE A LOSANGE. Yellowish-grey, with two zig-zag lines of reddish brown along the back, forming by their angles a series of lozenge spots. Latreille.

A native of America. Described as a new species, from a specimen in the Paris Museum.

LE CROTALE CANARD. Head obtuse; body greyish, with numerous black spots and lines upon the back and sides. Latreille.

A specimen of this species, between two and three feet in length, is preserved in the Natural History Museum at Paris.

CROTALUS, in *Ancient Geography*, a river of Italy, in the Locride territory, now called *Corace*. M. d'Anville places it in Brutium.

CROTALYSTRIÆ, or **CROTALISTRÆ**, in *Antiquity*, a kind of morrice dancers, admitted to entertainments, in order to divert the company with their dancing, and playing on an instrument called crotalus, whence they had their name. By an ancient poem, entitled "Copa," and ascribed by some to Virgil, it appears that those who played with the crotala danced at the same time. In these dances, performed chiefly by women, they practised a variety of wanton gesticulations and indecent attitudes and postures, so that these, as well as cymbals, were banished from the festivals of all Christians.

CROTAPHITES MUSCULUS, in *Anatomy*, a name sometimes applied to the temporal muscle. See **MASTICATION**.

CROTAPHIUM, in *Medical Writers*, is used for a pain in the head. See **HEAD-ACH**.

CROTCH, in *Rural Economy*, a term which is often provincially applied to signify a sort of hook.

CROTCHES, **CROCCIA**, in *Sea Language*, a name given to those crooked timbers that are placed under the keel, in the fore and hind-parts of a ship, upon which the frame of her hull grows narrower below, as it approaches the stem afore, and the stern-post abaft.

CROTCHES are also certain pieces of wood or iron, whose upper parts open in two horns, or arms, like a half-moon. They are fixed in the different parts of a ship, according to the uses for which they may be designed, which is usually to support the spare-matts, yards, &c.

CROTCHET, in *Midwifery*, an instrument used in extracting or drawing a fetus through the vagina, when the pelvis in the woman is so distorted, or straightened, as to make it impossible for it to pass in its entire and perfect state. In these cases, the head of the fetus is always previously opened, and the brain evacuated, to allow the bones of the cranium to collapse.

The crotchet appears to have been used for this purpose, from a very early period, as we find it described under the name of uncus, or a hook, by Hippocrates, and afterwards by Celsus, and by Aboecasis. Originally it consisted of a straight piece of iron, one end of which was turned down, forming a hook. The part turned down was made sharp, and fashioned like the head of a spear; which form it still retains. See *Plate of Midwifery*. In later times a wooden

a wooden handle has been added, as more convenient for the operator. About the middle of the last century, Mons. Levrett recommended curving the stem of the crotchet, which added much to the power, and to the utility of the instrument. He also advised using two blades, one to be applied on each side of the head of the child; but this is neither necessary, nor often practicable, as in cases requiring the use of the crotchet, the pelvis of the woman is too narrow to admit the introduction of a second blade. The cases in which the crotchet is employed, and the manner of using them, are described under the article LABORIOUS or DIFFICULT BIRTHS.

CROTCHET, in *Musical*, one of the notes, or characters of time, marked thus  equal to half a minim, and double a quaver.

It is not easy to conceive how this character comes by the name crotchet: the word is apparently borrowed from the French *crochet*, of *croc*, a *crook* or *hook*, used by them for what we call the *quaver*, or *half crotchet*; by reason of the additional stroke at bottom, which gives it an appearance of a crook.

A dot added to the crotchet, thus  increases its time by half; that is, makes it equal to a crotchet and a half, or to three quavers.

CROTCHET, in *Printing*, denotes a sort of line, sometimes straight, sometimes waved, but always turned up at each extreme: serving to bind or link together several articles, that are to be read together, before you proceed to the subdivisions, placed aside of them with similar or smaller *crotchets*; much used in genealogies, analytical tables, &c. for facilitating the division and subdivision of any subject.

CROTCHETS are also used for two opposite characters, serving to inclose what we call a *parenthesis*, or any other part of a discourse to be distinguished from the rest of the work; sometimes in this form [], and sometimes in this ().

CROTENAY, in *Geography*, a town of France, in the department of the Jura, and district of Poligny; 2 leagues S. E. of Poligny.

CROTENDORF, a small town of Saxony, in the circle of the Erygerbirge, with about 1000 inhabitants, famous for its quarries of beautiful white marble, which have furnished the marble for the interior ornaments of the king's catholic chapel at Dresden, for the statue of the king, and for the monument erected to the celebrated Gellert in Wendler's garden at Leipzig. The marble ornaments of the far famed town's hall of Amsterdam, have also anciently been furnished by the Crotendorf quarries, and it is but about twenty years ago that they have yielded astonishing large blocks for the monument erected at Zell in Hanover, to the late unfortunate queen Matilda of Denmark, sister to Geo. III. of England. The Crotendorf marble quarries were discovered between 1588 and 1593, by Joseph Maria Nossen. They are nearly 20 English miles in extent.

CROTON, in *Botany*, (*κροτων*, Distc.) Linn. Gen. 1083. Schreb. 462. Willd. 1718. Gært. 624. Juss. 389. Vent. 3. 496. (Ricinioides; Tourn. 423.) Class and order, *monocia monadelphia*. Nat. Ord. *Tricocæ*; Linn. *Euphorbia*; Juss. *Tithymaloides*; Vent.

Gen. Ch. Monoicous, rarely dioicous, or polygamous. *Male flowers*. *Cal.* Perianth either one-leaved, five-toothed, or five-cleft; or with five or more leaves. *Cor.* Petals five,

scarcely larger than the calyx; or none. *Nectary*: five small glands, inserted into the receptacle. *Male flowers*. *Stam.* Filaments from about five to fifteen, or more, the length of the flower, most commonly connected at the base; anthers roundish, didymous. *Female flowers*. *Cal.* Perianth of five leaves or more. *Cor.* Petals five, or more frequently none. *Pist.* Germ superior, roundish; styles three or more, generally bifid; stigmas simple or cleft. *Peric.* Capsule roundish, three-lobed at the sides, three-celled; cells two-valved. *Seeds* one in each cell.

Eff. Ch. Male and female flowers separate. Male. Calyx with at least five leaves or five divisions. Stamens from five to fifteen, or more. Female. Calyx of five leaves or more. Styles three or more. Capsule three-celled. Seeds solitary.

* *Stem woody.*

Sp. 1. *C. variegatum*. Linn. Sp. Pl. 3. Mart. 1. Lam. 1. Willd. 1. (*Codiaeum chrysofolium*; Rumph. Amb. 4. 65. tab. 25. Tjere-maram; Rheed. Mal. 6. 109. tab. 61. β . Rumph. tab. 26. γ . tab. 27.) "Leaves lanceolate, quite entire, smooth, variegated, petioled." A shrub, five or six feet high, with the habit of nerium oleander. *Branches* cylindrical, smooth, leafy towards the summit, tubercled towards the base. *Leaves* alternate, beautifully variegated with green and golden yellow, generally retuse. *Flowers* at the summit of the branches in slender racemes, peduncled, smooth, as long or longer than the leaves; bractes one to each flower, oval; calyx of the female about half the length of the germ. A native of the Moluccas and Japan, and of Malicollo and Tanna in the South Seas. It is cultivated for the beauty of its foliage in many parts of the East Indies, and is employed as an ornament both in times of festivity, and at the funerals of unmarried persons. 2. *C. cascarilla*. Linn. Sp. Pl. 4. Lam. 2. Willd. 2. (*C. lineare*; Mart. 2. Ricinoides *æliagni folio*; Plum. Sp. 20. Burm. amer. tab. 240. fig. 1. Catesb. Car. 2. 46. tab. 46. Tourn. 656.) "Leaves lanceolate, quite entire, petioled, flat and scaly above, shining and whitish underneath." Lam. A shrub from three to six or seven feet high. *Stem* short, thick; branches numerous, cylindrical, easily broken, leafy, covered with a smooth, greyish white bark. *Leaves* alternate, resembling those of the almond, not channelled, as in the next species; having their upper surface fludded with orbicular whitish scales, marked with a spot in the middle, as in hippophæ rhamnoides. *Flowers* small, in terminal spikes; males uppermost, with a five-leaved calyx and five whitish petals; females lower, with a very small five-cleft calyx, and without petals. The leaves, the young shoots, and especially the bark, have a pleasant aromatic odour when bruised or burnt. Lam. A native of Carolina and South America. The bark of this plant has been generally supposed to be the cascarilla of the shops. See CASCARILLA. Dr. Woodville, in the earlier part of his medical botany, expressed his doubts on the subject; and in his appendix to that work, declared himself fully convinced that the cascarilla is obtained solely from the cluytia cleuteria of Linnæus, which Swartz and Willdenow have removed to the present genus. See CLUYTIA *Eleuteria*. 3. *C. lineare*. Lam. 3. Hort. Kew. p. 374. Jacq. Am. 256. tab. 162. fig. 4. (*C. cascarilla*; Woody. Med. Bot. 41. *C. cascarilla* β . Willd. Ricinoides *resinarii folio*; Sloan, Jam. lut. 133. tab. 86. fig. 1.) "Leaves linear, on very short petioles, with two glands at the base, channelled and green above, tomentous-white underneath." La Marck was satisfied by well preserved specimens in the herbarium of Jussieu, that this plant is specifically distinct from the preceding,

ceding, though they have been confounded by Linnæus. The author of Hortus Kewensis appears to have been of the same opinion by his excluding the synonyms of Catesby and Plumier, quoted under *C. cascarilla*. A shrub, four or five feet high, erect, much branched; branches cylindrical, yellowish, somewhat tomentous. *Leaves* about an inch and half long, a line and half or two lines broad, exactly linear, retuse; clothed underneath with a dull white or yellowish down, which, when viewed through a lens, is found to consist of stellated hairs, a character which belongs to most of the hairy species of this genus; glands opposite, cylindrical, truncated, horizontal. *Flowers* in spikes. The whole plant has a pleasant smell. A native of the West Indies. In Jamaica it is called wild rosemary. The plant cultivated by Miller under the name of *C. cascarilla*, appears to have been the present species. 4. *C. cochinchinense*. Mart. 39. (*C. punctatum*; Lour. Cochinch. 581.) "Leaves alternate, lanceolate, quite entire, hoary underneath, shining, dotted; capsules scurfy." A middle sized tree with spreading branches. *Leaves* smooth, scentless. *Flowers* white; in simple oblong, terminal racemes; males on the upper part; calyx bell-shaped, with five divisions; petals five, lanceolate-egg-shaped, spreading; filaments fourteen, longer than the corolla; females below; calyx and petals as in the male; germ trigonous; styles three, short; stigmas quadrifid, filiform, inflexed. A native of woods in Cochinchina. 5. *C. compressum*. Lam. 20. Willd. 62. "Leaves alternate, entire, tomentous underneath; petioles somewhat decurrent; little branches compressed." *Branches* hard, somewhat woody, angular, a little pubescent or mealy towards the top. *Leaves* resembling those of *Solanum laurifolium*, petioled, almost smooth, and sprinkled with scarcely perceptible dots above, tomentous and greyish white underneath. *Flowers* in spikes at the extremity and forks of the branches. Found by Commerçon in Brazil. 6. *C. dioicum*. Mart. 42. Willd. 7. Cav. ic. 1. 4. tab. 6. "Leaves scattered, lanceolate, narrowed at the base, obtuse, quite entire, tomentous, nearly sessile; flowers dioicous." Whole plant covered with a soft nap. *Stem* cylindrical, with divaricating branches. *Leaves* silvery underneath, somewhat channelled, spreading. *Male flowers* in terminal spikes, pedicelled, with awl-shaped bractes; calyx bell shaped, half-five-cleft; corolla none; nectariferous glands five, yellow, placed in a ring at the bottom of the calyx; filaments twelve or thirteen, not united at the bottom, a little longer than the calyx and attached to it in its lower part, villous, green. *Female flowers* like the male in the calyx and glands, but on a different plant, and on three flowered terminal peduncles; germ roundish; styles three, united at the base, half-five-cleft. *Capsule* larger than a pea. *Seeds* egg-shaped, smooth. A native of Mexico, cultivated at Madrid. 7. *C. polygamum*. Mart. 51. Jacq. Amer. pict. tab. 263. fig. 59. "Leaves alternate, lanceolate, ferrated, thinly set with decumbent hairs." An upright shrub, four feet high, but little subdivided. *Branches* cylindrical, smooth, cinereous. *Leaves* almost three inches long, on very short petioles, acute, smoothish, green on both sides. *Flowers* usually appearing before the leaves, whitish, scentless, some hermaphrodite, others male and others female on the same, or on different plants; hermaphrodites, calyx five-leaved; petals oblong, longer than the calyx; germ three-grooved; style femitrid with bifid segments. A native of Carthage, in New Spain. 8. *C. dichotomum*. Willd. 19. "Leaves lanceolate, ferrated, hairy, tomentous underneath; spikes from the forks of the branches; branches dichotomous, divaricated." *Branches* thick, woody, greyish brown. *Leaves* half an inch long, on short petioles. *Spikes* half an inch

long. A native of St. Domingo. 9. *C. discolor*. Willd. 3. "Leaves elliptical, quite entire, obtuse, mucronat, petioled, densely tomentous underneath; flowers dioicous." Nearly allied to *C. cascarilla*; n. 2. A native of the Island of St. Croix in the East Indies. 10. *C. maritimum*. Willd. 4. Walt. Car. 239. (*C. disjunctiflorum*; Mich. amer. bor. 2. 214.?) "Leaves elliptical, quite entire, rather obtuse, hoary, tomentous underneath, spikes terminal, few-flowered." *Leaves* half an inch long, wrinkled on the upper surface; petioles long, tomentous. *Female flower* solitary at the base of the spike. 11. *C. lanatum*. Lam. 29. Willd. 65. "Leaves elliptical, quite entire, woolly on both sides; racemes terminal and from the forks of the branches; stamens bearded." Whole plant covered with a short, woolly, brownish down, giving it a sombre appearance. A low shrub, with loosely spreading branches. *Leaves* alternate, often opposite at the tops and under the forks of the branches, small, on short petioles. *Flowers* yellowish; males with at least ten stamens; females with three short, villous styles. A native of South America, near Monte Video. 12. *C. levigatum*. Mart. 46. Willd. 39. "Leaves elliptical, smooth and even on both sides, with one gland at the base, quite entire, or ferrated, obtuse; racemes terminal, elongated." *Branches* cylindrical, proliferous, pulverulent-scaly and cinereous near the top. *Leaves* petioled, clustered at the ends of the branches, two inches long or more, paler underneath, membranous, either quite entire, or slightly and obtusely ferrated near the top; stipules awl-shaped, deciduous. *Common peduncle* about seven inches long, erect, striated-angular, covered with farinaceous scales, mucicated after the fall of the flowers; calyx somewhat hirsute; stamens numerous. A native of Hainam. 13. *C. reticulatum*. Willd. 41. "Leaves oblong, acuminate, quite entire, smooth on both sides, reticulated underneath; raceme terminal, elongated." *Branches* cylindrical, dark brown; younger ones pubescent. *Leaves* three or four inches long; petioles pubescent. *Raceme* half a foot long. 14. *C. laurinum*. Mart. 35. Willd. 37. "Leaves oblong, acute, quite entire, somewhat thick and rigid, smooth, dotted underneath; petioles scabrous, dotted; racemes axillary, very long, spreading; stem arboreous." A native of Jamaica. 15. *C. ovalifolium*. Willd. 8. Welt. Sr. Cruc. 253. "Leaves oblong, obtuse, attenuated at the base, finely ferrated at the tip, petioled, smooth; little branches hairy." *Leaves* an inch long, green on both sides, thinly set with stellated hairs; petioles long. *Flowers* in a terminal spike; females three or four at the base, on long peduncles. A native of the islands of St. Cruz and St. Thomas. 16. *C. argyranthemum*. Willd. 12. Mich. amer. bor. 2. 215. (*C. punctatum*; Jacq. ic. rar. 3 tab. 161.) "Leaves oblong, quite entire, tomentous underneath, petioled; peduncles terminal, about two-flowered." *Calyxes* pedicelled, silvery white. A native of dry woods in Georgia and Florida. 17. *C. divaricatum*. Mart. 33. Willd. 28. Swartz. prod. 100. Flor. ind. sec. 2. 1187. "Leaves oblong, obtuse, ferrated, rough with hairs, with two glands at the base; racemes terminal, solitary; branches dichotomous, divaricated." A native of dry thickets in the West Indies. 18. *C. procumbens*. Mart. 49. Jac. amer. "Leaves wedge-shaped, acute, quite entire." A shrub, three feet high, smooth, scentless. *Stems* partly erect, partly procumbent. *Leaves* two inches long, alternate, petioled. *Flowers* small, green; peduncles axillary, very short, usually with four males at the top and two females below, petals of the females twice the length of the calyx. Common at Carthage in South America. 19. *C. citrifolium*. Lam. 26. Willd. 15. (*Ricinoides arbor, folio citri*; Plum. Sp. 20. Burm.

C R O T O N.

Burm. Amer. tab. 240. fig. 2. Tourn. 656.) "Leaves ovate-lanceolate, entire, covered with a shining meal; spikes axillary; capsules round, rough with warts, silvery." A tree about the size of an apple-tree, with a dark red bark. *Leaves* very numerous, alternate, petioled, in size and nearly in shape resembling those of the citron, but less firm. *Flowers* in spikes near a foot long: males at the top; calyx with five divisions: petals five, white, oval; stamens numerous; females below; calyx with five divisions, powdery. *Capsule* round, a little less than a hazel nut, covered with a silvery meal. *Seeds* oblong, convex on one side, angular on the other. Observed by Plumier in the island of St. Domingo. 20. *C. balsamiferum*. Linn. Mant. 125. Mart. 15. Lam. 4. Willd. 50. Jacq. Amer. 255. tab. 162. fig. 3. pict. 124. tab. 242. Hort. 3. tab. 46. "Leaves ovate-lanceolate, quite entire, with two glands at the base, scabrous, tomentous underneath; capsules tomentous." A shrub, three or four feet high, sweet-scented, erect, branched, diffuse, covered all over with a close yellowish down. *Leaves* scatteringly alternate, from two to three inches long, acute, on rather long petioles. *Flowers* small, in spikes both terminal and proceeding from the divisions of the upper branches; males uppermost, with a five-parted calyx and five white petals. It much resembles *C. humile*, (n. 59.) but its leaves are not heart-shaped. A native of the West Indies. The whole plant abounds with a thickish, yellowish, sweet-scented balsamic juice, which drops from it when it is cut or broken. In Martinico this juice is distilled with spirits of wine, and a cordial liquor obtained, which is introduced at the table and called Eau de Mante. 21. *C. erioanthemum*. (*C. lanatum*; Mart. 40. Lour. Cochinch. 581. "Leaves opposite, ovate-lanceolate, quite entire, smooth; corollas woolly." A large tree with spreading branches. *Flowers* white, in simple terminal racemes; males at the top; calyx tubular, five-parted, erect; petals five, egg-shaped, woolly within, the length of the calyx; filaments fifteen, the length of the corolla; females below; calyx permanent, five-leaved; the leaves spreading, egg-shaped, acute; corolla none; germ egg-shaped; style none; stigmas three, filiform, short, bifid, reflexed. *Capsule* egg-shaped, tubercled at the top. A native of woods in Cochinchina. La Marck having called another plant lanatum, (see n. 11.) we have been under a necessity of giving a new name to the present. 22. *C. farinosum*. Lam. 28. Willd. 61. "Leaves opposite, ovate-lanceolate, nearly entire, green above, covered with a hoary mealiness underneath; spikes slender." A beautiful shrub, remarkable for the strong contrast of colour in the upper and under sides of the leaves. *Branches* cylindrical, slender, smooth, greyish, loose, several times dichotomous. *Leaves* two inches long, in shape resembling those of common sage, on short petioles. *Spikes* two or three inches long, some terminal, others in the forks of the upper branches; female flowers at the base of the spike, white, mealy, with five acute divisions; germ roundish; styles three, quadrifid, widely expanding. Found by Commerçon in the island of Madagascar. 23. *C. umbellatum*. Willd. 42. "Leaves ovate-oblong, acuminate, quite entire, smooth on both sides; flowers in terminal umbels." Whole plant quite smooth. *Branches* cylindrical, cinereous-brown. *Leaves* three or four inches long, simply veined. *Umbel* simple, about six-flowered, on a capillary peduncle. A native of the East Indies. 24. *C. sericeum*. Lam. 25. Willd. 48. (*C. matourense*; Aubl. guian. 879. tab. 338.) "Leaves ovate-oblong, acuminate, silky-hoary underneath with two glands at the base; female calyxes ciliated." A tree. *Trunk* from eight to ten feet high, about nine inches in diameter, with an even cinereous bark; branches tender.

Leaves alternate, entire, on rather long petioles. *Flowers* in a long, loose, villous, cinereous spike; calyx of the males with five deep, acute divisions; petals five, lanceolate, cinereous; filaments eleven, villous at the base; calyx of the females with five oval, fringed leaves; styles from twelve to sixteen, curved inwards; bractes two, small, scale-like at the base of each pedicel. A native of Cayenne and Guiana. 25. *C. subulatum*. Lam. 27. Willd. 25. (*C. guianense*; Aubl. guian. 882. tab. 339.) "Leaves oblong-ovate, acuminate, serrated, with two glands at the base, ferruginous-tomentous underneath; capsules smooth." A smaller tree than the preceding, with a trunk not more than six inches in diameter. *Leaves* on long petioles. *Flowers* whitish, small, in axillary spikes near the ends of the branches. A native of Guiana. 26. *C. montanum*. Willd. 46. "Leaves ovate-oblong, acuminate, quite entire, with two glands at the base, tomentous and resinous dotted underneath." *Branches* cylindrical, pubescent. *Leaves* four or five inches long, petioled, a little narrowed at the base, somewhat scabrous on the upper surface, hoary and sprinkled with very minute scarlet, resinous dots underneath. *Racemes* axillary and terminal, two inches long. The hairs in this species are not stellated. Found by Klein on mount Kalisghar, near Velur in the East Indies. 27. *C. coccineum*. Mart. 45. Willd. 38. Vahl. symb. 2. 97. "Leaves somewhat egg-shaped, acuminate, quite entire, smooth on both sides, with two dark brown glands at the base, dotted with scarlet underneath; racemes terminal." *Branches* cylindrical, pulverulent-villous near the summit. *Leaves* two or three inches long, petioled, attenuated in the upper part, rather acute at the base, three-nerved, reticularly veined underneath and a little coloured by numerous, very minute, pellucid, scarlet dots; petioles an inch and half long, cylindrical. *Flowers* nearly sessile; racemes two inches long, either terminal and solitary, or crowded in the upper axils; peduncle yellow-ferruginous, angular; styles reflexed; germ white, dotted with scarlet. *Capsules* oblong, scarlet. Vahl. 28. *C. inophyllum*. Mart. 27. Willd. 14. Forst. prod. 355. "Leaves inversely egg-shaped, quite entire; stem arboreous." A native of New Caledonia. 29. *C. abnifolium*. Lam. 9. Willd. 13. "Leaves inversely egg-shaped, petioled, nearly entire, dotted with scattered stellated hairs; racemes elongated, nearly terminal." *Branches* dotted, tomentous towards the summit. *Leaves* alternate, more hairy underneath; young ones tomentous, whitish. *Flowers* in slender, loose racemes; peduncles and calyxes somewhat tomentous; filaments of the males ten, villous or bearded. *Capsules* almost sessile, roundish-oval, covered with small stellated hairs, which fall off here and there, and leave those parts smooth. When the capsules fall off, the receptacles of the seeds remain on the common peduncle with three teeth at their summit, which have the appearance of permanent pedicels. Specimens brought by Dombey from Peru. 30. *C. betulinum*. Mart. 47. Willd. 18. Vahl. symb. 2. 98. "Leaves egg-shaped, obtuse, unequally toothed, scabrous-dotted above, pubescent underneath; racemes axillary, longer than the leaf." The habit of a birch. *Branches* cylindrical, purplish; younger ones hoary, covered with scales and striated hairs. *Leaves* an inch long, with a minute pedicelled gland at each side of the base; petiole shorter than the leaf. *Flowers* small, a little remote, rough with hairs; calyx of the females with five linear, obtuse leaves. A native of the isles of St. Thomas and Domingo. 31. *C. glabellum*. Linn. Sp. Pl. 5. Mart. 5. Lam. 23. Willd. 16. (*C. fruticosum*, foliis subrotundo-ovatis, lpiculis axillaribus; Brown. Jam. 348. Mali folio arbor; Sloan. Jam. 59. Hist. 2. 30. tab. 174. figs.

C R O T O N.

figs. 3, 4.) "Leaves egg-shaped, rather obtuse, quite entire, even-surfaced; fruit peduncled." Seldom less than seven or eight feet high. *Leaves* alternate, petioled, glaucous underneath. *Fruit* smooth. According to Browne, all the parts of the plant are of an active warm nature, and have an agreeable smell. La Marck observes that Sloane's figures belong to trees from twenty to thirty feet high; and that in one of them the flowers are in simple terminal spikes, but in the other form lateral axillary panicles. A native of Jamaica. 32. *C. globosum*. Mart. 32. Swartz. prod. 100. "Leaves egg-shaped, obtuse, entire; peduncles in pairs; flowers dioecious; fruit globular, echinate-hispid." A native of Jamaica. 33. *C. punctatum*. Mart. 25. Willd. 45. Retz. Obs. 5. 30. "Leaves egg-shaped, acute, quite entire, tomentous underneath, dotted." *Flowers* in a spike. *Capsules* silky-hairy, scarlet. Sent from Ceylon by Koenig. 34. *C. fissiflorum*. Mart. 31. Swartz. prod. 100. "Leaves egg-shaped, acuminate, quite entire, smooth; flowers sessile, axillary, dioecious, with five stamens." A native of Hispaniola. 35. *C. organifolium*. Lam. 6. (Ricino affinis odorifera, teucriti folio; Sloan. Jam. Hist. t. 133. tab. 86. fig. 3.) "Leaves egg-shaped, acute, nearly entire, with two setaceous glands at the base, tomentous-hoary underneath." Resembling *C. lineare* (n. 3.) in the texture and colour of the leaves, but differing in their form. *Branches* very slender, cylindrical, diffuse, divided, villous only at the summit. *Leaves* alternate, small, entire or very finely toothed, with a longitudinal furrow above, nerved underneath, on rather long peduncles. A native of St. Domingo. 36. *C. philippense*. Lam. 14. "Leaves egg-shaped, somewhat acuminate, nearly entire, with two glands at the base, tomentous and reticulated underneath; capsules covered with a scarlet wool." *Branches* cylindrical, slightly tomentous at the summit. *Leaves* alternate, petioled, even and smooth above, nerved. *Flowers* in terminal racemes not longer than the leaves. A native of the Philippine islands; found by Sonnerat. 37. *C. lacciferum*. Linn. Sp. Pl. 12. Mart. 14. Lam. 13. Gert. tab. 107. (Aleurites laccifera; Willd. Ricinoides, circeæ folio; Burm. Zeyl. 201. tab. 91. Pluk. alm. 520.) "Leaves egg-shaped, somewhat acuminate, toothed, on long petioles; calyxes tomentous." A middle-sized tree. *Branches* few, long, spreading, angular, rugged. *Leaves* scattered. *Flowers* in simple terminal racemes, white, with five-leaved calyxes; males uppermost; corolla five-petaled; stamens from fifteen to twenty. *Capsules* small, globular, not grooved, enclosed at the base by the permanent spreading calyx. A native of Ceylon, Cochin-China, and Cambodia. A very fine lac exudes spontaneously from the tree, appearing like a small pearl or bud within the axils of its branches. It is used by the inhabitants of Ceylon to varnish their lances, the handles of their knives, &c. 38. *C. lignum*. Linn. Sp. Pl. 10. Mart. 12. Lam. 21. Willd. 6. Gert. tab. 107. (Pinus indica; Bauh. Pin. 492 n. 11. Lignum moluccense; Bauh. Pin. 393. n. 12. Ricinoides indica; Burm. Zeyl. 200. tab. 90. Granum moluccarum; Rumph. Arb. 4. 98. tab. 42. Cadi-avenien; Reed. Mal. 2. 61. tab. 33. Rai. Hist. 167. 1803. 1830. 1855. Supp. 112. (66.)) "Leaves egg-shaped, acuminate, ferrated, smooth, with two glands at the base; petioles shorter than the leaves; racemes terminal." A middle-sized tree. *Trunk* rather slender; branches few, smooth, spreading, leafy on their upper part. *Leaves* alternate-nerved; young ones studded with stellated hairs, which give them a dotted appearance. *Flowers* whitish, or inclining to yellow; males uppermost; calyx five-parted; petals five; stamens about sixteen; females below; calyx small, five-

leaved, stellated, reflexed under the capsule. *Capsules* almost the size of a hazel-nut, smooth, three-furrowed. *Seeds* oval-oblong, a little shining, convex on one side, very obtusely-angular on the other. A native of the East Indies, where it is cultivated for the sake of its medicinal, and particularly of its purgative qualities. Both its wood and its seeds are in use; but on account of their very violent acrid nature, they are little esteemed in Europe, and have not been admitted into the dispensaries either of London or Edinburgh. 39. *C. congestum*. Mart. 41. Lour. Coch. 582. "Leaves egg-shaped, serrated, smooth, veined, flowers cinnabarred, naked, axillary." *Stem* somewhat shrubby, five feet high, with many reclining branches. *Leaves* alternate, unequal. *Flowers* both male and female without petals; stamens eighteen. *Capsules* pendulous. A native of China, about Canton. 40. *C. dentatum*. (C. populifolium; Willd. 35. Mart. 38. Swartz. Prod. 101. Flor. Ind. Occ. 1197. Vahl. Symb. 2. 97.) "Leaves broad-egg-shaped, acuminate, ferrate-toothed, with two glands at the base (one, Vahl.); petioles the length of the leaves; racemes terminal, erect, solitary." *Branches* smooth, scarred. *Leaves* near together towards the top of the branches, with stellated fulvous hairs on both sides. *Calyx* of the male flowers smooth, coloured; of the females, with lanceolate, hairy, tooth-gashed leaves, and glandular teeth; germ rough with hairs. A native of Jamaica, and other parts of the West Indies. As both Miller and La Marck have a different populifolium (see n. 64, 65.) we have given a new trivial name to the plant before us. 41. *C. acuminatum*. Lam. 17. "Leaves egg-shaped, acuminate, some entire, others thin and slightly toothed, without glands, tomentous underneath; spikes axillary and terminal, tomentous-ferruginous." *Branches* somewhat tomentous, compressed towards the summit. *Leaves* large, obliquely nerved, reticularly veined; upper ones often opposite; petioles, peduncles, and calyxes ferruginous-tomentous. *Spikes* generally simple; filaments thirty or more, not united at the base. Found by Commerçon at Port Praslin in New Britain. It resembles *C. japonicum* (n. 55.), but differs in being shrubby, or perhaps a tree, and in having leaves not entirely smooth. 42. *C. rhombifolium*. Willd. 70. "Leaves rhomboid-egg-shaped, acuminate, sometimes repand, smooth on both sides, sprinkled with pellucid dots; racemes paniced, pubescent." *Leaves* some repand, others quite entire; younger ones covered with a slight pubescence. A native of the island of Ceylon. Distinguished from the preceding by the shape and smoothness of its leaves, and from *C. japonicum*, by having none of its leaves slightly three-lobed, as well as by its shrubby stem. 43. *C. paniculatum*. Lam. 16. Willd. 29. "Leaves egg-shaped, somewhat rhomboidal, mucronate, entire or slightly toothed, with two glands at the base, tomentous underneath; panicle ferruginous-tomentous." *Leaves* a little resembling those of black poplar, dark-green, and smooth above, whitish, inclining to ferruginous underneath. *Flowers* very numerous, small, sessile, in a rather large, branched panicle. Found by Commerçon and Sonnerat in the island of Java. 44. *C. jessoferum*. Tallow-tree. Linn. Sp. Pl. 9. Mart. 9. Lam. 22. (Stillingia sebifera; Willd. Ricinus chirensis sebifera; Per. Gaz. 53. tab. 54. fig. 3. Evonymo affinis; Pluk. Amath. 76. tab. 390. fig. 2.) "Leaves rhomboid egg-shaped, acuminate, quite entire, smooth, with two very small glands at the base." A tree about the height of a pear tree, and in habit resembling a cherry tree, with a light-grey, soft bark; branches long, flexible, smooth, leafy from the middle. *Leaves* scattered, numerous, becoming smaller, and forming tufts at the extremity of the branches, broader than long, resembling those of the black

poplar,

C R O T O N.

poplar, but not toothed, green and smooth on both sides, deciduous, turning red before they fall; stipules two at the base of the young leaves, membranous, linear-lanceolate. *Flowers* in spikes two inches long, and resembling catkins; males numerous, very small, pedicelled; calyx very short, one-leaved, almost truncated, or very little divided; stamens from three to five, but little longer than the calyx; females few, at the base of the spikes. *Capsules* oval, pointed, with three convex sides, smooth, hard. *Seeds* almost hemispherical, convex on one side, flattened and furrowed on the other, covered with a delicate snow-white substance. These seeds are attached by their upper interior part to three thread-like receptacles, and remain after the six valves of the capsule have fallen off, so that the spike then seems composed of small racemes with very white berries. A native of China, on the banks of rivulets. The Chinese obtain a kind of tallow from the seeds after they have been well cleared of the white substance in which they are enclosed, which would otherwise considerably lessen the quantity of oil. For this purpose they are steeped ten or fifteen days in water, after which this covering may be completely rubbed off, though not without some difficulty. The oil drops from the seeds like thick glutinous lamp oil, and soon hardens to the consistency of common tallow. This tallow is also obtained by boiling the seed, and skimming off the oil as it rises. Candles made of it are very white, but are sometimes coloured by adding to it a little vermilion; these candles, says sir George Staunton, are firmer than those of tallow, as well as free from all offensive odour; but they are not equal to those of wax or spermaceti. 45. *C. nutans*. Mart. 26. Willd. 34. Vahl. Symb. 2. 96. Forst. Prod. 354. "Leaves rhomboidal-egg-shaped, acuminate, undulated, smooth; glands marginal." Similar to the preceding; but its leaves are less acuminate, and the glands are not on the petiole at the insertion of the leaf, but on the margin of the leaf itself, a little above its base. *Spikes* two or three inches long. *Flowers* in two rows. A native of the Society and Friendly isles, and of the New Hebrides. 46. *C. bracteatum*. Lam. 18. Willd. 33. "Leaves opposite, especially the upper ones, acute, entire, with two glands at the base, tomentous underneath; racemes long, loose, bracteate." *Branches* cylindrical, several times dichotomous, cinereous, tomentous, a little ferruginous near the summit. *Leaves* petioled. Petioles, peduncles, calyxes, and germs tomentous and villous. *Raceme* from four to six inches long, simple, proceeding from the forks of the upper branches; bractes oblong-lanceolate, sessile, caducous. *Flowers* pedicelled, from two to five together in lateral bundles; females large; calyx with five oval-oblong leaves; germ large, trigonous; styles three, multifid, pencil-shaped. Found by Commerçon in the island of Madagascar. 47. *C. lucidum*. Linn. Sp. Pl. 11. Mart. 13. Lam. 24. Willd. 44. Swartz. Flor. Ind. Occ. 2. 1193. (*C. pallens*; Linn. Mant. 497. Mart. 36. Swartz. Prod. 100. *C. spicatum*; Berg. Trans. Roy. Soc. 1768. p. 132. tab. 7. *C. erectum*, glabrum; Brown. Jam. 347. n. 6.) "Leaves opposite, egg-shaped, acuminate, nearly entire, smooth on both sides; racemes erect, terminal; calyxes larger than the fruit." Calyx of the males ten-leaved, imbricated, hirsute on the inner side; corolla none; that of the females five-leaved; germ hirsute. A native of Jamaica. 48. *C. eriospermum*. Lam. 30. "Leaves opposite, egg-shaped, acuminate, quite entire; racemes compound; seeds involved in a reddish wool." *Branches* slender, cylindrical, smooth, leafy. *Leaves* green and smooth above, greenish underneath, with a fine down, chiefly on the edges. *Flowers* in axillary and terminal racemes. *Capsules* oval, dotted. *Seeds* several in each cell. Found by Commerçon in Brazil, near Rio-Ja-

neiro. La Marck's specimens were without flowers, and he very justly observes, that the polyspermous cells of the capsule render its true genus dubious. 49. *C. castuoides*. Lam. 31. "Leaves opposite, egg-shaped, toothed, smooth on both sides; petioles scabrous, channelled; spikes few-flowered." A small shrub. *Branches* very slender, slightly ferruginous-tomentous near the top. *Leaves* lessened at both ends. *Flowers* in short, ferruginous, terminal spikes; calyx and germ with short, stellated hairs; styles three, trifid or quadrifid. Found by Commerçon in the island of Madagascar. 50. *C. flavens*. Linn. Sp. Pl. 13. Mart. 20. Lam. 32. Willd. 63. (*C. frutescens* & villosum; Brown. Jam. 347. n. 3.) "Leaves heart-shaped, oblong, acuminate, quite entire, hoary above, tomentous underneath, with two pedicelled glands at the base; little branches densely tomentous." A shrub, two or three feet high. Petioles shorter than the leaves. Spikes from the forks of the branches. A native of Jamaica. 51. *C. Richardi*. Willd. 64. "Leaves very slightly heart-shaped, oblong lanceolate, mucronate, quite entire, scabrous, tomentous underneath, with two glands at the base." *Leaves* an inch and half or two inches long, obtuse, with a joint. Little branches and petioles with a yellowish down. *Raceme* two inches long, peduncled, terminal, and from the forks of the branches. 52. *C. Afroites*. Mart. 24. Willd. 66. Hort. Kew. 3. p. 375. "Leaves oblong-lanceolate, somewhat heart-shaped, scabrous, tomentous underneath, with two glands at the base; little branches more densely tomentous." Willd. "Leaves oval, somewhat heart-shaped, quite entire, stellate-tomentous on both sides. Little branches more densely tomentous." Hort. Kew. *Leaves* two inches long and more, green above, and covered with numerous elevated dots, and scattered stellated hairs, with two pedicelled glands at the base, the pedicels tomentous. *Raceme* terminal, and in the forks of the branches. Willd. A native of the West Indies. The last three species are nearly allied. 53. *C. leprosum*. Willd. 65. "Leaves cordate, lanceolate, quite entire, tomentous underneath; little branches more densely tomentous; spikes axillary." *Leaves* three inches long, green above, and set with numerous stellated hairs, densely tomentous, and white underneath. *Spikes* on long peduncles. No glands at the base of the leaves. A native of St. Domingo. 54. *C. mucronatum*. Willd. 32. "Leaves heart-shaped, roundish, elliptical, obtuse, mucronate, quite entire, tomentous on both sides." *Branches* and petioles ferruginous-tomentous. *Leaves* resembling those of mespilus cotoneaster, almost an inch long, thick, on long petioles. *Spikes* an inch, or an inch and half long, axillary, and terminal. A native of the warmer parts of America. 55. *C. albaefolium*. Mart. 29. (Ricnoides, althææ folio; Plum. Cat. 20.) "Leaves oblong-heart-shaped, tomentous; stem branched; spikes terminal." A shrub, six or seven feet high; branches covered with a yellowish down. *Leaves* two inches and a half long, one inch broad, on long petioles, acute, curved on both sides, with down like that on the branches. *Flowers* in long, loose spikes; males uppermost; corollas white, deeply five-cleft; stamens five, taper; females below; calyxes large, woolly. *Capsules* round. Sent to Miller from Jamaica by Dr. Houlston. 56. *C. arenaticum*. Linn. Sp. Pl. 14. Mart. 16. Willd. 55. Vahl. Symb. 2. 98. Gært. tab. 107. (*C. tiliaefolium*, β . Lam. Ricnoides, circææ foliis, media; Burm. Zeyl. 202. 11.) "Leaves heart-shaped, scabrous, somewhat serrated, petioled; stem arboreous." Linn. "Leaves cordate egg-shaped, serrated, scabrous, with petioled glands underneath at the base, and on the edges; racemes terminal." Vahl. "Leaves oblong, somewhat heart-shaped, finely serrated, scabrous,

CROTON.

scabrous, pubescent underneath, with two glands at the base; lowest ferratures with pedicelled glands; raceme terminal." Willd. A middle-sized tree. Branches spreading, subdivided, cylindrical, rugged, marked with interspersed minute and larger dots, tomentous towards the end, with stellated hairs. *Leaves* large, spreading, unequally serrated; younger ones acuminate, somewhat tomentous, with stellated hairs, especially underneath; older ones obtuse, almost naked, only a little hairy on the veins, paler, dotted and rugged underneath; petioles one-third of the length of the leaf, tomentous; stipules bristle-shaped, deciduous. *Racemes* two inches long, quite simple, rather erect; bracte bristle-shaped at the base of each pedicel. *Flowers* numerous, scattered, villous; males uppermost; leaves of the calyx numerous, egg-shaped; stamens villous at the base. Linn. and Vahl. Calyx of the females short, five-leaved, reflexed under the capsule. *Capsule* egg-shaped or globular, smooth, coriaceous, thick, brown, marked with six paler lines. *Seeds* ovate-oblong, convex on one side, angular on the other, rough on all sides, with obscure tubercles. Gært. A native of the island of Ceylon. Gærtner asserts that *halæcus littorea* of Linnæus is erroneously quoted by Linnæus as a synonym. It appears to have been solely on account of this synonym that La Marck was induced to make this species a variety of his *tilæfolium*, though he acknowledges that his plant does not in all respects correspond with Rumphius's description, and seems almost equally inclined to consider his mauritanium as the true aromaticum of Linnaeus. It is certainly very nearly allied, but we think not the same; we shall therefore keep them distinct, and leave it to future observers to determine their identity or difference. 57. *C. mauritanium*. Lam. 12. (*Halecus terrestris* aibus; Rumph. Amb. 3. 198. tab. 1. 7. A.) "Leaves cordate-oblong, acute, finely serrated, slightly scabrous; peduncles and petioles woolly; racemes terminal." A tree; young branches woolly, whitish. *Leaves* for the most part alternate, acute, green, and almost smooth above, but a little rough, with small woolly dots; slightly woolly and cinereous underneath. *Flowers* white, in woolly terminal racemes; males uppermost; calyx tomentous, one-leaved, with five divisions; petals five, white, woolly; stamens from thirty to fifty, short; females pedicelled; calyx and corolla as in the males; germ tomentous; styles at least twelve, short, villous. *Capsules* tomentous. *Seeds* egg-shaped, shining, with a somewhat triangular umbilicus. Found by Commerçon in the Ile of Bourbon. 58. *C. scabrum*. Willd. 56. "Leaves oblong-egg-shaped, cordate, acuminate, quite entire, scabrous above, hoary-pubescent underneath; racemes terminal." A shrub, eight feet high; branches cylindrical, hoary. *Leaves* three inches long and more; petioles hoary. *Racemes* an inch and half long, similar to the next species, but the leaves are much larger, somewhat different in form, are scabrous above, with dots only, not with stellated hairs, and are pubescent underneath, but not tomentous. A native of dry rocky ground about Caraccas. 59. *C. lumil.* Linn. Sp. Pl. 16. Mart. 17. Willd. 57. (*C. sidsifonium*; Lam.? *Croton fruticosum minus*; Brown. Jan. 5. 6.) "Leaves heart-shaped, quite entire, somewhat crenated, scabrous, tomentous underneath." Linn. "Leaves somewhat cordate-egg-shaped, acute, quite entire, scabrous above, tomentous underneath." Willd. "Leaves cordate-oval, entire, scabrous, hoary, tomentous underneath; racemes small, terminal." Lam. A shrub two feet high, with a smooth branching stem; branches hoary at the end. *Leaves* alternate, ruvous, clammy, scabrous, with warts which are terminated by minute white hairs, contiguous at the base; petioles somewhat hairy. *Flowers*

in terminal, erect spikes; males uppermost, from five to seven, smaller, whitish; calyx with five hoary leaves (with five divisions; Lam.); petals five, white, equal to the calyx (smooth and coloured without, villous at the edges and within; Lam.) filaments from twenty to twenty-four (at least six; Lam.) anthers compressed, whitish; females below, larger, greenish; calyx five leaved (tomentous, with five acute deep divisions; Lam.) corolla none; germ three-grooved, hirsute (slightly tomentous; Lam.) styles three, white, contiguous at the base, four-parted to the middle (bifid or trifid; Lam.) stigmas first white, then rufescent. *Capsule* somewhat hirsute. *Seeds* roundish. The smell of the whole herb is strong and balsamic. Swartz. A native of Jamaica. La Marck's plant was from St. Domingo, and does not appear to be materially different from that of Linnaeus. 60. *C. niveum*. Mart. 50. Jacq. Amer. pict. tab. 243. Lam. 10? "Leaves heart-shaped, acuminate, finely serrated, tomentous-shining underneath;" Jacq. "Leaves cordate-oblong, acute, entire, undulated at the edges, tomentous-silvery underneath." Lam. A shrub ten feet high, having in all its parts a pleasant aromatic smell. *Leaves* green above. *Flowers* in close spikes an inch long, coming out before the leaves; males very numerous; females few, either situated below, or intermingled with the males; calyx tomentous, somewhat ferruginous; corolla white; styles three, branched, the length of the germ, reflexed, and embracing it closely. The male flowers are in such vast abundance that when they fall off, they whiten all the ground. In the specimen from which La Marck formed his specific character, and which he believes to be the present plant, the leaves are either entire, or slightly undulated at the edges, not toothed or serrated. A native of the West Indies. 61. *C. salviaefolium*. Mart. 30. Mill. (*Ricinus salviaefolio*; Pet. hort. sic.) "Leaves heart-shaped, acute, tomentous; flowers in terminal and axillary spikes." A shrub near four feet high, with a silvery bark. *Leaves* about three quarters of an inch long, and half as broad at the base, tomentous on both sides, yellowish-green above, silvery underneath. *Flowers* small, white; calyxes woolly. *Capsules* roundish. 62. *C. nitens*. Mart. 34. Willd. 47. Swartz. prod. 100. Flor. ind. occ. 2. 1189. "Leaves somewhat cordate-egg-shaped, acuminate, entire, smooth, shining, silvery-squamous underneath; racemes axillary, erect, shorter than the leaves." *Leaves* covered underneath with minute scales, in each of which there is a pellucid point. A native of Jamaica. 63. *C. nicans*. Willd. 52. Swartz. Flor. ind. occ. 2. 1187. (*Ricinus dulcis populea fronde argentea*; Pluk. alm. tab. 220. fig. 5. Brey. prod. 2.) "Leaves cordate-egg-shaped, attenuated, somewhat tomentous, green and warty-squamous above, silvery shining underneath; racemes terminal, erect." A native of Jamaica. 64. *C. populifolium*. Lam. 7. (*Ricinoides foliis populi hirsuti*; Plum. Sp. 20. MSS. 4. tab. 1. 3. Tourn. 656.) "Leaves heart-shaped, acuminate, serrated, villous tomentous underneath; spike terminal." A middle-sized tree, but little spreading. *Branches* cylindrical, clothed with a short down. *Leaves* alternate petioled, sometimes a little angular, greenish above, whitish underneath. Male flowers uppermost; calyx with five divisions; petals five, white; stamens numerous; females, calyx quinquefid; styles three, bifid. *Seeds* sprinkled with small black dots. Found by Plumier in the island of St. Vincent. 65. *C. Milleri*. (*C. populifolium*; Mill. dict.) "Leaves heart-shaped, acuminate, light green above, woolly underneath; spikes short, lateral." A shrub, seven or eight feet high, covered with an ash-coloured bark, sending out many irregular branches. *Leaves* near four inches long, and two broad in their widest part, on slender petioles.

Flowers

C R O T O N.

Flowers whitish green. Sent from Jamaica to Miller by Robert Millar. 66. *C. quadrifetofum*. Lam. 19. "Leaves slightly heart-shaped, acuminate, finely serrated, rough, tomentous, with four bristles underneath at the base." *Branches* tomentous towards the top, with separate hairs which render them somewhat hispid. *Leaves* petioled, whitish green above and rough, with woolly points, very woolly underneath; with four rather long bristles at the base, each terminated by a truncated concave gland. *Flowers* in nearly terminal, woolly racemes, six inches long or more; calyx of the males tomentous, five-leaved; petals five, tomentous on the outside; filaments more than twenty, bearded at the base, but not at all united. Found by Dombey in Peru. 67. *C. puigens*. Willd. 52. Jacq. ic. var. 3. tab. 622. Collect. 4. p. 27. "Leaves deeply heart-shaped, very acuminate, finely serrated, scabrous above, tomentous underneath, with four glands at the base." Glands pedicelled, two on each side at the base of the leaf. A native of the Caraccas. It differs from the preceding in the form of the leaves, but seems only a variety. 68. *C. penicillatum*. Willd. 53. Ventenat choix 12. tab. 12. (*C. ciliato-glandulosum*; Orteg. dec. 4. 51.) "Leaves heart-shaped, acuminate, quite entire, glandular-ciliated, tomentous underneath, with a pencil-shaped bundle of pedicelled glands at the base, and two others at the base of the petiole." A shrub; little branches hoary-pubescent. *Racemes* two inches long, axillary, near the top of the branches; filaments not united. A native of Cuba. 69. *C. macrophyllum*. Mart. 27. Willd. 54. Swartz. prod. 100. Flor. ind. occ. 2. 1: 96. "Leaves cordate-roundish, acuminate, quite entire, thick, tomentous, nerved underneath." A native of Jamaica. 70. *C. tiliaefolium*. Lam. 11. "Leaves heart-shaped, roundish, scabrous, somewhat serrated, petioled; racemes axillary." A small tree, with a greyish bark. Upper part of the branches, petioles, nerves of the leaves, peduncles and calyxes whitish-tomentous. *Leaves* alternate, scarcely acute, on very short petioles. Found by Commerçon in the Isles of France and Bourbon. 71. *C. corylifolium*. Lam. 8. "Leaves heart-shaped, roundish, acuminate, serrated, dotted, nearly smooth on both sides." Small branches, petioles, peduncles, nerves of the leaves and young leaves somewhat tomentous and whitish. *Leaves* alternate, petioled, sometimes a little angular. *Racemes* four or five inches long, peduncled, solitary, lateral, near the tops of the branches. *Flowers* pedicelled. A native of the Antilles. 72. *C. moluccanum*. Linn. Sp. Pl. 15. Mart. 19. Lam. 15. Willd. 59. (*Nux juglans moluccana bifida*; Burm. zey. 170. Camirium; Rumph. amb. 2. 180. tab. 58. Camirium cordifolium; Gært. tab. 125. fig. 2. Ambinox five bancoulia; Commerf. MSS. Herb. and fig.) Nuts of Bancoul. "Leaves heart shaped, angular, scabrous, tomentous underneath." Linn. "Leaves somewhat heart-shaped, angular, obtuse, repand, scabrous, tomentous underneath." Willd. "Leaves heart-shaped, angular, with two glands at the anterior part of the base; calyxes of the male flowers two-parted." Lam. A thick low tree, branched like the common walnut tree. *Leaves* alternate or scattered, near the ends of the branches, large, with three or five angular lobes, smooth on both sides when completely unfolded, covered with a reddish mealy down when young; sometimes oblong, acute, nearly entire; petioles rather long. *Flowers* in a terminal, much branched panicle; males very numerous, on angular tomentous peduncles, without bractes; calyx tomentous; divided into two oval concave lobes, opposite to each other and almost equal; petals five, oblong, linear, almost twice the length of the calyx; stamens about ten, scarcely longer than the

calyx; females not seen by La Marck. Fruit a nut, broader than long, transversely oval, with a short point at its summit, containing, under a hulk somewhat resembling that of a common walnut, two woody shells (noyaux) about the size of a chestnut, rounded at the base, pointed at the summit, a little compressed laterally, with a cavity on the interior side, whitish, one-celled, enclosing a pleasant tasted kernel or seed. A native of the Moluccas and Ceylon, and according to Commerçon, naturalized in the island of Bourbon. We have confined ourselves to La Marck's description as it is the fullest, and taken from specimens recently obtained from Commerçon. Nothing can be more evident than that it cannot belong to this genus; and it is surprising that La Marck, who is generally ready enough to correct Linnæus, has passed it over with slightly observing that in its fruit it approaches aleurites, a new genus formed for a plant found by Forster in the islands of the South Sea. Jussieu afterwards observed, that it ought to be referred to that genus, which Gærtner has since called camirium, the original name in Rumphius, and of which he has given the following corrected generic character from the MS. notes of Dr. Solander. Male and female flowers separate, on the same plant. *Males*; calyx one-leaved, unequally two, three or four-cleft; one segment larger; corolla with five petals, oblong, narrowed at the base, inserted into the receptacle, longer than the calyx; stamens several, up to sixteen. *Females*; calyx and corolla as in the males; nectaries; five egg-shaped glands within the base of the petals; germ superior. *Drupe* dry, two-celled. *Seeds* solitary, nucamentaceous. The kernels of the present plant yield abundance of oil, which is used in the country for candles and other domestic purposes. 73. *C. gossypifolium*. Mart. 48. Willd. 73. Vahl. symb. 2. 98. tab. 49. "Leaves heart-shaped, three-lobed, tomentous, with two glands underneath at the base." A tall tree. *Branches* cylindrical, tomentous-hoary at the top. *Leaves* clustered towards the ends of the branches, alternate, nine inches long or more, thinly and slightly toothed, tomentous on both sides with stellated hairs, whiter underneath, soft; lobes egg-shaped, acute, middle one elongated; petiole one-third the length of the leaf. *Raceme* about a span long, terminal, erect, tomentous. *Flowers* numerous, scattered, males intermixed with females; germ hirsute, hoary. A native of the island of Trinidad. 74. *C. capense*. Linn. jun. Supp. 422. Mart. 21. Willd. 68. Thunb. prod. 117. "Leaves three-lobed-hastate, and lanceolate, quite entire. A native of the Cape of Good Hope. 75. *C. senegalense*. Lam. 33. Willd. 67. "Leaves hastate-oblong, tomentous underneath; flowers crowded, almost sessile; capsules scaly-shining." *Branches* slender, cylindrical, with a brown bark, clothed with scattered stellated hairs, white and almost tomentous near the top. *Leaves* generally alternate, scarcely an inch long, on short petioles. *Flowers* near the top of the branches; styles erect, tomentous on the outside. *Capsules* globular, with three roundish lobes; covered with white, silvery, orbicular scales, which are dotted in the middle. Found by Adanson in Senegal. 76. *C. trilobatum*. Willd. 72. "Leaves three or five-lobed, serrated, pubescent underneath; petioles pubescent." Exactly similar to *C. lobatum* (n. 96.) except in its woody stem, and the pubescence of its leaves and petioles; stamens ten, not united.

** *Herbaceous.*

77. *C. castaneifolium*. Linn. Sp. Pl. 1. Mart. 3. Lam. 36. Willd. 9. (*Ricinoides, castanææ folio*; Plum. Sp. 20. Tournef. 656. Burm. Amer. tab. 239. fig. 1. *Acalypha australis*;

C R O T O N.

australis; Linn.?) About three feet high. *Root* spindle-shaped, the length and thickness of the finger, white, fungous, fibrous. *Stem* cylindrical, appearing woody, but tender and full of pith, greenish, rough with stiff sharp hairs; branches somewhat zig-zag. *Leaves* alternate, near six inches long, sometimes pointed, nerved. *Spikes* axillary, on hispid peduncles; male flowers small, uppermost; calyx five-cleft; petals five, white; females below; calyx hispid, with six segments alternately larger and smaller. *Fruit* hispid, roundish, tricapular. Found by Plumier in St. Domingo. 78. *C. palustre*. Linn. Sp. Pl. 2. Mart. 4. Lam. 57. Willd. 11. (Rhinoides palustre; Mart. Cent. tab. 38.) "Leaves ovate-lanceolate, plaited, serrated scabrous." *Root* annual. *Stem* about a foot high, flattened, green, procumbent or erect. *Leaves* two or three inches long, about a quarter of an inch broad, smooth on both sides, striated by several lateral nerves; petioles half an inch long. *Flowers* in axillary spikes two inches long; males four or five, uppermost; females three or four. *Capsules* about the size of a pea, rough with warts or soft little spines, sessile. Raised by Miller from seeds sent by Dr. Houston, who discovered it near La Vera Cruz. Its appearance is much altered by cultivation. 79. *C. tricuspidatum*. Lam. 34. (*C. lanceolatum*; Willd. 6. Cav. ic. 6. 38. tab. 557. fig. 2.) "Leaves oblong-lanceolate, finely toothed, three-nerved; petals tricuspidate." *Stem* four or five feet high, erect, a little branched, slightly hispid with a few scattered stiffish hairs; branches striated, filiform. *Leaves* alternate, a little hispid at the edges, smooth on the surface, on short petioles. *Peduncles* axillary, many-flowered, shorter than the leaves; calyx of the male flowers with five or six lanceolate leaves; petals white, the length of the calyx (half the length; Cav.), with three (sometimes four; Cav.) points or teeth at the tip; glands five, small, attached to the receptacle of the calyx; filaments five, united at the base; females at some distance from the males; corolla none; germ roundish, villous; stigmas reflexed. Dombey Herb. and MSS. A native of Chili. 80. *C. microphyllum*. Lam. 35. Willd. 17. "Leaves oval, obtuse, entire, smooth; little branches and petioles rough with hairs; flowers lateral." Scarcely a foot high, much branched, panicled, in its foliage somewhat resembling *phyllanthus niruri*. *Branches* filiform, rough with small hairs, which are frequently terminated by glands. *Leaves* small, petioled, bright green. *Flowers* in very small, few-flowered, lateral racemes; leaves of the calyx five, lanceolate, expanding, often reflexed; filaments from five to seven, united at the base; styles six, simple. *Capsules* small, globular, smooth when ripe, with three two-valved cells. Found by Dombey in Peru. 81. *C. glandulosum*. Linn. Sp. Pl. 7. Mart. 7. Lam. 40. Willd. 26. Jacq. Ic. Rar. 1. tab. 194. (*C. scordioides*; Lam. 45. *C. minus* trichotomum; Brown. Jam. 346. *C. annum erectum*; Mich. Amer. 2. 214.) "Leaves oblong, serrated, nearly entire at the base, rough with hairs underneath, with two glands at the base; stem trichotomous; spikes lateral." A foot high or more. *Root* annual. *Stem* slender, hard, villous. *Leaves* alternate, opposite at the division of the branches, petioled. *Flowers* almost sessile, clustered in very short spikes in the forks of the branches and the axils of the upper leaves; males very small, from two to five, with about eight stamens; females two or three, very hispid; calyx with five spatulate divisions; germ villous, roundish. A native of Carolina, Jamaica, and Brazil. 82. *C. acutum*. Mart. 11. Willd. 41. "Leaves egg-shaped, serrated, acuminate, smooth, with two glands." *Root* annual. *Stem* angular, simple, smooth. *Leaves* alternate, unequally serrated, three or four inches long, two inches broad; petioles a finger's length; glands on the edge of the leaf above the base. *Flowers* in axillary, loose, angular, smooth racemes; males uppermost; calyx with five, lanceolate, smooth, spreading, deep divisions; petals white, woolly, the length of the calyx; filaments about twelve; females; corolla none; germ egg-shaped, villous; styles five; stigmas simple, obtuse. *Capsules* pedicelled, trigonous, obtuse, villous. Cultivated in Japan. 83. *C. capitatum*. Willd. 30. "Leaves oblong-oval, obtuse, rounded at the base, entire, tomentous on both sides; female flowers clustered in a kind of head at the base of the spike." Petioles, little branches, calyxes, and capsules tomentous-woolly. *Stem* erect. A native of North America, in the country of the Illinois. 84. *C. argenteum*. Linn. Sp. Pl. 8. Mart. 8. Lam. 41. Willd. 31. "Leaves cordate-egg-shaped, entire or slightly serrated, tomentous underneath; stipules ciliated; spikes terminal, somewhat capitate, bracteate." *Root* annual. *Stem* from eight inches to a foot high, pubescent, whitish, forked or trichotomous at the summit. *Leaves* petioled, alternate on the stem, opposite at the ends of the branches, soft, greenish above, with short stellated hairs which make them appear finely dotted, tomentous and almost silvery underneath. *Flowers* white, clustered, in short terminal spikes; bractes three, oval, hispid, toothed. A native of South America, about Vera Cruz. 85. *C. hirtum*. Mart. 28. Lam. 38. Willd. 27. Herit. Stirp. 17. tab. 9. "Leaves egg-shaped, serrated, with glanduliferous hairs at the base; spikes sessile; stem hispid." *Root* annual. *Stem* erect, cylindrical, glandular, with stellated hairs on each gland, dichotomous or trichotomous at the top. *Leaves* about three inches long, two and a half broad, alternate, except the uppermost, spreading, unequally serrated, acute, with three principal nerves, veined, wrinkled, hispid on the nerves, pale green on both sides, with a few pedicelled glands on the edge at the base, not on the petiole; stipules two, awl-shaped, hairy, permanent, surrounded at the base by several sessile glands. *Flowers* of a dusky herbaceous colour, sessile, clustered in short spikes both terminal and from the forks of the branches; bracte under each flower, the length of the calyx, linear, ciliated on each side, with three glandular hairs; males above; calyx five-leaved; corolla five-petalled; filaments ten; females below; calyx five-leaved; corolla none. *Capsule* rugged, rough with hairs. It differs from *C. palustre* in having sessile spikes, not axillary; and leaves three-nerved, not plaited, nor the nerves parallel: from *C. glandulosum* in having pedicelled glands. A native of Guiana. 86. *C. urticifolium*. Lam. 39. Willd. 49. "Leaves egg-shaped, somewhat cordate, acute, serrated, petioled; spikes hairy, terminal; calyxes reflexed." About a foot high. *Stem* cylindrical, tubular, branched and dichotomous in its upper part, clothed with white hairs near the summit. *Leaves* somewhat resembling those of *urtica dioica*, the common stinging nettle, or of *lamium album*, the white dead nettle, alternate, green on both sides, set with short stellated hairs chiefly on their nerves and upper surface. *Female flowers* pedicelled, segments of the calyx five, egg-shaped, obtuse, villous and whitish on the outside, dull red within; germ trigonous, woolly and whitish; styles six, deeply bifid, coloured. Found by Commerçon in Brazil. 87. *C. morifolium*. Willd. 10. "Leaves roundish-egg-shaped, acute, finely serrated, obsolete heart-shaped, petioled, pubescent underneath; spikes at the top and in the forks of the branches." *Branches* dichotomous, smooth. Calyx of the female flowers villous. *Capsule* pedicelled, set with scattered stellated hairs. Found by Humboldt in South America. 88. *C. triquetrum*. Lam. 43. Willd. 24.

"Leaves

C R O T O N.

“Leaves ovate-oblong, acute, finely serrated, tomentous; petioles decurrent with a tomentous-woolly line.” A foot or a foot and half high. *Stem* slender, herbaceous, but rather hard. *Leaves* three or four inches long, alternate, sometimes almost opposite, rounded at the base, with two small glands near the petiole, soft, nearly smooth and finely dotted above, tomentous and reddish-white underneath; petioles woolly and reddish. *Spike* terminal, dense, short, sessile, tomentous, ferruginous; flowers sessile; stamens ten or twelve. Found by Commerçon in Brazil. 89. *C. chamædrifolium*. Lam. 44. (*Tragia mercurialis* β & *acalypha indica* β ; Linn. *Acalypha reptans*; Willd. *Mahihot minima chamædrifolia*; Plum. Sp. 20. *Burm. Amer. tab. 172. fig. 2.* *Urtica minor incris spicata*; Sloan. *Jam. Hist. 1. 125. tab. 82. fig. 3.* *Tiaelpatlis*; Hern. *Mex. 293*) “Leaves somewhat heart-shaped, serrated, smooth; spikes terminal.” *Stems* several, four or five inches long, slender, short, more or less erect, branched, leafy. *Leaves* alternate, petioled, bright green. *Flowers* very small; males uppermost; calyx purple, with four divisions; stamens numerous, very white; females; calyx with eight divisions; germ roundish, trigonous; styles three, villous. *Fruit* reddish, vilous, tricapular. A native of St. Domingo and Jamaica. 90. *C. ricinocarpus*. Linn. Sp. Pl. 17. Mart. 18. Lam. 46. Willd. 58. (*Mercurialis androgyna*; Vir. Clif. 98. Roy. Lugdb. 203. *Ricinocarpos americana*, flore albo spicata; Boerh. Lugdb. 1. 254.) “Leaves somewhat heart-shaped, crenate; peduncles in racemes opposite to the leaves.” *Root* annual. *Stem* an inch high; branches alternate. *Leaves* alternate, petioled, smooth. *Flowers* in distinct clusters, males and females intermingled; common peduncle longer than the leaves; calyx three-leaved, narrow, white. A native of Surinam. 91. *C. tinctorium*. Linn. Sp. Pl. 6. Mart. 6. Lam. 42. Willd. 20. Gært. tab. 107. (*Ricinoides ex qua paratur Tournesol Gallorum*; Tourn. *Inst. 655.* *Nissol. Aët. 1712. p. 339. tab. 17.* *Heliotropium*; Bauh. *Pin. 253. Rai. Hist. 165.* *H. minus tricoccum*; Cluf. *Hist. 2. 47.* *H. parvum Dioecorides*; Lob. *IC. 161.*) “Leaves ovate-rhomboidal, repand, quite entire at the base, hoary on both sides; racemes terminal; capsules squamous-pubescent, pendulous.” *Root* annual. *Stem* a foot high, cylindrical, branched, sometimes dichotomous, leafy, tomentous, whitish. *Leaves* near two inches long, one inch and a quarter broad, alternate, undulated, often plaited, clothed with short stellated hairs; petioles slender, near four inches long. *Flowers* in short sessile racemes, at the extremity and in the forks of the branches; males most numerous, almost sessile; calyx tomentous, five-leaved; petals five, lanceolate; stamens eight, monadelphous; females on rather long peduncles. *Capsule* roundish, three-furrowed, tricoccous, tubercled. A native of the south of France, Spain, Italy, and Barbary. It is from the juice of this plant, called heliotropium or turnsole by the old botanists, that the colouring matter is obtained which is sold by the druggists under the name of turnsole, and not from the *helianthus annuus*, our common garden sun-flower, as some have erroneously supposed. See TURNSOLE. 92. *C. plicatum*. Mart. 43. Willd. 21. Vahl. *Symb. 1. 73.* (*C. tinctorium*; *Burm. Ind. 304. tab. 62. fig. 1. β Lam.*) “Leaves egg-shaped, obtuse, plaited, crenate, hirsute, hoary underneath, with two glands at the base; racemes few-flowered, terminal.” *Root* annual. *Branches* cylindrical, somewhat scabrous, hoary, hirsute on the upper part, with dense stellated hairs. *Leaves* resembling those of heliotropium supinum, half an inch long or more, wrinkled, rounded at the tip; petiole the length of the leaf, with a

purplish gland at its top, and two underneath at the base of the leaf. Inflorescence as in the preceding species. *Capsules* violet purple, pendulous. A native of Arabia Felix and the East Indies. 93. *C. obliquum*. Mart. 44. Willd. 22. Vahl. *Symb. 1. 78.* (*C. argenteum*; Forsk. *Ægypt. 75. n. 491*?) “Leaves ovate-lanceolate, quite entire, tomentous, without glands; stem tomentous.” Nearly akin to the preceding, but the hairs are less distinct, so that the whole plant appears tomentous; the leaves also are narrower and oblique on one side at the base. A native of Egypt. 94. *C. verbasifolium*. Willd. 23. (*Ricinoides ex qua paratur Tournesol Gallorum folio oblongo & villosa*; Tourn. *Cor. 45*.) “Leaves ovate-oblong, repand, petioled, tomentous on both sides, soft; racemes terminal; capsules scaly-pubescent, pendulous.” *Root* annual. *Stem* dichotomously branched, densely clothed with a white cottony down. *Leaves* two or three inches long. *Flowers* on long peduncles in proportion to the length of the raceme. *Capsules* purple, covered with white scales. Perfectly distinct from *C. tinctorium*. A native of Greece and the East. 95. *C. japonicum*. Linn. *jun. Supp. 422.* Mart. 10. Willd. 69. Thunb. *Jap. 270. tab. 28. 29.* “Leaves rhomboid-egg-shaped, acuminate, either quite entire, or a little three-lobed, smooth, five-nerved; racemes panicled, pubescent.” *Root* annual. *Stem* a foot high, simple, somewhat angular, tomentous near the top. *Leaves* alternate, peduncled, reticularly veined. *Racemes* sometimes solitary. A native of Japan. 96. *C. lobatum*. Linn. Sp. Pl. 19. Mart. 22. Lam. 47. Willd. 71. (*Ricinoides herbaceum, foliis trifidis f. quinquefidis*; Mart. *cent. tab. 46*.) “Leaves unarmed-ferrated; lower ones five-lobed, upper ones deeply three-lobed.” About a foot high. *Root* annual. Upper part of the stem, petioles, nerves of the leaves, and peduncles, rough with rather long white hairs. *Stem* leafy, with short alternate branches. *Leaves* generally alternate, soft, green above, hairy underneath, but only on the nerves; stipules awl-shaped. *Flowers* in lateral, slender, solitary spikes, a little shorter than the branches, males uppermost, small; calyx five-cleft, purple; petals five, very small, purple; females without a corolla; styles purple, fringed at the end, permanent. *Capsule* smooth, the size of a horse bean. Found by Houston about Vera Cruz in South America. 97. *C. spinosum*. Linn. Sp. Pl. 20. Mart. 23. Lam. 48. Willd. 74. (*Ricinus maderaspatanus*; Pluk. *Alm. 320. tab. 108. fig. 3*.) “Leaves palmate, five-lobed and three-lobed, spinous-ferrated; flowers close pressed to the stem, nearly sessile.” A native of the East Indies.

CROTON villosum; Forsk. See JATROPHA glandulosa.

Obf. La Marck justly observes, that the generic distinctions of croton, tragia, and acalypha, are purely artificial, and that they sometimes separate plants which, on a general comparison of their natural characters, will be found closely allied. He adds, that he sees no good reason why *jatropha gossypifolia*, f. curcas, and some others are not placed

placed among the crotons. It is evident, from the enumeration of species given above, that, as far as croton is concerned, these artificial distinctions have by no means been carefully observed in practice; and that the whole natural order must be more accurately investigated, before its really distinct genera and their true generic differences can be determined.

Propagation and Culture.—*C. tinctorium*, (n. 91.) is the only plant of this genus which grows naturally in Europe, but being peculiar to the southern part, cannot be raised in our climate without some care and attention. The seeds should be sown in the autumn, soon after they are ripe, in a small pot filled with light earth, and plunged into an old tan bed in a frame. In the spring the pot should be put into a fresh hot-bed, and when the plants are fit to remove, which will be in about a month, they should be set separately in small pots, plunged into another fresh hot-bed, and screened from the sun till they have taken root. The air may then be daily admitted to them, according to the warmth of the season, with only a small allowance of water. By this treatment, and by this alone, Mr. Miller was able to procure perfect seeds. All the other species, being natives of warmer countries, require a greater degree of artificial heat. The shrubby kinds must always be removed into the bark-stove in the autumn, and must be kept in a good temperature through the winter, when, as their leaves are not deciduous, they make a pleasing variety among other plants. Most of them may be increased by layers or cuttings, or both.

CROTON, or *Crotona*, *Cotrone*, in *Ancient Geography*, a town of Italy, in the most eastern part of the Brutian territory, situated on a small gulf north-west of the promontory Iacium. The Phœnicians, who first traversed this coast, are said to have been the first founders of the city. But Strabo, Dionysius Halicarnassensis, and others, trace it to a Greek origin; and ascribe its foundation to Myscellus, chief of the Achæians in the third year of the 17th Olympiad, B. C. 710. This Myscellus, it is said, being come to Delphos to consult the oracle of Apollo, about the spot on which he should build his city, met Archias the Corinthian there, who was arrived upon the same account. The god gave him a favourable audience, and after having fixed the purpose of each with regard to the place that would best suit their new settlements, he proposed different advantages to them, and left them, among other particulars, the choice of riches or health. The offer of riches interested Archias, but Myscellus preferred health; and if we may credit history, Apollo faithfully performed his promise to both. Archias founded Syracuse, which soon became the most opulent city of Greece. Myscellus laid the foundation of Croton, which acquired such reputation for the long life and innate strength of its inhabitants, that its name was used proverbially to signify a very healthy spot, the air of which was extremely pure. The people signalized themselves by a great number of victories in the Grecian games; and Strabo relates, (l. vi.) that in the same Olympiad, seven Crotonians were crowned in the Olympic games, and carried off all the prizes of the stadium. Crotona was also famous for its military achievements, and its schools of philosophy. In a contest with the Sybarites, 100,000 Crotonians, headed by the famous champion Milo, over whose shoulders a lion's skin was thrown, and himself armed with a club, like another Hercules, gained a complete victory over 300,000 Sybarites, so that few escaped, and their city was depopulated. It was a proverb among the ancients, "that the last of the Crotonians was the first of the Greeks," and it was

also said, "that in comparison with Crotona, other cities were little worthy of choice." In process of time, however, its glory declined; and 130,000 Crotonians were defeated by the Locrians at the battle of Sagra. It never recovered itself from this loss. Pyrrhus, having ravaged Crotona, and the city being too spacious for its inhabitants, it was reduced almost one-half its extent: and the river *Asarus*, which traversed it before, only washed its walls. The Romans having pursued Hannibal from this coast, reduced Crotona under their dominion: and under the consulate of P. Cornelius Scipio and T. Sempronius Longus, in 559, it became a Roman colony.

Croton river, in *Geography*, a north-eastern water of Hudson's river, in North America, which rises in the town of Fairfield in Connecticut, and running through Dutchess county, discharges itself into Tappan bay. Croton bridge crosses this river three miles from its mouth, in the high road to Albany. This bridge is 1400 feet long, supported by 16 stone pillars. Croton-falls present from this bridge an interesting object; the water precipitating itself 60 and 70 feet perpendicularly, with high slate banks, in some places 100 feet; and the river spreading itself into three streams, as it enters the Hudson.

CROTONA, in *Ancient Geography*, a town of Italy, in the Tyrrhenian territory, according to Steph. Byz.; Ptolemy calls it *Cortona*, and places it in the interior of Etruria.

CROTONA, in *Geography*, a town of Naples, in the province of Calabria Ultra; 12 miles east-south-east of St. Severina.

CROTONOPSIS, in *Botany*, (so called from its resemblance to Croton.) Willd. 1672. Scrotone; Poir. Enc. Mich. Amer. Class and order, *monachia pentandria*.

Gen. Ch. *Male flowers* situated above the females. *Cal.* deeply five-cleft; segments egg-shaped, obtuse, a little concave. *Cor.* Petals five, shorter than the calyx, and alternating with its divisions, linear, oblong. *Stam.* Filaments five, the length of the calyx; anthers two-celled. *Females* below in the same spike. *Cal.* as in the male, but with awl-shaped segments. *Cor.* none. *Pist.* Germ egg-shaped; stigmas three, almost sessile, very short, bifid. *Peric.* Capsule short, small, roundish-oval, one-celled, not dehiscent. *Seed* solitary, almost globular, adhering to the upper part of the capsule; embryo reversed, like the seed, enclosed in a very thick, fleshy, oily substance.

Ess. Ch. *Male*, Calyx five-cleft; petals five. *Female*, Capsule with one seed, not dehiscent.

Sp. C. *linearis*. Willd. 1. Poir. Michaux Amer. 2. 186. tab. 46. "Leaves linear-lanceolate." A weak herbaceous plant, covered in all its parts with white shining scales like those of *Hippophaë rhamnoides*. *Stems* erect, slender, siliiform, dichotomous. *Root* annual. *Leaves* about an inch long, alternate, nearly sessile, distant, narrow, quite entire, obtuse, or very slightly acute at the summit, green above, set with minute scellated hairs. *Flowers* in small, simple, slender spikes at the extremity of the branches; some of them axillary, on very short pedicels, alternate, small, with a very short bracte at the base. A native of Carolina, and the country of the Illinois. 2. *C. elliptica*. Willd. 2. "Leaves elliptical, obtuse both at the top and the bottom." Resembling the preceding, but the spines are shorter, and the leaves only half the length, and three times the breadth, rounded above and below. A native of Carolina.

CROTOPHAGA, in *Ornithology*, a genus of *Picæ*, having the bill compressed, semi ovate, arched, and carinated on the back, upper mandible angular at each edge; nostrils

pervious;

pervious; tongue compressed, and subulate at the tip; feet, in general, formed for climbing.

Species.

ANI. Blackish-violet; feet climbers. *Crotophaga ani*, Linn. *Psittaco congener ani*, Rai. *Le Bout de Petun*, Briss. *L'ani des Savanes*, Buff. Razor-billed blackbird, Catesby. Great Blackbird, Sloan. Lesser ani, Latham.

The length of this bird is thirteen inches and a half; its colour throughout black, partially glossed with purple, and about the neck faintly tinged with green on the margins. The base of the bill is beset with black bristles, which turn forwards, and the eye-lids are furnished with long hairs resembling eye-lashes. The tail is six inches long, of a very emarginated form, and like the rest of the ani tribe, composed of ten feathers; the lefs are black, and have the toes placed two before and two behind. This curious species is found in Jamaica, St. Domingo, and other islands in the West Indies, and also in Cayenne, and other parts of South America. Contrary to all other birds they live in societies, a number of them occupying a single nest in the construction of which they labour in concert, and make it sufficiently spacious for the reception of the whole company. After laying their eggs they sit on them close to each other in order to hatch them, each unanimously endeavouring to do their best for the good of the community, and when the young are hatched, the old birds attend mutually to the wants of the whole flock. Those birds have generally two broods in a year, and sometimes even three. The eggs are about the size of those of a pigeon, and of a sea-green colour, spotted at the ends. The food of these birds consists of worms, insects, fruits, and grain, in quest of which they are usually seen in flocks of twenty or thirty together. Like the common jay, they make a chattering noise, and are in no esteem as an article of food.

MAJOR. Blackish-violet; feathers edged with green; quill feathers dusky-green; feet formed for climbing. *Crotophaga major*, Briss. *Ani des Paletuviers*, Buff. *Grand Bout de Petun*, Buff. pl. enl. Greater ani, Lath.

This species exceeds the last in point of size, being as large as the jay, and measuring eighteen inches in length. The bill is of a more lengthened form, and rises higher on the top; the colour of its plumage corresponds with the other, except in having some of the feathers edged with green. It is affirmed that these two birds never associate with each other, though the manners of both are very nearly the same. Their haunts are different, the smaller ani frequenting the open savannas, and the larger only the salt marshes near the sea-coasts. They are of a docile disposition, easily tamed, and may be taught to speak like the parrot. The male and female are alike in the colour of their plumage.

VARIA. Variegated with rufous and black; feet formed for climbing. *Crotophaga varius indicus*, Ger. Orn. Varied Ani.

Length 11 inches; bill black, and curved: head, throat, and breast black; larger and middle wing-coverts, and also the tail black, the latter long; the rest of the body tawny-rufous; legs tawny-fuscous.

AMBULATORIA. Feet formed for walking. *Crotophaga ambulatoria*, Linn. Walking ani, Lath.

This appears to be a very ambiguous species; it is described on the authority of Linnæus, who informs us that it agrees with the two first mentioned species, except in the situation of the toes, which are placed three before, and one behind. The bird, according to Linnæus, is found in Surinam.

CROTOPHAGA, a name given by Forskal (Fann. Arab.) to the tock of Buffon, the black-billed hornbill of Latham, and the *Buceros nasurus* of Gmelin.

CROFORD, a town of Germany, in the circle of Westphalia, and duchy of Berg; 11 miles east-south-east of Homberg.

CROTOY, I.E. a small town of France, in the department of the Somme, not far from the mouth of that river; 15 miles north-west of Abbeville.

CROTTENDORF, a village of Saxony, in the circle of Leipzig, at a very little distance from Leipzig, which, together with *Anger* and *Reudnitz*, two other villages, goes by the general name of the *Kohl gärten*, (cabbage gardens), and constitutes one of the favourite walks of the inhabitants of Leipzig, and of the numerous strangers who visit that city at the time of its fairs. The fields of these villages are particularly devoted to horticulture, and are supposed to yield above twenty pounds sterling an acre annually.

CROTZKA, a town of Hungary, on the south side of the Danube, where a severe and destructive battle was fought in the year 1739, between the Imperialists and the Turks; it is 15 miles south-east of Belgrade.

CROU. See **CROULD**.

CROUCHE, a river of England, in the county of Essex, which runs into the sea; 10 miles north-east of Rochford, celebrated for its oyster-beds.

CROUCH-HILL STATION, near Banbury, in Oxfordshire. In the centre of the flat on the top of this noted hill, a station was chosen in 1799 for the government trigonometrical survey, and its situation was determined by an observation from Brill, distant 102,608 feet, bearing $39^{\circ} 20' 49''$ south-east from the parallel to the meridian of Dumfries, and another from Epwell distant 29,669 feet; whence is deduced its latitude $52^{\circ} 2' 59''.6$ N., and longitude $1^{\circ} 21' 11''.6$, or $5^{\text{m}} 24.7$ W. of Greenwich. This station was used with Epwell for determining the following places, viz. Adderbury spire, Aynhoe, Bloxham, Deddington, and Farthinghoe churches.

CROUCH river, in Essex, is navigable from the Thames, near its mouth at Foulness point, to Haul bridge. See **CANAL**.

CROUGH-NA-MALLEN, mountains in the northern part of the county of Mayo, Ireland.

CROULD, or **CROU**, LA, a small river of France, in the department of the Seine, which has its source near Tillay, and falls into the river Seine near St. Denys, six miles north of Paris.

CROUP, in *Medicine*, a disease of children, characterized by difficult breathing, with a peculiar ringing or croaking sound of the voice in speaking and coughing.

It may seem extraordinary, that a disease, so distinctly marked, should not have been accurately described before the middle of the 18th century. Authors, indeed, had noticed a dangerous angina, in which no tumour was to be seen in the neck or throat; but the peculiar symptoms of croup were not observed. Dr. Home of Edinburgh was, perhaps, the first to give a distinct account of the disease, in his treatise on the *suffocatio stridula*, or croup, in 1765. Michaelis, however, who afterwards published a work on this subject, calling the disease *angina polyposa sive membranacea*, Argentorato, 1778, says, that Martin Ghis, an Italian physician, published the first regular history of croup, in his "Lettre Mediche," Cremona, 1749. The disease is now well known in this country, especially on some parts of the sea-coast; but the inland counties are by no means free from it.

Croup seldom attacks infants before they are weaned; but after being weaned, the younger they are the more they are liable to it. As children advance in age, they are less subject to its attacks, and are rarely affected with it after the age of twelve years. But Dr. Cheyne saw the croup in a child of three months old at the breast; (Essay I. on the Diseases of Children, Edin. 1801.) and Mr. Rumsey observed it in a boy of thirteen, and in a girl of fourteen years of age. (Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge, vol. ii. p. 25.) Although it often attacks several children in the same family, it does not appear to be contagious. Mr. Rumsey remarks, in the excellent paper just quoted, that only one child in the workhouse at Chesham had the disease, when it was epidemic in that part of Buckinghamshire, although there were between twenty and thirty in the house; and similar exemptions occurred in families, where no pains were taken to prevent the intercourse between the sick and the healthy.

The croup generally begins with a short dry cough, wheezing, and other catarrhal symptoms, the general health not appearing to suffer. Soon, however, the wheezing becomes more observable, the cough more troublesome, and marked by a peculiar shrill sound, the respiration is performed with a wheezing or croaking noise, and at length grows very distressing and laborious. "At the beginning, or in slighter cases," says Mr. Rumsey, "the sound of inspiration resembled the passing of air through a piece of muslin; afterwards it was as if the noise came from a brazen tube. The cough was attended with a peculiar shrill sound, even at an early period of the disease, as well as the voice, where there was not a perfect hoarseness. Dr. Home describes it "vox instar cantus galli." I have heard those about the sick compare it to the noise which a fowl makes when caught in the hand. This peculiarity, however, is not easily expressed by words, but a knowledge of it is readily acquired by observation. I have known the sound of the cough alone greatly shock an unfortunate parent, who had already lost one child with the complaint."

By the end of the second, or on the third day, sometimes sooner, symptoms of affection of the system take place, as white tongue, thirst, increased heat, and frequent pulse; and the disease advances rapidly, not merely from violent general affection, but from the influence which it has upon the organs of respiration; the difficulty of breathing becoming now very distressing, the countenance being often flushed, and great inquietude and a continual inclination to change from place to place supervening. The child at the same time eagerly puts its fingers into its mouth, as if to pull away something which sticks in the passage.

All the symptoms are increased during the night, throughout the disease.

The cough is at first dry; but by the third day or sooner, the passage of the air is obstructed by viscid matter in the trachea, some of which is occasionally thrown up by coughing or retching. Occasionally also, portions of a film or membrane, of a whitish colour, are thrown up by violent coughing or retching; and the efforts made to dislodge it are often so distressing, that the child appears to be almost in a state of strangulation. This is succeeded by an abatement of all the symptoms, until a fresh quantity of the same substance is formed, when the distress recurs as before.

In many cases, the difficulty of breathing and appearance of suffocation are increased by paroxysms, so as to occasion extreme anxiety and inquietude, and suggesting the idea of spasm. And in other cases the disease, after continuing some time, appears suddenly alleviated; the breathing is

free, cheerfulness, appetite, and a disposition to amusement, take place. But a change, for the worse, comes on as suddenly, and death ensues; the livid and swelled face, and convulsive struggles, giving the little patient every appearance of one actually strangled.

When the internal fauces are viewed, as Dr. Cullen has observed, they are sometimes without any appearance of inflammation, but frequently a redness and swelling appear. But Mr. Rumsey remarks, that most of the cases which occurred in the winter were attended with inflammation and swelling of the tonsils, uvula, and velum pendulum palati; and frequently large films of a white substance were formed on the tonsils. The swallowing, however, was usually less impeded than might have been expected.

It is important to observe, that the danger in this disease is not to be estimated by the general state of the body; for there may be imminent danger, although hardly any symptoms of general disease have been noted. Those who expect to meet with a considerable affection of the system, will not be aware that so formidable a disease has begun its progress; since, for the first day or two, the child has only a slight cough and hoarseness, is in good spirits, perhaps even running about the room, and enjoying its amusements. The skin is often hot and dry, as the disease increases; but sometimes it is moist and relaxed throughout. Several instances of croup, terminating fatally in twenty-four hours, are recorded: more frequently, however, the child does not die before the third or fourth day, sometimes much later. When it terminates favourably, generally after having arrived at its height, a moisture is poured out on the skin, the fever declines, and the *croupiness*; and, lastly, the cough gradually wears away, after an expectoration of films and matter from the wind-pipe.

The croup, as has been invariably evinced by dissection, consists in an inflammation of the internal membrane of the wind-pipe; in consequence of which, a white pus-like matter is poured out, which ultimately is converted into a sort of membrane, of considerable tenacity. This impedes respiration, and finally suffocates the patient. This membranous lining appears to arise a little under the larynx, and is sometimes prolonged into the division of the trachea; and generally a quantity of a white fluid, like that brought up by the cough, is seen gurgling up on dissection. The attachment of the membrane is slight; and it is often found lying in a great measure loose in the trachea. This fact is commonly found free from any erosion or ulceration; but it frequently shews the vestiges of inflammation, and is covered with the white matter before mentioned.

As the disease is hence considered to be a peculiar inflammation of the trachea or wind-pipe, the usual remedies of inflammation have been generally adopted, and, when early employed, have often proved effectual. Bleeding, both general and topical, has often given immediate relief; and, by being repeated, has entirely cured the disease. The application of blisters to the external fauces has likewise been found beneficial. Vomiting, after blood-letting, seems to have been of frequent advantage, and sometimes suddenly relieves the disease, by promoting the discharge of the matter exuding from the lining of the trachea, or of the membrane, if already formed. The warm bath; fomentation, and the inhalation of the vapour of hot water, have been also used with occasional benefit.

All these expedients, however, too often fail of arresting the progress of this fatal disease. In addition to these, Mr. Rumsey administered cicuta; and also ether, in small and repeated doses, where the heat did not forbid it, and when some spasmodic affection appeared to accompany the other

symptoms. But these were equally ineffectual. Dr. Cullen, indeed, had already observed, that although he supposed that a spasm of the glottis is often fatal in croup, he had not found antispasmodic medicines of any use. Children are very averse to expectorate, and emetics afford the only means of dislodging the matter which collects in the trachea; the relief, thus obtained, is, however, commonly temporary only. After losing several patients, under these modes of treatment, Mr. Rumsley had recourse to the use of calomel, in the dose of from half a grain, to a grain or more, every four hours, accompanying it, in some cases, with mercurial friction. Under this management, he succeeded in carrying the disease to a safe termination in a number of instances. The cases are related at length. (*loc. citat.*) He concludes, however, with these candid and philosophical observations. "More extensive experience than I have yet had is requisite to determine whether, in mercury, we shall find a certain remedy for the disease. With regard to the above cases, it should be observed, that some recovered when mercury was not administered, or in such quantity as not to produce any effect; and in two patients, under the care of my brother, it was given unsuccessfully. Moreover, the disease was less severe towards the end of the epidemic constitution, which was the period when we adopted this plan: so that, admitting that all those patients, who recovered under such treatment, were *cured by mercury*, it does not follow that the same effects would have been produced, had it been given in the early cases; yet it surely merits farther trial, the ordinary mode of treatment being so unsuccessful." See *Trans. of a Soc. for the Improvement of Med. and Chir. Knowledge*, vol. ii. Cullen, *First Lines*, § 318. Home on the Croup. Michaëlis de Angina Polypola.

CROUP of a horse, in the *Manege*, the extremity of the reins above the hips. It should be large and round, so that the tops of the two haunch bones be not within view of each other. It should have its compass from the haunch bones to the very dock, or onset, of the tail; and should be divided in two by a channel, or hollow, all along to the neck. A rocking croup is when a horse's fore-quarters go right, but his croup swings from side to side; when such a horse trots, one of the haunch bones will fall, and the other rise like the beams of a balance; a sign that he will not be very vigorous.

CROUPADE, a leap in which the horse draws up his hinder legs, as if he meant to shorten and truss them up under his belly. See **BALLOEËDE**.

CROUPER, or **CRUPPER**. See **CRUPPER**.

CROUPIERE, in *Geography*, a small town of France, in the department of Puy-de-Dôme, on the river Dore; 24 miles E. of Clermont.

CROUSAZ, JOHN, PETER DE, in *Biography*, a Swiss divine, was born at Lausanne in the year 1669. He was intended, by his father, for the military line, and was accordingly instructed in all those branches of knowledge that are necessary to that profession. His attachment to literature and science was soon conspicuous, and he was allowed to follow the bent of his inclination, under very able professors at Geneva and Lausanne. Here he studied very diligently mathematics, philosophy, and theology, and in 1682 he sought farther improvement at Leyden, and from thence he went to the university at Paris, where he became acquainted with father Mallebranche, and other eminent characters. Two years afterwards he was ordained minister, and appointed professor. During 14 years he continued pastor of the church of Lausanne, and was exemplary and indefatigable in every undertaking. At this place he obtained other preferments, and in 1724 he was

appointed mathematical and philosophical professor at the university of Groningen, and shortly after was elected a foreign member of the royal academy of sciences at Paris. He was next appointed tutor to prince Frederic of Hesse Cassel, an office which he filled with great reputation till the year 1732, when, on account of his excellent character, he was nominated counsellor of embassies to the king of Sweden, uncle to his pupil, attended with a suitable salary. In 1737 he was elected professor of philosophy and mathematics in the academy of Lausanne, with the power of appointing a substitute, when either his health or increasing years should render such assistance necessary. He died in the year 1748, leaving behind him a high reputation as a scholar and a Christian. His works are very numerous, and on various branches of literature; but he is chiefly distinguished for his treatises on Logic, of which the principal is entitled, "A System of Reflections that may contribute to the Illustration and Extension of Knowledge, or a new Essay on Logic." This was first published in two vols. 8vo. and afterwards enlarged, and appeared in the duodecimo form in six volumes. He was an able defender of the Christian religion, and engaged in the well-known controversy with Anthony Collins. We have treatises likewise from the pen of Croufaz on geometry, algebra, and on several branches of metaphysics and polite literature. Moreri.

CROUTE, **SOUR-CROUTE**, or *Kroute*. As this preparation of cabbage has been found of sovereign efficacy as a preservative in long voyages from the sea-scurvy, it may not be unacceptable to give a concise account of the process for making it, according to the information communicated by an ingenious German gentleman.

The soundest and most solid cabbages are selected for this use, and cut very small, commonly with an instrument made for this purpose; not unlike the plain which is used in this country for slicing cucumbers. A knife is used, when the preparation is made with greater nicety. The cabbage thus minced is put into a barrel in layers, hand high, and over each is strewed a handful of salt and carraway seeds; in this manner it is rammed down with a rammer, *stratum super stratum*, till the barrel be full; when a cover is put over it, and pressed down with a heavy weight. After standing some time in this state, it begins to ferment; and it is not till the fermentation has entirely subsided, that the head is fitted to it, and the barrel is finally shut up, and preserved for use. There is not a drop of vinegar employed in this preparation. The Germans write this preparation in the following manner: Sauer kraut, or saurer kohle, that is, in their language, sour herb, or sour cabbage. See **BRASSICA**.

CROUTILLE, in *Geography*, a town of France, in the department of the Vienne, and district of Poitiers; $1\frac{1}{2}$ league S.W. of Poitiers.

CROUY, in Latin *Croziacum*, a small town of France, in the department of Seine and Marne, near La Ferté Milon; 12 miles N.E. of Meaux.

CROUZILLE, a small town of France, in the department of the Upper Vienne; nine miles S.E. of Limoges.

CROW, in *Agriculture*, the name of an iron bar, which is constructed with a claw at one end, and a sharp tapering point at the other, by which means it is capable of being employed as a lever, as well as a tool for forming holes in the ground for the reception of stakes, truncheons, &c. in making hedge fences.

Crow, *Cornix*, in *Ornithology*. See **CORVUS**. Virgil says that the croaking of the crow foreboded rain:

"Tum cornix plena pluviam vocat improba voce."

And it was thought to be a bird of bad omen, when seen on the left hand:

“ Sæpe sinistra cava prædixit ab illice *cornix*.”

England formerly abounded with crows: and in the reign of Henry VIII. an act was passed for their destruction. The crow is a bird which is partly injurious and partly beneficial to the farmer. See **ROOK**.

CROW, in *Mechanics*, an iron lever, furnished with a sharp point at one end, and two claws at the other. It has various uses, in heaving or purchasing great weights.

The name *crow*, or *raven*, *corvus*, was anciently given to several machines of war, used in the defence of places: one invented by Diades; another by the Tyrians, mentioned by Q. Curtius; another by Cn. Ovilius. Vitruvius calls the first the *demolishing crow*, *corvus demolitor*, and also *doprædator*: others call it the *crane*, *grus*. Polybius describes another invented by C. Duilius used against the Carthaginian fleet. They were all a kind of grappling-hooks; serving to drag things towards the engineer. That described by Q. Curtius was thrown out of a balista. See **CORBEAU** and **CORVUS**.

CROW-bar, a name often provincially applied to an iron crow or lever. See **CROW**.

CROW-berry, in *Botany*. See **EMPETRUM nigrum**.

CROW's-bill, an instrument used by surgeons, in their operations; especially for drawing bullets and other foreign bodies out of wounds. It has its name from its figure.

CROW creek, in *Geography*, a creek of America, which falls into the Tennessee, from the north-west, opposite the Crow town, 15 miles below Nickajack town.

CROW's-feet, in the *Military Art*. See **CALTROP**.

CROWS-feet, in a *Ship*, are small ropes, or lines, sometimes six, eight, or ten, reeved through the dead man's eye. They are used to suspend the awnings; or to keep the top-fails from fretting against the edges of the tops.

CROW foot, in *Botany*. See **RANUNCULUS**.

CROW-foot-Crane's-bill, in *Agriculture*, the common name of a plant of the perennial weed kind, (*Geranium pratense*), which is frequent in moist meadows and pastures. It has the stalk or stem, from two to three feet in height, of a reddish tinge, and forked or divided into two branches. The leaves are much divided, and the flowers large, flat, and of a blue colour. It has the denomination of crane's-bill probably from the bill-like form of the seed vessel.

CROW foot, a name given to different plants which are met with in meadows, fields, and pastures, by farmers, as the common pilewort (*ranunculus ficaria*); the lesser spearwort (*ranunculus flammula*); the narrow leaved crow-foot (*ranunculus reptans*); the round or cekry-leaved crow-foot (*ranunculus sceleratus*); the butter flower or butter-cups (*ranunculus acris*); the small-flowered crow-foot (*ranunculus parviflorus*); the gold-cup or bulbous crow-foot (*ranunculus bulbosus*); the creeping crow-foot (*ranunculus repens*); and the corn crow-foot (*ranunculus arvensis*). The first, according to the author of the Gloucestershire Report, has the roots knotty, rising little above the ground, and blossoming early in the spring, being principally found in such meadows as are rather moist, and eaten only by sheep. Withering remarks that the young leaves of this species may be eaten in the vernal months with other pot-herbs. It is asserted that goats and sheep eat it; while cows and horses reject it. Also, that the *curculio dorialis* is found upon it.

The second species is an inhabitant of meadows of the boggy kind, and the borders of small rivers. It is a plant

which is extremely acrid in its quality, so as when applied externally to inflame and blister the skin. The water distilled from it produces the most speedy vomiting, even more so than white vitriol, so as to be a proper remedy in cases of poison. According to Withering, horses eat it; while cows, sheep, goats, and swine refuse it.

The third sort is found on the stony borders of some extensive plats of water, and sometimes in fields somewhat inclined to moisture.

The fourth species is likewise found in watery situations. Every part of it is of a corrosive quality. It is eaten by goats; but cows, horses, and sheep refuse it, according to the author of the “Systematic Arrangement of British Plants.”

The fifth kind is very commonly met with in pastures and meadow lands. It is also very acrid, readily producing vesications on the skin. Linnæus states that sheep and goats eat it; but that cows, horses, and swine reject it; the two former leaving it untouched even under the most bare state of the pasture, in the opinion of Withering.

The sixth species is common both in meadows and corn fields, where the soil is of the gravelly kind. In the latter it is sometimes very troublesome.

The seventh sort is very common in meadows and pastures: and,

The eighth kind is found in these places, as well as in garden grounds where the situation is moist.

It is remarked by Mr. Pitt, in an excellent paper in the fifth volume of “Communications to the Board of Agriculture,” that these two last, with the fifth sort, are all common in the meadows and pastures in every part of the island that he is acquainted, so much so as to give a yellow tinge to the whole surface in the month of June; very abundant in the hay grounds about London, and indeed every where else: these plants are so prevalent in our meadows and pastures, and their good qualities have been so often questioned, that it seems highly proper that their effects should be precisely ascertained.” And that these three different species are all occasionally found wild with double flowers. In this state we frequently see the *bulbosus* and *acris* cultivated in the flower garden, especially the latter; but we should, says the above writer, derive more satisfaction from informing the farmer how he might effectually root them out of his pastures, than how he might cultivate them successfully in his garden, for they propagate themselves with great facility, and occupy a considerable space in good meadows. He is however disposed to think more favourably of these plants; for he has never known a practical farmer mention them as the least injurious; and it is certain of the *repens*, that cattle eat the foliage greedily with other herbage, and that if they refuse the other sorts in bare pastures, it is probably because they have been deprived of most of their foliage with the adjoining herbage, and the remaining part of the plant is too acrid to be eaten alone; and indeed cattle refuse the flowering stems even of grasses, when deprived of their leaves: these plants may therefore, it is supposed, be considered as seasoners and correctors, being suited to uses in the animal economy similar to that of salt, mustard, pepper, and vinegar at our tables, to correct the flatulent or putrid qualities of the more palatable and luxuriant dishes of the great table of nature; and though not eaten alone, are an agreeable and useful stimulant with other more simple food. If these plants have any noxious qualities, they have, he conceives, hitherto escaped the notice of farmers, all of whom could not be supposed, with any sort of reason, devoid of proper and necessary attention.

C R O W.

Mr. Rudge, in his "Survey of the Agriculture of Gloucestershire," however, considers them, especially the creeping sort, as useless weeds, having little to recommend them to notice but their gaudy appearance. And further, that the *acris*, *bulbosus* and *repens*, are acrid and biting to the taste, and therefore rejected by cattle nearly alike, though it is asserted that the last is more mild and palatable to some cattle; he, however, suspects that cattle eat it rather from necessity than choice, as from its creeping and spreading along the surface, it becomes so matted with the herbage that it must in some measure be taken up with it. It is added, that the stems or stalks of the two other species are left standing when the ground is quite bare around them; yet that, when made with the hay, their pungent quality is said to be lost, and the brightness of the blossom in the rick is a good sign of the crop having been well harvested.

The last species is a common weed in corn fields, and it has been asserted that in Italy, cows, horses, and sheep, eat it with greediness, though it is so acrid as to prove poisonous to the latter. A dog is said to have been destroyed by three ounces of the juice in four minutes. And it is suggested that its being almost solely confined to tillage lands, where cattle are excluded, is probably the reason why mischief has not been met with from it here.

Crow-garlick. See *ALLIUM vineale*.

Crow-gold, in *Mineralogy*, is the name in Bedfordshire, and some other districts bordering on the chalk strata, for the hematites or radiated nodules of golden pyrites, which are found in the beds of chalk: when exposed to the air in the face of a chalk-pit, or on the surface, crow-golds soon decompose and turn to an ochry dirt, which ultimately falls out and leaves a stained hole in the chalk. The Totternhoe or fire-stone beneath the chalk, is apt to contain these decomposing nodules, which very much disfigure buildings where such are used.

Crow Head, a cape of the county of Cork, Ireland, forming the N. western extremity of Bantry bay. Long. 10° 2' W. Greenwich. Lat. 51° 32' N.

Crow's Meadows, a river of America, in the north-west territory, which runs north-westward into Illinois river, opposite to which are fine meadows. Its mouth is 20 yards wide, and 240 miles from the Mississippi. It is navigable between 15 and 18 miles.

Crow-Net, in *Rural Economy*, the name of an invention for catching and securing various kinds of wild-fowl in the winter-season, and which is capable of being made use of in the day-time. It is constructed of good strong double thread or packthread of a fine kind; the meshes should be two inches wide, the length about ten yards, and the depth three; it must be verged on the side with good strong cord, and stretched out very stiff; on long poles prepared for that purpose. When you come to the place where you would spread the net, open it, and lay it out at its full length and breadth; then fasten the lower end of the net all along the ground, so as only to move it up and down; the upper end of the net must stand extended on the long cord; the further end being first staked or tied to the earth by a strong cord, about five yards distant from the net. Place this cord in an even line with the lower edge of the net. The other end must be at least twenty-five yards distant, to reach into some natural or artificial shelter, by the means of which you may lie concealed from the fowl, otherwise no good success can be expected. The net must be placed in such exact order, that it may give way to play on the fowl on the least pull of the cord, which must be done smartly, lest the fowl should prove too quick for you. This net may also be used for pigeons, crows, or other birds on

corn fields newly sown; as also on stubble fields, provided the stubble conceals the net from the birds.

In this last intention, it may often be found of considerable advantage to the farmer, in preventing the feed from being too much devoured by these voracious birds.

Crow, stare, in *Ornithology*, a species of the *LARUS*; which see.

Crow-slaves, in *Agriculture*, a name given to a part of a plough, signifying two upright pieces standing perpendicularly, inserted into the box of the plough, near the wheels, and each pierced with two rows of holes; by means of which they support a transverse piece, called the pillow of the plough, running across them, and serving to raise or sink the beam, by being pinned higher or lower, according as the ground is to be ploughed deeper or shallower. See *PLOUGH*.

Crow-stone, in *Mineralogy*, is the name of a fine-grained whitish, silicious stone, found under the third coal-strata, reckoning from the mineral or mountain lime-stone upwards, much used in the neighbourhood of Swanwick, Shirland, Stretton, Wingerworth, Brampton, Dronfield, and other places in Derbyshire, and in other districts on the western border of the great run of coals, for the repair of the roads. Crow-stone has attracted the notice of most English naturalists, from the numerous and large vegetable impressions which it contains, one in particular of two to four inches or more in diameter, and several feet in length, something like a kind of reed, only that a pith or middle part of the plant is visible; but the same seldom occupies the centre of the trunk, but is sometimes seen close to, and even on the outside of the stem, the surface of which is studded over with small holes, from the bottom of which small papillæ arise. One of these curious extraneous fossils has been figured by Mr. Parkinson, *Organic Remains*, *Plate III.* *fig. 1*; who justly concludes (p. 436.), the same to belong to the *fossilia incognita*; and we are satisfied, that a further and more minute search into the carboniferous strata, will place all the vegetable remains that are imbedded therein, among the same numerous class of organized substances. See our articles *COAL* and *COLLIERY*.

Crow-stones, in *Natural History*, is a name in some places of the anomia gryphons of Linnæus, and perhaps of other species of fossil shells. Mr. Wallcott, in his "Petrefactions found near Bath," has figured one of these (*fig. 34.*), found in the quarries of free-stone near Bath: similar shells, but probably of different species, occur in great numbers in other strata. The Clunch clay stratum (see *CLUNCH*), produces plenty of crow-stones; these in some parts are found in the gravel-pits and on ploughed lands, single, and somewhat rounded, and these the ignorant and superstitious of some places denominate the devil's toe-nails! Scotchmen of the same class in the Hebrides, according to Pennant (p. 232.), wear these shells about them as an amulet, for curing pains in the joints.

Crow-Taing, in *Geography*, a cape of Scotland, on the north-west of the island of Ronaldshay.

CROWBOROUGH STATION, in the parish of that name, in Sussex, is situated on the ridge of very dislocated and elevated strata, mentioned under *COAL*, as extending from near Hastings to near Guildford; which, notwithstanding its present great elevation, is upon a stratum many hundred feet below that of the chalk strata; which, with those of the whole district called the wealds of Sussex and Kent, and a similar part of Surrey, seem to owe their exposure on their surface to an enormous abrasion or denudation of this district when elevated, as it must have been, before the removal of all the upper strata in the British series. See *DE-*

NUDATION and ELEVATION of *strata*. This station is about 600 feet south of the site of the old Beacon, and was occupied by the trigonometrical surveyors in the year 1793. Its situation was determined by an observation from Botley hill, distant 89,492.5 feet, and bearing $23^{\circ} 3' 39''$ N.W. from the parallel to the meridian of Greenwich, and another from Leith hill, distant 128,332 feet; whence is deduced its latitude, $51^{\circ} 3' 9''.4$ N., and its longitude, $0^{\circ} 9' 9''.5$, or $36''.6$ E. of Greenwich. This station was used with Botley hill for fixing the piece of Bestbeach, Crowborough chapel, East Grinstead, Fairdean, Godstone, Mayfield, Rotherfield, and Tatesfield; with Brightling station for Dallington, Nailsham, and Homechurch; with Ditchling station for Brightling church, Chittingly, Ditchling church, Firsle, Newin, Little Horstead, Plumpton, Spittal, and Waldron churches; with Fairlight station for Willington, and with Leith hill station for Ditchling station, and for Hoathly church. From Leith hill station the ground at Crowborough station appeared depressed in an angle of $13' 48''$; at Brightling station it gave an elevation of $3' 54''$; and at Crowborough station, Leith hill appeared depressed $4' 8''$, Botley hill $3' 5''$, and Brightling windmill $12' 21''$; whence was deduced the height of the ground at this station above the level of the sea, 804 feet; the calculated mean refraction with Leith hill being $\frac{1}{3}$ th of the contained arc, and with Brightling $\frac{1}{2}$ th. (See Phil. Transf. 1795, p. 583.) The situation of the Old Beacon on Crowborough hill had been determined in 1788, by an observation from Botley hill, distant 88,975 feet, and another from Frant steeple, distant 30,949 feet; and its elevated and commanding view towards the coast of France, induced general Roy to point this out (Phil. Transf. 1790, p. 266.), as a proper spot for an English astronomer, with a well regulated clock and instruments, to be stationed, for making corresponding observations, with a French astronomer, stationed 100 miles, or more distant, on the Chalk hill, near Helfaut in France, on the instantaneous explosions of lights to be repeatedly fired, near Folkestone turnpike in England, and at Montlambert or at Fienne windmill in France, for the purpose of determining the difference of longitude of these English and French observatories, as a check on that deduced from angular measurements, or the **CONVERGENCY of Meridians**; which see.

CROWD, in *Agriculture*, a term frequently used provincially to signify the wheeling any thing in a barrow. Thus "to crowd," implies to wheel in a barrow.

CROWD, *to*, in *Sea Language*, is to carry an extraordinary force of sail on a ship, in order to accelerate her course on some important occasion.

CROWDING-BARROW, a name sometimes applied to a wheel-barrow.

CROWEA, in *Botany*, a genus of New Holland plants, (named in honour of James Crowe, esq. F.L.S., of Lakenham, near Norwich, who died Jan. 26, 1807, aged 56. This gentleman was extremely well versed in the botany of Britain, more especially in the genus *Salix*, to which he had paid particular attention, having collected and cultivated all the species he could possibly procure. Many of his remarks have appeared in Dr. Smith's *Flora Britannica*, and *English Botany*, tending to the economical as well as botanical illustration of this difficult and important genus, of which about four times more British species are now known than have appeared in any preceding writer upon them. The specific name of the original species, *Crowea Saligna*, alludes to Mr. Crowe's merits in this department. His botanical knowledge was applied no less happily to agricultural purposes on many occasions, and he excelled also in the study of Mosses, Lichens, and Fungi. *Sm. Tr. of Linn. Soc. v.*

4. 222. Class and order, *decandria monogynia*. Nat. Ord. *Rutaceae*, Juss. Vent.

Gen. Ch. *Cal.* of 5 leaves, cohering by their tapering bases round a stalk which elevates the rest of the flower, according to M. Ventenat's remark. *Cor.* Petals 5, regular, equal, ovate, spreading, inserted under a glandular nectary, which furrounds the base of the germen. *Stam.* Filaments 10, about half as long as the petals, awl-shaped, flat, fringed with dense hairs, by which they are matted together, by their lower half, into a tube; 5 alternate ones are rather shorter than the rest; anthers sessile about the middle of each filament, on the inside, oblong, of 2 cells, bursting longitudinally, and destitute of any erect gland, or appendage. *Pyl.* Germen of 5 lobes, smooth, somewhat depressed; style central, from the base of the germen: stigma capitate. *Peric.* Capsules 5, connected by their base, oval, slightly compressed, coriaceous, of 2 valves, enclosing an elastic, cartilaginous, bivalve arillus. *Seeds* solitary, kidney-shaped, brown.

Ess. Ch. Calyx of 5 leaves. Petals 5, sessile. Stamens flat, awl-shaped, connected by entangled hairs. Anthers fixed longitudinally to the inside of each filament. Style from the base of the germen. Capsules 5, combined. Seeds enclosed in an arillus. M. Ventenat, who first detected the singular structure and insertion of the base of the calyx-leaves, wishes to found the generic character on that circumstance, but the analogy of this natural order proves the anthers to afford the most essential difference. See *CORRÆA*, which belongs to the same order; also *BORONIA*, *Sm. Tracts on Nat. Hist. t. 4—7.*

Sp. 1. *C. saligna*. Willow-leaved Crowea. *Andr. Repos. t. 79. Vent. Jard. de la Malmaison, t. 7.* Leaves lanceolate, entire. Angles of the branches smooth. This beautiful shrub is about 3 feet high, branched; the branches angular, leafy, smooth. *Leaves* alternate, sessile, lanceolate, entire, tipped with a small point, smooth on both sides, and marked with a longitudinal rib. *Stipulas* none. *Flowers* axillary, solitary, on short simple smooth stalks, with two or three minute bractæas. Their colour is a fine pink, and the woolly tips of the stamens form an elegant pale tuft in the centre. A native of New South Wales, near Port Jackson, from whence it was first sent by John White, M.D. It thrives in a greenhouse, in light peat earth, flowering in autumn, but is rather tender, and will not bear much wet. The whole plant is aromatic when bruised, but less strongly scented than many of its natural order. It is propagated either by seeds or cuttings.

2. *C. angustifolia*. Narrow-leaved Crowea. Leaves linear, minutely toothed. Angles of the branches rough. More slender than the last, and distinguished by the rough or denticulated angles of the branches. *Leaves* very narrow, linear, obtuse, most distinctly toothed towards their extremity, pale-coloured beneath. *Flowers* about half the size of the foregoing, with the extremities of their filaments paler, and less woolly. *Style* hairy, about as long as the stamens. Found by Mr. Menzies, near King George's Sound, on the west coast of New Holland. It is as yet a stranger to our gardens.

It must be observed that the specific characters of *C. saligna* to be seen in the writers above quoted, were made without any knowledge of this second species. Such characters can by accident only have any meaning, a specific difference for a solitary species being evidently a most glaring absurdity. S.

CROWLAND, or **CROYLAND**, in *Geography*, an ancient town in Lincolnshire, England, is situated on an island, in a great fen, or level, watered by the Welland, the Washes, the

the Nyne, and the Shire drain. The wet soil of the neighbourhood formerly rendered the town almost inaccessible, and for a long time the only approach was on the N.E. side. Such were the difficulties and delays attending the passage of this dangerous road, that it produced the adage of "All the carts that come to Crowland are shod with silver." The inhabitants have since made a good causeway, a turnpike road, and numerous drains, which have converted many of their fens into corn-fields, and greatly improved the state of the air. The houses of the three streets are built on piles, the water-courses that separate them are adorned on each side by willows, and the communication is preserved by a most singular triangular bridge, the three sides of which, after an ascent too steep for carriages, meet, and form a curious pointed arch. Carriages, &c. pass under this bridge, where the Nyne, Welland, and Cattwater join, and form one stream, flowing hence through Spalding to the sea. This half-useless structure stands on the site of one mentioned in a charter granted by king Edred to the monks of Crowland, in 943; the date of the present bridge is not noticed by historians, but the outline is a convincing proof that the original bridge has long since perished; on the angle which communicates with the London road, is a statue said to be of Ethelbald king of Mercia, in a crown fleury, and with a globe in his right hand. Ethelbald is said to have founded the magnificent abbey at Crowland about the year 716, in consequence of a vow made before he ascended the throne. It was dedicated to the Virgin Mary, St. Bartholomew, and Guthlake, his confessor, and endowed with the isle of Crowland, released for ever from all secular payments; the charter granted to the abbot and brethren on this occasion, was exhibited to the Society of Antiquaries in 1734, by Robert Hunter, esq. then possessor of the site of the monastery. The Danes burnt the abbey in 870, and the monks were reduced by misfortunes to five, in 941, when Turketyl, brother to Edred, and chancellor in the reign of king Edmund, restored them to their pristine state, and Edred rebuilt the abbey in 948. A second conflagration, which occurred during the abbacy of Ingulphus, in the year 1091, deprived the monks of 700 volumes, containing the most valuable literature of the preceding time; after this event the monastery gradually recovered from its disasters, and flourished with great splendour till the dissolution, when the revenues amounted to 1083*l.* 15*s.* 10*d.* The inhabitants of Crowland paid a considerable sum annually to the abbots for the right of fishing in their neighbourhood; but their principal profits have for a very long time originated from their superior dexterity in decoying, and taking wild ducks in astonishing numbers. (See DUCK.) The ruins of the abbey are extremely interesting at present; they are richly adorned with sculpture; the foundations rest on piles, and some part of the remains is fitted up as the parish church. Crowland has a small weekly market on Saturday, and is 93 miles north of London. Howlet's Views in Lincolnshire, 410.

CROWLE, a town of England, in the county of Lincoln, with a weekly market on Saturday; 36 miles N. of Lincoln, and 169 N. of London.

CROWN, *Corona*, a mark of regal dignity; being an ornament worn on the head by kings and sovereigns, as a symbol of their authority.

Gallet derives the word *corona*, whence *crown*, from the Latin *cornu*, *horn*; because the ancient crowns were pointed in manner of horns; which were anciently, both by Jews and Gentiles, esteemed as marks of power, strength, authority, and empire. Hence, in the holy scripture, horns are used for the regal dignity; and accordingly *horn* and *crown*, in the Hebrew, are expressed by the same word.

In the remotest antiquity, the crown was only given to gods. Pliny says, that Bacchus was the first who used it. Pherecydes, cited by Tertullian, De Corona, says Saturn, Diodorus ascribes it to Jupiter after his victory over the Titans. Q. Fabius Pictor attributes the invention to Janus, adding, that it was an ornament he used in sacrificing. Leo the Egyptian says, it was Isis who first wore a crown; and that it consisted of ears of corn, the use whereof the first taught men.

In this most authors agree, that the crown originally was rather a religious than a civil ornament; rather one of the pontificalia, than the regalia; that it only became common to kings, as the ancient kings were priests as well as princes; and that the modern princes are entitled to it, in their ecclesiastical capacity rather than their temporal. See KING, &c.

The first crowns were no more than a bandelet, or headband, drawn round the head, and tied behind, as we still see it represented on medals, around the heads of Jupiter, the Ptolemies, and the kings of Syria.

Afterwards they consisted of two bandelets; by degrees they took branches of trees of divers kinds; at length they added flowers; inasmuch that Tertullian, De Corona, assures us, (from Claudius Saturninus, who had written expressly on the subject,) there was not any plant whereof crowns had not been made.

The woods and groves were searched, to find different crowns for the several deities; thus on medals, we find Jupiter's crown of flowers, more frequently of laurel; Juno's of the vine; that of Bacchus, the vine with grapes, vine-leaves, and branches of ivy, with flowers and berries; those of Castor, Pollux, and the river-gods, of bulrushes; that of Apollo, sometimes of laurel, sometimes of rushes; that of Saturn, new figs; that of Hercules, poplar; that of Pan, pine or alder; that of Lucina, dittany; that of Horæ, the fruits proper to each season; that of the Graces, olive-branches, as well as that of Minerva; that of Venus, roses; of Ceres, ears of corn, as well as that of Isis; that of the Lares, myrtle or rosemary, &c.

Crowns were not only used on the statues and images of the gods, by the priests in sacrificing, and by kings and emperors, but also on altars, temples, doors of houses, sacred vessels, victims, ships, &c.

The *agonothetæ* crowned those who were victors in the solemn games, warriors, &c.

Among the Romans there were various kinds of crowns, distributed as rewards of military achievements. The *oval* crown was the first, made of myrtle, and was bestowed on generals who had been victorious over slaves, or enemies unworthy of the Roman valour, and who were entitled to the honours of the lesser triumph, called *ovation*.

The second was the *naval* or *rostral* crown, consisting of a circle of gold richly chased: having on the edge four masts of ships, and as many heads of ships placed alternately; given to the captain who first grappled, or the soldier who first jumped aboard an enemy's ship.

— Cui belli insigne superbum

Tempora navali fulgent rostrata corona."

Virg. Æn. viii. v. 684.

Lipsius supposes the *navalis* and *rostrata* to have been two distinct species of crowns; but it is generally believed that they were the same kind of crown.

The third, called *vallaris*, or *castrensis*, was also a circle of gold, raised with pointed piles or palisades; given to him who first leaped into the enemy's camp, or forced the palisades or entrenchments.

The fourth, called *mural* crown, was a circle of gold, indented

dented or embattled, thus bearing some allusion to the figure of a wall; given to him who first mounted the wall of a place besieged, and there lodged a standard; this crown we also find given, on medals, to the particular genii and guardians of provinces and places.

The fifth, the *civic* crown, made of a branch of green oak; given to him who had saved the life of a citizen in a battle or assault. This was conferred on Cicero for detecting Cataline's conspiracy, and afterwards on Augustus Cæsar himself.

This was reckoned more honourable than any other crown, though composed of no better materials than oak boughs. Virgil (*Æn.* vi. v. 772.) calls it "*civilis quercus*:"

"Atque umbrata gerunt civili tempora quercu."

Plutarch (in Coriolan.) suggests, the reason why the branches of this tree should be made use of in preference to all others. For the oak wreath, says he, being otherwise sacred to Jupiter, the great guardian of their city, the Romans might, therefore, think it the most proper ornament for him who had preserved a citizen. Besides, the oak may very well claim the preference in this case, because, in the primitive times, that tree alone was thought almost sufficient for the preservation of a man's life; its acorns were the principal diet of mankind in the more early ages, and the honey, which was commonly found there, presented them with a very pleasant liquor. It was a particular honour conferred on the persons who had merited this crown, that, when they came to any of the public shows, the whole company, as well senate as people, should signify their respect, by rising up when they saw them enter; and that on these occasions they should take their seats among the senators, being also excused from all troublesome duties and services, in their own persons, and procuring the same immunity for their father, and grandfather by his side. (*Plin.* l. xvi. c. 4.)

The sixth was the *triumphal* crown, made of branches of laurel, or bay-tree, given to a general who had gained a battle, or conquered a province, and who was worthy of the honour of a triumph. This was afterwards made of gold; and not restrained only to those who actually triumphed, but presented on several other accounts, as commonly by the foreign states and princes to their patrons and benefactors.

The seventh, the *corona obsidionalis*, or graminea, made of grass or herbs found on the ground in the place besieged; given by common consent of the soldiers to generals who had delivered a Roman army besieged by the enemy, and obliged him to decamp. Besides these, we meet with the *corona aurea*, often bestowed on soldiers without any other additional term. Dion Cassius mentions a particular sort of coronet made with olive-boughs, and bestowed, like the rest, in consideration of some signal act of valour. Lipsius is of opinion that these succeeded the golden crowns when the latter were laid aside.

The eighth was also a crown of laurel, given by the Greeks to their athletes; and by the Romans to those who had negotiated, or confirmed a peace with an enemy; this was the least esteemed. Besides these, in antiquity, we meet with *radial* crowns, given to princes at their translation among the gods, whether before or after their death. Casaubon says, this sort of crown was peculiar to deities; yet it is certain Nero took it in his lifetime.

Athletic crowns were destined to crown victors at the public games.

Of these the *Olympic chaplet*, or *crown*, composed of the branches of a wild olive, and conferred on the conquerors in the Olympic games, merits particular notice. In order to enhance the value of these olive chaplets, and to render them

in some degree worthy of these games, which by way of eminence were styled *boly*, the Eleans pretended that the tree, from which they were always taken, was originally brought to Olympia by Hercules, from the country of the Hyperboreans; a people, whose situation no geographer, ancient or modern, has yet been able to determine. Pindar ascribes the honour of this exploit to Hercules, the son of Alcmæna, though others, as Pausanias informs us, gave it to the Idæan Hercules, who was earlier by some generations. The Eleans further pretended that this particular tree was selected and indicated to them, among many others of the same kind, by the Delphic oracle. For this purpose, as the fact is related in a fragment of Pælegon, they sent Iphitus, their king, after he had restored these games (for during the first five Olympiads, as this writer says, no one was crowned) to Delphi, to whom the god gave this answer, as we have it in West's Dissertation:

"To the swift victor be no more assign'd
The bleating offspring of the fleecy kind.
But from the olive, which spontaneous grows
In Pisa's vale, a verdant crown compose;
That olive, round whose venerable head
Her subtle textures hath Arachne spread."

Iphitus, upon his return to Olympia, having discovered, among the many wild olives that grew in the sacred grove, one which was covered with cob-webs, enclosed it with a wall; and from this tree was a chaplet or crown taken, and given to the conquerors. The first who was crowned was Daicles of Messene, who, in the seventh Olympiad, gained the victory in the stadium, or simple foot-race.

From this account we also learn, that the prize originally bestowed upon the Olympic conquerors was a lamb. Some have suggested, but erroneously, in Mr. West's opinion, that in some periods of these games, the crowns given to the victors were of gold. The Eleans, it is conjectured, substituted the cheaper one of an olive crown; and in order to sanction this change, and to give a lustre to their olive chaplet, they had recourse to fables, and to the authority of a Delphic oracle. With the same view they not only encompassed this sacred olive with a wall, and distinguished it by the name of "*Callistephanos*," *i. e.* the tree of the crowns of glory; but put it also under the protection of certain nymphs or inferior deities, whom from their office they called "*Callistephani*," and to whom they erected an altar near that consecrated plant. These crowns, for the purpose of exciting the emulation of competitors, were placed in their view, upon a tripod, or table, which, during the games, was placed in the middle of the stadium, or of the hippodrome, as the respective exercises required. In the interval of the games, they were kept, the former in the temple of Jupiter, the latter in the temple of Juno, at Olympia. The tripod was of brass, and seems to have been entirely laid aside after the table was made, which was composed of gold and ivory, the workmanship of Colotes of Paros, a disciple of Pafiteles. Branches of palm were exhibited on the same table, and conferred on the victors, with the crowns; these palm branches they carried in their hands, as emblems, says Plutarch, of the unsuppressive vigour of their minds and bodies, manifested in gaining the victory over their antagonists. The conquerors were summoned by proclamation to receive these tokens of victory; and accordingly they marched in order to the tribunal of the Hellanodics, where a herald, taking the crown of olive from the table, placed one upon the head of each of the conquerors; and giving into their hands branches of palm, led them in that equipage along the stadium, preceded by trumpets, proclaiming at the same time with a loud voice, their names, the name of their fathers, and their countries;

tries; and specifying the particular exercise in which each of them had gained the victory. Mr. West conjectures, that although the Olympic crowns were all composed of the branches of the sacred olive, they were distinguished from each other, either by the difference of their form, or the addition of some emblematic ornament peculiar to the several exercises. The racer's crown was different from the wrestler's, and so of all the rest. This conjecture, he conceives, is countenanced by a passage of Plutarch (*De Tranquil. Animi*), who seems to distinguish between these two last-mentioned crowns. This ingenious writer further suggests, that, besides the chaplet peculiar to the games, the conquerors in general received another composed of wings or plumes. That different degrees of merit were rewarded with different degrees of honour, and consequently with different crowns, Mr. West infers from the words of St. Basil (*Ap. Fab. Agon. l. iii. c. 1.*); "No president of the game," says he, "is so devoid of judgment, as to think a man, who, for want of an adversary, hath not contended, deserves the same crown (*ἰσὺν στεφάνῳ*) as one, who hath contended and overcome." Although he received a crown, yet it was different from that which he would have received if he had contended and vanquished. Before the victors at the Olympic games were put in possession of their crowns, they were saluted by the acclamations and applauses of the numerous assembly; by the warm congratulations of their friends, and even the faint and extorted greetings of their maligners and opposers. As they passed along the stadium, after having received their crowns from the Hellenodice, they were again saluted with the acclamations of the spectators, accompanied with a shower of herbs and flowers, poured on them from every side. It was also customary for the friends of the conquerors to express their particular respect to them, by accosting them and presenting them with chaplets of herbs, &c. binding their heads with fillets, ribbons, &c. West's Dissertation on the Olympic Games. See *OLYMPIC Games*.

The custom of *crowning* persons who had distinguished themselves in poetry and music, which was almost as ancient as the arts themselves, subsisted till the reign of Theodosius, when the *CAPITOLINE games*, being regarded as remnants of Pagan superstition, were utterly abolished. About the time of Petrarch, however, poetry recovered its ancient lustre and importance, or was invested with its former prerogatives. In the year 1340, Petrarch had the honour of receiving on the same day two letters, one from the senate of Rome and another from the university of Paris, inviting him to accept the laurel crown; and in the following year he was magnificently crowned at Rome. "The crown," said the senator who placed it on his head, "is the meed of virtue." Being conducted in great pomp, after the ceremony, to the church of St. Peter, he returned thanks to God for the honour that had been bestowed upon him, and then laid down his crown, that it might be placed among the offerings that were suspended to the roof of the temple. See *PETRARCH* and *LAUREAT*.

From some passages in Eusebius Cæsariensis, some authors conclude, that bishops had likewise anciently their crowns.

The Roman emperors had four kinds of crowns, still seen on medals, *viz.* a crown of laurel, a radiating crown, a crown adorned with pearls and precious stones, and the fourth a kind of bonnet, or cap, something like the mortier.

The first was ordinarily that used from the time of Julius Cæsar: the right of bearing it was granted him by the senate; some say on account of his baldness; and afterwards

continued to his successors. Justinian was the first who took that of the bonnet-kind.

The *papal crown* is composed of a cap or tiara, enclosed by three marquises coronets, having two pendants, like the bishops' mitres; and on its top a mound of gold; these three crowns represent the pretended triple capacity of the pope, *viz.* as high-priest, supreme judge, and sole legislator of the Christians.

Royal crowns were anciently open, but are now more or less closed at their tops with arches, and are called "imperial crowns."

The *imperial crown* is a bonnet or tiara, voided at the top like a crescent, with a circle of gold, adorned with precious stones and pearls, heightened with fleurs-de-lis, supporting a globe, with a cross at the top.

The *English crown* is adorned with four crosses, in the manner of those of Malta; between which are fleurs-de-lis. It is covered with four diadems, which meet at a little globe supporting a cross.

According to Selden, the kings of the Saxon race in England had a crown, like that of other nations, which at that time was only a plain fillet of gold; but king Egbert first fixed on the circle or fillet, with points or rays, resembling the crown worn by the emperors of the East; and king Edward, surnamed Ironside, topped the points with pearl. William the Conqueror is said to have had his circle flowery; but Sandford says, the coronet had on the circle points and leaves, the points being much higher than the leaves, and each of them topped with three pearls, and the cap or tiara topped with a cross patteé, as appears on the seal of that monarch. The crown worn by his son, William Rufus, was only enriched with points, pearled at their tops, and not accompanied with flowers. The crown of Henry I. is adorned with fleurs-de-lis only, a little raised, as is seen on his great seal and coin. Maud, queen of England, had her crown enriched with leaves and points, the leaves or flowers being higher than the points; and their successors to king Edward III. had their crowns variously enriched with points and fleurs-de-lis placed alternately, sometimes the one higher than the other. King Edward III. enriched his crowns with fleurs-de-lis and crosses patteé. Edward IV. had a close or arched crown, heightened with fleurs-de-lis and crosses patteé, and arched with four bars. Edward V. and Richard III. bore the same as king Edward IV. Henry VII. and VIII. had their crowns composed of fleurs-de-lis and crosses patteé, with two arches, embellished with pearls, &c.; and this form has been since continued. The *crown of England*, with which the kings of England are crowned, is called "St. Edward's Crown," made in imitation of the ancient crown said to be worn by that monarch, kept in the abbey church of Westminster till the beginning of the civil wars in England, when, with the rest of the regalia, it was stolen and sold in 1642. This very rich imperial crown of gold was made against the coronation of Charles II., and is embellished with pearls and precious stones, as diamonds, rubies, emeralds, and sapphires, and has a mound of gold on the top, enriched with a fillet of gold, embellished also with precious stones. Upon the mound is a cross of gold, embellished with precious stones, and three very large oval pearls, one fixed on the top, and two others pendant at the ends of the cross. It is composed, as all the imperial crowns of England are, of four crosses patteé, and as many fleurs-de-lis of gold, placed on a rim or circle of gold, all embellished with precious stones. From these crosses arise four circular bars or arches, which meet at the top in form of a cross; having at their intersection

tion a pedestal, on which is fixed the mound already mentioned. The cap within this crown is of purple velvet, lined with white taffeta, and turned up with ermine. This continues invariably the same for the purpose of coronation; but the jewels and precious stones are taken out of the crown of state, fixed in collets, and pinned into this crown; and when the coronation is over, they are taken out, and in their room are substituted mock stones to represent the real ones. The *crown of state*, so called because it is worn by the king whenever he comes in state to the parliament, was made instead of another, which was sold and destroyed in 1642, against the coronation of king Charles II., and worn only by that king in his return from the abbey to Westminster-hall. Since that time there is a very rich crown, embellished with diamonds, made for every succeeding king or sovereign queen, to wear for that day only at the coronation dinner in Westminster-hall. This is very rich, being embellished with several large diamonds, and a great quantity of pearl; but it is most distinguished by a very large ruby, set in the middle of one of the four crosses, and estimated at the value of 10,000*l.*, and also by the mound's being one entire stone of a sea-water green colour, known by the name of an "agmarine." The cap is of purple velvet, lined and turned up like the former. The *queen's circlet of gold*, worn by her majesty in proceeding to her coronation, is richly adorned with large diamonds, with a string of pearl round its upper edge. The cap is purple velvet, lined with white taffeta, and turned up with ermine richly powdered.

The *queen's crown*, with which every queen consort is crowned, was made for Catharine, queen of king Charles II., and originally called "St. Egitha's crown," in commemoration of Egitha, queen consort of king Edward the Confessor. It is a rich imperial crown of gold, set with very valuable diamonds, intermixed with other precious stones and pearls. It is composed of crosses and fleurs-de-lis, with bars or arches, and a mound and cross on the top of the arches, like the crown of St. Edward, only smaller and lighter. The cap is of purple velvet, lined with rich white taffeta, and turned up with ermine, or meniver pure, richly powdered. The crown of St. Edward is solely appropriated to the coronation of a sovereign queen; being never used for crowning a queen-consort.

The *imperial crown* of Scotland was, at the time of the union between England and Scotland, deposited in the crown room within the castle of Edinburgh, A. D. 1707. 6 Anne.

The *French crown* was a circle of gold, enamelled, of eight fleurs-de-lis, encompassed with eight arched diadems: bearing a-top a double fleur-de-lis, which is the crest of France.

The *Spanish crown* was a circle of gold, adorned with jewels and precious stones, and ornamented with eight leaves, but not closed with arches until the marriage of Philip II. of Spain with queen Mary of England: since that time it hath continued arched, with this difference, that it hath two more arches than the crown of England. Those of Bohemia, Poland, Denmark, and Sweden, are of the same form, ornamented with eight leaves, and closed like that of Spain.

The crowns of most other kings are circles of gold, adorned with precious stones, and heightened up with large trefails, and closed by four, six, or eight diadems, supporting a mound, surmounted with a cross. The crowns of France, Spain, and other foreign kingdoms, have no caps within them; neither have they any ermine, like the crowns of England. The *crown* of the grand duke of Tuscany still

remains open, and differs in its form from all others. It was placed on the head of Cosmus de Medicis by pope Pius V, when he honoured him with the title of grand duke of Tuscany in 1570.

The *crown* of Hungary is the same with that of France, Spain, &c.; but over it is another crown, composed of 16 plates of gold, from which arise two arches, having in their centre a cross, the ends of which are ornamented with large pearls: the plates are enamelled with busts of Jesus Christ and his apostles, as is also the flat part of the arches, and enriched with pearls, jewels, and precious stones. A fabulous tradition says, that this crown dropped from heaven, for the crowning of Stephen the first king of Hungary, in the year 1000.

The great Turk bears over his arms a turband, enriched with pearls and diamonds, under two coronets, the first of which is made of pyramidal points, heightened up with large pearls, and the uppermost is surrounded with crescents.

The *electoral crown*, or *coronet*, or *crozier* of Charlemagne, is a scarlet cap, turned up with ermine, and closed with a semi-circle of gold, all covered with pearls. On the top of it there is a globe with a cross thereon. It is borne by his majesty the king of England, on an escutcheon, in the fourth quarter of the royal achievement, as arch-treasurer of the sacred Roman empire.

CROWNS, or Coronets, of British princes of the blood royal. 1. The *crown* of the prince of Wales is a circle of gold, set round with four crosses-pattée, and as many fleurs-de-lis alternately; from the two centre crosses-pattée is an arch, adorned with pearls; in the middle of which is a ball and cross; and within the coronet is a crimson cap, lined with white farset, and turned up with ermine. Besides this, the prince of Wales has another distinguishing mark of honour, viz. a plume of three ostrich feathers, with an ancient coronet of a prince of Wales, with this motto, *Ich dien, i. e. I serve*. This device was at first taken by Edward prince of Wales, commonly called the Black Prince, after the battle of Cressly, A. D. 1346, where, having killed John king of Bohemia, he took from his head such a plume, and put it on his own. 2. The *coronet* of the princes of the blood royal is composed of a circle of gold, richly chased; on the rim or edge two crosses pattée, two strawberry leaves, and four fleurs-de-lis: within the coronet is a crimson velvet cap, lined with farset, and turned up with ermine: on the top of the cap, a rich tassel of gold and spangles.

CROWNS, or Coronets, of the British nobility. 1. That of a duke is a circle of gold richly chased; having on the edge eight strawberry leaves of equal height: a crimson velvet cap topped by a tassel of gold, and turned up with ermine of one row. 2. That of a marquis is a circle of gold, set round with four strawberry-leaves, and as many pearls, on pyramidal points of equal height, alternately: the cap, &c. as before. 3. An earl's has eight pyramidal points, with as many large pearls on the tops of them, placed alternately, with as many strawberry-leaves, lower than the pearls: the cap and tassel as before. Coronets were first assigned to earls in the reign of Henry III. 4. The viscount has only pearls, without any limited number, placed on the circle itself, all round: cap, &c. as before. Coronets were first assigned to viscounts in the reign of king James I. 5. A baron has only six pearls, set at equal distance, on the golden border of ermine; not raised, to distinguish him from the earl; and limited, to shew that he is inferior to the viscount.

The barons originally wore only a crimson cap turned up with

with white fur; but by a grant, dated August 7, in the 13th year of Charles II., they obtained the privilege of wearing coronets according to their respective dignities: and in 1665, king Charles II. granted his royal warrants to the officers of arms in Scotland and Ireland, for the peers of each of these kingdoms to wear the same fashioned coronets with those of England, according to their several degrees. These coronets consist of a circlet of gold, with six pearls only on the rim, a cap, tassel, &c. No peer or peeress, under the dignity of princes and princesses of the blood royal, ought to have the circle or rim of their coronet enriched with either precious stones or jewels, or embellished with any pearls, except those mentioned to encompass the coronet of the baron, viscount, earl, and marquis; but this rule is now so little regarded by herald painters, that the coronets on the carriages of many of the peers and peeresses are represented as having their arms studded, and ornamented with pearls, precious stones, &c. The balls on the English coronets are commonly called pearls; but they are always made of silver.

The eldest sons of peers, above the degree of a baron, use the coronet appertaining to the father's second title; and none of the younger sons use coronets.

The coronet of the kings of arms is a plain circle of gold, bearing sixteen leaves, eight of which are higher than the others; on the bands are engraved the following words, "Misere mei Deus."

The arms of the archbishopric of Canterbury are borne by the present archbishop, as they have likewise been borne by some of his predecessors, timbered with a mitre affronté, encircled by a ducal coronet, and with two labels or pendants fixed to it, hanging waved and folded on each side of the shield. As for the coronets belonging to the late titled dignities of France, it is now needless to recount them. See the Plates of crowns and coronets under the title Heraldry.

Ch. Paschal has wrote expressly de Coronis. Baudelot, in his History of Ptolemy Auletes, has a number of curious observations on the same subject, that had escaped Paschal. Du-Cange gives us a curious dissertation on crowns; and Schmeizell, a German, a treatise of royal crowns, both ancient and modern.

CROWN, in Architecture, denotes the uppermost member of the cornice; called also corona and larmier.

CROWN, in Astronomy, is a name given to two constellations; the one called septentrionalis, and the other meridionalis. See CORONA.

CROWN of an Arch, among Bricklayers, signifies the top or part denominated the key-stones among stone-masons. See HAUNCH and SPANDRIL.

CROWN, in Commerce, is a general name for coins both foreign and domestic, of or near the value of five shillings sterling.

In its limited sense, crown is only applicable to that popular English coin which bears the name, and which is equivalent to five shillings, or sixty English pence; or to six livres French money. According to the statute, these consist of 111 parts of silver and 9 of copper in 120, or $\frac{111}{120}$ the fine, as the assayers term it: the weight is $\frac{1}{17.34}$ of a pound troy = 464.5161 English grains = .066359 lb. avoirdupoise. But, in its extensive sense, it takes in several other coins; as the French ecu, which we call the French crown, struck in 1641 for sixty sols, or three livres; also the patagon, dollar, ducatoon, six-dollar, and piastre, or piece of eight.

CROWN, in an Ecclesiastical Sense, is used for the clerical

tonsure; which is the mark or character of the Romish ecclesiastics.

This is a little circle of hair, shaved off from the crown of the head; more or less broad, according to the quality of the orders received. That of a mere clerk is the smallest; that of priests and monks the largest.

The clerical crown was anciently a round list of hair, shaved off around the head, representing a real crown: this is easily observable in several ancient statues, &c. The religious of St. Dominic and St. Francis still retain it.

CROWN of the Virgin. See ROSARY.

CROWN, in Geometry, a plane ring included between two parallel or concentric peripheries, of unequal circles; generated by the motion of some part of a right line round a centre, the moving part not being contiguous to the centre.

The area of this is had, by multiplying its breadth by the length of a middle periphery, which is a mean proportional between the two peripheries that bound it.

Let D be the middle point of the breadth AB (Plate II. Analysis, fig. 23.); let CB = a, and CA = r. Let the circumference of the outer circle be c, and its area will be $\frac{ca}{2}$, and the area of the inner circle will be $\frac{cr^2}{2a}$, this

quantity being a fourth proportional to a^2 , r^2 , and $\frac{ca}{2}$; then the difference of these two areas, or the area of the crown, will be $\frac{ca}{2} - \frac{cr^2}{2a} = \frac{c}{2} \times \frac{a+r}{a}$: but $a-r$

is equal to AB, the breadth of the crown, and $\frac{c}{2} \times \frac{a+r}{a}$ is the circumference of the circle, whose radius is CD; because CD is an arithmetic mean between CA and CB, and therefore equal to $\frac{r+a}{2}$, and the circumfer-

ences of circles are as their radii, or $a : c :: \frac{r+a}{2} : \frac{c}{2} \times \frac{a+r}{a}$.

CROWN, or Coronet, in Heraldry, is used for the representation of that ornament, in the mantling of an armoury; to express the dignity of the person who bears it.

The crown here is of more antiquity even than the helmet; and it was used as a symbol of victory and triumph. See CROWN supra.

CROWN, among Jewellers, the upper work of the rose diamond, which all centres in the point at the top, and is bounded by the horizontal ribs.

CROWNS, pearled, or flowered, those with pearls, or leaves of smalage, parsley, &c. Such were anciently almost all crowns, even those of sovereign princes: though they were not used in their armours, till about two hundred years ago. See CROWN supra.

CROWNS, radiated, or pointed, are those of the ancient emperors, which had twelve points; representing, as some will have it, the twelve months of the year.

CROWN Royal, Order of, an order of knighthood, which, some say, was instituted in 802; the knights of which bore a crown embroidered with gold, on a white robe. Others deny the existence of such an order.

CROWN of Colours, in Meteorology, certain coloured rings, which, like halos, appear about the body of the sun and moon, but of the colours of the rainbow; and at a less distance than the common halos. These crowns sir Isaac

Newton shews to be made by the sun's shining in a fair day, or the moon in a clear night, through a thin cloud of globules of water or hail, all of the same bigness; and according as these globules are bigger or less, the diameter of these crowns will be larger or smaller; and the more equal these globules are to each other, the more crowns of colours will appear; and the colour will be the more lively. See *CORONA* and *HALO*.

CROWN of the Cable, in *Sea Language*, denotes the bights which are formed by its several turns.

CROWN, in *Music*, a rest marked by a reversed C, with a point in the middle of it, thus ☞

CROWN, Clerk of the. See *CLERK*.

CROWN, Pleas of the. See *PLEA*.

CROWN, Officers of the. See *OFFICER*.

CROWNS, Thundering, in *Military Language*. These are two, three, or four circles tied together with a thread of wire, round which they fasten grenades, pistol barrels, charges, &c. They cover the whole with hairs of hemp or tow, and combustible materials. Setting fire to these circles, they roll them upon the works of the besiegers. They are also made use of for repelling attempts to mount the breaches, when they are peculiarly called *thundering crowns*. In other cases, they are commonly called *circles a feux*.

CROWN-Glass, denotes the finest sort of window-glass. See *GLASS*.

CROWN-Grafting. See *ENGRAFTING*.

CROWN Imperial, in *Botany*. See *FRITILLARIA Imperialis*.

CROWN Imperial, in *Gardening*, is a well-known plant of the flowering kind, of which different species are cultivated in flower-gardens for their great elegance when in blow: and there are likewise, annually, a great number of varieties produced from the seeds of each of these distinct species, which, when intermixed in the different compartments, afford not only an extremely pleasing but interesting appearance, to those who are curious in flowers. The modes of culture and management will be described under the proper head. See *FRITILLARIA*.

CROWN Imperial Shell, in *Conchyliology*. See *VOLUTA*.

CROWN-Office, a court or office under the king's-bench, of which the king's coroner or attorney there is commonly matter; so called, because the crown is more immediately concerned in what is therein transacted. See *COURT of King's-bench*. Though none of the officers under the lord chief-justice of the king's-bench are employed in summoning a parliament; yet many of them have business in other matters, during the sitting of the parliament: as in cases of error, &c. but more especially on trials of peers; wherein the clerk of the crown is chief manager. He has likewise, out of parliament, all indictments in the crown, informations, recognizances; and a multitude of other business runs through his hands, as the writings of all pleadings, declarations, and other proceedings upon records; but the executive part is left to his secondary or deputy. See *INFORMATION*.

CROWN-Post, in *Architecture*, a post which in some buildings stands upright in the middle, between two principal rafters; and from which there go struts or braces to the middle of each rafter. It is otherwise called a *king's-piece*, or *joggle-piece*. See *POST*.

CROWN-Scab, in *Veterinary*, a disease in horses, consisting in a humour that breaks out round the coronet, of a sharp itching nature, and attended with scurfiness. The best remedy for this disorder is a mixture of equal parts of marsh-

mallow ointment, and yellow basilicon, spread on tow, and laid round the coronet.

CROWN Island, in *Geography*, an island in the Eastern Sea, near the N.E. coast of New Guinea. S. lat. 5° 18'. E. long. 141° 50'.

CROWN-Point, a township of North America, the most southerly of Clinton county in the state of New York; so called from the celebrated fortress which was in it, and which was garrisoned by British troops from the time of its reduction by general Amherst, in 1759, till the time of the American revolution. The point upon which it was erected by the French, in 1711, extends towards the north, into lake Champlain. After it was repaired by the British, it was the most regular and expensive of any constructed by them in America. The adjoining barracks, formed of stone, are capable of containing 2000 troops. It had also several outworks; but it is altogether in ruins, the walls of the barracks excepted, and the ditches on the south side, which were wide and deep, cut through immense rocks of limestone, and are still perfect. Before it was given up by the British, the powder magazine blew up, by which accident a great part of the works was destroyed; and since its evacuation, other parts have been demolished and ransacked in searching for bricks, lead, and iron shot. The view from this fort of old buildings overgrown with ivy, of the lakes, and of the distant mountains beyond it, is very fine. The fort, and 700 acres of good cleared land adjoining to it, are the property of the state of New York, and are leased out at the rate of about 33*l.* 10*s.* a-year, which is appropriated for the use of a college. *Crown-Point* is the most advantageous spot on the shores of lake Champlain for a military post, as it is not commanded by any rising grounds in the neighbourhood, which is the case with Ticonderago, the old fort and barracks of which are in ruins; and as the lake is so narrow here, owing to another point running out on the opposite side, that it would be absolutely impossible for a vessel to pass, without being exposed to the fire of the fort. The point opposite to *Crown-Point* is called *Chimney-Point*, on which are a few houses. The township of *Crown-Point* has no rivers; a few streams, however, issue from the mountains, which serve for mills and common uses. The mountains, which extend along the whole length of lake George, and part of lake Champlain, abound with moose deer, and the other inhabitants of the forest. In 1790, this township contained 203 inhabitants; and by the state census in 1795, it appears that there are 126 electors. The fortress lies in N. lat. 44° 26'. W. long. 73° 36'.

CROWN, Right of, Jus Coronæ, in *British History*, denotes the right of succession to the throne in these kingdoms. In this sense the crown, according to judge Blackstone, is by common law, and constitutional custom, hereditary, in a manner peculiar to itself; so that the right of inheritance may from time to time be changed, or limited, by act of parliament. The succession is such, that the next heir of the crown takes possession on the death or demise of the last proprietor; not by any *jure divino* title, but that kind of hereditary right which owes its origin solely to the founders of our constitution. The succession likewise resembles that of the heirs to landed estates, under particular exceptions: thus, the crown descends lineally to the issue of the reigning monarch, as from king John to Richard II., and to the first born of the male issue, as in the case of Edward V., who was preferred to Richard his younger brother, and Elizabeth his elder sister; but on failure of the male line, it descends to the female issue: thus Mary I. succeeded Edward VI., and the line of Margaret queen of Scots, the daughter

daughter of Henry VII., inherited on failure of the descendants of Henry VIII. Among the females, the crown descends to the eldest daughter and her issue, and not, like common inheritances, to all the daughters at once: thus queen Mary, on her brother's death, was the sole successor, though her sister Elizabeth was living. Moreover, the lineal descendants of any person deceased claim, as their ancestor would have done, if he had been still living. Thus, Richard II. succeeded his grandfather Edward III., in right of his father the Black Prince, to the exclusion of all his uncles. On failure of lineal descendants, the crown is vested in the next collateral relations of the late king, if they are lineally descended from the blood royal, as in the case of Henry I. who succeeded to William II., John to Richard I., and James I. to Elizabeth, being all derived from the Conqueror, who was then the only regal stock: nor is there any exception, as in common descents, to collateral relations of the *half-blood*. Thus Mary I. inherited after Edward VI., and Elizabeth after Mary, though born of Henry VIII. by different mothers.

However, this hereditary right is by no means indefeasible; because the immediate heir has been, and may be, excluded by the supreme legislative authority of this kingdom; to which it belongs to defeat this hereditary right, and by particular entails, limitations, and provisions, to exclude the immediate heir, and vest the inheritance in any one else. Under this controul, the crown naturally descends either to the *heres natus*, if the course of descent is unimpeded, or to the *heres factus*, in consequence of a particular settlement: because the king never dies, and there can be no *interregnum*.

Egbert, in the beginning of the ninth century, was the sole monarch of this kingdom; possessing the throne of the West Saxons by a long and undisturbed descent from his ancestors of above 300 years; and acquiring the other kingdoms of the heptarchy, some by conquest, but most of them by a voluntary submission. From Egbert, to the death of Edmund Ironside, through a succession of fifteen princes, the crown descended regularly, with very little deviation. In the three succeeding reigns, the succession was suspended by force; at length, upon the death of Hardicanute, the Saxon line was restored in Edward the Confessor, who indeed was not the next heir, because his brother Edmund Ironside had a son living, then an outlaw in Hungary. On his decease, without issue, Harold II. usurped the throne, though the right remained in Edgar Atheling, son of Edward the outlaw. At this time William the Norman invaded England, pretending a right to the crown from a grant of Edward the Confessor; and his conquest transferred the succession of the crown to a new family. (See CONQUEST.) From the Conqueror, as from a new stock, the race of Saxon kings being dropped for the present, it descended to his sons William II. and Henry I., the eldest son Robert being kept out of possession by his brethren. Henry was succeeded by Stephen of Blois, grandson of William I. by his daughter Adelicia, his elder brother Theobald waving his claim, and Matilda or Maud, the daughter of Henry I. and the grand daughter of Edward the outlaw, to whom the succession properly belonged, being excluded by force. However, her son Henry II., as heir to the Conqueror, succeeded Stephen, though the proper heirs in the Saxon line were the sons of Malcolm king of Scotland, by Margaret, the daughter of Edward the outlaw. From Henry II. the crown descended to his eldest son Richard I., and on his death was seized by his brother John, the youngest son of Henry, the right being vested in his nephew Arthur. On the death of Arthur,

and his sister Eleanor, without issue, the crown properly descended to Henry III. the son of John, and from him, in an hereditary line of six generations, to Richard II., and this right of succession was declared in parliament by stat. 25 Edw. III. s. 2. When Richard resigned the crown, as he had no children, the right reverted to the issue of his grandfather Edward III. and particularly to the posterity of Lionel, duke of Clarence; but Henry duke of Lancaster usurped the crown under the title of Henry IV., pretending to be a successor by right line of the blood royal. Parliament, by stat. 7 Henry IV. c. 2. settled the inheritance of the crown and kingdom in him and his heirs. He was regularly succeeded by his son and grandson, Henry V. and VI. In the last of these reigns the house of York began to assert their dormant title, and established it in the person of Edward IV. At his accession, the distinction of a king *de jure*, and a king *de facto*, first occurs; and by stat. 1 Ed. IV. c. 1. the three Henries are styled kings *in dolo*, and not of right. This king was succeeded by his eldest son Edward V., who was deposed by his unnatural uncle Richard III. under a pretence of bastardy. During the tyrannical reign of Richard, Henry VII., earl of Richmond, assumed the regal dignity, and his possession was established by parliament in the first year of his reign. He afterwards married Elizabeth of York, the undoubted heiress of the Conqueror, in whom the right of the crown was vested. Henry VIII. succeeded by indisputable hereditary right, and transmitted the crown to his three children in successive order; and stat. 25 Hen. VIII. cap. 12. provides for the regular succession in his descendants. This statute was repealed by 28 Hen. VIII. c. 7., by which Elizabeth and Mary were bastardized, after the king's divorce from Anne Boleyn. They were again legitimated, and the succession restored by 35 Henry VIII. c. 1. The right both of Mary and Elizabeth is again expressly recognized by parliament, after their respective accession; and parliament explicitly asserts its right of directing the succession of the crown, by stat. 13 Eliz. c. 1. On the death of queen Elizabeth, without issue, so that the line of Henry VIII. became extinct, James VI. of Scotland, and I. of England, was the lineal descendant, from the alliance of Margaret, eldest daughter of Henry VII., by Elizabeth of York with James IV. of Scotland; and in him were united not only the claims of different competitors since the Conquest, but likewise the right of the Saxon monarchs, because he was the direct lineal heir of Malcolm, who married Margaret, grand-daughter of Edmund Ironside. Several instances have occurred, in this abstract of the history of the descent of the crown, in which parliament has interposed to fix, direct, and limit the succession; particularly, under Henry IV. Henry VII. Henry VIII. queen Mary, and queen Elizabeth; to which we may also add the stat. 1 Jac. I. c. 1, which recognizes the succession lawfully descending to king James. King James had little reason to value himself, as he did in his first speech to the parliament, March 19, 1603, on his hereditary right and lineal descent. However, parliament, after hearing this speech, was so complaisant as to echo back, not merely in an address, but in an act of the legislature, his words and sentiments on this subject. This act is intitled a "most joyful and just recognition of the immediate, lawful, and undoubted succession, descent, and right of the crown," and expressly declares and enacts "that immediately upon the dissolution and decease of Elizabeth, late queen of England, the imperial crown of the realm of England, and of all the kingdoms, dominions, and rights belonging to the same, did by *inherent birth-right*, and lawful and undoubted succession, descend and come un-

to his most excellent majesty, as being lineally, justly, and lawfully next and sole heir of the blood royal of this realm." This hereditary right to the crown, of which king James here boasted, was a mere chimera, contradicted by the general tenor of cullom from the Norman invasion to his time; by the declared sense of his immediate predecessors; by many solemn proceedings of parliament; and by the express terms of law. Our kings of the Norman race were so far from succeeding as next heirs to one another, and in a regular course of descent, that no instance can be produced of the next heir's succeeding, which is not preceded and followed by instances of the next heir's being set aside. Thus, Edward I. succeeded his father Henry III., but his father Henry III. and his grandfather John, had both been raised to the throne in plain defiance of hereditary right; the right of Arthur, nephew to John, and the right of Arthur's sister, cousin-german to Henry. Edward II. succeeded his father Edward I.; but Edward III. deposed Edward II.; the parliament renounced all allegiance to him, and Edward III. held the crown by a parliamentary title, as much as William III. The British race began in Henry VII., and from him alone king James derived that right, which he asserted in such pompous terms: and if any prince ever came to the crown without the least colour of hereditary right, it was Henry VII. He had no pretence to it, even as heir to the house of Lancaster. His wife, indeed, might have come as heir of the house of York; but the title of his wife was not regarded either by him or the parliament, in making this new settlement. He gained the crown by the good will of the people. He kept it by the confirmation of parliament, and by his own ability. The national union of the two roses was a much better expedient for quiet than a foundation of right. It took place in Henry VIII.; it was continued in his successors, and the nation was willing that it should be perpetuated in James and his family. But neither Henry VIII., nor his son Edward VI., who might have done so with much better grace, laid the same stress on hereditary right, as king James did. One of them had recourse to parliament on every occasion, where the succession to the crown was concerned; and the other made no scruple of giving the crown by will to his cousin, in prejudice of his sister's right. This right, however, such as it was, prevailed: but the authority of parliament was called in aid by Mary, to remove the objection of illegitimacy, which lay against it. Elizabeth had so little concern about hereditary right, that she neither held, nor desired to hold, her crown, by any other tenure than the statute of the 35th year of her father's reign. In the 13th year of her own reign, she declared it by law high treason, during her life, and a præmunire, after her decease, to deny the power of parliament, in limiting and binding the descent and inheritance of the crown, or the claims to it.

The attempt to obtain a bill of *exclusion* in the latter end of the reign of Charles II. evidently supposed that the crown was hereditary, and at the same time liable to the controul of parliament. This attempt proved ineffectual, and James II. succeeded.

However, in consequence of his abdication in 1688, and the declared vacancy of the throne, the lords and commons, representing all estates of the people of the realm, invited over William prince of Orange, and the princess Mary, eldest daughter of king James II., and declared them king and queen, during their lives, and the life of the survivor of them; and settled the crown on the issue of queen Mary; and on failure of such issue, on the princess Anne of Denmark, and her issue. Stat. 1 W. and M.

c. 2. On failure of that to the issue of king William, who was the grandson of Charles I., and nephew as well as son-in-law of king James II., being the son of Mary, his eldest sister. This settlement included all the protestant posterity of king Charles I., except such other issue as king James might at any time have, which was totally omitted through fear of a popish succession. These three persons, king William, queen Mary, and queen Anne, did not take the crown by hereditary right or *descent*, but by way of donation or *purchase*, as the lawyers call it; by which they mean any method of acquiring an estate otherwise than by descent.

By stat. 12 and 13 W. III. c. 2. the princess Sophia, youngest daughter of Elizabeth, queen of Bohemia, who was the daughter of James I., the nearest of the ancient blood royal, and not incapacitated by professing the popish religion, and the heirs of her body, being protestants, and married to none but protestants, were declared next in succession after king William, the princess Anne, and their issue; and it is enacted that they should join in communion with the church of England, as by law established. This is the last limitation of the crown that has been made by parliament; and these several actual limitations, from the time of Henry IV. to the present, clearly prove the power of the king and parliament to create, or alter the succession. It is, indeed, now again made highly penal to dispute it; for by the statute 6 Anne c. 7. it is enacted, that if any person maliciously, advisedly, and directly, shall maintain by writing or printing, that the kings of this realm, with the authority of parliament, are not able to make laws to bind the crown, or the descent thereof, he shall be guilty of high treason; or if he maintain the same by only preaching, teaching, or advised speaking, he shall incur the penalties of a præmunire. After the death of queen Anne, the crown descended to George I. eldest son of the princess Sophia; from him to George II. and last of all to our present gracious sovereign George III. Hence it is easy to collect that the title to the crown is at present hereditary, though not quite so absolutely hereditary as formerly: and the common stock or ancestor, from whom the descent must be derived, is also different. Formerly, the common stock was king Egbert; then William the Conqueror; afterward in the time of James I. the two common stocks united, and so continued till the vacancy of the throne in 1688: now it is the princess Sophia, in whom the inheritance was vested by the new king and parliament. Formerly the descent was absolute, and the crown went to the next heir without any restriction; but now, upon the new settlement, the inheritance is conditional, being limited to such heirs only, of the body of the princess Sophia, as are protestant members of the church of England, and are married to none but protestants. Blackstone's Commentaries, vol. i. chap. 3. See KING and PARLIAMENT.

CROWN-bird from Mexico, in *Ornithology*, the *Touraco* of Edwards, Buffon, and Latham, and the *Cuculus Persa* of Gmelin; which see.

CROWN-wheel of a watch, is the upper wheel next the balance, or that which drives the balance.

CROWN-work in *Fortification*, is a kind of work not unlike a crown. It has two fronts and two branches, and is sometimes made with three whole bastions and two branches, but generally with one whole bastion, two demi bastions, and two wings or branches. It is usually erected before a curtain or a bastion, and commonly serves to enclose some buildings that cannot be brought within the body of the place, or to cover the town-gates, or to occupy some commanding or advantageous spot of ground, which the

the enemy might otherwise make use of against the place.

From the salient angle, A, of the bastion TR A S V, (*Plate VIII. Fortificat'on, fig. 19.*) as a centre with a radius equal to about 120 toises, describe an arc of a circle cutting the capital of the bastion produced in the point B; from the said point B, set off or inscribe the chords B C, B H, each of them equal to 110 toises; on each of which, as on an exterior side, construct a front of a polygon, by drawing perpendiculars, D E, K I, to the middle points, D, K, of the exterior sides, B C, B H, the lines, B E O, C E N, B I Q, H I P, of defence through the inward extremities, E, I, of the said perpendiculars, and finding the flanks, G N, F O, L P, M Q, according to Vaub'in's first method for constructing the body of a place. If you follow him, you will make the perpendiculars, D E, K I, each equal to about 18 toises, and the faces, B G, B L, of the bastion, and those C F, H M, of the demi-bastions, each equal to about 30 toises, and will make the branches C a, H b, when produced, terminate on the faces of the adjacent ravelins within 25 toises of their extremities. But if in constructing such a work, you wish to make the flanks either equal to, or in a given ratio to the perpendiculars, you must have recourse to Mr. Glenie's rule, delivered in the article CONSTRUCTION *military*, the only one for this purpose that has ever been delivered by any writer on fortification.

The ditch of this work should be about 12 toises broad, and opposite to the branches its counter-carp is parallel to the same, but in front terminates, when produced at the shoulders, like the great ditch of the body of the place. The parapet should always be 3 toises thick, in order to resist cannon shot.

Sometimes small ravelins, having their capitals equal respectively to about 35 toises, are made opposite to the curtains of the crown-work, with ditches before them of about 8 toises wide.

CROWN-Work is also a term sometimes made use of to denote the most advanced part of a work when besieged.

CROWNED, in *Farriery*. A horse is said to be crowned, when by a fall, or other accident, the knee is so hurt, that the hair falls off, without growing again.

CROWNED *horn-work*, is a horn-work, with a crown-work before it.

CROWNING, in *Architecture*, is understood, in the general, of any thing that terminates, or finishes a member or decoration.

Thus, a cornice, a pediment, a croteria, &c. are called crownings. Thus, also, the abacus is said to crown the capital; and thus any member or moulding is said to be crowned, when it has a fillet over it; and a niche is crowned, when it is covered with a capital.

CROWNING, in *Sea Language*, denotes the finishing part of a knot made at the end of a rope. It is performed by laying the first strand over the walling, and the second strand across over the first, and the third strand across over the second, and through the bight of the first; then hauling the ends tight. These crownings are useful in all kinds of floppers.

CROWTH, or CRÛTH, an instrument of music (see *Plate, Music*.) resembling a violin, formerly in common use in the principality of Wales, as a tenor accompaniment to the harp; but now become extremely rare in that country. The length is $20\frac{1}{2}$ inches, the breadth at bottom $9\frac{1}{2}$, tapering towards the top to 8 inches; its thickness is $1\frac{8}{16}$, and the finger board measures 10 inches in length. It has six strings, supported by a flat bridge, placed obliquely to the sides, and

is played on with a bow. A, A, represent the apertures for the hand; B, B, the strings conducted under the end board; C, C, the pegs, and *d, d*, the sound holes. The fifth and sixth strings are the unison and octave of G, the fourth and third the same of C, and the second and first the same of D; so that the second pair of strings are a fourth, and the third a fifth to the first.

Some have supposed this instrument to have been the parent of the violin; but it is much more extensive in its compass. Two or three of the lower strings are often struck with the thumb, and serve as a base accompaniment to the notes sounded with the bow.

This instrument was not peculiar to Wales; since a figure of it has been lately discovered among the outside ornaments of the abbey church of Melros, in Scotland, built about the time of Edward II.

From the name *crowth* is derived *crowther*, a *crowder*, as a common fidler is now called. The use of this instrument is almost lost.

The Welsh had also a three-stringed crowth, which was the ancient base viol.

CROXAL, SAMUEL, in *Biography*, was born at Walton on Thames, of which place his father was vicar. The exact date of his birth has not been ascertained. He was educated at Eton, and from thence he removed to St. John's college Cambridge, where he was distinguished for his poetical turn, and also for his attachment to the whig interest, in defence of which he employed his talents during the latter end of queen Anne's reign. His political pieces are now little known, and he is chiefly remembered by his translation of Æsop's Fables, a work which, in some shape or other, is read by almost every young person. His first situation in the church was at Hampton, Middlesex, of which place he was vicar. After this he had successive preferments of considerable emolument, and lived in the enjoyment of some of them to an advanced age: he died Feb. 13, 1752. His principal works are, 1. "The Fair Circassian," for which he was highly blamed by his contemporaries, in having prostituted his muse to purposes of licentiousness, by converting the Song of Solomon into an amorous dialogue between a king and his mistress: "Such a profanation," says Mr. Cragg, "was not to be expected from a clergyman." 2. "Scripture Politics," being a view of the original constitution, and subsequent revolutions of the Jews. This work was intended as an introduction to the knowledge of the Old Testament, adapted to uninformed readers. Two years before his death, he published "The Royal Manual," which was generally supposed to be written by himself; though, in his preface, he stated it to have been the production of the celebrated Andrew Marvel. Dr. Croxal was the author of some single sermons, published at different times, and on particular occasions. *Biog. Brit.*

CROY, in *Geography*, a small town of France, in the department of the Somme, 6 miles N.W. of Amiens. It had the title of a dukedom before the French revolution of the year 1789.

CROYDON, a township of America, in the state of New Hampshire and county of Cheshire, adjoining Cornish, and about 18 miles N. E. of Charlestown, incorporated in 1761, and containing, in 1775, 143, and in 1790, 537 inhabitants.

CROYDON *Town*, a vicarage in Croydon hundred, in the county of Surrey; this town is situate near to the ruptured edge of the London clay-stratum, having the sand under the same exposed on the surface on the S. E. and S. W. sides of the town, and a little further on the chalk strata appear from under these. In 1805, the Surrey iron rail-way

(northern

(northern part) was completed up to this town from the Thames at Wandsworth, and the southern part of the railway, under the same title, was completed to Merlham, and in 1807 the Croydon canal was also completed, opening a communication from the Thames at Rotherhithe to this town. See CANAL.

CROYDON Canal, is the parliamentary name of a navigable canal, extending about $9\frac{1}{2}$ miles in the counties of Kent and Surrey, between the grand survey canal near Deptford, to the N. E. corner of the town of Croydon. See CANAL. For seven miles at the southern end, this canal is cut in the top or surface of the London clay-stratum elevated above its natural position, the remaining $2\frac{1}{2}$ miles descend by a series of locks and deep-cuttings down the edges of the same strata, and prevented while cutting, and still in many of its new banks, the finest opportunity which has perhaps ever occurred, of examining the several stratified and extraneous matters, comprising this interesting part of the British series of strata. See CLAY strata.

CROYLE STONE, in *Mineralogy*, a kind of spar, consisting of small crystals, mentioned by Woodward, as found in the mines in the peak of Derbyshire.

CROZAT, in *Geography*, a canal of France, in the department of the Aisne, which begins at St. Quentin, and terminates at Chauny. It has ten locks, and is 41,866 metres, or 21,358 fathoms long. However, since the year 1798, its navigation has been completely interrupted by the bad state of its locks. Herbin. *Statistique de la France*, vol. v. p. 118.

CROZET, a small town of France, in the department of the Loire; 12 miles N. W. of Roanne.

CROZIER, in *Natural History*, is the name of a fossil shell described by Breynius with open spiral turns, somewhat like a bishop's crozier. (See CROSTER.) Da Costa, *Conchology*, Tab. II. figs. 18 and 19, has figured a recent shell from the Indies, which he thinks resembles closely this fossil shell.

CROZIERED ABBOT. See ABBOT.

CROZON, in *Geography*, a small town of France, in the department of Finistère, chief place of a canton, in the district of Chateaulin, with a population of 7942 individuals. The canton itself has 7 communes and 12,188 inhabitants, upon a territorial extent of $237\frac{1}{2}$ kilometres.

CRUACHAN BEN, a solitary mountain of Scotland, in Argyleshire, which is very high, (being about 3300 feet above the sea) and situate near the sea, on which account general Roy recommended that it should be used with Ben Nevis for a series of accurate experiments on terrestrial refraction. See Phil. Transf. 1790, p. 246.

This mountain, according to Mr. Jameson, consists, at the base, of slate and micaceous schistus, which is followed by granite to the top.

CRUANACARRA, a small island in the Atlantic Ocean, near the west coast of the county of Galway, Ireland. Long. $9^{\circ} 59'$ W. Greenwich, lat. $53^{\circ} 15'$ N.

CRUANAKILLY, a small island in the Atlantic Ocean, near the west coast of the county of Galway, Ireland. Long. $9^{\circ} 59'$ W. Greenwich, lat. $53^{\circ} 18'$ N.

CRUCCINI, or **CRUZINI**, a small town of France, in the island of Corsica, department of Liamone, not far from Vico. It is the chief place of a canton, in the district of Vico, and has 1126 inhabitants.

CRUCES, a town of South America, in Terra Firma, 5 leagues from Panama, situated on Chagre river, which begins to be navigable at this place; and distant from the mouth of the river, by the nearest course, 21 miles, but by the several windings of the river 43 miles. At this town is a

custom-house, where an account is taken of all goods brought up the river.

CRUCHES à feu, Fr. These are earthen pots or pitchers with two handles, which are with grenades full of powder without fuses. The interstices or intervals between the grenades are also filled with powder. The mouth of the cruche, or pot, is covered with sheep skin, which, by means of the handles, is firmly tied round the neck of it. A match is then fastened to each handle, which, after being lighted, the cruche is thrown upon the enemy when they attempt to mount the breach in a work. As soon as it falls it breaks, and the fire of the matches communicates itself to the powder and grenades. In case of a deficiency of shells, they might be thrown by the besieged into the works of the besiegers, or by the besiegers into the works of the place besieged.

CRUCIAL INCISION, in *Surgery*, an incision, or cut, into some fleshy parts, in form of a cross.

CRUCIAN, in *Ichthyology*, a species of cyprinus, common in many of the fish-ponds about London, and other parts of the south of England, though probably not a native fish. The meat of it is coarse, and little esteemed. See CYPRINUS.

CRUCIANELLA, in *Botany*, (diminutive of crux, so called because some of the species have their leaves in fours, placed cross-ways.) Linn. gen. 126. Schreb. 163. Willd. 186. Lam. Ill. 161. Gært. 131. Juss. 197. Vent. 2. 566. (Rubeola; Tourn.) Class and order, *tetrandria monogynia*. Nat. Ord. *Stellatae*, Linn. *Rubiaceae*, Juss.

Gen. Ch. *Cal.* Involucre two or three leaved, or two-parted; leaves linear lanceolate, keeled, acuminate, often connivent-compressed; proper calyx none. *Cor.* monopetalous, funnel-shaped; tube filiform; border four or five cleft; segments acuminate, inflexed. *Siam.* Filaments four or five, placed in the mouth of the tube; anthers simple. *Pyl.* Germ inferior; egg-shaped, compressed; style filiform, bifid; stigmas two, obtuse, or capitate. *Peric.* Capsules two, connate, naked, not dehiscent. *Seeds* solitary, oblong. (*Pericarp* none, except the external coat of the seed; Gært.)

Est. Ch. Involucre to each flower two or three leaved, or two-parted; proper calyx none, corolla superior funnel-shaped, with a filiform tube; capsules two, oblong, naked.

Obs. Linnæus and Jussieu consider the involucre as a proper calyx, to which Gærtner, La Marck, and Ventenat object, as contrary to the general character of the family.

Sp. 1. *C. angustifolia*. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Ill. Pl. 61. Willd. 1. Gært. tab. 24. fig. 3. Sabb. Hort. 2. tab. 12. (Rubeola angustiore folio; Tourn. 130. Rubia angustifolia spicata; Bauh. pin. 334. Barrel. ic. 550. Pseudo rubia; Moris. hist. 3. § 9. tab. 22. fig. penult.) "Erect; leaves in sixes, linear; flowers in spikes." Root annual, fibrous. *Stems* several, from six to nine inches high, procumbent at the base, afterwards ascending very slender, quadrangular, smooth. *Leaves* narrow, acute, shorter than the internodes. *Spikes* two or three inches long, terminal, erect, imbricated, not interrupted, variegated with green and white. *Corollas* scarcely longer than the bractes and the involucre. A native of the south of France and Italy. 2. *C. mucronata*. Roth. cat. bot. 1. 27. "Erect; leaves in fours, linear, mucronate; spikes alternate; involucre three-leaved." According to Willdenow scarcely more than a variety of the preceding species. 3. *C. bifolia*. Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Willd. 2. (Rubia; Barrel. ic. 520 and 549. R. spicata cretica; Clus. hist. 2. 177. R. latifolia; Bauh. pin. 334. Rubicola latiore folio; Tourn.

Tourn. 130.) "Procumbent; leaves in fours, lanceolate; flowers in spikes." Nearly allied to *C. angustifolia*, and as Linnaeus himself suspected, perhaps only a variety. Ray observes that it differs from it only in having broader leaves and spikes, and in being a larger plant. Like it, it is sometimes erect. A native of the island of Candia, Italy, and the south of France. 4. *C. monspeliaca*. Linn. Sp. Pl. 5. Mart. 6. Lam. 3. Willd. 9. (*C. repens*, foliis fenis, foicis longis; Sauv. monsp. 104. *Rubia spicata repens*; Magn. monsp. 225. *Rubeola lupina*, spica longissima; Tourn. 130.) "Procumbent; leaves acute; those on the stem, in fours, egg-shaped; on the branches, in fives or sixes; flowers in spikes." Root annual. Stems several, a little ascending in their upper part, branched, somewhat rough at the angles. Spikes five or six inches long, slender, variegated; corollas longer than the bractes. A native of the south of France and the county of Nice. 5. *C. maritima*. Linn. Sp. Pl. 4. Mart. 5. Lam. 4. Willd. 7. (*Rubia maritima*; Bauh. pin. 334. *R. marina*; Barr. ic. 355. *Rubeola maritima*; Tourn. 130.) "Procumbent, somewhat shrubby; leaves in fours, mucronate; flowers opposite, quinquefid." Root perennial. Stems about a foot long, almost woody, permanent, branched, leafy their whole length. Leaves short, ovate-lanceolate, acute, stiff, glaucous, edged with white. Bractes egg-shaped, mucronate, glaucous, with white and scarious edges; growing crosswise in fours and forming a loose spike. Flowers in the axils of the bractes, almost sessile, yellowish, sometimes with a tinge of red on the outside, shutting in the day, and opening at night, sweet-scented; the divisions of the border ending in very long points. A native of France, Italy, and Candia. 6. *C. Aegyptiaca*. Linn. Mant. 38. Mart. 3. Lam. 5. Willd. 3. (*C. herbacea*; Forsk. Aegypt. 30.) "Leaves in fours, chiefly linear; flowers in spikes, quinquefid." Root annual. Stems not at all woody, procumbent and diffuse near the root, erect-spreading in the upper part. Leaves revolute, somewhat scabrous on their upper surface, and at the edges; the lowest egg-shaped, those next above lanceolate, the rest linear. Spikes terminal, solitary, rather loose. Bractes lanceolate, not keeled. Flowers small, longer than the bractes, yellowish-white; divisions of the border mucronate, as in the preceding species. A native of Aegypt. 7. *C. patula*. Linn. Sp. Pl. 3. Mart. 4. Lam. 6. Willd. 4. Læf. It. 68. "Diffuse; leaves revolute at the edges; bractes linear-awl-shaped, a little scabrous, flowers feathered." Root annual. Branches spreading. Leaves scabrous. Flowers axillary, yellow, quinquefid, firm. A native of Spain. 8. *C. ciliata*. Lam. 7. Willd. 5. (*C. diffusa*; Roth. Cath. Bot. 1. 26.) "Diffuse, generally in fours, linear, keeled; bractes linear, ciliated; flowers scattered." Root annual. Stems six or seven inches high, slender, feeble, quadrangular, leafy, branched. Leaves acute, often revolute at the edges, a little scabrous on the upper surface. Bractes in a loose terminal spike, opposite, acute, strongly keeled. Flowers sessile in the axils of the bractes, solitary; leaves of the involucre ciliated like the bractes, erect, but not connivent; germ rather large, wrinkled. Seeds egg-shaped, covered with obtuse scale-like tubercles, variously contorted. A native of the Levant. 9. *C. pubescens*. Willd. 6. (*Rubeola cretica incana*; Tourn. Cor. 5.) "Erect; leaves generally in sixes, linear, pubescent; heads of flowers peduncled, axillary and terminal." Whole plant hoary-pubescent. Stem obtusely quadrangular. Flowers purple; tube three times the length of the involucre; border flat, with five obtuse divisions. A native of Candia. 10. *C. capitata*. Lam. Ill. 1410. Willd. 8. Billard. Icon. Pl. Syr. Decaf. 1. tab. 3. "Procumbent,

somewhat shrubby; leaves in sixes, ovate-lanceolate; flowers in heads, quinquefid." Root perennial, horizontal, strong, woody. Stem about three inches long, weak, naked near the bottom, with filiform branches. Leaves acute, scabrous, revolute at the edges. Flowers dark-coloured, some peduncled, others sessile; involucre one-leaved, two-parted, with six or seven teeth. A native of mount Lebanon, near the summit. 11. *C. hispida*. Mart. 7. Mill. "Stem hispid; leaves lanceolate, hirsute, opposite; flowers in a terminal umbel. Stems quadrangular, rough, prickly, bending downward. Flowers blue, quadrifid. 12. *C. americana*. Mart. 8. Mill. "Stem erect, villous; leaves linear lanceolate, hirsute, opposite; flowers axillary, solitary. Stem near three feet high, shrubby, branched. Leaves covered with stinging hairs. Flowers pale blue. The last two were sent by Dr. Houlton from La Vera Cruz in New Spain. The plants grew in the Chelsea garden very well during the summer, but perished in the autumn before the seeds were ripe.

CRUCIATA, *C.* Bauh. Tourn. Barr. &c. See ASPERULA, GALIUM, RUBIA, and VALANTIA.

CRUCIATA montana minor flore caruleo; Barr. See ANAGALLIS monelli.

CRUCIATÆ, in Entomology. See CICADA.

CRUCIBLE, in Chemistry. Crucibles are small vessels made of earthenware metal, or other materials, employed by chemists in operations with the naked fire, such as fusions and reductions of metallic ores in the small way, vitrifications of earthy mixtures, calcinations, &c. &c. The construction of these vessels is of no small importance to the chemist; and many observations will suggest themselves with regard to their selection and proper use.

1. *Of earthen crucibles.* Formerly, when chemists made their own crucibles and fire-pots, the subject engaged much of the attention of such eminent practical operators, as Pott, Glauber, Agricola, Cramer, &c. and more lately a considerable improvement has been made by that eminent scientific manufacturer, the late Mr. Wedgewood.

A pottery ware, which should unite all the requisites for a good crucible, should be infusible at almost any heat, close and compact in texture, so as to retain saline and metallic fluxes for a considerable time, without being materially acted on by them, or allowing them to pass through; and should be able to bear sudden changes of temperature, without cracking or splitting. It is found, however, that all these requisites are incompatible in the same ware; so that a selection must be made, according to the intended use.

For enduring the most intense heat, without fusion, the hard, coarse, brown crucibles, originally made at Waldenburg, in Hesse, have long been the most esteemed. They are manufactured, according to Pott, by mixing a very refractory clay with a coarse sand, the finer parts of which have been separated by the sieve and rejected. These vessels are not turned on the potter's lathe, as this would require a considerable portion of water to bring them to the requisite degree of plasticity, but the mass is barely moistened, and is then fashioned into the proper shape, by being strongly rammed into an iron mould. The crucibles are then very slowly dried and baked. The genuine Hessian crucibles are extremely hard, and (unless filled with any substance that acts as a powerful flux) they are only softened, but not melted down, by a heat of sufficient intensity for any chemical operation. Though the coarseness of their texture tends to render them porous, this defect is counteracted, in a great measure, by the very small quantity of water used in making them, and the consequent smallness of the

shrinkage whilst drying; and their coarseness enables them to bear a pretty rapid heating and cooling without cracking.

The ordinary brown crucible ware used in this country, is whiter and finer than the Hessian, but is softer, more crumbly, and much more porous; so that litharge, when in fusion at a full red heat, runs through this ware nearly as easily as water soaks through a sponge. It is also more fusible than the Hessian, though it is sufficiently refractory for most purposes.

The most infusible material for fire-pots that is known, and which resists the operation of saline fluxes for the longest time, is a mixture of burnt and unburnt clay; and this is the composition of the large pots or crucibles used in glass-making. The peculiar advantage of this mixture is, in substituting baked clay to sand, or any other silicious earth, and thus increasing the proportion of alumine, which is an earth of difficult solution in fluxes, and diminishing that of flint, which is more soluble.

Crucibles intended for the fusion of metals are much improved by a mixture of plumbago. This substance is infusible *per se*, and being protected from the action of the air by being involved in the clay, its carbonaceous ingredient escapes combustion. It has the additional advantage of having no affinity whatever with the earths, and, therefore, does not dispose them to fusion; and the unctuous softness of this material gives a great smoothness to the surface of the crucible, which prevents it from detaining any portion of the melted material when poured out. The black-lead ware will bear sudden heating and cooling better than any other; and it is so soft, that it may readily be sawed or cut with a jagged knife, whereby the chemist may easily fit himself with stoppers, covers, &c.; but its extreme porousness renders it unfit to retain any kind of saline flux.

The useful fire-ware invented by Mr. Wedgwood is a very fine, hard, close grained porcelain biscuit, made of very pure clay and flint, which are brought to extremely fine powder before they are worked. This gives a closeness of texture superior to any other pottery; so that crucibles made of it will long retain saline fluxes; and retorts will serve for the distillation of the most corrosive liquors, without requiring any glazing. Experience has shewn, however, that no kind of earthenware remains impervious to air, when very strongly heated. The great inconvenience attending the Wedgwood fire-pot ware is, its extreme liability to crack whilst heating or cooling, which is owing to its porcelainous hardness, and the closeness of its texture. This inconvenience is, in some measure, remedied, by giving the crucible a slight coating of loam or clay.

It is often required, in chemical operations, to line the inside of a crucible with charcoal; as, for example, in the reduction of many of the simple metallic oxyds, or carbonated oxyds, such as the oxyds of manganese, copper, or lead, and for other purposes. This is sometimes done by cutting down a piece of charcoal to fit the cavity of the crucible, and then scooping a hollow in the charcoal; but it is a better and more speedy way to mix up some charcoal powder with a very little linseed meal, to moisten the mass just sufficient to make a slightly adhesive mass to line the crucible with it, and to dry it in a red heat, by which the volatile parts of the linseed fly off, and a sufficiently firm charcoa is left.

The form of the ordinary earthen crucibles is round, or three-cornered, or sometimes barrel-shaped; and they are usually furnished with stoppers of the same material, with a small hole through the top, opening obliquely, to allow the escape of any vapour, when the joining is closed by lute,

and at the same time to prevent any of the dust of the fuel from falling in. As the lower part of the crucible would escape the greatest heat of the furnace, if put immediately upon the bars, and would be liable to crack by the current of cold air, the crucible is generally set on a solid earthen stand, which raises it an inch or two from the grate. The lid of the crucible may be luted on by a mixture of clay and sand; or, if it is required to be quite impervious, a mixture of pipe-clay, with about a tenth of glass of borax, may be employed, which, in a red heat, consolidates into a semi-fused tenacious mass.

Crucibles are also made of silver, iron, and platina. A silver crucible is almost indispensable in the analysis of earths and stones when they require to be first treated with caustic alkali; for, if earthen vessels are used for this purpose, the alkali acts also on the substance of the crucible, and thus much confusion is introduced in the process; whereas pure silver is not in any way acted on by alkali. The silver employed for this purpose should be freed from alloy, either by cupellation, or by being recovered from luna cornea. Silver, when perfectly pure, and laminated into a thin plate, is fusible at a full red heat, not more intense than can be made in a common fire; so that a crucible of this material will but just bear the heat required for the perfect fusion of the fixed alkalies, and will hardly retain the melted alkali for any great length of time. It is found, however, that this heat is by no means necessary, for most earths are completely *resolved*, or rendered soluble in water or acid, by previous ignition with alkali, for about an hour, in a heat short of fusion.

When a very strong heat is required to be given to the mixture of alkali and earths, chemists sometimes employ an iron crucible, previously cleaned and smoothed on the inside, which is often found very useful for other purposes.

Lastly, we may mention platina as a material for crucibles, which has been found of such singular utility for a vast variety of uses, that it is almost indispensable to the analytical chemist. Platina has the advantage of bearing the utmost intensity of heat without fusion, and not being in any degree oxydated by exposure to air, the smoothness and polish of the surface remain uninjured; so that substances which are heated in it may be detached with great ease and accuracy. There are few substances that act on platina; so that most operations that require heat may be performed safely in vessels made of this valuable metal: the particular mode of working it will be mentioned under the article PLATINA. It unfortunately happens, however, that the alkalies, when in strong fusion, dissolve a sensible portion of this metal; and hence it is not equally valuable with pure silver under these circumstances. When platina crucibles are strongly heated, in contact with coak or coal, they should be enclosed loosely in crucibles of earthenware, otherwise the vitreous slag of the coal is apt to adhere strongly to the outside of the platina vessel, and cannot be got off without much difficulty.

CRUCICOLÆ, q. d. *worshippers of the cross*, a designation given to the primitive Christians, by the heathens.

CRUCIFERÆ, in *Botany*, the third natural order of the thirteenth class in the system of Jussieu. It consists of dicotyledonous polypetalous hypogynous plants, with the following peculiar character. *Calyx* four-leaved, alm. it always deciduous. *Petals* four, disposed in the form of a cross, alternate with the leaves of the calyx, most frequently furnished with claws, inserted into an hypogynous disk. *Stamens* six, with the same insertion; four longer, in opposite pairs; two shorter, solitary, and opposite to each other, between the pairs; each of the pairs, and of the solitary filaments

filaments opposite to a leaf of the calyx. *Germ* simple, situated upon the stamiferous disk, which is sometimes tumid between the longer and shorter stamens, and thence appears quadriglandular; style one or none; stigma most frequently simple. *Fruit* either a silique or a silicle, *i. e.* either long or short; generally two-celled, and with many seeds, two-valved; valves opening lengthwise, and entirely separating from each other; partition membranous, seminiferous on each of its edges, sometimes extending beyond the valves, and forming a kind of beak. Perisperm none. *Stems* herbaceous, rarely shrubby. *Leaves* alternate (in a single instance, opposite.) *Flowers*, for the most part, not axillary, scattered, or in terminal spikes, rarely panicled.

This family is universally allowed to be a very natural one, and, with some slight variations, has been kept separate by most systematic botanists. It corresponds exactly with the Linnæan class tetradynamia, except that it excludes cleome, a rather anomalous genus, which does not well accord with the others, and which Jussieu has therefore removed to the capparides, his next succeeding natural order. Jussieu has thrown the genera, as Linnæus had done before him, into two divisions, according to the length of the seed-vell, and the absence or presence of a style. Ventenat has made some alteration in the arrangement and number of genera. In his "Tableaux du regne Vegetal," the order stands thus: I. *Eruceæ*. Style scarcely any. Fruit a silique, two or many-celled, terminated by a kind of tongue or beak; raphanus; raphanistrum, separated from the preceding; sinapis; brassica. II. *Cheiranthoides*. Style scarcely any. Fruit a silique, two-celled, terminated by a point, which is commonly very short; arabis, including turritis; hesperis; cheiranthus; erythimum; silybrium; radicle, separated from silybrium; cardamine; dentaria. III. *Athyoides*. Style apparent. Fruit a silicle, two-celled, rarely one-celled. Lunaria; rieotia, separated from lunaria; bilcutella; clypeula, including peltaria; alyssum; vesicaria, separated from alyssum; draba; cochlearia; coronopus, separated from cochlearia; iberis; thlaspi; capfella, separated from thlaspi; nasturtium, separated from lepidium; lepidium; camelina, separated from myagrum; anallatica; vella. IV. *Myagroides*. Style apparent, or scarcely any. Fruit a silicle, from one to four-celled, valveless; cells with only one seed in each, some of them often abortive; myagrum; rapistrum, separated from myagrum; bunias; erucago, separated from bunias; cakile, separated from bunias; pugionum, also separated from bunias; crambe; isatis.

Most of the plants of this natural order are hot to the taste, contain a portion of volatile alkali, and are reckoned detergent, diuretic, and antiscorbutic. The roots or leaves of several of them are some of the most common esculent vegetables, and are esteemed nutritious to man and to beast. It appears, from some experiments made in France by Deyeux and Beanmé, that these plants contain sulphur, combined with their odorous principle; and that this combustible body, reduced to the state of an elastic fluid by its combination with hydrogen, constitutes their aroma.

CRUCIFIX, a cross, whereon the body of Jesus Christ is fastened in effigy; much used by the Romanists in their churches, and other places, to recognize the passion of Jesus Christ, and direct their prayers to.

There are some chapters wherein Jesus Christ is the first canon, and the income of the canonry goes to the subsistence of the *crucifix*.

CRUCIFIXION, an ancient form of execution, by fastening the criminal to an erected cross. See CROSS.

CRUCIFORM FLOWER, *flos cruciformis*, in *Botany*, is

so called from the resemblance of its four spreading petals to a cross. Such flowers constitute a very natural order of plants; as well as a class in Tournefort's system, and even in that of Linnæus; his *Tetradynamia* being entirely composed of such, with the exception of *Cleome*, which some botanists judge to be improperly placed there, even according to the Linnæan character of that class. See CRUCIFERÆ, COROLLA, and CLEOME. S.

CRUCIS, EXPERIMENTUM. See EXPERIMENTUM.

CRUCITA, in *Botany*, Juss. See CRUZITA.

CRUCKFALLA, in *Geography*, a mountain of the county of Donegal, Ireland, near Bloody Farland-point.

CRUCOLI, a town of Naples, in the province of Calabria Citra; 6 miles S.E. of Curati Vecchia.

CRUDE, something that has not passed the fire, or has not had the degree of concoction, *i. e.* of heat, requisite to prepare it for eating, or some other use.

Crude, or raw silk, is that which has not been put in boiling water, to unwind it from off the cod; nor boiled in water and soap, to fit it for dyeing.

CRUDE *sugar*. See SUGAR.

CRUDE *antimony*, is that which comes immediately from the mines, without any preparation, except once melting.

CRUDE *humours*, in *Medicine*, or rather in the old humoral pathology, were the humours in an unconcocted state. In the early state of inflammation, when the secretions are thin and watery, they were termed *crude*, in contradistinction from the subsequent state of suppuration, when a thick and purulent discharge takes place, which was said to be *concocted* or digested. The terms were extended, by analogy, to all the discharges from the body in febrile diseases in general, as we have shewn under the heads of CONCOCTION and CRISIS; which see.

CRUDEN, ALEXANDER, in *Biography*, well known for his excellent Concordance of the Bible, was born in 1701 at Aberdeen, where he received his grammar learning: he afterwards studied at Marischal college, with a view of entering the church. Unfortunately, before the period arrived when he could be admitted to officiate as a public instructor, such decided symptoms of insanity appeared in his conduct, as rendered confinement necessary. Throughout the whole of his life he believed that he was delegated by Heaven to reform a guilty world; and his conduct in a thousand instances demonstrated an ardour and zeal for the good of his fellow-creatures, that merited the highest applause. Thrice, however, was he shut up in a private mad-house, in which, if the nature of his disease did not lead him to exaggeration, he was cruelly treated. Once indeed he brought his action against a respectable physician, and other persons connected with him; the cause was tried, and Cruden was unable to make out a case. The verdict was given in favour of the defendants; but to the public he made an appeal; and the description of the treatment which he experienced, or which he asserted that he had experienced, cannot fail to excite the commiseration of every feeling heart. That most deplorable malady to which humanity is subject, is, we fear, too frequently treated with a degree of harshness that cannot be justified upon any principles. On his release from his first confinement he came to London, and engaged in some respectable families as private tutor. In the same employment he spent some years in the Isle of Man, and in 1732 he opened a shop in London, under the Royal Exchange, as bookseller, and employed all his vacant time as a corrector of the press. In the following year he began to compile his great work, *viz.* "A complete Concordance of the Holy Scriptures of the Old and New Testament." We can scarcely conceive any literary work that

that required more patient labour than this, and few have been executed with greater accuracy. He had nearly executed the whole before he looked for public remuneration. The first edition was published in 1737, and dedicated to queen Caroline, who had led the editor to expect her patronage; her majesty unfortunately died a few days before the work could be got ready. The author's affairs were now embarrassed; he had none to look to for assistance, and in a fit of despondence he gave up his trade, and became a prey to melancholy. Shortly after this, he assumed the title of "Alexander the Corrector," maintained that he was divinely commissioned to reform the manners of the age, and restore the due observance of the sabbath. To prophecy he appealed, in which he saw his own character delineated. He sought, however, for earthly honours, and requested of his majesty the dignity of knighthood, and earnestly solicited his fellow-citizens to elect him member for the city of London. Both were deaf to his entreaties, and he turned from public offices to duties for which he was better qualified. He laboured almost incessantly, sometimes in works of pure benevolence, and at others as corrector of the press, and seldom allowed himself more than four or five hours for sleep. In 1770 he left Aberdeen for London; he took lodgings at Islington, where he died November the first. In private life Mr. Cruden was courteous and affable, ready to assist all that came within his reach, as well with his money as with his advice, which was founded upon the principles of practical religion. He was, with regard to doctrines, a Calvinist; but, what is much better, he was a good man, and, like his great Master, exercised in works of piety and true benevolence. *Biog. Brit.*

CRUDEN, in *Geography*, a bay of Scotland, formed by a river of the same name, on the east of the county of Aberdeen; 8 miles S. of Peterhead.

CRUDIA, in *Botany*, (named after a botanist called Crudey, by whom the plant was communicated to Schreber.) Schreb. 711. Willd. 821. Class and order, *decandria monogynia*.

Gen. Ch. *Cal.* Perianth one-leaved; tube short, compressed-top shaped, gibbous before at the base, with an oblique mouth, permanent; border four-parted, unequal, spreading, deciduous; upper segment roundish, concave; the others egg-shaped, very obtuse, less concave. *Cor.* none. *Stam.* Filaments ten, filiform, a little broader at the base, bent in the middle, inserted into the neck of the calyx, and twice the length of its segments; anthers roundish, adnate. *Pist.* Germ. leynitar-shaped, lispid, erect, affixed to the bottom of the calyx by a pedicel as long as the tube, inclined to the upper segment; style capillary, inflexed the length of the stamens, proceeding from the back of the germ; stigma thickened, obtuse. *Peric.* Samara very large, egg-shaped, one celled. *Seeds* two, roundish, depressed.

Ess. Ch. Calyx one leaved; border four parted. Corolla none. Filaments dilated at the base. Samara with about two seeds, egg-shaped.

Sp. 1. *C. spicata*. Willd. 1. (*Apelatoa spicata*; Aubl. Guian. 1. 363. tab. 147.* "Leaves pinnated; leaflets oblong-lanceolate, acuminate." *Root* perennial. *Leaves* alternate, smooth. *Racemes* simple, axillary. Willdenow, under the genus *pterocarpus*, has directed this species to be removed from the present genus, probably for a reason which Mr. König has shewn to be ill-founded, on the authority of Aublet's original specimen in the herbarium of sir Joseph Banks. See *Annals of Botany*, vol. 1. p. 358. 2. *C. aromatica*. Willd. 2. (*Touchoiroa aromatica*; Aubl. Guian. 215. tab. 148.*) "Leaves simple, elliptical, acuminate."

Different from the preceding chiefly in having simple leaves. Both species are natives of woods in Guiana.

CRUDITY, in *Medicine*, the condition of the humours previous to concoction. See CRUDE.

CRUELTY, in *Ethics*, is a habit of mind, directly opposed to mercy and compassion, disposing men to take delight in inflicting misery and punishment, and in satiating the thirst after these, by beholding the torture and anguish of the sufferers, independently of any consideration of injury received or suffered. According to the arrangement of Dr. Hartley, it belongs to that class of affections which lead us to rejoice at the misery of others. Cruelty and malice, says this writer (*Obs. on Man.* p. 284.) are the genuine and necessary offspring of anger indulged and gratified. They are most apt to arise in proud, selfish, and timorous persons, those who conceive highly of their own merits, and of the consequent injustice of all offences against them; and who have an exquisite feeling and apprehension in respect to private gratifications and uneasinesses. Cruelty to brute animals indicates a mind destitute of reflection and sensibility. In the more atrocious instances of it, it either springs from, or tends to cherish, a savage disposition; and in those cases, in which it forms a part of men's amusements and pastimes, it is culpable in its source, and injurious in its effects. Bull-baiting, cock-fighting, and such sports, which some have reckoned as manly, are remnants of barbarity; and there are other amusements and sports, which ought to be restrained and discouraged on account of the cruelty that attends heedlessness and wantonness; but as it is of pernicious influence it ought to be checked and prohibited, particularly in the early periods of life. As a preservative against all wanton acts of cruelty, even in favourite pastimes, we would recommend, more especially to young persons, the perusal of Thomson's *Spring*, in his *Seasons*. It may serve to check the practice, or at least to diminish the pleasure, of those who torture worms and other insects in the amusement of fishing; and of others who, for the indulgence of a vitiated appetite, blend the most unfeeling cruelty with the arts of cookery. Referring to the former species of cruelty, the humane and moral poet describes it in the following lines:

"But let not on thy hook the tortur'd worm,
Convulsive twist in agonizing folds;
Which, by rapacious hunger swallow'd deep,
Gives, as you tear it from the bleeding wretch,
Of the weak, helpless, uncomplaining wretch,
Harsh pain and horror to the tender heart."

In the education of youth, it is of great importance that no wanton, and more especially no deliberate act of cruelty, should be permitted or encouraged.

CRUGER, or KRUGER, THEODORE, in *Biography*, an engraver, born at Munich about the year 1576, but though a native of Germany, he resided during the greater part of his life in Italy. He appears to have attempted the manner of Francesco Villamena; but his prints, though executed in a bold style, lose their effects from his ignorance of the distribution of light and shade. He died at Rome about the year 1650. His plates are usually marked with a cypher, composed of the initials of his name; amongst them are the following:

Vita D. Joannis Baptistæ ex archetypo Andræ Sartii, &c." A set of 18 middle sized prints, in which are included the frontispiece, the portrait of Andrea, two subjects from Francia Bigio, and four single figures, representing Justice, Faith, Hope, and Charity.

The "Last Supper," after the same painter, a large plate lengthways. Huber. Manuel des Arts.

CRUGER, or KRUGER, THEODORE, (also called Ver Crus by the Flemings, and Dalla Croce by the Italians,) an engraver, born about the year 1646, by some supposed to be the son of the last-mentioned Cruger. This artist, in 1710, was employed, with three others, to engrave the Florentine gallery. There are some other plates by him, etched and retouched with the graver, in a style which does not shew any great merit. We shall only notice the following works of this master :

A Portrait of Ludovicus Adimari, engraved from P. Dandini; a small plate.

A portrait of a gentleman, from P. Bordone, in the Florentine gallery, folio.

A portrait of a lady, from the same, in the same collection, folio.

A portrait of the wife of Giorgione, from a painting by that master in the same gallery, folio.

St. Francis at prayers, from Carlo Maratta. Huber. Strutt.

CRUGER, or KRUGER, MATTHIAS, brother to the elder Theodore. This artist engraved some plates from Guido and other masters, as well as from his own compositions. Strutt.

CRUGER, LOUIS. See KRUG.

CRUICKSHANK, WILLIAM, a distinguished anatomist, was born at Edinburgh in the year 1746. At the age of fourteen he was sent to the university in that city, and after studying some years there, he was removed to Glasgow. He was intended by his father for the church, and as he was very diligent, and forward in classical learning, he early employed a part of his leisure hours in teaching Greek and Latin to the younger students, and in that capacity was engaged in the family of provost Buchanan: shewing at length a stronger propensity to medicine than to theology, he was placed under the care of Mr. Moore, surgeon, at Glasgow. From Mr. Moore Mr. Cruickshank removed, in 1771, to London, where he was soon introduced, and made librarian to Dr. William Hunter, in which office he acquitted himself so well, that on the secession of Mr. Hewson, he became the assistant, and, in a little time, joint lecturer in anatomy, with the doctor. He had here full scope for his abilities, and as he was as diligent as he was skilful, he added largely to the beautiful collection of anatomical preparations with which the museum of Dr. Hunter was filled, particularly by his curious injections of the lymphatic vessels. The result of his acquirements in this branch of anatomy, which he cultivated with assiduity and success, he published in 1786, under the title of "The Anatomy of the Absorbent Vessels of the Human Body." In this work, which was re-published in 1790, he demonstrated the structure and situation of the valvular lymphatic absorbents. On the death of Dr. William Hunter, which happened in the year 1783, Mr. Cruickshank became partner in the lectures with the doctor's nephew, Dr. Baillie, and had with him the joint use of the museum, for the purpose of illustrating the lectures. The museum has since, agreeably to the direction of Dr. Hunter in his will, been sent to Glasgow. In 1795, Mr. Cruickshank communicated to the Royal Society an account of the regeneration of the nerves. The paper was printed in the Philosophical Transactions for that year. The same year he published a pamphlet on insensible perspiration; and in 1797, an account of appearances in the ovaria of rabbits, in different stages of pregnancy; but his fame rests upon, and is best supported by his anatomy of the absorbents, which continues to be considered as the most correct and valuable work

on the subject, now extant. He died on the 27th of June, 1800. Annals of Medicine, vol. v.

CRUISE, from the German *kruifs*, *a-crofs*, signifies to cross to-and-fro, to sail up and down within a certain space of the sea, called the *cruising* latitudes, in quest of vessels, or fleets of an enemy, &c.

CRUISERS, in the Navy, are small men of war, made use of to-and-fro in the Channel, and elsewhere, to secure our merchant-ships and vessels from the enemy's small frigates and privateers. They are generally such as sail well, and are commonly well manned; and, indeed, the safety of the trade in the Channel, and up and down the soundings, and other places, absolutely requires the constant keeping out of such ships at sea.

CRUIT, in Geography, is an island in the Atlantic ocean, near the West coast of the county of Donegal, Ireland, Long. 3° 10' W. Greenwich. Lat. 55° 2' N.

CRULAY, a small town of France, in the department of the Eure, 12 miles E. of Verneuil.

CRUMAU, or KRUMAU, or *Krumtow*, a town of Moravia, in the circle of Znaim; 16 miles N.N.E. of Znaim.

CRUMAU, or *Krumlaw*, a town of Bohemia, in the circle of Prachatitz, on the river Moldaw; 17 miles S.E. of Prachatitz, and 76 S. of Prague.

CRUMENA, from *κρυμνω*, *pendeo*, *I bang*, in Zoology, the name given by Cardan, and some others, to the purse or pouch which the opossum has under its belly, and into which it receives the young in time of danger.

Scaliger, supposing there might be other animals, as well as the opossum, to which nature might have given this sort of pouch, has erected a general distinction, under the name of *animalia crumentata*; but the opossum is the only species yet known to belong to this genus. The only instance that naturalists seem to afford us of a like provision of nature for the care of the young, is what is related of some of the fish kind. Oppian, in his *Halieutics*, mentions this property of receiving the young into the body, in time of danger, to be in the dog-fish, and in the squatina, and some others; and Tyson observes, that, in the anatomy of a female dog-fish, he saw two slits under the belly, closed up in their natural state, but easily distensible, so as to be capable of receiving the young fish; and that these went not into the womb, nor any other peculiar part, but only into the cavity of the abdomen.

The account given by Oppian is, that, in time of danger from a storm, or from any fish or prey pursuing the young fry, they go into the parent's belly. If, therefore, after this account of Tyson's, any young fish should ever be found loose in the cavity of the mother's belly, it will prove the truth of this passage in Oppian, which has been so much disputed. Phil. Transf. No. 239, p. 120.

CRUMENTATA, a term used by Julius Scaliger to express such animals as have a pouch or bag under their belly, into which young ones may be received in time of danger. See OPOSSUM.

CRUMHUBELL, a silver mine in Silesia, which produces galena and silver ore, was thought by some to be the most elevated above the sea of any known mine, but Sterzingen silver-mine in the Tyrol (elevated 7512 French feet) and some others, are still higher.

CRUMIRUM, in *Ancient Geography*, a town of Lower Pannonia.

CRUMLIN CANAL, sometimes, though improperly, called *Kevo Chapel* canal, (under which name it is shortly described in our article CANAL.) This canal, or water-level, in its general direction, is nearly west, with a bending course of two miles, in the county of Glamorgan in South Wales;

it is throughout about level with the highest tides, or 22 feet above low-water mark in the Bristol Channel; it commences within ten yards of the river Neath, at Trueman's-hall shipping staith, which is opposite to the commencement of the Neath canal at Giant's-grave-pill, and proceeds through Crumlin bog to Lan-y-wern colliery, whence a tram-road proceeds in a tunnel, half a mile into the hill, and there intersects the same great vein of run or bituminous coals, which Messrs. Smith and Co. are working at Lanfallet. This canal is about 26 feet wide at top, 14 at bottom, and 3 feet deep, and was cut under the direction of Mr. Thomas Dadford, senior, at the sole expence of Edward Elton, esq.; who, it is to be feared, is but slightly remunerated by the small trade thereon, for his heavy expences in the undertaking. Crumlin bog, of about 700 acres, was since drained by a company of leasers, under lord Vernon and the lords of Neath abbey estate, to whom the same belongs.

CRUMLIN-Water, a small river of the county of Antrim, Ireland, which rises in mount Devis, and falls into Lough-Neagh.

CRUMMEL-BOTTOM, or *Cranwell-Bottom* quarries; these are situate near the village of Ealand, in the West Riding of Yorkshire, and furnish great part of the excellent paving-stone which is now so generally used in the foot pavements in London, by means of the Calder and Hebble navigation, which passes close by them. (See *CANAL*.) This valuable stone, and the white or grey slate from the same quarries, are the produce of the fourth grit-stone rock, reckoning upwards from the mineral or Derbyshire lime stone strata. This rock is remarkable in every part of its course through the kingdom for its abundance of mica, in small plates, so disposed as to occasion the stone to split with the utmost ease and truth, almost as thin as we please. Near Halifax the same is quarried in such large slabs as to floor the largest kitchens with only four or six stones; and it also splits so readily and truly in other directions, that long beams are not unfrequently cleaved out of it, of which some very remarkable specimens are, or were very lately, to be seen opposite to the late sir William Staines's stone-wharf in Millbank-street, Westminster.

CRUMNOCK LAKE, or *Water*. in Cumberland, lies on the N.W. of Buttermere; it is about four miles long, and half a mile in breadth, has three small islands in it, one of which is a naked rock, the others are covered with wood. This lake is extremely deep and clear, and contains abundance of char fish, from six to eight ounces weight each. The Coker river is fed from this lake, which itself receives the waters of Buttermere, and Lowes-waters.

CRUMP ISLAND, a small island in the West Indies about a mile long, near the N.E. end of the island of Antigua. N. lat. 17° 14'. W. long. 61° 25'.

CRUNA DEL CONDE, a town of Spain, in Old Castile, on the Duero, near Aranda de Duero.

CRUNARAD, or *CRUMARAD*, a hill of the county of Donegal, Ireland, 2 miles N. of Killibegs. It has a remarkably sharp top, and is much higher than any of the hills eastward of it, which makes it an excellent mark for finding the entrance of Killibegs harbour. McKenzie.

CRUNI, in *Ancient Geography*, a town of Greece, in the Peloponnesus, placed by Strabo between Chalcis and Pyle. — Also, a river of the Peloponnesus, which is near the fore-mentioned town. — Also, a town of Lower Mælia, upon the Euxine sea, N.E. of Odesus, and W. of the Cape Petrias.

CRUOR of the Blood, is a term synonymous with *Craffamentum*.

CRUPEZIA, in *Antiquity*, wooden shoes, or clogs, worn by the Mesochori.

CRUPINA, in *Botany*, a name by which some authors call the *carduus stellatus*, or star thistle.

CRUPPER is used by some for the hind or round part, or rump of a horse, comprehended between the place of the saddle and the tail. See *HORSE*.

The word is formed from the French *crouppe*, which signifies the same. It denotes also a thong of leather put under a horse's tail, and fixed to the saddle, to prevent it from being thrown forward. See *SADDLE*.

CRURA CLITORIDIS, in *Anatomy*, a term synonymous with *corpora cavernosa clitoridis*.

CRURA Cerebelli, are two portions of medullary substance, forming the trunk of the arbor vitæ, and joining the upper and back part of the pons varolii. See *BRAIN*.

CRURA Cerebri, are two large processes of medullary matter, departing from the inferior surface of the cerebrum, to join the pons varolii at its anterior part, where they unite at an acute angle. They are called by Soemmering *processus medulle cerebri*. See *BRAIN*.

CRURA Diaphragmatis, two portions of muscle, arising from the bodies of the lumbar vertebræ, and fixed to the posterior part of the greater diaphragm. They constitute the lesser diaphragm. See *DIAPHRAGM*.

CRURA fornicis, in the brain. There are four of these, viz. two anterior, and two posterior. The former are distinct round medullary chords, arising separately in the anterior lobes of the brain, and uniting to form the pillar or body of the fornix: the posterior crura are thin, broad, and flat; and united by the medullary expansion, termed *trigonus* or *psalterium*. They run along the anterior part of the great hippocampus. See *BRAIN*.

CRURA penis, are the same as the corpora cavernosa of that part.

CRURÆUS, or *CRURALIS Musculus*, in *Myology*, derives its origin from the anterior rounded surface of the os femoris, and proceeds in a straight direction to the basis of the patella. It cannot be at all separated from the vastus internus, and for the most part is as intimately united to the vastus externus. These three muscles should indeed be included under one name and description. The cruralis will assist in extending the knee-joint.

CRURAL, in *Anatomy*, is a term applied to the vessels, &c. of the lower extremity; viz. to the femoral artery and vein. There is an *anterior crural nerve*, derived from the lambar nerves, which supplies the front of the thigh. See *NERVE*.

CRURAL Arch, is the space left under the lower border of the tendon of the external oblique muscle, where it passes from the spine of the ilium to the pubis. The broad insertion, which the tendon has into the angle and crista of the pubis, gives to this part a concave form, which justifies the appellation of crural arch. The space in question is completely filled by various parts, which are passing between the thigh and the pelvis. Its outer part contains the iliacus internus, and psoas magnus muscles; between which, on the anterior part, lies the anterior crural nerve. Next to these muscles, towards the inside, is the femoral artery; and its corresponding vein is still nearer to the pubis. The trunks of the lymphatics of the lower extremity enter the pelvis, about the femoral vessels; and there is frequently a large gland, or more than one, under the tendon.

CRUS, denotes all that part of the body which reaches from the buttocks to the toes; and is divided into thigh, leg, and foot.

CRUSA, in *Ancient Geography*, a town of Asia Minor, in the Ceramic gulf.

CRUSADES.

CRUSADES. See **CROISADES.**

CRUSÆI, a people of Macedonia, who inhabited the country called Crysis in Mygdonia.

CRUSCA, an Italian term, signifying *bran*, or what remains of meal after the flour has been sifted out. It is only in use among us to denote that celebrated academy called *Della Crusca*, established at Florence, for purifying and perfecting the Tuscan language.

The academy took its name from its office, and the end proposed by it, which is to refine the language, and, as it were, to separate it from the bran. Accordingly, its device is a sieve, and its motto, *Il piu bel fior ne coglie*; that is, *It gathers the finest flour thereof*.

In the hall or apartment where the academy meets, M. Monconis informs us, every thing bears allusion to the name and device: the seats are in form of a baker's basket; their backs like a shovel for moving of corn; the cushions of grey fatten in form of sacks, or wallets; and the branches, where the lights are placed, likewise resemble sacks.

The vocabulary *Della Crusca* is an excellent Italian dictionary, composed by this academy.

CRUSIUS, **GOTTLIEB LEBRECHT**, in *Biography*, a German engraver, born in the year 1730. He studied design some time at Leipzig, and made drawings for the booksellers. He afterwards began to engrave, and went to Paris to complete his studies. He then again established himself at Leipzig, where he was principally employed in decorating the publications of the day. He had a brother named Carl, who likewise engraved for books, and died in 1779. Heineken.

CRUSSEILLE, in *Geography*, a small town of France, in the department of Mont Blanc, formerly the duchy of Savoy; 9 miles N. of Annecy.

CRUSSER, in *Commerce*, a piece of coin in Germany, valued at about three farthings.

CRUSSOL, in *Geography*, a small town of France, in the department of the Ardeche, with an ancient castle; 9 miles S. of Tournon.

CRUST of the Earth, in *Geology, a term implying the rocks and strata which are within the reach of geological observation, by means of valleys, fissures, mines, &c. It seems more than probable, that the whole of this is composed of stratified matters, formed from aqueous depositions, since much dislocated and broken in some parts, and being very thick and assuming a crystalline structure in others. See **STRATA**.*

With some early writers, the term crust was applied only to the alluvial mixtures or mould, &c. which cover the strata in most instances.

CRUSTA LACTEA, a *Medical* term, applied to a species of itchy running scab, which appears in the face of infants one or two years of age: they are generally observed in infants at the breast, that have not yet cut their teeth. However, the disease sometimes also appears later, as it has been met with in children of four or six years of age; and indeed it is not a disease of infants alone, for it has also, though rarely, been observed in adults. Children that are liable to it, are mostly attacked with it as often as they cut a tooth. Instead of the diarrhoea and cough, which are the more ordinary attendants of teething, the eruption appears in these subjects; and again dries up when the tooth is cut, as then the irritation has ceased. See the article **ACHOR**.

This disease is not attended with fever: it always appears first in the face, on the cheeks, mouth, lips, and forehead, in small ulcers of the size of a lentil, which contain a pale yellow gelatinous fluid. These small ulcers soon burst, per-

haps as soon as the second day, and form a scab or crust, in colour resembling milk that has been dried down over the fire, from whence also the disease takes its name. In the small-pox a similar scab is produced; but it is not so thick, nor so often reproduced. In the crusta lactea the bottom of the pustule is reddish, and the detached pustules have a pale red margin, like those of the small-pox; but the eruption does not itch, and it soon breaks. When the scab has fallen off, another is soon produced. The pustules soon coalesce, occupy a large portion of the surface, sometimes also approach the eye, rendering the cornea dim; whilst the albuginea becomes inflamed, which produces intolerance of light; and the whole face becomes covered, as it were, with a mask of scabs. They frequently appear also upon the breast and belly, and at length even upon the extremities; but only in a sporadic manner. Sometimes the patients are at the same time affected with scrophulous tumours. Frequently this eruption is kept up, by the patients' rubbing and scratching; so that the disease still continues for a long time, in consequence of the perpetual irritation.

This eruption Mr. Wichman terms the genuine crusta lactea, from which he distinguishes two other species of eruptions of the face: namely, when it is more violent, the *crusta serpiginea*; and that of the worst kind, the *crusta serofulosa*. The crusta serpiginea, which seems to him to be a combination of the crusta lactea with some other dyscrasia, and perhaps is of a herpetic nature, occurs also without fever, in children that are in other respects in perfect health, and chiefly in infants at the breast; appearing first in the cheek, in the vicinity of the parotid gland, where it forms a scab, which gradually spreads upwards to the forehead, and even behind the ear: it seldom occurs after the infant has been weaned; and more frequently in those infants that are suckled by hired nurses, than those who receive suck from the mother. It soon occupies a larger extent of surface, sometimes one several inches in diameter, upon the cheek, and forms a small scab of a darker colour. It is never attended with small ulcers, but rather with miliar eruptions; though these are of a darker colour than usual, and soon break. The pustules in this disease discharge a great deal, and contain an acrid fluid, producing an intolerable itching, which is not found in the crusta lactea, unless when complicated. The disease does not yield to those remedies which are useful in the crusta lactea, but spreads, if it be left time to do so, into wet itching spots. Sometimes also it spreads over the face, frequently attacks the eye-lids, but not the ball of the eye; and often, on the other hand, it occupies the hairy scalp. Weaning does not remove it; and if proper remedies are not applied, it may continue for years, and exhaust the strength of the patient. The fluid which runs out produces redness and itching in the parts with which it comes into contact.

In general, those children who are corpulent, who eat immoderately, whose mothers are of a scrophulous constitution, and who are nourished with milk of a bad quality, are most liable to this disease. The predisposition of an infant to the disease may be known, when its face is proportionably too full, when yellowish-red or dark-red spots appear upon its cheeks, when its urine has a fetid smell, and when the infant is much inclined to rub its cheeks.

In these cases, the health of the mother or nurse should be carefully inquired into, and whether she has had the same disease in her infancy. The mother or nurse may drink a decoction of sarsaparilla, and take every morning and evening about ten grains of rhubarb and flowers of sulphur. The infant should take, every two or three days, a small table-spoonful of tincture of rhubarb; and the dose should

be increased, whenever it is colicive. But in the simple genuine *crusta lactea*, more antacids, especially lime-water and magnesia, are chiefly recommended. Antimonial and mercurial medicines may also be tried.

When the milk of the mother or nurse is not thought to possess the requisite qualities, or when she seems not to be perfectly healthy, the infant should immediately be weaned, or a better breast of milk be found for it. The child's pap should be made with stale bread crumb, boiled in a mixture of equal parts of milk and water, with the occasional addition of a little Venetian soap and sugar.

As a remedy in this disorder, some have greatly recommended the *vicia tricolor*.

CRUSTACEOUS ANIMALS, a class of creatures, chiefly of the aquatic kind, and which are distinguished by having the body enclosed in a semi-calcareous crust, consisting either of one very large, and a number of small pieces; or of a series of annulations, nearly of an equal size throughout. They respire by means of distinct gills like fishes; and, like insects, are provided with jaws, feelers at the mouth, and antennæ either two or four in number; the eyes in general two, or one apparently; and the feet numerous and articulated.

The French naturalists divide all crustaceous animals into two orders: *crustacés pédicelés*, and *crustacés sessilacoles*. The first of these are composed, for the most part, of the Linnæan canci, or the crab and lobster tribe, as already noticed under our article **CANCER**: the other includes his genera of Illus, oniscus, lepidisma, and monocinus; the whole of which are comprehended, in the system of that author, among the apterois tribe of insects. See articles **CANCER** and **ENTOMOLOGY**.

CRUSTULA, in *Medical Writers*, the same as *ecchy-mosis*, in the eye, being a descent of the blood from the arteries into the *tunica conjunctiva*, occasioned by a wound, stroke, &c.

CRUSTUMERIUM, in *Ancient Geography*, a town of Italy, in the country of the Sabines, situated on the eastern bank of the Tiber, a little to the north of Fidenæ. According to Cuvierius, the ruins of this town appeared, in his time, in a woody tract, a little to the east of Marcigliano Vecchio. Livy calls the hills in its neighbourhood "Montes Crustumini." This town was taken and destroyed by the Romans in the 4th year of Rome, and the inhabitants were removed to the capital.

CRUSTUMINUS AGER, a territory of Italy, so called by Piny. and placed in Etruria.

CRUSTUMIUM, a river of Italy, in Umbria, between Ariminus and Pisaurus.

CRUSY, in *Geography*, a small town of France, in the department of the Hérault; 9 miles S. of Saint Pons.

CRUTCHED, or **CROUCHED Friars**; so called from the figure of a crutch, or the letter T, which they bore on their cloaks upon the left shoulder. Having been instituted to attend upon the sick and the infirm, in hospitals adjoining to their convents, they adopted the crutch as their distinctive badge. St. Anthony of Egypt, the patriarch of the Eastern monks, was the patron saint of their mother house, or first establishment, which was founded near the city of Vienne in Dauphiné, about the latter end of the eleventh century. Hence the painters have been accustomed to represent the patriarch himself with this badge upon his shoulder. The Crutched friars had a convent and hospital in a street in London, which still bears their name; besides other establishments at Oxford, Colchester, Guildford, and Reigate.

CRUX, in *Entomology*. See **CARABUS**, **CASSIDA**, **CICADA**, **CIMEX**, **COCCINELLA**, **CURCULIO**, and **PHALÆNA**.

CRUX Herrings. See **HERRING**.

CRUX Haven, in *Geography*, a sea-port town of Germany, situated on the north coast of the duchy of Bremen, in the German ocean, between the mouths of the Elbe and the Weser. N. lat. 53° 56'. E. long. 8° 6'.

CRUYLIUS, or **CRUYL**, **LEVINUS**, in *Biography*, a designer and engraver, born in Gand about the year 1640. In 1667 we find him at Rome, having become an ecclesiastic. This artist etched, from his own designs, a considerable number of views of Rome, enriched with figures, and executed with great delicacy and spirit; and amongst others a set in 23 plates, 1665. We have likewise, by him, many drawings on vellum, which are designed upon a very small scale with incredible neatness and accuracy. Huber. Manuel des Arts.

CRUYS, in *Geography*, a small town of France, in the department of the Alps; 9 miles S.W. of Sisteron.

CRUYSFIORD, a bay on the coast of Norway; 20 miles S.W. of Bergen.

CRUYSHAGE, in *Ichthyology*, the name of a fish of the shark kind, the *SQUALUS Tiburo* of Gmelin, somewhat approaching to that strange fish, the *zygæna*, but much less monstrous, its head being only triangular, or something like the figure of a heart, whence Wilughby has named it *zygæna affinis capite triangulo*. The eyes are very small, and are placed as in the *zygæna*, at the sides of the head: the mouth is small and triangular, and placed a vast way below the end of the nose, and is furnished with three rows of very small teeth. See *SQUALUS Tiburo*.

CRUYS-HAUTHEM, in *Geography*, a small town of France, in the department of the Escaut, chief place of a canton, in the district of Gand, with a population of 5145 individuals. The canton itself contains 10 communes, upon a territorial extent of 85 kilometres, and 17,158 inhabitants.

CRUZ, **JUAN PANTOJA DE LA**, in *Biography*, a painter, born in Madrid in the year 1561. He was the scholar of Alonzo Sanchez Coello, whom he succeeded as painter of the chamber under king Philip II. Juan sometimes painted history, but his *forte* lay in portrait. He died in 1610.

Under this name, J. S. Müller, an English artist, has engraved two plates, intitled "Writing the Billet," and "Delivering the Billet." Heineken, however, considers them as no other than fictitious imitations of the Spanish style. Cumberland. Heineken.

CRUZ, **DE LA**, **DON JUAN**, and **DON MANUEL**, two artists, probably brothers, born at Madrid about the year 1750. In 1777, were published in that city a set of 12 folio plates, representing Spanish costume, designed by Don Manuel, and engraved by Don Juan. They are entitled, "Collection de Trajes de España, tanto antiguos como modernos." Huber. Manuel des Arts.

CRUZ, **ST.** See **St. CROIX**.

CRUZ, **Santa**, a port on the western coast of America, situated on the east coast of the gulf or bay of Bucarelli, the entrance of which is, according to the determination of La Pérouse, about W. long from Paris 136° 15', or, according to an observation of captain Cook, 227° E. of Greenwich, and N. lat., according to the plan of the Spaniards, 55° 15'. This gulf runs upwards of eight leagues inland, contains several large islands, and presents in its circumference 11 fine harbours, where ships may anchor with safety. Maurelle says, that he does not know a single port in all Europe that could be preferred to that of Santa Cruz. When Maurelle visited this port in 1779, he was soon visited by the Indians in its vicinity. Traffic commenced, the Indians exchanging

ing their furs and various trifles for glass-beads, pieces of old iron, &c. These Indians are of a clear olive colour, many of them having nevertheless a perfectly white skin. With a well-proportioned countenance, they are robust, courageous, arrogant, and warlike. Their clothes consist of the undressed skins of otters, sea-wolves, beaver (a species of deer), bears, and other animals taken in the chase. Several wear boots of smooth skins, laced up before; their hats, in the form of a cone, are woven from fine bark of trees; on their wrists they wear bracelets of copper, iron, or fins of whale; and round the neck, necklaces of fish-bone or copper. Their ear-rings are mother-of-pearl, or plates of copper, embossed with a topaz coloured rosin and jet beads. Their hair is long and thick, held together in a small queue by a comb, and tied with a narrow piece of coarse linen. The aspect of the women is pleasing, their colour fresh, their cheeks of a lively red, and their hair long and plaited. About the loins they tie a long robe of smooth skin, which covers them from the neck to the feet, and the sleeves reach down to the wrists. Over this gown they put skins of otters, or other animals, as a defence from the weather. All the married women have in their lower lip a large aperture, filled up by an oval piece of wood, the smallest diameter of which is about an inch; and its size is larger or smaller, as the person who wears it is older or younger. The girls only wear a copper needle, which crosses the lip in the part where the ornament is afterwards placed.

In war these Indians wear cuirasses and shoulder-pieces, resembling the whale-bone stays of Europeans; round the neck is a large coarse gorget, covering them up to the eyes; and on the head is a helmet, generally made of the head of some wild beast. From the waist to the foot they have a kind of apron, like the cuirass, formed of narrow boards tied together with threads, and thus rendered flexible. From the shoulder to the knee hangs a fine skin. With these arms they are invulnerable to their enemies. Their offensive weapons are arrows and bows, lances headed with iron, iron-knives longer than European bayonets, and small hatchets of silx or green stone, so hard as to cleave the closest wood without having its edge turned.

Their language is pronounced with great difficulty; and they speak from the throat with a motion of the tongue against the palate. Near the Port, where these Indians attend the market, they seem to be diligent and laborious; and they supply purchasers with a great variety of articles; such as well-woven stuffs, shaded with various colours, skins of otters, bears, &c.; well-woven coverlets of common cloth, and large ribbons of the same; skins of the seal, of which this cloth is made; wooden trenchers, curiously wrought; painted canoes; and a great variety of trinkets, of their own device and manufacture. They furnish the market also with great plenty and variety of fish, salmon, cod, perch, &c. The banks are lined with shells; and they use a great quantity of mother-of-pearl for ear-rings, but it did not appear to these voyagers whence they obtained it. Their food consists of fish, boiled or roasted, herbs and roots that are the produce of their mountains, and the flesh of animals taken in the chase. Maurelle was not able to ascertain whether they had any ideas or forms of religion: he observed, however, that they sometimes inclined their bodies towards the sun, but could not tell whether it was an act of devotion. In two islands he found three bodies laid in boxes, and decked in their furs, which were placed in a little hut, on a platform of the branches of trees.

Their country is hilly, the mountains very high, and their slope almost always extending to the sea. The soil, which is limestone, is covered with lofty pine-trees; and as they

are easily blown down, they rot and form a thick mould, in which are found nettles, camomile, wild celery, anise, elder, wormwood, sorrel, and many other plants.

They have ducks, mews, divers, kites, ravens, geese, cranes, gold-finches, and other small birds. These people are addicted to theft; and so eager were they for obtaining iron, cloth, and other stuffs, that they sold their children to procure them. The environs of this port are inhabited by different tribes inimical to each other. At the new and full moon the sea rises in the harbour of Santa Cruz to 17 feet 3 inches; and it is high-water at $\frac{1}{4}$ past 12 at noon. The lowest tides are 14 feet 3 inches; and the night tides exceeded those of the day by 1 foot 9 inches. *La Pérouse's Voyage*, vol. i.

CRUZ, Santa, a considerable town on the north coast of the island of Cuba, about 30 miles E. by N. of the Havana, and 115 N.W. by N. of Cadiz.—Also, the chief town of Cozumel island.

CRUZ, Santa, a town of Mexico, or New Spain, about 75 miles N. by E. of St. Salvadore, on the Pacific Ocean. It is situated on the gulf of Dulce, which communicates with the sea of Honduras.

CRUZ, Santa, De la Sierra, a province or bishopric of the vice-royalty of La Plata or Buenos Ayres in South America, in the audience of Chareas. This province is a government and captain generalship; and though its jurisdiction is of large extent, not many Spaniards are found in it; and the few towns are in general missions, comprehended only under the name of Paraguay missions. The missions belonging to the Jesuits, in the parts dependent on this bishopric, are those called *Indian Chiquitos*, which see. On this nation borders another of Pagan Indians, called *Chiriguanos*, which see. This province may be ranked among the warm regions beneath the chain of mountains; and trades in honey, sugar, and bees.

CRUZ, Santa, De la Sierra, the capital of the preceding government, lies 80 or 90 leagues E. of Plata. It was originally built somewhat farther toward the S.E. near the Cordillera of the Chiriguanos. It was founded in the year 1548, by captain Nuffo de Chaves, who called it Santa Cruz, from a town of that name near Truxillo in Spain, where he was born. But the city having been destroyed, it was rebuilt in the place where it now stands. It is neither large nor well built, nor has it any thing that entitles it to the title of a city. It may, indeed, be regarded rather as a military station than a regular town. It was erected into a bishopric in the year 1605. The chapter consists only of a bishop, dean, and archdeacon; having neither canons, prebendaries, nor other dignitaries. The usual residence of the bishop is in the city of *Masque-Pocona*, 80 leagues from Santa Cruz de la Sierra.

CRUZ, Santa, a town in the island of Teneriffe, the road of which was observed, in the "Embassy to China," to be $28^{\circ} 28' N.$ lat., and the longitude $16^{\circ} 26' W.$ of Greenwich; the variation of the compass was $17^{\circ} 35' W.$ of the pole; and the tide rose perpendicularly 6 feet. Several observations were made by *La Pérouse*, and his associates, at Santa Cruz, from which the N. lat. was fixed at $28^{\circ} 27' 30''$, and the longitude $18^{\circ} 36' 30'' W.$ from Paris. In this port English men of war do not salute, because the Spaniards are forbidden to make a return. Beef, mutton, pork, goats, poultry, fruits, and vegetables, are very good and reasonable; and for ships bound to the southward, and requiring refreshments, this place is preferable in many respects to Madeira, particularly as that wine is stronger and cheaper; a pipe, containing 120 gallons, not exceeding in price 10*l.* The town of Santa Cruz is pleasantly situated, and, though

not so crowded with inhabitants as Funchal, it is better laid out, more open, cleaner, and more comfortable. The well-built pier stretched out into the sea; the contrivances for safe and easy landing near it; the handsome almeyda, or mall, along the quay, shaded with several rows of trees; the fountain adorned with marble statues in the square, all apparently of late construction, denote a government attentive to the improvement of the place. The walks and rides in the neighbourhood of the town are more level and agreeable than those near Funchal in Madeira; and those who visited them found that they breathed a lighter purer air than usual, and felt, says sir G. Staunton, that they were in a fortunate island. The governor of the island resides at Santa Cruz; though the courts of justice are held at St. Chrolophe de Laguna, the capital of the island. All the stones of the beach, and all the ground and rocks in the neighbourhood of Santa Cruz, are manifestly volcanic. The buildings of both Santa Cruz and Laguna exhibited no trace of any other kind; and as no limestone is found in Teneriffe, the lime is supplied from the neighbouring islands.

CRUZADO, or CROISADE, an expedition to the Holy Land. See CROISADE.

CRUZADO, or *Cruzade*, in *Commerce*, is a Portuguese coin, struck under Alphonfus V. about the year 1457, at the time when pope Calixtus sent thither the bull for a croizade against the infidels.

It had its name from a cross, which it bears on one side; the arms of Portugal being on the other.

CRUZADO, *Bull of*, a bull published every two years in Spanish South America, and containing an absolution from past offences by the pope, and among other immunities, permission to eat several kinds of prohibited food, during Lent, and on meagre days; the monks employed in dispersing these bulls, extol their virtues with all the fervour of interested eloquence; the people, ignorant and credulous, listen with implicit assent; and every person in the Spanish colonies, of European, Creolian, or mixed race, purchases a bull, which is deemed essential to his salvation, at the rate set upon it by government; this price varies according to the rank of different persons. Servants, or slaves, pay the value of 1s.; other Spaniards pay 8 reals; and those in public office, 16 reals; the price has also varied at different periods. From the produce of this bull, there arises an annual revenue of 150,000 pesos.

CRUZINI. See CRUCCINI.

CRUZITA, in *Botany*, Linn. gen. 167. Schreb. 224. Willd. 259. J. fl. 85. Class and order, *tetrandria digynia*. Nat. ord. *Atriplices*, Juss.

Gen. Ch. *Cal.* Perianth four-leaved, permanent; leaves egg-shaped, concave; two inner ones with a very thin lacinated margin. *Braçtes* three, at the base of the calyx, permanent; anterior one linear, acute; lateral ones egg-shaped. *Cor.* none. *Stam.* Filaments four, capillary, a little shorter than the calyx; anthers small. *Pist.* Germ superior, egg-shaped, obtuse, compressed; style very short, two-parted; segments spreading; stigmas simple. *Peric.* none, except the diverging calyx, which falls off with the seed. *Seed* solitary, egg-shaped.

Ess. Ch. Calyx four-leaved, with three braçtes on the outside. Corolla none. Seed solitary, enclosed by the calyx.

Sp. C. *hispanica*. Loef. it. 203. *Stem* tall. *Leaves* opposite, lanceolate, quite entire. *Flowers* spiked, collected into a panicle. A native of South America, in the province of Cumana. The trivial name given to it by Linnæus is founded on a mistake.

CRUZY, in *Geography*, a small town of France, in the department of the Yonne, 9 miles north-east of Tonnerre.

CRY. See HUE, CLAMOR. HARO, &c.

CRYA, in *Ancient Geography*, a cape of Asia Minor, about the middle, and towards the north-west part of the gulf of Glaucus; this promontory was west-north-west of that of Telmissus.—Also, a fountain of Asia, in Cappadocia, near Cesarea.—And also, a town of Asia Minor, in Caria, according to Pliny; and in Lycia, according to Steph. Byz.

CRYASSA, or CRYASSUE, an ancient town of Asia Minor, in the northern part of the gulf of Glaucus, north of cape Crya, and north-west of the town of Telmissus.

CRYEON *INSULÆ*, three small islands, situated in the northern part of the gulf of Glaucus, one of the three is a rock, and Steph. Byz. calls the other two Carysis and Alina. He adds, that they belonged to the town of Crya.

CRYMNA, a town of Asia Minor, in Lycia, probably the same with the *Cremna* of Strabo.

CRYMODES, from *κρυος*, cold, in *Medical Writers*, a cold shivering fever, but often accompanied with an inflammation of the inner parts.

CRYNIS, in *Ancient Geography*, a river of Asia Minor, in Bithynia.

CRYON, a river of Asia Minor, which, according to Pliny, discharged itself into the Hermus.

CRYPSIS, in *Botany*, (from *κρυσις*, a concealment, the spike of flowers being concealed within the sheath of the leaf.) Hort. Kew. 1. 48. Schreb. 1710. Lam. Ill. 108. Vent. 2. 97. (Pallasia, Scop. hist. nat. 62. Antitragus, Gært. 507.) Class and order, *triandria digynia*; Lam. *Diandria*; Hort. Kew. Willd. Natural order, *gramina*.

Gen. Ch. *Cal.* Glume one-flowered, two-valved; valves oblong, lanceolate, flattish, somewhat unequal. *Cor.* Glume two-valved, longer than the calyx; valves lanceolate, awnless, somewhat unequal. *Stam.* Filaments three, often only two, capillary, longer than the corolla; anthers oblong. *Pist.* Germ superior, oblong; styles two, capillary; stigmas feathery. *Peric.* none; the corolla enclosing the seed. *Seed* solitary, egg shaped, acute.

Ess. Ch. Calyx two-valved, sessile, lanceolate. Corolla two-valved, longer than the corolla, awnless.

Sp. 1. C. *aculeata*. Hort. Kew. 1. 48. Mart. Lam. Ill. 856. tab. 42. fig. 2. Willd. Schoebæ Marocco, part 1. p. 22. (Schœnus aculeatus, Linn. Sp. Pl. 2. Anthoxanthum aculeatum, Linn. jun. Supp. Phleum aculeatum. Lam. Enc. Phleum schœnoides, Jacq. Aufl. 5. 29. App. tab. 7. Agrostis aculeata, Scop. Cam. n. 89. Antitragus aculeatus, Gært. 27. tab. 30. Pularis vaginiflora, Forsk. disc. 19. Gramen album capitulis aculeatis, Bauh. Pin. 7. Tneat. 108. Schench. gram. 85. Moris. hist. 5. 195. & 8. tab. 5. fig. 3. Gramen spicatum, spicis in capitulum foliatum congestis, Tourn. 517.) "Spikes capitate-hemispherical, smooth, surrounded by an involucre of two or three mucronate, rather prickly, sheathing leaves; stems branched." *Root* annual. *Stems* several, from four to seven inches high, diffuse jointed, leafy. *Leaves* from one to three inches long, a line and half broad, glaucous or whitish, very acute; sheaths short, smooth, striated. *Spikes* enveloped in the leaves of the involucre, which are longer than the spike, and finally become horizontal; glumes of the calyx a little shorter than those of the corolla; stamens two or three. A native of Spain, Italy, and the south of France, on dry sandy or rocky ground. 2. C. *schœnoides*. Lam. Ill. 855. tab. 42. fig. 1. Desfont. Atl. 1. 62. (Phleum schœnoides, Linn. Sp. Pl. 5. Lam. Enc. 5. Jac. coll. 1. 111. Cypsis

Crypsis aculeata β. Hort. Kew. Willd. *Gramen maritimum* *typhnum* brevis & crassiori spica; Schench. agroth. 86. Monti. gram. 50. fig. 35. good) "Spikes jevically egg-shaped, smooth, furrounded at the base by a foliaceous sheath; stems branched, procumbent." *Root* annual? *Stems* several, from six inches to a foot long, smooth, with eight or ten yellowish, slightly protuberant knots. *Leaves* from three to five inches long, a line and half broad, smaller in the upper part of the stem, a little glaucous; sheaths smooth, striated, shorter than the internodes; lower ones cylindrical, closely surrounding the stem; upper ones loose, swelling in the middle, somewhat compressed. *Spikes* at the summit of the stem and branches, and from the axils of the upper leaves, oval-oblong, obtuse, from four lines to half an inch long, or more, scarcely more than two lines broad, on very short peduncles, furrounded only at the base by the floral leaves; flowers numerous, from four to six together on pedicels scarcely half a line long; stamens two or three; style filiform, simple, the length of the stamens, terminated by the two stigmas. A native of Spain, Italy, and the south of France. Dr. Roth, in his supplementary remarks on Willdenow's edition of the *Species Plantarum*, has referred this plant to Schreber's new genus *spartina*, on account of its simple style; and has added to it *dactylis stricta* of Dr. Solander, in *Hortus Kewensis*, and of Dr. Smith, which is distinguished by the same character. But as this genus has not been taken up either by professor Martyn, in his greatly improved edition of *Milner's Dictionary*, nor by La Marck in his *Illustrations of the Encyclopædie*, nor by Willdenow, we have left the present plant where La Marck placed it. We have not been able to discover from what plant Schreber drew his natural character of *spartina*, which does not correspond in all points with that before us. Dr. Hort has likewise formed a new genus for this grass, which he calls *heleochloa*, adding to it *phleum alopecuriodes* of Mitterpaek; but has not ascribed to it a single style. La Marck also has not mentioned this remarkable particular in his description given in the *Encyclopædie*, though it is expressed in the figure, afterwards published with his *Illustrations*. See *Annals of Botany*, vol. i. p. 140, and p. 297.

CRYPSIS arenaria; Lam. III. See *PHALARIS arenaria*.

CRYPT, (*Martyrium, Confessio, Holy Hole*;) formed of κρυπτε, *abscendo, I hide*; whence κρυπτη, *crypta*; is a subterraneous vault or chapel, constructed under the high altar, or eastern end in most ancient cathedral, abbey, and collegiate churches, for preserving the bodies of martyrs, or other saints, and for the performance of divine worship. The primitive Christians, having been accustomed in the times of persecution to hold their religious assemblies in the catacombs, where these were to be met with, as at Rome, Naples, Nola, Lyons, &c. as we learn from Tertullian ad Scapulam, cap. 3, and from the decrees of the emperors and prefects against such assemblies, (Euseb. Hist. l. vii. c. 11. l. ix. c. 2.) affected, upon the ceasing of persecution, to build their churches over, or near to such sepulchres of the martyrs; and, in situations where these were not to be found, they fabricated subterraneous vaults, called crypts, (being quite distinct places from the common cœmeteries,) in which they deposited such remains of martyrs, or other saints as they could procure; and which they furnished with altars and other requisites for the stated worship. This appears from Gregory of Tours, an author of the sixth century, and from subsequent writers. In William Thorn, the monk of Canterbury, mention is made of a particular collect to be said in the service performed in the crypts. The crypt under St. Peter's Church of the Vatican at Rome, called the Confession of St. Peter, and Li-

min; Apollolorum, is provided with diverse altars, and also with priests to officiate at them; but it is prohibited, under pain of excommunication, as an inscription in the vault testifies, for any woman to enter into it, except on Whit-Monday, on which day it is equally unlawful for men to visit the place. See the crypts under Canterbury, York, and Winchester cathedrals, also under the churches of St. Grimbald at Oxford, Christ Church in Hampshire, Wimburn in Dorsetshire, Dorchester in Oxfordshire, now used as a bone house, &c. See likewise representations of the crypts of Grantham, Peterborough, Waverly, and Wells, in "Carter's Ancient Architecture of England," vol. i. plates lxxviii. lxxix. M.

S. Ciampini, describing the outside of the Vatican, speaks of the cryptæ of St. Andrew, St. Paul, &c. About two furlongs to the northward of Latikea or Laodicea in Syria, are several of these cryptæ or sepulchral chambers, hollowed in the rocky ground, some 10, others 20 or 30 feet square, but of low height, and never proportionable. A range of narrow cells, wide enough to receive one coffin, *sarcophagus*, or *κλινη*, and long enough sometimes for two or three, runs along the sides of most of these sepulchral chambers, and appears to be the only provision that was made, provided, indeed, they were only made for the reception of the dead. One of these cryptæ is held in great veneration by the Greeks; they call it "St. Teek'a," in commemoration of some acts of penance and mortification that are said to have been performed here by that first virgin martyr. In the middle of it there is a fountain, supposed to be instrumental in producing miraculous visions, and extraordinary cures. Here they bring diseased persons, and after having washed them with holy water, and perfumed them, they return confident of a speedy cure. Here likewise the aged and infirm pretend to receive warnings of their approaching dissolution, while the young are made to foresee a train of events that are to occur in the future course of their lives. The sepulchral chambers near Jebilce, Tortosa, and the Serpent fountain, together with those that are commonly called the "Royal Sepulchres at Jerusalem," all of which communicate with each other by narrow entrances, are of the like contrivance and workmanship with the cryptæ of Latikea; as were, probably, the cave of Machpelah, and the other sepulchres of the sons of Heth. (Gen. xxiii. 6.) Instead of those long narrow cells that are common in most of the other cryptæ; some of those at Jerusalem are single chambers, others have benches of stone, ranged one over another, upon which the coffins were to be placed. To these we may join the sepulchre where our Saviour was laid, which was also hewn out of the natural rock, (Matt. xxvii. 60.) and lay originally under ground like the others; but by St. Helena's cutting away the rock round about it, that the floor of it might be upon a level with the rest of the pavement of the church, it is now a grotto above ground, or curiously overlaid with marble. It consists of one chamber only, without cells, benches, or ornaments; being about seven feet square, and six high; and over the place where the body was laid has been erected, for many years, an oblong table of stone, or thorus, *κιβητιον*, 3 feet broad, and nearly of the same height, which serves the Latins for an altar. The low narrow door or entrance, where the stone was fixed and sealed, till rolled away by the angel, still continues to conduct us within it; and as this was not situated in the middle, but on the left hand, and as the grave where Christ was laid, may well be presumed to have been placed within it, on the right hand, or where the altar is at present, we may, from these circumstances, well account for Mary and John (John, xx. 5, 11.) being obliged

“to stoop down, before they could look into it.” The sepulchre of Lazarus was likewise of the same kind; as were the sepulchres of the prophets, as they are now called, with many other caves that are met with on the mount of Olives; which might, all of them, have either served, or have been originally designed for burying places, having their proper stones, or opercula, to lay upon them, or to shut them up. Shaw's Travels, p. 264, &c.

Vitruvius used the word *crypta* for a part of a building, answering nearly to our cellar; Juvenal, for a *cloaca*.

Hence *crypto-porticus*, a subterraneous place, arched, or vaulted; used as an under-work, or passage, in old walls. See *CRYPTO-porticus*.

The same is also used for the decoration at the entry of a grotto.

CRYPT is also used by some of our ancient writers for a chapel, or oratory under ground.

CRYPTA, in *Anatomy*; a name given to glands which are supposed to be of the most simple form; viz. such as consist of a simple bag, with a direct and short opening.

CRYPTANDRA, in *Botany*, (from *κρυπτός*, to cover or conceal, and *άνδρα*, a man, in allusion to the five scales which conceal the stamina), is a New Holland genus of plants, first established by the writer of this article in the 4th volume of the Linnæan Society's Transactions, p. 217. Class and order, *pentandria monogynia*. Nat. Ord. probably *Rhododendro* of Jussieu.

Gen. Ch. *Cal.* perianthium of five leaves, inferior, permanent, membranaceous. *Cor.* of one petal, much longer than the calyx, tubular or bell-shaped, externally pubescent, its margin in five regular and equal segments. Scales five, alternate with the segments of the corolla, and inserted at their base, vaulted, roundish. *Stam.* five, inserted into the tube of the corolla at its summit, under each of the scales; filaments very short; anthers roundish, vertical, beardless, of two cells. *Pist.* Germen superior, roundish, three-lobed; style simple, straight, as long as the tube of the corolla; stigma small, three cleft. *Peric.* Capsule of three valves and three cells, the partitions formed by the inflexed margins of the valves. *Seeds* solitary in each cell, roundish, compressed.

Ess. Cn. *Calyx* of five leaves. *Corolla* tubular; its limb five-cleft, with five vaulted scales between the segments. *Stamina* inserted into the top of the tube, under each scale. *Stigma* three-cleft. *Capsule* superior, of three valves, and three cells formed by the inflexed valves. *Seeds* solitary, compressed.

Species 1. *C. ericoides*. Leaves linear, acute. Corolla funnel-shaped, externally bristly. *Sm.* *MSS.* Stem shrubby, much branched, slender; the branches leafy, and clothed when young with silky hairs or bristles. Leaves a quarter of an inch long, fasciculated, opposite, smooth, linear, acute, keeled, on short stalks. Flowers in dense, leafy, terminal heads, apparently reddish, clothed externally with white, silky, close-pressed bristles. 2. *C. amara*. Leaves spatulate, obtuse. Corolla bell-shaped, externally hoary. *Sm.* *MSS.* Stem shrubby, of humble growth like the foregoing, being about three feet high, wand-like, beset with numerous, alternate, short, leafy branches, clothed with short starry pubescence. Leaves fasciculated and scattered, the length of the former, but spatulate, obtuse, entire, smooth, on short stalks. Flowers about the summits of the branches, clustered, with one or two straggling axillary ones, on very short stalks. Their colour seems to be internally reddish; their shape is campanulate and short, and they are clothed externally with close, white, hoary pubescence. *Calyx* brown. Every part of this

species is bitter, especially the leaves. The young twigs have the flavour of Peruvian bark, *Cinchona*, and it is much to be wished that the plant should be submitted to chemical and medical experiment. It flowers in May.

Both species of *Cryptandra* grow in the neighbourhood of Port Jackson, New South Wales, from whence Dr. White long ago sent dried specimens to Europe. We have not had any information of their introduction to the European gardens, but they both deserve cultivation for their elegance, having the aspect of *Erica*, or rather of some of the smaller kinds of *Daphne*. The flowers of the second species, being nearly closed, and therefore exhibiting only their white outside, look like little clusters of pearls, as has been remarked by those who have seen them growing wild. S.

CRYPTIA, *i. e.* the AMBUSCADE, in *Grecian Antiquity*, a cruel practice, subsisting among the Lacedæmonians, and by some ascribed to Lycurgus, of lessening the number of their slaves when they were thought to be too numerous. Such as had the care of the Spartan youth, selected the stoutest of them, and having armed them with daggers, sent them out to destroy their unhappy slaves, either by surprizing them in the night, or falling upon them in the day, when they were at their work, and defenceless. Plato (*de Legib. et de Republ.*) condemns this law; and Plutarch (*in Vit. Lycurg.*) denies that it was made by Lycurgus; whereas Aristotle expressly lays it to his charge; but whenever or however it was made, it was undoubtedly a cruel and unnecessary expedient, in all respects unworthy of a virtuous people. See HELOTES.

CRYPTOCEPHALUS, in *Entomology*, a genus of the Coleoptera tribe, the antennæ of which are filiform; feelers four in number; thorax margined; wing-cases emarginate, and the body sub-cylindrical. Gmelin. A number of the insects in this genus belong, in the Linnæan system, to the Chrysomela tribe, from which they have been separated by Fabricius, and other late writers. The Fabrician character of the genus *cryptocephalus* is taken principally from the structure of the mouth; according to this writer they have four filiform feelers; the jaw furnished with a single tooth, the lip horny and entire, and the antennæ filiform. Most of the species described by Gmelin in this genus, appeared in the first instance in the works of Fabricius.

Species.

LONGIPES. Dusky-black; wing-cases pale, with three black spots; fore legs long. Fabr. *Clytra longipes*, Laichart.

Found on the nut-tree in Germany. The antennæ are short, serrated, and black; dots on the wing-cases, disposed two in the middle, and one at the base; legs black.

3-PUNCTATUS. Blackish-blue; wing-cases testaceous with three black dots; anterior legs long. Fabr.

Described from a specimen in the museum of Dr. Allioni; it is nearly allied to the last but smaller, and inhabits Italy.

SALICIS. Black and polished; wing-cases red with three black dots. Fabr.

Found in Saxony, according to Hybner. The antennæ are black and short; head and thorax deep black, and without spots; wing-cases variable from red to testaceous; body black.

6-NOTATUS. Deep black; wing-cases testaceous, with two dots and line behind of black. Fabr.

A small species found in Barbary, and first observed by Fabricius in the cabinet of M. Desfontaines. The antennæ are

CRYPTOCEPHALUS.

are long; thorax black and immaculate; wing-cafes smooth; future black.

6-MACULATUS. Black, thorax red and immaculate, with three black dots. Fabr.

A native of Italy, in the cabinet of Dr. Allioni.

4-PUNCTATA. Black; wing-cafes reddish yellow, with two black dots; antennæ ferrated. Fabr. *Donov. Brit. Inf. Chryfomela.*

4-PUNCTATA. Linn. *Melontha, Geoffr.*

Found on the nut-tree in Europe.

4-NOTATUS. Blue-black; wing-cafes red with two blue-spots; antennæ short. Fabr.

Inhabits Barbary; legs black. Prof. Vahl.

LÆTUS. Green-bronzed; wing-cafes testaceous, with two black spots. Fabr.

Discovered by Hybner in Saxony. The head is green, and brassy; thorax brassy, with testaceous margin; wing-cafes smooth; body blackish, at the tip brassy; legs brassy, with the shanks testaceous.

ATRAPHAXIDES. Black; thorax red, with three black spots; wing-cafes testaceous, with three black spots; shanks rufous. Fabr. *Chryfomela atraphaxidis, Pallas.*

A native of Siberia, preserved in the Bankian cabinet. The antennæ are ferrated and cinereous; thorax rufous, with three contiguous spots at the base; legs rufous; thighs black.

LUNULATUS. Black, polished; wing-cafes yellow, with a black lunule band, and dot at the tip. Fabr.

Described from a specimen in the Bankian museum; the native place unknown; antennæ short and ferrated; body black.

12-MACULATUS. Black; thorax and wing-cafes red, with four black dots on each. Fabr.

Native of the Cape. The antennæ are short, ferrated, and reddish at the base; thorax rounded and smooth. Bankian Cabinet.

DORSALIS. Ferruginous; future black, near the tip ferruginous. Marsh. Ent. Brit.

A small species found in Britain.

MARGINELLUS. Black; margin of the head, thorax, and body, together with the legs, yellow. *Donov. Brit. Inf.* Discovered in Coombe wood, Surrey; rather larger than the last.

FRONTALIS. Deep-black and glossy; front, anterior part lateral; margin of the thorax, and wing-cafes, with the legs yellow. *Cryptocephalus frontalis, Marsh. Ent. Brit.*

OBSTITUS. Testaceous; antennæ and margin of the wing-cafes black. Fabr.

A native of America. The antennæ are ferrated, and black; abdomen cinereous fuscous.

LINEATUS. Reddish; thorax with two black spots; wing-cafes with two black lines. Fabr.

Described from the Bankian cabinet, as a native of the Brazils.

TRIDENTATUS. Blueish; wing-cafes testaceous; dot on the shoulder black. *Chryfomela tridentata, Linn.*

An European species found on the willow and poplar, and described by Fabricius in his *Suppl. Ent.* under the name of *elytra tridentata*.

TAXICORNIS. Blue; wing-cafes testaceous and immaculate; antennæ ferrated.

Inhabits Italy, Dr. Allioni. Very much resembles the last.

VENUSTUS. Grey brown; two spots on the thorax, and margin yellow; wing-cafes yellow with two black fillets.

Described by Fabricius from a specimen in the collection of Dr. Hunter, obtained from America.

GORTERIÆ. Black and glabrous; thorax and wing-cafes with four yellowish dots.

Inhabits the Cape of Good Hope. *Chryfomela Gorteriæ, Linn. Amœn. Acad.*

8-PUNCTATUS. Black; thorax rufous; wing-cafes testaceous, with four black dots. Naturf.

Found on plants in Barbary by professor Vahl.

MAXILLOSUS. Head and thorax fulvous; wing-cafes yellow, with a black dot at the base, scutell black.

A native of the Cape of Good Hope; in the Bankian Cabinet.

AURITUS. Deep-black, a yellowish spot on each side the thorax; shanks yellow. *Herbst. Chryfomela aurita, Linn.*

Found on the nut-tree in Saxony.

LENTISCI. Blue; wing-cafes blood-red, with rough blue spots. Fabr. *Chryfomela variolosa, Linn.*

Inhabits Africa, where it occurs on the lentiscus. *Muf. Desfontaines.*

DIDYMUS. Rufous, wing-cafes with three black spots, the anterior one double behind. Fabr. *Donov. Inf. New Holland.*

Discovered in New Holland by sir Joseph Banks.

4-MACULATUS. Rufous; head at the base, and two spots on the wing-cafes, blue. Fabr. *Chryfomela 4 maculata, Linn.*

A native of Germany, and feeds on the nut-tree.

FLAVICOLLIS. Black; thorax fulvous with six black dots; wing-cafes pale, with two dots. Fabr.

A Siberian insect, described from the Bankian cabinet.

LONGIMANUS. Dull-brassy; wing-cafes testaceous with a black dot at the base. Fabr. *Chryfomela longimana, Linn.*

Inhabits Sweden, on the trifolium montanum.

LAR. Rufous; wing-cafes fuscous glossed with blue; anterior legs elongated.

A native of South America. The wing-cafes striated with dots.

MARGINATUS. Brassy-black, with yellow wing-cafes; margin black. Fabr. *Cryptocephalus phaleratus, Act. Hall.*

Found on plants in Europe, chiefly Germany.

PUBESCENS. Thorax and elytra dull-brassy and pubescent. Fabr.

An American species. The body is entirely covered with cinereous down; scutell black.

2-PUNCTATUS. Black and polished; wing-cafes red, with two black dots; antennæ length of the body. *Geoffr. Chryfomela 2-punctata, Linn.*

This and the following species inhabit Europe, and feed on the nut tree.

LINEOLA. Deep-black and glossy; wing-cafes red; line in the middle black; antennæ length of the body.

2-MACULATUS. Deep-black; thorax fulvous; wing-cafes testaceous with two black dots. Fabr. *Chryfomela melanocephala, Act. Hall.*

Inhabits Italy, Dr. Allioni.

CORDIGER. Thorax variegated; wing-cafes red, with two black dots. *Geoffr.*

An European species, found on the nut and willow.

BOTHNICUS. Deep-black; a longitudinal red line on the thorax. Fabr. *Chryfomela botnica, Linn.*

A native of Sweden.

FRENATUS. Deep-black; head, thorax, and legs rufous; two black dots on the thorax. Fabr.

Found in Austria, and nearly allied to the former; head rufous, with the posterior margin black.

CRYPTOCEPHALUS.

OBSCURUS. Dusky-black; posterior legs elongated. Fabr. *Chryfomela obscura*, Linn. Mant.

An European species; feeds on various plants.

VITIS. Glossy-black; thorax globose; wing-cafes rufous. Geoffr.

A species extremely destructive to the vine in the south of Europe.

CORYLI. Black; thorax and wing-cafes testaceous; suture black. Fabr. *Chryfomela coryli*, Linn.

PLAGIOCEPHALUS. Black; thorax and wing-cafes testaceous; head thickish. Fabr.

Found in the south of France according to Schestdt. It bears some affinity with the species *coryli*, which also inhabits Europe. The antennæ are short, serrated, and black; head thick, prominent, and black; scutell black.

PALLENS. Black with cinereous hairs; thorax and wing-cafes pale. Fabr.

Described from a specimen received by Dr. Pflug, from China.

VARIEGATUS. Black; abbreviated dorsal line, and margin of the thorax red; wing-cafes testaceous. Fabr.

A native of Italy. Dr. Allioni. The head is black with a yellow dot between the antennæ; legs black.

TRIFASCIATUS. Above testaceous; band on the thorax, and three on the wing-cafes black. Fabr.

This, according to Dr. Pflug, is found in China; the head is black, with a large frontal testaceous spot, and the body black.

RUFICOLLIS. Black; thorax rufous; wing-cafes testaceous; anterior legs long; thighs armed with a single tooth at the tip. Fabr.

A specimen of this species found at St. Helen's is preserved in the Bankian cabinet; it has been also met with by professor Helwig in Italy. The antennæ are thick and much serrated; legs testaceous; thighs marked with a black line.

NIGRIFES. Head and thorax rufous; wing-cafes pale, legs black at the tip. Fabr.

A native of America. The antennæ are black with the base rufous.

6-PUNCTATUS. Black; thorax variegated; wing-cafes red with three black spots. Fabr. *Chryfomela 6-punctata*, Linn.

Inhabits plants in Europe.

COERULANS. Glossy-blue; antennæ fuscous. Fabr.

Described from an African specimen in the Bankian cabinet. The antennæ are short and serrated.

VIOLACEUS. Black-blue; antennæ and legs black; wing-cafes somewhat striated. Fabr.

Inhabits Germany. Same size as the last, but has the antennæ black, and not serrated.

CUPREUS. Glossy copper-red, beneath blue. Fabr.

Found in Cayenne, Von Rohr. The under surface is dusky.

RUBRIFRONS. Blue, and glossy; front with the band on the thorax, and the thighs red. Fabr.

Native place unknown. The antennæ are fuscous with the base rufous.

CALCARATUS. Violaceous; head, thorax and thighs dented and rufous. Fabr.

Inhabits Sierra Leona. Bankian cabinet.

LOBATUS. Dusky-blue, with the posterior shanks lobate at the tip. Fabr.

Found by Hübner in Hungary. It is of a middle size; the antennæ black, with the base testaceous: head and thorax blue; wing-cafes dusky.

RUFIPES. Blue or green, and glossy; legs rufous. Fabr.

Native of the Cape of Good Hope. Bankian cabinet.

CYANEUS. Blue, thorax and legs rufous. Fabr. *Melicentha*, Geoffr.

Found in France by Mallet.

CINCTUS. Head and thorax rufous; wing-cafes black; margin rufous. Fabr.

Described as a native of South America from a specimen in the Hunterian collection.

BUCEPHALUS. Blue, mouth, margin of the thorax, and the legs red. Fabr. *Chryfomela bucephala*, Aët. Hail.

Inhabits the *Anthyllis vulneraria* in Saxony.

COLLARIS. Blue, and glossy; sides of the thorax, tips of the wing-cafes, and the thighs red. Fabr.

Native of Siberia. The antennæ rufous at the base; body black; legs and thighs rufous.

SERICIFUS. Green-blue; antennæ black. Geoffr. *Chryfomela sericea*, Linn.

Found on the willow in Europe.

NITENS. Glossy-green; mouth and legs testaceous. Fabr. *Chryfomela nitens*, Linn.

An European insect, found on the nut tree.

GLABRATUS. Violaceous; thorax and wing-cafes brassy; antennæ fuscous. Fabr.

Inhabits Brasil. The antennæ are fuscous with the base ferruginous; wing-cafes smooth; beneath entirely violet.

LIMBATUS. Ferruginous with rufous thorax; suture of the wing-cafes glossy-blue. Fabr.

A native of Cayenne. Schulz.

NITIDULUS. Thorax polished brassy; wing-cafes blue; head, antennæ at the base, and the legs yellow. Fabr.

Found in the southern part of Russia. Boeber. The wing-cafes are somewhat punctated; body black.

LABIATUS. Black and glossy; mouth, legs, and antennæ at the base, yellowish. Fabr. *Chryfomela labiata*, Linn.

An European species, found most commonly on the rose.

VITTATUS. Black; margin of the wing-cafes, and abbreviated stripe yellow. Geoffr. and Schæff.

Found on graminiferous plants in the south of Europe.

FLAVILABRIS. Violaceous, and polished; mouth pubescent; antennæ and legs black. Fabr. *Cryptocephalus parvulus*, Mill.

Inhabits the alder in Saxony, Schaller. The wing-cafes are marked with dotted lines.

FLAVIPES. Black and polished; head and legs pale yellow. Fabr. *Cryptocephalus paracenthesis*, Schrank.

Found in Italy by Dr. Allioni.

FLAVIFRONS. Blue-black and polished, front and legs yellow. Fabr.

A native of Germany, about Kiel.

HÜBNERI. Black; head and wing-cafes at the tip, and the legs yellow. Fabr.

Found by Hübner in Germany.

MORAEI. Deep black; wing-cafes with two spots and margin yellow. Fabr. *Chryfomela moraei*, Linn. Schæff. &c.

An European species.

8-GUTTATUS. Deep-black, wing-cafes with four yellow spots. Fabr.

Met with on the ash in Saxony by Hübner.

15-GUTTATUS. Rufous; three spots on the thorax and six on the wing-cafes, yellow. Fabr.

Inhabits Brasil. The antennæ are black, with the base yellowish; anterior thighs marked with a yellow spot.

CRYPTOCEPHALUS.

10-PUNCTATUS. Thorax testaceous, with a black marginal stripe; wing-cafes yellow, with ten black dots. Fabr. *Chryfomela 10-maculata*, Linn. *Cryptocephalus hieroglyphicus*, Herbt.

Native of Europe. The head is testaceous, with the posterior margin black; legs yellow, with the thighs of the hinder legs black.

12-PUNCTATUS. Thorax fulvous, with two black dots; wing-cafes testaceous, with five black dots. Fabr.

Described as a native of Germany, from the cabinet of Loewenkiold.

HAEMORRHOIDALIS. Blue; tip of the wing-cafes and legs fulvous. Fabr.

Found in France, near Paris. Bosc.

2-PUSTULATUS. Deep-black; a rufous spot at the tip of the wing-cafes. Fabr. *Cryptocephalus poda*, Lach.

2-FASCIATUS. Rufous; two spots on the thorax, and two bands on the wing-cafes black. Fabr.

Native of Africa.

4-PUSTULATUS. Black; wing-cafes smooth, with two rufous spots. Fabr. *Chryfomela 4-pustulata*, Linn.

Inhabits Sweden.

NOTATUS. Black; wing-cafes striated with dots; band and spot at the tip testaceous. Fabr.

Found in America. Mus. Dr. Hunter.

HISTRIO. Black; thorax and wing-cafes varied with ferruginous; legs ferruginous, joints black. Fabr.

Native of Italy. The head is black; orbits rufous; thorax black, with ferruginous margin, and three abbreviated lines; wing-cafes punctured with ferruginous spots at the tip.

SCOPOLI. Black; thorax rufous; wing-cafes rufous, with two blue bands; legs black. Panz. *Chryfomela scopolina*, Linn.

Found in Germany, and the southern parts of Europe.

KOENIGII. Rufous, with two blueish spots on the wing-cafes. Fabr.

Discovered in Tranquebar by Dr. Koenig.

PARACENTHESIS. Wing-cafes yellow, with small line and three dots black. *Chryfomela paracenthesis*, Linn.

Feeds on the willow and alder in Europe.

HORDEI. Brassy, and polished; front coppery. Fabr. Inhabits Barbary. The antennæ are serrated and black; anterior legs elongated.

CONCOLOR. Brassy-green, and polished; antennæ yellowish at the base; front impressed. Fabr.

A native of Europe.

PINI. Testaceous; wing-cafes pale and irregularly punctured; antennæ fulvous. *Chryfomela pini*, Linn. Fn. Succ.

Inhabits the pine, and is chiefly found in Sweden.

RETICULATUS. Thorax and wing-cafes white, reticulated with testaceous. Fabr.

A native of Cayenne. The head is testaceous, with the orbits of the eyes white; thorax white, with four testaceous lines; breast black; abdomen and legs yellowish.

PUSILLUS. Thorax fulvous; wing-cafes striated, testaceous, and spotted with black. Fabr.

Half the size of *C. pini*. The head is fulvous; the antennæ pale; eyes black; wing-cafes with two dots at the base, and a black band behind; body black; legs pale.

MINUTUS. Thorax fulvous; wing-cafes striated, testaceous, and immaculate. Fabr.

Inhabits Germany, near Kiel.

GRACILIS. Deep-black; head and thorax fulvous; wing-cafes with a white marginal line and base. Fabr. Geoffr.

A small species. The antennæ black, with the base rufous; thorax rufous and immaculate; legs rufous.

PYGMAEUS. Deep-black and polished; wing-cafes testaceous; future black.

Found in France by Bosc. This insect is very small; the head is black, with the front yellow; thorax at the anterior margin and sides yellow; wing-cafes striated; body black; legs yellow.

BIGUTTATUS. Black; head, tips of the wing-cafes, and legs yellow. Gmel.

A native of Saxony.

CASSIMILIS. Blue-black; head with two yellow spots; antennæ and front legs yellow. Herbt., &c.

Inhabits Prussia, near Berlin.

ORNATUS. Black; head with a bilobate fulvous spot; thorax with a yellow line and margin. Herbt.

PEREGRINUS. Black, glabrous; head, thorax, and wing-cafes blue. Herbt.

Found in India.

LATICLAVUS. Black; head, thorax, and wing-cafes rufous; future and edge of the wing-cafes black; antennæ serrated. Fort. Nov. Inf.

VRIDANS. Green; wing-cafes margined. Lepech. It.

This and the two following are natives of Russia.

8-NOTATUS. Thorax and wing-cafes yellow, with four black dots on each. Lepech.

6-NOTATUS. Black; thorax edged with rufous; wing-cafes with two dots and four spots of black. Lepech.

MULLERI. Black, and downy; wing-cafes with two red dots. Müll.

A native of Denmark.

MUSCIFORMIS. Green-blue; thorax red with a blue spot; shanks ferruginous. Geoffr.

This, and the five succeeding species, are natives of France.

VIBEX. Black; wing-cafes striated, red with a black margin, and four spots. Geoffr.

PUNCTATUS. Blue with scattered punctures; shanks of the anterior legs ferruginous. Geoffr.

PARISINUS. Black, striated; legs rufous. Geoffr.

ERYTHROUS. Black, striated; thorax and legs red. Geoffr.

FULVUS. Head and thorax fulvous; wing-cafes pale. Geoffr.

FERRUGINOSUS. Black and polished; antennæ twice as long as the body; wing-cafes with a yellow spot at the tip. Schrank.

MULTICOLOR. Wing-cafes yellow with two scarlet bands. Hornft.

This is a native of Java. The thorax is red; abdomen black at the tip.

SUMATRANUS. Wing-cafes yellow with a chestnut spot in the middle. Hornft.

COFFEA. Thorax with a transverse groove; abdomen green; wing-cafes yellowish. Hornft.

Inhabits Bantam, on the coffee, the berries of which it resembles in size, and appearance, as well as colour.

ORIENTALIS. Yellow, thorax rufous with a transverse groove; wing-cafes black-blue. Hornft.

Inhabits the East.

BATAVIENSIS. Head, thorax, and wing-cafes, with the legs livid. Hornft.

Inhabits Java.

JAVANUS. Black; thorax, and wing-cafes red spotted with black; antennæ black, with the base rufous. Hornft.

Inhabits Java.

CYANOCEPHALUS. Head, margin of the thorax; shells, base

CRYPTOCEPHALUS.

bale and tip of the thighs violet; crown and thorax scarlet. Lefk.

FLAVIFRONS. Black, polished; front, mouth, legs, base of the antennæ and edge of the shells yellowish. Lefk.

FUSCATUS. Brown; head, thorax, and shells violet; the latter deeply punctured. Lefk.

CHROCEPHALUS. Black; head, antennæ, and wing-cafes yellow, the latter with four black dots and one at the tip. Lefk.

CHRYSOPUS. Black, glabrous; wing-cafes punctured in striæ; head, tips of the wing-cafes and legs yellow.

SUTURALIS. Black, glabrous; wing-cafes yellow, with black future, and fillet connected at the tip. Lefk.

The six preceding species are natives of Europe.

† *Cryptocephalus*, Gmelin.—*Cistela*, Fabr.

Lip bifid; Body oblong.

CERVINUS. Livid; legs fuscous. *Chrysomela cervina*, Linn.

Found on plants in Britain and other parts of Europe.

Donor. Brit. Inf.

CINEREUS. Livid; wing-cafes and legs brown. *Cistela cinerea*, Fabr.

Found in Germany, and considered by Helwig to be a variety or sexual difference of the other.

LIVIDUS. Livid; antennæ fuscous. *C. livida*, Fabr.

Described from a specimen in the Banksian cabinet taken at Terra del Fuego.

CERAMBOIDES. Black; thorax narrowed before; wing-cafes striated and testaceous. Herbst. *Mordella*, Geoffr.

Inhabits Europe, chiefly the northern parts.

LEPTUROIDES. Deep-black; thorax square; wing-cafes striated and testaceous. *Cistela rufitarfis*, Lefk Reis.

Found in the south of Europe.

TESTACEUS. Black; thorax, wing-cafes, and abdomen testaceous. *Cistela testacea*, Fabr.

Inhabits Barbary, on the chrysanthemum.

PICIFES. Black; thorax square; wing-cafes testaceous; antennæ and shanks pitchy.

Found on plants in Denmark. Schæstedt.

SULPHUREUS. Yellow; wing-cafes sulphureous. *Chrysomela sulphurea*, Linn. *Tenebrio lutea*, Geoffr.

Feeds on umbelliferous plants, in Europe.

RUFICOLLIS. Deep-black; thorax ferruginous; wing-cafes striated. Fabr.

Inhabits southern Europe.

BICOLOR. Black; wing-cafes and legs sulphureous.

A native of Germany.

CARULEUS. Black; wing-cafes striated and blueish.

Found on plants in Barbary, by professor Vahl.

NIGRIPENNIS. Ferruginous; head, and striated wing-cafes black. Fabr.

Inhabits the south of France.

ANALIS. Reddish; antennæ, spot on the wing-cafes, and the tail, black. Fabr.

The spot on the wing-cafes is situated at the base, and in some specimens there are two spots on each wing-cafe, one at the base, the other at the tip.

Found by Dr. Koenig at Tranquebar.

RUFIPES. Black; wing-cafes smooth; antennæ and legs ferruginous. Fabr.

A native of Germany.

FULVIPES. Black; wing-cafes striated; legs ferruginous. Fabr.

Inhabits same country as the preceding.

VARIANS. Griseous; eyes black; wing-cafes somewhat striated. Fabr.

Inhabits Saxony, and is rather smaller than the following species.

MURINUS. Black; wing-cafes striated, and with the legs testaceous. Herbst. *Chrysomela murina*, Linn.

FERRUGINEUS. Testaceous; head and thorax fuscous; wing-cafes striated. *Cistela ferruginea*, Fabr.

THORACICUS. Fuscous; thorax and legs ferruginous; wing-cafes smooth. *Cistela thoracica*, Fabr.

Inhabits Saxony. Hybner.

FLAVIPES. Black; wing-cafes dusky, with a yellow spot at the base; base of the abdomen, and legs yellow. Fabr.

Described from the Banksian cabinet; the native place unknown.

EVONYMI. Testaceous; abdomen greyish; wing-cafes smooth.

Inhabits Germany, on the evonymus.

HUMERALIS. Black; dot at the base of the antennæ ferruginous. Fabr.

Found by Hybner in Saxony.

MAURUS. Black; wing-cafes substriated; base of the antennæ and legs ferruginous. *Cistela maura*, Fabr.

PALLIPES. Black and polished; base of the antennæ, and legs pale. Fabr.

A native of Germany.

MORIO. Black, dusky; legs testaceous. Fabr. *Cistela gibbosa*, Thunberg.

Found in Sweden, Paykull.

ANGUSTATUS. Thorax and wing-cafes dull-rufous, in the middle black. *Cistela angustata*, Fabr.

Inhabits Britain. The head is black; antennæ brown; legs ferruginous.

PALLIDUS. Pale; head and tips of the wing-cafes brown. *Cistela pallida*, Fabr.

Found in Britain.

AERUGINEUS. Yellow; head and breast black; wing-cafes greenish. *Cistela aeruginea*, Fabr.

An African insect; met with on the flowers of the aescynonema, to which it is extremely destructive.

FESTIVUS. Ferruginous; wing-cafes blue-green, with ferruginous margin. *Cistela festiva*, Fabr.

Inhabits the Cape of Good Hope.

ALVICUS. Black; thorax rufous; wing-cafes blue. Fabr.

Found in the same country as the preceding; the segments of the abdomen are rufous at the edges.

SVITTATA. Testaceous; margin of the wing-cafes, and stripe in the middle black. Fabr.

A native of Carolina, in the cabinet of Monf. .

HIRTUS. Hairy; head and thorax rufous; wing-cafes blue. *Cistela hirta*, Fabr.

Inhabits the Cape of Good Hope.

PUBESCENS. Pubescent, grey; head and abdomen fuscous. Fabr.

Found in Denmark. The antennæ are ferruginous at the base; future of the wing-cafes blackish; body dark; legs grey.

SEX-LINEATUS. Ferruginous; wing-cafes yellow, with three small black yellow lines. *Cistela sex-lineata*, Fabr.

Described from the Banksian cabinet; native place unknown.

ALPINUS. Black, polished; wing-cafes chestnut, and wrinkled, with the future black. Moll.

Inhabits Alpine parts of Europe.

STRIGOSUS. Reddish; abdomen black; front with two, thorax three, and wing-cafes four black bands. Sulz.

This,

This, and the eleven succeeding species, are found in Europe.

FORSTERI. Subvillous, brown, with longitudinal interrupted blackish bands. Schæff.

PUSTULATUS. Black, oval; wing-cafes with a rufous waved spot. Forst. Nov. Inf.

DENIGRATUS. Entirely shining black. Forst.

4-FASCIATUS. Sub-oval; black; with striated wing-cafes. Forst.

HOLOSERICUS. Oval; brown-green; wing-cafes with longitudinal interrupted dusky bands. Forst.

CAPUCINUS. Ferruginous; head, thorax, and wing-cafes brown, the latter with crenated striæ; antennæ and legs ferruginous. Muf. Lefk.

CONSPERSUS. Above covered with yellowish dust, beneath sprinkled with silvery; antennæ brown; legs rusty brown. Lefk.

SULPHURATUS. Brown; antennæ, legs, and shells fulphur; ends of the legs brown. Lefk.

TRUNCATUS. Brown; wing-cafes smooth; antennæ and legs reddish yellow; thorax truncated behind. Lefk.

BRUNNEUS. Brown; abdomen dark brown; wing-cafes smooth. Lefk.

RUFITARSIS. Oblong; head, body, antennæ, and legs, brassy-black and hairy; wing-cafes testaceous, punctured; tarsi rufous. Lefk.

Inhabits near Luface.

Cryptocephalus, Gmel. *Crioceris*, Fabr.

BITUBERCULATUS. Fulvous; wing-cafes pale, furnished with a fulvous margin. *C. tuberculata*, Fabr.

A native of Africa. Bankian Cabinet.

BIDENTATUS. Yellow; wing-cafes black; with the tip reddish. Same country and cabinet as the preceding.

MELANOCEPHALUS. Rufous; head black; wing-cafes violet.

A native of New Holland. Antennæ black; feet rufous.

LUNULUS. Black; thorax pale; lunule, on the wing-cafes, margin and two bands pale.

Inhabits Cayenne. Antennæ black in the middle; body black; abdomen and legs pale.

OCHRACEUS. Testaceous; dot on the thorax and abdomen black; tail fulvous. Herbst.

OCHREATUS. Testaceous; breast and shanks black.

Found in Guadaloupe.

LAPPONICUS. Black; margin of the wing-cafes, antennæ, and legs yellow.

Inhabits Lapland, on the birch.

NIGRITUS. Ferruginous; antennæ, breast, and base of the abdomen black; thorax cylindrical, impressed each side.

Native of Germany.

NIGRIPES. Thorax cylindrical, yellow; antennæ, breast, and legs black.

Inhabits New Holland; the antennæ black.

OCULATUS. Thorax cylindrical, yellow; wing-cafes black at the base, with a yellow dot.

Inhabits the same country as the last; the antennæ are yellow, and as long as the body; wing-cafes slightly striated; breast and thighs black.

MELANOPUS. Blue; thorax and legs rufous. Sulz.

A native of Europe.

VIOLACEUS. Black-violet; wing-cafes striated.

Inhabits near Paris; body oblong and flat.

EQUESTRIS. Head and thorax testaceous; wing-cafes reddish-brown, with the margin, line at the base, and band in the middle yellow.

A native of Cayenne; antennæ and legs yellowish; body black.

4-MACULATUS. Thorax rufous; wing-cafes testaceous, with two black spots.

Found in the southern parts of Germany. The head is black; antennæ testaceous; abdomen black; breast and legs testaceous.

PARVUS. Brown; two spots on the head; antennæ fulvous at the base.

Discovered in the vicinity of Berlin. Herbst.

TRISTIS. Black; wing-cafes blue, with striæ of punctures; legs fulvous.

Native of Austria. Herbst.

TRICOLOR. Black; thorax cylindrical, gibbous at the sides; head, future, and margin of the wing-cafes ferruginous; wing-cafes testaceous; legs, antennæ and feelers reddish-yellow. Lefk.

GIBBUS. Thorax cylindrical, gibbous at the sides; head, thorax, and legs reddish-yellow; wing-cafes black, and deeply punctured.

A native of Europe.

OCHROPUS. Black; wing-cafes brown; thorax, base of the antennæ, and legs yellow; thighs brown at the base. Lefk.

Inhabits Europe.

AQUATICUS. Black; thorax spotted; margin, broad suture of the wing-cafes, and the legs yellow. Müll.

Inhabits Denmark.

Besides the above, Gmelin includes in his genus *cryptocephalus*, the three Fabrician genera *erotylus*, *logria*, and *dryops*; which see respectively.

CRYPTOGAMIA, in *Botany*, (from *κρυπτος*, *secret* or *hidden*, and *γαμος*, *marriage*.) the twenty-fourth and last class of the sexual system of Linnæus, formed for several very numerous families of plants, in which the parts essential to their fructification have not been sufficiently ascertained, or are too small to admit of their being accurately described and referred to any of the preceding classes. It is divided by Linnæus into four orders, Filices, Musci, Algæ and Fungi. See those words. The order Hepaticæ has been added since. Mr. Kirwan, and some other geological writers, have maintained, that plants of this class and of the culmiferous kind are frequently found on the bituminous shales, which alternate with coal, but the whole of such vegetable remains seem, when minutely examined, to belong to no known genera, but to belong to the *incognita* of a former vegetable race, probably sub-aqueous. See **COLLIERY**.

CRYPTOGRAPHY, the art of secret writing, or writing in cipher. See **CIPHER** and **DECIPHERING**.

The word is compounded of *κρυπτω*, *I hide*; and *γραφω*, *I describe*.

CRYPTO-PORTICUS. This word, taken etymologically, means a dark subterraneous gallery; see the article **CRYPT**.

If we were to judge (says Winckelman) by the remains of antique edifices, and particularly by those of the Villa Adriana at Tivoli, we might be led to believe that the ancients preferred darkness to light; for in fact we find scarcely any chamber or vault among these ruined edifices which has any appearance of windows. It seems probable that in some the light was only admitted through an opening in the middle of the vault, but as the vaults are generally fallen this point cannot be ascertained.

The inhabitants of Italy were naturally attached to the shade

shade and coolness of half-lighted apartments, the long galleries of the Villa Adriana, which were undoubtedly *crypto-porticoes*, receive a feeble light at each end from embrasures near the ceiling.

The term *crypto-porticus* appears, however, to have acquired a more extended meaning than might have been inferred from its etymology, and in fact to have had the same meaning as our word gallery; thus Pliny, describing the *crypto-porticus* of his house of Laurentum, which he says partakes of the beauty and grandeur of public works, mentions windows on each side looking towards the sea and upon the garden, as well as a smaller number placed above the others. In warm and serene weather they were all opened, but otherwise they were only opened on that side which was sheltered from the wind. See GALLERY.

CRYPTOSTOMUM, in *Botany*, (from *κρυπτός* *hidien*, and *στομαχ*, the *moult*.) Schreb. 344. Willd. 390. (Montabea: Juss. 420. Aubl. 274.) Class and order, *pentandria monogynia*. Nat. Ord. undetermined.

Gen. Ch. *Cal.* Perianth one-leaved, funnel-shaped, swollen at the base, coloured with a five-cleft border; segments lanceolate, acute, unequal. *Cor.* Monopetalous, funnel-shaped; tube very short, inserted into the throat of the calyx; border five-cleft; segments lanceolate, acute, unequal, converging. *Nectary* broad, arched, five-toothed, adnate to the base of the corolla and closing its mouth. *Stam.* Filaments none; anthers five, each of them attached to one of the teeth of the nectary. *Pistl.* Germ roundish, in the bottom of the calyx; style cylindrical, the length of the calyx; stigma capitate. *Per.* Berry dry, globular, three-celled. *Seeds* one in each cell, egg-shaped, acute, marked with a large hilum or scar.

Eff. Ch. Corolla funnel-shaped, inserted into the calyx. Nectary one-leaved, closing the corolla. Berry dry, three-celled, with one seed in each cell. Obs. Jussieu calls the nectary a five-toothed filament.

Sp. C. *laurifolium*. (C. guianense; Gmel. Montabea Aubl. guian. 2. 680.) A bushy shrub. *Stems* several, five or six feet high or more, branched. *Leaves* alternate, nearly sessile, elliptical, entire, acuminate, smooth. *Flowers* white, four or five in a cluster on a short axillary peduncle, sweet-scented. *Berries* yellow. *Seeds* resembling an almond, eaten by the Creoles. A native of Cayenne and Guiana.

CRYPTUS, in *Ancient Geography*, a port of Arabia Felix, placed in the strait of the Persian gulf.

CRYSTAL, **CRYSTALLIZATION**, or **CRYSTALLOGRAPHY**, in *Chemistry*. The Greeks called ice crystal, (*κρυσταλλος*;) from the remarkable facility with which it liquefies. By the Roman naturalists the same term was afterwards applied to the substance at present named rock-crystal, because, from its colourless transparency, and from its being procured among the Alps and other cold mountainous regions, it was supposed to differ from common ice only in being more indurated by long-continued frost, and therefore more permanent. But the symmetrical figure of rock-crystal, consisting of a six-sided prism terminated by six-sided pyramidal summits, is equally remarkable as its lustre and transparency; and as soon as it was observed that nitre and certain other salts were also capable, by particular management, of exhibiting a similar prismatic form, the word crystal assumed a more general meaning, and was applied to all those regular polyhedral transparent solids which are presented to our notice by nature or art. In this sense the word is employed by the old chemists, and the crystalline form was considered as peculiarly characteristic of saline substances. By degrees it was found that the same tendency to symmetrical arrange-

ment, which had been noticed in the class of salts, obtained also in many of the metallic ores, and in a variety of other bodies belonging to the mineral kingdom; and at length some able naturalists and chemists began to be of opinion that, with the exception of matter in the state of vegetable or animal organization, every solid substance in nature was capable of being crystallized.

All compound bodies may be considered as made up of *integrant* particles, each of which is again composed of *elementary* ones. Thus a mass of common salt consists of a vast multitude of little cubes, which are its integrant particles, each of which is resolvable into muriatic acid and soda, which are its elementary ones. With the latter of these crystallization has nothing to do, nor is it possible to ascertain their forms, since they are not decomposable by means which have any relation to form. Thus, when a piece of common salt is pounded in a mortar, the concussions that it receives are continually destroying the adhesion between its integrant particles; and though it is incapable of being actually and completely resolved, on account of the comparative coarseness of the instruments that we are obliged to make use of, yet we see an evident approximation to this. Now a body, that is mechanically divisible, must be produced by the adhesion or aggregation of its constituent particles, and these, both with regard to their forms and the manner in which they adhere to each other, are proper objects of measurement and mathematical calculation. The case, however, is widely different with regard to the elementary particles of which the integrant molecules are composed; these are incapable of being in the smallest degree separated by percussion or mechanical force, and therefore the mode of their combination is not capable of being explained by geometrical calculation.

It has been the practice of some late authors to extend the meaning of the term crystallization so as to make it synonymous with the attraction of aggregation; this, however, appears to be injudicious; the latter comprehends every species of formation by which solids are produced, but the former expresses only that regular arrangement of homogeneous integrant particles by which, when interrupted, crystalline lamina, and, when uninterrupted, entire crystals are produced; aggregation therefore includes crystallization, which is only a mode or species of the former. It is of importance to bear in mind that not only a regular external figure, but a regular internal structure, is necessary to constitute a crystal, otherwise a column of basalt might be considered as a prismatic crystal, an error which some of the older mineralogists have actually fallen into.

Hardly any of the crystallizations that are performed by nature have been imitated by art: in return, however, chemistry has been able to effect the crystallization of a variety of substances, chiefly salts, which are not found crystallized naturally; and by taking proper advantage of this circumstance, has succeeded in obtaining them in a state of greater purity than any other method could afford them.

All substances, in order to be crystallized, require that their integrant molecules should be separated from each other by the intervention of a medium, in which they may move freely, according to the attraction of their crystalline polarity. But this necessarily implies two distinct operations; for the same attraction exerted by the medium, or solvent to overcome the attraction of a body, and reduce it to its integrant molecules, will also prevent the efficacy of its crystalline polarity. It is necessary, therefore, after having destroyed the aggregation of a solid by the requisite quantity of a solvent, to abstract by degrees such a portion of it, that the attraction of the remainder shall be inferior to the

the crystalline polarity of the substance dissolved. The simplest solvent that can be employed is caloric, and many great advantages attend its exclusive use. A number of cases, however, occur, in which its application is impossible, except in combination with some liquid menstruum, as water or alcohol.

Solids that are easily volatilized, without decomposition, at a moderate temperature, may be obtained in a crystalline state by gradual sublimation in close vessels. Thus, when grey oxyd of arsenic is exposed to a low red heat, the aggregation of its integrant molecules is destroyed, and it is converted into a vapour, which at the same, or any higher temperature, would continue in a permanently elastic state. This is the first part of the process, namely, the separation from each other of the integrant particles of the arsenic, in consequence of the addition of caloric, which interposes itself between them. The second part of the process, or the formation of crystals, depends on the tendency to an equilibrium, by which heat is characterized, and its being able to pass with readiness through media that are impervious by other bodies. When, therefore, the vapour, consisting of caloric and oxyd of arsenic, arrives in the upper part of the vessel, the caloric passes through, like water through a filter, while the oxyd of arsenic is left behind; this latter, therefore, is continually increasing in proportion to the remaining caloric, till the crystalline polarity of the particles of arsenic becomes superior to the attraction of the caloric. As soon as this takes place, a stratum of particles begins to be deposited on the inner surface of the containing vessel, and these serve as a basis, to which all the succeeding ones attach themselves, according to their peculiar mode of arrangement, in proportion as their crystalline attraction becomes superior to the affinity exerted by the caloric. In this way not only are volatilizable substances, when unmixed with others, obtainable in a pure crystalline state, but they may often be separated hereby from intimate mixture or combination with bodies of greater fixity. Thus, benzoic acid is separable in a crystalline form from the resin with which it is naturally combined, by taking advantage of its ready volatility at a moderate heat: thus, also, the manufacturers of sal-ammoniac separate this salt from sulphat of soda, and procure it of a crystalline texture by the application of a heat sufficient to sublime the former, while it has no such action on the latter.

Bodies may be made to assume the crystalline state, not only by the process of sublimation, but in many cases by a temperature only sufficient to fuse them. Thus, if we melt in a crucible a quantity of bismuth, or antimony, or sulphur, and afterwards cool it as slowly as possible, till a thin crust has formed on the surface, and then, by means of a pointed iron, pierce two small opposite apertures through the crust, and quickly pour out by one the still fluid portion while the air enters by the other, there will appear, on removing the upper crust, by means of a chisel, a cup-shaped hollow, studded with crystals, which will be more or less perfect, according to the magnitude of the original mass, the slowness with which it has been cooled, and the dexterity with which the fluid part has been evacuated.

There are, however, but few chemical substances, comparatively, that can be obtained in a crystalline state by the agency of heat alone; for some are decomposable by fire, and others are either infusible, or require such a high temperature for this purpose, as to make its application exceedingly troublesome and inconvenient. In effecting the crystallization of nearly the whole of the compound salts, and a few other bodies, recourse has been principally had

to the agency of water and alcohol, as these two fluids exert a considerable solvent power on the substances exposed to their action, without however decomposing them; and being themselves readily volatile, at a moderate temperature, they may be abstracted with sufficient slowness to allow the substances held by them in solution to be deposited in a crystalline form.

When a mass of salt (nitre for example) is immersed in water of the common temperature, the cohesive attraction of its particles is opposed by the solvent power or chemical attraction of the water. At first the nitre, being surrounded on all sides by particles of uncombined water, begins to be rapidly dissolved; but as the solution proceeds, this effect becomes more and more languid, till at length it entirely ceases; when the number of uncombined particles of water is so far reduced, that the sum of the solvent forces of those that are in contact with the nitre exactly counterbalances the attraction of cohesion, by which the undissolved residue of the nitre is held together. When this state of equilibrium takes place, the solution is said to be saturated; but although this is the case, as long as it undergoes no increase of temperature, yet, in proportion as the heat of the water is raised, the solvent power of the liquid is greatly augmented. The salt therefore that is contained in boiling hot water, may be considered as rendered fluid by the combined action of the heat and the water; and if this menstruum is completely saturated, it is manifest, that in proportion as it cools, the cohesive attraction between the particles of nitre will gain the ascendancy, and continue to act till the opposing forces find themselves again in equilibrium. All salts, therefore, which are more soluble in hot than in cold water, are in part deposited from a saturated solution by mere cooling, and if this is done gradually, and without the interference of any materially disturbing cause, the particles, as they consolidate, will arrange themselves in regular crystals.

When a solution of this kind has deposited by cooling all the saline particles which it was enabled to hold by its increased temperature, in addition to those which were retained by the mere action of the water, it is obvious that recourse must be had to the abstraction of the liquid menstruum itself, if we wish to procure from it any additional crystals. We therefore subject the whole to a boiling heat, which has the double advantage of driving off part of the water, and enabling the remainder, in consequence of the increased temperature, still to hold the salt in solution. When the evaporation has proceeded some time, a saline pellicle begins to appear on the surface of the liquor, which is a proof that the cohesive attraction of the particles of salt is obtaining a superiority over the solvent power of the hot water, and by continuing the evaporation, the whole of the water will be driven off, and the salt deposited in an amorphous uncrystallized mass; but if, when the pellicle appears, the solution is slowly cooled, it will deposit, as at first, in a crystalline state, all that portion of salt which, in the cold saturated solution, was combined with the water which has evaporated. Thus, by successive evaporation and gradual cooling, all substances, capable of crystallizing, and which are more soluble in hot than in cold water, may be procured in their proper crystalline forms.

A few salts, especially muriat of soda, (common salt) are nearly equally soluble in water of any temperature; these therefore can only be obtained in a crystalline state, by a carefully regulated evaporation.

All crystals that are formed in water retain a portion of this fluid; which is called the *water of crystallization*. Its proportion varies in different salts, and appears to be in an inverse ratio to the force of their crystalline polarity. Thus,

C R Y S T A L.

fulphat of pot-ash, which requires a large quantity of water to counterbalance the cohesive force of its particles, contains but little water of crystallization; whereas fulphat of soda, which is readily soluble in water, holds more than half its chemical weight of this fluid. This water appears to be in a state of combination with the salt, and not simply interposed between its laminae: the affinity however which it exerts, is but feeble, at least in those salts into the composition of which it enters largely, since a considerable proportion of it is driven off merely by exposure to the air. In these cases, the crystal moulders away to powder, and entirely loses its peculiar form and texture.

If a crystallizable salt is perfectly pure, its solution will continue to afford crystals by the common treatment to the very last drop; but as all salts have a greater or less chemical action on each other, it usually happens, when two or more co-exist in the same solution, that after crystals have been obtained by successive evaporations and coolings, the remaining portion of fluid, though changed to saturation with saline matter, refuses to yield any more crystals. This liquor, whatever may be the nature of its contents, is known by the general appellation of *mother water*. Those salts, the crystals of which are permanent in the air, have the strongest degree of crystalline polarity; in those which are efflorescent, this force is considerably less, but it is the weakest of all in those that deliquesce on exposure to the air. Now, if two salts are dissolved together in the same quantity of water, provided they do not decompose each other, and especially if their ratios of solubility are different; although they are rendered more soluble by their mutual affinity, yet they may be obtained again in the crystalline state without leaving any mother water. Thus, equal parts of nitrat of pot-ash and fulphat of pot-ash, though soluble when mixed together in less water than would have been necessary for both separate, afford by evaporation, successively, and in proportion to their solubility, first fulphat of pot-ash, and then nitrat of pot-ash, without leaving any uncrystallizable liquid. But on the other hand, if nitrat of soda, and fulphat of soda are subjected to the same experiment, both of which have only a slight tendency to crystallize, and are of nearly equal solubility, only a small quantity of fulphat of soda will separate by crystallization, all the nitrat and the remainder of the fulphat remaining liquid and uncrystallizable. When the mutual action of the two salts is sufficient to effect a double decomposition of them, it is necessary to take into consideration the solubility of the new salts, in order to make a correct estimate of the quantity of uncrystallizable residue. Thus, if equal parts of fulphat of magnesia and muriat of soda are mixed together, although the ratio of solubility of the two is different, and their force of crystallization also considerable, yet the liquor can hardly be made to yield any crystals at all; for in consequence of a mutual decomposition, muriat of magnesia, a deliquescent salt, and fulphat of soda, an efflorescent one will be formed; and the slight crystalline force of the latter will be almost wholly annulled by the extreme solubility of the former.

In many instances, the disturbance occasioned by ebullition and other causes of agitation, prevents the formation of regular crystals. But though this is the case, it does by no means follow that the entire absence of external motion is peculiarly favourable to crystallization. The solutions of those salts that are much more soluble in hot than in cold water, and have but a feeble power of crystalline polarity, may, if kept still, be cooled by degrees considerably below their congealing or crystallizing point, and still retain their fluidity; apparently because the attraction of their particles, in itself feeble and opposed by the affinity

of the water, is held in equilibrium because no one particle has a preponderating power over those in its vicinity; for if a piece of the same kind of salt that is contained in the solution, be introduced, even with the utmost precaution, the inferior attraction of the mass will be immediately exerted on the adjacent particles, and a rapid growth of crystals will take place, radiating from this mass as their centre of attraction. Crystallization may also be induced in similar circumstances, merely by agitation, but when this is the case, it is always confused and irregular.

Although several varieties of form in crystals had been observed by chemists and naturalists, yet they were rather objects of vague curiosity than of scientific attention, before the time of Linnæus. This able man, who aspired to be the classifier and lexicographer of the whole terrestrial world, observed a resemblance more or less perfect between the forms of various salts, and of several of the native crystallized minerals. The faculty of crystallizing he considered as peculiarly characteristic of saline substances, and hence concluded that all the crystallized earthy minerals were compounded of earth and some particular salt, to the latter of which was owing their external figure. Hence, because both nitre and quartz crystallize in the form of hexahedral prisms, terminated by hexahedral pyramids, he considered the former as the type of a whole genus, of which the latter was one of the species. So again, observing that alum and the diamond crystallize in pyramidal octohedrons, he arranged the latter as a species of the genus alum. The principal foundation of this theory, namely, that the particular forms of earthy crystals are owing to the presence of a salt, was soon after demonstrated by Wallerius and others, to be wholly groundless, yet the hypothesis, however erroneous, had already induced mineralogists to pay more attention to the forms of crystals than they had heretofore been accustomed to do, and thereby prepared the way for the more important discoveries of Romé de Lisse.

It was in consequence of the minute, ingenious, and multiplied labours of this able philosopher, that crystallography first assumed the appearance of science. He accurately examined all the crystalline forms that fell under his observation, delineated them with accuracy, ascertained the measurement of their principal angles, and arranged them with great sagacity, into species and varieties. Out of the various forms which each species exhibited, he selected one, which, from its simplicity, appeared to possess the fairest claim to be considered as the primitive form of the species; and from this, by supposing it truncated in different directions, he deduced, in a most ingenious manner, a regular gradation through the least to the most complex of the forms belonging to each species. He also made the interesting discovery, that the principal of the angles formed by the incidence of the circumscribing planes on each other, are always of the same dimensions, notwithstanding the truncatures and other modifications undergone by the primitive figure; and also that the dimensions of these angles vary in every different species, although the general figure of the crystals may be the same. Thus, having ascertained that the primitive crystalline form both of alum and nitre, is the pyramidal octohedron, composed of two four-sided pyramids united at their bases, he found that the two species might be accurately distinguished by the incidence of the corresponding planes of the two pyramids on each other; the amount of this angle in the octohedrons of alum being constantly 110° , and in those of nitre 120° .

The great objection to the system of Romé de Lisse is, that the forms which he has selected as the primitive ones

in each species are not demonstrated, but only presumed to be so, on account of their simplicity. The whole theory of truncatures also is allowed by the author to be merely hypothetical, or rather to be wholly different from the method pursued by nature in the formation of crystals, there being no example of any one variety of these being ever produced by the actual truncation of the primitive figure. In consequence of these objections, Bergman was induced to suppose, that the varieties in crystallization are not owing to truncations of the primitive figure, but to the superposition of secondary laminæ upon its faces, either in regular, or variable and decreasing proportions. According to this hypothesis, it would follow, that if the external laminæ of any crystals were taken off in regular succession, the remaining nucleus would be constantly approaching to the primitive form, and would at length actually arrive at it. This Bergman demonstrated to be the case with that variety of calcareous spar called dog-tooth spar, by an actual dissection of the crystal; he discovered the various directions of the crystalline laminæ of which it is composed, and by removing these in succession, he arrived at a rhomboidal solid, divisible only by planes parallel to its surfaces, and therefore un susceptible of undergoing any further change of form. But in an attempt to apply this brilliant discovery to another variety of calcareous spar, he was not equally successful as at first, and appears to have proceeded no further in the investigation of the subject.

Much about the time of Bergman's discoveries, M. Hany had begun to investigate the same subject; he duly appreciated the discovery of the Swedish philosopher, adopted his fundamental proposition, and by a most masterly combination of algebraical and geometrical reasoning, with unparalleled dexterity in the dissection of crystals, he has produced a theory of their formation most remarkably beautiful and consistent, and which has been applied by him with the happiest success, in the resolution of the most intricate figures, and the reduction of them to the most simple primitive forms. We shall therefore conclude this article by a detailed view of M. Hany's Theory of the Structure of Crystals.

The mechanical division of crystals is the only method by which their primitive forms can with certainty be determined; and from the results of a multitude of these dissections, the following general conclusion (subject to certain restrictions, which will be hereafter mentioned,) may be deduced; that all crystals belonging to the same species, (that is, which agree in their chemical composition,) however great may be the difference of their external figures, are reducible by the successive abstraction of their laminæ to one and the same primitive form. This will best be illustrated by a few examples.

Take a regular hexahedral prism of calcareous spar, (CRYSTALLOGRAPHY, *Theory of*, Plate I. *figs.* 1, 2.) If an attempt is made to divide this, upon the edges adjacent to the bases, it will be found that only three alternate edges at the upper extremity of the crystal, represented by the letters *lf, cd, bm*, will admit of being thus divided: it will also be found that only three alternate edges at the lower extremity can be divided, and that these edges instead of corresponding with those of the upper extremity as *l'f', c'd', b'm'*, are the intervening ones *d'f', b'c', l'm'*. The six sections being made in the direction above indicated, will produce a like number of trapezoidal planes, three of which are represented in *fig. 2*, namely, *ppoo, aakk, nnii*. Each of these planes will exhibit a degree of pough and lustre, by which it will be readily recognized as the area of one of those crystalline laminæ of which the whole solid is com-

posed; and if the prism is divided in any other direction, it will be evident, from the roughness and dullness of the fractured surface, that such section does not correspond with any of the natural joints of the crystal. The division of the crystal being continued in a direction parallel to the first sections, it will happen, on the one hand, that the areas of the bases will be continually lessening, and at the same time that the height of the lateral faces will be diminishing, and where the bases are completely obliterated the prism will have been converted into a dodecahedron, with pentagonal faces, six of which, as *ooiOe, oIkii*, &c. are the residues of the original faces of the prism, and the six others, as *EAIoo, OA'Kii*, &c. are the immediate results of the mechanical division.

The section of the crystal being still persevered in, it is obvious that the terminal planes will preserve their figure and dimensions, while the height of the lateral ones will be continually diminishing, till the points *o, k*, of the pentagon *oIkii*, coinciding with the points *i, i*, and so of the other points similarly situated, each lateral pentagon is reduced to a simple triangle, as in *fig. 4*. And when, at length, by a continuation of the same mechanical division, these triangles have disappeared, all the original faces of the prism being completely obliterated, the primitive nucleus of the crystal will be obtained, in the form of an obtuse rhomboid, the large angles of which, *EAI*, or *EOI*, measure $101^{\circ} 32' 13''$.

If, for a second example, we take a crystal of dog-tooth calcareous spar (*fig. 6*), it will be found that, by making one section through the edges *EO, OI*; a second through *JK, GK*; a third through *GH, EH*; a fourth through *OI, IK*; a fifth through *GK, GH*; and a sixth through *EH, EO*, the primitive rhomboid will be at once obtained; whence it follows, that the edges above-mentioned correspond with the lateral edges of the primitive nucleus, as is obvious, at first sight, from *fig. 7*, which represents this primitive figure, inscribed in a pyramidal dodecahedron, with scalene triangular faces.

Thus, in like manner, all the crystalline forms of calcareous spar, even those that differ the most from the primitive one, may be reduced by mechanical division in the directions of their laminæ to the rhomboid.

It has already been mentioned, that the primitive form of each species is constant, not only in its figure, but also in the dimensions of its angles; but when we find that there are several rhomboids of calcareous spar, which differ very materially from each other in the measurements of their angles, it may be thought that this circumstance invalidates the above assertion. But this objection, though plausible, is by no means real; for none of these secondary rhomboids are divisible parallel to their sides, and, therefore, want the essential characteristic of a primitive crystal; further, they are all reducible to the primitive form by the successive removal of their external laminæ, as we shall proceed to shew, in the instance of the secondary rhomboid, the plane angles of which, surrounding the summits, are $75^{\circ} 31' 20''$, and which is represented by *fig. 8*, inclosing its primitive nucleus. In order to effect the mechanical division of this crystal, sections must be made parallel to the six terminal edges *st, su, sn*, at one extremity, and *s't', s'u', s'n'*, at the other, so that every one of these secondary planes shall intercept equal and similar portions of the two adjacent faces of the rhomboid. These sections will produce the six pentagons *r, r, r, r, r, r*, (*fig. 9*) and it is easy to perceive that, by successive sections parallel to these, the original faces of the rhomboid will be obliterated, and the primitive rhomboid *AA* (*fig. b.*) will be produced. It is

C R Y S T A L.

to be remarked also, that the faces of this primitive rhomboid incline in the same degree towards the common axis, as the edges st, su, sn , &c. to which these faces are parallel. But the edges above mentioned form larger angles with the axis, than would be produced by the oblique diagonals sn', st', su' , or, which is the same thing, by the faces $stn'u, sn'u, stu'n$; whence it is obvious that, in the rhomboid extracted by mechanical division, the angles of the summit will be sensibly larger than the corresponding ones in the containing rhomboid.

If, instead of calcareous spar, a crystal belonging to another species is divided in a direction parallel to its laminæ, a different shaped nucleus will be eliminated. For example, a cube of fluor spar will afford a regular octohedron, by dividing it parallel to its eight solid angles; these will first be replaced by an equal number of equilateral triangles; and, at length, when the faces of the cube have entirely disappeared, the crystal will be converted into the regular octohedron. Thus also the primitive form of heavy spar will be found to be a straight prism with rhomboidal bases; that of apatite, a regular hexahedral prism; that of galena, a cube, &c. It is not always necessary to dissect a crystal, in order to reduce it to its primitive form; for we find natural rhomboids of calcareous spar, octohedrons of fluor spar, &c. which, in every respect, exactly correspond with the primitive nuclei extracted mechanically from other varieties of the above species. These natural primitive forms, however, are, upon the whole, of less frequent occurrence than the secondary, or derivative forms.

The number of primitive forms, as yet ascertained, is only six; namely, the parallelepiped (including the cube and rhomboid); the octohedron; the tetrahedron; the regular hexahedral prism; the dodecahedron, with rhombic planes, all equal and similar; and the dodecahedron, with triangular planes composed of two straight pyramids, united by a common base.

The nucleus, or primitive form of a crystal, is, however, by no means the ultimate result of its mechanical division; for every primitive form admits of successive sections parallel to its faces, till it becomes no longer visible to the naked eye; and certain nuclei are also susceptible of transverse or diagonal sections, the result of which is a figure different from that of the primitive crystal. The form produced by the ultimate division of a crystal, may be considered as the representative of its *integrant particles*, and this is the last term to which mechanical division is capable of being carried; the elementary, or chemical component particles, not being susceptible of separation from each other by any other means than chemical attraction, which is wholly different from mechanical force.

If the primitive form of a crystal is a parallelepiped, and can be subdivided only by sections, parallel to its faces, it is evident that the figure of the integrant particles is the same as that of the primitive nucleus. Thus, the primitive form of calcareous spar is a rhomboid; and because this rhomboid is divisible only by sections, parallel to its faces, it necessarily follows, that the form of its integrant particles is also a rhomboid. But it is possible that the primitive parallelepiped may be divided also by planes not parallel to the external faces. For example; let $AA'KH$ (*fig. 10.*) be a rhomboid, divisible at the same time, parallel to the six rhombs by which it is bounded, and in the direction of the short diagonals of the faces. These latter sections will divide the rhomboid into six tetrahedrons, which, in *fig. 10.* are represented as surrounding the nucleus, which may thus be considered as made up of tetrahedral integrant particles. This peculiarity of structure is found in the tourmaline.

An example of the integrant particles, differing in figure

from the primitive nucleus, although this latter is divisible only parallel to its external faces, is afforded by the apatite. The primitive form of this mineral is a regular hexahedral prism, which may be subdivided only by sections parallel to its bases and sides; but from this division will result an assemblage of triangular prisms, as is plain from the mere inspection of *fig. 40.* in which one of the bases of the prism is represented as divided into equilateral triangles, each of which is the base of a small triangular prism, representing an integrant particle.

It is worthy of remark, that the forms of the integrant particles of all crystals may be reduced to one or other of the three above-mentioned, namely, the tetrahedron, the most simple of all the pyramids; the triangular prism, the most simple of all the prisms; and the parallelepiped, the most simple of all those solids, the faces of which are parallel to each other by pairs. And since every plane solid must be bounded by at least four surfaces, it is evident that the three forms above-mentioned, in which the number of faces is successively four, five, and six, are possessed of the greatest simplicity possible.

This general simplicity is, however, by no means incompatible with almost infinite variety in the dimensions of the integrant particles, and the measurements of their several angles. Thus, the parallelepiped may be rectangular, forming a cube or square prism; or may be oblique-angular, forming an infinite variety of rhomboids. The triangular prism also may be equilateral or isosceles; and the pyramidal tetrahedron may exhibit analogous diversities.

There are, however, certain forms of integrant particles, as well as of primitive nuclei, which are common to two or more different substances. Iron pyrites and common salt, for example, have each of them a cube for their primitive nucleus: ruby and native bismuth present the regular octohedron. But it is remarkable, that all those forms which are common to several minerals, are characterized by the utmost possible simplicity and regularity, as the cube, the regular octohedron, the dodecahedron with rhombic planes.

It remains to give a brief account of the peculiar modes of arrangement followed by the integrant particles, by which are produced those regular coverings of crystalline laminæ, which disguise, under such various forms, one and the same primitive nucleus.

Now, experiment and observation shew, that this covering matter is an assemblage of laminæ, which, proceeding from the primitive nucleus as a centre, constantly decrease in extent, either on all sides, equally, or more on some than on others. This decrement is effected by regular subtractions of one or more rows of integrant particles, either on the sides or solid angles of the primitive form. A few simple instances will serve to give a clear idea of the laws to which these decrements are subject.

Let ss' (*fig. 11.*) represent secondary crystal, in form of a rhomboidal dodecahedron, with a cube for its primitive nucleus. In order to extract this nucleus, it is necessary to remove, successively, the six solid angles, composed of four planes each, as s, r, t , &c. by sections passing through the short diagonals of the three rhombic faces, of which the summits OA' are composed; the planes of these sections will form as many squares, $AEOI, EOO'E, IOO'I$, &c. *fig. 12.* which are the faces of the cube.

Now, suppose that each of the faces of the cube supports a series of decreasing laminæ, composed of cubical particles, every one of which exceeds that immediately above it, by one row of particles on each of its four sides; the necessary result, therefore, will be the formation of six quadrangular pyramids, resembling flights of steps, resting on the

CRYSTAL.

the six faces of the primitive cube. Three of these pyramids are represented in *fig. 13*, having their summits at *s, t, r'*. These six quadrangular pyramids are composed of twenty-four triangles, as *O s I, O t I, &c.*; but because the decrement is uniform, from *s* to *t*, and so of the rest, the opposite triangles of two adjacent pyramids are on the same level and form a rhomb, as *s O t I*. The surface of this secondary solid will, therefore, be bounded by twelve equal and similar rhombs, or, in other words, the rhomboidal dodecahedron (*fig. 11.*) will be recomposed.

This dodecahedron is represented in *fig. 13*, in such a manner, that the progressive decrement of the superposed laminæ is visible to the naked eye. The cubical nucleus, it is to be observed, has each of its faces composed of 17 rows of integrant particles, which will give 289 for the area of each surface, and 4913 for the solid contents of the cube. This primitive form is covered by eight superposed laminæ, (the upper consisting of a single particle) the length of the sides of which are equal, respectively, to 15, 13, 11, 9, 7, 5, 3, 1 particles, forming a series, the common difference of which is 2, there being one row subtracted from each end.

If, to the above representation of integrant particles, which, however coarse, has yet the advantage of being obvious to the eye, we substitute, in imagination, the almost infinitely delicate structure of real crystals, we must conceive the primitive nucleus as composed of a vast multitude of cubes, each of which singly is imperceptible; in which case, the number of superposed laminæ will also be far greater than in the preceding hypothesis. Hence it will follow, that the striæ, formed upon the faces of the dodecahedron, by the alternate salient and re-entering angles of the superposed laminæ, though they really exist, will yet, from their minuteness, be invisible to the naked eye.

In the example just given, the ratio of the decrement is equal to two rows of integrant particles subtracted from the breadth of the superposed laminæ; therefore, the height of the pyramid thus produced is equal to half the length of one of the sides of its base; but the ratio may be equal to one, three, four, five, or six rows, in which cases the height will be to the breadth of the pyramid, as 1 : 1, $\frac{1}{3}$: 1, $\frac{1}{4}$: 1, $\frac{1}{5}$: 1, $\frac{1}{6}$: 1. But the decrements of these superposed or secondary laminæ, may be considered as taking place, not merely in breadth, but in height; and the ratio or common difference of these latter may also vary from one to six rows of integrant particles, in which cases the height will be to the breadth of the pyramid, as 1 : 1, 1 : $\frac{1}{2}$, 1 : $\frac{1}{3}$, 1 : $\frac{1}{4}$, 1 : $\frac{1}{5}$, 1 : $\frac{1}{6}$. It not unfrequently happens, that these two kinds of decrement are united in the same crystal; and to this circumstance it is that the great variety of crystalline forms, under which the same substance appears, is chiefly to be attributed.

The dodecahedral iron pyrites, with pentagonal faces, is an example of the combination of the two modes of decrement. The primitive nucleus of this substance is a cube, the position of which, with regard to the circumscribing dodecahedron, is evident from the mere inspection of *fig. 15*. In this the superposed laminæ, instead of forming pyramids, as in the foregoing example, compose very obtuse, wedge-shaped solids, bounded by two trapeziums, as *O I p q*, *A E p q*, and two isosceles triangles *E p o*, *A q I*.

Now suppose a decrement to take place by two rows in breadth between the sides *O I* and *A E*, *I I'* and *O O'*, *E O* and *E' O'*, and so in like manner on the opposite squares, and that a decrement, by two rows in height, takes place at the same time between the sides *E O* and *A I*, *O I* and *O' I'*, *O O'* and *E E'*; it is then obvious

that the two kinds of decrement are carried on upon the different faces of the cube in such a manner as to cross each other at right angles in three directions. And the decrement, by two rows in breadth, tending to produce a more inclined face than the decrement by two rows in height, each pile of superposed laminæ will terminate not in a point, but will produce a wedge-shaped solid, *fig. 16*, that is to say, it will be terminated by the edge *p q* or *t n*; and if the directions of these two edges are compared with that of the edge *r s*, (*figs. 14* and *15.*) which terminates the pile raised on the face *E O O' E'* of the nucleus, it will be plain that these three edges are perpendicular to each other.

Further, each trapezium, as *O p q I* (*figs. 15* and *16.*) being on the same plane as the triangle *O t I*, which belongs to the adjacent pile, will be confounded with it, and the result of this union will be the pentagon *p O t I q*, whence it follows that the whole solid will be bounded by twelve equal and similar pentagonal faces, on account of the regular form of the nucleus and the symmetry of its decrements.

Both the kinds of decrement which we have hitherto described, commence from the sides or edges of the primitive nucleus; but these are not sufficient to explain all the varieties of form presented by secondary crystals. Both observation and calculation demonstrate that there are also decrements commencing from the angles, and proceeding in a direction parallel to the diagonals of the faces. This is proved from the circumstance, that the same substances which, having a cube for their primitive nucleus, appear under the forms of the pentagonal and rhomboidal dodecahedrons, are also found under that of the regular octohedron. It seems, indeed, at first sight, very possible to deduce this octohedron from a decrement on the edges of the cubic nucleus, for if the secondary laminæ are considered as superposed only on two opposite faces of the cube, as for example on *A E O I*, and *A' E' O' I'*, (*fig. 20.*) there will be formed on these bases two pyramids, and if the faces of each pyramid are supposed to be prolonged till they meet, which will be effected merely by a continuation of the same law of decrement by which the pyramids themselves are formed, there will be produced an octohedron, the angles of which will vary as the decrement has been made by the subtraction of one or more rows. But it may be demonstrated by calculation, that no law of decrement, however complex, will produce an octohedron, the faces of which are equilateral triangles, if this decrement takes place from the edges of a cubical nucleus.

On the other hand, if we actually dissect a regular octohedron, moulded on a cube, we shall perceive that this primitive nucleus is so situated with regard to the octohedron, that each of the eight solid angles of the former correspond with the centres of the triangular faces of the latter; a fact wholly irreconcilable with the hypothesis of a decrement on the edges. *Fig. 20*, represents this arrangement, and it is obvious that in order to disengage the nucleus, it is necessary to destroy the six solid angles of the octohedron by sections perpendicular to the axes passing through these same angles, and therefore of course parallel to the faces of the cube.

In order to explain the law of decrement on the angles which takes place in the preceding example, let *O I I' O'* (*fig. 21.*) be one of the faces of the cubic nucleus, subdivided into a multitude of lesser squares, which are the bases of an equal number of integrant particles. These rows of particles may be considered in two different directions, namely, as parallel to the sides, as the row *a, n, q, r', s'*, or as parallel to the diagonal of the face, as the rows *a, b, c, d, &c. n, l, h, m, &c. q, v, k, u, &c.*

The

CRYSTALS.

The particles of the rows parallel to the sides, touch each other by one of their faces, and are in a state of simple juxtaposition. But the particles of the rows parallel to the diagonals, touch each other only by one of their edges, and each row is, as it were, locked into that adjacent to it on each side. Now it appears that the laminae superposed on the faces of a cubic nucleus, or of any other, not infrequently decrease by the subtraction of diagonal rows of particles. In this case the secondary faces thus produced, are not striated, (as they are where the decrement takes place parallel to the edges,) but set, all over, with points, which being all on the same level, and of extreme minuteness, appear to the eye like a plane surface. If now we suppose all the laminae superposed on a cubical nucleus, to decrease by one row on all the angles of the nucleus, this decrement will produce the regular octohedron, the mechanical division of which has been already described.

In order to explain the operation of this law of decrement, let $\Delta E O I$, (*fig. 23, A.*) be the upper surface of a cubical nucleus composed of eighty-one smaller squares representing an equal number of integrant particles. The first of the superposed laminae will be of the form represented (*fig. 23, B.*) and will be so placed on the face of the nucleus, that the points e, a, o, i , of the latter, correspond with the points e', a', o', i' , of the former. According to this disposition the squares Ee, Aa, Oo, Ii , (*fig. A.*) remain uncovered, which is the first effect produced by the particular decrement just mentioned. It is further to be observed, that the sides QV, PN, LC, FG , (*fig. B.*) exceed by one row the corresponding sides AE, EO, OI, IA , (*fig. A.*), this being necessary in order that the nucleus should be covered on the above sides, and that the solid should increase in the usual manner in those parts to which this particular law of decrement does not extend.

The upper surface of the second laminae will be similar to $BKH D$, (*fig. 23, C.*) and it is to be placed on the preceding, so that the points e'', a'', i'', o'' , may coincide with the points e', a', i', o' , *fig. B.*, in consequence of which the squares which have their external angles situated at Q, S, R, V, P, T, M, G , &c. will be left uncovered by the subtraction of one row of particles. It is to be observed, also, that the solid continues to increase on the sides analogous to EA, EO, AI, OI , (*fig. A.*); but as the effect of the decrement is continually contracting the surface of the laminae, in the direction of the diagonals, there is only a single cube added on the sides B, K, H, D , (*fig. C.*) not subject to the decrement, instead of the five cubes by which the preceding lamina is terminated on the sides QV, PN, LC, FG , (*fig. B.*)

The surfaces of the superpole laminae, which hitherto have been octagonal, as *fig. B.*, having by the progressive effect of the decrement become square, as *fig. C.*, will now decrease on all their sides at the same time, so that the next lamina will have for its surface the square B', K', H', D' , (*fig. D.*) being less by one row of particles on each side than the preceding square (*fig. C.*) and so placed upon it that the points e, f', a', g' , (*fig. D.*), correspond with the points e, f, a, g , (*fig. C.*)

The *figs. E, F, G, H, I*, represent the five succeeding laminae necessary to complete the pyramid, the latter of which, forming the summit of the pyramid, is only a single cube.

From the above description it will appear that the laminae superposed on the base E, A, I, O , (*fig. A.*) produce by the effect of their decreasing edges, four faces, which produced from the points E, A, O, I , incline towards each other, forming a pyramidal summit.

It is to be remarked, also, that the superposed laminae begin by increasing in length, as is obvious from *figs. B* and *C*, and then gradually diminish, as is represented in the succeeding figures. Hence it follows that the secondary faces themselves first enlarge to a certain point, and then diminish, so that they form, as it were, two triangles, joined at their bases, or in other words, a quadrilateral figure. One of these is represented *fig. 24*, in which the inferior angle o coincides with the angle O of the primitive nucleus (*fig. 20.*) and the diagonal ix , represents the side HK of the lamina $BKH D$ (*fig. 23, C.*); and because the superposed laminae that produce the triangle iox (*fig. 24.*) are less in number than those of which the triangle ixx is composed, the latter triangle will be much higher than the former.

The surface of the secondary crystal will therefore be made up of 24 quadrilateral planes, disposed in threes round each solid angle of the nucleus; but, as in decrements that take place by one row on every edge, the opposite faces on each edge are in the same plane, so in decrements by one row on the angles, the three secondary faces that are produced round each solid angle, as O (*fig. 20.*) are also on a level, and may therefore be considered as forming only a single one; and since a cube has eight solid angles, each composed of three plane ones, the secondary crystal will have eight faces, which, on account of the regularity of the nucleus, will be equilateral triangles; so that the whole crystal will be a regular octohedron. One of these triangles is represented, *fig. 25*, so as to show the arrangement of the small cubical particles by which it is produced.

The above may serve to give a general idea of M. Haüy's Theory of Crystallography, for a more full account of which we refer the curious reader to the first vol. of this author's "Traité de Minéralogie."

CRYSTALS, in the *Arts* When any piece of workmanship in crystal is become foul and dark, the method of recovering its lustre without hurting its polish, is this: mix together six parts common water, and one part brandy; boil these over a brisk fire, and let the crystal be kept in it, in a boiling state, a quarter of an hour; then take it out, and rub it carefully over with a brush dipped in the same liquor; after this, it is not to be left to dry of itself, but to be wiped with a clean napkin, and its surface will by this means be perfectly cleaned, and rendered as bright as at first, without that injury to the points of the cutting, or to the surfaces of the planes or facets, which would naturally have been the consequence of doing it by mere rubbing or wiping.

Natural crystal may be reduced, by calcination, into the state of the bodies proper for making glass with alkali salts, and makes a most fine and valuable frit. The method of doing it is this: calcine natural crystal in a crucible; when it is red hot, throw it into cold water to quench it; repeat this eight times, covering the crucible, that no dust or ashes may get in and mix with the crystal; dry this calcined mass, and reduce it to an impalpable powder; mix three pounds of this powder with two pounds of pure salts of polverine, or with a quarter of a pound of red lead, and with these make frit, and with the proper quantity of manganese, or other tinging substance; wash this often in cold water, and after a proper time, work it; it will yield a most beautiful glass. Some have pretended to colour crystals by thus tusing them, and imparting the various tings to them while in a melted state. But as they cannot be fused by the heat of furnaces, without the medium of some fluxing body added to them, their texture and properties

perties are so changed, or rather the glass produced by the composition is so different from the crystal itself, that there does not appear to be any advantage in employing rock crystal in such a composition preferable to flints. *Hand. Arts*, vol. ii. p. 327.

Natural crystal may be coloured of several colours, without melting or running it into glass, in the following manner. Take a number of pieces of fine, clear, and pure crystal, of various sizes, of white arsenic, and yellow orpiment in powder, of each two ounces; sal ammoniac, one ounce; powder this also, and mix them well together; put this powder into a strong crucible; and lay upon it the pieces of crystal in their natural state, then cover this crucible with another, mouth to mouth; lute them well, and when the lute is dry, set them in coals, which kindle by little and little; and when they begin to fire, let them kindle of themselves, and they will then smok very much. Let this be done in a large chimney, taking care to avoid the fumes. When it fumes no more, let the fire go out of itself, and let all stand till cool; then unlute the crucibles, and take out the crystals; those at top will be coloured to a fine yellow, with a deep and pale red, the colours of the common fine and balas ruby, with beautiful spots; and those which are at the bottom upon the powder, will be of a watery colour, mottled like that of the viper. This crystal comes out so fair from this process, that it may be cut as a gem; and though many are spoiled, yet, in making a large quantity, there are always some fair and perfect. *Neri's Art of Glass*, p. 117. See DOUBLETTS, and OPAL.

Baptista Porta directs to colour crystals by keeping them immersed for four or five hours in a melted mixture of sulphur, crude antimony, orpiment, arsenic, and tutty. In these operations, the crystals seem to imbibe some of the vapours of the metallic substances; though the method of giving colours to crystals by cementation seldom or ever fairly succeeds.

CRYSTAL, *Rock*, in *Mineralogy* and *Natural History*. See QUARTZ.

CRYSTAL-glass, the purest sort of glass, forming the basis of the facitious gems. For a particular description of which, see GLASS, *the manufacture of*.

CRYSTAL, or CREAM of tartar, is tartar purified and dissolved, and again crystallized. For an account of its properties, and the method of preparing it, see TARTRITE of potash, (*acidulous*.)

CRYSTAL of tartar chalybeated, or ferrum tartarizatum; see IRON, *tartrite of*.

CRYSTAL mineral, called also mineral anodyne, and sal prunella, is nitre detonated with sulphur, thus; put a pound of nitre in a crucible, and set that in a furnace; and when the nitre is in fusion, let it be detonated with a dram of sulphur; after the detonation is over, pour the fluid into moulds, where it soon hardens into a white crystalline mass.

CRYSTALS of silver, or luna. See SILVER, *nitrat of*.

CRYSTALS of Mars, called also salt, or vitriol of Mars: See IRON, *sulphat of*.

CRYSTALS of Venus, or of copper, is nitrat of COPPER; which see. Acetite of copper, or crystallized verdegris, is also sometimes called by this name.

CRYSTAL of Iceland, or Island, is very pure calcareous spar, in oblique rhomboidal prisms; for a particular description of which, see LIMESTONE, *foliated*.

The Iceland crystal is electrical, and when rubbed will draw up straws, feathers, and other light substances, in the same manner that amber does.

The vast masses of white spar which are found in the lead

mines of Derbyshire, though they are not externally of the paralleloiped figure of the Iceland crystal, nor have any thing of its brightness or transparence in the general lump; yet when they are broken, they separate into rhomboidal fragments, and some of these are found to be tolerably pellucid: all those which are so, have the property of the Iceland crystal; and being laid upon paper, where a black line is drawn, they all shew that line double in the same manner as the real Iceland crystal does.

Iceland crystal bears a red heat without losing its transparency; and, in a very intense heat, calcines without fusion; steeped a day or two in water, it loses its natural polish.

It is very soft, and easily scratched with the point of a pin; it will not give fire on being struck against steel; and ferments, and is perfectly dissolved in aqua fortis. It is found in Iceland, from whence it has its name; and in France, Germany, and in many other places. In England, fragments of other spars are very often mistaken for it, many of them having, in some degree, the same property.

Bartholine, Huygens, and sir Isaac Newton, have described the body at large, but have accounted it either a crystal or a talc, errors which could not have happened, had the criterions of fossils been at that time fixed; since sir Isaac Newton has recorded its property of making an ebullition with aqua fortis, which alone must prove that it is neither talc nor crystal, both these bodies being wholly unaffected by that menstruum.

The phenomena of this stone are very remarkable, were first suggested by Bartholine, and have been examined with great accuracy by M. Huygens, and sir Isaac Newton.

1. Whereas in other pellucid bodies there is only one refraction, in this there are two; so that objects viewed through it appear double.

2. Whereas in other transparent bodies, a ray falling perpendicularly on the surface, passes straight through, without suffering any refraction; and an oblique ray is always divided; in Iceland crystal, every ray, whether perpendicular or oblique, becomes divided into two, by means of the double refraction. One of these refractions is, according to the ordinary rule, the sine of incidence out of air into crystal, being to the sine of refraction as five to three; but the other is perfectly new. The like double refraction is also observed in crystal of the rock, though much less sensibly.

When an incident ray is thus divided, and each moiety arrives at the farther surface, that refracted in the first surface after the usual manner, is refracted entirely after the usual manner at the second; and that refracted in the unusual manner in the first, is entirely refracted after the like manner in the second; so that each emerges out of the second surface, parallel to the first incident ray. Again, if two pieces of this crystal be placed over each other, so that the surfaces of the one be parallel to the corresponding ones of the other; the rays refracted in the usual manner in the first surface of the first, are refracted after the usual manner in all the other surfaces; and the same uniformity appears in the rays refracted after the unusual manner; and this in any inclination of the surfaces, provided their planes of perpendicular refraction be parallel.

From these phenomena sir Isaac Newton infers, that there is an original difference in the rays of light; by means whereof some are, here, constantly refracted after the usual manner; and others in the unusual manner. Were not the difference original, and did it arise from any new modifications impressed on the rays at their first refraction, it would be altered by new modifications in the three following ones; whereas, in fact, it suffers no alteration at all.

Again,

Again, he hence takes occasion to suspect, that the rays of light have several sides, endued with several original properties; for it appears from the circumstances, that these are not two sorts of rays differing in their nature from each other, one constantly, and in all positions, refracted in the usual, and the other in the unusual manner; the difference is; the experiment mentioned, being only in the position of the sides of the rays, to the plane of perpendicular refraction. For one and the same ray is refracted sometimes after the usual, and sometimes after the unusual manner, according to the position of its sides to the crystal; the refraction being alike in both, when the sides of the rays are pointed the same way to both, but different, when different.

Every ray, therefore, may be considered as having four sides, or quarters; two of which, opposite to each other, dispose the ray to be refracted after the unusual manner; and the other two in the usual. These dispositions, being in the rays before their incidence on the second, third, and fourth surfaces; and suffering no alterations, for what appears in their passage through them, must be original and connate.

Father Beccaria corrects the observations of Huygens and Newton concerning the refraction of rock or mountain crystal. The double refraction of the latter happens, when a ray passes through two sides that are inclined to each other, and consequently issues coloured; whereas that of the Iceland crystal is made by the passage of a ray through two parallel sides, and therefore it issues colourless. He suggests, that there may be other substances, in which there is a manifold refraction. Gravesande had a prism of Brasil pebble, which had a double refraction at each angle, but of a different kind from one another. *Phil. Transf.* vol. lii. part ii. p. 487, &c. Mr. B. Martin prepared several prisms of Iceland crystal, which exhibited not only a double but a multiple refraction. A single prism produced a six-fold refraction; and by combining several prisms, a number of refractions was obtained equal to the product of those of the single prisms; *i. e.* a prism which afforded two images applied to one of six, produced a prism of twelve images, &c. He farther observes, with respect to Iceland crystal, that though the sides of its plane of perpendicular refraction be parallel to one another, a beam of light transmitted through them will not be colourless; in which property it differs from all other known substances. See Martin's *Essay on Iceland Crystal*, or Priellley's *Hist. of Vision*, period vii. § 8. p. 543, &c. See REFRACTION.

CRYSTALLINE LENS, or *CrySTALLINE Humour*, in *Anatomy*, a transparent body, nearly spherical in form; imbedded in the anterior part of the vitreous humour, where it is enclosed by the membrana hyaloidea passing before and behind it; which portions of membrane form its capsule. See EYE.

The crystalline is set in the anterior part of the vitreous humour, like a diamond in its collet; and is retained there by a membrane which surrounds it; and which, for that reason, is called the capsule of the crystalline. This membrane is sometimes also called crystallioides; and by others, on account of its fineness, which resembles that of a spider's web, arachnoides.

It is the configuration of the crystalline that occasions persons to be either myopes, or presbyta; *i. e.* to be either long, or short-sighted; a discovery first suggested, and proved by Maurolycus of Messina, in a treatise, *De Lumine & Umbra*, published in 1575. Bapt. Porta thought that this humour was the principal seat of vision.

The crystalline being of two consistences, outwardly like a jelly, but toward the centre as hard as salt; hence some

authors think, that its figure may be varied; which variation they suppose to be effected by the ligamentum ciliare. Hence, Dr. Grew, and others, ascribe to the ciliary ligament a power of making the crystalline more convex, as well as of moving it to or from the retina: accordingly, by the laws of optics, something of this kind is absolutely necessary to distinct vision: for, as the rays from distant objects diverge less than those from nigh ones; either the crystalline humour must be capable of being made more convex, or more flat; or else there must be an elongation of the eye, or of the distance between that and the retina.

The crystalline humour, when dried, appears to consist of a vast number of thin, spherical laminae, or scales, lying over one another. Leewenhoek reckons there may be two thousand of them in one crystalline; each of these, he says, he has discovered to consist of a single fibre, or fine thread, wound up in a stupendous manner, this way and that, so as to run several courses, and meet in as many centres; and yet not interfere nor cross in any place. *Phil. Transf.* N^o 165, and 293.

The vessels of the crystalline humour of the eye are all the branches of an artery, which being sent off from the artery which enters at the central part of the retina, passes through the vitreous humour, and when it reaches the crystalline, disperses its branches along the surface of the lens like radii, till they are exceeding minute, when they pierce into its substance. *Med. Ess. Edinb.* vol. i. p. 337.

M. Petit, the physician, has many minute observations and experiments on the colour, consistence, measure, weight, &c. of the crystalline humour of the eye, and its capsule in different animals: but his observations are so numerous, that we can only take notice of some of them. He observed, that in serpents and fishes the crystalline is nearly spherical; whereas in all other animals which he examined it was lenticular, the anterior surface being less convex than the posterior.

This humour hardens with age, and is not so hard in men as in birds, quadrupeds, and fishes; its hardness increasing in the order here expressed.

He also observes, that the crystalline changes colour with age, becoming gradually more and more tinged with yellow, after the age of twenty-five years, in proportion to its hardness.

He shews, in confirmation of Leewenhoek's discovery, that the crystalline consists of concentric laminae: he always found the capsule transparent, and denies any connection between this membrane and the crystalline, or that there are any vessels going from the one to the other; but affirms that the crystalline is nourished by absorbing the lymph lodged between it and its capsule.

But Albinus discovered this to be a mistake; and that, on the contrary, it is connected with the capsule by means of several vessels, which, passing through small perforations in the capsule, are inserted at the extremities of it, and spread along the back part of it; and that it receives its nourishment by vessels, which are the branches of the central artery passing through the vitreous humour, and divided into several branches in the back part of the capsule, and transmitted to the interior parts of the crystalline, by which it is also suspended.

Dr. Porterfield has accounted for the greater central hardness of the crystalline; as the rays of light, which fall near its axis, and would consequently be less refracted than those that fall more obliquely nearer the extremities, have hereby their refraction increased, and are made to converge and meet with those at the same point with those that pass through it nearer its edge.

When

When the crystalline or vitreous humours are fallen out of the eye, it is easy to conceive, that not only the sight, but the figure of the eye, must be entirely destroyed; therefore, in an accident of this kind, the eye must at first be dressed with compresses dipped in warm wine, or spirit of wine, and afterwards with some vulnerary balsam. But it sometimes happens, when only the tunica albuginea, and sclerotica, are slightly wounded, the cornea and uvea remaining unhurt, that the eye recovers itself: and though both the vitreous and crystalline humours fall out by the wound, yet they are renewed again by the efficacy of nature, and the office of light performed as well as before the injury happened.

The crystalline is the subject of the disease called a CATARACT, and the operation of COUCHING. See EYE.

CRYSTALLINE Heavens, in the *Old Astronomy*, two orbs, imagined between the primum mobile and the firmament, in the Ptolemaic system, in which the heavens were supposed solid, and only susceptible of a single motion.

King Alphonsus of Arragon is said to have introduced the crystallines, to explain what they called the motion of trepidation, or titubation.

The first crystalline, according to Regiomontanus, &c. serves to account for the slow motion of the fixed stars; which makes them advance a degree in seventy years, according to the order of the signs, viz. from west to east; which occasions the precession of the equinox.

The second serves to account for the motion of libration, or trepidation; whereby the celestial sphere librates from one pole towards another, occasioning a difference in the sun's greatest declination.

But the moderns account for these motions in a much more natural and easy manner.

CRYSTALLIZATION, in *Chemistry*. See CRYSTALL.

CRYSTALLOGRAPHY. See CRYSTAL.

CRYSTALLOMANCY, the art of divining, or foretelling, future events, by means of a mirror; wherein the things required are represented.

It is also called catoptromancy. The first from *κρυσταλλος*, *congealed water*, or *crystal*; and the second from *κατοπτρον*, *mirror*, and *μαντια*, *divination*.

CRYSTINE, in *Commerce*, a silver coin in Sweden, equal to fourteen sols and eleven deniers French. They have also demi-crystines.

CSAKATHURN, in *Geography*, a town of Hungary, situated on a small river between the Muer and the Drave; celebrated for its wine; 20 miles W. of Camischa, and 95 S. of Vienna.

CSABA, a small town of Hungary, in the county of Bekes, on the river Theifs, inhabited by a colony of Bohemians.

CSABRAG, a small town of Hungary, with an ancient castle. There are some mines in its neighbourhood. It is situated in the province of Nagi Hont, and in the district of Buzok.

CSAKA TORNYA, or CSAKATHURN, a small town of Hungary, in the county of Szala, belonging to the counts of Altheim, with a magnificent castle, the fortifications of which are fast decaying. In one of the walls of the castle-yard are the ruins of a monument, erected to a Roman tribune by his wife, under the reign of Antoninus Pius. G. A. H. Gubert. *Journal d'un Voyage en Allemagne*, Paris, 1803.

CSAKOVAR, a small town of Hungary, in the banat of Temesvar, on the river Temes.

CSAKVAR, a small town of Hungary, in the county

of Szabolts, with an old ruined castle, belonging to the family of the Csaki, who descend from the count Szabolts, one of the seven Hungarian leaders that invaded Hungary in the ninth century.

CSANAD, a small town of Hungary, in the county of the same name, on the river Maros. It is the see of a bishop, and carries on a flourishing trade; 64 miles N. of Belgrade, and 200 S.E. of Vienna.

CSEIKO, a small town of Hungary, in the county of Bars, district of Leva; famous for its good wine.

CSEKLES, a small town of Hungary, in the county and district of Presburg, with a handsome palace belonging to prince Esterhazy. It is situated on an eminence.

CSENGER, a small town of Hungary, in the county of Szathmar, with an old castle.

CSEPREG, a small, but formerly very populous, town of Hungary, in the county of Oedenburg or Sopron.

CSERAPUXA, a town and castle of Hungary; 8 miles N.E. of Eriau.

CSERNA, a river of Hungary, which runs into the Danube, near Orsova.—Also, a town of Slavonia; 20 miles S. of Elzek.

CSERNECK, or CSEZNECK, a small town of Slavonia, in that part which is called the bannat of Slavonia, and in the county of Posseg.

CSERNIGRAD, or TARKAVARA, a small town of Slavonia, in that part which is called the bannat of Slavonia, and in the county of Sirmi, on the river Drave. It was anciently fortified, and still retains some traces of a fortress.

CSESZTE, a small town of Hungary, in the county and district of Presburg, on a pleasant eminence near Bibersburg castle.

CSIKVAR, a small town of Hungary, in the county of Stuhl Weissenburg, with an old castle on the river Carvitz.

CSOGOD, a town of Transilvania; 16 miles E. of Udvarhely.

CSOKAKU, a town of Hungary, at the conflux of the rivers Kores and Theifs; 22 miles N. of Zegedin.

CSONGRAD, CZONGRAD, or CZONGRODT, a considerable town of Hungary, in the county of the same name, with an ancient castle, situated at the confluence of the rivers Kores and Theifs.

CSOTORTOK, a small town of Hungary, in the county and district of Presburg, not far from the ancient castle of St. George, which is now a heap of ruins.

CTEMENÆ, in *Ancient Geography*, a town of Greece, in the Æliotide part of Thessaly.

CTENITA, or CTENOIDES, names sometimes given to those peccans which have one of their shells very convex. See PECCEN.

CTESIBIUS, in *Biography*, a mathematician of Alexandria, who was contemporary with Ptolemy king of Egypt, in the 165th Olympiad, about 120 years before Christ. His memory is particularly cherished as the inventor of the pump. The circumstance that led to the discovery was purely accidental. On lowering a mirror into his father's shop, he observed that the counterpoise, which was included in a cylinder, produced a sound, by driving the air before it; and upon examining the phenomenon more closely, he concluded that he might make an instrument, in which sounds should be produced by means of the action of water, driving the air before it. This invention was carried into effect by the emperor Nero. Ctesibius was the inventor, likewise, of a clepsydra, or water-clock. Water was made to fall upon a wheel, or a train of wheels, which were turned by it. The

wheels communicated their motion to a small wooden image, which, by being gradually raised, pointed with an index to the proper hours, that were engraved on a column near the machine. The invention was probably the means of the more modern construction of the sand-glasses for measuring time, which seem an imitation of the clepsydra. Ctesibius was author of a treatise, "Geodesia, or the Art of dividing and measuring Bodies," which is said to exist in the library of the Vatican. Moreri.

CTESIDEMO, an ancient painter, who is celebrated for his picture representing Hercules taking of Oechalia, a city of Bœotia; and for another of Laodamia ascending the funeral pile. Della Valle.

CTESIFONTE, **CHERSIFONTE**, or **CTESIPHON**, the architect who designed the famous temple of Diana at Ephesus, about 550 years before the Christian era. This edifice, which was 200 years in building, was commenced under his direction, and continued under that of Metagenes his son; and is the same which was afterwards fired by Erostratus, actuated, as it is said, in this barbarous enterprise, by no other motive than that of immortalising his name. Milizia Mem. degli Architetti.

He invented a machine that was used to transport the columns of the temple, from the quarries from which they were hewn, to the building of which they were to make a part. This machine consisted of a square frame of wood, of sufficient dimensions to enclose a whole column, with a socket at each end, into which certain strong iron pivots, proceeding from the column itself, were received. By this contrivance, the column became a kind of rolling-stone.

CTESILOCO, the scholar of Apelles, was known by his picture representing the birth of the Egyptian Bacchus, where Jupiter seemed to moan effeminately in the midst of the goddesses, assisting at the labour. Pliny depreciates this painting as highly indecent. It is conjectured by Della Valle, that this artist may have been the same with Ctesiloco, who is said to have been the disciple and brother of Apelles. Della Valle.

CTESIPHON. See **CTESIFONTE**.

CTESIPHON, in *Ancient Geography*, a city of Asia, in Parthia, situated on the eastern bank of the Tigris, opposite to, and at the distance of only three miles from, Seleucia. This city was founded, according to Ammianus Marcellinus (l. xxiii. c. 20.), by Vardanes, and walled and fortified by Pacorus, supposed by Valelius to have been the Orodes, whom Ventidius defeated. Polybius (l. v. c. 45.), Tacitus, Herodian (l. iii. c. 9.), and Strabo (l. xvii.), speak of Ctesiphon as the metropolis of the whole Parthian empire. It was at first an inconsiderable village; but as the Parthian monarchs frequently pitched the imperial camp on the plain in its vicinity, and the innumerable attendants on luxury and dissipation resorted to the court, it insensibly advanced to be a great city. Under the reign of Marcus, A. D. 165, the Roman generals penetrated as far as Ctesiphon and Seleucia; and both cities experienced the same assault and detolation. Although Seleucia sunk under the fatal blow, Ctesiphon, in about 33 years, had so far recovered its strength, that it was able to maintain an obstinate siege against the emperor Severus. The city was, however, taken by assault; the king, who defended it in person, escaped with precipitation; 100,000 captives, and a rich booty, rewarded the fatigues of the Roman soldiers. Notwithstanding these misfortunes, Ctesiphon succeeded to Babylon and Seleucia, as one of the great capitals of the East. In summer, the monarch of Persia enjoyed at Ecbatana the cool breezes of the mountains of Media; but the mildness of the climate engaged him to prefer Ctesiphon for his winter-residence. In the

time of Julian, Ctesiphon was a great and populous city; and Coche, as the only remaining quarter of Seleucia was called, was merely its suburb, connected with it, as we may suppose, by a permanent bridge of boats. The united parts contributed to form the common epithet of Al Modain, "the cities," which the Orientals have bestowed on the winter-residence of the Saffanides; and the whole circumference of the Persian capital was strongly fortified by the waters of the river, by lofty walls, and by impassable morasses. Julian having, after a severe contest, taken possession of Coche, pursued the Persians to the gates of Ctesiphon; and holding a council of war, he declined the siege of the city, as a fruitless and pernicious undertaking, though he was led by an army of 60,000 Romans, A. D. 363. In the year 637, the walls of Ctesiphon, which had resisted the battering-rams of the Romans, yielded to the darts of the Saracens. Said, the lieutenant of Omar, passed the Tigris without opposition: the capital was taken by assault; and the disorderly resistance of the people gave a keener edge to the sabres of the Moslems, who shouted with religious transport, "this is the white palace of Chosroes, this is the province of the apostle of God." The spoils, says Abulfeda, surpassed the estimate of fancy or numbers; and another historian (Elmacin) defines the untold and almost infinite mass by the fabulous computation of three thousands of thousands of thousands of pieces of gold. One of the apartments of the palace was decorated with a carpet of silk, 60 cubits in length, and as many in breadth: a paradise, or garden, was depicted on the ground; the flowers, fruits, and shrubs, were imitated by the figures of the gold embroidery, and the colours of the precious stones; and the ample square was encircled by a variegated and verdant border. The rigid Omar divided the prize among his brethren of Medina. The picture was destroyed; but such was the value of the materials, that the share of Ali alone was sold for 20,000 drachms. The sack of Ctesiphon was followed by its desertion and gradual decay. One of the most considerable ruins of Assyria is the hall of Chosroes at Ctesiphon.

CTISIANA, a town of Africa, in Mauritania Tingitania, according to Ptolemy.

CTYPANSA, a town of the Peloponnesus, in Triphyla, according to Strabo. It is called Tympanæa by Polybius, and Tympancia by Ptolemy.

CUADAC, in *Geography*, a sea-port town of Asia, in Torquin, on a river of the same name.

CUAMA, a river of Africa, at the mouth of which the city and fortress of Sofaia are situated, called by the Arabs and Negroes Zambere and Embouco. Its spring-head is not known; but it surrounds, in some measure, the kingdom of Monomotapa, dividing it on the west from that of Abutua, and on the north from Chicova, Sacomba, and Mauruca. It receives in its course, among other streams of lesser note, the Mangania, Mazeno, and Suabo; and, dividing into two branches, discharges itself into the Indian sea, at four mouths, from north to south, distinguished by as many names; viz. Kilirano, Linda, Cuama, and Luava; or, according to others, Penhamez, Lunagoa, Arruyga, Manjovo, Guadire, and Rueriva.

CUANARAMA, a mountain of New Andalusia, in S. America, which rises 6400 feet above the level of the sea.

CUANDU, in *Zoology*, Coendou of Buffon, Brazilian Porcupine of Pennant, and *Hystrix prebensilis* of Gmelin; which see.

CUARIUS, in *Ancient Geography*, a river of Greece, in Eœotia, according to Strabo.

CUATLACHTLI, or *Lupus Indicus*, in *Zoology*, a

name given by Fernandez to the Mexican wolf, or *CANIS Mexicanus* of Gmelin.

CUB, in *Rural Economy*, a name sometimes applied to a young fox, and also provincially to signify a cattle crib.

CUB, *North*, in *Geography*, a small island in James's bay, Hudson's bay. N. lat. $54^{\circ} 25'$. W. long. $85^{\circ} 50'$.

CUB, *South*, a small island in the same bay. N. lat. $55^{\circ} 42'$. W. long. $86^{\circ} 30'$.

CUBA, in *Ancient Geography*, a town of India, placed by Ptolemy on this side of the Ganges

CUBA, in *Geography*, a name given by the natives of San Salvador to a very large island of the West Indies, one of the Great Antilles islands, when it was first discovered by Columbus in 1492; but he gave it the name of Juanna, or, as some say, Ferdinand, in honour of king Ferdinand, his master. But it soon recovered its Indian name, which it has ever since retained. This celebrated navigator entered the mouth of a large river with his squadron; but as he approached the shore, all the inhabitants fled to the mountains; those who were deputed to examine the interior parts of the country, whilst he was careening his ships, found that about 60 miles from the shore, the soil was richer and more cultivated than any they had hitherto discovered; and, besides many scattered cottages, they saw one village which contained above 1000 inhabitants. The people, though naked, seemed to be more intelligent than those of San Salvador, and treated them as if they had been sacred beings, allied to heaven, paying them respectful attention and kissing their feet; they also gave them to eat a certain root, resembling in its taste roasted chestnuts, and a singular species of corn, called maize, which roasted whole, or ground into meal, was palatable food. They perceived no four-footed animals, except a species of dogs, which could not bark, and a creature like a rabbit, but of smaller size; and they observed some ornaments of gold, which, as the natives reported, was found in "Cubanacan," by which they meant the middle or inland part of Cuba. Columbus visited almost every harbour, from Porto del Principe, on the north coast of Cuba, to the eastern extremity of the island; but, whilst he admired the beauty of the scenery, and the fertility of the soil, he was disappointed by not discovering any quantity of gold. Cuba was not ascertained to be an island till the year 1508, when a captain, named Sebastian, sailed round it by order of Obando, the governor of Hispaniola, for Columbus supposed it to be a part of the continent; nor was it completely conquered by the Spaniards, who sacrificed an incredible number of the inhabitants, till the year 1511. In this year the admiral, Jago, or Don Diego, Columbus sent Jago Velasquez with about 300 men, from Hispaniola, in order to take possession of the island, and to plant it; and he settled on the south coast, near a port which he called by his own name, and which for extent and security may be reckoned one of the finest in the world. While Velasquez was governor of Cuba, he built the city, and port of the Havannah; the houses of which at first were built of wood; afterwards they were constructed of stone, and a fort was erected at the mouth of the harbour. But this port has been often pillaged both by French and English pirates. (See HAVANNAH.) The other principal towns are Santa Cruz, about 63 miles E. of Havannah, Porto del Principe, on the same coast, about 300 miles S.E. of Havannah, Baracoa, on the N.E. part of the island, with a convenient harbour for small vessels, and St. Jago, formerly the capital and the residence of its government.

This island commences on the east side at N. lat. $20^{\circ} 20'$, approaches on the north the tropic of Cancer, and extends

from W. long. $73^{\circ} 50'$, to $85^{\circ} 30'$, about $11^{\circ} 40'$, from east to west, or 690 geographical miles from Cape Antonio on the west, to Cape Mayzi on the east; but it is narrow, in proportion to its length, being in some parts not above 12 or 14 leagues, and at most but 120 miles in breadth. It contains about 38,400 square miles. It lies W. of Hispaniola, N. of Jamaica, and the bay of Honduras, E. of the meridian of Yucatan, and S. of the great bank of Bahama, and the Florida stream; and commands the entrance of both the gulfs of Mexico and Florida, and the windward passage; so that the Spaniards, who are the sole possessors of it, may with a tolerable fleet not only secure their own trade, but annoy their neighbours. The command of this island is entrusted with a governor, or captain-general, who decides all affairs, civil and military; and its finances are under the direction of an intendant. It is divided into 18 jurisdictions, each of which has a magistrate. A chain of mountains extends the whole length of the island from east to west, and divides it into two parts; but the land near the sea is in general level, and flooded in the rainy season. Like most islands in the West Indies, it is subject to storms, but the climate is, upon the whole, healthy, and even temperate; for though in this latitude there is no winter, the air is refreshed with rains and cooling breezes. The rainy months are July and August; the rest of the year is hot. The soil is equal in fertility to any in America, producing ginger, long pepper, and other spices; aloes, mastic, cassia, sassa, manioc, maize, cocoa, &c. Tobacco is one of its principal productions, and it is supposed to have the most delicate flavour of any produced in the New World. The cultivation of sugar has lately been introduced; but the indolence of the inhabitants renders it in every respect much less productive than it might otherwise be. The quantity of coffee is inconsiderable. Not more than 100th part of the island is cleared. The chief plantations are on the beautiful plains of Savannah, and are cultivated by about 25,000 slaves. The other inhabitants are said to amount to about 30,000. Among the trees are oaks, firs, palms, cotton trees, ebony, and mahogany. In 1763 bees were introduced by some emigrants from Florida, and they multiplied so much in the hollows of old trees, that they soon obtained enough for their annual consumption. In 1777 they exported honey to the amount of 715,000 pounds. The island abounds with mules, horses, sheep, wild boars, hogs, and fine black cattle. The horned cattle have increased so much that the forests are filled with droves of them, which run wild, and are hunted and killed for their hides and tallow. The chief birds are paroquets, turtle doves, and partridges; water-fowl are numerous; and on the coast turtles are abundant; mullets and shads are the principal fish. The copper-mines, which are in the eastern part of the island, furnish all the Spanish colonies with utensils of that metal; small pieces of gold and silver are collected in the sand of the rivers, which makes it probable that there are veins of these metals in the mountains. Few countries have better ports than Cuba; the most considerable and best known are the Havannah and St. Jago; which see.

CUBA, a town of Portugal, in the province of Alentejo; 3 leagues N.N.E. of Beja.

CUBA, in *Mythology*, a goddess among the Romans, thus called from *cubo*, I lie down, who was invoked in order to make children sleep.

CUBÆA, in *Botany*, Scop. Schreb. 702. Willd. 814. (Tachigali; Aubl. Tachigaha; Juss. 349.) Class and order, *decandria monogynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth one-leafed, top-shaped, spreading, permanent, five-parted; divisions roundish, concave; four erect; the fifth and lowest larger, declining. *Cor.* Petals five, oblong, nearly equal, furnished with claws, inserted into the neck of the calyx; three upper ones erect; two lower ones declining. *Stam.* Filaments ten, villous at the base, inserted into the calyx below the petals; three upper ones shorter, filiform, erect, close-pressed to the upper petals; the seven lower ones longer, capillary, longer than the lower petals, and incumbent on them; anthers oblong. *Pil.* Germ oblong, pedicelled; style capillary; stigma acute. *Peric.* Legume long, coriaceous, villous, swollen, obliquely acuminate, one-celled. *Seeds* several, somewhat kidney-shaped.

Eff. Ch. Calyx top-shaped, five-parted. Petals five, nearly equal, irregular. Stamens inserted into the calyx, long, all fertile, three upper ones shorter. Pericarp a legume.

Sp. 1. *C. paniculata.* Mart. 1. Willd. 1. Aubl. Guian. 1. 372. tab. 143. fig. 1. "Leaves pinnated; leaflets opposite." A tree sixty feet high, much branched at the top; smaller branches triangular. *Leaves* large, alternate; leaflets in six pairs, somewhat egg-shaped, acute, entire, green and smooth above, somewhat downy underneath, and of an ash-coloured green. *Stipules* two, opposite, at the base of the leaf-rib. *Flowers* very numerous, on short peduncles, in long terminal trigonous spikes, which form an ample panicle. 2. *C. trigona.* Mart. 2. Willd. 2. Aubl. tab. 143. fig. 2. "Leaves pinnated; leaflets alternate." Very similar to the preceding, and perhaps should be considered as a mere variety. Both kinds are natives of Guiana in woods, on the banks of rivers. The trivial name of the latter is ill chosen, the leaves in both having a triangular midrib.

CUBAGUA, in *Geography*, a small island about 8 miles long, near the coast of Cumana, in South America, between the island of Margarita and the continent, discovered by Columbus in the year 1498, and afterwards chiefly visited by the Spaniards for the sake of the pearls found on its coasts; but in 1524 the banks of pearls disappeared, and the fishermen, who were Indians from the Lucayos islands, were nearly exhausted. The soil is dry, barren, and nitrous, without fresh water, and producing little besides rushes. N. lat. $10^{\circ} 56'$. W. long. $63^{\circ} 30'$.

CUBAIMAROU, a river of the island of St. Vincent, which runs into the sea, in a bay of the same name, on the south coast of the island. N. lat. $13^{\circ} 6'$. W. long. $61^{\circ} 11'$.

CUBAN, or KUBAN, a province of the southern division of Russia, in Europe, is the government of Taurida, between the 45th and 47th degree of north latitude, bounded to the south by Circassia; to the west by the Black Sea, and the gulf of Taman; to the north and north-east by the sea of Afoph; and to the east by the government of Caucasus. It is a level and not very fertile country, inhabited chiefly by Tartars, who lead a wandering pastoral life on the banks of the Cuban, a considerable river, from which the country derives its name. Before their submission to the Russian empire, they had their particular khan or chief, and could bring 40,000 men into the field; but whole tribes of them have deserted, and gone over to the Turks. They are of Mongolian origin, and a very unsettled people. Their inclination to rob has not yet been changed, though they have been much reduced by severe, capital, and merited punishments.

The Cuban passed under the domination of Russia, at the same time with the *Crim* or *Crimea* (which see), in the year 1784, and in the last treaty with the Ottoman Porte, the river Cuban was fixed upon as the boundary of the Russian

empire in that quarter. This river falls into the Euxine or Black Sea. It is the *Hypanis* of the ancients. It rises in the Caucasian mountains, and is formed by the confluence of a number of small rivers. With the river Tumefek it makes several islands between the sea of Afoph and the Black Sea, of which one of the finest is the isle of Taman. A principal arm of the Cuban falls northward into the sea of Afoph, and the other southward into the Euxine. The river in general, and the first arm in particular, has a rapid course and clear water; but that arm which falls into the Black Sea, flows in a very gentle current, has a troubled water and forms at its mouth a pretty spacious bay, which however is so shallow that it can never serve as a haven.

The Cuban has neither rocks nor water-falls, and therefore is well adapted to being navigated with vessels that do not draw much water. It admits to the right the rivers Barakla and Barsukta; to the left the Yassik, Yassi, Urp, Sagraffa, Laba, Karabokan, and several other small rivers. In the mountainous part of the country, watered by the Cuban, its banks are very steep; but in the lower regions they are flat. Here the country is one continued Steppe, almost entirely destitute of wood, but in other respects tolerably fertile. The isle of Taman, which is considered as part of the Cuban, has an excellent, and in some districts ever verdant soil. See TAMAN.

The mountains in the superior regions of the Cuban are thickly covered with forests; and not far from this river, at a place called Athuel, is a lake of salt water. Tooke's View of the Russian Empire. P. S. Pallas's Travels through the Southern Provinces of the Russian Empire.

CUBATURE, or CUBATION, of a solid; the measuring of the space comprehended in a solid; as a cone, pyramid, cylinder, &c. or finding the solid content thereof. The cubature regards the content of a solid, as the quadrature does the superficies of a figure. See SOLID.

CUBBITTING, in *Farriery*. See CRIB-biting.

CUBBRIDGE-HEADS, in *Ship building*, is sometimes used for the bulk-heads of the fore-castle, and the half-deck: the first being called the *cubbridge-head before*; the other the *cubbridge-head abaft*.

CUBCABIA, in *Geography*, a considerable town of Africa, in the country of Darfûr, situated on the road from Cobbe to Bergoo, and containing many inhabitants. This town is the key of the western roads, and the depôt of all the merchandize that is brought from that quarter. A market is held here twice a week, in which the chief medium of exchange, for articles of small value, is salt, which the inhabitants make by collecting and boiling the earth of those places where horses, asses, or other animals have been long stationary. This market is celebrated for a quantity of "tokeas," and for the manufacture, if it may be so called, of leather, which they dexterously strip of the hair, tan, and then form into large sacks for corn, water, and other purposes. The "tokeas" are cotton cloths, 5, 6, or 8 yards long, and from 8 to 22 inches wide; they are strong but coarse, and form the covering of the whole lower class of both sexes. The inhabitants are partly Fûrians, who speak their own language, partly Arabs, and partly emigrants from some of the western countries, as Bergoo, &c. Brown's Travels in Africa, p. 238.

CUBDENSIS, in *Ancient Geography*, an episcopal see of Africa, in the proconsular province.

CUBE, in *Geometry*, a regular or solid body, consisting of six square and equal faces, or sides; and its angles all right, and therefore equal.

The

C U B E.

The word comes from *κῦβος, tessera, die.*

The cube is also called *hexahedron*, because of its six sides. The cube is supposed to be generated by the motion of a square plane, along a line equal to one of its sides, and at right angles to it: whence it follows, that the planes of all sections, parallel to the base, are squares equal to it: and consequently, to one another.

To describe a rete, or net, whence any given cube may be constructed, or with which it may be covered. On the right line A B (Plate III. Geometry, fig. 52.) set off the side of the cube four times: on A erect a perpendicular, A C, equal to the side of the cube A I, and complete the parallelogram A C D B: with the interval of the side of the cube, in the line C D, determine the points K, M, and O; lastly, draw the right lines, I K, L M, N O, and B D, produce I K and L M, each way to E and F, and to G and H; till EI=IK=KE, and GL=LM=MH, and draw the right lines E G, F H.

To determine the surface and solidity of a cube.—As the surface of a cube consists of six equal squares, a side multiplied by itself and the product by six, will give the superficies; and the same product, again, multiplied by the side, the solidity.

Hence, if the side of the cube be 10, the solidity will be 1000; if that be 12, this will be 1728: wherefore the geometrical perch being ten feet, and the geometrical feet twelve digits, &c. the cubic perch is 1000 cubic feet, and a cubic foot 1728 cubic digits, &c.

Hence, also, cubes are in the triplicate ratio of their sides; and are equal, if their sides be so.

CUBE, duplication of *a*. See DUPLICATION.

CUBE, scenography of *a*. See SCENOGRAPHY.

CUBE, or CUBIC number, in *Arithmetic*, is a number arising from the multiplication of a square number by its root: or, it is formed by multiplying any numbers twice by themselves. Thus, if the square number four be multiplied by its root two, the factum eight is a cube or cubic number; and the number two, with respect to it, a cube root.

Also, the cubes of

1, 2, 3, 4, 5, 6, 7, 8, 9, 10.

are . . . 1, 8, 27, 64, 125, 216, 343, 512, 729, 1000. Thus a table of cubes may be easily formed for any series of numbers.

Hence, since as unity is to the root, so is the root to the square; and as unity is to the root, so is the square to the cube: the root will, also, be to the square, as the square to the cube: that is, unity, the root, the square, and the cube, are in continual proportion; and the cube root is the first of two numbers that are mean proportionals between unity and the cube.

All cubic numbers, whose root is less than 6, *v. g.* 8, 27, 64, 125, being divided by 6, the remainder is their root itself. Thus, 8, being divided by 6, 2, the remainder of the division, is the cube root of 8. For the cubic numbers beyond 125, as 216, the cube of 6, divided by 6, leaves no remainder; 343, the cube of 7, leaves a remainder of 1, which added to 6 gives the cube root of 343. And 512, the cube of 8, divided by 6 leaves 2, which added to 6, makes the cube root of 512. So that the remainder of the divisions of the cubes above 216, divided by 6, being added to 6, always give the root of the cubic number divided, till that remainder be 5, and, consequently, 11 the cube root of the number divided: but the cubic number above this, being divided by 6, there remains nothing, the cube root being 12; thus, if you continue to divide the higher cubes by 6, you must not add the remainder of the division to 6 but to 12, the first multiple of 6, and thus

coming to the cube of 18: the remainder of the division must not be added to 6, nor to 12, but to 18; and so on *in infinitum*.

M. de la Hire, from considering this property of the number 6, with regard to cubic numbers, found, that all other numbers raised to any power whatsoever, had each their divisor, which had the same effect with regard to them that 6 has with regard to cubes. And the general rule he has discovered is this: if the exponent of the power of a number be even, *i. e.* if that power be raised to the 2d, 4th, 6th, &c. power, it must be divided by 2; and the remainder, if there be any, added to 2, or to a multiple of 2, gives the root of the number corresponding to its power, *i. e.* the 2d or 6th root, &c. But if the exponent of the power of the number be uneven, *i. e.* if it be raised to the 3d, 5th, 7th, &c. power, the duple of that exponent will be the divisor, which shall have the property here required.

It appears, from a due examination of the cubes of the natural numbers, that their third differences are all equal to each other, being the constant number 6. Let m^3, n^3, p^3 , be any three adjacent cubes in the natural series of cubes, that is, let them be such whose roots m, n, p , have the common difference 1; then because $n=m+1$, we shall have $n^3 = m^3 + 3m^2 + 3m + 1$; and because $p=n+1$, we shall have $p^3 = n^3 + 3n^2 + 3n + 1$; so that the differences between the 1st and 2d, and between the 2d and 3d cubes, are $n^3 - m^3 = 3m^2 + 3m + 1$ } the 1st difference, and the difference of these differences, *viz.* $3n^2 + 3n + 1 - 3m^2 + 3m + 1 = 3 \cdot n^2 - m^2 + 3 \cdot n - m = 3 \cdot n + m + 1 = 6 \cdot m + 1$, is the 2d difference. In like manner the next second difference is $6 \cdot n + 1$; and the difference of these two differences is $6 \cdot n - m = 6$, which is therefore the constant third difference of all the series of cubes. And hence that series of cubes will be found by addition only; *viz.* by adding always the 3d diff. 6 to find the column or series of 2d differences, and adding these always for the first differences, and again adding these always for the cubes themselves, thus:

3d Differences.	2d Differences.	1st Differences.	Cubes.
6	6	1	0
6	12	7	1
6	18	19	8
6	24	37	27
6	30	61	64
6	36	91	125
6	42	127	216
6	48	169	343

Peletarius, among various speculations concerning square and cubic numbers, shews that the continual sums of the cubic numbers, whose roots are 1, 2, 3, &c. form the series of squares whose roots are 1, 3, 6, 10, 15, 21, &c.

Thus: $1 = 1 = 1^2$
 $1 + 8 = 9 = 3^2$
 $1 + 8 + 27 = 36 = 6^2$
 $1 + 8 + 27 + 64 = 100 = 10^2, \&c.$

Or, in general, $1^3 + 2^3 + 3^3 + 4^3, \&c. \text{ to } n^3 = \frac{1}{2} n \cdot n + 1$. It is also a property of these cubic numbers, that any number, and the cube of it, being divided by 6, leave the same remainder; the series of remainders being 0, 1, 2, 3, 4, 5, continually repeated. Or, that the differences between the numbers and their cubes,

This name was also given to the balcony or loggia, in which the emperors were placed at the public games.

CUBIDIA, in *Natural History*, the name of a genus of spars. The word is derived from $\kappa\upsilon\beta\acute{\omicron}\varsigma$, a die, and is given them from their being of the shape of a common die, or of a cubic figure. These bodies owe this shape to an admixture of particles of lead, and there are only two known species of the genus. 1. A colourless crystalline one, with thin flakes, found in the lead mines of Yorkshire, and some other parts of the kingdom. And, 2. A milky-white one, with thicker crusts. This is found in the lead-mines of Derbyshire and Yorkshire, but is usually small, and is not found plentifully.

CUBII, in *Ancient Geography*, a people placed by Ptolemy in the vicinity of the Marzotide lake.

CUBING of a Solid. See **CUBATURE** and **SOLID**.

CUBIT, a long measure, used by the ancients, especially the Hebrews; taken from the ordinary extent of a man's arm, between the elbow and the tip of the hand.

In the Scripture, we find cubits of two lengths; the one equal, according to Dr. Arbuthnot, to 1 foot 9 inches $\frac{3}{8}$ of an inch, our measure; being the fourth part of the fathom, double the span, and six times the palm: the other equal to 1 $\frac{3}{4}$ foot, or the four hundredth part of a stadium. The Romans, too, had a cubit, equal to 1 English foot, 5 inches, $\frac{4}{8}$ of an inch. F. Merfenne makes the Hebrew cubit 1 foot, 4 digits, and 5 lines, with regard to the foot of the Capitol. According to Hero, the geometrical cubit is 24 digits; and, according to Vitruvius, the foot is $\frac{2}{3}$ of the Roman cubit, *i. e.* 16 digits, or finger's-breadth. The cubit was a measure of length used in England in the earlier period of its history, when the different parts of the body, &c. were resorted to as measures on different occasions, without much regard to their exact relation to each other, but which subsequent writers have thus stated. The English cubit or fore-arm = 864 hairs' breadth = 54 barley corns = 24 digits or finger's breadths = 18 inches = 16.8895 French pouces, or thumb's breadths = 8 nails = 6 palms, or hand's breadths = 4 $\frac{1}{2}$ hands, or clenched fist's breadths = 2 spans = 1 $\frac{1}{2}$ foot = $\frac{1}{2}$ a yard, or whole arm = $\frac{2}{3}$ pace or step = $\frac{2}{3}$ English ell or arm = $\frac{1}{4}$ fathom, or arm's reach = $\frac{1}{4}$ pole, or rod = 2 27 27 links = .2346 toise of France = .4570 metre of France.

CUBITÆUS EXTERNUS, or *ulnaris*, in *Anatomy*, the first of the extensor muscles of the fingers; thus called, as being placed along the cubitus externally. It rises from the external protuberance of the humerus, and, passing its tendon under the *ligamentum annulare*, is inserted into the fourth bone of the metacarpus, that sustains the little finger. See **ULNARIS extensor**.

CUBITÆUS INTERNUS, the first of the flexors, placed along the cubitus, withinside the arm. It rises from the internal protuberance of the humerus, and part of the ulna; upon which it runs along till it passes under the *ligamentum annulare*, and is inserted by a strong and short tendon into the fourth bone of the first order of the carpus.

CUBITALIS, from *Cubitus*; is an adjective used sometimes in naming parts which are connected with, or adjacent to, the ulna; hence we have a cubital artery and nerve, and cubital muscles.

CUBITA BICEPS. See **BICEPS**.

CUBITUS, a term applied to the ulna.

CUBITUS, *fractured and luxated*. See **FRACTURE** and **LUXATION**.

CUBITUS, a measure of length, adopted by Linnæus for describing the dimensions of plants = 17 French inches = 204 lines = 18.11775 English inches = 1.50981 English feet.

CUBLANC, in *Geography*, a small town of France, in the department of the Correze; 12 miles S.W. of Brives.

CUBO-CUBO-CUBUS. See **CUBUS-CUBI**.

CUBO-CUBUS, the term whereby Diophantus, Vieta, &c. distinguish the sixth power; which the Arabs call *quadratum cubi*.

CUBOIDES OS, in *Anatomy*, one of the bones of the tarsus. See **SKELETON**.

CUBROS GEZIRA. See **GEZIRA Cubros**.

CUBUS-CUBI, a name whereby the Arab writers, and those who follow them, denominate the ninth power, or a number multiplied eight times by itself continually; which Diophantus, and after him Vieta, Oughtred, &c. call *cubo-cubus*.

CUCADMA, or **CUCUNDA**, in *Ancient Geography*, a town of Asiatic Sarmatia, placed by Ptolemy near the river Burens.

CUCANA, in *Geography*, a town of Italy, belonging to the state of Venice, in the country of Friuli; 7 miles W. of Palma la Nuova.

CUCASBIRI, in *Ancient Geography*, one of the fortresses of Thrace, constructed by Justinian in the province of Rhodope.

CUCCHIARA, in *Geography*, a small island in the Adriatic, near the coast of Naples; 6 leagues N.W. from Vieta.

CUCCI, or **CUCCUM**, in *Ancient Geography, a place of Pannonia, near the Savus, placed, in the Itinerary of Antonine, between Bononia and Cornacum; and supposed to be the present Cerolicka or Curufca.*

CUCHECUNNA, in *Geography*, a town of Asia, in the country of Candahar; 68 miles W.N.W. of Candahar.

CUCKFIELD, a market-town in Suffex, in the Rape of Lewes, is situate in a high and commanding situation, although it is built upon the lowest stratum in the series, which any where makes an extent of surface, in the road between London and Brighton. About two-thirds of a mile south of the town, this stratum produces a quarry of tolerable free-stone, with which anciently the town was built; it is a yellowish stone, whose grit is exceeding fine, and the lower beds in the quarries have numerous black ferruginous septa or joints between the stone; under which is a pipe-clay stratum, producing wood-coal in detached pieces (see **COAL** and **COLLIERY**); and this clay it seems to be, which holds up the water in the very dislocated and porous district in which this town stands, and supplies the wells therein with water, but rather scantily. This is a neat pretty town, the foot-paths being paved with red paving-bricks, of a very fine and durable quality, manufactured from a stratum of red pottery clay, which appears about four miles south of this town. Some parts of the stone found in this Cuckfield stone stratum, are separated by layers of mica, which fits it for splitting, so thin, as formerly to have been much used for slating buildings; other parts are separated by curious wavy joints, that present matter of curious speculation to the naturalist. The land round this town, particularly on the south side, is of good quality. The spire of this church is furnished with a conductor, and, like most others in Suffex, is covered with wooden shingles, which have assumed a blue cast, exactly resembling slate in colour and appearance. Its situation was determined in the government trigonometrical survey in 1793, by an observation from Ditchling station, distant 38,568 feet, and bearing 12° 20' 25" S.E. from the parallel to the meridian of Greenwich, and another from Chanctonbury ring, distant 67,789 feet; whence is deduced its latitude 51° 0' 18."3 N., and longitude 0° 8' 29."8, or 34' W. of Greenwich.

CUCKING.

CUCKING STOOL, COKESTOOL, or CASTIGATORY, anciently called *tumbrel* and *trebucket*; an engine for the punishment of scolds and iniquit women, by ducking them in the water. It is frequently corrupted into *ducking-stool*, because the residue of the judgment is, that when they are placed in it, they shall be plunged in the water for their punishment.

Kitchen says, "Every one having a view of frank-pledge, ought to have a pillory and a tumbrel." This machine was much in use, even among our Saxon ancestors, who called it *scolding-stole*, or *scolding-stool*.

The punishment was anciently also inflicted on brewers, and bakers, transgressing the law; who were thereupon, in such a stool or chair, to be ducked in *stercore*, some muddy or stinking pond. This was anciently written *gazing-stool*; in Domesday it is called *cathedra stercoris*.

CUCKMERE, in *Geography*, a river of England, which runs into the sea, 3 miles W. of Beachy head.

CUCKOLD'S POINT, a cape on the E. coast of the island of Barbadoes. N. lat. 13° 32'. W. long. 58° 25'.

CUCKOW, in *Ornithology*. See **CUCULUS**.

CUCKOW, *green yellow bellied*, of Edwards. See **TROGON Curucui**.

CUCKOW-Flower, in *Botany*. See **CARDAMINE pratensis**.

CUCKOW-Flower, in *Agriculture*, is the name of a plant, the (*lychnis flosculi*), which is a common weed in meadows and pastures. It is likewise denominated meadow cuckow-flower, meadow plinks, rugged robin, &c.

CUCKOW-Lamb, in *Rural Economy*, is a name applied in some districts to such a lamb as is yearned in April, or the following month, because it falls in what is termed cuckow-time. These are generally either the lambs of very young or very old ewes, occasioned by their taking ram late in the season. These lambs are usually of the weakest and smallest sort, and therefore both the ewes and lambs should have the best keep, in order to fatten the lambs for the butcher; as such diminutive lambs are improper to be kept for more-sheep flock in most cases, except where necessity obliges the farmer to have recourse to them.

CUCKOW Pint, in *Botany*. See **ARUM**.

CUCKOW-Spit, in *Agriculture*, a name sometimes applied to the frothy substance which is occasionally observed on plants, and which is supposed to afford protection to insects from the heat of the sun, and the attacks of the spider. But it has been supposed by Mr. Lise to be nothing more than the nocturnal dew which descends upon the fork or joint of the plant, and which is worked into a froth by the insects.

CUCKSOO. See **COOSCOOSOO**.

CUCQ, in *Geography*, a small town of France, in the department of the Pa'n, 18 miles N.E. of Caltres.

CUCUBALUS, in *Botany, (Plin.) Tournefort, Cl. 8. § 1. gen 3. Gært. 491. Smith Flor. Brit. 2. 464. Clafs and order, *deandria trigynia*. Nat. Ord. *Caryophyllei*; Linn. and Juss.*

Gen. Ch. *Cal.* one-leaved, inflated, five-cleft half way down, permanent. *Cor.* Petals five; claws nearly the length of the calyx, generally more or less crowned; expansion semibifid. *Stam.* Filaments ten, awl-shaped, inserted alternately into the claws of the petals; anthers oblong. *Pist.* Germ pedicelled, globular, smooth; styles linear, villous their whole length on the interior side; stigmas acute. *Peric.* Berry black, shining, spherical, soft, pulpy, not dehiscent, at first three-celled, but afterwards the partitions shrivel up, and disappear. *Seeds* numerous, attached to a free central receptacle.

Eff. Ch. Calyx one-leaved, inflated. Petals five, furnished with claws. Berry superior, finally one-celled. Seed numerous.

Sp. *C. bacciferus*. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Eng. Bot. 1577. Gært. tab. 77. fig. 7. (*Silene baccifera*; Willd. *Silene fifia*. Salisb. Prod. 302. *Cucubalus* Plinii; Lugdb. 1429. Tourn. 339. Dill. in Rai. Syn. 257. Alone scandens *baccifera*; Bauh. pin. 250. *Viscago*; Hall. Helv. n. 912. *Lychnanthus volubilis*, Gmel. in Act. Petrop. 1759. v. 14. 225. tab. 17. fig. 1.) Berry-bearing chickweed. *Root* perennial, creeping. *Stems* several, annual, three feet long, weak, straggling, much branched, dichotomous, cylindrical, hollow, rough with deflexed hairs. *Leaves* opposite, petioled, widely spreading, egg-shaped, acute, entire, pubescent, pale green, resembling those of *stellaria nemorum*. *Flowers* axillary and terminal; calyx large, bell-shaped, membranous, pubescent; segments reflexed as the fruit ripens; petals greenish-white, distant. A native of France, Italy, Switzerland, Germany, &c.; admitted as an English plant by Dillenius into his edition of Ray's Synopsi, on the authority of specimens sent to Dr. Richardson by Mr. Fowlkes of Llanbeder, near Ruthin, and said to have been gathered in the island of Anglesea; but no other botanist has been fortunate enough to find it there, or in any other part of Great Britain.

Obs. The only essential difference between this genus and *silene*, as settled by Linnæus, and received by most succeeding botanists, is the want of a crown to the claws of its petals. It has been justly observed by La Marck, that this distinction is not only purely arbitrary, and separates plants which are closely united by other natural character; but also that it is in itself by no means in all cases sufficiently clear and determinate; the crown being occasionally obsolete in some plants, which generally have it distinctly marked, and always so small in others, as to make it scarcely visible, and to occasion a doubt to which genus the plant ought to be referred. He adds, but rather inconsistently, that he has retained the Linnæan distribution solely for the sake of facilitating the study of the species, as those already arranged under *silene* are very numerous, and difficult to determine. Gærtner and Dr. Smith have restored Tournefort's original generic character of *cucubalus*, and considered the plant before us as the only species hitherto known. We adopt without hesitation the idea of these eminent botanists, and refer all the species which have a real capsule to the genus *silene*.

CUCUJUS, in *Entomology*, a genus of coleoptera, established by Fabricius, and adopted by Gmelin, in the last edition of the Linnæan Systema. The character of the genus, after the Linnæan method of classification, consists in having the antennæ filiform; feelers four, and equal, the extreme joint truncated, and thicker; lip short, bilid, with linear distant divisions; and the body depressed.

Three of the species belonging to the present genus were known to Linnæus; these are, *depressus*, *cæruleus*, and *flavipes*. The first he considers as a *cantharis*, and describes under the specific name of *sanguinolenta*: the *cæruleus* is the *tenebrio depressus* of that author, and the *flavipes* his *cerambyx planatus*. Swederus gives two new species (*maculatus* and *rufus*), in the Stockholm Transactions, the rest were described originally from various cabinets by Fabricius, who, with much propriety, embodied this natural tribe into a distinct genus. The essential or generic character laid down by Fabricius, is chiefly taken, as usual in the System of that author, from the structure of the mouth; the four equal feelers having the extreme joint truncated, and thicker; the short bifid lip with linear distant

tant divisions; and the antennæ being moniliform and filiform, constitute the Fabrician character of the cucujus genus.

Species.

DEPRESSUS. Thorax denticulate, and with the wing-cases rufous; legs simple and black. Fabr. *Cantbaris sanguinolenta*, Linn.

The antennæ are hairy and black; head depressed with an obtuse-angular globule each side. A native of Germany, according to Frisch and Hattorf.

SULCATUS. Thorax grooved, black; wing-cases marked with crenated striæ.

Found in putrescent wood in Croatia. Saldoner.

RUFIPES. Thorax fulcated; wing-cases black and punctured; antennæ and legs ferruginous.

This is the largest species of its genus, and is found in rotten or decaying wood in Barbary. The antennæ are pale ash, with the first joint black; thorax narrowed behind, and marked with three distinct grooves.

CÆRULEUS. Thorax fulcated and black; wing-cases striated and blue; abdomen rufous. Fabr. *Tenebrio depressus*, Linn.

Found in Germany. The head is black, with the mouth piceous; legs black.

FESTIVUS. Thorax fulcated, black; wing-cases striated, blue; margin of the abdomen, and flanks rufous.

Inhabits the same country as the preceding, and is about half its size.

CASTANEUS. Thorax fulcated, black; wing-cases striated; margin of the abdomen and the legs testaceous.

Described from the cabinet of Smidt as a native of Germany.

DUBIUS. Thorax denticulated and rufous; wing-cases black; antennæ filiform, and the length of the body. Fabr.

Native of North America. The antennæ are very long, and flexuous, with the last joint acute, in which latter particular it differs from the rest of the genus; it does not appear to us as strictly appertaining to this genus.

FLAVIPES. Thorax denticulate and black; legs yellowish; antennæ length of the body. Fabr. *Cerambyx planatus*, Linn.

Inhabits northern Europe, and preys on bark of trees.

DERMESTOIDES. Thorax fulcated, and fuscous; wing-cases smooth and testaceous.

A small species found in Germany. The antennæ are short. Thorax marked with two grooves. Smidt.

TESTACEUS. Thorax somewhat square, unarmed; body testaceous; thighs compressed.

Inhabits Europe, and is found under the bark of the birch tree.

MUTICUS. Thorax unarmed and black, with an impressed dot each side; wing-cases fuscous and striated.

Found in Germany. Hattorf.

MONILIS. Thorax unarmed, black; margin with spots on the wing-cases, ferruginous.

A native of Germany.

RUFUS. Rufescent; antennæ, feelers, and legs black; head gibbous; wing-cases softish. Swederus Nov. Act. Stockh. Inhabits the island of Sumatra.

MACULATUS. Sordid yellow; thorax unequal, squarish; legs, and subquadrangular spot on the wing-cases, black. Swederus.

CUCULARIS MUSCULUS, in *Anatomy*, a name under which the trapezius muscle is frequently described.

CUCULLA, a cowl. See **ABBOT**, and **COWL**.

CUCULLANUS, in *Natural History*, a genus of worms

which infest the intestines of various quadrupeds, birds, and fishes. The character of the genus consists in the body being sharp-pointed behind, and obtuse before: the mouth orbicular, with a striated hood. Several species and varieties of these destructive creatures have been detected by the continental naturalists, especially by Goeze and Müller, who observed most of them to be viviparous.

Species.

* *Infesting the Mammalia.*

TALPÆ. Inhabits the common mole of Europe.

This sort is gregarious, and lives enclosed in a membrane spirally twisted in the fat about the peritonæum. Goeze.

OCREATUS. Body fasciolated; tail sheathed.

Found by Goeze in the intestines of the mole; this creature is believed to be of the oviparous kind; it resembles a piece of straw, is about two inches in length, and lives in clusters or societies.

MURIS. In the lesser intestines of the mouse. Goeze.

** *Infesting Birds.*

BUTEONIS. Inhabits the intestines of the buzzard. Goeze.

*** *Infesting Reptiles.*

RANÆ. Tail foliaceous.

Infests the intestines of the frog.

**** *Infesting Fishes.*

LACUSTRIS. Body rufous, the anterior part truncated. Müll.

Several varieties of this kind of worms are described by writers. Goeze speaks of one (*var. α*) peculiar to the conger eel; another (*perca*) to the river perch, and a third (*lucio-perca*) to the perca lucio-perca. Müller and Pallas observed another variety (*cernua*), in the ruffe, and Goeze two others, one in the salmon (*farionis*), and another in the trout (*fularis*). All these are very fertile, and generally infest the intestines; the last mentioned kind is found also in the liver.

ASCAROIDES. Head orbicular, and hooked each side; tail rounded, short, and pointed, with two exerted spicules.

Infests the stomach of the *silurus glanis*. These are about an inch long, of a greyish-white colour, resemble the maggot of a musca fly, and live together in clusters.

MURINUS. Yellowish-ash, obtuse in front. Müll.

There are two varieties of this kind, *cirratus* and *muticus*, the first of which, as the name implies, is furnished with cirri, the other is unarmed; these are oviparous, and are found in the intestines of the common cod-fish. The body of this species is long, flexuous, round, pellucid, and very finely striated across; the head broad, gut orbicular, and appearing as if burnt on the fore part. The male is armed with blackish, setaceous, bicuspidate prickles at the tail, near the vent; female distinguished by a tuberculate aperture in the middle of the body.

CUCULLARIA, in *Botany*. Schreb. 11. Willd. 16. Class and order, *monandria monogynia*.

Gen. Ch. *Cal.* Perianth one-leaved, deeply four-parted; segments roundish, unequal; two upper ones smaller, divaricated. *Cov.* Petals four, unequal, inserted into the calyx; upper one ascending, wedge-shaped, hollowed, emarginate; lower one larger, inversely egg-shaped, rounded, concave; two lateral ones smaller, vertical, oblong, covered on the lower side by the larger petal; claws broad, short. *Ned.* at the base of the upper petal, corniculate, long, incurved,

curved, obtuse, prominent between the upper distant segments of the calyx. *Stam.* Filament solitary, petal-shaped, oblong, growing broader before, cowl'd at the top, inserted into the bottom of the calyx below the germ, longer than the lower petal, and incumbent on it; cells of the anther two, separated, linear, adnate to the filament within the cowl. *Pist.* Germ egg-shaped, three-furrowed; style filiform, recurved, incumbent on the upper petal; stigma flat upwards, curved below. *Peric.* three-celled. *Seeds* numerous.

Eff. Ch. Calyx four-parted. Petals four, unequal, upper one spurred. Filament petal-shaped. Anther with separated cells.

Sp. C. excelsa. Willd. (*Vochoy guianensis*; Aub. Guian. 1. 18. tab. 6.) A lofty tree. *Leaves* opposite, inversely egg-shaped, acute, veined. *Flowers* yellow, in terminal racemes. A native of Guiana. *C. excelsa* of Vahl is a different species. See *Annals of Botany*, vol. ii. p. 185.

CUCULLARIA; Buxb. See *VALANTIA cucullaria*.

CUCULLATE FLOWERS, among *Botanists*, are such as resemble a *cucullus*, or monk's hood, or cowl. See *CUCULLUS*.

CUCULLUS was anciently a traveller's cap; called also *cowl*, *goul*, or *gula*: whence the name passed to the monks, among whom it signified their frock and cap, which were of one piece.

CUCULLUS, in *Botany*, is used by professor Willdenow to express a peculiar kind of *Nectarium*, or honey-bag, quite distinct from the other parts of the flower, as in *Aconitum*, or Monk's Hood, in which the part in question is double, standing on a pair of stalks, and looking like a couple of little birds. In *Aquilegia*, the columbine, there are five honey-bags, ranged alternately with the petals. The term is also applied, by the same author, to a very different organ, whose nature has not generally been understood, in the *Asclepias*. The anthers in this genus grow out of the stigma, so that none can be more truly gynandrous. They consist of a pair of masses of naked conglutinated pollen, as in the *Orchis* family, and the *cucullus* of Willdenow is a membranous case, or *lamina*, proceeding from the base of the flower, where stamens are usually inserted, and serving to cover and shelter the anther, with which, however, it is totally unconnected. S.

CUCULUS, in *Ornithology*, the cuckow genus. These are of the *picæ* order; their bill is smooth, and a little curved; nostrils surrounded by a small rim; tongue sagittate, short, and pointed; feet formed for climbing. As a secondary character, it may be added, that the toes are usually placed two forward, and two backward, and the tail cuneated, and consisting of about ten soft feathers.

Species.

CAPENSIS. Greenish-brown; beneath white lined with black; cheeks, chin, throat, tail, and upper wing-coverts rufous; tail-feathers white at the tips. *Cuculus capensis*, Gmel. *Coucou du Cap de Bonne Esperance*, Buff. *Édolio*, Kolb. Cape cuckow, Lath.

One of the species of cuckow, found at the Cape of Good Hope; its length is about twelve inches; bill and legs brown, the irides yellow.

GLANDARIUS. Tail wedge-shaped; head somewhat crested; wings brown spotted with white and cinereous; band over the eyes black. *Cuculus glandarius*, Linn. *Cuculus Andalusie*, Briff. *Le grand coucou tacheté*, Buff. Great spotted cuckow.

This is the size of the magpie. The bill is black; crest bluish-ash; shoulders, upper wing, and tail-coverts brown

spotted, quill-feathers brown; tail blackish, with the tips white. Inhabits Andalusia.

CANORUS. Cinereous; beneath whitish, transversely streaked with brown; tail rounded, blackish, dotted with white. *Cuculus canorus*, Linn. *Cuculus*, Geln. *Il cuculo*, Olin. *Coucou*, Buff. *Kuckuck*, Wirling. Common cuckow.

This is the cuckow common to the British isles, and which extends also throughout most part of Europe, Asia, and Africa. The length of this bird is about fourteen inches, the bill black, and two thirds of an inch long; the plumage in general cinereous, transversely barred with deep brown or black streaks; the two middle tail-feathers black, with the tips white, the rest marked with white spots on each side the shafts, and the legs short and yellow. The female differs a little from the male, the neck both before and behind being of a brownish-red, the tail barred with the same colour, and black, and spotted on each side the shaft with white. The young are brown mixed with ferruginous and black.

Those birds feed principally on insects, or when brought up from a young state, as they sometimes are, they will eat bread and milk, fruit, eggs, and flesh, either cooked or raw. It is well known that the cuckow does not hatch its own eggs, but deposits the eggs in the nests of some other birds, generally those of the hedge-sparrow, water wagtail, or yellow hammer, and leaves the care of the young to their foster parents. The cuckow comes into England about the middle of April, or at least its note of love is heard for the first time in the season about that time. It is only the male that sings, and his note ceases before the end of July, though the cuckows do not take their final leave till the end of September, or beginning of October. They migrate from the north of Europe at the close of summer, and pass the winter in the warmer parts of Africa.

The rufous cuckow, *le coucou roux* of Brisson, is a variety of this bird.

TAITENSIS. Fuscous spotted with ferruginous; beneath hoary white, longitudinally striated with fuscous; tail cuneated, and marked with numerous ferruginous brown bands. *Cuculus taitensis*, Mus. Carl. *Cuculus taitius*, Gmel. *Ara wereroa*, Cook's Voyages. *Le coucou brun varié de noir*, Buff. Society cuckow, Lath.

About the size of a magpie, and nineteen inches long; it inhabits Otaheite, where it is called by the natives *arevareva*. The same species is also found in New Zealand and Tongataboo.

MINDANENSIS. Tail rotundate; body golden-green spotted with white; beneath white, undulated with blackish. *Cuculus Mindanensis*, Linn. *Le coucou varié de Mindanao*, Buff. Mindanao cuckow.

Larger than our common cuckow, and measures fourteen inches and a half. It inhabits Mindanao, and other of the Philippine islands.

SCOLOPACEUS. Tail wedge-formed; body clouded with grey and brown. *Cuculus scolopaceus*, Linn. *Le boutfallik*, Buff. *Coucou tacheté de Bengale*, Pl. Enl. Brown and spotted Indian cuckow, Edwards. Indian spotted cuckow, Lath.

Length fourteen inches. This species inhabits Bengal. The bill is dirty yellow-green; the plumage on the upper part rufous, with the feathers edged with brown; wing-coverts white, edged with brown; quills and scapulars transversely striated with brown, and rufous; tail cuneiform, seven inches and a half in length, subrufous, and crossed with oblique broad bands and brown; legs dirty greenish-yellow. In Bengal this bird is known by the name of Boutfallick.

MACULATUS.

CUCULUS.

MACULATUS. Tail elongated; body grey-green, glossed with fuscous, and variegated with white spots; beneath fasciated with brown and white; head black. *Coucou tacheté de la Chine*, Buff. Chinese spotted cuckow. Lath. Syn.

Inhabits Bengal and China; length fourteen inches.

PUNCTATUS. Tail cuneiform; body blackish dotted with rufous, beneath rufous streaked with black; tail-feathers banded with rufous. *Cuculus punctatus*, Linn. *Coucou brun piqueté de roux*, Buff. Rufous spotted cuckow. Lath.

Larger than the common cuckow. The female differs in having the rufous spots on the upper part less numerous than in the male, and the under surface paler. The species is found in the East Indies, and in the Philippine islands.

PANAYUS. Tail entire; body fuscous, with yellowish-rufous spots beneath, and tail banded with rufous and black; thorax black spotted with yellow. *Cuculus panayus*, Gmel. *Coucou tacheté de l'isle de Panay*. Son. Panayan spotted cuckow. Lath.

Inhabits the island of Panay. The beak is black; irides yellow; legs lead colour.

ORIENTALIS. Tail rotundate; body black, glossed with green; bill fuscous. *Cuculus orientalis*, Linn. *Cuculus indicus niger*, Briss. *Le Coucouel*, Buff. *Coucou noir des Indes*, Pl. Enl. Eastern black cuckow, Lath.

Size of a pigeon; length sixteen inches; bill and legs greyish. A native of India. A variety of this bird about fourteen inches in length is found in Mindanao, and another not longer than a blackbird in Bengal.

INDICUS. Tail rounded; body black; wings, and tip of the tail with three irregular transverse white lines. *Cuculus Indicus*, Gmel. Eastern black cuckow. Lath.

Inhabits India, flies in flocks, and feeds on insects. Length sixteen inches. Bill strong and whitish; legs blueish.

VETULA. Tail cuneated; body brownish, beneath testaceous; eye-lids red. *Cuculus vetula*, Linn. *Cuculus Jamaicensis longirostris*, Briss. *Le coucou à long bec*, Tacco, Buff. Long-billed rain cuckow, Lath.

Found in Jamaica, where it frequents woods and hedges all the year round; and feeds on seeds, small worms, and caterpillars, as well as the smaller kinds of serpents, frogs, lizards, and small birds. This bird is of such a gentle disposition, as to suffer the negro children to catch it with their hands. Its length is fifteen inches. This bird is said to be unusually noisy before rain, whence it has obtained the name of rain-cuckow, or long-billed rain-cuckow.

PLUVIALIS. Olive-ash, beneath rufous; chin and throat white. *Cuculus pluvialis*, Gmel. *Cuculus Jamaicensis*, Briss. *Picus major leucophæus*, Raii. *Le coucou dit vieillard*, Buff. Rain cuckow. Lath.

Inhabits the same country as the last; length from sixteen to seventeen inches long, and sings before rain. Both this and the former species are known in Jamaica by the name of Old Man.

MINOR. Olive-ash, beneath reddish; chin white. Mangrove cuckow.

Length twelve inches; its general appearance much resembling the rain-bird. It inhabits Cayenne, and lives on insects, especially those large caterpillars which feed on the leaves of the mangrove.

SERRATUS. Tail cuneiform; head crested; body black and glossy; on the wing a white ferrated spot. *Cuculus serratus*, Mus. Carl. Crested black cuckow. Lath.

Inhabits the Cape of Good Hope. This bird is twelve

inches and a half in length; the tail rather longer than the body; plumage of the thighs lax and long; legs black.

SENEGALENSIS. Tail cuneated; body grey, beneath white; cap and tail-feathers blackish. *Cuculus Senegalensis*, Linn. *Coucou du Senegal*, Pl. Enl. *Rufalbin*, Buff. Straight-heeled cuckow. Lath. Syn.

The length of this bird is fifteen inches and a half, its bulk exceeding that of our common cuckow. This bird inhabits Senegal. The bill is black; rump and upper tail-coverts brown, with deeper streaks; quill-feathers rufous, with brownish tips; legs grey; the inner hind-claw straight and longer.

BENGALENSIS. Ferruginous with white lines; beneath yellowish brown; tail cuneated. *Cuculus Bengalenfis*, Gmel. Lark-heeled cuckow. Brown Illustr.

Rather larger than a lark, and, like that bird, having the hind toe furnished with a long straight claw. This curious species inhabits Bengal.

HONORATUS. Tail cuneated; body blackish, spotted with white, beneath barred with white, and cinereous. *Cuculus honoratus*, Linn. *Cuculus Malabaricus navius*, Briss. *Cuil*, Buff. *Coucou tacheté de Malabar*, Pl. Enl. Sacred cuckow.

Inhabits Malabar, and being a great enemy to snakes and other noxious reptiles, is held sacred by the natives. Its length is eleven inches and a half.

PUNCTULATUS. Tail cuneated; body brown, the tips of the feathers sub-rufous; beneath dirty-white. *Cuculus punctulatus*, Gmel. Punctated cuckow. Lath.

Native of Cayenne; length nine inches.

GUIRA. Crested, yellowish-white; tail and wings brown; head brown in the middle, yellowish at the sides; neck yellowish in the middle, and brown at the sides. *Cuculus guira*, Gmel. *Guira acangatarata*, Raii. *Le guira cantara*, Buff. Brazilian crested cuckow. Lath.

Found in the woods of Brasil. The bill is yellowish; irides fuscous; and the legs sea-green.

AMERICANUS. Tail cuneated; body above cinereous, beneath white; lower mandible pale yellow. *Cuculus Americanus*, Linn. *Cuculus carolinensis*, Briss. *Le vieillard à ailes rouffes*, Buff. *Coucou de la Caroline*, Pl. Enl. Carolina cuckow. Catesby.

Length twelve inches. Inhabits Carolina, principally in woods.

PISANUS. Tail cuneated; body above varied with white and black, beneath white; head black, crested; chin and breast rufous. *Cuculus pisanus*, Gmel. Pisan cuckow. Lath.

Taken at Pisa in the year 1739. Its size rather exceeds that of the common cuckow.

MELANOLEUCOS. Black, beneath white; tail cuneated with the tip white; wings with a white spot; head sub-crested. *Cuculus melanoleucus*, Gmel. *Jacobin huppé de Coromandel*, Buff. Coromandel crested cuckow.

Length eleven inches. A native of Coromandel. The bill is black; legs fuscous.

MADAGASCARIENSIS. Olive-waved with brown, beneath tawny, chin olive-yellowish. *Cuculus Madagascariensis*, Gmel. *Coucou verdâtre de Madagascar*, Buff. Great Madagascar cuckow. Lath.

Measures twenty-one inches and half in length. The species inhabits Madagascar.

CHRYSOCEPHALUS. Head yellow; breast and shoulders lead colour; quill-feathers black; tail yellowish-brown, with numerous black bars. Gmel.

Inhabits South America.

DOMINICUS. Tail wedged; body grey-brown, beneath whitish;

CUCULUS.

whitish; three lateral tail-feathers white at the tip. *Cuculus dominicus*, Gmel. *Le cendrillard*, Buff. St. Domingo cuckow. Lath.

Inhabits St. Domingo, Guiana, and Louisiana. Length ten inches.

CAYANUS. Tail wedged; body purplish-chestnut; beneath cinereous; tail-feathers white at the tip. *Cuculus Cayanus*, Linn. *Coucou piaye*, Buff. Cayenne cuckow. Lath.

Found near rivers in Cayenne. The length is sixteen inches: it is of a docile disposition, and easily tamed. The legs and claws are grey-brown; quill-feathers brown at the tips; tail chestnut, and ten inches long. There are two varieties of this species, one of which is purplish beneath, and measures only ten inches and a half long. The other has the bill red; head cinereous; chin and breast rufous, and belly cinereous black.

TRANQUILLUS. Black, beneath inclining to cinereous; tail cuneated, upper wing-coverts edged with white. Gmel. Cayenne black cuckow.

Length eleven inches; bill and irides red. This bird is of a solitary nature, and inhabits Cayenne.

TENEBROSUS. Black; belly and thighs rust colour; rump and vent white; tail cuneated. *Cuculus tenebrosus*, Pallas. *Le petit coucou noir de Cayenne*, Buff. White-rumped black cuckow. Lath.

Inhabits Cayenne, where it frequents trees growing near the water side; it builds in hollow trees, or on the ground, and feeds on insects. Length eight inches and a half.

PYRRHOCEPHALUS. Black, beneath white; crown scarlet, surrounded by a circle of white; tail long, with the tip white. *Cuculus pyrrhocephalus*, Zool. Ind. Red-headed cuckow.

Frequent in the woods of Ceylon. The bill is curved, of a greenish-yellow colour; head and neck marked with small white spots; legs blueish. Length sixteen inches. This kind feeds on fruits.

CAERULEUS. Tail rounded; body blue. *Cuculus caeruleus*, Linn. *Tait fou*, Buff. *Coucou bleu de Madagascar*, Pl. Enl. Blue cuckow. Lath.

Size of the common cuckow; legs and feet black. Inhabits the island of Madagascar.

SINENSIS. Tail long, cuneated; body blue, beneath white; tail-feathers with a white spot at the tips. *Cuculus sinensis*, Linn. *Sanhia de la Chine*, Buff. Chinese cuckow. Lath.

Length thirteen inches; bill, irides, legs, and claws red; crown white, dotted with blue, the rest of the head and chin blackish, and a round patch on the cheeks of white.

AFER. Brassy-green; beneath shining grey; head and neck cinereous; crown brassy-black; tail even, golden-green, beneath black. *Cuculus afer*, Gmel. *Le vouroudriou*, Buff. *Le grand coucou de Madagascar*, Pl. Enl. African cuckow. Lath.

The bill of this bird is straight, blackish, and two inches long; legs reddish; claws black. The total length of the bird fifteen inches. This species inhabits Madagascar.

CUPREUS. Golden-copper; belly and thighs yellow. Cupreous cuckow. Lev. Mus.

Native place uncertain, supposed to be Africa. Its size that of a lark. Tail cuneated, with one or two of the exterior lateral feathers marked with a triangular white spot at the tip; bill and legs black.

INDICATOR. Rusty-grey, beneath white; eyelids naked and black; shoulders marked with a yellow spot; tail cuneated and rusty. *Cuculus indicator*, Gmel. *Le coucou indicateur*, Buff. *Maroc*, *Lobos Abyssin*. Honey guide, Phil. Transl. Honey cuckow, Lath.

The length of this bird is seven inches. The bill is brown at the base, and surrounded with bristles; feathers of the thighs white, with a longitudinal black streak; quill-feathers above brown, beneath grey-brown; the first tail-feathers are very narrow and rusty, the next footy, the inner edge whitish.

The manners of this bird, according to Dr. Sparrman, who particularly describes it, are very singular. The bird feeds principally on honey; and by its note, when in quest of this favourite food, points out to the natives the hiding-places in the trees where the wild bees deposit their stores. The morning and evening are the times of its feeding; and it has a shrill note, which the Hottentot and Dutch hunters carefully attend to, and answer from time to time, till the bird appears in sight, on which they follow it, till it alights on the trees in which the honey is concealed. The hunters never fail to reward their guide with a portion of the booty. Dr. Sparrman assures us, that he has several times been present at the taking of the nests of the wild bees in this manner; but could only obtain two specimens of the birds, both which were females: the inhabitants highly valuing the bird for its useful habits, and conceiving it criminal to destroy it. A nest was shewn Dr. Sparrman, with an assurance of its belonging to this bird: it was composed of slender filaments of bark, interwoven into the form of a bottle; the neck and opening being downwards, and a string, in an arched manner, was suspended across the opening, and fastened to the two ends, supposed to be contrived for the bird to perch upon.

PERSA. Tail equal; head crested; body blueish-green; quill-feathers blood-red. *Cuculus persa*, Linn. *Le touraco de Guinée*, Buff. Crown bird from Mexico. Albin. *Touraco*, Edwards. Mexican cuckow.

Inhabits various parts of Africa, and feeds on vegetables.

REGIUS. Black, with a blue gloss; quill-feathers crimson; bill red, with a yellow front; back of the head purple. Royal cuckow.

Found in the interior parts of Africa.

BRASILENSIS. Tail nearly equal; head crested; body red; quill-feathers yellowish. Linn. *Le couroucoucou*, Buff. Red crested cuckow. Lath.

Inhabits Brasil. Length ten inches; bill pale red; crest red, variegated with black; belly mixed with yellowish; quill-feathers and tail yellow, with a shade of black.

CRISTATUS. Tail rounded; head crested; body shining greenish-ash. Gmel, &c. Madagaicar crested cuckow. Lath.

The length of this bird is fourteen inches. Its bill and legs black; irides orange; breast claret; belly whitish, glossed with rufous; wings and tail beneath cinereous; exterior tail-feathers tipped with white. Inhabits Madagascar.

ÆGYPTIUS. Brown, beneath tawny-white; head, neck, and cuneated tail green; wings rufous. Gmel. Egyptian cuckow.

Length from fourteen to sixteen inches. The bill is black; irides shining red; upper tail-coverts rufous, inclining to green; three last quill-feathers rufous; legs blackish. This kind inhabits Egypt, and feeds on locusts. The bird supposed to be the male is of a shining black colour, with rufous wings.

POLIOCEPHALUS. Tail somewhat cuneated; body above brownish-ash, beneath white, barred with grey; tail-feathers black, with dusky bars. *Cuculus poliocephalus*, Gmel. Grey headed cuckow.

Inhabits India, and very much resembles the last.

SONNERATIÆ.

SONNERATII. Banded with black; above rufous-brown, beneath white; tail-feathers spotted with black. *Cuculus Sonneratii*, Gmel. Sonnerat's cuckoo.

Size of a blackbird. Bill, irides, and legs yellow. Inhabits India.

HEPATICUS. Tail cuneated; body undulated with brown and black; rump ferruginous; bill, tips of the wings, and bands on the tail black, beneath whitish, waved with black; legs yellow. *Cuculus hepaticus*, Gmel. Liver-coloured cuckoo.

Length thirteen inches and a half. Tail-feathers rusty-brown, barred with black, tipped with white, and marked with a small white terminal spot. Native place unknown.

FLAVUS. Testaceous, beneath yellowish; crown and chin pale grey; tail cuneated, black with white lines. *Cuculus flavus*, Gmel. Yellow-bellied cuckoo.

Eight inches in length. The bill and legs yellowish; irides yellow. Inhabits the isle of Panay.

AURATUS. Tail cuneated; body above golden-green, beneath white; five streaks on the head; wing-coverts, secondary quill and tail-feathers at the tip white. *Cuculus auratus*, Gmel. Gilded cuckoo.

Inhabits the Cape of Good Hope. The length of this bird is seven inches. Bill greenish-brown; legs grey.

LUCIDUS. Above green, beneath white; each side a green-gold lunule; quill-feathers and tail brown. *Cuculus lucidus*, Gmel. Shining cuckoo.

A native of New Zealand. Length seven inches. Bill and legs blue; lower tail-coverts white.

COROMANDUS. Tail cuneated; body black, beneath white; collar white. *Cuculus coromandus*, Gmel. Collared cuckoo.

Inhabits Coromandel. Length twelve inches and a half.

CORNUTUS. Tail cuneated; crest bifid; body footy. *Cuculus cornutus*, Linn. Horned cuckoo.

The bill of this bird is greenish-yellow; irides red; crest moveable, and resembling horns; body beneath, with the legs and claws cinereous; tail tipped with white. Inhabits Brazil, and is about twelve inches in length.

DISCOLOR. Reddish-brown; crest biid and orange; two exterior tail-feathers white, the rest white at the tip. *Cuculus discolor*, Gmel. Brown cuckoo.

A native of the East Indies.

PARADISEUS. Two exterior tail-feathers very long and dilated at the tip; head crested; body green. *Cuculus paradiseus*, Gmel. *Le coucou à longs brins*, Buff. Paradise cuckoo.

Inhabits Siam. The length of this bird is eighteen inches. The bill blackish; legs and claws grey.

CUCUMBER, in *Botany*. See **CUCUMIS**.

CUCUMBER, *single-seeded*. See *SICYOS angulata*.

CUCUMBER, *small creeping*. See *MELOTHIA pendula*.

CUCUMBER, *snake*. See *TRICHOSANTHES anguina*.

CUCUMBER, *spiriting*, or *affes*. See *MONORDICA elaterium*.

CUCUMBER, in *Gardening*, is a well known tender plant of the exotic kind, much cultivated in hot-bed frames for the fruit. See **CUCUMIS**.

CUCUMIS, in *Botany*, (derived by Varro from *curvor*, alluding to the crookedness of the fruit. Συκος; Theophr. supposed by some critics to be the קִיפָּה, or gourd of the prophet Jonah.) Linn. gen. 1092. Schreb. 1479. Willd. 1741. Gært. 552. Juss. 395. Vent. 3. 515. Class and order, *monocia syngenesia*, Linn. *Monocia monadelphia*, Willd. Nat. Ord. *Cucurbitaceæ*, Linn. Juss.

Gen. Cha. Males. Cal. perianth one-leaved, bell-shaped, the margin terminated by five awl-shaped teeth. Cor. ad-

nate to the calyx, bell-shaped, five-parted; divisions egg-shaped, veiny-wrinkled. Stam. Filaments in three sets very short, inserted into the calyx, converging; two of them bifid at the tip; anthers five, adnate, linear, serpentine upwards and downwards. *Receptacle* trigonous, truncated, in the centre of the flower. Females separate, but on the same plant. Cal. Perianth as in the male, superior, deciduous. Cor. as in the male. Stam. Filaments acuminate, very small, without anthers. *Pistl.* Germ inferior, large; style cylindrical, very short; stigmas three, thick, gibbous, two-parted, turned outwards. *Peric.* Pome (Berry; Gært; Vent. Smith.) three-celled; partitions membranous, soft, distinct. *Seeds* numerous, ovate-acute, compressed, sharp-edged, generally in a double row.

Ess. Ch. Calyx five-toothed. Corolla five-parted. Filaments in three sets. Stigmas three. *Seeds* sharp-edged, without a border. In this genus are comprehended three of Tournefort's; cucumis, melo, and colocynthis, with part of his anguria.

Sp. 1. *C. colocynthis*. Bitter cucumber, or coloquintida. Linn. Sp. Pl. 1. Mart. 1. Lam. 8. Willd. 1. Woodv. Med. Bot. vol. iii. pl. 175. Blackw. tab. 441. Salb. Hort. 1. tab. 70. (*Colocynthis fructu rotundo major*; Bauh. pin. 313. Tourn. 107. Rai. hist. 642. *C. amara cathartica*; Lob. Ic. 645.) "Leaves multifid; pomes globular, smooth." *Root* annual. *Stems* slender, trailing, angular, scabrous with short hairs, branched. *Leaves* petioled, deeply and obtusely sinuated, green above, whitish and clothed with short hairs underneath. *Flowers* small, yellowish, axillary, solitary. *Fruit* the size of an orange, globular, yellowish when ripe, with a thin coriaceous rind, containing a white spongy intensely bitter pulp. A native of the Levant. The dried pulp separated from the rind is imported into this part of Europe from Aleppo, and is the coloquintida of the shops, the *κόκκυβις* of the Greeks, and the alhandal of the Arabs. For its medical qualities, see **COLOCYNTHIS**. 2. *C. prophetarum*. Linn. Sp. Pl. 2. Mart. 2. Lam. 9. Willd. 2. Jacq. hort. tab. 9. Blackw. tab. 589. (*Colocynthis pumila*; Shaw. afr. 164.) "Leaves heart-shaped, five-lobed, finely toothed, obtuse; pomes globular, spinous-muricated." *Root* annual. *Stems* a foot and half long, trailing, slender, striated, rough with short distant hairs. *Leaves* petioled, greenish, rough underneath, cloven half way down into three lobes, the two lateral lobes more or less deeply two-lobed. *Fruit* variegated with alternate greenish and yellowish streaks, vyeing in bitterness with coloquintida. A native of Arabia. 3. *C. Africanus*. Linn. jun. Supp. 423. Mart. 4. Lam. 10. Willd. 3. Herm. Par. 133. tab. 134. Rai. hist. 3. 334. "Leaves palmate-sinuated, acute; stem angular; pomes oval, echinate." *Stems* numerous, slender, trailing. *Leaves* petioled, quinquefid. *Flowers* yellow, small; males on filiform, somewhat villous peduncles. A native of the Cape of Good Hope. 4. *C. anguria*. Linn. Sp. Pl. 3. Mart. 3. Lam. 11. (*Anguria americana, fructu echinato eduli*; Tourn. 107. *C. anguria folio*; Sloan. Jam. 103. Pluk. tab. 170. fig. 3. *C. subhirsutus minor*; Brown. Jam. 353.) "Leaves palmate-sinuated; pomes globular, echinate." *Root* annual. *Stems* four or five feet long, angular, hispid. *Leaves* petioled, deeply sinuated, rough. *Flowers* yellow, axillary, small as those of bryony. *Fruit* whitish. A native of the West Indies, where the green fruit is eaten, but is far inferior to our common cucumber. It is also frequently used, with other herbs, in soups, and is esteemed an agreeable wholesome ingredient. 5. *C. acutangulus*. Linn. Sp. Pl. 4. Mart. 5. Lam. 7. Willd. 5. Jacq. hort. 3. tab. 73, 74. (*C. longus indicus*; Grew Mus.

Muf. 229. tab. 17. fig. 2. Petola; Rumph. Amb. 5. 458. tab. 149. Picinna; Rheed. Mal. 8. 13. tab. 7.) "Leaves round-angular; pomes with ten acute angles." *B.* "Fruit shorter, somewhat top-shaped." *C. indicus striatus*; Pluk. Alm. 123. tab. 172. fig. 1. *Root* annual. *Stem* climbing, slender, pentagonal, almost smooth. *Leaves* petioled, heart-shaped, sharply angular, ferrate-toothed, green above, pale underneath, rough with very short hairs. *Flowers* yellowish, rather large; males in a terminal raceme, bracteate; females solitary, axillary. *Fruit* six or eight inches long, lessened towards the peduncle, terminated by a pointed deciduous operculum, smooth, becoming dry and woody when ripe. A native of the East Indies, China, and Tartary. Its fruit, when half ripe and tender, is eaten either boiled or pickled, but is rather insipid. Loureiro observes, that the operculum attributed to the fruit is not noticed by Rumphius, nor was it found in the plants examined by himself in Cochinchina and China. 6. *C. conomon.* Mart. 12. Lam. 6. Willd. 6. Thunb. Flor. jap. 324. (Kwa; Kämpf. Amœn. 811.) "Leaves angular, somewhat lobed, toothed; pomes spindle-shaped, ten-furrowed, smooth." *Root* annual. *Stem* decumbent, striated, rough with scattered hairs. *Leaves* petioled, heart-shaped, nerved, green above, pale underneath, rough with hairs on both sides, especially on the nerves underneath; petioles about three inches long, hairy. *Flowers* yellow, axillary, clustered, on short lipid peduncles. *Fruit* the size of a man's head. A native of Japan, where it is cultivated in great abundance. Its flesh is firm, and is a common food with the Japanese. 7. *C. melo.* Common or musk melon. Linn. Sp. Pl. 5. Mart. 6. Lam. 1. Willd. 8. (*Melo vulgaris*; Bauh. pin. 310; Tourn. 104. Rai. hist. 644. Blackw. tab. 329.) "Angles of the leaves rounded; pomes generally either torulose or reticulated." *Root* annual. *Stems* trailing to a great length, much branched, furnished with tendrils, scabrous. *Leaves* alternate, petioled, slightly toothed, rough with short bristly hairs. *Flowers* yellow, rather small, axillary, solitary, on short peduncles; calyx covered with white hairs; corolla wrinkled, ribbed, with bristles on the ribs on the outside; germ nearly globular, covered with white hairs. The pistiferous flowers have been observed in England to have large, apparently fertile anthers, and to be therefore really hermaphrodite, but as they are accompanied by flowers which have stamens only, the pollen in their anthers is probably defective. This peculiarity has not been noticed by the French botanists. *Fruit*, as in most plants which have been long in a state of general cultivation, very various in its size, form, and other qualities; commonly roundish or oval, sometimes a little flattened at both ends; in some varieties the size of a man's head; in others, of a moderate size; and in others, much smaller; the external surface of some even; of others, warty; of others, more or less netted; and of others, marked with rounded, protuberant longitudinal ribs; the colour either grey, yellowish, or green; rind thickish and rather hard; flesh white, green, yellow or reddish, abundant, tender, succulent, of an agreeable taste, and pleasant smell, sometimes a little resembling that of musk; the inner pulp watery, appearing to consist of broken fibres sweet-tasted. *Seeds* numerous, commonly in a double row, flattish oval, covered with a tough skin similar to parchment, which contains a sweet oleaginous, saponaceous kernel. The melon is generally esteemed one of the most delicious summer fruits, and when taken in moderate quantity is of easy digestion; but if taken to excess is apt to produce violent and sometimes dangerous disorders in the stomach and bowels. It is pe-

cularly refreshing in hot climates, where it is of a superior quality, abounds more in saccharine matter, and is said rarely to disagree. In Europe it is commonly eaten with sugar, and if pepper or ginger be added, it is less likely to produce any unpleasant consequences. In France it is eaten as a sauce to boiled beef, and, as Mr. Pinkerton asserts, is then perfectly harmless. The flesh is also preserved for the same purpose in vinegar and sugar, which, seasoned with cinnamon and cloves, makes a pleasant wholesome composition and will keep several years. The wild plant from which these luxurious varieties have been derived is unknown, but is said by Linnæus to be a native of Tartary. For a more particular account of the principal varieties, and of the manner in which they are cultivated, see the article CUCUMIS, in *Gardening*. 8. *C. muricatus.* Willd. 7. "Leaves heart-shaped, angular; angles rounded, hoary underneath; pomes cylindrical, muricated." *Leaves* similar to those of the preceding, pubescent; younger ones tomentous on both sides. *Male flowers* axillary, clustered, very short, peduncled; females solitary. A native of Tranquebar, Klein. 9. *C. dudaim.* Linn. Sp. 6. Mart. 7. Lam. 5. Willd. 9. (*C. orientalis*; Walth. Hort. 133. tab. 21. *Melo variegatus*; Dill. Elth. 223. tab. 77. fig. 218. *Melo pusillus*; Pluk. Alm. 143.) "Angles of the leaves rounded; pomes cylindrical, with the navel retuse." *Root* annual. *Lower leaves* roundish, upper somewhat angular; both slightly villous and toothed, green above, paler underneath. *Flowers* yellow, divided into five or six roundish segments, slightly crenate. *Fruit* the size and form of an orange; rind smooth, sometimes sparingly warty, slightly furrowed only at the top, variegated with green and dark orange streaks, and with oblong unequal green spots, yellow when fully ripe, and at length whitish; with a whitish musky smell, and a whitish insipid pulp. A native of the Levant. 10. *C. Chate.* Linn. Sp. Pl. 7. Mart. 8. Lam. 4. Willd. 10. (*C. ægyptius rotundifolius*; Bauh. pin. 310. Tourn. 104. Chate; Alp. Ægypt. 114. tab. 116. Vcl. Ægypt. 47.) "Hirsute; angles of the leaves rounded, toothed; pomes spindle-shaped, attenuated at both ends, rough with hairs." *Root* annual. Whole plant villous, almost tomentous, whitish green, with the habit of the common melon, but decidedly distinguished by the form of the fruit. *Stems* procumbent, villous, obtusely pentagonal, zig-zag, branched. *Leaves* petioled. *Flowers* yellow, small, axillary. A native of Egypt, where it is much cultivated for the sake of the fruit, which is esteemed wholesome, and eaten both raw and cooked, but when raised in our climate, is very indifferent. A pleasant refreshing beverage is also obtained from it in the following manner. When the fruit is quite ripe, but not separated from the stem, a hole is made in its upper end, into which a stick is introduced, for the purpose of bruising the pulp; the hole is then closed up with wax, and the fruit, still fixed to the stem, is placed in a hole underneath, and covered with earth. At the end of a few days the pulp becomes entirely dissolved, and with the addition of a little sugar, is fit for use. 11. *C. pubescens.* Willd. 11. "Leaves heart-shaped, somewhat angular, rather acute, sharply toothed, scabrous; pomes elliptical, obtuse, pubescent." *Root* annual. *Fruit* three inches long, near one inch thick, obtuse at both ends; green when young, and marked with rather obscure narrow longitudinal streaks; afterwards entirely white. 12. *C. maculatus.* Willd. 12. "Leaves heart-shaped, obtusely angular, roundish-obtuse, finely toothed, scabrous; pomes elliptical, narrowed at the base, smooth." *Root* annual. *Fruit* somewhat similar to that of the preceding, but smooth, and narrowed at the base, marked when young with broad green streaks; white when ripe,

C U C U M I S.

ripe, and variegated with green spots. Native country unknown. 13. *C. sativus*. Common cucumber. Linn. Sp. Pl. 8. Mart. 9. Lam. 2. Willd. 13. Gært. tab. 88. fig. 3. Sabb. Hort. 1. tab. 63. Black. tab. 4. Lam. Ill. 795. Bauh. pin. 310. "Angles of the leaves right; pomes ovate-oblong, scabrous." *Root* annual. *Stems* creeping, hispid, rough. *Leaves* larger, longer and thicker than those of the melon, less rounded, with sharper and more projecting terminating angles. *Flowers* yellow, axillary; germ oblong, obscurely angular, not hairy, but mucicated with prickles springing from a smooth warty substance. *Fruit* elongated, almost cylindrical, obtuse at both ends, scabrous, with warts, yellowish, white or green in different varieties; rind thin, coriaceous; flesh spongy; primary cells three or four, each divided into two secondary ones, and these again into the proper cells of the seeds, filled with a pulvulent jelly. Supposed to be a native of Tartary, cultivated in almost every part of the civilized world. For its most remarkable varieties and the mode of its cultivation, see the article CUCUMIS, in *Gardening*. 14. *C. anguinus*. Linn. Sp. Pl. 10. Mart. 10. Willd. 14. (Petola anguina; Rumph. Amb. 5. 407. tab. 148.) "Leaves lobed; pomes cylindrical, very long, even-surfaced, twisted." *Root* annual. *Flowers* smaller than others of the genus, with a long tube. *Fruit* three feet long, or more, red when ripe, with a rank smell, and bitter taste. A native of the East Indies. According to La Marek it is only a variety of *trichosanthes anguina*. 15. *C. flexuosus*. Linn. Sp. Pl. 9. Mart. 11. Lam. 3. Willd. 15. Bauh. pin. 310. Tourn. 104. (*C. oblongus*; Dod. Pempt. 662. *C. anguinus flexuosus*; Lob. Ic. 639.) "Leaves angular, somewhat lobed; pomes cylindrical, furrowed, curved." *Root* annual. *Stems* slender, creeping, villous. *Leaves* petioled. *Flowers* small, yellow, axillary. *Fruit* the size of a large pear, thicker at the upper end, smooth, even-surfaced, of a delicious flavour. A native of the East Indies; cultivated in Japan, where it is called by the Dutch basket melon.

CUCUMIS triphyllus; Plum. See ANGURIA *trifoliata*.

CUCUMIS, in *Gardening*, comprehends plants of the tender trailing annual kind, of which the species mostly cultivated are the common cucumber, (*C. sativus*) and the common or musk melon, (*C. melo*).

In the first of these species the roots are constituted of many long slender white fibres, the stems being likewise long, rather slender, and very branchy at their extremities, either trailing on the surface of the ground, or climbing by means of clasps; the leaves are large and angular, on long erect footstalks, with much bristly roughness. The flowers have the segments of the calyx much longer, and the corolla of a deeper yellow colour, than in the melon. They are male and female on the same plant, in the same or different fruits, the latter being succeeded by oblong rough fruit.

In the second species the roots are composed of a great number of very stout wide spreading fibres, the stems being

procumbent or trailing to a considerable length, very much branched, and furnished with tendrils for climbing; the leaves are palmate-5-nate, or entire, slightly toothed, having rounded corners and rough with bristles; the flowers are pale yellow in colour, lateral and solitary, those which are termed female having four large anthers, with the germ sub-globular, and covered with white hairs.

It has been suggested by Martyn, that the discovery of what are usually termed female flowers, being *real* hermaphrodites with fertile anthers, renders it less necessary to convey the males to them, as practised by some, than is commonly supposed.

The fruit is of a roundish or oval form, blunt, usually furrowed longitudinally, occasionally netted, and warted, or carbuncled, being from four to twelve inches in length and diameter, of a yellowish green, or white colour, and having a firm pulp, musky, reddish, seldom green. It is said to have been first introduced into Europe from Persia.

Of the first of these species, or the cucumber, the principal varieties are, the *common rough green prickly*, which is six or seven inches long, with a dark-green skin, closely set with small prickles, and which is hardy, a plentiful bearer, but does not fruit early. The *short green prickly*, which is three or four inches long, with a rather smooth skin, but having small black prickles; it is one of the hardiest and earliest sorts. The *long green prickly*, which is from six to eight or nine inches long, thinly set with prickles, and a good bearer; there is a sub-variety also with white fruit. The *early green cluster*, which is shortish, early, with the flowers in clusters. The *long smooth green Turkey*, with large stalks and leaves, and the fruit generally from ten to fifteen inches long, with a smooth rind without prickles. The *long smooth white Turkey*, which is less watery, and of a better quality. The *large smooth green Roman*, with long large fruit, quite smooth. The *long white prickly Dutch*, with fruit eight or ten inches long, white, with small black prickles, which is a bad bearer, less hardy, but the fruit not so watery, and with fewer seeds.

And of the second sort or melon, there are also numerous varieties, but those most deserving of cultivation are, the *Cantaleupe*, so called from a place near Rome, where it has been long cultivated. Its flesh, when in perfection, is delicious, and may be eaten with safety. The outer coat is very rough, and full of knobs and protuberances like warts; it is of a middling size, rather round than long, and the flesh, for the most part, of an orange colour. There are several sub-varieties, such as the *large black carbuncled*, or *black-rock*, which is of a blackish green-colour; the *large green carbuncled*; the *large white carbuncled*, and the *orange*. The *Romana*, which is forwarder in the season than the above. The *suocado*, which is also a good sort when cultivated for early fruit, but inferior to the cantaleupe. The *zatte* is likewise a good sort, but very small, seldom bigger than a large orange; it is a little flattened at the two ends, and the outer coat is warted like the small cantaleupe. The *small Portugal*, sometimes termed the *dornier melon*, is a pretty good fruit, the plants generally producing them in plenty. It may be cultivated for an early crop. And the *black Galloway*, introduced from Portugal by lord Galloway, is likewise a good sort for early cultivation, as the fruit ripens in a very short time from its first setting. There are likewise some other varieties which may be cultivated.

Method of Culture.—In the raising and producing of these different fruits, much care and attention are necessary, as well as a considerable degree of skill in the regulation, management, and application of the heat which is required to bring them to maturity in the best and most perfect manner.

Mode of Culture in the Cucumber kind.—The common method of raising these plants is by sowing the seeds annually in hot-beds covered by frames and glasses, for the early production of fruit, and in the open ground for the late crops. The former mode must, however, in general, be that which is practised in some degree or other, till the season becomes perfectly warm and settled, as towards the latter end of May or beginning of June. Various are the methods of applying heat in the producing of this fruit, at early and late periods, which have been employed and recommended; but those which seem to have had the greatest success are *dung hot-beds, bark hot-beds, steam-pans, and flued pits*. It is sufficiently obvious that, in whatever manner artificial heat is made use of in this intention, the great point to be attended to is, that of communicating and continuing it in as regular and equal a way as possible. But there is another circumstance which equally deserves consideration in the business; which is, that of its being accompanied with a suitable degree of moisture. It is conceived to be principally on this account that stable-dung answers more completely in the raising of this sort of fruit than tanner's bark, or the use of flued pits, which have been more lately had recourse to for the purpose. The author of the Forcing Gardener has remarked that the deficiency of this gentle moist heat is the reason why bark hot beds are less useful for raising the early crops, but highly serviceable in the late ones, as they have the effect of "drying off the external damps which are then prevalent," and of course hasten the maturity of the fruit. In other cases the plants "are impatient in a dry fire heat."

The most material, and, indeed, chief objections to the employing of the steam of boiling water in the forcing of cucumbers, are the great difficulty of keeping the heat up in a regular manner, and the vast trouble that attends the use of it.

The great and principal inconveniences that have been met with in the forcing of this fruit on dung hot-beds, are the danger of injuring the plants by too much heat, and that of their being blanched by the rank steam that mostly abounds. In order, therefore, to obviate these inconveniences, it has been attempted to raise these fruits on the beds of the preceding year by means of linings of fresh dung; but in practice it has not only been found that such beds are equally liable to damps; but at the same time exposed to much risk and inconvenience from the frequent loss of heat in the linings, which are made use of for the purpose.

On these different accounts it is therefore conceived probable that, until some more convenient mode of applying and keeping up a regular moist heat be discovered, than has hitherto been made use of, the practice of procuring this sort of fruit on fresh made dung hot-beds, must be had recourse to as the best and most certain method for the early crops in all cases.

In the raising and cultivating of the cucumber in this way, the apparatus and materials which are principally necessary in carrying it to any considerable extent, are a sufficient number of frames or pits of different sizes, with glass lights for covering them, so as to prevent the entrance of water and air. And it is usual, where this culture is much attended to, and practised in the most perfect manner, to have a one-light frame for the seed-bed; a two-light one for pricking out the young plants, and nursing them in; and two or more two-light frames for their fruiting in: but they may be cultivated very well, on a small scale, with one or two small frames, or proper pits. See *Forcing FRAME* and *FRAME*.

In order to the constructing of the hot-beds, the prin-

cipal material is that of fresh horse-dung in neither too long or too short a condition, but such as is proper for taking on the process of fermentation. It should be had in the proportion of about one cart-load to each light, and be prepared for the purpose by being well shaken together into a heap, ten days or a fortnight before it is made use of; as by this means a regular heat will be brought on, and the rank heat and steam, as well as the disagreeable smell, be removed. Some gardeners, in order to promote these intentions, and render the preparation more perfect, have the whole turned over once or twice. Care, however, should be taken, that the reduction of the dung be not carried too far before it is put on the bed: as, where that is the case, too little heat will afterwards be produced, and there will be want of regularity in its being supplied.

In cases where this sort of material is scarce, and there is bark at hand, beds for the purpose may be made with it, having only dung for the outides; but care must be taken, that they be so covered as that the roots of the plants never reach the bark, as it cankers and destroys them in a very short time, by which much loss and disappointment must be sustained.

In respect to the manner of making beds for this sort of culture, some gardeners, where proper forcing grounds are not provided, with a view of neatness, sink the foundations of them; but this should never be practised, except where the soil is very dry and gravelly, as the stagnation of moisture is very prejudicial in the bottoms of such beds. If the soil be of a moist retentive nature, it will indeed be highly beneficial to have the bottoms raised to some height above the surface of the natural ground. Besides, where they are not sunk, the heat from the linings is more beneficially applied, and, at the same time, with greater facility and convenience.

In all cases where proper forcing grounds are not made use of for the culture of these plants, open, dry warm, sheltered situations, which decline to or have southern aspects, should be chosen for the purpose.

The earthy material, or mould for covering the beds with, should be of a light, good, rich quality, prepared by being thrown into a heap for several months before it is employed. The author of the Scotch Forcing Gardener advises three-fourths of the richest black loam that can be procured from a pasture, and one-fourth of vegetable mould from decayed tree-leaves, mixed and incorporated well with a due proportion of good stable-dung, as the best for this purpose. The rotten dung of old hot-beds is, however, most commonly employed with such earthy substances as those just mentioned.

But the mould made use of for the more early crops should be laid up in some open place, where it may be kept in a rather dry condition, to render it more fit for the purpose, when it may be wanted.

And when it is to be made use of, it should not be rendered fine by sifting; as when made too fine, it is apt to be too close and compact, and by that means not only to prevent the roots of the plants from perfectly establishing themselves, but confine the heat too much, and endanger the plants in that way in a considerable degree.

In addition to these, some small pots will be wanted, where this sort of culture is attempted at an early period, both for the purpose of sowing the seed in, and that of pricking the young plants out into, that they may be removed and transplanted with greater ease, certainty, and convenience, and with less danger of being injured in their growth. It is usual for each pot to contain two or three plants, which are generally sufficient for a one-light frame.

Pots

Pots of the sizes denominated thirty-twos and forty-eights are commonly made use of in this intention.

In addition to these requisites, bafs mats are necessary to cover the glasses in the nights with, and when the weather is cold and bad. Straw, and other similar substances, may be employed for the same use; but they are much less convenient than mats. The periods of sowing and beginning the works of forcing, in order to have this sort of fruit in the early season, must vary according as it is wanted; but for the very early crops, as those to be cut in the end of December, and the following month, and in February, March, and April, it should, for the former, be done towards the end of October and beginning of the following month; and for the latter, in December, January, and the beginning of February. But for later crops, such as those to come in in June and the following month, it should be in April and May; and still later crops are often produced on ridges, in the open ground, without artificial heat being employed.

The common and general practice is, however, chiefly to have only three crops: the first in March or April, on hot-beds under glasses; the second in May and June, under hand-glasses; and the last on ridges, as just mentioned.

But in order to have the crops come in regularly, an exact attention should be paid to the periods of putting in the seed, and beginning the work of forcing; as without this there must be great uncertainty.

In respect to the choice of seed for the different crops, the early short and long prickly sorts are mostly made use of for the first or early crops; but the latter for the general ones, and those of the other larger kinds for the later crops. The seed should be taken from the earliest fruit, and at the first or second joints, and be perfectly well ripened. And, in order to prevent its running too luxuriantly into vine, it should be kept two years or more before it is made use of; or, when employed while fresh, be kept some weeks or months in a dry, warm situation, as by this means the plants fruit better, from their growth being in some measure restricted.

Method of forming the Beds and raising the Plants.—In the early and more forward culture of this vegetable, it is mostly the practice, where there are sufficient conveniences, and plenty of dung or other materials, to have recourse, as has been suggested above, to two or more hot-beds under frames; as a small one for sowing the seeds upon, and a large one for growing the plants upon; or, sometimes the second is made of a more moderate size, and used for nursing the plants in, previous to their being set or ridged out in the large one, for the purpose of producing fruit. However, by making the beds of a good size, and in a substantial manner, with due attention to linings, they may be grown very well on one or two hot-beds. When cultivated on a small scale, seldom more than one is indeed employed in the raising of this sort of fruit.

In regard to forming the beds, attention must be paid to the size of the frames, and to making them considerably larger than the boxes. Some gardeners advise only a few inches; but Mr. Nicol thinks they should extend beyond the frames, at least eighteen inches all round the frame.

In the business of building the beds, the dung, prepared as mentioned above, should be used in the following manner, beginning with the most littersy part, and afterwards using that which is more reduced. The different parts should be well shaken and mixed together, and beaten down with the fork, or trodden equally in, where very littersy, once or twice as the work proceeds, till they are made up to the full height of five feet in the back, and four in the front

of the frame. Some gardeners suppose two feet and a half, or three feet, to be sufficient, when the beds are merely intended for just raising the plants; but the former practice is probably always the best, where plenty of materials can be easily procured. When thus prepared, it is the custom of some to let them remain with the frames and glasses upon them for a few days, that the rank heat may be brought up; and when it begins to go off, to cover them over with mould, prepared in the manner already described, to the depth of five or six inches, sowing the seed in little drills half an inch deep, when the mould is a little warmed. Others cover them almost immediately with dry earth, tan, or other similar material, to the depth of five or six inches, sowing the seeds in small pots filled with mould, plunging them previously for a little time in the beds; cautiously guarding against too much heat at first, by drawing up the pots when necessary.

The author of the Scotch Forcing Gardener, however, directs that when the beds have been made to the height mentioned above, they should be tarfed over in a careful manner, as in forcing asparagus, and the frames then placed upon them; laying dry fine sea or pit-sand in a sloping direction, according to the frames, over the whole, to within six inches of the lights, and above that two inches in thickness of light sandy loam. The seeds should then be sown in small garden pots or pans, filled with entire vegetable mould from decayed tree-leaves, and covered to the depth of half an inch; plunging them to the brims in the centres of the beds endways, and a foot from the backs. The glasses should then be placed over them in the common manner; when, in the course of twenty-four hours, the beds will in general take on heat, when a little air should be constantly admitted, by lifting the backs of the lights an inch or more in height, and the fronts about half that height, except when there is frost, in order to discharge any rank heat or vapour that may be produced in such circumstances.

It is necessary that the frames should be carefully matted up every night, when the sun begins to decline, and be uncovered before eight o'clock in the morning, when the season will permit: as perfect a regard should be had to this as those of air and water. And Mr. Nicol says, that "a little kindly steam in the morning is a good symptom, but it ought never to be encouraged to any great extent." He never wishes to see more steam in the beds at this time of the day, than what is entirely dispelled in the first hour after the frames are uncovered and exposed.

It is proper that the bottoms of the pots or pans should be occasionally continued to be examined, to see that the heat is not too violent; raising and watering them, with water brought to a proper temperature, in the beds when necessary. And as soon as the plants have attained about two inches growth, they should be pricked out into other small pots, filled with the same sort of mould, three or four in each, putting them as far distant in each as possible, the mould being settled to their roots by a little water; replunging them in the beds to their brims, the surfaces of which being previously wrought over to the full depth of the sandy covering, and another stratum of sandy loam applied as before. They should be carefully nursed in these situations, by due attention to the admission of air, the giving of water, and the regulation of steam; continuing occasionally the examination of the bottoms of the pots, to guard against too much heat being applied to the roots of the plants.

And while the plants are thus carefully brought forward to the proper state for being set or ridged out in the fruiting hot-beds, which is the case when they have acquired a vi-

C U C U M I S.

gorous growth, and put forth three or four rough leaves, some stable dung, in proportion to the extent of the frames, should be got ready in the manner directed above for forming the fruiting beds, which should be made up in the same way as the former. The frames and lights should then be placed over the beds, in order to bring up the heat, and protect them from being injured by wet: and when the heat has become moderate, which will require time in proportion to the extent of the framing, the beds should be earthed or moulded over, the surfaces of them being previously rendered even. In performing this business, the earth should be applied in such a manner as to form a sort of hillock in the middle of each light, within about a foot or eighteen inches from the backs of the frames; the whole of the other parts being covered equally to the depth of two, three, or more inches. The author of the Scotch Forcing Gardener, however, directs, that when the dung is suspected of heating to too great a degree, the beds should be turfed all over, as mentioned above: but where this is not the case, a large round turf placed in the middle of each light, exactly under the parts where the plants are to be placed, may be sufficient; the surface of the dung, in this case, being previously covered over to the depth of six inches with light sand, or well rotted old tan, which should be first made perfectly dry. The turf is, however, rejected by many as wholly unnecessary.

But whichever practice is made use of, the beds will in general be in a proper state for putting the plants in in about twenty-four hours; but before this is done, the mould or earth should be drawn up, so as to raise the hillocks to within five or six inches of the glasses, exactly over the turfs, where they are used, leaving them ten inches or a foot in breadth at the tops or upper parts.

In the operation of planting or ridging out the plants, a hole should be formed in each hillack, sufficiently large for the complete reception of the plants, with the entire balls of earth about their roots, up to the level of the surfaces of the hills, covering them over with a little mould; the whole being then settled with a little water, previously brought to the proper state of warmth, and the glasses put on. It is the practice with some, in order to promote the adhesion of the mould about the roots of the plants, to have recourse to watering the pots before they are turned out of them.

When the plants have been thus set out, they should be carefully attended to in respect to air, water, covering in the nights and bad weather, the state of heat of the beds, linings, the occasionally moulding of the spaces between the hills, and the stopping and training of the plants; in all which much care is requisite.

In regard to regulating the fire, the state of the season and the beds should be fully considered; and air admitted accordingly, by raising the back part of the lights. The waterings should be cautiously given in the winter and early spring, but more freely as the warmth of the weather advances; shutting down the frames for some time after each application. In the more early crops, much less water will be requisite than in those in which the season is more advanced; and the former will stand in need of much less frequent waterings over heat than those of the latter. In these latter, shade is likewise occasionally necessary, when the weather is sunny. The glasses should be carefully covered up with mats every evening, before the influence of the sun is wholly gone, and when the weather is very severe, more than one mat may often be found necessary. The mats should constantly be removed the first thing in the morning, or as soon as the sun rises upon the frames, when the state of the weather will admit; but in very severe

weather, not removed at all, or but a very little in the middle of the day.

And the heat of the beds is likewise to be particularly regarded at first, by a frequent examination of the tryng-sticks; and regulated in such a manner as to promote the healthy growth of the plants. When it continues too great, it should be let off, by making holes in the sides of the beds, and the use of fresh earth on the surfaces.

But when the heat of the beds begins evidently to decline, recourse must immediately be had to the application of linings of fresh dung round them, so as to keep up a due degree of heat; care being constantly taken to repeat them as frequently as may be necessary, and, at the same time to guard against the prejudicial effects of too great heat.

And these linings Mr. Nicol advises to be covered by turf or mould, and to have the sides and ends of the beds cut off, and formed with them.

But the business of earthing the beds between the hillocks should be gradually performed, as soon as the heat is become perfectly moderate; the mould for the purpose being previously laid in some part of the frame. Mr. Nicol considers fifteen inches as a good medium for the earth above the sand or tan, and thinks the business should be done either a few days before or after the application of the linings.

And the business of pruning or stopping is by some begun while the plants are in the nursery-beds; but others defer it till after the plants are ridged out in the fruiting-beds.

The author just noticed does not think it at all material to pick out the heart-buds, as soon as the plants have formed their rough leaves; as, from the most accurate trials, and the most minute observation, he is convinced "it is of no manner of consequence whether the buds are picked out or not." He "feldom thinks of picking or pinching, till the plants begin to put forth runners or vines; nor even then, unless they happen to put forth too few to furnish their sides of the frames, till he preserves the rudiments of the fruit."

But it is then, he supposes, time to stop those vines which have fruit *shewn*; but the others may be suffered to run to the length of six or eight joints, and be then stopped, to cause them to put out fertile ones, which they seldom fail to do, when the plants are in a healthy state of growth.

In cases in which an extraordinary quantity of male blossoms appears, it is recommended that part of them be rubbed off in a gentle manner with the finger and thumb; as the knife should never be made use of, unless in cutting out old vines. But this should never be attempted where there is not a very full blow, as it is proper to assist nature without either spurring or thwarting her. And when the female blossoms are in a state of sufficient forwardness, they may be carefully impregnated with the strongest and most healthy of the males, by which the swelling of the fruit may be greatly promoted; for though the fruit may be formed, yet to a tolerable size, and be fit for the table without, it will not ripen its seed. And though the *farina* of the male blossoms may often be deposited on the renals by means of the wind and insects, it is the safest mode, in the early culture of these plants, to have it performed by the hand, as handsome set fruit may be set apart for seed with more certainty. In the execution of this work, which some suppose the most properly performed the day or day after the flowers of both sorts are fully open, the best way is to gather the male blossom with a short stem, removing the petal or *corolla* carefully from about the *stamina* and *anthera*, and then take the stalk of the blossom betwixt the finger and thumb, and

apply

C U C U M I S.

apply the top of the stamina to the centre of the three stigmas of the female blossoms, and, by giving it a slight twirl, discharge a portion of the farina into the stigmata of the female; making use of a fresh male blossom for each impregnation.

As soon as this has been performed, the plants begin to grow vigorously, and produce large quantities of fruit. Great care should therefore be taken to keep the vines in due order, and not too thick or crossing one another; all the withered and decayed leaves being removed, as well as the others; when too numerous or too irregularly placed.

And air should now be admitted more freely; increasing the proportion daily, as the season advances. More large and repeated waterings should likewise be given from the rose of the pot; and the advantage of warm showers may be taken, as the weather becomes more warm. Few plants require more of this fluid than these, at this period of their growth. When the season becomes fine in May, the glasses may be wholly removed during the day-time. About the middle of the following month, a lining, when necessary, may be applied to the fronts of the frames, in the same way as advised for the other parts; which will continue a due degree of heat, as long as it will be requisite to attend to the state of the bottom heat in the beds.

It may be observed, that in the early culture of the cucumber, it is a good practice never to depend for raising the plants upon the first sowing; but to continue sowing occasionally, both in the nursery and fruiting hot-beds, in pots, managing the plants in the same way as those in the seed-bed; as by this means plants of different growths will be constantly at hand, for the supplying of accidents, as well as for succession crops or other purposes.

Method of Culture under hand or other Glasses.—In this method of cultivating the cucumber, the seed should be sown towards the latter end of March, or beginning of the following month, on an old hot-bed; having the plants in a proper state for being set or ridged out about the beginning of May, which is in general sufficiently early for their succeeding well in this mode of culture. The most proper sort of seed for this purpose is that of the *long prickly green* cucumber.

The beds for this purpose should be prepared of hot dung, somewhat in the manner directed for the early crops; being made from two to three feet in thickness, and about three in width, along the ground in a straight line, having the distance of from three to four feet from each other. The most usual method is to form them in long trenches, or in holes of a foot and half in depth; but they may be made on the level surface, where this mode is attempted at an early period. In either method the beds should be directly earthed over, raising the mould into little hillocks for the reception of the plants, the hand-glasses being immediately placed over them; and in the course of a day or two, the earth will be in a suitable condition for receiving the plants. These should be put in, in the middle of the hills, three or four in each, with balls of earth about their roots, in the same manner as practised in the other crops; a little water being given at the time, and the glasses put on, proper shade being had recourse to when necessary, from the great heat of the sun.

Besides, air and water should be afforded in due proportion, according to the state of the weather and the heat of the beds; keeping the glasses covered well with mats in the nights, and when the season is severe.

As soon as the heat in these beds begins to decline, more earth should be applied between the hills of plants, and some fresh dung externally, by way of linings, to preserve and

keep up the due degree of heat as much as possible, when the weather continues cold. And as the warmth of the season advances, air and water should be given more freely, as there may be occasion.

As soon as the glasses have become pretty full with the plants, they should be raised a little, that the runners may extend themselves without, and be properly trained and pegged down; continuing to attend them carefully in respect to covering in the nights, and admitting air and water, the last being frequently applied all over the beds in these cases.

By this mode of culture, cucumbers may be provided from about the latter end of May till the beginning of September, and sometimes a little longer.

Method of Culture on Ridges in the open Ground.—In this method of raising cucumbers, a warm sheltered situation, which is open to the south, and where the soil is dry, good, and rich, should be fixed upon; the land being well dug into a trench, and a suitable proportion of rotten dung covered in; the surface being formed into a foot or more of bank, sloping towards the south. Some gardeners, however, divide the ground, after being neatly dug over, into beds five or six feet in width, with ridges of a foot or a foot and a half between them, which is also a neat and good method.

In either method of management, the seed should be put in as soon as the beds are ready; in the former, towards the back parts, and in the latter, along the middle, to the depth of about half an inch, six or seven seeds in a place, an inch or two apart; light sprinklings of water being occasionally given afterwards, till the plants begin to appear.

The most suitable and proper season for performing these sowings is about the end of May, or first part of June, according to the state of the weather, and other circumstances.

The principal management and culture which is necessary, during the growth of these crops, is that of keeping the vines perfectly free from all sorts of weeds, thinning the plants out to proper distances, directing the runners in a regular manner along the surface, and keeping them properly watered, according to the state of the season, and other circumstances.

These kinds of crops chiefly come in about the middle of August, and are principally employed as picklers; for which purpose the beds should be carefully looked over two or three times every week, on dry days, and all fresh collared as are in a proper state, as about one or two inches in length, and the thickness of the finger.

Whenever the weather proves wet, they should be guarded as much as possible from the moisture, as under such circumstances they are very apt to become spotted, and to have a bad appearance.

In the business of saving cucumber seed, some of the best and most early cucumbers of the general frame crops should be reserved till perfectly ripened; when they must be separated from the vine, and be laid in a proper place to dry; the seeds being then separated from the pulp, and rendered more perfectly dry, when they may be put up for use, for which they are, as has been seen, in the most proper condition, after they have been kept two or three years, and are in a perfectly dry condition.

The chief and most prejudicial insect that infests crops of this sort is the aphid, which is shewn to be present by the curling up of the leaves, and is readily destroyed by fumigating with tobacco, or in the manner which has been advised for the peach. See *AMYGDALUS*.

Method of Culture in the Melon kind.—In the business of raising

raising this sort of fruit, the same kind of contrivances and apparatus is necessary as in the culture of the cucumber; but it is better if the frames or pits have rather more depth, and are somewhat larger in their other dimensions. But in the view of having melons ripe at an early period, as in May or the following month, brick pits without any cross flues through them, have been found in practice highly useful by Mr. M'Phail. The pit in each frame being about three feet six inches in width, ten feet in length, and three feet deep below the surface of the flues. In the construction of these pits, it is considered the best and cheapest method to carry up brick walls four inches in thickness, to a proportionate height above the flues, securing them at the top with a proper light frame of wood for the lights to rest upon.

Some advise that the beds (for the early crops especially) should be prepared in the same manner, and with materials of the same kind as for the cucumber; but that the later ones may be produced in hot-beds formed of tanners' bark, either wholly or in great part.

In the brick pits, the author of the "Gardener's Remembrancer" makes use of well fermented dung in first filling of them, being so worked as that the noxious particles may have passed off by evaporation. Upon the surface of this well prepared dung, about a foot in depth of good rich earth is deposited. That which is of a loamy pliable quality is considered the best. Such as is procured from the surface of a common which has been long subject to the pasturage of sheep, after being laid in a heap until it becomes rotten, and then well broken down and pulverized, is likewise well suited for this purpose. But mould from a good quarter of the kitchen garden will answer.

When these sorts of pits are employed, it is suggested that the dung in the pits may continue several years, and that it is not necessary for the earthy material which is intended for the plants to grow in, to be renewed every season, as it will be sufficient to add each year, by incorporating it with the surface mould, about a foot in depth of some rich good earth, with a proper quantity of well rotted dung or vegetable mould.

For the ripening of this fruit at a late period, as in July and the two following months, the same practical writer has recourse to beds made of dung, from two to three feet in height; that which has been previously employed for melons in early forcing, being made use of, as being best suited to the purpose in consequence of its not being liable to heat violently, and from its noxious vapours having been discharged.

It is likewise stated, that the leaves of trees, where they can be provided in sufficient quantity, are very proper for forming beds of this sort, provided dung is provided for making linings round them.

Where pits are made use of for early forcing, the flues which surround the bed of earth in each frame are kept clear of earth to admit the heat to pass freely from them to warm the air in the frames, till the weather becomes suitably fine; and with dung beds a similar space is left unfilled up next the insides of the box frames, close to the linings, for the same purpose, being closed with earth when the season becomes fine.

Mr. M'Phail further states, that such beds of dung, or of the leaves of trees as are formed in the winter season for forcing asparagus or lettuce, and in the spring for bringing forward at a more early period, than by the natural climate, plants of the cauliflower and lettuce kinds from seeds will be suitable for planting melons upon, at the latter end of May or beginning of the following month; as by these,

and the assistance of linings of hot dung, heat enough is produced at this season, to bring melons of the best quality to a state of maturity. It is further suggested, that of whatever sorts of materials the beds for this purpose be formed, the air which is afforded by them should be perfectly sweet, which in practice is readily known by the smell, but which is sometimes difficult to produce, as when the materials of which the beds are formed are too moist, they become sour by stagnation, and till that be removed, which often requires time, the plants will not have a proper growth; but besides this, such foul air has the tendency of producing various prejudicial insects.

The same writer conceives, that in covering beds of these kinds, eight or ten inches in depth of earth or mould, are quite sufficient for the roots of the plants to run in, as their roots do not naturally run deep, but spread out horizontally near the surface, especially by the forcing heat of the beds.

But Mr. Nicol thinks that these beds in the early culture should be turfed all over in a rather stronger manner than in those of the cucumber, and be covered with a compost consisting of one half of strong brown loam, a quarter light black loam, an eighth vegetable mould, and the same quantity of stable dung.

The most proper season for sowing the seed for the very early crops, is about the middle of January; but the beginning of February is probably a better period: and sowings should be made twice in March for successive crops. These different sowings should be made on hot-beds, or in pots of light mould plunged in hot-beds prepared for the purpose, as in the cucumber; or the pots may be placed in such old hot-beds of that sort as are at work, the same care and management being employed in the raising and nursing of the plants as in those of the cucumber kind. Mr. M'Phail, however, either sows them in the bed of earth where they are to remain and fruit without being transplanted, or in pots in a hot-bed to be afterwards transplanted, when the rudiment of the first rough leaf begins to appear, into smaller sized pots to the number of two or three plants in each; being, when they have made two or three rough leaves planted out, where they are to produce fruit, about a foot from the glass, and the earth well pressed round the ball.

As soon as the plants have attained five or six weeks growth, or have two or three rough leaves, and are beginning to send forth runners, they are in general in a proper state for being planted or ridged out in the fruiting-beds, which should be prepared in the above manner, or as in those for cucumber plants: and after being well moulded over, the pots of plants put in with the full balls of earth about their roots exactly in the same way as was practised for cucumbers, immediately placing the glasses over them. Where the beds are sweet, Mr. M'Phail advises that the lights should be kept shut down nearly close from the time they are planted out till they have made good roots which is shewn by the shoots, in order to raise as great a heat as a warm lining and the sun could afford, carefully covering in the nights when necessary, as is sometimes the case in May and June.

After this, the plants should have air admitted pretty freely, and be kept in a moderate state of moisture till they begin to show fruit, great care being taken that the heat is not too great, and to keep the beds as free from steam as possible; but from that period until the fruit is fully set, and has begun to swell, the waterings should be very sparing, especially when the season is moist and rainy.

As the heat in the beds begins to decline, it should be refreshed by the application of linings, in the same manner

CUCUMERS.

as practised for cucumbers; and the spaces between the hills of plants must be gradually filled up with mould nearly the same height.

And as the runners proceed in their growth, they should be trained in a regular manner; and when they have three joints length they must be stopped. Some, however, stop them before, when they first begin to put forth runners. By these stoppings, the vines are induced to throw out lateral runners which afford fruit. Mr. Nicol directs, that the vines that have fruit on them should be shortened at the second joint above it, and that such as have none should be trained regularly to the length of seven or eight joints, and then stopped, to induce them to put forth new vines, which mostly show fruit at the second or third joint. It is of much importance in this state of the plants to keep up a due degree of heat, as they not only set the fruit much better and more plentifully where it is the case, but continue their growth in a more perfect manner. The young fruit mostly shows itself with numerous male blossoms; these should not be picked off as is sometimes the practice, as their farina is necessary for fecundating the female flowers, which in the early crops may be performed in the manner directed for the cucumber. While the fruit is setting, air should always be pretty freely admitted when the weather is suitable.

And when the fruit is perfectly set, water should be given in larger proportions till it has done swelling and begins to become ripe, when it should be very sparingly employed; as where given in too great abundance, the flower of the fruit is not only much impaired, but it is often burst, and rendered less valuable by such means.

It is also necessary, that in proportion as the melons increase in size, pieces of slate or tile should be placed under each of them, as it not only prevents them being injured by the damp, but prevents their acquiring an earthy flavour. It is the practice with some to cover the whole surface with tiles, or some straw or other similar substance, but this is not by any means judicious, as the first causes too much heat by the reflexion that is produced, and the latter not only confines the moisture, but has a tendency to generate and harbour noxious insects of different kinds.

With regard to the management of the vines, as the fruit approaches to the state of maturity, they should not be suffered to retain too many leaves, nor these permitted to shade it from the influence of the sun. It is necessary to look over and examine them frequently, but never to prune them too greatly at one time, as where that is done the plants are apt to sustain much injury by bleeding too much. Fresh air should be continued to be admitted freely whenever the state of the weather will allow of its being done with propriety.

This is a sort of fruit which generally becomes ripe in the course of six or seven weeks from the time of its setting, and should be cut as soon as ever it has obtained that state, as when delayed much of the fineness of flavour is lost. The signs of maturity are a sort of cracking at the base about the stem, having a fine yellow colour, and affording a fine fragrant smell with a degree of softness about the top. It should be cut with a portion of the stem, and laid in a dry airy situation till wanted for use or sale.

It has been observed by the author of the "Scotch Forcing Gardener," that many of the early sown kinds are capable of "producing a second crop, equal both in quantity and quality to the first." With this intention he advises, that after the first crop has been cut, the vines be "shortened back to the last live joint on each; the beds being well watered, and protected from the effects of the mid-day sun for eight or ten days, at which time the plants will

begin to push forth afresh, and show fruit in plenty." We believe, however, that this practice is but seldom found to answer well.

Method of Culture under Hand or other Glasses. It is occasionally the practice with gardeners to raise melon crops on ridges under hand, or other sorts of glasses, especially when the season is fine and sufficiently warm.

The ridges in these cases must be formed with good prepared stable dung, in the same manner as practised in forming those for cucumbers; and also moulded or earthed into small hillocks in the same way, only rather more earth should be employed in the case of the melon. The plants may be raised in the seed or other beds, and be carefully nursed in a similar method, till they are in a proper state of growth to be set out, which in this sort of culture should not be done till towards the middle or latter end of May, according to the state of the season, and the nature of the climate.

The plants should be turned out of the pots, and set or ridged out, one on each hillock, in the same way as those of the cucumber kind; shade and a slight watering being given at the time, and the glasses immediately put over them.

And after being thus planted out, the same care and management are necessary as in the other crops, in respect to air, water, covering in the nights, and bad weather, training and stopping the plants, as well as in moulding up the spaces between the hills, and the application of linings when required. As soon as the vines begin to fill the glasses, they should be trained on the outside of them, the glasses being raised upon blocks, but still left upon the plants protecting the vine on the outside as much as possible from wet, when the season is bad and rainy.

And the same directions are applicable after the setting of the fruit, until it becomes in a state proper for cutting, as in the frame crops or those in pits.

Method of Culture in flued Pits.—This is a method which, as has been already remarked, is principally made use of for raising late crops of this sort of fruit, but is capable of being made use of in the early crops likewise. It is practised and recommended both by Mr. Nicol and Mr. M'Phail.

The plants for this purpose may be raised in hot-beds, or under hand or other glasses, until they are of a suitable growth to be planted in the pits, which is as described above.

It is sufficiently early, in general, to commence this sort of culture about the middle or latter end of June, as at this period but little bottom heat will be wanted; and the old beds that have produced other crops may be converted to this use. The Scotch Forcing Gardener directs that one-third new be mixed with the old tan or dung in order to renew the heat, levelling the whole to the bottom of the flues quite round. Turning is considered by him as unnecessary, but mould should be applied to the thickness of about fifteen inches, so as to raise the whole surface to the height of the tops of the flues.

And when the beds are thus prepared, the plants should be put in, in a line along the middle of them in the pits, at the distance of about two feet from each other, care being taken to keep their roots as much as possible from reaching the tan or bark. See *BARK-pit*.

In this way in their after-management, the plants require the same care according to the season, both in regard to air, water, training, stopping, and impregnating, as has been directed for the crops in the frames and other methods.

But towards the latter end of August or beginning of the following

following month, when the heat of the beds in the pits begins to be deficient, and there is much moisture and cold, it will mostly be requisite to have recourse to the aid of fire heat, in order to fully maturate such fruit as is not already thoroughly ripened. The fires should, however, at first be slow, and only made in the evenings; but afterwards increased, as the severity of the season demands, so as that it may raise the heat of the air in the pits to about 70 degrees of Fahrenheit's thermometer, in the evenings and mornings, about eight o'clock. Mr. Nicol, indeed, directs, that in order to admit air sufficiently, and keep up a proper degree of heat in dull hozy weather, a little fire should be made in the morning; and that as the growth of the plants is now over, water should be made use of with much caution, being wholly discontinued as soon as the fruit has attained its full growth and perfection.

In respect to the seed employed in the culture of this sort of fruit, it should be such as is taken from the best plants of the most curious varieties, and which has been perfectly ripened, and preserved for one or more years in some dry place, as new seed seldom answers well in the cultivation of this sort of fruit.

There are many insects which do great damage to these plants. The *acarus*, or *red spider*, is one that frequently does much injury to the melon, when the season is dry and there is a dry heat in the beds. Its attacks are shewn long before it becomes visible, according to Mr. Forsyth, by the "leaves curling and cracking in the middle."

And as a remedy in this situation, he advises, when the weather is warm and sunny, the watering them all over the leaves from a watering-pot with the rose upon it, or an engine, about six o'clock in the morning, and about eight to shade them with mats, when the sun shines, shutting the frames down close till towards eleven, then to admit air in a small proportion, continuing the mats till about three in the afternoon, and then removing them. In this way the leaves are prevented from injury by the sun while wet. And when there is a south or south-west wind, the waterings may be repeated about three in the afternoon, shutting up the frames to produce a strong exhalation, and destroy the insects. In the operation, as much water as possible should be thrown on the underside of the leaves, gently turning the vines for the purpose. The lights and sides of the boxes should likewise be well watered; and before the frames are made use of again they should be well washed inside and out, first with water, and then soap-suds and urine in a state of mixture. Where melons have been infested with the spider the preceding season, none of the earth or mould should be made use of again, as it may do much injury.

In the business of sprinkling the leaves, water that has been several days exposed to the sun, or made soft by wood-ashes, should be employed if possible.

But the author of the *Scott's Forcing Gardener* observes, that water at some periods cannot be thus applied without much injury to the plants, and that the leaves and vines are so brittle and tender, that they cannot be brushed or touched without harm being done. It is of course obvious, that much care and circumspection is necessary in extirpating these insects by the use of water. Mr. M'Phail, after suggesting that the plants should "be duly attended to in giving them plenty of heat and water," adds that, "late in the spring, and in the summer months, they should be occasionally watered all over their leaves, till the earth in which the roots of the plants grow, be perfectly soaked, and then the frames shut down with a great heat in them." This he considers as only imitating and assisting nature, as in his

method, by means of pits, there is nothing to obstruct the superabundant water, as it oozes through the beds freely. He further suggests that "in hot dry weather the plants should be sprinkled frequently with clean water about four o'clock, and the lights shut down immediately for the night."

CUCUMIS capparis, in the *Botanical Writings* of the Arabians, a name given by Avicenna, and others, to the plant which produced the fruit called bel. This fruit was like the capers in shape, and had a hard shell over its kernel, like that of a hazel-nut. Such is the description they give of it, and of the fel and sel, two other fruits as like it in shape, and other respects, as in virtue.

CUCUPHA, an ancient form of *Medicine*; being a cap, or cover for the head, with cephalic powders quitted in it; worn in many nervous distempers, and particularly such as more immediately affect the head: as against catarrhs, defluxions, &c. It is now much out of use.

CUCURBIT, *CUCURBITA*, in *Chemistry*, an earthen, or glass vessel, called also body; of the figure of a gourd, or a pear; wherein are put the matters to be distilled.

It is sometimes also made of tin, and sometimes of brass, tinned. When a distillation is to be made, they fit on to it a glass head with an aperture, and a neck proportional. Thus fitted, it is called an *alembic*; which see.

CUCURBITA, in *Botany*, (so called, according to Scalliger, from the curvature of the fruit.) Linn. gen. 1051. Schreb. 1478. Willd. 1740. Gært. 554. Juss. 326. Vent. 3. 516. Class and order, *monocia syngenesia*; Linn. *Monocia monadelphia*; Willd. Nat. Ord. *Cucurbitaceae*, Linn. Juss.

Gen. Ch. Male flowers. *Cal.* Perianth one-leaved, bell-shaped, the margin terminated by five awl-shaped teeth. *Cor.* monopetalous, adnate to the calyx, somewhat bell-shaped, five-parted; segments veiny-wrinkled. *Nectary* a small concave triangular gland in the centre of the flower. *Stam.* Filaments united, in three sets, adnate to the calyx; anthers five, serpentine upwards and downwards, linear. Females. *Cal.* Perianth as in the male, superior, deciduous. *Cor.* as in the male. *Nectariferous gland* concave, spreading. *Stam.* Filaments barren, very short, united into a slender ring at the base. *Pist.* Germ large, inferior; style conical, short, trifid (quinquefid; Gært.) stigmas dilated, turned outwards in a zig-zag manner. *Peric.* Pome (Berry; Gært. Vent. Smith) generally three-celled; partitions membranous, soft, distinct. *Seeds* numerous, compressed, with a tumid border, obtuse, placed in a double row.

Ess. Ch. Calyx five-toothed. Corolla five-parted. Filaments in three sets. Pistil three-cleft. Seeds with a tumid border.

This genus includes four of Tournefort, cucurbita, pepo, meopepo, and anguria.

Sp. 1. *C. lagenaria*. Bottle gourd, or calabash. Linn. Sp. Pl. 1. Mart. 1. Willd. 1. "Leaves heart-shaped, somewhat angular, tomentous, with two glands underneath at the base; pomes woody." A native of moist ground in America. 2. *C. idololatrica*. Willd. 2. "Leaves heart-shaped, cuspidate, generally obsolete three-lobed, pubescent, with two glands at the base; pomes pear-shaped." A native of Guinea. 3. *C. ficocaria*. Willd. 2. Molina Chil. ed. germ. 316. "Leaves angular, somewhat lobed, tomentous; pomes woody, globular." A native of Chili. 4. *C. aurantia*. Willd. 4. "Leaves somewhat heart-shaped, generally three-lobed, cuspidate; sharply and finely toothed, scabrous; pomes globular, even-surfaced." 5. *C. ovifera*. Linn. Mant. 126. Mart. 3. Willd. 5. "Leaves lobed;

CUCURBITA.

lobed; pomes inversely egg-shaped; tendrils with seven digitated divisions." Linn. "Leaves heart-shaped, angular, five-lobed, finely toothed, pubescent; pomes inversely egg-shaped, marked longitudinally with linear stripes." A native of the country about Atrachan. 6. *C. umbellata*. Willd. 6. "Leaves heart-shaped, angular, five-lobed, finely toothed, scabrous; male flowers umbelled; pomes tomentous." A native of the East Indies. 7. *C. hispida*. Mart. 2. Willd. 7. Thunb. Fl. Jap. 322. "Leaves angular; stem and petioles hispid." A native of the East Indies and Japan. 8. *C. pepo*. Pumpkin or pumpkin. Linn. Sp. Pl. 2. Mart. 4. Willd. 8. "Leaves lobed; pomes even-surfaced." Linn. "Leaves heart-shaped, obtuse, somewhat five-lobed, finely toothed; pomes roundish or oblong, even-surfaced." Willd. A native of the East Indies, Cochinchina, and China. 9. *C. verrucosa*. Linn. Sp. Pl. 3. Mart. 5. Willd. 9. "Leaves lobed; pomes knobby-warted." Linn. "Leaves heart-shaped, deeply five-lobed, middle lobe narrowed at the base, finely toothed; pomes roundish-elliptical, warted." Willd. 10. *C. subversuosa*. Willd. 10. "Leaves heart-shaped, deeply five-lobed, middle lobe narrowed at the base, finely toothed; pomes club-shaped-elliptical, somewhat warted." 11. *C. melopepo*. Squash. Linn. Sp. Pl. 4. Mart. 6. Willd. 11. "Leaves heart-shaped, obtuse, generally five-lobed, finely toothed; pomes with depressed knobs tumid at the edge." 12. *C. citrullus*. Water melon. Linn. Sp. Pl. 5. Mart. 7. Willd. 12. "Leaves many-parted." Linn. "Leaves five-lobed; lobes sinuate-pinnatifid obtuse; pomes elliptical, even-surfaced." Willd. A native of the South of Italy and Sicily. 13. *C. mammosa*. Willd. 13. Molina Chil. 316. "Leaves many-parted; pomes spheroidal, with papilike elevations." A native of Chin.

This genus is very nearly allied to cucumis, being distinguished from it chiefly by the tumid border of the seeds. Its species, like those of cucumis, are annual with herbaceous stems, furnished with tendrils, and, according to circumstances, either procumbent or climbing. Like all other plants which have been long cultivated in different climates; it has branched out into innumerable varieties, which are the glory of the horticulturist; but generally prove a provoking stumbling block in the way of the systematic botanist, and often baffle his most laborious researches.

Duchefne, a French naturalist, in a course of several years, made numerous experiments on the plants of this genus with a view to determine which are really distinct species and which are merely varieties. The result of his labours was a conviction that there are three original races which do not naturally propagate with each other, and from no two of which a cross breed can be artificially produced. La Marek has adopted his general ideas, and has published them, with a few alterations, in the Encyclopédie Methodique. He is of opinion that there are four original species. As this arrangement has not appeared in our language, we shall lay it before our readers, though much abridged, to bring it within our proper limits, and shall retain the French names when corresponding English ones do not occur.

I. The calabash, or white-flowered gourd. *Cucurbita leucantha*; Duchefne. *C. lagenaria*; Linn. "Corollas widely spreading, somewhat declated; seeds truncate-emarginate at the tip." Lam. Leaves almost round, pale green, soft, woolly, slightly viscid and odorous, with two small conical glands underneath near the insertion of the petiole. Flowers white, almost wheel-shaped. Fruit, at first, pale green; when fully ripe, dull yellow, varying greatly in form and size; flesh spongy, very white. Seed with a border

not entirely surrounding it, but forming a kind of appendicles at its sides, giving it a square, not an oval form. The varieties of this original species may be reduced to three principal families. 1. The *cougourde*, or *proper bottle gourd*. *C. lagenaria*; J. Bauh. 2. 216. Tourn. 107. *C. lagenaria*; flore albo, folio molli; Bauh. Pin. 313. Morif. Hist. 2. 23. § 1. tab. 5. fig. 1. *C. prior*; Dod. Pempt. 648. This variety is distinguished by the form of the fruit, having, next the peduncle, a long tail, like the neck of a bottle, which, in one sub-variety, is swollen near the bottom, and joined, by a contraction, to the upper part of the fruit. 2. The *proper gourd*.¹ *C. latior*, folio molli, flore albo; J. Bauh. 2. 215. *C. major fessilis*, flore albo; Bauh. Pin. 312. *C. latior*; Dod. Pempt. 669. Morif. § 1. tab. 5. fig. 2. Fruit large, tumid, with a hard shell. The young negroes fix one of the dried fruits under each of their arms, to assist them in supporting themselves, when they are learning to swim. It is from a resemblance in the form of the fruit, and the purposes to which it is applied, that the West Indians have called the crescentia of Linnæus the calabash-tree. (See CRESCENTIA.) Hence also the cucurbits of the chemists are said to have received their name. 3. The *trumpet*, or *long gourd*. *C. longa*, folio molli, flore albo; J. Bauh. 2. 214. Rai. Hist. 638. Morif. Hist. 2. 24. § 1. tab. 5. fig. 3. Rumph. Amb. 5. 297. tab. 144. *C. longior*; Dod. Pempt. 669 and 707. *C. americana teres & b. cubalis*; Tourn. 107. The great length which the fruit of this variety sometimes acquires, depends, in a considerable degree, on its position. When it lies on the ground, it is often curved in the shape of a crescent, and sometimes becomes tumid at both ends, like a pill. It differs also much in size. The thickest have the tenderest rind, and the most fleshy pulp. They are eaten in America, and in the South of Europe. The last two varieties differ chiefly in size, and are united by several intermediate ones. They are considered by Sauvages as properly one, distinguished from the first by having toothed, not entire leaves.

The first variety is said by Hasselquist to grow in all parts of Egypt, and in Arabia, wherever the mountains are covered with a rich soil. The poor people eat it boiled with vinegar; or fill the shell with rice and meat, making it into a kind of pudding. The rind of all three, especially of the first, is hard, and almost woody, when dry, and is made into drinking cups, bottles, and other domestic utensils, for the use of the lower ranks of people. This species appears to be a native of Asia, Africa, and America; and it is only since the discovery of the latter, that many of its numerous varieties have been obtained.

II. The *potirón*, or *large-fruited gourd*. *C. maxima*; Duchefne. *Melopepo fructu maximo albo*; Tourn. 106. *C. aspera*, folio non albo, fructu maximo albo fessili; J. Bauh. 2. 221. *Pepo maximus indicus compressus*; Lob. Ic. 641. *Pepo compressus major*; Bauh. Pin. 311. Rai. Hist. 642. *Cucurbita pepo*; Linn.? "Flowers bell-shaped, broadish internally at the base; border reflex and; fruit round, compressed." Lam. Duchefne doubts whether this be really an original species. Sauvages, the first botanist who called it *potirón*, pronounces it distinct from the next, and characterises its fruit in concise but lively terms, as a sphere with compressed poles, and narrowed meridians, well delineated in Tournfort's figure, tab. 34. La Marek agrees with him, and observes, that it differs from the following in the form of the flowers, in its roundish heart-shaped leaves, on nearly horizontal petioles, and in the greater strength and size of all its parts. The fruit, in particular, is sometimes not less than thirty pounds in weight; with

CUCURBITA.

with a fine rind, and a firm but juicy melting flesh. La Marek observes, that its enormous size is probably the effect of cultivation. It was not known before the sixteenth century, and no account of its origin has been preserved, a circumstance which seems to us to strengthen the doubt, with respect to its being an original species. There are three principal varieties: the common yellow, with a fine yellow flesh, which is the largest; the large green, with an orange-red flesh; and the small green, which is much esteemed on account of its continuing in a state fit for eating longer than the other kinds.

III. The pepo, or pumpkin gourd. *C. pepo*; Duchef. *C. ovifera*, *C. pepo* β. *C. verrucosa*, and *C. melo-pepo*; Linn. "Flowers bell-shaped, narrowed within at the base; border erect." This species, like the preceding, has bell-shaped yellow-flowers; but its corolla is narrowed at the base, so as to be almost funnel shaped, and its border is always erect. Both have whitish elliptical, not truncated or emarginate seeds. The present may be divided into two principal families. 1. The *melon gourd*, or *musk gourd*. This family is rather of an ambiguous nature, and has been little noticed by botanists. The oval form of its seeds, the size, shape, and colour of its flowers, the angular figure of its leaves, and the disposition of its branches, pronounce it a gourd; but its soft woolly leaves, its pale-coloured and nearly wheel-shaped flowers, the long green points of its calyx, and the milky taste of its fruit, indicate its alliance to the calabashes. In the French West India islands it is called *citrouille melonnée*, and is cultivated in the south of France and Italy, under the name of *citrouille musquée*. Like the next family, it has numerous varieties, distinguished by the shape and colour of the fruit, as it is either flattened at the ends, spherical, oval, cylindrical, or pistil-shaped, is greater or less in size, and more or less ribbed; is of a deeper or paler green on the outside, and has its flowers varying from a very pale yellow to a deep orange. 2. The *polymorphous gourd*. The common character of this family depends on the size and regularly conical shape of its flowers, the oblique, or almost erect, never-horizontal direction of its leaves, and their brown colour and roughness, resulting partly from the dryness and brittleness of their surface, though their nerves and veins are very succulent; and partly from their hairs, which are stiff and tumid at the base. In all other respects it is variable, without end. It may, however, be divided into five subordinate families; α. the false oranges and false colquints. *C. polymorpha colocyntha*; Duchef. *Pepo rotundus aurantii forma*; Bauh. Pin. 311. *C. minima lutea amara*; J. Bauh. 2. 231. *Cucurbitula pilâ palmarâ non multo major rotunda*; J. Bauh. 2. 218. *Pepo fructu minimo spherico*; Tourn. 105. *C. magnitudine aurantii*; J. Bauh. 2. 226, &c. *Colocynthis pomiformis cortice maculato*; Bauh. Pin. 314. This family, of which the false oranges may be considered as the principal, and the false colquints as a variety, is, from the following characters, supposed by Duchesne and La Marek to approach nearest to the primitive state of the gourd. *Leaves* about the length of the petiole, moderately cut. *Male and female flowers* equally distributed over the whole plant, making it very fertile. *Fruit* spherical, with a diameter only double that of the flower, regularly three-celled; rind forming a rather solid shell, at first dark green, at length of a lively orange; flesh yellowish, fibrous, bitterish, soon becoming dry, and then acquiring somewhat of a musky flavour. *Seeds* very numerous, rather large. β. The coucourdettes, false pears, or milky colquints. *C. polymorpha pyridaris*; Duchef. *Colocynthis pyriformis, five pepo amarus*; Bauh. Pin. 313, and *C. oblonga*; Bauh. Pin. 313. Tourn. 108.

C. five colocynthis amara pyriformis variegata et oblonga viridis et parva alba; J. Bauh. 2. 230. 229. *C. ovifera*; Linn. Mant. 126. This division is very constant in its principal characters; and though it has many varieties, they diverge from each other very little, so that it almost seems to claim the rank of an original species. Its leaves are rather more cut, and it is altogether commonly more slender than the preceding. Its flowers are the smallest in the whole genus; its seeds are small, and very much elongated; its fruit also is small, often pear-shaped, or at least egg-shaped; the rind generally brownish-green, marked with milk-white bands and spots; the flesh very white, at first moist, afterwards fibrous and friable. γ. The barbarine. *C. verrucosa*; Bauh. Pin. J. Bauh. Linn. *Melo-pepo verrucosus*; Tourn. *C. Turbinatæ majores albæ, & variegati coloris*; J. B. The fruit of this division is distinguished by the remarkable warts or tumours on its surface; it is sometimes about the size of an orange, but in most of its varieties larger; its shell hard and woody, generally entirely yellow or spotted, but sometimes marked with green bands. δ. The giramous and citronilles. *Oblong-fruted cucurbita. Pepo oblonga*; Bauh. pin. 311. Tourn. 105. *C. folius asperis five Zuccha*; J. Bauh. 2. 218. *C. pepo* β. Linn. *Pepo vulgaris*, Rai. hist. 639. *Pepo virginianus*; Bauh. pin. 311. *Macocks virginiani*; Rai. hist. 641. This division takes its chief character from its oblong fruit. The giramous are distinguished from the citronilles by their flesh, which is commonly paler, and always of a finer texture; and by their leaves, which are generally more deeply cut, those of the latter being often only angular; but their most striking difference is in the size and colour of the fruit; which in the former is often very large, and generally of a dark green colour; in the latter small, pale green, yellow, or even white. There are, however, intermediate varieties which bring them together. One of these has long been known in the south of Europe by the name of Malta or Barbary cucumbers. ε. The Patisson, or squash, *melo-pepo clypeiformis*; Bauh. pin. 312. Tourn. 106. Lob. ic. 643. *C. melo-pepo*; Linn. *C. clypeiformis five siciliana*; J. Bauh. 2. 224. Also *C. clypeatæ & affines omnes*, J. Bauh. &c. The plants of this division affect a kind of contraction in all their parts, an hereditary malady, which has been continued more or less strongly marked through several ages, and may always be reproduced at pleasure by sowing the seeds of the most deformed plants. The stems and branches are peculiarly stiff and strong, in consequence of their knots being placed near together; hence instead of extending themselves easily along the surface of the ground, they rise abruptly on one side or the other, sometimes almost perpendicularly, and do not touch the earth till they are weighed down by the increasing heaviness of their fruit. The small flowers have, in consequence, peduncles more than double the usual length, without which they would not find room to expand; the petioles also are similarly lengthened, and not being able to support the leaves, are several times curved, as if they were about to become twining. The stems, it is observed by Linnæus, are furnished with tendrils, though they are neither climbing nor procumbent; but Loureiro asserts that in China and Cochinchina they always climb, whenever they meet with any proper support. The fruit has a fine rind, like that of the false colquints, but generally softer with finer, white, and rather dry flesh. It is generally four or five-celled, and varies much in its form, being sometimes round, sometimes pear-shaped, and frequently appearing as if it was squeezed in by the nerves of the calyx; its flesh swells into various protuberances, which sometimes form ten longitudinal ribs, and sometimes surround either its apex

CUCURBITA.

or its base; sometimes it is contracted in the middle, and suddenly expands into a large head, like that of a young mushroom: sometimes it is entirely flattened like a buckler, and either regularly or more frequently irregularly plaited. The seeds are short and roundish, with an uneven surface. This variety is common to both hemispheres, and is much cultivated in the warmer climates, as a wholesome esculent. The fruit is commonly gathered in America when half grown, and eaten boiled as a sauce to meat. It is of great use in long voyages, as it may be kept for several months fresh and sweet.

IV. The pasteque and water melon. *C. anguria*; Duches. *C. cucullus*; Linn. *Anguria cucullus dicta*; Bauh. pin. 312. Tourn. 106. *Citrullus folio colocynthidis fec- to*; J. Bauh. 2. 235. *Anguria indica*; Rumph. amb. 5. 400. tab. 146. fig. 1. *Citrullus officinarum*; Lob. ic. 640. Jacq. five *anguria*, Pl. Bras. 263. "Corollas somewhat wheel-shaped; seeds coloured; leaves lacinated." Lam. The deeply divided leaves of this species are stated by Lin- næus and other botanists to be its peculiar character. This, however, is not perfectly correct; some of the varieties of the gourd having their leaves almost, if not quite as much lacinated. But those of the water melon may always be distinguished by the firmness and brittleness of their sub- stance, and their much more nearly vertical direction. The corolla is less spreading than that of the calabashes; and smaller, less bell-shaped, more deeply cut, and of a paler yellow than that of the gourds. The fruit is roundish or oblong, with a fine, thin, even rind, remarkable for its spines, stellated like those of the sea urchin, not parallelo- gram, as in the gourds. The seeds are constantly of a deeper colour than the flesh; while in the three other species they are always much paler. Duchesne mentions three principal varieties, α , with firm flesh, β , with reddish flesh, γ , with whitish flesh. The first is particularly distinguished in the north of France by the name of pasteque, and is eaten only as a preserve, or baked with sweet wine, like Burgundy pears. The two latter are the true water melons, so much esteemed in all hot countries for their pleasant, cool, refreshing flesh, which is always of a deep colour, and so succulent that it melts in the mouth; the central pulp is so fluid, that, like the milk of the cocoa nut, it may be sucked or poured out through a hole in the rind, and affords an agreeable be- verage; but this must be done when the fruit is first gathered, otherwise it will soon decay; the fruit is therefore generally brought to the market with the hole plugged up. It is a native of the East Indies, Cochinchina, and China, and is mentioned by Maregrave as growing in Brazil, but may have been brought thither by the Portuguese. On account of its excellent qualities, it is much cultivated in all the warmer countries of the four quarters of the globe, and is said by Hasselquist to serve the Egyptians for meat, drink, and physic, as long as it continues in season, which is from the beginning of May to the end of July, or the beginning of August.

Propagation and Culture—The calabashes and the gourds may be propagated by sowing their seeds on a hot-bed in April. When the plants are sprung up, they should be transplanted into another moderate hot-bed, where they should have a great deal of air, and be treated hardily; as soon as they have got four or five leaves, they may be trans- planted into holes made in an old dunghill, and be allowed a good deal of room to spread. They are sometimes for the sake of ornament fastened to walls, pales, or hedges; and sometimes trained over harbours, which they soon entirely cover, affording a pleasant shade. The orange-shaped gourd is generally preferred for this purpose, on account of its

handsome fruit. None of the kinds are cultivated in this country as esculents. The calabashes are more tender than the gourds, and require a more careful treatment; but if covered with hand-glasses when young, they will flower and fruit in the open air. The water melons may be raised in the same manner, and on the same beds with melons and early cucumbers, only they must have more room, and must be constantly kept in a good heat, with a free admission of air in favourable weather. The best sorts to cultivate in our climate are those with small round fruit, which come from Africhau: for those with large fruit scarcely ever ripen: but in the best state to which they can be brought here, they are not much esteemed, and are very seldom raised.

CUCURBITA sinensis, fructu longo anguino vario, flore can- dido; Till. Sabbat. See *TRICHOSANTHES Anguina*.

CUCURBITA, in *Gardening*, comprises plants of the trail- ing herbaceous annual kind; of which the species prin- cipally cultivated are, the bottle, or long gourd, (*C. lagen- aria*;) the pompon, or pumpkin gourd, (*C. pepo*;) the warted gourd, (*C. verrucosa*;) the squash gourd, (*C. melo- pepo*;) and the water melon, (*C. citrullus*.)

The first species has a thick, trailing, downy stem, branch- ing into numerous spreading runners, extending along the surface of the ground, fifteen or twenty feet in length. The leaves are large, roundish, heart-shaped, and woolly; the flowers large and white, succeeded by whitish-yellow fruit, shaped similar to a bottle, having a large roundish belly, and smooth neck, two or more feet in length, and from nine to eighteen inches or more round, with a ligneous durable shell.

In the second species the stem is thick, angular, extremely hispid, branched, climbing by means of bifid tendrils, or extending to the distance of forty feet. The leaves cor- date, large, roundish-angular toothed, wrinkled and hairy on both sides. The flowers are of a yellow colour; and the fruit roundish, ovate globular, or oblong-ovate, being pale green on the outside, having within a spongy insipid white pulp or flesh. Its season of flowering is from June to August.

The stalks in the third species are trailing, very branchy and spreading, running on the ground as in the last sort; the leaves are large and lobated, and the flowers yellow, be- ing succeeded by fruit of a roundish, knobby, warted ap- pearance, white, and of a middling size.

In the fourth species the stem is roundish, hairy, pro- cumbent, or climbing. The leaves lobed-angular, and the flowers yellow: the fruit large, reddish-yellow, or yellowish- white both within and without, mostly roundish, but often flat at both top and bottom, constantly torulose, but rarely warted. It is common in North America.

The stem in the fifth species is round and striated, long, branched, and hairy; the flowers are yellow; and the fruit large, smooth, round, or oblong, a foot and a half in length, within watery, sweet, very red or pale. It is a native of South America.

There are numerous varieties in all these different species. In the first species the chief of these are, the common long-fruited, the long protuberant-bellied, the long sickle- shaped, the long-taper, and the long-turbinated bottle- gourd.

Of the second sort there are several varieties, as the com- mon large round-fruited yellow, the oval yellow, the oblong yellow, the whitish-fruited, the stone-coloured, the flesh-co- loured, the parti-coloured, the marbled small round, the orange-shaped, the pear-shaped, the turbinated, the hemi- spherical or semi-globular, the egg-shaped, the striped

roundish, the striped egg-shaped, the striped turbinated, and the striped pear-shaped pompon, &c.

Of the third kind the principal varieties are, the roundish-warted, the oblong-warted, the flat-warted, the bottle-shaped-warted, the orange-shaped-warted, the lemon-warted, and the yellow-fruited.

Of the fourth sort the varieties are, the common broad flat, the buckler-shaped, the conical citron-shaped, the flat-sided, the turbinated, the hemispherical, the depressed, the star-shaped, the white-striped, and the yellow-striped squash-gourd.

And of the fifth species the chief varieties are, the large round red fleshed, the large round white fleshed, the large oblong, and the small round water melon.

Method of Culture.—In the manner of raising of most of these plants, as well as in that of their after culture, the aid of artificial heat and shelter is generally requisite, especially when to be forward at an early period.

Method of Culture in the Gourd kind.—This is always effected by sowing the seed annually, either on slight hot-beds, or in the open ground, in the spring months; but the former is probably the best mode, as the plants are more early. In the first method, it should be performed about the latter end of March, or the middle of April; and when the plants have attained a pretty strong growth, and been hardened by the free admission of air, they should be carefully removed into the situations where they are to remain in the open ground with balls of earth about their roots, as unless this be done they do not succeed so perfectly.

In the latter mode of raising the plants, the seed may be sown in the natural ground where the plants are to remain, about the middle of May; open sunny situations being provided for the purpose. The mould should be made fine, and the seed put in to the depth of about half an inch, three or four seeds in a place being sufficient.

Some gardeners properly advise the putting in a little dung in the situations where the seeds are to be sown, in order to forward the plants, and when they come up, to protect them by hand-glasses. This is particularly useful for the more tender kinds, and, in all the sorts, renders them considerably more forward.

When the plants are of some considerable growth, they should be thinned out to one or two good plants, and be plentifully supplied with water when the season is hot and dry, especially after they have begun to run or spread; as by this management they will extend very considerably, and grow with much greater vigour.

Where any of the sorts are cultivated for the purpose of ornament, they should be trained to strong stakes in order to show their flowers more fully, and appear more ornamental.

The seed should always be saved from the best and most perfectly ripened fruit of the different kinds, being carefully freed from the pulp, and preserved in a dry situation till the period at which it is wanted.

Method of Culture in the Water Melon kind.—The usual mode of culture in these plants, is by sowing the seed annually about the latter end of February or beginning of the following month, on pretty substantial hot-beds, keeping them protected by the glasses when the weather is bad; after the plants have attained a little growth, they should be pricked out into small pots, two plants in each, being replanted in the hot-bed. When they begin to throw out runners, they should be removed into the fruiting hot-bed in the same manner as practised for cucumbers and melons, only one pot of plants being employed for a two or three light frame; the beds being previously earthed over, and

hillocks raised to the height of twelve or fifteen inches in order to receive them.

The necessary after-management in regard to stopping the plants, the admission of air, the giving of water, covering the glasses in the nights, and keeping up the heat in the beds by linings, must be regulated in the same manner as for the melon. The spaces between the hills should be gradually earthed up, and the vines be trained so as to fill the frames without crossing, or being too much crowded. When the vines begin to shew and set fruit, the heat should be well supported and kept up, that they may be so brought forward as to ripen in due time. When the fruit has attained the state of maturity, it turns rather yellow, and becomes somewhat soft at the top, as in that of the melon.

In the cultivation and management of all the sorts and varieties of these plants, where the object is the fruit, such seed as has been kept some years should constantly be employed, as new seed is apt to grow too luxuriantly, and the vines of course afford but a very scanty supply.

CUCURBITACEÆ, in *Botany*, the forty-fifth natural order in the *Philosophia Botanica* of Linnæus, and the thirty-fourth in the *Posthumous Prælectiones* published by Giseke. In the *Philosophia Botanica* it contains the following genera: passiflora, feuillea, momordica, trichofanthes, cucumis, cucurbita, bryonia, sicyos, melothria, gronovia? In the *Prælectiones*, anguria and elaterium are added, and the whole placed in the following succession; gronovia, anguria, elaterium, sicyos, melothria, bryonia, cucurbita, cucumis, trichofanthes, momordica, feuillea, passiflora. In this order there are no proper trees, but some have a perennial, woody, climbing stem; in others the stem is herbaceous, but the root perennial; the rest are annual. The leaves in all are alternate and simple. The stipules always at the origin of the leaves. The glands are generally on the petioles, or at the base of the leaves, or in the leaf itself. All have tendrils by which they climb whenever they find suitable supports, without which they are more or less procumbent. The calyx is five-cleft or five-parted. The corolla is one-petalled, five-parted, but in many is so deeply cut as to seem five-petalled. The stamens are inserted, not on the receptacle, but on the inside of the calyx, to which the corolla is attached. The filaments are generally five, but so connected as to seem only three. The anthers are often united, so as to form one serpentine body, the apex of one growing to the base of another. The style is rather thick, and the stigmas most commonly three, often bifid. The fruit is generally fleshy, three-celled, having its seeds bedded in pulp, and on that account rather a berry than a pome. Most of the genera are either monoicous or dioicous. The fruit of none is positively wholesome, and of some highly pernicious, but of others is generally thought pleasant, and if eaten with caution, and not in too great quantities, is at least innocent.

The cucurbitaceæ are also the second natural order in the fifteenth class of Jussieu, of which he has given the following character. *Flowers* monoicous, or more rarely dioicous, or very rarely having in each perfect stamens and pistils, as in gronovia and melothria. *Calyx* (the corolla of Linnæus and Tournefort) superior, contracted, just above the germ, dilated beyond, quinquesid, shrivelling, falling off late, with five green appendages on the outside at the base of the bell-shaped expansion, (the calyx of Linnæus and Tournefort,) which may be called exterior segments of the calyx, since they fall off with it. *Corolla* none. *Stamens* of the barren flowers most frequently five, inserted into the contracted part of the calyx; filaments and anthers, in some distinct, in others entirely or partially united; anthers one-celled, oblong, fixed to the top of the filaments, often running

running into a twice-curved line, four of them generally in pairs, and the fifth solitary. *Germ* abortive, or barren. *Filaments* of the fertile flowers barren, or none. *Germ* inferior. *Style* one, or rarely several. *Stigma* most frequently divided. *Fruit* inferior, berried, often with a solid rind or shell, one-celled, with one or many seeds, or many-celled with many seeds; receptacles of the seeds lateral, or affixed to the inner surface of the fleshy part. *Seeds* cartilaginous or crustaceous; corculum flat, without a perisperm.

Root most commonly tuberous. *Stem* herbaceous, climbing or prostrate, zig-zag. *Leaves* alternate, furnished with axillary tendrils, simple, heart-shaped, or palmate, or rarely digitate, often rough, or studded with callous points. *Flowers* axillary, one or more on a peduncle. The genera are thus arranged by Jussieu. I. *Style* single. Fruit one-celled, with one seed. *Gronovia*, *ficyos*. II. *Style* single. Fruit one-celled, with numerous seeds. *Bryonia*, *elaterium*. III. *Style* single. *Fruit* many-celled, with numerous seeds. *Melothria*, *anguria*, *momordica*, *cucumis*, *cucurbita*, *trichosanthes*, *ceratofanthes*. IV. *Styles* several. *Dubious cucurbitaceæ*. *Feuillea*, *lanonia*. V. Allied to the cucurbitaceæ, distinguished chiefly by a superior germ. *Passiflora*, *murucua*, *taconia*, *papaya*.

Ventenat has the same genera, only adding *luffu* from *Cavanilles*, and omitting *feuillea* and *lanonia*, without taking them up in any other part of his work.

CUCURBITIFERA *arbor. subtundis foliis confertis*; Pluk. See CRESCENTIA *cucurbitina*.

CUCURBITIFERA *trifolia spinosa medica*; Pluk. See CRATEVA *masfnelos*.

CUCURBITINI LUMBRICI, in *Zoology*, are broad worms that breed in the intestines, like the seed of a gourd.

CUCURBITULA, in *Surgery*, a cupping-glass, or instrument, used in the operation of cupping. See CUPPING-Glass.

CUCURI, in *Ichthyology*, the Brazilian name of a fish of the shark kind, but not mischievous, called *caffion* by the Portuguese.

It is about two feet and a half long. The head ends in an hyperbolic figure, and the mouth is placed far below its end; it has only one row of teeth, and those very small; its eyes are of the size of a large pea; its belly is of a silver white. Willughby.

CUCURON, in *Geography*, a small town of France, in the department of Vaucluse; 9 miles S. of Apt.

CUCURUCU, in *Zoology*, the name of a serpent found in America, growing to ten or twelve feet long. It is very thick also in proportion to its length, and is of a yellowish colour, strongly variegated with black spots, which are irregularly mixed among the yellow, and often have spots of yellow within them, and are plainly black. It is a very poisonous species, and greatly dreaded by the natives; but its flesh is a very rich food, and greatly esteemed among them, when properly prepared. Ray.

CUD, in *Rural Economy*, a term applied to the imperfectly masticated food in animals of the cattle and some other kinds, which is brought back from the first stomach, to be chewed over again in a more gradual and deliberate manner, at the leisure of such sorts of beasts; being, after this process, transmitted into the second stomach to be digested more perfectly. When this process is lost, or the power of the animal to perform it suspended, it is supposed by some to be in a morbid condition, and to require the use of strengthening remedies of the acid and aromatic bitter kinds: whence, to chew the cud, signifies to ponder, think, or ruminate upon a thing.

CUD-Weed, in *Botany*. See ATHANASIA, GNAPHALIUM, and FILAGO.

CUDA, in *Ancient Geography*, a river of Spain, in the territory of the Lusitanians, which ran from the S. to the N., and discharged itself into the Durus.

CUDDALORE, in *Geography*, a town of Hindoostan, on the coast of Coromandel, in the Carnatic, situated near where St. David stood, now belonging to the English. It was taken by the French, under the command of general Lally, in the year 1758; and again in 1781; but in 1783 it underwent a severe siege by the British forces, under the command of general Stuart. At this time it was become the principal place of arms held by the enemy on that coast, who had made great exertions in fortifying it; and it was garrisoned by a numerous body of the best forces of France, well provided with artillery, and every necessary for a vigorous defence. The contest was severe, and at length the British forces proved victorious. Peace between the belligerent powers of Europe terminated the dispute. Cuddalore, where the French have had a factory, and within sight of Pondicherry, is naturally a very strong situation; and would have been the most commodious, perhaps, for the chief British settlement; since the security of Tanjore, and the convenience of supplies from it, must ever be a capital object. Besides, as the S.W. monsoon is the season of naval warfare, Pondicherry has the advantage of being to windward of Madras; and the French, at the same instant, accomplish the double purpose of keeping to windward, and of protecting their capital settlement; and receive assistance from it in return. The British fleet, in order to watch the enemy, retires 100 miles from their principal settlement, and receives only a precarious assistance from the shore; that is, from Cuddalore, or its neighbourhood, their usual station. N. lat. 11° 41'. E. long. 79° 45' 45".

CUDDAPAH, a town of Hindoostan, and capital of a province which bears the same name; belonging to the Nizam of the Deccan, through which passes the river Pennar. The town is situated on the route from Pondicherry and Arcot to Canoul; distant from Hydrabad S. 230 miles, from Madras N.W. 153 miles, from Nagpour S.W. 551 miles, and from Seringapatam N.E. 220 miles. N. lat. 14° 32'. E. long. 78° 54'.

CUDDAPAH, a country of Hindoostan, bounded on the N. by the country of Golconda, on the E. by the Carnatic, on the W. and S.W. by the Mysore; ceded to the Nizam of the Deccan by Tippoo Sultan. The principal towns are Cuddapah, Gandicotta, and Combam.

CUDDY, in a *First-rate Man of War*, is a place lying between the captain lieutenant's cabin and the quarter-deck; and divided into partitions for the mailer, and other officers.

It denotes also a kind of cabin near the stern of a lighter, or barge of burden.

CUDRESIN, in *Geography*, a town and bailiwick of Swisserland, in the canton of Berne, on the N.E. borders of the lake of Neuchatel. This town was taken by assault, in 1475, by the Swiss cantons, and allotted to the cantons of Berne and Friburg, who restored it to the duke of Savoy. In 1536 the inhabitants surrendered to the Berrois without resistance, under which canton it remains; 5 miles S.E. of Neuchatel, on the other side of the lake, and 2½ W. of Berne. N. lat. 46° 59'. W. long. 0° 44'.

CUDUPARITI, in *Botany*, Rheed. See GOSSYPIMUM *arborcum*.

CUDWORTH, RALPH, in *Biography*, the well-known author of the "Intellectual System," was born at Aller, in Somersetshire, in the year 1617. He was educated at first under his father, who was a man of some celebrity in the church; but at his death, which happened while our author

was only about eight years old, he was transferred to the tuition of his father-in-law, Dr. Stoughton. He made so rapid a progress in grammar learning, that at the age of 13 he was deemed fit for, and actually admitted, a pensioner of Emanuel College, Cambridge. Here he took his degrees, and about 1639, or 1640, he was elected fellow of his college, and became so eminent as an instructor of youth, that at one and the same time he had 28 pupils; a circumstance which, at that time, had never been known in the largest colleges in the university. Among the young men committed to his care were Mr., afterwards sir William Temple, and the celebrated Tillotson. He was shortly after presented to the rectory of North Cadbury in Somersetshire; and in 1642 published a treatise on the Lord's Supper, which gave rise to a long controversy, that seems to have been completely set at rest by an able work on the same subject, by Dr. Bell, prebendary of Westminster. In 1645 he was unanimously elected Regius professor of Hebrew; an office for which his great learning, and skill in the Oriental languages, peculiarly qualified him. He now devoted almost all his time to his academical pursuits and studies. In 1647 he printed a sermon, which he had preached before the house of commons: the dedication contained some admirable sentiments upon the nature of religion, and the value and importance of learning; which reflect much honour on the liberality of his principles, and was a well-timed reproof to the prevailing bigotry and fanaticism of his contemporaries. In 1651 he took the degree of doctor of divinity; and, because his income at the college was not adequate to his wants, he left the university; but was shortly after solicited to return, to which he consented, and was chosen master of Christ's College, Cambridge. Here he spent the remainder of his days. In 1656-7 he was appointed, by the grand committee for religion, to confer about a new translation of the Bible; whose labours were terminated by the dissolution of the parliament. Shortly after he obtained the vicarage of Athwell in Herts; and in 1678 he was installed prebendary of Gloucester. In the same year he published "The true intellectual System of the Universe;" a work full of capital reasoning, and containing much curious learning. The object of this publication was to confute the principles of atheism, which had been but too prevalent, as an opposite extreme to the cant and hypocrisy so common in the times of the commonwealth. Many excellent divines lifted up their voice, and exerted their pens against the atheism, profaneness, and irreligion, which was encouraged by the licentious court of Charles II.; but none with more vigour and success than Dr. Cudworth. "None better knew," says the learned Mosheim, "how to use the arms of reason and learning, to conquer the presumptuous ignorance of Hobbes, who had acquired a great reputation at court." The Intellectual System was only a part of what Dr. Cudworth had intended; but death prevented the completion of a labour, which, in its present unfinished state, has acquired for the author a large share of solid reputation. The candid critic will, however, see and acknowledge defects in this system. Dr. Cudworth was attached to the Platonic philosophy, and frequently, like his master, enveloped truth with mystery. In his physics he has adopted the corpuscular system, adding, to the doctrine of atoms, that of a certain middle substance between matter and spirit: to this he gave the appellation of "plastic nature," which he supposed to be the immediate instrument of the divine operation. This hypothesis was the foundation of a controversy between Bayle and Le Clerc. Dr. Cudworth died in 1688, at Cambridge, in his 71st year. He left behind him other works, published, and in MS.; the latter, after many re-

volutions, have found a place in the British Museum. They were left by the author to lady Masham, his daughter, who preserved them with pious care so long as she lived. They were afterwards sold to Mr. Davis, a bookseller in Piccadilly, who parted with them, as the MSS. of Mr. Locke, to the proprietors of a Bible that was edited by Dr. Dodd. This, says Dr. Kippis, was the origin of Dr. Dodd's Bible. Such extracts having been made as were deemed necessary for the purpose, the originals were returned, when Mr. Davis sold them outright for 40 guineas, as the MS. of Locke. The deception was soon discovered, and their proper owner traced. The purchaser claimed a return of his money; and they were at length negotiated for by the curators of the British Museum, as the remains of the excellent Dr. Cudworth. Of their author it may with strict justice be affirmed, that he was not only distinguished by very extensive learning and profound knowledge in metaphysics and philosophy, but by exemplary piety, and great moderation and rectitude of character, which rendered him an honour to the institutions where he presided, to the university of Cambridge which he adorned, and to the church and age in which he lived. Mr. Granger observes, that Dr. Cudworth held the same rank in metaphysics that Dr. Barrow did in sublime geometry; and his daughter bestyles the learned and accomplished lady Masham, whose memory deserves to be held in high honour, both for her own attainments, and her unshaken friendship to Mr. Locke. *Biog. Brit. Mosheim.*

CUE, or QUEUE, the hair tied in form of a tail. Military men, and particularly soldiers, have been made to wear queues of different forms, at different times.

CUE, an *item*, or *innuendo*, given to the actors on the stage, what, or when, to speak. See PROMPTER.

CUE, in *Geography*, a town of Persia, in the province of Adirbeitzan; 100 miles S.S.W. of Tauris.

CUENCA, a jurisdiction or province of the vice-royalty of New Granada, or Santa Fé, in South America, bordering on the southern parts of Riobamba, and divided into two departments, of which the capital is one, and that of Alausi the other, which reaches to Riobamba, is governed by a deputy of the corregidor, and besides the Asiento, contains four villages; but that of the city of Cuenca includes 10. This district, which is situated on the table land of Quito, is of benign temperature, producing abundance of cattle, sugar, cotton, and grain, and has considerable manufactures of cotton cloths. The terrible earthquake in 1797, which totally ruined the city of Riobamba, so that of 9000 persons, only about 400 escaped, seems not to have extended south so far as Cuenca. Among the great variety of mines in this province, those of gold and silver are not, according to the common opinion, the least numerous. From a story, which is of ancient date, and which has descended from one generation to another, related by Ulloa, it is inferred, that a hill in this district, called "Supay-urca," or the Devil's-hill, contains an inexhaustible treasure.

CUENCA, the capital of the above-mentioned jurisdiction, situated in S. lat. 2° 53' 49", and long. 29° 25' W. of the meridian of Quito, on a spacious plain, along which, at about half a league N. of it, runs a little river, called Machangara; and close to the S. side of the town runs another, known by the name of Matadero. Besides these, at the distance of a quarter of a league, runs another, called Yanuncay; and about the same distance is another, named Los Banos, from a village of that name through which it runs. All these rivers are in some seasons fordable; but at others, can only be crossed with safety over the bridges.

The plain in which Cuenca stands extends about six leagues from N. to S ; and the four rivers form, at a small distance, by the conflux of their streams, a very large river. To the S. of the town is another plain, about two leagues in extent, and exhibiting, by its great variety of regular plantations of trees, a very delightful appearance through the year. The streets of this town are straight, and of a convenient breadth; the houses of unburnt bricks, are tiled, many of them being of one story; and the suburbs, inhabited by the Indians, are mean and irregular. The town is supplied with water by several streams; and on account of its admirable situation, and the fertility of the adjacent soil, it might be rendered the paradise, not only of the province of Quito but of Peru itself; but its advantages are, either through ignorance or indolence, not duly improved. Cuenca was founded in the year 1557, by Gil Ramirez Davalos. It contains three parishes; that of the great church consists of Spaniards and Mestizos; the two others, called San Blas and San Sebastian, are appropriated to the Indians. Here are convents of Franciscans, Dominicans, Augustines, and the fathers of Mercy; a college of Jesuits, and two nunneries. Here is also an hospital, though so ill managed as to be in ruins. The magistracy is composed of regidores and ordinary alcaldes, chosen annually; and their head is the corregidor. Here is also a chamber of finances; the revenues of which consist of the tribute of the Indians of this department, together with that of Alausi, the jurisdiction of Loja, and the government of Jean de Bracamoros; the duties on provisions, and the customs collected at Naranjal. The inhabitants are of a very indolent temper; and the vulgar are rude, vindictive, and very profligate. The women, however, are generally very industrious: they spin and weave bays, famous for their quality and brilliancy of colour, in every part of Peru. They also buy and sell, and manage the whole of the little commerce, by which their families are supported; whilst the males surrender themselves to sloth, and its concomitant vices. The whole number of inhabitants in this town is computed at 20 or 30,000 persons; and those both of the town and jurisdiction are commonly known by the name of Morlacos. The adjacent country is finely interspersed with farm-houses and plantations of sugar-canes; some parts are cultivated for corn, others appropriated to sheep and horned cattle, from the milk of the last of which they make great quantities of good cheese.

CUEÇA, a town of Spain, in New Castile, anciently called *Conça*, the see of a bishop, suffragan of Toledo, situated between two lofty mountains and two small streams, which form the Xucar; taken by the earl of Peterborough in 1706, and soon retaken by the duke of Berwick; 75 miles E. of Madrid, and 100 W.N.W. of Valencia. N. lat. 40° 10'. Long. 14° 35' E. of the Peak of Teneriffe.

CUERA, or **ZUERA**, a town of Spain, in Arragon, on the Gallega; 10 miles N. of Saragossa.

CUERENHART, or **COORNHART**, **DIRICK**, or **THEODORE VOLKHART**, in *Biography*, an engraver and a literary character. was born at Amsterdam in the year 1522. He resided a long time at Haarlem, where, in concert with other artists, he engraved many subjects from the scriptures, from the designs of Martin Hemelick, Francis Floris, and other masters. His plates are wrought in a careless negligent manner, imitating pen-drawing. They are chiefly middling-sized, engt. ways, and marked sometimes with his name, at others with a cypher, composed of D. V. & C.

Cuerenbert is so lets remarkable for his engravings than for the singular adventures of his life, which was published at Amsterdam at the head of his works in 1630. The

strange opinions which he maintained, in his several religious disputes, occasioned him to be frequently imprisoned, and at length banished his native country, when he retired to Gouda, where he died in 1590. He had the honour to count the celebrated Henry Gotzcius amongst his disciples. Huber. *Mann-l des Arts*.

CUERNABACA, or **CORNAVACA**, in *Geography*, a town of N. America, in the province of Mexico; 20 miles S.S.W. of Mexico.

CUERPO. *To walk in cuerpo*, is a Spanish phrase for going without a cloke; or without all the formalities of a full dress.

CUERS, in *Geography*, a town of France, in the department of the Var; 12 miles N.E. of Toulon, and 9 miles N. of Hières. It is the chief place of a canton, in the district of Toulon, with a population of 4890 individuals. The canton itself has 14,899 inhabitants, in 9 communes, upon a territorial extent of 507½ kilometres.

CUEYTE, a river in the island of Cuba, which abounds with alligators.

CUFA, or **СУРНА**, a town of Asiatic Turkey, in the Arabian Irak, near the frontiers of Arabia Deserta, on the branch of the Euphrates called Nahr-Isa; 60 miles from Bagdad. The *Cufic* characters, which prevailed among the Arabians for about 300 years, were denominated from this place, where they are said to have been invented. The Cufic alphabet, which continued to be used in writing so late as the 10th century, and on coins down to the 14th century, is now found only in the oldest Mahometan MSS. About the year 920, a new system of writing, called "Nikki" was formed and introduced, which, with some variation, still continues to be the general hand-writing of the East. See *ARABIC Language*.

CUFF, or **CUFFE**, **HENRY**, in *Biography*, a distinguished scholar, and secretary to the unfortunate earl of Essex, was born at Hinton in Somersetshire, where he received the early parts of his education, and from thence removed to Trinity College, Cambridge. He was greatly distinguished among his contemporaries, and became fellow of the college. The impetuosity of his temper led him into difficulties, and a display of his wit caused him to be banished from his college. His reputation was, however, so considerable, that he was invited to, and admitted a member of, Merton College, where he took his degree of M. A., was made fellow, and afterwards promoted to the Greek professorship; and was chosen proctor of the university. When the earl of Essex was appointed to the lord lieutenancy of Ireland, Mr. Cuffe was appointed his secretary, obtained the noble lord's confidence, and was probably regarded more as a friend than a servant in this high station. The earl was charged with projects of ambition very unsuitable to the views of any subject. Conscious, perhaps, of his master's innocence, or indignant at the treatment he had met with, Cuffe repelled the idea of that submission which was recommended by some of his other and more prudent friends. The earl at length fell a victim to his imprudence; was tried, and convicted, and suffered death. Previously to the execution of the sentence, he charged his secretary with being not only accessory to, but author of, all his misfortunes. On this charge, which was aggravated by other circumstances, he was brought to trial, convicted, and suffered death at Tyburn. He acted with great firmness and heroism, repelling with becoming indignation the several insinuations made against him. By Camden, lord Bacon, and sir Henry Wootton, his memory was treated with a severity, which later writers have thought in a great measure unmerited.

He

He left behind him some MSS. ; of these one was published about six years after his death, entitled, "The Differences of the Ages of Man's Life, together with the original Causes, Progress, and End thereof." Biog. Brit.

CUFRATENSIS, in *Ancient Geography*, an episcopal town of Africa, in the Byfacene territory.

CUGUACUARA, or CUGUACUARANA, in *Zoology*, the name of an American beast of prey, the brown Patagonian cat, usually confounded with the tyger, and described by Maregrave as one of the three species of American tygers, the *jaguara* and *jaguarcte* being the two others. It is the *Cougour* of Buffon, and the *FELIS Concolor* of Gmelin ; which see.

CUGUACUETE, and CUGUACUAPARA, the Brazilian names of an animal of the *Cervus* kind, seeming to be the male and female of the same species, and not distinct animals. The former, according to Maregrave, has no horns ; but the cuguacuate of Piso has palmated horns, and is probably the male ; the horns are composed of three branches ; they send out one near the insertion, and from this they run up single to the extremity, where they are bifid. As in the roe-deer, the female has no horns, it is probable that the individual pointed out by Maregrave was the female. Upon the whole, the descriptions given of these animals, by both these writers, demonstrate that they are roe-bucks, similar to those of Europe. Marcg. Bras. 235. Piso Ind. p. 97, 98. Smelley's Buffon, vii. 31.

We have not seen the animal in England ; but its horns, which are very singular in their shape, are preserved in the museum of the Royal Society. This is the animal which Johnson has figured under the name of the *capreolus marinus*. Tab. 33.

CUGUPUGUACU, a name by which Maregrave calls a Brazilian fish of considerable size, and a very good taste, the *PERCA guttata* of Gmelin ; which see.

CUI *ante Divortium*, in *Law*, a writ, which a woman divorced from her husband hath, to recover lands or tenements from him to whom her husband alienated them during marriage ; because during the marriage she could not gain-say it.

CUI *in Vita*, is a writ of entry, which a widow hath against him to whom her husband alienated her lands or tenements in his life-time ; specifying, that, during his life, she could not withstand it.

CUJAS, JAMES, in *Biography*, a celebrated French jurist, was born at Toulouse in 1750. His origin was low, but his talents and industry overcame every obstacle to his rising greatness. He attained a speedy and a deep knowledge of the learned languages. Ferrier was his preceptor in the law ; but the progress which he made in ancient jurisprudence was the result of his own researches. He took for his guides, and as handmaids to the science, the analogy of words, and the facts in history. He became a public professor in his native city ; from thence he was invited to the university of Cahors ; and, after some other changes, he became, at the urgent request of Emanuel Philibert, duke of Savoy, professor at Turin. He finally returned to Bourges, where he died in 1590, at the age of 70. His memory has been honoured by the notice and applause of Joseph Scaliger and De Thou. The former speaks of him as a man of a social and most friendly disposition, who not only lived on familiar terms with his pupils, but might truly be denominated their father. Under Cujas some of the most celebrated magistrates in France were educated ; and from him they imbibed liberal and patriotic principles. De Thou insinuates that his life had been threatened by the bigots of

the time ; and to his deep regret for the subversion of all justice, and regard to the public good, that writer imputes the death of Cujas, at an age beyond which he might have been expected, from the soundness of his constitution, to have lasted. His works are still in considerable reputation. They were first printed together in 5 vols. folio, at Paris, 1584. Mereri.

CUJAVIA, in *Geography*, a province of the grand duchy of Warsaw, which, since the peace of Tilsit, belongs to the king of Saxony, and had formed a part of the late acquisitions of Prussia from Poland. It is irrigated by the Vistula ; has a bishop, who resides at Inowladislaw ; and contains the two palatinates of Brzesc or Kujawski and of Wladislaw or Ino Wladislaw, Young Wladislaw. This country is uncommonly fertile, and has many lakes which abound with fish.

CUJAVUS, in *Botany*, *agrestis* ; Rumph. See *PSIDIUM pomiferum*.

CUJAVUS *domestica* ; Rumph. See *PSIDIUM pyriferum*.

CUICHOCA, in *Geography*, a lake of S. America, in the province of Quito and jurisdiction of Otabalo, about a league in length, and half a league in breadth ; situated in a plain, on the side of a mountain of the same name. Near the middle of this lake are two islands, abounding with wild cuyes, a species of rabbits, and deer, which often swim to the main land ; but, when pursued by the hunters, disappoint them by gaining the lake, and swimming back to their retreat.

CUICULUM, or CUICULI, in *Ancient Geography*, an episcopal town of Africa, marked in the Itinerary of Antonine ; 25 miles from Sitifi.

CUJETE, in *Botany*, Plum. See *CRESCENTIA*.

CUIL, in *Ornithology*, a name given by Buffon to the *CUCULUS honoratus* of Gmelin ; which see.

CUILLE', in *Geography*, a small town of France, in the department of the Mayenne ; 21 miles N.W. of Chateau Gontier.

CUILLER a Canon, Fr. a sort of sheet of copper or brass, rounded, and one-third open. It is of different sizes, and serves for drawing or taking out the powder of the charge of a cannon.

CUILLI. See *CULLY*.

CUILLIER, in *Ornithology*, a name given by Buffon to the *CANCROMA canrophaga* of Gmelin.

CUIRASSE, a piece of defensive armour, made of an iron plate well hammered ; serving to cover the body, from the neck to the girdle, both before and behind.

Some derive the word, by corruption, from the Italian *cuore*, *heart* ; because it covers that part : others from the French *cuir*, or the Latin *corium*, *leather* ; whence *coriaceus* : because defensive arms were originally made of leather.

The cuirasse was not brought into use till about the year 1300, though they were known both to the ancient Greeks and Romans in different forms.

Hence, *cuirassiers*, the cavalry armed with *cuirasses*.

In the Roman calendar, we find the name of St. Dominic the *cuirassed* ; a title given to a saint of the eleventh century, from his constant wearing of an iron *cuirasse*, by way of penance.

CUIRASSIERS, are a sort of heavy cavalry armed with cuirasses. The different German powers had regiments of cuirassiers, and have now troops under this denomination. The late king of France had also one regiment of them ; and Napoleon Buonaparte has cavalry now that go by that name, and are esteemed the best that he has.

We have had none, however, in England since the revolution.

CUIRIRI, in *Ornithology*, the name of a Brazilian bird of the *Lanius* or shrike kind, in no respect differing from the *pitanguaguacu*, but that it has a yellow spot upon its head. Probably this is the male of the same species. See **LANIUS Pitangua**.

CUISSARS, or *Cuiffards*, Fr. were plates or scales made of beaten iron, which were put on below the under part of the cuirasse, and served for covering and protecting the thighs. This armour was called *Cuiff*.

CUIT, in *Ornithology*, a name given by Buffon to the **CORACIAS Bengalenfis**.

CUITE, Fr. a technical term to express the preparation of saltpetre for the making of gun-powder. See **SALTPETRE**.

CUITPALLI, in *Natural History*, the American name of a very beautifully variegated stone, found in New Spain, and some other places: its name expresses the painted stone. It is a species of jasper of a beautiful green, variegated with very beautiful lines, and clouds of black, and is in some parts transparent.

CUIZEAUX, in *Geography*, a small town of France, in the department of Saône and Loire, 30 miles S.E. of Châlons. It is the chief place of a canton, in the district of Louhans, with a population of 1694 individuals. The canton itself contains 10 communes and 9760 inhabitants, upon a territorial extent of 150 kilometres.

CUIZERY, a small town of France, in the department of Saône and Loire, with 1301 inhabitants, 18 miles S. of Châlons. It is the chief place of a canton, which reckons a population of 8816 individuals, in eleven communes, upon a territorial extent of 122½ kilometres in the district of Louhans.

CUL DE CHANDRON, Fr. the rounded bottom of the funnel, or the excavation of a mine after it has produced its effect.

CUL de Cobe, in *Geography*, a bay of the island of Martinico, on the N. part of the Cul de Sac Royal.

CUL de four, a sort of low, spheroidal vault, oven-like.

Coul de four of a niche, denotes the arched roof of a niche on a circular plan. See *Mem. Acad. Scienc. an. 1719*, p. 363.

CUL de lamp, a French term, properly signifying the bottom of a lamp. It is applied in architecture to several decorations, both of masonry and joinery, used, in vaults and ceilings, to finish the bottom of works, and wreathed somewhat in manner of a *testudo*; particularly a kind of pendentive in Gothic vaults.

CUL de Sac, in *Geography*, a general term for a bay in the West India islands.

CUL de Sac des Anglois, a bay of the island of Martinico, on the S.E. coast, a little to the south of Cape Ferrar.

CUL de Sac François, a bay of the island of Martinico. N. lat. 14° 34'. W. long. 60° 53'.

CUL de Sac, Grand, a bay in the W. coast of the island of St. Lucia.—Also, a bay on the N. coast of the island of Guadaloupe. N. lat. 16° 30'. W. long. 62° 53'.

CUL de Sac Marin, a bay on the S. coast of the island of Martinico. N. lat. 14° 31'. W. long. 60° 45'.

CUL de Sac, Petit, a bay of Guadaloupe, 7 miles S. of Grand Cul de Sac.

CUL de Sac, Robert, a bay of the island of Martinico, on the east coast. N. lat. 14° 34'. W. long. 60° 59'.

CUL de Sac, Royal, a bay on the W. coast of the island of Martinico. N. lat. 14° 30'. W. long. 60° 59'.

CUL de Sac, Vache, a bay of the island of Martinico. N. lat. 14° 31'. W. long. 60° 57'.

CULANT, a small town of France, in the department of the Cher; 15 miles E. of Châtres, and 12 miles S.W. of St. Amand.

CULARO, in *Ancient Geography*, a town of Gallia Narbonnensis, which separated the Allobroges from the Vacautiani. It was rebuilt by Gratian, and called Gratianopolis; now Grenoble.

CULATÉ, is the part beyond the vent, or inner mould of a piece of ordnance, and which terminates in a large knob or button of metal.

CUL-BLANC, in *Ornithology*, a name given by Buffon to the **MOTACILLA Oenanthe**.

CULBUTE, in *Midwifery*, a supposed evolution of the fœtus in the womb, occurring about the end of the seventh month of pregnancy. See **BIRTH**; also **FŒTUS, position of**, in the womb.

CULBUTER UNE COLONNE, Fr. To overthrow a column. This phrase is frequently made use of when cavalry attack infantry, and throw them into confusion by a brisk and rapid charge.

CULCASIA, in *Botany*, a name given by some of the old writers to an Egyptian plant growing near the seashores. It is by many supposed to have been the *colocasia*, but improperly. The resemblance of the name was the only thing that gave the idea of its being this plant; but the virtues attributed to it, and the uses it was put to in the common affairs of life, shew that it was the *kali* or *cali*, the plant of whose ashes they made a salt useful in many arts, and still the basis of the glass and soap manufactures, and called by Avicenna *ujjen*.

CULCITÆ, Lat. Beds which, of some kind or other, have been in use from the highest antiquity. They were first of herbs or grass, then of feathers, and afterwards of wool. (See **BED**.) In proportion as the Romans departed from the severity of their original mode of living, they wished to have beds with them when embodied as soldiers and on actual service, in spite of prohibitions to the contrary. Scipio Africanus Numantinus observing the prohibitions to be useless, set himself an example of submission and self-denial, by forbidding a bed to be prepared for him, and reposing on a bundle of hay only. When a general such as Scipio gave so fine an example of self-denial, even the softest and most effeminate mult have accustomed themselves to the ground. It does not from thence follow, however, that the commander of an army should sleep on the bare ground. It is sufficient that he has once set the example. For he in general stands more in need of rest than any other man, as his sleep is sometimes frequently interrupted during the night; and his spirits, exhausted by the fatigues of watching, require to be recruited, to enable him to resume his labours and attend to the duties of next morning.

CULCITANUS, in *Ancient Geography*, an episcopal see of Proconsular Africa.—Also, a see in the Byzacene territory.

CULCUA, a Roman colony of Africa, placed by Ptolemy in Numidia.

CULCUL, a sort of grain brought from Egypt to Constantinople, where it is much esteemed, especially when fresh. Authors are not agreed what plant it is produced from.

CULDEES, or **KULDEES**, in *Church History*, a designation given to the monks, or priests, in Scotland, in the first ages of Christianity, whence the term passed into Ireland.

They were called *culdees*, quasi *cultores dei*, from their great piety and devotion. Others, however, derive their name from the cells or cells in which they lived. This monastic order commenced, both in Scotland and Ireland, about the middle of the 6th century: and St. Columba is acknowledged to be its founder. This eminent person, distinguished by a greater degree of useful knowledge and rational piety, than those which generally prevailed at that early period, arrived from Ireland and succeeded Palladius, at a considerable interval after his departure or death; and soon gained such an ascendant both over princes and people, that he became a kind of dictator among the Scots and Picts, in civil as well as religious matters, for more than 30 years. Having obtained a grant of the small island Hù, Hu, or Iona, one of the Ebudæ or Hebrides, he there built a monastery, which was long considered as the mother and queen of all the monasteries in Scotland; and its abbots, though only presbyters, were respected as the chief ecclesiastical persons among the Scots, out of regard to its founder St. Columba, who, as Bede informs us, was a presbyter, and not a bishop. In this monastery many excellent persons received their education, and were sent from thence, not only to instruct the Scots and Picts, but even to convert the Saxons. These missionaries were a kind of presbyters, who lived in small societies, and travelled over the neighbouring countries, preaching and administering the sacraments. To each of their cells there was one who had some kind of superintendency over the rest, managed their affairs, and directed their missions; but whether or not he enjoyed the title and authority of a bishop in this period, is not certainly known. The council of Ceale-hythe, held A. D. 816, decreed, that no Scotch priest should be allowed to perform any duty of his function in England; and it therefore seems to have suspected that they had no bishop; for, indeed, the chief reasons assigned by that council for refusing to keep communion with these Scots Culdees were, that they had no metropolitans amongst them; that they paid little regard to other orders; and that the council did not know by whom they were ordained, *i. e.* whether they were ordained by bishops or not. (Spelm. Concil. t. i. p. 329.) The rectors or bishops of the several cells of Culdees were both chosen, and ordained, or consecrated, by the members of these societies; and this was probably the ground of the dissatisfaction expressed by the council of Ceale-hythe. When the cells or monasteries of Scotland came to be enlarged, better built, and better endowed, they were long after this possessed by these Culdees, or secular clergy, who had the privilege of choosing the bishops in those places where sees of bishops were established. (Boeth. Hist. Scot. l. 10.)

Few writers have done justice to the Culdees. They seem to have been too much attached to simple truth and pure Christianity, to find favour with those who aimed at wealth and power, and enjoyed the benefit of human impositions and prevailing ignorance. Even Bede, venerable as he was, though he bestows upon them great and just commendation, cannot avoid passing some censure upon them, and seems to have regarded them as schismatics, in the worst sense of that word. "They followed," says this ancient writer, "uncertain rules in the observation of the great festival; only practising such works of charity and piety as they could learn from the prophetic, evangelical, and apostolical writings;" thus insinuating some reflection both on Columba and his successors. Ledwich, in his 'Antiquities of Ireland,' pronounces upon them an high eulogium. "It is true," says he, "they did not adopt the corruptions of the Anglo-Saxon church, or the super-

sitions which had contaminated Christianity for centuries. They preserved their countrymen from the baleful contagion, and at length fell a sacrifice in defence of their ancient faith. Superstition found them her most determined foes. The Culdees continued, until a new race of monks arose, as inferior to them in learning and piety, as they surpassed them in wealth and ceremonies, by which they captivated the eyes, and infatuated the minds of men. The conduct of the Romanists towards them was in every place uniformly persecuting. The Romish emissaries were obliged to exert all their cunning to remove the prejudices in their favour, and where force could not, seduction often prevailed: at last they lost all their privileges, their old institutions, and retained barely the name of their pristine celebrity." The overthrow of the Culdean worship was finally effected by pope Adrian, A. D. 1155, when he claimed the sovereignty of these islands, and, in the plenitude of his presumption, bestowed Ireland on Henry II. Mr. Ledwich informs us, that in Mondincha, an island of Ireland, in the county of Tipperary, stood a Culdean abbey and church, where several of the order resided; and it appears that, in 1185 they "had not conformed to the reigning superstition; they devoutly served God," says this historian, "in this wild and dreary retreat, sacrificing all the flattering prospects of the world for their ancient doctrine and discipline."

CULÈ'E D'UN PONT, Fr. the arch of a bridge next to the land. The phrase is also used by some writers to denote the butment of masonry which supports that arch.

CULEMBACH, in *Geography*, a district or marquise of the circle of Franconia, in Germany; bounded on the W. by the bishopric of Bamberg; on the S. by the territory of Nuremberg; on the E. by the palatinate of Bavaria and Bohemia; and on the N. by Voegtland and part of the circle of Upper Saxony. It is about 50 miles long, from N. to S., and 30 broad from E. to W. It abounds with forests and high mountains; the most considerable of the latter are those of Fichtelberg, which are covered with pine-trees. From these mountains spring four large rivers, *viz.* the Maine, the Sala, the Eger, and the Nago. See BAREITH.

CULENBACH, a town of Germany, the capital of the above-described marquise. It is well fortified, and is situated at the confluence of two branches of the river Maine. It was pillaged and burnt by the Hussites in 1430, and by the inhabitants of Nuremberg in 1573. N. lat. 50° 12'. E. long. 11° 28'. See BAREITH.

CULEMBURG, a town of the United States, in Guelderland, situated on the S. side of the Leck. The lords of Culemburg were very powerful in the year 1150. In the year 1555 it was erected into a comté by Charles V. in favour of Florent de Pallant, one of the confederate nobles, who presented the remonstrance against the inquisition, and in favour of liberty of conscience, to the dukes of Parma, April 5, 1566. During the succeeding troubles, he retired to Culemburg, where he lived peaceably, and died in the year 1598. As he died without children, the comté descended to the comte de Waldeck, who had married the heiress by a collateral line; 27 miles S.S.E. of Amsterdam, and 16 N. of Bois-le Duc.

CULERA, CAPE, a cape of Spain, on the coast of Valencia. N. lat. 39° 8'. Long. 16° 25' E. of the Peak of Teneriffe.

CULEVRAS, CAPE, a cape of America, on the N. coast of the isthmus of Darien. N. lat. 9° 36'. W. long. 78° 52'.

CULEUS, the name of a measure of liquids, the greatest

of all the measures among the Romans: it contained twenty amphoræ. Columella reckons the culeus of wine, at the vineyard, to be worth three hundred nummi, or seventy-five denarii, that is, according to the English rate, a hundred and forty gallons, three pints and a half, for two pounds eight shillings, and fivepence farthing, which is about a halfpenny the pint. Columella, lib. iii. cap. 3.

The culeus is by others described to contain 160 congii, or 960 sextarii. We read of *dolia culearia*, and *sesquiculearia*, the latter of which must have been very large, being about $3\frac{1}{2}$ hogheads, and therefore larger than our pipes.

The word culeus is used also by some Roman authors for a leather sack.

CULEX, in *Entomology*, a genus of the dipterous order. The mouth is furnished with a single-valved exerted flexile sheath inclosing five bristles; feelers of two or three joints; antennæ approximate and filiform.

These insects are of the gnat tribe, and subsist on the blood and juices of larger animals, which they suck by means of their proboscis. In the larva state they live in stagnant waters; they have a small cylindrical respiratory tube near the tail, and the head armed with hooks by means of which they seize upon and secure their prey. The pupa is incurvated and subovate with respiratory tubes near the head. The genus contains many species not described by authors.

Species.

PIPIENS. Cinereus with eight brown rings. Linn. Fn. Suec. &c.

Inhabits Europe and the greater part of Asia and America, about watery places, and is every where known by its shrill buzzing noise, and severe puncture. It appears in immense numbers in Lapland during their summer. This is the common gnat of our country. The antennæ of the male are pectinated.

According to Kalm the Musquetoës are a variety of this insect.

ANNULATUS. Brown; abdomen and legs annulated with white; wings spotted with brown. Fabr.

Found in Europe, chiefly in Germany and Denmark. It is the same size as the former; the proboscis is half the length of the body; segments of the abdomen edged with white, and the first segment marked with a white dorsal line.

TRIFURCATUS. Brown, with pale lines on the thorax. Reaum.

Inhabits swamps and marshes of Europe.

CILIARIS. Brown-testaceous; wings fringed. Gmel.

A rare species found in Europe; its size is half that of the common gnat; the antennæ black with verticillate hairs; abdomen brownish.

CUTESCENS. Yellow; wings hyaline; rib yellowish. Fabr.

Found in marshes in Denmark.

HÆMORRHOIDALIS. Brown; abdominal margin fringed with rufous hairs. Fabr.

The largest of the gnat tribe. The species is a native of Cayenne. The antennæ are beset with thick verticillate hairs, the first joint naked, and of a shining blue colour; head brown, with the crown shining blue; legs blue, thighs testaceous beneath; wings white, with a brown rib.

CILIATUS. Back, with two yellow dorsal lines on the thorax; legs yellow. Fabr.

Smaller than the last, and inhabits Carolina.

PULICARIS. Brown; wings white with three dusky spots. Linn.

Inhabits Europe and America.

REPTANS. Black with hyaline wings; legs black with a white ring. Linn.

Very abundant in the north of Europe, and is extremely troublesome.

MORIO. Black, with white wings; hind-thighs clavate and ferrated. Fabr.

A species found in England; the antennæ are beset with tufted hairs, and the anterior thighs are pale at the base.

EQUINUS. Black; abdomen brown; front white. Linn.

Inhabits Europe, and is often found secreted among the hairs of horses.

STERCOREUS. Testaceous; wings reticulated; line on the thorax, and three on the abdomen blackish.

Native of Europe; frequent on the dung of quadrupeds.

VARIEGATUS. Cinereous; legs varied, black and white. Schranck.

Found in Austria. Head and poisers black; wings fringed.

ARGENTELUS. Back covered with silvery scales. Poireret.

Described in Journ. de Physique as a native of Barbary, which country it infests in great abundance.

CULIACAN, in *Geography*, a province of Mexico, in the domain of New Biscay, lying on the gulf of California, and bounded on the N. by Cinaloa, on the E. by New Biscay, on the S. by the Pacific Ocean, and on the W. by the fore-mentioned gulf, or Vermilion sea; about 240 miles long, and 200 broad. The soil is fertile, and the air salubrious. It has some silver mines. The chief towns are Culiacan, Petatlan, and St. Miguel.

CULIACAN, the capital of the above-mentioned province, situated on a rivulet which runs into the river Umay, called also the river of Culiacan; 481 miles N.W. of Mexico. N. lat. $24^{\circ} 32'$. W. long. $106^{\circ} 23'$.

CULINARY, an epithet frequently added to *fire*; determining it to be a common fire, excited in wood, coals, or other ordinary fuel; in contradistinction to solar fire, or that raised by the action of a burning glass; also to central fire; to animal fire, &c.

The word is formed from the Latin *culina*, kitchen; this being the chief place of such fires. See FIRE.

CULINARY Plants, in *Gardening*, are all such plants as are made use of in the art of cookery, as articles of food, or for the purpose of garnishing and ornamenting various kinds of dishes.

CULL, anciently *Collops Magnus*, or *Cullu*, in *Geography*, a poor sea-port town of Africa, situated at the bottom of the gulf of Stora, in the eastern province of Algiers, with a tolerable port, into which flows the river Zeamah. The French African company has a small factory in this place, where they purchase, as they do at Bona, corn, oil, leather, wax, and wool, and constantly keep a resident agent, who has charge of the correspondence between Bona, Algiers, La Calle, and Marseilles. N. lat. $36^{\circ} 50'$. E. long. $6^{\circ} 40'$.

CULLEN, WILLIAM, in *Biography*, an eminent practitioner, and teacher of medicine, was born at Lanerk, in Scotland, in the year 1712. His parents, who were respectable, but not wealthy, after giving him the usual school education of the country, put him apprentice to a surgeon and apothecary at Glasgow. At the conclusion of the term of his apprenticeship, he was engaged as surgeon to a vessel trading to the West Indies, in which he made several voyages. Quitting at length this situation, he settled as surgeon and apothecary at a village in the parish of Shotts, whence, after a short stay, he

C U L L E N.

removed to Hamilton. He here formed a connexion with Mr., afterwards Dr. William Hunter. As they had not sufficient business to employ the whole of their time, with a view of turning their leisure to advantage, and of improving themselves in their profession, they agreed, each of them in their turn, to pass a winter at some university. Mr. Cullen went the first winter to Edinburgh, and entered himself as pupil in the several classes. That he attended diligently to his studies while here was manifest, by his being soon after able to commence teacher. The following winter Mr. Hunter came to London, and entering into the service of Dr. William Douglas, as assistant in his dissecting room, he soon made himself so useful as to induce the Dr. to offer him a share in his lectures, an offer too advantageous to be rejected by the young adventurer; though by this means the partnership engagement between Mr. Cullen and Dr. Hunter was dissolved, it made no breach in their friendship. They continued to correspond with each other during the remainder of their lives. Cullen, while he remained at Hamilton, had the good fortune to be introduced to the duke of Argyle, while on a visit in the neighbourhood, and to assist him in some chemical pursuits. But a more fortunate circumstance was his being sent for to the duke of Hamilton, who had been suddenly seized with a complaint, sufficiently violent to alarm his family for his safety. The method adopted by Cullen was so judicious as to give relief to his noble patient, and to gain him the entire approbation of Dr. Clarke, who lived at some miles distance, and had also been sent for. About the same time he married Miss Johnson, the daughter of a neighbouring clergyman, by whom he had several children. In the year 1746, he took the degree of doctor in medicine, and was appointed teacher of chemistry in the university of Glasgow, to which place he had removed a small time before. He had now an opportunity of displaying his talents, which in a particular manner fitted him for the office of a teacher. His fondness for method and arrangement, his distinctness of enunciation, his vivacity of manner, and his knowledge of the science he taught, made his lectures peculiarly interesting to his pupils. In the mean while his reputation, as a practising physician, kept pace with his fame as a teacher, so that there were few cases of difficulty in which he was not consulted. In 1751 he was appointed professor in medicine to the university; and in 1756, on the death of Dr. Plummer, chemical professor at Edinburgh, he was invited to accept that chair. This offer was too advantageous to be refused. Quitting, therefore, his engagements at Glasgow, he went to Edinburgh, and in October in the same year, commenced his lectures. He soon became as great a favourite there as he had been at Glasgow, and found his course attended by a greater number of pupils than any of the other professors, excepting the teacher of anatomy. For this he was indebted not only to the great attention he paid to the business, and his complete knowledge of the subject, but to his address, in managing his pupils, whom he treated with kindness and familiarity, inviting them to his house, allowing them the use of his library, and readily giving his advice and assistance in all their difficulties. Some share of his popularity may also be attributed to the novelty of his opinions, or to a new theory on the causes of diseases, which he occasionally introduced into his lectures. Dr. Alison, lecturer on the *Materia Medica*, dying in the year 1760, Dr. Cullen was appointed to fill his place; the duties of which he continued to perform until the year 1766, when, in conjunction with Dr. Gregory, he was appointed lecturer on the practice of medicine in the place of Dr. Rutherford. He now resigned the chair

of chemistry to Dr. Black, who had been his pupil, and who in that line more than rivalled his teacher. The year following, Dr. Gregory dying, Dr. Cullen had the sole possession of the practical chair, which he held to within a few months of his death. This happened on the 5th of February, 1790, he being in the seventy-seventh year of his age. Though he lived to this great age, yet no deficiency was observed in his memory, or in the distinctness and clearness of his delivery. His lectures were not written, but given from short notes; they were therefore constantly varied, and the illustrations frequently entirely new. Finding his lectures on the *Materia Medica* were printing, he obtained an injunction against their being issued, until he had corrected them; and they were permitted to appear in 1772. In 1789 he gave an enlarged and improved edition of them, in two volumes, in 4to. Fearing a similar fate to his "*Lectures on the Practice of Medicine*," he published them in 1784, in four volumes 8vo., but his most esteemed work is his "*Synopsis Nosologiae Practicae*," in two volumes 8vo. It has passed through several editions. The fourth impression, published in 1785, contains his last corrections. The first volume contains the nosologies of Sauvages, Linnæus, Vogel, Sagar, and Macbride: the second his own, manifestly an improvement on those of his precursors. A small publication concerning the recovery of persons drowned, and seemingly dead, completes the works of this eminent professor. *General Biography*.

CULLEN, in *Geography*, a royal burgh in the county of Banff, Scotland. At one period this place was under the jurisdiction of an hereditary constable, which office was held by the earls of Findlater, when it was termed *Inverculan*, "from its situation at the mouth of the burn of Cullen, or Cullen, which at the north end of the town falls into the sea." The present earl of Findlater is almost sole proprietor of the town, and hereditary provost, under whom the government is administered by three bailies, a treasurer, dean of guild, and 13 counsellors. Cullen labours under two serious disadvantages, the want of a harbour, and that of water for domestic purposes; the latter is confined to one solitary spring, but the former might be obtained for the expenditure of a few hundred pounds. The exertions of an earl of the above family established a manufacture of linen and damask about 50 years past, which still flourishes, and yet the general appearance of the houses is mean, and the streets filthy. Two villages, named Cullen and Portknockies, near the town, are inhabited by fishermen, who possess 14 or 15 boats, and supply Cullen and the country plentifully with fish, besides which, they salt and dry large quantities of cod, ling, skate, and haddock, which they export in open boats to Leith, Montrose, Arbroath, and Dundee.

The soil of the parish of Cullen varies considerably; a large portion is a deep rich loam, other parts are of strong clay, and as it approaches the shore, there is a mixture of sand and gravel. The district extends about four miles southward from the sea, and is three miles in breadth; the surface generally declines towards the north and east, and Bin-hill is the only eminence entitled to the term of mountain, which is situated two miles from the sea, and one south-west of Cullen; this grand hill is 1050 feet above the level of the ocean, and has recently been planted with various species of trees to the summit; Cullen-house, the seat of the earl of Findlater, is surrounded with plantations formed about 25 years past by the earl, during which period 8000 Scots acres of land have been set with upwards of 30,000,000 of trees. The mansion stands upon a perpendicular rock 50 feet higher than the burn of Cullen, and the communication

ation with the parks and woods is formed by a handsome stone-bridge over the burn, the single arch of which is 64 feet high, and 84 in width; the nature of the surface of this domain produces the richest description of landscape; and the view from the house commands a fine circuit of country to the south; nor is that to the north, including the frith of Moray, less beautiful. The antiquities of this parish are confined to the ruins of a castle situated on an eminence close to the sea, near the town of Cullen, and those of a house where Elizabeth, queen of king Robert Bruce, is said to have died. The farms of the district are generally small, inclosed, and in a state of high cultivation, and the population amounted to 1718 in 1791. Sinclair's Statistical Account of Scotland.

CULLEN, a fair town of the county of Tipperary, Ireland; at a bog near which was found a golden crown, weighing six ounces, and many other ancient curiosities, of which an account is given in the Philosophical Survey of the South of Ireland.

CULLIAGE, or CULLAGE, a right usurped by the ancient lords, and established by a shameful custom, which gave them the first night with their vassals' brides.

The word is formed from the French *col, podex*, the breech.

It is said this right was established by Euenus III. king of Scotland, and finally abolished by Malcolm III. a compensation being settled in its stead; as occasioning frequent revolts of the vassals against their lords. See MARCHETA.

CULLION, in *Botany*. See ORCHIS.

CULLODEN, in *Geography*, a heath of Scotland, in the county of Inverness, about nine miles distant from Inverness, surrounded with hills, except on the side that lies open to the sea, and celebrated by the victory obtained in April 1746, on the part of the duke of Cumberland, over Charles Stuart, the Pretender, which completely terminated the hopes of this family and its friends. In less than half an hour after the commencement of the action, the rebels were totally routed. The French piquets, after covering the retreat of the highlanders, retired to Inverness, and surrendered themselves prisoners of war. An entire body of the rebels marched off the field in order, with their pipes playing, and the Pretender's standard displayed; the rest were defeated with great slaughter, and the field was covered with the dead and wounded. The road, as far as Inverness, was strewed with the bodies of the slain. Twelve hundred, or as some say, 3000 rebels were slain or wounded in the field and in the pursuit. The earl of Kilmarnock was taken, and in a few days lord Balmerino surrendered; and was conveyed, with other leaders of the rebellion, by sea to London, there to await their fate. The glory of this victory, in which the duke of Cumberland acquired great honour by his skill and valour as a commander, was unhappily sullied by the barbarity of the soldiers, who thirsted for revenge. It is said, that they traversed the field of battle, and massacred those miserable wretches who lay maimed and expiring. The vanquished adventurer rode off the field accompanied by a few horsemen; and having conferred with the old lord Lovat, dismissed his followers, and wandered about, a wretched and solitary fugitive, among the isles and mountains, for about four months, enduring such a variety of hardships and sufferings, as no other person ever survived. In less than an hour, his hope wholly vanished, and the rebellion was completely extinguished. When the news of this battle arrived in England, the nation was transported with joy, and extolled the duke of Cumberland as a hero and deliverer. Both houses of par-

liament congratulated his majesty on the auspicious event. They decreed, in the most solemn manner, their public thanks to his royal highness, which were transmitted to him by the respective speakers; and the commons, by bill, ad led 25,000*l. per annum* to his former revenue.

CULLITON. See COLYTON.

CULLOOR, a town of Hindoostan, in the country of Golconda; 15 miles W. of Rajamundry, and 100 E. of Hydrabad.

CULLUMPTON, or COLLUMPTON, a town of England, in the county of Devon, with a weekly market on Saturday. Here are manufactures of sagathies, ferges, and other woollen goods; 11 miles N. of Exeter, and 159 W. of London.

CULLY, or CUILLI, a small but handsome town of Switzerland, in the canton of Berne, district of Lausanne, delightfully situated on the banks of the Leman, or lake of Geneva, and remarkable for its excellent wine, which is reckoned one of the best of the famous wines *de la Vaux*. From an inscription which has been found here, in honour of Bacchus, with the epithet *Libero Patri Gouliensi*, this town is supposed to be very ancient. In 1440 Louis de la Palu, bishop of Lausanne, gave the inhabitants leave to enclose it within walls, and to surround it with ditches.

CULM, in *Botany*. See CULMUS.

CULM, in *Agriculture*, is a term sometimes applied to the haulm, trunk, or straw of such plants of the grass kinds as elevate their leaves, flowers, and fruits according to the definition of Linnæus; and in which the trunks or stems are tubular or hollow; having in many cases knots or joints distributed at suitable lengths or distances throughout their whole extent; the leaves being long, sleek, and situated either near the roots in large numbers, or proceeding singly from the different joints of the stalk, which they embrace at the base, like a sheath or glove. The haulm is most commonly garnished with leaves; sometimes, however, it is naked, or devoid of leaves, as in a few species of cypress-grasses. Most grasses have a round cylindrical stalk or stem, but in some species of cypress-grass, and others, it is triangular. The stalk is sometimes entire; that is, has no branches; sometimes branching, as in the *sebanus aculeatus* and *capensis*; and not seldom consists of a number of scales, which lie over each other like tiles. And lastly, in a few grasses the stalk is not interrupted with joints, as is the case in the greater part of them. The space contained betwixt every two knots or joints is termed by botanical writers *internodium* and *articulus culmi*. This sort of trunk often affords certain marks of distinction in discriminating the species of the plants. Thus, in some kinds the species are scarcely to be distinguished, except by the angles of the *culmus* or stalks. These, in some of the species are met with to the number of five, in others to six, and in others to still more, as ten.

CULM, or KULM, in *Geography*, a town of the grand duchy of Warsaw, which, since the peace of Tillit in 1807, belongs to the kingdom of Saxony, and formerly belonged to Prussia, was built in 1239, on an eminence near the banks of the Vistula, 90 miles S. of Dantzic. It was bequeathed by one of the ancient dukes of Mazovia to the knights of the Teutonic order. The inhabitants afterwards withdrew themselves from the dominion of the latter, and submitted to Poland. While the Teutonic knights had the sovereignty of Culm, the high tribunal of Prussia was held in this city. Hence the law of Culm was in such reputation that there were few places in Prussia where it was not received.

Culm is a large city, but thinly inhabited. It was anciently

ciently one of the Hanseatic towns, carried on an extensive trade, and contained considerable warehouses, built by English merchants. Its commerce, however, began to decline in the beginning of the fourteenth century, when Danzig rose into notice. It also suffered considerably during the wars in Poland. In the year 1457 the knights of the Teutonic order, from whom Culm had revolted, made themselves masters of it again; but in a few years after it was retaken by the Poles, who raised it to a bishopric. In 1544 Culm suffered greatly by fire. In 1678, bishop John Malachowsky attempted to repeople the town, by attracting settlers from all parts; and it is worth recording, that, though a Roman Catholic dignitary, he was sufficiently enlightened to grant the colonists the free exercise of the religious worship to which they might be attached.

The trade of Culm was once more reviving, and commencing to flourish under the dominion of Prussia, when the short war of 1806 and 1807 annihilated again its fair prospects. There was at Culm a Prussian military academy, for sixty young noblemen. Culm has five Catholic convents, and a Catholic college, which, however, is hardly deserving of that name.—Also, a hill of considerable magnitude in the midst of the Saxon village of Reichenau, in the circle of the Erzgebirge.

CULM, in *Minerology*, a variety, according to Kirwan, of the native mineral carbon, but less pure, differing from it chiefly in being more brittle, and emitting, when ignited, a disagreeable smell. Its colour is black; lustre from three to four; not easily kindled, but when ignited burns a long time without flame or smoke, does not cake, and leaves but little ashes. The specific gravity is 1.396. It seems to be the glanz-kohle of Werner. It is found in Wales. See *COAL-balls*.

CULMAIN, in *Geography*, a town of Germany, in the circle of Bavaria, and Upper Palatinate; 14 miles E. of Bayreuth.

CULMBACH, or CULEMBACH, HANS VON, in *Bio-graphy*, a painter, and an engraver on copper and on wood. He is said to have been a disciple of Jacob Wolch, and afterwards to have received instructions from Albert Durer. He died in 1545.

This artist marked his plates with J. C. or H. v. C. We shall only notice the following, which are in a dry, stiff manner:

“A Soldier armed, conversing with a female Peasant,” 1517. “The Crucifixion of our Saviour, with the Virgin and St. John, one on each side the Cross.” “St. Michael killing the Dragon,” copied from M. Schoen. Heineken.

CULMBACH, in *Geography*, a town of Germany, in the circle of Franconia, in the margraviate of Bayreuth, which, till the year 1806, belonged to Prussia. It was anciently the principal town of the margraviate, which went likewise by the same name. The town is seated on the river Mayne, near the old castle of Plaffenbourg, 27 miles S.E. of Cobourg, and 30 N.E. of Bamberg. E. long. $11^{\circ} 28'$. N. lat. $50^{\circ} 13'$.

CULMIFEROUS PLANTS, in *Agriculture*, are all such as have smooth jointed or knotted stems, and in which the seeds are enveloped or wrapped up in a sort of chaffy husks or coverings. All the grains, and most of the grasses, as well as many other plants, are of this kind.

CULMINATING POINT, in *Magnetism*. See *MAGNET*.

CULMINATION, in *Astronomy*, the transit of a star or planet over the meridian, or that point of its orbit wherein it is at its greatest altitude.

Hence, a star is said to *culminate*, when it passes the meridian.

To find the culmination of a star, or the line wherein it passes the meridian. On a meridian line A B (*Plate V. Astronomy, fig. 43.*) stretch a thread, DC, perpendicularly; and from D to E, another DE, cutting the meridian obliquely, at any angle: the triangular thread, DCE, will cut the plane of the horizon in the meridian line, or at right angles; and consequently will be in the plane of the meridian.

The eye, therefore, being so placed, as that the thread DE may cover the thread DC; wait till the star be bisected by the triangle DCE; for then the eye and the star will, together with the triangle DCE, be in the same plane; consequently the star is in the meridian.

To find the culmination of a star by the globe, see *GLOBE*.

There are few days when one or more stars do not come to the meridian with the sun, and then they have the same right ascension with him:—also, at some time of the year, the sun must have the same right ascension which any proposed star has; though at other times he may have a less, and so precedes, or comes to the meridian before that star; or a greater, and so follows that star, and comes to the meridian later. Hence is derived the following method of finding the culmination of the stars. Rule. Subtract the sun's right ascension for the proposed day, from the right ascension of the given star; the difference will be the time of the star's culmination, nearly. Then say, as 24^h is to the daily change of the sun's right ascension, so is the time of culminating, nearly, to a fourth number, which, being subtracted from the time of culminating, nearly, will give the true time of the star's culmination. If this time be less than 12^h it happens in the afternoon; but if more than 12^h , the excess above 12^h will shew the time next morning. N.B. 24^h must be added to the star's right ascension, if the sun's right ascension be greatest.

If the time of the star's culmination be wanted for any other meridian besides that of Greenwich, or London, add the longitude in time to the time of culmination nearly, if the longitude be west, or take their difference if it be east, and use that sum or difference instead of the time of culmination nearly; observing only in the latter case, that if the longitude in time be greater than the time of culminating nearly, the minutes and seconds resulting from the proportion must be added to the time of culmination nearly, instead of being subtracted from it.

To find the time of the culmination of the moon, or any planet. Mr. Keith has given the following rule in his “*Trigonometry*,” b. iii. c. 2. Take the difference between the sun's and planet's motion in right ascension in 24 hours, if the planet be progressive, or their sum, if retrograde. Then, as 24 hours diminished by this sum or difference, when the planet's motion is greater than the sun's, or increased by it when the sun's apparent motion is greater, is to 24 hours; so is the planet's right ascension at noon, diminished by the sun's, to the time of its transit. Note. If the sun's right ascension be greater than the planet's, 24 hours must be added to the planet's right ascension before you subtract.

CULMITZSCH, in *Geography*, a small town of Saxony, in the circle of Neustadt, remarkable for a rich quarry of slate in its neighbourhood.

CULMORE FORT. See *LONDONDERRY*.

CULMSEE, or CULMENSEE, a small town of the grand duchy of Warsaw, which, since the peace of Tilsit, belongs to the kingdom of Saxony. It was built in 1251, and contains the cathedral church of the bishopric of Culm.

CULMUS, in *Botany*, a Culm or Straw, is the peculiar stem

stem of the grass, corn, and reed tribe. It bears both leaves and flowers, though sometimes the former are situated only about the lower part of the Culm. There are also many rushes which have none but radical leaves; yet their stem is by analogy called a *Culmus*, and not a *Scapus*. The nature of this kind of stem is better understood than defined. It is almost always cylindrical, rarely triangular, never square. It is mostly simple, rarely branched; generally consisting of several joints or knots, but sometimes, as in rushes, uninterrupted. For the most part it is hollow, and lined with a fine brilliantly white film; sometimes it is filled with pith. Its cuticle is hard, and contains stony earth. This sort of stem is not found in any dicotyledonous plant, but only in such as have either one cotyledon, or none at all. S.

CULPABILIS. See *Non est culpabilis*.

CULPÆUS CANIS, &c. in *Zoology*, the Arctic fox, or **CANIS VULPES LAGOPUS**; which see.

CULPEPPER, NICHOLAS, in *Biography*, student, as he calls himself, in physic and astrology, was the son of a clergyman, by whom he was sent, after receiving a preparatory education, to the university of Cambridge. There making but a short stay, he was put apprentice to an apothecary, under whom he appears to have acquired a competent knowledge of the *Materia Medica*, and of the method of preparing and compounding medicines. On completing the term of his apprenticeship, he came to London, and settled in Spital Fields. This was about the year 1642. By the whole tenor of his writings we find he joined, or, at least, favoured the Puritans, and those who were engaged in those unhappy times in overturning the constitution of the country. But his warfare was with the college of physicians, whom he accused of craft and ignorance. Like the popish clergy, he says, they endeavoured to keep the people in ignorance of what might be useful either in preserving or restoring health. To counteract their endeavours, he published, in 1649, a translation of the "Dispensary of the College of Physicians," in small 4to., adding to the account of each drug and preparation a list of their supposed virtues, and of the complaints in which they were usually given. He also published an Herbal, which has passed through several editions, and is still in repute as a sort of family guide. He tells you in this book under what planet the plants are to be gathered, which he thinks essential in preserving their virtues. He intended, he says, treating of the diseases incident to men, at the different periods of their lives, and as a beginning, gave a directory to midwives, treating in it of the method of insuring a healthy progeny, and then of the management of new-born children. Though this book is of very small value, it passed through many editions. He died at his house in Spital Fields in 1654.

CULPEPPER, in *Geography*, a county of Virginia, in America, between the Blue Ridge and the Tide-Waters, which contains, by the census of 1800, 18,700 inhabitants, of whom 7348 are slaves. The court-house of this county is 45 miles from Fredericksburg, and 95 from Charlottesville.

CUL-PRIT, in *Law*, a term used by the clerk of the assize, or clerk of the arraigns, on behalf of the crown, when a person is indicted for a criminal matter.

After the indictment is read in court (which is the crown's charge against the prisoner at the bar), he is asked if guilty, or not guilty? If he answers *not guilty*, there is next a replication from the crown, by continuing the charge of guilt upon him; which is expressed by pronouncing the word *cul-prit*; *cul* being an abbreviation of the Latin word *culpa*, *guilt*, or *culpabilis*, *guilty*, and *prit* (now *pret*) the old French word for *ready*; or, as others rather think, the

Latin *apparet, appears*: or rather, *qu'il paroit*, let it appear so, *i. e.* not guilty.

From this formula, therefore, of the clerk of the arraigns, the prisoner is deemed guilty of the crime charged on him; and that the crown is ready to prove it upon him: this sense of the term *prit* being deduced from the year-books, and other ancient repositories of law.

That this is the true explanation of the term, seems evident from the form of the entry of the record of the trial, when drawn at large.

By this replication, the king and the prisoner are at issue. How our courts, says judge Blackstone, came to express a matter of this importance in so odd and obscure a manner, "*rem tantam tam negligentem*," can hardly be pronounced with certainty. It may, perhaps, however, be accounted for by supposing, that these were at first short notes, to help the memory of the clerk, and remind him what he was to reply; or else it was the short method of taking down in court, upon the minutes, the replication and averment; "*cul-prit*," which afterwards the ignorance of succeeding clerks adopted for the very words to be by them spoken. But, however it may have arisen, the joining of issue, (which, though now usually entered on the record, is no otherwise joined in any part of the proceedings) seems to be clearly the meaning of this obscure expression; which has puzzled our most ingenious etymologists, and is commonly understood as if the clerk of the arraigns, immediately on plea pleaded, had fixed an opprobrious name on the prisoner, by asking him, "*cul-prit*, how wilt thou be tried?" for, immediately upon issue joined, it is inquired of the prisoner, by what trial he will make his innocence appear. This form has, at present, reference to appeals and approvements only, wherein the appellee has his choice either to try the accusation by battle or by jury. But upon indictments, since the abolition of ordeal, there can be no other trial but by jury, *per pais*, or by the country; and, therefore, if the prisoner refuses to put himself upon the inquest in the usual form, that is, to answer that he will be tried by God and the country, if a commoner; and if a peer, by God and his peers; the indictment, if in treason, is taken *pro confesso*; and the prisoner, in cases of felony, is adjudged to stand mute, and if he perseveres in his obstinacy, shall now be convicted of the felony. Stat. 12 Geo. III. c. 20. When the prisoner has thus put himself upon his trial, the clerk answers in the humane language of the law, which always hopes that the party's innocence, rather than his guilt, may appear, "God send thee a good deliverance."

CULROSS, in *Geography*, a royal borough and seaport, in the county of Perth, Scotland, is situated on the north shore of the Frith of Forth, whence it appears to great advantage, elevated on an abrupt ascent. The town consists of two streets, intersecting each other at right angles. It received its charter from James VI. in 1588, and is still in possession of all the original privileges granted by that royal act. James IV. and Charles II. granted the inhabitants the exclusive privilege of making *girdles* of iron, an utensil used in Scotland for baking unleavened bread; but the girdles cast at Carron having superseded them, the town has evidently declined; nor has their hitherto considerable trade in salt and coals been more successful lately than was an attempt to extract tar, naphtha, and volatile salt, from pit-coal, commenced by the earl of Dundonald, who expended large sums in erecting works for this purpose at Culross. The harbour is perfectly safe; but several sunk rocks obstruct the entrance, and thus prevent the admission of ships of considerable burden, though the spring tides rise about sixteen feet.

The parish of Culrofs is nearly four miles square; and, except the sudden ascent from the shore, may be pronounced almost level. The fourth portion of the soil is in a state of excellent cultivation; but the north is little more than a vast marsh, susceptible of no other improvement than planting. Part of the district abounds with iron ores and iron-stone, free-stone of superior quality, and coals: and at Kincardine, four miles from Culrofs, fish are caught to the amount of 1000*l.* per annum, by *cruives*, an invention calculated to facilitate the labours of the fisherman. The monastery of Culrofs, situated above the town, was founded by Malcolm, thane of Fife, in 1217, who dedicated it to the Virgin Mary and St. Servanus, and endowed it for an abbot and nine monks of the Cistercian order. Near the ancient abbey church is the magnificent seat of Culrofs, erected about 1590, by Edward lord Kinlofs, and now the property of the earl of Dundonald; besides which, the parish contains an elegant mansion, named Valley-field, the residence of sir Charles Preston, and the vestiges of two Danish camps. The population was 1442 in 1792.

CULTELLATION, a term which some authors use for the measuring of heights and distances by piecemeal; that is, by instruments which give us such heights and distances by parts, and not all at one operation.

CULTIVATION, in *Agriculture*, the art of tilling, preparing, and improving the soil by means of labour and manure, or other similar methods, so as to render it in a fit condition for affording plentiful crops, of different kinds, at suitable periods, according to the nature of the climate, situation, and other circumstances in which it is placed. It is the art of bringing Land into such a state of texture and confidence, as that the roots of cultivated vegetables may be permitted to spread and extend themselves in the most proper manner for deriving their nourishment from it; and that water and other matters necessary for the perfect growth, vegetation, and support of such plants as crops, may be contained and preserved in it in the most favourable manner for these purposes.

This is a business of course, which consists of different divisions or distinctions, in respect to its nature, as,

1. Tillage, in all its different branches.
2. Manuring, or the application of composts, and other substances.
3. Weeding, or the removal of all sorts of noxious plants.
4. Managing grafts-plants, or grafts husbandry.

The proper management, in regard to all these, and some other circumstances, constitute what may be termed cultivation, or field husbandry. See **TILLAGE** and **HUSBANDRY**.

CULTIVATOR, a name given to an implement, somewhat of the horse-hoe kind, invented for the more convenient and effectual sowing of the earth or mould. (See **HORSE-HOE DRAG**, **EXTIRPATOR**, &c.) The implements of this kind, which are employed in agriculture, are constructed in very different ways, according to the nature and circumstances of the land, and the particular crops and uses for which they are designed. In *Plate X. on Agriculture*, *fig. 1*, there is the representation of one, which is made upon a very simple plan, and which is recommended by the writer of the Agricultural Survey of the County of Nottingham. The dimensions of which are these: from *a* to *b*, the length of the first bull, 4 feet 6 inches. From *c* to *d*, the length of the second bull, 3 feet 9 inches. From *a* to *e* 16 inches; the teeth 2 feet long, and bent near the bottom, for the share part to lie flat on the earth, and placed one foot from each other. From *e* to *f*, the length of the beam is 6 feet. From *g* to *h*, the length of the iron axle-tree for the small wheels, 1 foot 6 inches. From *i* to *k*, the

length of the iron that shifts through the beam, and fastens with a screw at *l*, 2 feet.

The great advantage in this tool is, that the teeth are so placed, that they intersect each other; and being only twelve inches apart, by thus intersecting, the distance is reduced to six inches; and from the breadth of the share being full three inches, the intermediate space is further reduced, so that the distance is ultimately so small, that the whole of the ground must be perfectly broken down and reduced into a fine state of mould, in consequence of which, the purpose of ploughing is not only answered, but that of harrowing likewise, without the roots of the quick-grass being cut in two; which is a benefit that cannot be obtained by ploughing. And from the teeth standing in a forward direction, and bending in that way, they likewise bring up all the roots to the surface of the land, which is another important point that cannot be gained by the plough. And there is a considerable abridgement of labour with this tool, which is another circumstance of great consequence to the farmer; as with four horses and one man, from six to seven acres are capable of being worked over in the course of a day, especially where the soil is of a sandy quality. And at *fig. 2*, is shewn a *corn cultivator*, which is employed in Essex, where the grain is sown at narrow intervals, by Mr. Rogers, and other farmers, as stated in a survey of that district, by Mr. Young. The handles from Cook's machine are capable of being attached to it. The dimensions are as below:

		Feet.	Inches.
From <i>a</i> to <i>b</i>	- -	4	7
<i>c</i> to <i>d</i>	- -	4	7
<i>c</i> to <i>a</i>	- -	0	9
<i>d</i> to <i>f</i>	- -	0	9
<i>a</i> to <i>e</i>	- -	0	10
<i>e</i> to <i>g</i>	- -	0	5
<i>g</i> to <i>h</i>	- -	0	4

This is found a very useful and convenient implement in these cases, for working between the narrow rows of white corn-crops.

Fig. 3, exhibits the representation of a *bean cultivator*, which is made use of by the same farmer at Ardleigh, and which is found in practice to be a most excellent tool.

The dimensions of it are these:

		Feet.	Inches.
From <i>a</i> to <i>b</i>	- -	4	0
<i>a</i> to <i>c</i>	- -	1	3
<i>b</i> to <i>d</i>	- -	1	3
<i>c</i> to <i>f</i>	- -	1	0
<i>f</i> to <i>g</i>	- -	0	5
<i>g</i> to <i>h</i>	- -	1	0
<i>h</i> to <i>i</i>	- -	0	5

And at *fig. 4*, is exhibited a *double cultivator*, which is found useful on the farm of C. C. Western, esq. in the same county.

The dimensions of this are as below:

		Feet.	Inches.
From <i>a</i> to <i>b</i>	- -	6	0
<i>c</i> to <i>d</i>	- -	1	10
<i>b</i> to <i>h</i>	- -	1	9
<i>e</i> to <i>b</i>	- -	6	0
<i>f</i> to <i>h</i>	- -	1	2
<i>f</i> to <i>g</i>	- -	0	11
Diameter of wheels	- -	2	1

This is a very powerful and effective implement, and dispatches much work with facility.

An improved implement of this sort is likewise shewn at *fig. 5*, which is found of great utility in preparing and bringing

stiff heavy soils into a fine state of mould. It is well calculated for this purpose, from the weight which it possesses, and its great length of coulters. In this tool *a, b, c, d*, are the beams or buils in which the shares or coulters are placed, and which have a sort of triangular form; *d, d, d*, the three wheels, which are capable of being raised or depressed, and *e, e*, the handles.

Implements of this kind are also sometimes constructed of a compound description, so as to operate, with certain additions, in respect to shares, as *scarifiers* and *scufflers*; and, when complete, as a cultivator. Mr. Cook is the inventor of an useful tool of this nature. See SCARIFIER and SCUFFLER.

CULTRARIUS. See POPÆ.

CULTURE, in *Agriculture*, the art of tilling, improving, or bettering the condition of lands, by such practices as are the most adapted to their peculiar nature and qualities, whether under the systems of grain or grass husbandry.

CULTURE, *Row*, is that mode of cultivation in which the crops are sown or set in rows or drills, at certain distances, by means of the hand or machinery. See DRILL-HUSBANDRY, and DRILL.

CULVER, in *Rural Economy*, a name provincially given in some districts to the pigeon.

CULVER-HOUSE, a name sometimes applied to signify a pigeon-house, or dove-cot.

CULVERINE, a piece of artillery longer than ordinary cannon of the same caliber. Its length is generally about ten feet six inches. The famous culverine of Nancy is 22 feet long, and throws a bullet of 18 lb. They do not make use of this piece, as it does not throw a ball so far as cannon of the same bore. It is at Dunkirk. See CANNON. Hence a soldier of militia in the 15th century, was called by the French *coulevrenier*. He wore an habergeon, or small coat of mail, or armour with sleeves, a gorgerin, or neck-piece, and a head-piece, and brass placard before, with a dagger and cutting-sword.

CULVERT, an arched drain for the passage of water; these occur very frequently under roads, and still more so under navigable canals, for conveying rills and brooks of water from the upper to the lower side of the road or canal, and even for discharging the rain water out of hollows on the upper side of a canal. When such a drain or arch under a canal sinks down in the middle, in order to clear the bottom of the canal, it is said to be "broken-backed." Under the article CANAL we have treated pretty fully on the construction of culverts, and have only here further to add some remarks on the culverts for large canals, like the Inverness and Fort William, or Caledonian Canal, where it is difficult for the engineer in a short space of time to ascertain the size of culverts for some ravines, sufficient for discharging their flood waters, and not be liable to choak by timber and other matters hurried down some of the streams from mountainous districts, and where it is often advisable to construct two arches, in such glens as are deep enough to admit of it, the larger of which may serve for a road-arch, or communication under the canal, at all times but during great floods, by which the inconvenience and expence of bridges over the canal may be saved, in many instances. At Bannvie, a culvert, or aqueduct, as the same are called when they exceed a certain size, under canals, was finished under the Caledonian Canal, in the spring of 1806, by Mr. Thomas Telford, consisting of two arches 9 feet wide, and 10 feet high each, their bottoms being paved with stones on edge, to serve for the passage of carts, cattle, &c., which otherwise must have had a pair of swing bridges over this large canal, which is too wide to admit of one bridge

to turn or swing across it. We lately had occasion to notice some places on the upper side of the Grand Junction Canal, in Buckinghamshire, where the culverts are made so small that sudden rains have been known to inundate one or more houses, while bushes, straw, and other matters are always liable to choak up or diminish the water-way, so as to endanger the lives of the inhabitants, were such to happen in the night of a rainy season.

CULVERTAIL, in *Ship Building*, is used for a manner of letting one timber into another, so that they cannot slip asunder. The fastenings of a ship's *carlings* into the beam is so performed. See DOVE-TAIL.

CUMA, in *Geography*, a town of the island of Gdolo, situated at the bottom of a large bay.—Also, a small island in the Mediterranean, near the coast of Italy; five miles west of Naples. See CUMÆ.

CUMÆ, in *Ancient Geography*, *Cuma*, or *Cyme*, an ancient city of Italy, in the Campania, west of Naples, and north of Baiæ, situated near the sea, on a lofty rock or hill, which afforded a beautiful and extensive prospect, and a proper place for the foundation of a citadel. It is said to have been founded in times of remote antiquity by two colonies of Greeks; one of which migrated from a city of the same name in Æolia, and another from Chalcis in Eubœa; and both of them accustomed to maritime occupations, sailed in pursuit of discoveries into the Mediterranean, and established themselves on the coast of Italy. These two colonies, after some previous adventures, settled on the same spot, and determined to share in common the honour and advantage of the situation in which they were established. Accordingly, the Cumæans gave their name to the new city, and the Chalcidians gave theirs to the inhabitants, so that the city of Cumæ was inhabited by Chalcidians. This colony, in process of time, became very powerful, and extended itself along the coast of Naples. The first establishment of the Cumæans was at a place called "Dicearchia," which was adapted to the accommodation of their vessels; and it afterwards took the name of Puteoli or Puzzuoli. The Cumæans soon perceived that they had not chosen the most favourable spot for a permanent and flourishing settlement; the gulf of Naples presented a more commodious and desirable situation; but as their capital had been consecrated to the gods, and the lares had possession of their houses, they thought it impicthy to abandon it. However, they built a second town at the bottom of the gulf, and this they called "New Cumæ," or *Νεαπολις Κομαίων*. Such was the origin of the name, and of the town of Naples. The Cumæans made also another establishment at Baiæ. Cumæ, founded as we have related by Greek emigrants, became the seat of commerce, the parent of Naples, and the capital of a state that ruled the seas before either Rome or Carthage were heard of. Its prosperity was of long duration, while the power of infant Rome was confined within the narrow limits of her own plain. Under the sway of Aristodemus, Cumæ afforded an asylum to Tarquin the Proud, the deposed king of Rome, whom all the neighbouring potentates had in vain attempted to assist, and had refused to relieve. This harbinger of a banished prince had attained the height of power by subverting the liberties of his country. In the 64th Olympiad, about the 524th year B. C., the Tyrrenians attacked Cumæ, in hopes of plundering her rich stores, the fruits of long and prosperous traffic, but were driven off with loss; in this emergency, the republic owed its safety to the courage and conduct of Aristodemus, and rewarded his services with every token of honour which a free state could bestow. He soon became so popular a leader, as to excite the jealousy of the senate; with a view to his destruction, they sent him with a very small force to defend

defend the city of Anicia against the Tuscans; but by the exertion of great military talents, Aristodemus terminated the campaign gloriously, and when he returned to Cumæ, availed himself of the attachment of the troops for destroying his enemies, and usurping the sovereign authority. He reigned many years with despotic authority, but at length, as it has happened to many other tyrants, was betrayed by his own creatures, and, with his whole family, put to the sword. As Rome advanced in her fortunate career, the glory of all the neighbouring powers faded away before her; the Cumæans, in their turn, submitted to her yoke, and were treated with lenity; but real liberty was gone, and trade abandoned their shores; at length, the dullness and solitude of the place grew so profound, as to become proverbial: "vacuæ Cumæ," "Quieta Cyme, &c." Indeed, the Cumæi were noted for their stupidity. "Cumæ is stupid to a proverb," says Strabo, (lib. 13.); and he assigns these reasons for it. *First* of all; they were 300 years before they thought of laying a duty on merchandise imported into their harbours, and before they found that they inhabited a maritime city. *Secondly*. Having mortgaged their porticoes for a certain sum of money, and failing to pay it at the time stipulated in the contract, their creditors would not allow them to walk under them; but, when the rains began to fall, those creditors, being touched with compassion, caused it to be published, that the Cumæans might, if they pleased, take shelter under their own porticoes: which gave occasion to this railery: "The Cumæans had not the sense to know that they had a right to stand under their own porticoes when it rained, till they were informed of it by the voice of the crier." Cumæ was farther reduced to a lower state by the Goths; and at last, being a mere receptacle for thieves, it was, in the year 1207, totally ruined and forsaken. The rocky hill upon which the citadel of Cumæ stood, is the produce of an eruption, and hollowed into many spacious caverns, amongst which we now look in vain for the grotto where the "Cumæan sibyl" (see *SIBYL*) pronounced her oracles; this sanctuary was undermined and destroyed in the Gothic war. Agathias informs us that it served as a foundation for one of the principal towers of the fortrefs. When Narfes invested the citadel, he caused this rocky cover to be cut through in several directions, and then propped up with beams; when every thing was ready for the assault, the wood was set on fire. As soon as the proppes were consumed, the rocks gave way, and the walls fell with them into the temple; and on these accumulated ruins the imperial troops entered the breach. If antiquarians may be credited, the cave which was the abode of the Cumæan sibyl, extends three Italian miles in length, to the lake Avernus, where it has another entrance; but in several parts the passages have been ruined; and at the entrance near Cuma, it is not possible to advance above 200 paces. This part of it is cut out of a rock, and is of considerable height and breadth. Some years ago, the imperial general Wenzel caused an aperture with 51 steps to be cut in the side of the cave, for the convenience of coming out of it; but the peasants have since stopped it up.

Cumæ extended across the plain towards the east, where many ruins are still to be seen. A large brick arch, called "l'Arco Felice," thrown across a chasm in the ridge that bounds the plain on the east side, is supposed to have been a gate of the city, or a passage under a Roman aqueduct, and not a monument of the ancient Cumæan republic. In Lucan's time, about A. D. 62, Cumæ appears to have been a very populous city, from the following passage:

"——— Acidalia quæ condidit Alite muros
Euboicam referens fecunda Neapolis urbem."

"Where the fam'd walls of fruitful Naples lie,
That may for multitudes with Cumæ vie."

The adjacent country still retains a luxuriant fertility, especially towards "Torre di Patria," where it produces abundance of fig-trees.

CUMÆ, a town of Asia, in Æolia, the largest and most beautiful in this province, according to Strabo. Some have said that Homer, and also Ephorus, were of this city. It was episcopal, as we learn from the acts of the council of Ephesus, held in the year 431.

CUMAMUS, in the *Materia Medica*, a name given by many of the ancients to CUBEBES.

CUMANA, in *Geography*, a province of the government of Caracas in South America, including also Barcelona, which, however, has never formed a distinct province, but being included in the grant to the Wallees, was esteemed a part of Venezuela. The town of Barcelona was founded in 1634, on a plain, one league from the mouth of the river Neveri. The population is computed at 14,000; but the town is disagreeable, and is only noted for feeding swine. The population of the province of Cumana amounts, according to Depons, to 80,000.

The town of Cumana is the most ancient in the Caracas, having been founded in the year 1520, on a sandy soil, about a league from the sea. The heat of the climate is very great; nevertheless the population is computed at 24,000, and is thought to be on the increase. It is, however, subject to frequent earthquakes, which Humboldt supposes to proceed from the volcanoes of Cumucuta, which force out sulphur and hot-water. The caverns of Chuchenaro emit an inflammable gas, which shines in the night, especially after rains, to the height of 100 fathoms. The population of Cumana is composed chiefly of Creoles, who are industrious, and fond of their native place. The great article of trade is salted fish, which is sent to Caracas and the windward islands; the industrious inhabitants being from Catalonia, and the Canaries. Cumana is difficult of access, and might present a defence of about 5000 men. N. lat. 10° 12'. W. long. 66° 40'.

CUMANA, *New*, or *New Andalusia*. See *Spanish GUIANA*.

CUMANAGATE, a small town in a bay on the coast of Terra Firma, in the province of Cumana; situated on a low flat shore, which abounds with pearl oysters.

CUMANCHES, a tribe of warlike Indians, who every year enter the province of New Mexico, to the number of about 1500 men. Their country is unknown, as they always march prepared for war, which they carry on against all the other tribes. They encamp in tents made of the skins of buffaloes, and which are carried on the backs of large dogs trained for that purpose. The men are only clothed down to the navel, and the women to their knees. When they have concluded the traffic which brings them to this province, consisting in the skins of wild goats and buffaloes, and little children, whom they have made captives, for they kill the men and women, they withdraw till another year.

CUMANDA GUACU, in *Botany*, a name for certain very large Indian kidney-beans, which roasted, confused, and exhibited with an egg, are given for fluxes of the belly; boiled, made into a cataplasm, and applied to the belly, they are said to cure colic pains; and they are in this form applied to apostemations, with a view of resolving them.

CUMANIA, or COMANIA, in *Ancient Geography*, *Kizlar-Kalesi*, a fortrefs situated on an elevated rock, before the Caucasian gates according to Pliny. He says that it was provided

provided with a good garrison, for defending the passage which led to an immense number of barbarians, who inhabited the regions on the other side of Caucasus.

CUMARCA, in *Ichthyology*, a species of *Stromateus*; which see.

CUMARUNA, in *Botany*, Aubl. Guian. Pl. 296. Lam. Ill. Pl. 601. Class and order, *diadelphia decandria*.

Gen. Ch. *Cal.* Perianth top-shaped, one-leaved, three-toothed. *Cor.* Petals five, two lower ones shorter. *Stam.* Filaments ten, nine united at the base. *Ferac.* Legume, with a single seed.

Sp. C. A tree. *Leaves* alternate, pinnated; leaflets few, alternate, egg-shaped, veined. *Flowers* in a terminal panicle. A native of Guiana.

CUMBACH, in *Geography*, a small town of Germany, in the Principality of Saxe-Gotha, remarkable for a fish-pond of 120 acres, which yields excellent carp and eels.

CUMBER, a port town of the county of Down, Ireland, situated on a branch of the lake of Strangford. It has a very fine strand near it, and a race course two miles in circuit. It is 8½ Irish miles N. of Dublin, and about 9 S. E. from Belfast.

CUMBERLAND, RICHARD, in *Biography*, an English bishop of considerable celebrity, was born in London in the year 1632; he received his classical learning at St. Paul's school, whence, about the year 1640, he was removed to Magdalen College, Cambridge. Here he took his degrees, and pursued his studies with a view to the practice of medicine. Physic, however, he soon relinquished for the study of theology; and being elected fellow of the college, he took orders, and obtained the rectory of Brampton, in Northamptonshire, where he continued in the zealous discharge of the duties attached to his office, till the year 1667, when he came to London, and was chosen chaplain to sir Orlando Bridgman, then chancellor, who shortly after presented him with the living of Allhallows, in Stamford. In this situation he devoted himself as well to the immediate duties of his profession, as to philosophical studies. In 1672 he published a treatise, in quarto, entitled, "De Legibus Naturæ Disquisitio Philosophica, &c." This work, which was intended as a refutation of the tenets of Hobbes, obtained for its author a high degree of reputation. It has been twice translated into English, with additions. In 1680 he took his doctor's degree; and in 1686 he published, "An Essay towards the Recovery of the Jewish Weights and Measures, comprehending their Monies, by Help of an ancient Standard, compared with ours of England, &c." Dr. Cumberland was always attached to the doctrines of the church of England; and on account of his zeal in defence of the principles of the revolution, he was selected as a fit person to fill the see of Peterborough. To this high honour he was appointed without any solicitation, and solely on account of his learning, virtues, and zeal; he is said even not to have known the fact, till he read an account of it in the public newspapers. In 1691 he entered upon the duties of the episcopal office, which he performed for many years with the greatest assiduity. He died in the year 1718, of a paralytic stroke, in his 87th year. His life had been active, and his various pursuits required deep study and intense thinking; but his faculties were strong till almost the last period of his mortal existence. So great was the vigour of his mind, that, at the age of 84, when bishop Wilkins presented him with a copy of his Coptic Testament, he set about studying the language, and made so rapid a progress in it, that he was able to read the greater part of the version with the most critical attention. After the death of bishop Cumberland, his son-in-law, Mr. Payne, published "Sai-

choniatho's Phœnician History, translated from the first Book of Eusebius, de Preparatione Evangelica, &c." upon which the venerable prelate had bestowed much time and research; and in the course of the inquiry he was led to other subjects, an account of which he left behind him in MS., which was published by the same editor, under the title of "Origines Gentium Antiquissimæ, or, Attempts for discovering the Times of the first Planting of Nations." The character of this learned prelate was highly esteemed by his contemporaries; his principles were moderate; and he was candid towards those whose sentiments did not correspond with his own. His manners were unassuming, condescending, and affable; and his piety was the result of excellent habits formed in early life. He was hospitable without ostentation; and by his example, as well as by his advice, he did every thing in his power to render the clergy in his diocese respectable, useful, and happy. *Biog. Brit.*

CUMBERLAND, in *Geography*, a maritime county in the northern part of England, bordering Scotland, is bounded on the west by the Irish Sea, into which its western coast projects, somewhat in the form of a bow, to an extent of nearly 70 miles; on the north it is separated from Scotland by Solway Frith, the Scots Dyke, and the river Liddal; its eastern side is skirted by the counties of Northumberland and Durham, the dividing limits being mostly artificial; to the south its boundaries are Westmoreland and Lancashire: from the former it is partly separated by Uils-water and the river Eamont, and from the latter by the river Uddon. The greatest extent of the county is about 80 miles, but its mean length not more than 60; its general breadth is nearly 35; and its circumference 224. It contains 970,000 acres: of these 342,000 comprise the mountainous districts; 470,000 are enclosed, and chiefly under cultivation; 150,000 are in low commons, capable of improvement; and 8000 in lakes and waters. Cumberland is divided into five wards, synonymous with the hundreds in other counties; but so called here, from the inhabitants of each division being formerly obliged to keep watch or ward against the irruptions of the Scots, in times of warfare. It contains one city, Carlisle, 17 market-towns, 112 parishes, 22,445 houses, and 117,230 inhabitants. The ward of Alledale, above Darwent, is in the diocese of Chester; all the other part of the county in that of Carlisle. The representatives in parliament are six, *viz.* two for the county, two for Carlisle, and two for Cockermouth. Cumberland pays one part of the land-tax, and provides 200 men for the militia.

The surface of the county is extremely irregular and broken. The south-western district exhibits a gigantic combination of lofty, rugged, and rocky mountains, promiscuously thrown together, but enclosing many beautiful, though narrow, vallies, as well as fine lakes, rivers, and some extensive woodlands. On the eastern confines, another range of hills stretches along to Scotland, but possesses much less picturesque beauty than the former. In the front of this last assemblage, a considerably broad tract of low ground extends the whole length, unobstructed by any high mounts, partly cultivated, partly heathy common, and watered by the Eden, and numerous brooks and rivulets. This tract becomes very extensive before it reaches Carlisle; stretching across the county to Wigton, and thence towards Workington, including all the northern part of the county. Along the western shore there is a strip of cultivated land, from two to four or five miles in width. The woodlands are but few; and the general appearance of the county is bleak and naked, from the extensive moors which so frequently present themselves to the eye of the traveller. The soils of this district are exceedingly various, but have been classed under the divisions of sterile clays, or strong rich loams, which occupy

CUMBERLAND.

but a small portion of the county, and are chiefly appropriated to the growth of wheat; dry loams, including the different degrees from the rich brown loams to the light sandy soils, and occupying the greater portion of the land; wet loam, generally on a clay bottom, and adapted to grazing; and black peat-earth, which is very prevalent in the mountainous districts, and particularly those adjoining Northumberland and Durham. The enclosed grounds are kept free from moles by an excellent practice observed in the different parishes, of hiring persons to destroy them for a term of years, at a certain annual salary, which is raised like the regular parochial taxes, and does not exceed an halfpenny *per* acre.

The buildings of this county are chiefly of stone, except in the market-towns, where the houses are generally of brick; and near the borders of Scotland, where they are mostly constructed with clay or mud. Most of the old farm-houses, cottages, and out-houses, are thatched with straw, and the stones of the walls laid with clay instead of mortar; but the more modern buildings are generally covered with slate, and their walls cemented with lime: in those districts, however, where clay or mud walls prevail, the advances of modern improvements are admitted with some reluctance; the people considering them as an expensive and unnecessary luxury. Many of the houses are covered with a very fine blue slate, the best kinds of which are procured in Borrowdale.

The principal manufactures of Cumberland are the spinning and weaving of cotton into calicoes, corderoys, and other articles; and the printing of cotton. The former has not been many years introduced: it was first planted at Dalton, and soon extended to Carlisle, Warwick-Bridge, Corby, Comersdale, and a few more places. The seat of cotton-printing is at Carlisle, the population of which place has thereby been much increased. In some of the market-towns are small manufactories of checks and coarse linens. At Egremont eighteen looms are employed in the manufacture of sail-cloth; and at Whitehaven, where it was only introduced in 1786, several hundred hands are employed in the different branches of the same manufacture. Three or four paper-mills are employed in different parts of the county; a manufactory of coarse earthen ware has been long carried on near Dearham; and near Workington are the Seaton iron-works, which employ several hundred workmen. Many private families knit and spin their own stockings; and every village is supplied with a weaver or two, who weave their home-made cloth.

The mineralogical substances of Cumberland are extremely rich and variegated, and exist in such abundance in the different parts of the county, that a description of the whole would, of itself, constitute a work of considerable magnitude. In the calcareous genus is limestone, of various colours, texture, and hardness. The quarries at Overend contain impressions of many kinds of shells, with ammoniæ, entrochi, and allerix; and a great variety of marine exuvix are found in the limestone on the moors near Gilsand Spa. Mathe, with shells in it, of a brownish colour, is met with at Little Stainton and Dacre; dusky-green, veined with white, at Crof-fell; yellowish, grey, lead-colour, and brown, with or without shells, on the banks of the Peteril; and blueish-black, clouded with lead-grey, veined and spotted with white, hard, free from cracks, and admitting of a fine polish, near Kirkofwald. Beautiful specimens of spar of various colours, amorphous, and crystallized in different forms, are found in the lead mines of Aldifton-Moor; and, since the study of mineralogy has become fashionable, have been sold for considerable sums. In the mines between

Keswick and Aldifton it has been met with, crystallized in hexagonal prisms, terminated at one end by a pyramid. Gypsum is found in many parts of the county: its colour is mostly white, veined, clouded, and spotted with red; sometimes brown and grey; of compact, even fracture. It frequently, however, exhibits a considerable variety of appearance, even in the same quarry; and at Newbiggen is met with not only compact, but splintery, fibrous, foliated, and crystallized: in the latter state, the crystals are pure and colourless, arrow-headed, and irregularly disposed, forming the resemblance of a cock's-comb. It lies embedded in red argillaceous marl, between two large strata of sandstone: the upper, solid, hard, and fine-grained; the under, loose, friable, and coarse. The stratum varies considerably in thickness; and in some places, immediately below it, there is a thin bed of a soft umber-like substance, which, on examination, appears to be decayed wood. The lead-mines of Aldifton-Moor contain a great variety of fluors, compact, foliated, amorphous, and crystallized. The colours are red, green, blue, yellow, purple, violet; and of all gradations, from very pale to almost black. They are sometimes found studded with brilliant quartz crystals, and with crystallized galena. In the magnesian genus is mica, which is found of many different colours, interspersed and incorporated with several kinds of stones, and particularly in most of the sandstone rocks. Spangles of silvery mica are met with in a red, slaty, friable stone, near the river Caldew, in the quarries on the Peteril, and various other places. The steatites, semi-indurated, white, streaked with pale green, has been found at Hill-Top and St. John's; and some of the solid white kind in Langnor iron-mine, at Borrowdale, and at one or two other places. Some small rounded masses of serpentine are met with in many parts on the sea-shore, and sometimes, but rarely, in ploughed grounds. Asbestos has been discovered in the lead mine at Northend, and in some of the mountains, where it presents a great variety of appearance, as it seems to graduate into different substances.

Of the silicious genus are quartz crystals, which are found in the mines of Aldifton-Moor, beautifully transparent, and of various forms and colours: some of the yellow kind are but little inferior in brilliancy to the Brazilian topaz. Garnets are not unfrequently found in micaceous stones; and some beautiful small ones have been met with in the neighbourhood of Keswick. Cornelians of various tints, but principally of different shades of red, are often discovered on the sea-shore, and near the surface of the earth in many other places. Jaspers of different colours, often veined, clouded, and spotted, are generally met with in beds of rivers, and on or near the surface of the ground. Many substances of the argillaceous genus are found in different parts of the county. Trap, whinstone, and toadstone, exist almost every where; the two latter generally in detached pieces on the surface. Schistus, of several varieties of colour, is found in immense strata in many parts; and schistose clay, frequently of a tabulated structure, resembling the leaves of a book, is met with in most coal-mines, at Gilsand, Keswick, and various other places. Terra-porecellanea, or porcelain clay, the kaolin of the Chinese, is found at Barrock, near Nebbles: it is of a white and cream colour, mostly friable, and dusty; it contains minute particles of shining silvery mica. On the banks of Uilswater, tripoli is frequently discovered in rounded lumps, of a greenish colour, in gravel beds sometimes, and in coarse martial clays. Fossil, or pit-coal, is found in many parts of the county, and of very different qualities. It is met with at various places along the eastern mountains; but is easiest of access, and in the greatest abundance, on Talkin and Tindale Fells, whence Carlisle, Penrith, and

CUMBERLAND.

Brampton are chiefly supplied. On the west side of the river Caldew, near Calbeck, and thence to Maryport, Workington, and Whitehaven, it exists in great abundance; and many coal-mines are constantly at work in this district, and particularly at Whitehaven. Some very large pits have also been opened at Workington and Tindale Fell, near Brampton. Thin layers of jet are sometimes found in the rocks on the Irthing, in small detached pieces in the bed of that river, on the sea-shore, and near the surface of the earth in other places. Wallerius, and other eminent chemists, have supposed it to be asphaltum, condensed and hardened by length of time. It bears a fine polish; and is frequently worked into toys, bracelets, boxes, buttons, and other articles. The famous black-lead, or wadd mines, are situated at the head of Borrowdale, in a place extremely difficult of access, and, for the riches and qualities of the substance, are unequalled by any in the world. The mines lie to the east of a very steep mountain, which forms the west side of the vale of Stomathwaite. There are two workings: the lower one is about 340 yards above the level of the sea, and its perpendicular depth about 105 yards; the upper one is nearly 390 yards above the sea, and its depth about 30. The strata of the mountain are very irregular, and broken; and the black-lead appears to have been formed in the fissures. The mineral itself does not exist in regular strata, but is found in irregular masses. It is described as lying in the mine in form resembling a tree, having a body or root, and veins or branches spreading from it in different directions: the root or body is the finest black-lead, and the branches the worst; growing proportionally more inferior, as they become distant from the parent stem. The veins, or branches, sometimes shoot out to the surface of the ground; yet these indications are very rare. The black-lead is generally embedded in a blue rock, which is not unfrequently stained as black as the mineral itself to the depth of two or three feet; sometimes there is a wet sludge between the rock and the black-lead; at others it is found in lumps, or lumps, in a body without branches. In the deepest mine, the black-lead lies in two veins, crossing each other; the main body, and richest in quality, being at the point of intersection: these veins fall perpendicularly to the depth of 40 fathoms. The blue stone, where the black-lead is commonly found, has often a stratum of hard granite above it. Quartz crystals are frequently discovered in the working. The country in the immediate vicinity of the wadd mines has been described by a native of Cumberland (Mr. George Smith), as full of cataracts and rivers, that are precipitated from the crags with an alarming noise; and the summit of the mountain itself, in whose bowels this valuable mineral is produced, has been depicted by the same gentleman as truly terrifying. "Not a herb was to be seen but wild savine, growing in the interstices of the naked rocks; while the horrid projection of vast promontories, the vicinity of the clouds, the thunder of the explosions in the slate quarries, the distance of the plain below, and the mountains heaped on mountains that were piled around us, desolate and waste, like the ruins of a world which we had survived, excited such ideas of horror as are not to be expressed." The value of this substance, and the singular fraud of an owner of a contiguous part of the mountain, who secretly sunk a shaft, and opened a passage diagonally to the mine, occasioned an act of parliament to be made in the reign of George II. to prevent its being stolen, by subjecting the criminal to the same punishment as for felony. In this act there is a recital, that black-lead hath been discovered in one mountain or ridge of hills only in this kingdom; and that "it hath been found, by experience, to be necessary in the casting of

bomb-shells, round-shot, and cannon-balls." The chief use to which it is now applied is drawing; and the lead of some pencils made at Kefwick is of so very fine a texture, that it bears a point nearly as sharp as that of a needle. Some assert that it may be used medicinally, to ease the pains of the gravel, stone, strangury, and colic.

The principal metallic substances of Cumberland are lead, copper, and iron ores. The lead mines are chiefly in Aldston-Moor, on the south-east borders of the county, where about 1100 men are employed, and clear to the owners upwards of 16,000*l.* per annum. In working some of these mines, the miners frequently meet with large breaks in the rock, like grottoes, wholly encrusted with the most beautiful spar, which, on entering, has the richest appearance imaginable. The whole cavern, by the light of a candle, reflected from a thousand points, appears as if bespangled with gold, silver, and diamonds. These internal openings are generally closed up as soon as found; the spar they contain being a great temptation to the workmen to neglect the service of their employers, as they could obtain more by gathering and selling spar than by their own business. Galena is found, in a lit varieties, in the mines in the vicinity of Aldston, Kefwick, and Caldbeck; and it not unfrequently contains a considerable portion of silver. The lead ores, in the mines of Aldston-Moor, are found lying in cracks or fissures. These fissures, though commonly nearly perpendicular, are never wholly so; and in whatever direction they are found, they always incline downwards from that side where the strata are highest: thus, in a vein from north to south, if the strata should be raised higher on the south side the fissure than on the north side, its inclination will then be from the south downwards to the north. The copper ores are commonly combined with sulphur, and generally contain both iron and arsenic. The most considerable copper-mines are near Caldbeck, at Heskett New-Market in Borrowdale, and at Newlands in the neighbourhood of Kefwick, where the celebrated mine of goldscarp is situated; from which, by the old workings, and written documents, it appears that immense quantities of copper have formerly been obtained. Specimens of copper ores have been found in the mountains named Hard-knot and Wrynose, and at some other places. Ochreous iron ores, resembling those called by Mr. Kirwan highland argillaceous ores, are very commonly met with either on or near the surface, in most parts of the county, especially in moory soils, and where the under-stratum is a coarse martial clay. They appear to have been deposited by water, as they are generally found concreted with small stones, roots, and other substances. In the parish of Egremont, at a place called Crowgarth, is the most singular mine of iron ore supposed to be in Great Britain. It lies in the earth, at the depth of 12 fathoms; and the thickness of the band of ore, which is hard solid metal, is between 24 and 25 feet. It was never known to be much wrought till the years 1784 and 1785, when it was more generally opened; and so great has been the demand for it, at Carron foundery in Scotland, and some other places, that, in 1791 and 1792, the annual exportation was 20,000 tons and upwards. At Langnor, between Whitehaven and Egremont, many varieties of the hæmatites are found, and sometimes, from their colour and shape, are called kidney ore. Native Prussian blue is sometimes found in the peat-moss of this county, and in clay, particularly that of Etterby-scar, near Carlisle; its qualities, however, are different from the artificial.

Among the semi-metals, blende, pseudo-galena, or black-jack, is met with in the greatest plenty. Its forms and colours are very different: some is bluish, resembling galena; black,

CUMBERLAND.

black, or greenish-black, like pitch; of a glassy shining surface, often crystallized, in irregular pyramids, and other irregular figures; sometimes containing silver, arsenic, and other substances. Oxyd of zinc has been found at Borrowdale and Ousley. A mine of cobalt was discovered about ten years since, in the parish of Croftwaite, near Cowdale, about four miles from Keswick; but has hitherto been little regarded. Antimony has been found at Bassenthwaite; and in the stratum under the coal at Tindale Fell, oxyd of manganese, tinged and intermixed with pyrites and mica: it has also been discovered at Caldbeck.

This county abounds with lakes, some of which will be hereafter described under LAKE. The principal are known by the names of Ulls-water, which occupies an area of about 9 miles in its greatest length, by about three quarters of a mile, on an average breadth; Thirlmere, or Leathes-water, a narrow irregular sheet of water, about 3 miles in length, skirts the immense base of Helvellyn; Derwent-water, or Keswick lake, is rather of an oval figure, and extends nearly 3 miles in length, and about half so much in breadth; Bassenthwaite-water, or Broad-water, which is nearly 3 miles north of Keswick lake, abounds with beautiful scenery, and is 4 miles long, and 1 in its greatest breadth; Over-water, in a barren situation between Binsey and Caldbeck-fells, is about half a mile in length, and in breadth somewhat more than a quarter of a mile; Lowes-water, beautifully situated near the north-western extremity of the mountains above Mellbreak, is about a mile long, and a quarter broad, and, contrary to all the others, discharges its waters at the southern end; Crummock-water expands its pellucid bosom beneath some lofty mountains, and extends nearly 4 miles in length, and half a mile in breadth; Buttermere-water, about a mile south of Crummock-water, from which it is separated by a luxuriant vale, is about a mile and half long, and half a mile broad, into which numerous torrents pour down from the mountains, one of the roaring cataracts falling between four and five hundred yards; Ennerdale-water spreads among the mountains near to Whitehaven, and guarded, on every side but the west, with craggy and almost impassible heights, possesses a space of about 2 miles and half in length, its greatest breadth being about three quarters of a mile; Wait water expands its crystal surface in the bosom of Walsdale, to the length of 3 miles, and breadth, in the widest part, of three quarters of a mile; Burn-moortarn, seated among the widest mountains at the head of Miterdale, covers about 250 acres; Deveck-water occupies about 300 acres, amongst the hills south-east of Ravenglass; Talkin-tarn and Tindale-tarn possess about 40 or 50 acres each, on the moors south-east of Brampton; and Turn-wadling spreads its waters over 100 acres, on a barren common, 1 mile west from the river Eden, at Armathwaite.

The mountains of Cumberland are exceedingly numerous, and many of them of immense elevation, and singular structure. They enter into the composition of almost every view; and either by their sublime heights, their romantic forms, the dignified grandeur of their aspects, the immensity of the rocky masses that compose them, or the wild, awful, and imposing majesty of their appearance, are well calculated to give birth to interesting emotions.

The rivers and smaller streams of this county are very numerous. The principal are the Eden, the Eamont, the Duddon, the Ehen, the Derwent, the Great, the Cocker, the Ellen, the Waver, the Wampool, the Caldew, the Petril, the Esk, the Liddal, the Line or Laven, the Ithling, and the Gelt. Hutchinson's History of the County of Cumberland, 2 vols, 4to. Houteman's Topographical Description of Cumberland, &c. 8vo.

CUMBERLAND, a county of America, in New Brunswick, comprehending the lands at the head of the bay of Fundy, on the basin called Chebecton, and the rivers that flow into it. It has several townships; three of which are settled are Cumberland, Sackville, Amherst, Hillsborough, and Hopewell. It is watered by the rivers Aulac, Missiquash, Napan, Macon, Memramcook, Petcodia, Chepodie, and Herbert; the three first of which are navigable, for three or four miles, for vessels of five tons; the Herbert is navigable to its head, 12 miles, in boats; the Napan and Macon are shoal rivers; the others are navigable four or five miles. The town of Cumberland has coal-mines.

CUMBERLAND, a county in the district of Maine, E. of York county, and has the Atlantic ocean on the S., and Canada on the N. Its sea-coast, formed into numerous bays, and skirted with many fruitful islands, is nearly 40 miles in extent in a straight line. Saco river, which runs south-easterly into the ocean, separates between this county and York on the S.W. Cumberland is divided into 33 townships; its capital is Portland; and the number of its inhabitants, by the census of 1800, is 37,918. The soil of this county, as well as that of York, is, to a great extent, light and lean; great part being pine-plains.

CUMBERLAND, a county in New Jersey, bounded S. by Delaware bay, N. by the county of Gloucester, S.E. by cape May, and W. by the county of Salem. It is divided into seven townships, of which Fairfield and Greenwich are the chief: it contains 9529 inhabitants, 75 of whom are slaves.

CUMBERLAND, a county of Pennsylvania, bounded N. and N.W. by Mifflin, E. and N.E. by Susquehanna river, which separates it from Dauphin, S. by York, and S.W. by Franklin county; 47 miles in length, 42 in breadth, and containing 18 townships, of which Carlisle is the principal. This county is generally mountainous; but between N. and S. mountain, on each side of Conedogwinet creek, there is an extensive, rich, and well-cultivated valley. It contains 25,386 inhabitants, of whom 228 are slaves.

CUMBERLAND, a county in Virginia, on the N. side of Appamatox river, which divides it from Prince Edward; 25 miles long, 15 broad, and containing 9839 inhabitants, of whom 5711 are slaves.
