CUMBERLAND, a county of N. Carolina, in Fayette district, containing 7608 inhabitants, of whom 2097 are slaves. In this county is a township of the same name.

CUMBERLAND, a county of Kentucky, containing 3284 inhabitants, of whom 236 are slaves.

CUMBERLAND, the north-eastermost township of Providence county, in the state of Rhode island, containing 2056 inhabitants.

CUMBERLAND, two towns of Green county, in the state of Pennsylvania, containing 1277 inhabitants.—Also, a township in York county, Pennsylvania.—Also, a township of Washington county, in the same state.—Also, a township of Adams's county, in the same state, containing 1263 inhabitants.—Also, a township of the same state, in the county of Bedford.

CUMBERLAND, a post town, and the chief township of Alleghany county, in Maryland, lying on the N. bank of a bend of Potowmack river, and on both sides of the mouth of Wilt's creek. It contains about 100 houses, a court-house, gaol, market-house, and three churches, one for Roman Catholics, one for Methodists, and one for German Lutherans.

CUMBERLAND Bay, a bay on the west coast of the island of St. Vincent. N. lat. 13° 12'. W. long. 61° 18'.—Also, a bay on the N.E. coast of the island of Juan Fernandez.—

Also,

Aifo, a large bay, so named by captain Cook, in January, 1775, in the S. Atlantic ocean, near the coast of the isle of Georgia, a few miles E. of Possession bay, in S. lat. $54^{\circ} 5'$. W. long. $37^{\circ} 18'$.—Also, a bay in the most northern part of America, opening under the polar circle, running to the N.W. and W., and supposed to communicate with Baffin's bay on the N. N. lat. $66^{\circ} 44'$. W. long. $65^{\circ} 20'$.—Also, a harbour on the E. side of Washington's isles, on the N.W. coast of N. America; S. of Shitkifs, and N. of Cummahtwan.—Also, a harbour on the S.E. coast of the island of Cuba, reckoned to be one of the finest in the West Indies, capable of sheltering any number of ships; 20 leagues E. from St. Jago de Cuba. N. lat. $20^{\circ} 3'$. W. long. $76^{\circ} 50'$.

CUMBERLAND, *Cape*, a cape on the island of Espirito Santo, one of the New Hebrides, in the S. Pacific ocean. S. lat. $14^{\circ} 39'$. E. long. $166^{\circ} 47'$.—Also, a cape on Kerguelen's land, $1\frac{1}{2}$ league S.E. $\frac{1}{2}$ S. from Christmas harbour.

CUMBERLAND *Fort*, a fort of the United States of America, in New Brunswick, situated at the head of the bay of Fundy, on the E. side of its northern branch. It is capable of accommodating 300 men.—Also, a fort which formerly stood in Cumberland township, in Alleghany county, Maryland, at the W. side of the mouth of Will's creek.

CUMBERLAND *Fort*, a strong place at the S.E. point of Portsea island, in Hampshire, commanding the entrance into Langstone harbour. In the government trigonometrical survey, in 1793, the west chimney of the governor's house in this fort was observed from Butser hill, distant 70,049 feet, and Rook's hill, distant 74,863 feet; whence is deduced its latitude $50^{\circ} 47' 21''$. 7 N., and longitude $1^{\circ} 1' 43''$, or 4^m . $6'.9$ W. of Greenwich.

CUMBERLAND *Gap*, a place having a post-office, in Claiborne county, and state of Tennessee; 528 miles W. from Washington.

CUMBERLAND *House*, a factory belonging to the Hudson bay Company, situated in New South Wales, in North America, on the S. side of Pine island lake. N. lat. $53^{\circ} 56' 41''$. W. long. $102^{\circ} 13'$.

CUMBERLAND *Island*, an island on the coast of Camden county, in the state of Georgia, between Prince William's sound at the S. end and the mouth of Great Satilla river at its N. end, and 20 miles S. of the town of Frederica. It is about 20 miles in circumference. N. lat. 31° . W. long. $81^{\circ} 40'$.—Also, an island in the South Pacific ocean, so called by captain Wallis in June, 1777, lying low, and about the size of queen Charlotte's island, or 6 miles long, and 1 wide. S. lat. $19^{\circ} 18'$. W. long. $140^{\circ} 36'$. Variation of the needle $7^{\circ} 10'$ E.

CUMBERLAND *Islands*, a cluster of islands near the N.E. coast of New Holland, so called by Cook in June, 1770, forming a passage, called, from the day of its discovery, "Whitunday passage." S. lat. $20^{\circ} 36'$. W. long. $211^{\circ} 28'$.

CUMBERLAND *Mountain*, a mountain of N. America, occupying a part of the uninhabited country of the state of Tennessee, between the districts of Washington and Hamilton and Mero district, and between the two first-named districts and the state of Kentucky; the north-easterly part of the ridge being the dividing line between Kentucky and Virginia. The ridge is generally about 30 miles broad, and extends from Crow creek on Tennessee river from S.W. to N.E. In Tennessee it enlarges in width to 50 miles, and with a surface so level, that it may be called the high lands.

On both sides of the mountain is found limestone. The mountain consists of the most stupendous piles of craggy rocks of any mountain in the western country. It is inaccessible for miles, in some parts, even to the Indians on foot. In one place, near the summit, it has a very remarkable ledge of rocks, about 30 miles long, and 200 feet thick, presenting to the S.E. a perpendicular face. Morfe.

CUMBERLAND *River*, a river of N. America, called by the Indians "Shawanee," and by the French "Shavanon," which falls into the Ohio, 10 miles above the mouth of Tennessee river, and about 24 miles due E. from fort Maffac. It is navigable for large vessels to Nashville in Tennessee, and from thence to the mouth of Obed's or Obas river. The chief branches, some of which are navigable to a great distance, are the Caney fork, 100 yards wide, joining it 120 miles above Nashville, Harpeth, Stones, Red, and Obed's. The head waters of this river are separated by the Cumberland mountains from those of Clinch river. Its course, till it comes to the fourth line of Kentucky, is S.W., then westerly, in general, through Lincoln county; thence S.W. into the state of Tennessee, where it encloses, by its windings, Sumner, Davidson, and Tennessee counties; it then takes a north-westerly direction, and re-enters the state of Kentucky, and from thence preserves nearly a uniform distance from Tennessee river to its mouth, where it is 300 yards wide. It is navigable without interruption for more than 500 miles. In passing through Mero district, it meanders form several peninsulas, 14 or 15 miles round, and about one across the isthmus. Maife.

CUMBERLAND *River*, a place so called, where a post-office is kept, in Tennessee; 13 miles from Cumberland mountain, and 81 from the Crab orchard in Kentucky.

CUMBERLAND *Township*, a township in Upper Canada, lying partly in the county of Stormont, and partly in Dundas, and being the sixth township on ascending the Ottawa river.

CUMBRAY, GREAT and LITTLE, islands of Scotland; the former is about 6 miles in circuit, and lies at the mouth of the river Clyde, between the isle of Bute and the county of Air; the latter is smaller, and about half a mile from the former.

CUMBU, or COOMBOO GOOMBAW, a large and populous city, in the route from Lassa in Thibet to Pekin in China, where is situated, near a small river, a spacious and celebrated putala, or temple of public worship, (Buddhala, the mansion of Buddha.) When the Lama of Thibet, at the earnest solicitation of the Chinese emperor, determined to pay him a visit, he began his journey from Tifolumbu in July, 1779; in 46 days he reached Duchu, or Doochoo, seated on the banks of a river of the same name, where a messenger from the emperor met him, and presented to him pearls, silks, and many other valuable articles, with a rich palanquin; after a journey of 21 days more, he arrived at Thuchiar, or Thooktharing, receiving in his progress every possible token of respect and homage. Here he was met by eight persons of distinction, and 2000 troops, who were commissioned by the emperor to attend him; but the lama, having received their presents of gold, silver, horses, mules, silks, &c. dismissed them; and proceeded thence to Cambu, to the temple of which many thousand devout persons annually resort. Here he was detained four months, on account of a great fall of snow; and during his stay he received from the emperor costly presents of pearls, a curious watch, snuff-box, and knife all ornamented with jewels, besides many curious brocades and silks. At this place, and in other stages of his journey, he was importuned by all ranks

ranks of people for a *mark of his hand*, which, being coloured with saffron, he impressed on clean paper. Many thousands of these were printed, dispersed among the people, and preserved as the most sacred relics. At this place he was again presented, by the emperor's orders, with a very rich palanquin, a large tent, 20 horses, several mules, &c: the whole amounting in value to upwards of 25,000 illeungs; an illeung of silver being worth about 7s. After several months the lama pursued his journey, followed by a very numerous train of attendants, receiving costly presents in every stage of his progress, and at length was introduced with singular parade to the emperor's presence; who expressed a wish to be instructed in the mysteries of his religion. After an intercourse of some months, the lama sickened of the small-pox and died; nor was less attention paid to his corpse than to his person whilst he lived. It was deposited in a temple of gold; and the emperor distributed silver on the occasion, to the amount of four lacks of rupees, to the devout persons who attended and offered prayers over the corpse. Another lack of rupees was distributed before the corpse was removed, in order to be carried in the temple of gold, enclosed within another of copper, into his own country. After a tedious journey of more than seven months, they arrived at Digurlee, or Teshoo Loomboo, the place of the lama's residence, whilst he lived. Here his remains were deposited in a most superb pagoda, or monument, built for that purpose; and the two temples of gold and copper, brought from Pekin, were carefully fitted up, and set up in the pagoda, immediately over the spot where the corpse was laid. Turner's Emb. to Tibet, Appendix.

CUMELE, and CUMELBOTANE, in *Botany*, the name by which the Greek writers have described the *lupulus* or hop.

CUMERIUM PROMONTORIUM, in *Ancient Geography*, a promontory of Italy, which advanced into the Adriatic sea, to the north of Aniona, and near it.

CUMI, a town of Ethiopia, situated, according to Pliny, on the banks of the Nile.

CUMIANA, in *Geography*, a town of France, in the department of the Pô in Piedmont in Italy, which formerly belonged to Sardinia. It is the chief place of a canton, in the district of Pignerol, with a population of 4507 individuals. The canton has 8 communes, and 9050 inhabitants.

CUMIERES, a small town of France, on the river Marne, in the department of the Marne; 3 miles N.W. of Epernay; famous for its excellent champagne wine.

CUMILLUM MAGNUM, in *Ancient Geography*, a place of Italy, marked in the Itinerary of Antonine on the route from Rimini to Dertona, supposed to be the present *Ci-gomol*.

CUMIN, in *Botany*. See CUMINUM.

CUMIN, *Baslard*. See LAGOECIA.

CUMINIODES, Tourn. See LAGOECIA.

CUMINUM, (Heb. כִּמְוִן , Isaiah xxviii. 25. 27. כִּמְוִן , Sept. Diosc. *Cymium*; Plin.) Linn. Gen. 351. Schreb. 483. Willd. 547. Gært. 126. Juss. 221. Vent. 3. 19. Clus and order, *pentandria digynia*. Nat. Ord. *Umbellatae*, Linn. *Umbelliferae*, Juss.

Gen. Ch. Universal and partial umbels four or five-rayed, uniform. Leaves of the general involucre three or four, capillary or trifid, at least as long as the umbel; of the partial one, three or four, bristle-shaped, as long as the rays of the partial umbel. *Cal. proper* superior, very small, five-toothed. *Cor.* Petals five, emarginate, inflexed, somewhat

unequal. *Stam.* Filaments five; anthers simple. *Pist.* Germ inferior, larger than the flower, oval-oblong; styles two, very small; stigmas simple. *Fruit* oval-oblong, striated. *Seeds* two, convex on one side, flat on the other.

Ess. Ch. Fruit oval-oblong, striated. Partial umbels about four. Involucre three or four-leaved.

Sp. *C. cyminum*. Cumin. Linn. Sp. Pl. Mart. Lam. Willd. Gært. tab 23. Lam. Ill. Pl. 194. Woodv. Med. Bot. tab. 191. (*C. femine longiore*; Bauh. Pin. 146. Moris. Hist. 279. § 9. tab. 2. 1. *C. fativum*; Cam. Epit. 518. Rai. Hist. 433.) *Root* annual, white, oblong, slender. *Stem* six or seven inches high, smooth, striated, leafy, branched. *Leaves* alternate, rather distant, finely cut like those of anise or fennel; segments few, almost capillary, about an inch long, generally bitenate, the two lateral ones often simply bifid. *Flowers* small, white or purplish; three or four, seldom five in each partial umbel. *Fruit* aromatic, crowned with the minute teeth of the calyx, terminated by the short reflexed styles. *Seeds* with nine shallow filiform furrows on the convex side, smooth or slightly hispid. A native of Egypt and Syria. It is cultivated for sale in Sicily and Malta, whence the rest of Europe is supplied with the seeds. They have an aromatic, warm, and bitterish taste, with a strong, but not disagreeable, smell; contain a large quantity of essential oil, and are supposed to possess a carminative and stomachic power, equal, if not superior, to most of those of the umbelliferous plants. The Dutch are said to put them into their cheese, and the Germans into their bread. In Malta the plant is called *cumino aigro*, or hot cumin, to distinguish it from anise, which they call *cumino dolee*, or sweet cumin.

CUMINUM *femine rotundiore* & *minore*; C. Bauh. See PIMPINELLA *anisum* β .

CUMINUM *sylvestre, capitulis globosis*; C. Bauh. See LAGOECIA.

CUMINUM *sylvestre, siliquatum pone*; Dalch. See HYPECOCUM *creatum*.

CUMMASBAWAS, or CUMMASBAAWAA, in *Geography*, a sound and village on the E. side of Washington island, on the N.W. coast of North America. The port is capacious and safe; and its mouth lies in N. lat $53^{\circ} 2' 30''$, and W. long. $228^{\circ} 22'$. At this port the women take the precedence of the men in every point, and particularly in their commercial concerns.

CUMMINGTON, a township of America, in the state of Massachusetts and county of Hampshire, lying about 20 miles N.W. of Northampton, and containing 985 inhabitants.

CUMNER, or CUMNAR, a vicarage in Berkshire, in the hundred of Horner. On the hill in this parish, which is near to Oxford, a station was chosen in the government trigonometrical survey in 1799, about 130 feet W. of the centre of the clump of trees; the situation of which was determined by an observation from Shotover hill, distant 29,231.5 feet; and bearing $76^{\circ} 58' 3''$ N.E. from the parallel to the meridian of Dunnose; and another from Whitebrin hill, distant 14,714.3 feet; whence is deduced its latitude $51^{\circ} 44' 2''.4$ N., and longitude $1^{\circ} 18' 18''.4$, or $5^m 13^s.2$ W. of Greenwich. This station was used with Shotover station, for settling the place of Oxford observatory, in connection with this survey.

CUMPETES, in the *Materia Medica*, a name given by some of the Greek writers to the *carpesia* of Galen and others. This was an aromatic drug, and was the younger shoots and tender twigs of an odoriferous tree, growing on some mountains in Pamphyha, which were collected in the spring,

spring, and, when dried, were used as a succedaneum for the cinnamon. The word *cumpetes* often occurs in Myrcellus; but there is some doubt in the orthography, whether it be *cumpetes* or *cumpetes*: there seems most reason to believe the latter is the proper word. Charito mentions this drug in his antidotes; and the commentators usually explain it by the word *carpesia* or *carpasus*, a name by which they understood, though improperly, the cubebs. The Greeks of the later ages, and the Latin writers who succeeded them, all fell into the same error, of calling the *carpesia* the cubeb; though the accounts of the ancient Greeks are against it. Nay, Avicenna seems to have given into the same error; for he has transcribed into his chapter of cubebs what Galen says of the *carpesia*.

CUMPULUNGO, in *Geography*, a town of Walachia; 56 miles N.N.W. of Bucharest.

CUMSTWITH LEAD-MINE, in Cardiganshire in Wales, was worked by the mine adventurers of England, about the year 1700. It was famous for its bellies of ore, from 4 to 7 yards broad, from 10 to 30 yards long, and from 4 to 7 yards high, with sometimes only a leader of an inch thick between these, for 5 or 10 yards together, both in sinking and driving: in some places the ore was found interwoven, as it were, with the substance of the rock.

CUN, or CUNNING, at sea. See COND.

CUNAXA, in *Ancient Geography*, a place of Asia, in Assyria, situated on the left bank of the Euphrates, and at the distance of five stadia from Babylon, where the combat took place between Cyrus and Artaxerxes.

CUNCULIANA, an episcopal town of Africa, in the Byzacene territory.

CUNDIER, JACQUES, in *Biography*, a French painter and engraver, who flourished at the commencement of the 17th century. He engraved the portraits of the first presidents of Aix in Provence; a book in folio, 1624; as well as other prints from different matters. Heineken.

CUNEGES, in *Geography*, a small town of France, in the department of the Dordogne, chief place of a canton, in the district of Bergerac. It has but 407, but the canton contains 9252 inhabitants, in 18 communes, upon a territorial extent of 197½ kilometres.

CUNEGO, DOMENICO, in *Biography*, an engraver of considerable eminence, who was born at Verona in the year 1727. At first he studied painting in the school of Francesco Ferrari, but afterwards entirely renounced the pallet for the graver. Many of the finest prints in that beautiful selection, entitled, the Scuola Italica, published at Rome by the late Mr. Gavin Hamilton, are by the hand of this master. At an advanced period of life, Cunego formed a design of publishing the entire work of Michael Angelo, in the Sistine chapel; and though the encouragement he met with was not sufficient to enable him to complete so noble an undertaking, we are indebted to him for transcripts of several parts of that chapel, which were never previously engraved, independent of prints in outline, upon a small scale, of the entire work. Domenico had two sons, Aloysio, born in 1757, and Joseph, born in 1760, who both practised the art of engraving, with a success, however, very unlike that of their father.

CUNEI, in *Ancient Geography*, a people of Spain, who are supposed to have inhabited a district called *Cuneus*, corresponding to the kingdom of Algarve.

CUNEL, in *Conchology*. There are several fossil shells which authors refer to this genus, whose species have no existence among the known recent shells. Da Costa has figured one of these, *Tab. 6. fig. 5.* which is most cautiously

fluffed. Other fossil cunei are reticulated, and some fulcated, &c.

CUNEI, in *Natural History*, a name given to those *telline*, which have one side of their shell much more extended than the other. See MUSCLE.

CUNEIFORM LEAF, in *Botany*. See LEAF.

CUNEIFORME, in *Anatomy*, a name given to several bones. The sphenoid bone is often mentioned by that name. There is an os cuneiforme in the first phalanx of the carpus; and there are three ossa cuneiformia in the tarsus. See SKELETON.

CUNELIONE, in *Ancient Geography*, a town of Albion, situated, according to the Itinerary of Antonine, between Verulacione and Spinæ; now Marlborough, Wiltshire.

CUNETTE, in *Fortification*. See CUVETTE.

CUNEUS, in *Ancient Geography*, a country of Spain, in Lusitania, since called the kingdom of Algarve.—Also, a promontory of Spain, in Lusitania, now Cabo di Santa Maria.

CUNEUS, one of the mechanical powers; more usually, by English writers, called the WEDGE; which see.

CUNEUS, among the Romans, a term often used to signify that part of the theatre where the spectators sat, on account of its resembling the figure of a wedge.

This term is often found in the descriptions of the ancient theatres and amphitheatres, and is thus explained. The seats being disposed circularly, were divided at regular distances by flights of steps, which gave access to them, and to the vomitoria, or doors of entrance. These stair-cases being directed to the centre of the circle, divided the seats into sections of the shape of a wedge, cuneus, from which circumstance they were named.

CUNEUS, the wedge, was also a form of battle frequent among the Romans. See WEDGE.

CUNEUS, *Parabolic*. See PARABOLIC *Cuneus*.

CUNGI, CONGI, or CUGNI, BATISTA, in *Biography*, of Borgo S. Sepolcro, a painter of the 16th century. He assisted Giorgio Vasari, in company with Cristoforo Gherrardi, in his works in the refectory of S. Michel in Bosco, at Bologna.

There was also a Francesco Cungi living at the same time, who was probably the brother of Batista. Vasari.

CUNGI, CONGI, or CUGNI, LIONARDO, a painter, native of Borgo S. Sepolcro, who flourished in the 16th century. Vasari describes him as a most excellent designer; and informs us, that he drew the whole of the Last Judgment of Michael Angelo with such intelligence, that Pierino del Vaga was induced to purchase it at a considerable price, and preserved it with great care during the remainder of his life. Vasari.

CUNI, in *Ancient Geography*, a place of Asia, in Gedrosia, according to Ptolemy.

CUNICI, a town of the largest of the Balearic islands, which, according to Pliny, enjoyed the same privileges with those of Latium.

CUNICULARIÆ INSULÆ, islands of the Mediterranean, placed by Pliny between the islands of Corfica and Sardinia. They are mere rocks.

CUNICULUS, in *Zoology*, a species of animals of the *lepus* or hare-kind, called in English rabbit. See LEPUS *Cuniculus*.

For several other species of *Cuniculus*, see CAVIA, MUS, and DIPUS.

CUNICULUS, in *Mining*, a term used by authors, in distinction from *puteus*, to express the several sorts of passages and cuts in these subterranean works. The *cuniculi* are those direct

direct passages in mines, where they walk on horizontally; but the *pulei* are the perpendicular cuts or descents.

It is an observation with our miners, that the damps so much dreaded in all mines, happen generally in the horizontal cuts; but Dr. Brown, in his examination of the gold and silver mines in Hungary, observes, that they as often happen there in the *pulei* or *scachts*, as in the *cuniculi* or *stollen*. Another observation as to damps with us is, that they are most frequent in clayey and soft places under ground; but in those mines they are as frequent where the matter is hard stone; and one of the most mischievous that had then lately happened, was in a place every way surrounded with stone so hard, that the tools of the miners could scarce work through it; and the descent had, in the very spot where the damp was, been made by means of gun-powder. In some of the *cuniculi* in these mines, there are damps that regularly return on certain occasions; as if the lower end of the *cuniculus* be filled up with water, certain parts in going to it are always affected with damps, which will put out a lamp or candle the moment it enters them, and often do great mischief to the miners in passing them. Phil. Transf. No. 48. See DAMP.

CUNILA, in Botany. (Plin. *κωνίδα*; Nicand.) Linn. gen. 35. Schreb. 46. Willd. 59. Lam. Ill. 47. Juss. 111. Vent. 2. 328. Clafs and order, *diandria monogynia*. Nat. Ord. *Verticillatae*. Linn. *Labiatae*, Juss.

Gen. Ch. Cal. Perianth one-leaved, cylindrical, striated, with five somewhat unequal teeth, permanent. Cor. One-petalled, ringent; upper lip erect, flat, emarginate; lower lip three-parted; segments rounded; middle one emarginate. Stam. Filaments two fertile, two without anthers; anthers roundish, didymous. Pist. Germ superior, four-parted; style filiform; stigma bifid, acute. Peric. The calyx closed at the throat with shaggy hairs. Seeds four, egg-shaped, minute.

Ess. Ch. Calyx five-toothed, corolla ringent; upper lip erect, flat. Two of the filaments barren. Seeds four.

Sp. 1. *C. mariaria*. Linn. Sp. 1. Mart. 1. Lam. 1. Willd. 3. (*Satureia origanoides*; Linn. Sp. Pl. Ed. 1. *Thymus tolus ovatis acuminatis serratis*; Gron. Virgin. 04. *Calamintha mariana*; Pink. Mant. 35. tab. 344. fig. 1. *C. erecta virginiana*; Morif. Hist. 3. 413. § 11. tab. 19. fig. 7.) "Leaves egg shaped, serrated; corymbs terminal dichotomous." Root perennial. Stems about a foot high, erect, slender, almost woody, obtusely quadrangular, smooth, branched. Leaves opposite, sessile, acute. Flowers small. The whole plant has an aromatic taste and smell, exactly resembling pennyroyal. There is a variety almost scentless, with narrower leaves, and smaller heads. A native of Maryland and Virginia. 2. *C. pulegioides*. Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Ill. Pl. Willd. 4. (*Melissa pulegioides*; Linn. Sp. Pl. Ed. 1. *M. floribus verticillatis*; Gron. Virgin. 167. Kalm. It. 2. 314. Eng. Ed. 1. 592.) "Leaves oblong, two-toothed; flowers in whorls." Root annual. Stems seven or eight inches high, erect, pubescent, branched. Leaves opposite, toothed, smooth above, roughish with very short hairs underneath, on short petioles. Flowers in axillary whorls, shorter than the leaves continued from the upper to the lower pair of leaves; two lower divisions of the calyx bristle-shaped, ciliated. A native of North America. It has a strong scent, and an infusion of it is said by Kalm to be used by persons who have taken cold and have a pain in their limbs. 3. *C. thymoides*. Linn. Sp. Pl. 3. Mart. 3. Lam. 3. Willd. 5. (*Thymus pulegioides*. Linn. Sp. Pl. Ed. 1. *Acinos thymifolus & facie*; Morif. Hist. 3. 404. § 11. tab. 19. hg. 6. *Calamintha minima*,

thymi folio; Tourn. 194.) "Leaves oval, quite entire, flowers in whorls; stem quadrangular." The habit of the preceding. Stem six or seven inches high, erect; branches few, simple, short. Leaves obtuse, smooth, striated underneath. Whorls from the top to the bottom of the stem. A native of the south of France, about Montpellier. 4. *C. capitata*. Linn. Fil. Supp. 87. Mart. 4. Lam. 4. Willd. 1. "Leaves egg-shaped; flowers terminal; umbel roundish." Stem five or six inches high. Leaves somewhat oblong, smooth. Flowers purple; calyx smooth, striated; anthers black. Obs. Von Biberstein is of opinion that this is no other than *Ziziphora clinopoides* of the Species Plantarum. See Annals of Botany, vol. ii. p. 405. 5. *C. fruticoso*. Willd. 2. (*C. frutescens*; Donn. Cat. Cambrig. 5. "Leaves linear, revolute at the margin, tomentous underneath; flowers axillary; stem shrubby. A plant of dubious genus; with the habit of rosemary. Flowers large. A native of New Holland.

CUNILA *Bubula*, a name by which Pliny, and some other authors, have called the wild marjoram or origanum.

CUNILAGO, is used by some authors for the *corymb*.

CUNINA, or CUNIA, in Mythology, a goddess who had the care of little children, attending the cradle, and watching them while they were asleep.

CUNINGHAM, FRANCIS, in Biography, a painter, born in Scotland in the 18th century. He studied at Rome under Antonio Mengs, and afterwards travelled into Spain, France, Russia, and Prussia. He resided at Berlin in 1788. He seems to have been principally employed as a portrait painter. From his pictures are engraved, amongst others, enumerated by Heineken, the following portraits; Frederic II. king of Prussia embracing two levettes, a whole length, by D. Cunego; Frederic William II., a whole length, by the same; Frederic duke of York, by Townley; Catherine II. empress of Russia, by the same. Heineken.

CUNINGHAM, WILLIAM, a physician and engraver, who resided at Norwich in the middle of the 16th century. In 1559 he published a work entitled "A Cosmographical Glass," for which he engraved with his own hand several plates, and amongst the rest a large map of Norwich. Walpole.

CUNINGHAM, in Geography, a district of Scotland, in the county of Ayr.

CUNIO, DANIELLO, in Biography, a Milanese painter of the 15th century, who was the scholar of Bernardino Campi, and executed many works with the cartoons of his master, in the state of Milan. This artist, in company with Girolamo del Leone, painted in the palace of prince Triubri, at Maléo, the most celebrated enterprises of the emperor Charles V. He is likewise said to have distinguished himself in landscape. Orlandi.

CUNIO, RIDOLFO, a painter in Milan, probably a brother or near relation of Daniello Cunio. He was the scholar of Gio. Batista Crespi called Il Cerano; and amongst other public works at Milan, painted the picture of S. Antonio in the church of S. Marcelino. His cabinet pictures, in which he introduced conflagrations or nocturnal effects, are much esteemed. He was living about 1650, Orlandi.

UNION-CHARION, in Ancient Geography, a promontory placed by Ptolemy in the S.E. part of the island of Sardinia.

CUNISTORGIS, in Ancient Geography, a large town of Spain, in Lusitania, situated in the country of the people called *Cunet*, according to Appian.

CUNITZ, in Geography, a small town of Germany, in the

the principality of Saxe-Weimar, with 348 inhabitants, on an eminence near an ancient castle, from the ruins of which there is a most delightful view.

CUNLHAT, a small town of France, in the department of Puy-de-Dôme, chief place of a canton, in the district of Ambert, with a population of 2825 individuals. The canton has four communes, and 8810 inhabitants, upon a territorial extent of 107½ kilometres.

CUNNERSDORF, a small town of Saxony, in Upper Lusatia, five miles from Görlitz, with a beautiful castle, and quarries of very fine chalk stone, famous for its excellent police.

CUNNINGHAM, ALEXANDER, in *Biography*, was son of the parish minister of Etrick, near Selkirk in Scotland. Little is known of him till his appointment as tutor to the sons of the earl of Hyndford, and to lord Lorne afterwards John duke of Argyll. He was often consulted on political subjects, and was a zealous advocate for whig principles. In the reign of George I. he was appointed resident minister at Venice, where he remained from 1715 to 1720. From this period he was probably engaged in literary pursuits. The time of his death, like that of his birth, has never been exactly ascertained, though the former is supposed to have happened about the year 1737. He left behind him "A History of Great Britain, from the revolution to the accession of George I.," written in Latin, which was translated by Dr. Hollingherry, and published by Dr. Thomson in two volumes 4to. in the year 1787. This work is spoken of as possessing much original matter, and containing many facts which had never before been brought to the light. *Biog. Brit.*

CUNNINGHAM, WILLIAM, practised medicine at Norwich from 1556 to 1559, and afterwards in London, where we find him giving lectures in anatomy at the Barber-Surgeon's-hall, in 1563. He was author of "Speculum Cosmographiæ five de principiis Navigationis," lib. v. London, 1559, fol. and 4to. Two letters between W. C. and John Hall, chirurgeon, touching the cure of the pox, 1565. MS. Bodl. A new almanack and prognostication, calculated for the longitude of London, for the year 1556, Lond. 8vo. An invective epistle in defence of astrology, quoted in William Fulke's invective against astrologers.

Gale, in his Institution of a chirurgeon, makes mention of a work written by Cunningham, and intended for publication on the venereal disease, called by him Chamæleontia, from some supposed resemblance between persons afflicted with it, and the chamæleon. It appears, from the following dialogue between two fictitious persons, Yates and Field, that the treatment of it was similar to that employed in siphylis.

"John Yates,—I judge his new invented way of curation to be extreme and dangerous to the patient, for both the fumes and strait order of diet with the woods, are well known to be dangerous, and yet many times doth not that which they promise. But yet, if his way be perfect, it is more to be liked, and he worthy praise.

"John Field,—His way is void of danger, easy to the patient, exact also, and perfect."

Dr. Cunningham wrote prefatory epistles to some works of Gale and Halle, which shew him to have been a man of considerable learning. Aikin's Biographical Memoirs of Medicine.

CUNNINGHAM'S Island, in *Geography*, an island of Upper Canada, situated at the W. end of lake Erie, S. westerly of the Bass islands, and southerly of Ship island.

CUNNINGHAMIA, in *Botany*. Schreb. gen. 1720. Mart. Mill. (Malanea; Lam. Ill. 174. Antirhea; Vent.

2. 581. Malanea & Antirhea; Juss. 203, 204.) Class and order, *tetrandria monogynia*. Nat. Ord. *Rubiaceæ*, Juss.

Gen. Ch. *Cal.* Perianth one-leafed, four-toothed, very small, permanent. *Cor.* monopetalous; tube short; border four-cleft; lobes egg-shaped, spreading. *Nectary* a rim furrounding the base of the style. *Stam.* Filaments four, inserted into the throat of the tube; anthers roundish or oblong. *Pist.* Germ inferior, roundish; style siform, bifid; stigmas obtuse. *Peric.* Drupe egg-shaped, crowned with the calyx; nut two-celled. *Seeds* one in each cell, oblong.

Eff. Ch. Calyx superior, very small, four-toothed. Corolla monopetalous, with a short tube. Drupe two-celled, two-seeded.

Sp. 1. *C. farmentosa*. Mart. (Malanea; Desf. Enc. 1. Lam. Ill. 1468. tab. 66. fig. 2. Aubl. Guian. 3. tab. 41.) "Leaves egg-shaped, wrinkled, tomentous underneath; racemes axillary, compound, elongated." A shrub. *Stem* about six feet high, four or five inches in diameter, with a reddish, wrinkled, cracked bark. *Branches* supporting themselves by the trunks, and climbing to the tops of very large trees; branchlets numerous, very long, slender, knotty, clothed with a reddish down, many of them hanging down to within eight or ten feet of the ground. *Leaves* two on each knot, opposite, six or seven inches long, about four broad, entire, often a little rolled inwards; green above; reddish and downy, with prominent veins underneath; petioles scarcely half an inch long; stipules two to each leaf, acute, tomentous, caducous. *Flowers* small; in loose, axillary, solitary, compound, tomentous racemes, which are longer than the leaves, blueish; stamens rather long. *Fruit* oblong oval, smooth. A native of Guiana. 2. *C. bifurcata*. (Malanea bifurcata; Desf. 2. Lam. 1466.) "Leaves egg-shaped, acute at both ends, nearly smooth; peduncles forked at their upper part; flowers unilateral." A shrub. *Branches* woody, opposite, obscurely four-cornered, greyish, leafy chiefly towards the top. *Leaves* two inches long, or more, about an inch broad, opposite, entire, green on both sides; with tufts of hair underneath, springing from transparent glandular points at the axils of the nerves; petioles from three to four lines long, channelled; stipules accompanied by short whitish hairs above the place of their insertion. *Flowers* small, sessile, in two, but apparently unilateral rows, which are situated on each of the forks of the short, axillary, solitary common peduncles. *Drupe* scarcely half the size of a grain of wheat, oval, beset with very short hairs. Supposed to be a native of the Caribbee islands. 3. *C. nitida*. (Malanea nitida; Desf. 3. Lam. Ill. 1467. Langeria lucida; Swartz. prod. 48.?) "Leaves egg-shaped, quite smooth, shining; peduncles dichotomous." Whole plant smooth, with the exception of very small tufts of hairs, on glandular transparent points, at the axils of the nerves, underneath the leaves. *Branches* woody, greyish, cylindrical, with a rather uneven bark. *Leaves* three or four inches long, about an inch and half broad, opposite, entire, on very short petioles; stipules intrafoliaceous, oval-acuminate, caducous. *Flowers* small, sessile, or nearly so, alternate, a little distant from each other on the ramifications of the common petioles; common petioles nearly the length of the leaves, axillary, solitary, several times dichotomous. *Fruit* oval, about a quarter of an inch long; nut oblong, angular. A native of the Caribbee islands. 4. *C. verticillata*. (Malanea verticillata; Desf. 4. Lam. Ill. 1465. Pl. 66. fig. 1. Antirhea; Juss. Commerf.) "Leaves inversely egg-shaped, acuminate, whorled, generally in threes; peduncles axillary, forked." A small tree. *Branches* woody, cylindrical, smooth, greyish. *Leaves* entire, smooth above, with small

tufts of hair underneath, as in the two preceding species, about two inches and a half long, and little more than one broad; petioles about a quarter of an inch long; stipules intrafoliaceous, lanceolate, acute. *Flowers* small, sessile, unilateral, near together on the upper part of the forks of the common peduncle. Common peduncles axillary, solitary, slightly hairy, an inch long or more; calyx cloathed with short hairs; corolla hairy on the outside, longer in proportion than in the other species; anthers oblong, almost sessile. *Fruit* about the size of a grain of wheat. A native of the isles of France and Bourbon.

CUNNOR, in *Geography*, a river of S. Wales, which runs into the Tave, in the county of Glamorgan.

CUNNUS, in *Anatomy*, the *puendum muliebre*; or the anterior parts of the genitals of a woman, including the *labia pudendi*, and *mons Veneris*.

CUNOCEPHALI, in *Mythology*, from *κυν*, *dog*, and *κεφαλη*, *head*, a kind of baboons, or animals with heads like those of dogs, which were wonderfully endowed; and preserved, with great veneration, by the Egyptians, in many of their temples. It is related, that by their assistance the Egyptians found out the particular periods of the sun and moon, and that one half of the animal was often buried, while the other half survived; and that they could read and write. This strange history, Dr. Bryant imagines, relates to the priests of Egypt, styled *caben*, to the novices in their temples, and to the examinations they were obliged to undergo, before they could be admitted to the priesthood. The Egyptians, being much addicted to the study of astronomy, founded their colleges upon rocks and hills, called *caph*, and from their consecration to the sun, *caph-el*; whence the Greeks deduced *κεφαλη*, and from *caben caph-el* they formed *κυνοκεφαλος*. *Caben-caph-el* was some royal tennary in Upper Egypt, whence they drafted novices to supply their colleges and temples. By this etymology he explains the above history. The death of one part, while the other survived, denoted the regular succession of the Egyptian priesthood. As the *cunocephali* are said to have been sacred to Hermes, who was the patron of science, and particularly styled *caben*, or *canis*, their college and temple were probably in the nome of Hermopolis; and the *cunocephali* are said to have been worshipped by the people of that place. They formed a sacred college, whose members were persons of great learning; and their society seems to have been a very ancient institution. They were particularly addicted to astronomical observations; and by contemplating the heavens, styled *Ouran*, they learned to distinguish the seasons, and to divide the day into parts. The *cunocephali* are also found in India, and other parts of the world. Herodotus (lib. iv. c. 191.) mentions a nation of this name in Libya; and speaks of them as a race of men with the heads of dogs. In the vicinity of this people, he places the *acephali*, men with no heads, but with eyes in the breast. These and the *acephali* were thus denominated from their place of residence, and from their worship; the one from *Caben-caph-el*, the other from *A-caph-el*; each of which appellations is of the same purport, the right noble, or sacred rock of the sun. Many places were named *Cunocephale*; all which were eminences, or buildings situated on high, agreeably to the etymology above given. The citadel of Athens was so called by Xenophon; and those who speak of the *Cunocephali* describe them as mountaineers. There was a promontory of this name upon the coast of the Red sea, mentioned by Strabo; and another in Coreyra. Bryant's *Analysis of Ancient Mythology*, vol. i. p. 329, &c.

CUNODONTES, a people mentioned by Solinus, and Isidorus, and by them supposed to have the teeth of dogs.

They were probably denominated, says Dr. Bryant, from the object of their worship, the deity *Chan-Adon*, which the Greeks expressed *Κνωδων*, and thence called his votaries *Cunodontes*. *Ibid.* vol. i. p. 341.

CUNONIA, in *Botany*, (from J. C. Cuno of Amsterdam, who described his own garden in Dutch verse, 1750.) Linn. Gen. 556. Schreb. 761. Willd. 884. Juss. 310. Vent. 3. 284. Class and order, *decandria digynia*. Nat. Ord. *Saxifragæ*. Juss.

Gen. Ch. *Cal.* five-leaved, much shorter than the corolla; leaves egg-shaped, concave, acute. *Cor.* Petals five, inversely egg-shaped, spreading. *Stam.* Filaments ten, awl-shaped, longer than the petals; anthers roundish, didymous. *Pist.* Germ superior, conical; styles two, the length of the stamens; stigmas obtuse. *Peric.* Capsule oblong, acuminate, two-celled. *Seeds* numerous, roundish.

Ess. Ch. Corolla five-petalled. Calyx five-leaved. Capsule two-celled, acuminate, many-seeded. Styles longer than the flower.

Sp. C. *capensis*. Linn. Sp. Pl. Mart. Lam. Ill. Pl. 371. (*Oosterdykia floribus spicatis pentapetalis*; Burm. Ar. 259. tab. 96. *Arbuscula arbnti alari foliis*; Pluk. alm. 45. tab. 191. fig. 4.) A shrub. *Stem* knotty, leafy towards the summit, terminated by a singular oval-oblong petioled leaflet, which Linnæus calls a gland, although it is an inch long or more. *Leaves* large, opposite, petioled, winged; leaflets five or seven, lanceolate, ferrated, very smooth. *Racemes* in terminal pairs, one on each side of the singular leaflet, erect. *Flowers* very numerous, small, pedicels, several proceeding from one point. A native of the Cape of Good Hope.

CUNONIA *floribus sessilibus*; Buttn. Mill. ic. See ANTHOLYZA *cunonia*.

CUNTLINE, in *Rigging*, denotes the intervals between the strands of a rope.

CUNTUR, in *Ornithology*. See CONDOR and VULTUR *Gryphus*.

CUNUGUATI, CUNUGNALES, or *Nueva Ville Rié*, in *Geography*, a town of South America, in the government of Buenos Ayres, and province of Paraguay.

CUNUSITANI, in *Ancient Geography*, a people placed by Ptolemy on the E. coast of the island of Sardinia.

CUOLAGH, or QUOYLACH Bay, in *Geography*, lies at the south side of the entrance into Kenmare river, on the south-west coast of Ireland. At the head of it is a safe and well sheltered creek for small vessels. Long. 9° 53' W. Lat. 51° 38' N.

CUOMI, a town of China, of the third rank, in the province of Chang-tong; 15 miles N.W. of Kiao.

CUOZGNE', a town of France, in the department of the Doire, in Piedmont, in Italy, which formerly belonged to Sardinia. It is the chief place of a canton, in the district of Ivécé, with a population of 3250 individuals. The canton has 13 communes, and 7847 inhabitants.

CUP, CALYX, a vessel so called, of various forms and uses. In the Ephem. German. we have a description of a cup made of a common pepper-corn, by Oswald Nerlinger; which holds one thousand two hundred other ivory cups, each having its several handle, all gilt on the edges; with room for four hundred more.

CUPS, among *Herbalists*, are those short green husks in which flowers grow; some being divided into two, three, four, five, or six leaves. See CALYX.

CUP-fountain. See FOUNTAIN.

CUP-galls, in *Natural History*, a name given by authors to a very singular kind of galls found on the leaves of the oak, and some other trees. They are of the figure of a cup,

or drinking-glasses, without its foot, being regular cones, adhearing by their point or apex to the leaf; and the top, or broad part, is hollowed a little way.

Beside this species of gall, the oak-leaves furnish us with several others; some of which are oblong, some round, and others flattened; these are of various sizes, and appear on the leaves at various seasons of the year. They all contain the worm of some small fly; and this creature passes all its changes in this its habitation, being sometimes found in the worm, sometimes in the nymph, and sometimes in the fly state, in the cavity of it.

CUP shell. See SHELL.

CUPA, among the Ancients, a kind of boats, used in laying bridges over rivers, being broad below, and narrow above.

CUPAMENI, in Botany. Rheed. See ACALYPHA indica.

CUPANIA, (named from F. Cupani, a Franciscan monk of Sicily, author of *Plantæ Siculæ*, 1692, and *Hortus Catholicus*, 1696.) Linn. Gen. 279. Schreb. 645. Gært. 1051. Juss. 149. Molina; Juss. 248. Commers. Clafs and order, *ortandria monogynia*. Nat. Ord. *Tribilata*; Linn. *Sapindi*; Juss.

Gen. Ch. Cal. Perianth five-leaved, (five-parted? Swartz) inferior; leaflets oblong, erect, (egg-shaped, acuminate, concave; Sw.) Cor. Petals five, cowered at the top, upright, (clawed, ciliate; Sw.) Stam. Filaments eight, capillary, longer than the calyx, erect, (from the base of the corolla, broader at the bottom, villous, the length of the petals; Sw.) anthers incumbent. Pist. Germ egg-shaped (roundish, three-cornered; Sw.); style short, tritid (at the tip, awl-shaped, the length of the stamens; Sw.) stigmas blunt, (small, almost upright; Sw.) Peric. Capsule coriaceous, turbinate-ovate, three-lobed, (obtusely three-cornered, large; Sw.) three-celled, three-valved. Seed solitary, (two in each cell; Plum.) with a bell-shaped crenate aril, embracing the seed like a calyx, (coloured, fastened to the seed above the middle; Sw.)

Sp. 1. *C. tomentosa*. Mart. 1. Willd. 1. Swartz. Prod. 61. Fl. Ind. Occ. 2. 657. (*Trigonis tomentosa*; Jac. Am. 102. 1.) "Leaves pinnated; leaflets inversely egg-shaped, retuse, ferruginous-tomentous underneath." A small upright tree, twelve feet high. Younger branches and ribs of the leaves slightly tomentous. Leaves alternate, half a foot long; leaflets usually three pairs, without an odd one, alternate, oblong, attenuated at the base, emarginate, serrated. Racemes seven inches long, axillary, erect, simple. Flowers yellowish, small, numerous, on short pedicels. Jacq. A native of Hispaniola, on woody mountains. 2. *C. glabra*. Mart. 2. Willd. 2. Swartz. Prod. 61. Fl. Occ. 2. 659. (*C. arborea, foliis oblongis crenato-ferratis, distiche et alternatim sitis, racemis laxis propendentibus*; Brown. Jam. 178. *C. Americana*; Linn.? *C. castaneæ folio, fructu fericeo & ramoso*; Plum. Gen. 45. *Burm. Amer. tab. 110*?) "Leaves pinnated; leaflets egg-shaped, obtuse, crenated, smooth." A shrubby tree, twelve or fourteen feet high. Leaves large. Racemes loose, drooping. Brown. A native of Jamaica and Hispaniola. 3. *C. saponarioides*. Mart. 3. Willd. 3. Swartz. Prod. 62. Fl. Ind. Occ. 2. 661. "Leaves pinnated; leaflets oblong, attenuated, quite entire, scabrous-pubescent underneath." A native of the West Indies. 4. *C. laevis*. (Molina; lævis; Willd. Lam. Ill. Pl. 305. fig. 1.) "Leaves pinnated, in two pairs; corymbs panicle; fruit inversely egg-shaped, truncated, triquetrous." Leaves abruptly pinnated; leaflets opposite, oblong, obtuse, attenuated at the base, quite entire. Panicle axillary, composed of small corymbs. A native of the island of Bourbon. 5. *C. canescens*. (Molina; canescens; Willd. Roxb. Corom. 1. 43. tab. 60.) "Leaves pinnated, in two pairs; racemes panicle; fruit egg-shaped."

Bark of the branches cinereous, scabrous. Leaves abruptly pinnated; leaflets elliptical, rather acute, quite entire. Panicle axillary, shorter than the leaves, composed of long racemes. A native of the East Indies. 6. *C. alternifolia*. (Molina; alternifolia; Willd. Lam. Ill. Pl. 305. fig. 2.) "Leaves pinnated; leaflets alternate, retuse; panicle clove." Leaflets about eight, alternate, inversely egg-shaped, very slightly retuse, quite entire, petioled. Panicle axillary, shorter than the leaves, composed of small corymbs. A native of the island of Bourbon.

Obs. There is much discrepancy in authors with respect to this genus and its species. The original cupania of Linnæus contained only one species, taken up by him from Plumier, and described as a pentandrous plant, with a three-leaved calyx, a small tritid style, and a one-celled, three-valved capsule, containing six seeds, embraced by a bell-shaped aril in the manner of a calyx. La Marck, in the *Encyclopedie Methodique*, has also but one species, which he considers as the *C. americana* of Linnæus, quoting Plumier, and adding Brown's Jamaica-plant as another synonym. Not having seen the flowers, he copies their generic characters from Linnæus, but gives the following description of the fruit, taken from a dried specimen in his possession. Capsule top-shaped, coriaceous, silky, and reddish on the outside, three-celled, three-valved, opening from the summit to the base, with the adhering partitions. The specimens from which Gærtner described the fruit of his *C. americana* came from Jamaica, and have only one seed in each cell: hence, he was induced to doubt whether it be not a different species from the Domingo-plant of Plumier, which is said to be silky white, and to have two seeds in each cell. He agrees with Linnæus in attributing to it an aril, of which La Marck takes no notice, and differs from the last-mentioned author in describing the capsule as perfectly entire in its lower part, and splitting into valves only half way down. Willdenow thinks it uncertain whether the *tomentosa* or *glabra* of Swartz be the *americana* of Linnæus. Jussieu separates cupania and *molinæa*; and Willdenow states that they differ in the latter's having no style and no aril to the seeds. But Mr. Dryander (*Linnæan Transactions*, vol. ii. p. 232.) pronounces them the same genus. Under the sanction of such high authority, we have not scrupled to unite them, though we have not ventured to attempt the establishment of an essential character. Professor Martyn, in his edition of Miller, refers from *molinæa* to cupania; but under that article he has inserted only Swartz's three species of cupania. La Marck, in the plates of his *Illustrations*, has figured two species of *molinæa*; but as the letter-press to that work is not finished, we are not able to ascertain his ideas concerning the genus. He has given no figure of cupania. The gelonium of Gærtner, formed from some imperfect specimens of a tree found in the isle of Bourbon, seems to differ from cupania chiefly in having a two-celled capsule.

CUPAR, or COUPAR OF FIFE, in Geography, a royal burgh, and county town of Fifeshire, Scotland, is seated on the northern bank of the river Eden, nearly in the centre of the county.—It is also the name of a parish, which comprehends an area of about five miles in diameter, and is divided into two parts by the river Eden. The borough, at an early period, was possessed by the thanes of Fife, who held their courts of justice here. It is now a respectable well-built town, with paved streets; and is governed by a provost, three bailies, a dean of guild, and thirteen counsellors. Among the public structures of the town, the church, with a handsome spire, is prominent. Next to which is the court-room and town-house; but the public gaol for the county is reprobated by Dr. Campbell, in his communication to sir

John Sinclair, as mean, filthy, and, in every respect, disagreeable to the character of the place, and of the district. In Cupar and its neighbourhood, a considerable quantity of coarse linens is manufactured: and it is stated, that "about 500,000 yards are annually stamped" in this town. The linen merchants are said to pay annually about 45,000*l.* to the manufacturers. In the year 1794, 223 looms were employed in this business. Here are also some considerable tanyards, and a bleach-field; also brick and tile-fields. In the year 1800, Cupar contained 796 houses, and 4463 inhabitants. Sinclair's Statistical Account of Scotland.

CUPAR, or COUPER of ANGUS, so named, to distinguish it from Cupar in Fifeshire, Scotland, is a considerable town and parish, situated in the valley of Strathmore, and lying partly in Angus, and partly in Perthshire. The parish occupies an area of above five miles in length, by one in breadth, and contains nearly 2400 acres. The lands are mostly inclosed; and agriculture has been progressively improving for the last twenty years. In the parish are five mills, and a considerable linen manufactory, the extent of which may be partly estimated, when it is known, that in the year 1792 there were 97,810 yards of brown linen stamped here. At the bleach-field of Balgirtho, about 200,000 yards are annually whitened. The population of the parish, in 1793, according to the report in Sir John Sinclair's Statistical work, was 2076, "an increase of 585 within the preceding forty years. According to the reports of 41 Geo. III. A. D. 1800, the parish then contained, in the Perth division, 420 houses, and 2169 inhabitants; and in the Angus division 59 houses, and 247 inhabitants; making a total of 479 houses, and 2416 persons. In the parish are the vestiges of an encampment, of a square form, comprehending about 24 acres, and said to have been formed by the army of Agricola, in his seventh expedition. (See Roy's Military Antiquities.) Within the vallum of this fortress, Malcolm IV. in 1142, founded, and richly endowed, an abbey for Cistercian monks. Parts of the building remain.

The town is seated on a rivulet, which divides it, and also the counties. It is 12 miles from Perth, and nearly the same distance from Dundee. Here are a weekly market on Tuesday, and four annual fairs. In the year 1781, a tannery was formed here, and has produced so much, as to turn out, in one year, 2600 hides of leather. The town has gradually improved; and its streets are provided with lamps and pavements. Sinclair's Statistical Account of Scotland.

CUPEA, a town of European Turkey, in the province of Moldavia, 20 miles N. of Suczava.

CUPEL, or CUPELLATION, in *Chemistry*. Cupellation is a process employed in the assay of gold and silver, by which the alloy, or base metal, with which any sample of the noble metals may be mixed, is separated, and its proportion ascertained. The rationale of this process is founded on the following facts.

Of all the metals hitherto discovered, three alone (namely, gold, silver, and platinum,) are incapable of being oxydated or rusted by mere exposure to air, either when solid or in fusion; and hence gold and silver anciently acquired the name of *noble* metals. All other metals tarnish and are oxydated when kept in fusion in open vessels, (some with extreme ease, others not without difficulty,) so that by constantly removing the skin of oxyd as it forms, and exposing fresh surfaces to the air, the whole metal may be finally changed into oxyd. Hence when a mixture of a *noble* and a *base* metal (or in other words, of a metal unchanged, and of one oxydable by fusion,) are melted and exposed to air, the base metal gradually changes to an oxyd, and is thrown off in the form of coloured scales or

glassy pellicles, and the noble metal remains unaltered. This separation, however, is not in all cases equally accurate, for where the *alloy* or base metal is not very easily oxydable, and where the proportion of the alloy to the noble metal is but small, the affinity which the latter exercises towards the former is so great, and increases so much with the decreasing proportion of the alloy, as to protect it completely from any further action of the air, and to preserve it in the metallic state. Thus, for example, if a mixture of equal parts of silver and copper are kept in fusion in an open vessel, a crust of brown oxyd of copper readily forms, which, if removed, is succeeded by other crusts that continue to be produced, but with increasing difficulty, till the copper is only about a twelfth of the mass; but after this point scarcely any continuance of heat will complete the oxydation of the remaining portion of the alloy.

The same, however, does not take with lead when alloyed with silver, for on fusing the mixed mass the lead speedily oxydates on the surface, and at the same time vitrifies into litharge, and if this is removed, every particle of lead may be thus extracted, and the silver alone left behind perfectly pure.

Now it is found that when a triple alloy of silver, copper, and lead, is mixed together (the quantity of lead being several times greater than that of the copper) the oxydability of the copper is so much increased by the presence of the lead, owing to the affinity of the two oxyds, and the solubility of the copper oxyd in that of the lead when in fusion, that the silver is no longer able to protect any portion of the copper from oxydation, and the whole alloy is removed from the noble metal, even to the last sensible particle.

This, therefore, is the principle on which the process of cupellation is founded, namely, that of mixing the alloyed noble metal with a considerable portion of lead, exposing the whole to a melting heat with access of air, and thus converting to an oxyd both the lead and every other base metal present in the mass, till the noble metal is left behind perfectly pure.

This process is performed both in the large way in extracting silver from the ore and refining it, and in the small way in assaying those mixtures of gold and silver with different alloys which are used in such large quantities for plate, coin, &c. &c. The former, indeed, is technically called refining, and the latter only cupellation, and some little variation in the management of each takes place, but the principle in both is precisely the same.

Cupellation is usually performed in a furnace contrived for the purpose, and capable of giving a pretty intense heat. The body of the furnace is a hollow four-sided prism, in the middle of which is fixed an earthen vessel called a muffle, of an oven shape, vaulted at top, entirely open at one end, and with a flat floor at bottom. The open end of the muffle comes in close contact with a corresponding hole in the side of the furnace, and is luted to it, and the closed end projects as far as the centre of the furnace. By this contrivance the muffle is heated by the fuel round it, whilst not a particle of the burning charcoal can fall into its cavity, and a gradation of heat is also obtained within it, being the most intense at the closed end which is in the centre of the fire, and the least at the open end contiguous with the hole in the side of the furnace. The cavity of the muffle being large in comparison with the vessels which it is to contain, a considerable body of heated air is constantly circulating over the melted metal, which is necessary to keep up the constant oxydation of the lead and alloy on which the process of cupellation depends.

But as it would be nearly impracticable to keep up the requisite

C U P E L L.

requisite heat within the muffle, whilst one side was entirely open to the external air, a small vestibule or shelf of iron is made to project a few inches from this opening, on which several long cylinders of charcoal are heaped up whilst the process is going on, which take fire by touching the end of the red-hot muffle, and partially block up the opening, so as fully to heat the outer air in passing to it.

The melted metal is contained in small earthen vessels called *cupels*, which are small solid cubes or cylinders about an inch or an inch and a half across, and with a small depression at top which lodges the melted globule. The cupels may be made of any earth of little cohesion, such as the ashes left after the lixiviation of the saline residue of burnt wood, which are much used in *refining*; but for *cupellation*, or assaying in the small quantities, the cupels are made entirely of bone-ash or phosphat of lime, which possesses the qualities of porosity and infusibility in an eminent degree. This is ground to a fine powder, then a little moistened with water, and the mass (which possesses scarcely any cohesion) is forcibly struck into an iron or a brass mould, where it takes the requisite form, and on drying becomes solid enough for use. The cupels are so small that several of them may be ranged side by side on the floor of the muffle, and they are so extremely porous that the fused oxyd of lead sinks into their substance with as much ease as water into a lump of chalk, but all of the globule of metal that remains in the metallic state is detained in the little cavity on their surface. It should be observed, that the cupels cannot absorb more than their own weight of litharge at the utmost, so that the quantity of metal used and the required proportion of lead must be regulated accordingly.

Experience has shewn the extreme accuracy and nicety of manipulation requisite to conduct cupellation with uniform exactness, and yet there is no process in which accuracy is of more real importance, since the quantities operated on are at most only a few grains, which are taken as samples of the purity and consequent value of very large masses of gold and silver. Hence, too, scales and weights of uncommon delicacy are required.

Cupellation of Silver.

For the assay of silver a clean piece of the metal is taken, which is not more than 36 grains, and less if the alloy appears abundant, is laminated, and weighed with the utmost care. It is then wrapped up in a piece of sheet-lead of the proper weight, or both the silver and lead are folded in paper ready for use. The purity of the lead is important; for all lead naturally contains a little silver, which, if not removed, might make a sensible error in the assay. The lead is, therefore, always revived from litharge; in which state it is remarkably pure, and contains no more than $\frac{1}{2}$ grain of silver in the pound, which quantity may be entirely neglected.

The mode of proportioning the quantity of lead to the estimated quantity of alloy in the silver will be presently noticed.

The fire being kindled, and the floor of the muffle sprinkled with chalk, to prevent the cupels from being glued to it in the process, the muffle and empty cupels are first made fully red-hot, and the cylinders of charcoal are put against the open end of the muffle, as already described. The silver and lead are then dropped into the cupel, and the charcoal replaced. The metals immediately melt together; and, when red-hot, the following appearances take place. The melted globule begins to send off dense fumes, which rise to the roof of the muffle, and at the same time

a thin stream of red fused matter is seen constantly flowing down the sides of the globule to the surface of the cupel, through which it sinks. This fume is the oxyd of lead evaporated by the heat, and the stream of fused matter is the melted litharge, together with the copper or other alloy of the silver which is thus extracted from it. In proportion to the intensity of the heat are the density of the fume, the violence with which it is given off, and the rapidity with which the melted oxyd *circulates*, as it is termed, or falls down the sides of the metal. As the cupellation advances, the melted globule becomes rounder, and its surface more freaky, till, in about fifteen or twenty minutes, according to circumstances, all the lead and alloy are vitrified and absorbed by the cupel, the last portions of litharge collect in large bright streaks, which disappear with great rapidity, shewing the melted metal beneath bright with iridescent colours, which suddenly after becomes opaque, and exquisitely white and brilliant, exhibiting the clean surface of pure melted silver. This last appearance is called the *lightning* of the metal, and it is highly beautiful, as if a red curtain was suddenly withdrawn from the metal. The operation is now finished, and the cupel is drawn forwards to the open side of the muffle, that it may cool gradually before it is removed; for, if it were suddenly fixed, the globule is apt to shoot into an arborescent surface in the act of congealing, by which small particles are thrown out of the cupel and lost, and the assay is spoiled.

In the cupellations made at the mint assay-office, two assays are made of the same metal, and no sensible difference between the weight of the two buttons is allowed to pass, as ascertained by scales, that turn with the $\frac{1}{1200}$ th of a grain.

The process is considered as well performed when the button of silver adheres but slightly to the cupel; when its shape is very considerably globular, and not flattened at the margin; when it is quite white, clean and brilliant, and not fouled or spotted with any remaining litharge. In this state of purity, the surface of the button is never quite smooth, but is somewhat scaly or striated, the effect of a very strong tendency to crystallization, which perfectly pure silver possesses, but is not found in plate or alloyed metal. Under the microscope, this irregularity of surface is still more observable, and the scales seem to incline to a pentagonal form.

Where the alloy of the silver is only copper, as is usually the case, the cupel round the button is stained of a brown grey.

The management of the fire in cupellation is of great importance. If it is so intense that the cupel can scarcely be distinguished from the muffle, and the fume of litharge can hardly be discerned through the dazzling heat, not only much of the lead is volatilized to mere waste, but even a portion of the silver is carried off along with it, which renders the assay inaccurate. Even silver alone, and in the greatest purity, may be evaporated by intense heat as M. Tillet (an ingenious French chemist, and master of the mint at Paris) found, by an experiment, in which a button of pure silver was intensely heated for two hours, and had lost thereby no less than $\frac{1}{3}$ of its weight. If one vessel is inverted over another that contains the silver, in this case the inside of the upper one is found studded with minute globules of silver, when viewed through a common lens. On the other hand, when the fire is too slack in cupellation, the litharge is not fully melted as it forms, and, therefore, is not absorbed by the cupel, but lies on the surface as a red scoria, and the circulation is very sluggish. The proper medium of heat is, when every thing within the muffle is fully red-hot; when

the

C U P E L.

the fume of litharge is abundant, and visibly rises to the top; and when the circulation goes on rapidly, and the button continues very globular. Towards the end of the process, the heat should be increased as the button, by the constant abstraction of the lead, becomes constantly less easily fusible.

It has been already mentioned, that in cupellation all the alloy of the silver is carried down into the cupel along with, and dissolved in the litharge, provided lead enough be used. But it was also found by M. Tillet, that a small portion of the silver is at the same time carried down with the lead; so that, when perfectly pure silver is cupelled with lead of known purity, the button of silver left after the process never weighs quite so much as before, even though the heat employed is so moderate as not to volatilize any of the silver. As a proof that some of the silver is carried down into the cupel, M. Tillet ground this vessel to powder, and fused it with a reducing flux, whereby he recovered nearly all the lead that had been used, and which now contained ten times as much silver as its natural retent of this noble metal, nine tenths of which, therefore, must have been derived from the button of silver during cupellation. Accordingly, on cupelling this lead, *per se*, it left behind all this excess of silver, and now only carried down its natural retent, which amounts to about $\frac{1}{115}$, or half a grain in a pound French.

It remains to give the proportions of lead to alloy, which have been found the most useful in cupellation, and the method of estimating the quantity of alloy previous to this operation, with sufficient exactness to guide the artist. The ancient assayers used for this purpose small slips or bars of metal, made with pure silver and copper, in known proportions, in a regularly increasing series, from the least to the greatest quantity of alloy usually required. These sets of bars were called *touch-needles*; and, by comparing the silver to be assayed with these needles, in colour, tenacity, and other external marks, its proportion of alloy was guessed at with sufficient accuracy to determine the quantity of lead required in the cupellation. These needles are now, however, almost totally disused in silver-assaying, as an experienced assayer is able to judge of the fineness of silver, with quite sufficient accuracy, by the ease with which it is cut, the colour and grain of the fresh-cut surface, the malleability, the appearances on being heated red-hot, and other tokens.

The proportion of alloy (if copper) to the silver being found with sufficient exactness, that of the lead is thus estimated. Copper, when taken by itself, requires from 10 to 14 times its weight of lead for complete scorification on the cupel. But all admixtures of fine metal tend to protect the copper from the action of the litharge, the more, in proportion to the quantity of fine metal. Thus, when one part of copper is mixed with three of silver, no less than 40 parts of lead are required; and one part of copper with 11 of silver require 72 parts of lead. It should be observed, however, that a considerable difference in the respective proportions of lead to copper is observed by different assayers, though the general principle of increasing the lead in proportion to the quantity of fine metal is indisputable.

The following table will shew some of the proportions used in the French mint, as given by M. Tillet, and also others used by the German chemists, as given by Gren:

Copper.	with	Silver.	requires	Lead.
1	$\frac{1}{1}$	0	—	10.
1	—	$\frac{1}{15}$	—	17 Fr.
1	—	$\frac{1}{11}$	—	28 Fr.
1	—	$\frac{1}{3}$	—	20 Ger.
1	—	$\frac{1}{3}$	—	29 Fr.

Copper.	with	Silver.	requires	Lead.
1	—	$\frac{1}{2}$	—	30 Fr.
1	—	1	—	32 Fr.
1	—	2	—	36 Fr.
1	—	3	—	40 Fr. and Ger.
1	—	4	—	56 Ger.
1	—	5	—	48 Fr.
1	—	7	—	64 Ger.
1	—	11	—	72 Fr.
1	—	15	—	96 Ger.
1	—	23	—	96 Fr.
1	—	30	—	128 Ger.

Cupellation of Gold.

The process of cupellation is the same for gold as for silver, the alloy, in both instances, being worked off by lead; but several curious circumstances take place with mixtures of gold with other metals, which are not easily explicable. When pure gold is mixed with lead and cupelled, the whole of the lead is not separated, as it is with pure silver, but a small portion remains combined with the gold sufficient to impair its colour and ductility. If, besides gold and lead, the mixture contains copper to the amount of $\frac{1}{2}$ of the gold, the whole of the lead will now be separated in cupellation, but almost the whole of the copper will remain. If, in addition to the above ingredients, the alloy contains a somewhat greater proportion of silver than it does of copper, this latter is separated by cupellation, but a little of the lead remains. But if the amount of silver equals or exceeds that of the gold, all the lead and copper are separated, and only the gold and silver remain.

As, therefore, the object of cupellation is to separate the whole of the alloy of base metal, it is necessary, in assaying gold, to add first a very considerable quantity of silver, then to work off the copper, and other base metal, by lead on the cupel, and afterwards to separate the gold and silver by the process of *parting*, as it is called, by means of nitric acid.

The assay of gold, therefore, is more complicated than that of silver, and requires the intervention of this latter metal. The quantity of silver must, as already mentioned, be at least equal to that of the gold, to enable the lead to extract all the copper in cupellation; but, in fact, the silver is generally three times as much as the gold, otherwise, though all the copper may be removed by a much less proportion, the subsequent separation of the silver from the gold by nitric acid cannot well take place. For it is found that, unless the silver be in this large quantity, the gold, which is not itself touched by the nitric acid, also protects a portion of the silver from the acid, and the separation is not complete.

The cupellation of gold therefore is conducted in the following manner: the quantity of copper or other alloy present, being first estimated as accurately as possible in the way that will be presently mentioned, as much fine silver is added to the mixture, as will make the gold only a *fourth* of the mass when the base alloy has been removed. If the gold is already alloyed with any silver, a proper allowance is of course made for the estimated quantity. This proportioning of the silver to the gold, and melting them together, is called *quartation*, the gold being reduced thereby to one-fourth of the mass of noble metal. To the mixture the requisite quantity of lead is then added (which is nearly the same as in silver assaying) and the cupellation is conducted exactly in the same manner, only that a higher heat may be given, as the silver in this mixture is not volatilized by a strong fire, as it is in mere silver assaying. The *lightning* takes

takes place here also when every particle of lead and other base metal is removed, and only the gold and silver are left on the cupel.

The separation of these noble metals by nitric acid, and the exact process of parting, will be described under GOLD. It may be just mentioned, however, that the button is first flattened, and then rolled out into a small coil, and then put into a glass, and with boiling nitric acid, by which all the silver is extracted, and the gold alone is left behind in perfect purity.

The quantity of alloy in any mixture of gold with other metals is estimated previous to cupellation, partly by the general appearance (the nature of the alloy being known) and partly by the use of the touch-stone. In judging by the general appearance alone, much advantage may be derived from touch-needles, but the case is more complicated here than in silver assaying, since three metals at least are concerned in gold assaying, namely, gold, silver, and copper. Therefore if these needles are used, there must be several sets of them adapted to the nature of the alloy.

The trial by the touchstone is another simple and very ingenious method of forming some estimate of the proportion of alloy in any gold mixture. For this purpose the piece of metal to be tried is rubbed hard upon a piece of black basalt or black pottery, so as to make a broad bright metallic streak by the abrasion of some of the metal. This shews at once the true colour of the alloy, which may also be compared with another streak made by a touch-needle beside it. A drop or two of nitric acid is then spread upon the streak, and after remaining about ten seconds, it is washed off, and the effect observed. If the streak preserves its golden colour unaltered, the metal is judged to have a certain degree of fineness, as gold is insoluble in this acid; if it looks red, dull, and coppery, it is less fine; if the streak is almost entirely effaced, the metal contains very little gold; and thus by the assistance of this acid, an experienced assayer will come at a sufficiently accurate knowledge of the quantity of alloy to guide him in the addition of lead and silver in the cupellation. It is found however that though pure nitric acid will readily dissolve copper singly, it will not act sensibly on this metal, when in mixture with twice its weight of gold, so effectually does the gold protect the copper against this powerful acid. But if a small proportion of muriatic acid is added, the copper will be dissolved when the gold is not more than three-fourths of the mixture, and thus the power of this test is much extended. Vauquelin, in his "Manuel de l'Essayeur," recommends for this purpose an acid composed of 98 parts of nitric acid of 1.34 sp. gr., 2 parts of muriatic acid of 1.173 sp. gr., and 25 parts of water. This does indeed compose a nitro-muriatic acid, which is the proper solvent for gold, but the gold on the touch-stone is not in this case sensibly acted on, owing to the shortness of the application, and the very small proportion of muriatic acid.

Touching is also of great use in determining the value of wrought trinkets which cannot spare so much as 8 or 10 grains for a regular assay.

Cupellation of Alloys of Platina.

On account of the great specific gravity of platina, it was long apprehended that gold might be adulterated with it to a considerable degree without being easily detected, for as platina is equally unoxidable by air as gold and silver, it cannot be scorified by lead on cupel, and being insoluble in nitric acid its separation from gold is not readily effected. It is not difficult, however, to detect this metal when mixed with gold or silver even in very small proportion.

Gold alloyed with so little as one *per cent.* of platina and cupelled in the usual way, with thrice its weight of silver, differs from gold and silver alone in requiring a much greater heat for cupellation and complete fusion of the button; otherwise, when all the lead is worked off, the button remains flat, like a piece of money, and its surface knotty. Even when the button is well fused its edges are much thicker, and rounder than in common gold assays, its colour duller, and especially it appears remarkably crystallized on its surface. Also in cupellation, when the last portions of lead are worked off, the button appears puffy, scarcely iridescent, and does not lighten, or become suddenly brilliant as silver and gold alone, or gold and silver do.

Silver bears alloying with platina better than gold does; but this is never done fraudulently. When the platina does not exceed 5 *per cent.* of the silver, it works easily on the cupel, but the lightning is less observable than with pure silver, and, in particular, the property of crystallizing is still more conspicuous. When the platina amounts to a quarter of the mixture, the button or cupel flattens, and becomes puffy even before all the lead is run off, and its surface shoots up into knobs which, when seen by a magnifier, appear clusters of crystalline points.

Some remarkable occurrences take place with the alloys of gold or silver with platina, when treated with nitric acid, which will be mentioned under that metal.

CUPER, GILBERT, in *Biography*, was born in the duchy of Guelderland, in 1644: his early education was at Nimeguen, and he finished his studies under Gronovius at Leyden. At the age of 25 he was appointed professor of history at Deventer. He was also raised to the principal offices of the magistracy of that city. Here he died in 1716. He published many works of considerable merit; particularly "Observations on various Greek and Latin Authors;" "A Collection of ancient Monuments relative to Egypt;" "An Explanation of the Apotheosis of Homer;" and a "History of the Three Gordians." He maintained a friendly correspondence with the principal literary characters of his time, by whom he was highly esteemed, on account of his great learning. He was elected foreign member of the academy of inscriptions at Paris. *Moreri.*

CUPERIUM, in *Ancient Geography*, a place of Thrace, in the vicinity of Zurule.

CUPERTINO, in *Geography*, a town of Naples, in the province of Otranto; $5\frac{1}{2}$ miles N.E. of Nardo.

CUPHA, in *Ancient Geography*, a river of European Sarmatia.—Also, a town of Africa, in Libya, placed by Ptolemy near the Niger.

Gen. Ch. *Cal.* Perianth one-leaved, tubular, striated, five or six-toothed, upper tooth broader, permanent. *Cor.* Petals five or six, inserted into the throat of the calyx, the two upper ones larger. *Stam.* Filaments ten or twelve, in three ranks, unequal, two of them shorter and more hairy; anthers roundish. *Pist.* Germ egg-shaped; style permanent. *Peric.* Capsule oblong, one-celled, valveless, covered by the calyx, and bursting irregularly with it by the enlargement of the receptacle of the seeds. *Seeds* from five to ten, lenticular, erect, attached to the filiform lateral branches of a columnar, triquetrous, free, cartilaginous receptacle.

Ess. Ch. Calyx five or six-toothed, unequal. Petals five or six, unequal, inserted into the calyx. Capsule one-celled; receptacle triquetrous.

Sp. C. *cupressifolius*. Jacq. hort. 2. 83. Pl. 177. Lam. 18. Pl. 477. Mart. tab. 44. fig. 9. (*Lythrum cuphea*; Linn. jun. Supp. 249. *Balsamina Pinto*; Vandell. fasc. 1771. 17. tab. 3. *Root* annual. *Stem* a foot high, cylindrical, erect, pubescent-viscid, purplish, branched. *Leaves* opposite, reticled, ovate-oblong, quite entire, even-surfaced. *Flowers* purple, lateral, solitary, on short peduncles; calyx swollen at the base, pubescent-viscid; nectary a reflexed scale within the gibbous part of the calyx. *Capful* bursting longitudinally by the protrusion of the lengthened receptacle, loaded with the unripe seeds, which come to maturity in the open air. A native of moist shady ground in Brazil. It is readily raised from seed in our botanic gardens.

CUPID, in *Mythology*, one of the companions of Venus, and the god of love. The Cupids were anciently supposed to be very numerous, and accordingly they were the offspring of different parents; but there were two which were the chief, viz. *Eros*, the son of Jupiter and Venus, who delighted in inspiring his votaries with refined sentiments of virtuous love; and *Anteros*, of inferior, and, indeed, contrary character, the descendant of Mars and Venus, or, as some say, of *Aerebus* and *Nox*. The former is said to have been the cause of love, and the latter is represented as the cause of its ceasing; and, therefore, the antiquarians at Florence usually call the two little Cupids at the foot of the Venus of Medici by the names of *Eros* and *Anteros*; and in the air of their faces, and also in their form and attitudes, there is something that corresponds with these names; the upper one being lighter, and of a more pleasing aspect, and the lower one more heavy and sullen. Their darts are of a different nature; that of *Eros* golden, which procures love; and that of *Anteros* leaden, which causes hatred.

Cupid is commonly represented as a child, with soft and fine hair, almost always naked, of a good shape, inclining to plumpness, and furnished with wings, a bow, quiver, and darts, and sometimes with a lighted torch. The ancient artists and poets represent Cupid either as idle and playful, or as very powerful, and governing all things, so that Venus, without his assistance, is weak and impotent. Thus Virgil, *Æn.* i. 668.

“Nate, meæ Vires, meæ magna potentia, solus?”

sometimes caressing, and sometimes tormenting the goddess Psyche, or the soul, riding in a car drawn by two Psychees, or by two butterflies, riding on a lion or a dolphin, &c.

The famous statuary Praxiteles, who flourished about the 114th olympiad, B. C. 324, acquired great honour, by his statues of Cupid. The orations of Cicero against Verres have given celebrity to the marble Cupid, which the orator represents as a rival to one still more famous by the same artist, that formed the pride and the wealth of the Thespians:—a statue spared by Memmius, when he plundered the cities of Greece. We learn from Pausanias, that this marble Cupid of Praxiteles, which was the idol of the Thespians, perished (after a variety of adventures) in a fire at Rome. It has been said that the marchioness of Mantua possessed, in the year 1573, the Cupid of Praxiteles, and the sleeping Cupid of Michael Angelo; but against this fact the testimony of Pausanias has been alleged. Nevertheless, though the Thespian statue suffered the fate reported by Pausanias, the marchioness might possess another Cupid executed by Praxiteles; because it appears that there existed two marble Cupids of acknowledged beauty, by this illustrious sculptor; and among the statues described by C. Illustratus, two Cupids, by the same artist, in bronze, are celebrated as works of exquisite perfection. On one of these, perhaps, the following

epigram was written; though Junius imagined that it was composed on the Thespian Cupid, and that the poet has taken the liberty to turn the marble into brass. We shall subjoin a verified translation of this Greek epigram, translated into Latin by Grotius, from Mr. Hayley's “*Essay on Sculpture*.”

“Julian, the Egyptian prefect, on the Cupid of Praxiteles.”

“Praxiteles, proud slave of my command,
Thus form'd my statue with his fetter'd hand,
Me, couch'd within him, he in bronze portray'd
For Phryne, who with love the gift repaid.
She made her captive mine. To hearts that burn,
Love is for love the only just return.”

CUPINOVA, in *Geography*, a town of Servia, on the river Save; 4 miles S. S. W. of Belgrade.

CUPIUS, JACOBUS, in *Biography*, a painter of quadrupeds, living in the 17th century. From the compositions of this artist R. Persyn engraved 13 plates, which were published by N. Vischer in 1641. Heinecken.

CUPOLA, in *Architecture*, the same with *dome*.

The word is Italian, formed of the barbarous Latin *cup-pola*, otherwise called *thola*, and *fornix*.

CUPPÆ, in *Ancient Geography*, a place in Mysia, situated, according to the Itinerary of Antonine, in the route from Nicomedia to Viminacum.

CUPPING, in *Surgery*, is one of the modes of inviting blood to a particular part of the body, by means of a vessel named a CUPPING-GLASS; and it is usual, after the application of this instrument, to employ scarifications, for the purpose of extracting the accumulated fluids. The comparative advantages of local and general blood-letting are elsewhere explained. (See the articles BLEEDING and SCARIFICATION.) The operation of cupping is by no means difficult; but in large cities it is very much confined to a particular class of practitioners, named CUPPERS, who extract blood in this way with great facility, sometimes to the quantity of a pound in six or seven minutes. Cupping was practised by the ancient Greeks, Romans, and Arabians, and the figure of a cupping-apparatus may be seen in the surgical works of Albucasis; though the methods, formerly in use, were not nearly so convenient and effectual as those employed by the moderns.

When a cupping-glass is applied alone, without scarifying the part, this operation is named dry cupping; and it is had recourse to where we desire to produce a greater flow of blood to a part than is usual, or to draw the milk into women's breasts, or to elongate their nipples, &c. The immediate effect of cupping any part is, to remove the superincumbent weight of the atmosphere upon it, and thereby to occasion a relatively greater degree of pressure on the adjacent parts. The blood is thus urged into the small arteries and veins, so as to produce a considerable redness under the cupping-glass, at which place the skin is also much elevated, and rather inflamed.

The exhaustion of the air from the cupping-glass is generally effected either by an air pump, or by the flame of a wax taper; but the latter mode is now commonly preferred, and is much the most expeditious method. When blood is to be drawn, we first use the glass, and apply the scarificators immediately after its removal; then again fix the glass on the same spot, and leave it there till the blood has flowed freely. To remove the glass, it is only necessary to raise one edge of it a little, so as to admit the air; and after every removal, the skin should be wiped clean with a sponge and

warm

warm water, to keep the scarified surface in a fit state for a renewal of the bleeding. If more than six or eight ounces of blood be intended to be extracted, several glasses, and as many scarifications, will be required; and the depth of the punctures must be in proportion to the quantity of blood demanded, unless the structure of the part forbids our making any other than very superficial wounds. No other dressing is required after cupping, than a piece of fine old linen.

CUPPING-Glass, is a vessel formed somewhat like a bell, applied to several parts of the body, in performing the operation above described. Among the ancients this instrument was composed of horn, wood, brass, silver, &c. When a cupping glass is to be used with an air-pump, for exhaulting it, a small aperture is left in its upper part, which is covered with a valve; but when the air is to be excluded by the flame of a lamp, &c. it must be entire at its upper part, and open at the bottom only.

CUPPIS, in *Geography*, a town of Sweden, in the province of Finland.

CUPRÆ, or **CUPPA**, in *Ancient Geography*, a maritime town of Italy, in the Picenum. Ptolemy places it between Tronto and Matrinum. It is thought to be the present St. Benedetto. Ptolemy also points out another town of this name, in the interior of Picenum, on the mountains beyond Tronto; supposed to be the present Loretto.

Pyramidal common cypress. Cupressus; Bauh. Pin. 488. *C. meta* in fastigium convoluta, quæ femina Plinii; Tourn. 587. Gært. tab. 91. fig. 1. Lam. Ill. Pl. 787. fig. 1. β . Horizontalis. Hort. Kew. Spreading common cypress. *C. ramos extra se spargens*, quæ mas Plinii; Tourn. 587. The pyramidal

variety is a large ever-green tree, very straight, with a brown bark; the wood hard, compact, pale or reddish, with deep veins, of a penetrating pleasant smell, and very durable; branches almost from the bottom of the stem, upright, and forming a pyramid, in the manner of the Lombardy poplar, so close as to be impenetrable to the rays of the sun. *Leaves* small, opposite, entirely covering the young branches; more distinct on the older ones, where they appear in pairs, decurrent, and clasping the stem; green, smooth, a little pointed, permanent, changing into a kind of scales on the oldest branches, where they become dry, and are partly united with the bark. The colour of these leaves in winter is of a dull sombre cast; but in spring they assume a brighter hue, and give a lively appearance to the tree, even before the expansion of the new leaves. *Flowers* on trees that are at least ten or twelve years old; male catkins from the end of the last year's branches, small, yellowish, three lines long, often very numerous; female catkins much fewer; generally at the end of the branches which spring from wood two years old. *Fruit* strobile, (Galbanus; Gært.; the name given by the ancients to the fruit of the cypress; but it does not at all differ from a strobile, as the term is used by modern botanists, and applied to the fruit of other coniferous plants) ovate-globular, an inch in diameter, not ripening till the following spring; scales large, angular, peltate, corky, slightly convex on the outside, radiately striated, mucronate in the centre, supported on the inner side by a thick angular peduncle; nuts four or more, adhering to the lower part of the peduncle, small, bony, but easily cut with a knife, inversely egg-shaped, compressed, or irregularly angular, covered with a dun-coloured membranous skin, which is extended into a very narrow rim surrounding the nut, one-celled. *Seed* linear-oblong, somewhat cylindrical, of a bay colour. The spreading variety is distinguished at once by its habit, and is so strikingly different from the pyramidal one, that La Marck would pronounce it a distinct species without hesitation, if both kinds were not said to be produced indiscriminately from the same seeds. Miller, indeed, asserts that his horizontal cypress is perpetuated from seeds without variation, and is distinguished from the spreading variety of the common cypress by having its branches more exactly horizontal; but La Marck asserts that this plant, if really a distinct species, is little known to botanists. If, as appears probable, it be *C. horizontalis* of the Hortus Kewensis, it is considered by the very able writer of that work as only a variety of *C. sempervirens*. Linnæus calls the young shoots which bear the fructification *frondes*; and has been followed in this respect by the author of Hortus Kewensis, as well as by La Marck, who calls them in French *feuillaisons*, a word which seems to have been invented by himself for the purpose. Linnæus was probably induced to employ the term in the present instance by the remarkable adnate insertion of the leaves, which appears to incorporate them with the branch; but Willdenow is more correct in calling them what they really are, little branches (*ramuli*); the term *frons* being, as Dr. Smith observes in his "Introduction to Botany," properly confined to the plants of the class cryptogamia. A native of the south of Italy, the Levant, some parts of the Russian empire, China, &c. and cultivated as an ornamental plant in all the warmer parts of Europe, particularly about palaces; no other tree being thought to blend so well with stone buildings. It is not uncommon about Marseilles, Rome, &c.; and is said to be so long-lived, that, if we may believe Pliny, there were in his time trees growing at Rome which were more ancient than the city itself. We are told, that the gates of St. Peter's church at Rome, made of cypress-wood, had lasted from the time of Con-

CUPRESSUS.

stantine, 1100 years, as fresh as new, when pope Eugenius IV. ordered gates of brass in their stead. Some maintain that the wood, *gophir*, of which Noah's ARK was made, was cypress; and Plato preferred it to brass itself, for writing his laws upon it. On account of the gloomy hue of its leaves, especially in winter, it was esteemed by the ancients a suitable ornament of their burial places, was sacred to Pluto and Proserpine, and was used at the funerals of persons of fashion. Hence, with the poets, it obtained the epithets *atra*, *funesta*, *funebria*, and *feralis*. It was introduced into England more than two hundred and fifty years ago, according to Turner, and is still found in old gardens. It has been strongly recommended by Evelyn and Miller, as worthy of more general cultivation in this country, for the sake of the valuable qualities of its timber, which would as soon come to perfection, and prove as profitable as that of the oak. Evelyn praises it for its hardness; but professor Martyn observes, that it has never been planted in any considerable quantity among us, evidently because it cannot resist the attacks of our winter frosts and spring blasts. Its wood, having a pleasant smell, taking a fine polish, and not being liable to be eaten by insects, is esteemed for cabinet furniture and other similar purposes. It was used by the Greeks, in the time of Thucydides, for the coffins of their eminent warriors; and many of the chests which enclose the Egyptian mummies are made of it, affording a decisive proof of its almost incorruptible nature. 2. *C. glauca*. Glauca or Portugal cypress. Lam. 2. (*C. lusitanica*; Willd. 2. Tourn. 587. Duham. Arb. 1. 198. Mill. Dict. *C. pendula*; Mart. 5. L'Herit. Stirp. 15. tab. 8. Hort. Kew. 3. 373.) "Leaves acute, glaucous, glandular, imbricated in four rows; branches hanging down." Lam. "Little branches quadrangular; leaves imbricated in four rows, adpressed, glaucous, keeled; strobiles somewhat globular; branches pendulous." Willd. "A small tree, known at first sight by its glaucous foliage and pendulous branches. *Leaves* small, lanceolate, acute, adnate in their lower part, opposite, with a gland, or rather resiniferous hollow on the back; those on the lower branches in somewhat distant pairs, dryish, rusted, and rather prickly. *Flowers* similar to those of the preceding species, but smaller; male catkins smaller and more obtuse. *Cones* about the size of a common cherry, blueish before they become dry. *Seeds* short, almost orbicular, compressed, angular. A native of the East Indies, on the coast of Malabar; but has been long naturalized in Portugal, where it grows to a considerable timber-tree, though in England it is not more than fifteen feet high. It has been cultivated here more than a hundred years; but being rather tender, is now a rare plant in our gardens and plantations. 3. *C. pendula*. Lam. 4. Willd. 4. Thunb. Jap. 265. (Finora; Kämpf. Amœn. 883.) "Leaves opposite, egg-shaped; little branches dichotomous, pendulous." A tree not more than six feet high, erect, and entirely smooth. *Branches* alternate, lax, leafless, very compound; little branches biliform, covered with leaves, long, lax, spreading, altogether pendulous. *Leaves* decussated, imbricated, egg-shaped, with a point at the end which bends a little outwards, very short. Observed by Thunberg, but without fructification, on the mountains of Japan. 4. *C. thyoides*. White cedar, or arbor vitæ leaved cypress. Linn. Sp. Pl. 2. Mart. 3. Lam. 3. Willd. 5. (*C. uana maritima*; Pluk. Mant. 61. tab. 345. fig. 1.) "Leaves imbricated; fronds two-edged." Linn. "Leaves imbricated, close pressed, with a single gland on the back; fronds flattened, turned different ways." Lam. "A small or middle sized ever-green tree, naturally forming a regular elegant head. *Branches* not pendulous; little branches flattened,

not placed in the same plane as in the arbor vitæ, but standing two ways. *Leaves* of a delicate green colour, small, opposite, imbricated in four rows on the little branches, with their point close to the branch. *Flowers* of the male catkin, according to L'Heritier, with pedicelled, not peltate scales, and only two anthers; of the females, with two stigmas. A native of North America, China, and Cochinchina. In the English gardens it seldom rises much higher than fifteen feet. Loureiro rates that in China it is not more than eight feet high; but in North America it is considerably larger, and is used for posts and rails, but does not last in the ground so well as what is there called red cedar (*Juniperus Virginiana*). Canoes and even houses are made of it; but it is most esteemed for shingles. It was first introduced into England by Peter Collinson, in 1736. 5. *C. columnaris*. Mart. 7. Forst. Flor. Austr. n. 351. "Leaves imbricated, awl-shaped, furrowed; strobiles cylindrical, elongated." A native of New Caledonia and Norfolk island.

** *Leaves free, detached, more or less open, not imbricated.*

6. *C. juniperoides*. African or Cape cypress. Linn. Sp. Pl. 4. Mart. 4. Lam. 5. Willd. 7. "Leaves opposite, decussated, awl-shaped, spreading." *Branches* loose, spreading. *Leaves* near an inch long, of a light green colour, continuing in verdure all the year. *Cones* black when ripe. A native of the Cape of Good Hope. 7. *C. japonica*. Linn. jun. Supp. 401. Mart. 6. Lam. 6. Willd. 6. Thunb. Jap. 265. Gært. tab. 91. fig. 5. Lam. Ill. Pl. 787. fig. 2. "Leaves in four rows, sickle-shaped, compressed, furrowed, decurrent." Thunb. A very lofty, straight tree. *Leaves* resembling those of the spruce fir, or rather those of yew, larger than in the other species, in three or four rows, not opposite, numerous, linear, acute, bent inwards, with four longitudinal furrows, green and somewhat shining above, marked with two whitish streaks underneath, an inch and half long, and little more than a line broad. *Male catkins* several together in a terminal spike, with intermediate leaves, egg-shaped, obtuse, smooth. *Female strobiles* solitary, few, globular, on the lower branches; scales peltate, coriaceous-membranous; variously angular below; cleft above into three or four membranous lanceolate-acuminate, erect segments; the anterior part finally extended into a long, acuminate, keeled, recurved beak; peduncle thick, striated, curved. *Nuts* four or six in each scale, united in pairs, inversely egg-shaped, lenticularly compressed or angular, surrounded with a very narrow membranous edge. *Seed* somewhat cylindrical, black. The wood is soft, and yields readily to the tool; on which account it is much used for cabinets, and other furniture, that are varnished or japanned. If it be kept some time under ground, and then macerated with water, it takes a blueish colour. 8. *C. disticha*. Deciduous cypress. Linn. Sp. Pl. 2. Mart. 2. Lam. 7. Willd. 3. (*C. americana*; Catc. Car. 1. 11. tab. 11. *C. virginiana*, *foiis acacie deciduis*; Comm. Hort. 1. 113. tab. 59. Duham. Arb. 1. 198. tab. 82. Pluk. Alm. 125. tab. 85. fig. 6.) "Leaves in two rows, spreading." Linn. "Leaves linear, in two rows, deciduous, spreading." Lam. One of the largest trees in North America, sometimes seventy feet high, thirty feet in circumference at the surface of the ground, and twenty at the height of six feet. *Branches* extending almost horizontally. *Leaves* acute, in two rows, and very near together on the little branches, whence they have been compared to the leaves of acacia by some of the older botanists, who mistook the little branches for common petioles, and thought the leaves winged; whereas they are strictly simple, about half an inch long, flat, slightly curved, and of a lively green colour, appearing towards the end of

May,

May, and falling off about the middle of November, previous to which they become red. *Cones* larger, with stronger scales than those of the common cypress. *Seeds* also larger, very angular, shining, exuding drops of red, transparent, penetrating resin. A native of North America, where it grows naturally on ground covered with water three or four feet deep, and is one of the few resinous trees which flourish in such situations. As it is hardy, and endures the cold of our climate, it would probably be planted to advantage in marshes on a large scale. Its wood is light, fine-grained, and very durable, whence it is much used in North America for various kinds of carpentry work, and is particularly excellent for shingles. It was introduced into this country by John Tradescant, senior, before the year 1640, but has not become common. La Marek saw, at Monceau in France, on an estate formerly belonging to M. Duhamel, a beautiful villa of these trees in very moist ground, on each side of a small stream, some of which began to bear fruit in 1779. There is a variety in which the leaves are less spreading, rather remote, somewhat scattered, and scarcely in two rows, which is not so handsome a tree.

CUPRESSUS fructu quadrivalvi; Shaw. See THUJAN *articulata*.

CUPRESSUS, in *Gardening*, comprehends plants of the ever-green and deciduous ornamental tree kind; of which the species chiefly cultivated are the ever-green cypress (*C. sempervirens*), the deciduous cypress tree (*C. disticha*), the white cedar or arbor vitæ leaved cypress (*C. thyoides*), the Portugal cypress (*C. penulula*); and the fir has been distinguished into the upright and horizontal or spreading kinds.

Method of Culture.—These plants, in all the different sorts, may be raised either from seeds or by cuttings of the young shoots; but those procured from the seeds are by much the best plants in general.

In the first of these methods, the seed, being provided and obtained from the cones, by exposing them to a moderate degree of heat, should be sown towards the latter end of March, or beginning of the following month, on a warm bed or border, where the soil is rather light and mellow, and has been rendered fine by being well dug over, covering it in, to the depth of about half an inch. When the season proves dry, slight waterings should be occasionally given; and, during the summer, the plants be kept free from weeds, and be watered a little when the weather is hot. In the winter time they should be protected from frosts, by mats, or other contrivances. They must be continued under this management till they have attained two years' growth, when they may be removed in the beginning of the spring, and planted in nursery rows, in a warm situation, at the distance of eighteen inches or two feet, and eight inches or a foot apart. When they have had three or four years' growth in these rows, they will be in proper condition for being finally set out where they are to remain. The best time for performing this business is in the beginning of spring, when the season is fine.

They are capable, however, of being raised in a more expeditious manner, by sowing the seeds in pots or tubs of light earth, and plunging them in a moderate hot-bed; as in this way they will be fit for removing into nursery rows, in the course of twelve months, or a little longer.

But as seed of this sort is slow in vegetating, this last method is the most proper for it, as shade may be more conveniently provided during the summer months, and protection in a sunny exposure in the winter; and when the plants do not appear in the course of the first year, the aid of a hot-bed may be conveniently had in the following spring, by which they will be brought forward with expedition to the state proper for being planted out in nursery-rows.

And in the second mode, the cuttings made from the young shoots should be planted in a warm sheltered situation, either in the early autumn or spring months; care being taken to have them daily supplied with water in the following summer. Afterwards the plants should be managed in the same manner as these raised from seed.

This method may be attempted with all the sorts; but those of the ever-green kind are extremely slow in striking root.

The plants raised in this way are likewise much slower in their growth than those which are produced from seeds.

In their general culture, these plants should always be suffered to take their natural growth, without clipping or cutting them.

All these sorts, from their beautiful growth and closely-placed foliage, have a very ornamental effect in the fronts of large plantations, as well as in groups, with other trees, on the sides of lawns, or other parts of pleasure-grounds. They have likewise a fine appearance in clumps, or planted out singly; and also in groups of from three or four to eight or ten of the different kinds, introduced where the extent of mown-grass ground is considerable.

And the ever-green sorts, from their beautiful pyramidal growth, produce an agreeable variety, in assemblage with other sorts of plants, when planted near ornamental or other buildings of that description.

The large tree growing sorts may likewise be introduced with great effect, in the front parts of plantations of timber trees.

CUPRUM. See COPPER.

CUQ-TOULZA, in *Geography*, a small town of France, in the department of the Tarn, chief place of a canton, in the district of Lavaur, with 1002 inhabitants. The canton has 10 communes, and 4904 inhabitants, on a territorial extent of 117½ kilometres.

CUQUENI, or *CUCUENI*, in *Ancient Geography*, a people of Gallia Aquitania, according to Ptolemy.

CURA AVENACEA, a diet-drink of oats, much recommended by some authors in various distempers.

CURAÇAO, or *CURAZAO*, in *Geography*, an island in the Caribbean sea, about 50 or 60 miles from the continent, 9 or 10 leagues in length, and about 4 in breadth, formerly belonging to the Dutch, who took it from the Spaniards in 1632, but captured by the English in January, 1807. The soil of this island is naturally barren, and the climate is far from being salubrious; but the Dutch, by their indefatigable industry, have converted the pastures, which formerly furnished a great number of cattle, into plantations for sugar and tobacco, and rendered it, in a variety of respects, productive. It has good salt-works, which afford a considerable supply of this article to the English islands and the colonies on the continent. This island has been rendered peculiarly advantageous to the Dutch, by the contraband trade, which is carried on between the inhabitants and the Spaniards, and by its harbour's being the rendezvous to all nations in time of war. The Dutch ships from Europe have been accustomed to touch at this island for intelligence, or pilots, and then to proceed to the coast of the Spanish main for trade; in addition to which, there is a constant intercourse between Curaçao and the Spanish continent. In the island are numerous warehouses, full of the commodities of Europe and the East Indies; consisting of all sorts of woollen and linen cloth, laces, silks, ribbands, iron utensils, naval and military stores, brandy, the spices of the Moluccas, and the calicoes of India, white and printed. One of the principal advantages derived by the Dutch from this island is owing to their trade in African slaves; three or four cargoes of whom have been annually

brought hither, for the supply of Carthagea, Porto Bello, and other towns on the continent of America. These they sell at a high price, and with them they vend all the kinds of goods above enumerated. The Spaniards pay in gold or silver, coined or in bars, cocoa, vanilla, Jesuits' bark, cochineal, and other valuable commodities. The trade of this island, in times of peace, is said to be annually worth to the Dutch no less than half a million sterling; but in time of war, it is much greater; for it then becomes the common emporium of the West Indies. The French resort hither to buy beef, pork, corn, flour, and lumber, which are brought from the continent of North America, or exported from Ireland: so that, in peace or war, the trade of this island has been rendered very flourishing and lucrative to the Dutch. On the south side of the east end of the island is a harbour, called Santa Barbara; but the chief harbour is at the distance of about 3 leagues, where the Dutch have a very good town, and a strong fort. The town is one of the largest and finest in the West Indies; the public buildings are numerous and handsome; the private houses commodious; and the magazines large, convenient, and well stored. N. lat. between 12° and 15°. W. long. between 60° and 70°.

CURACAO, in *Ichthyology*, a species of *Chatodon*; which see.

CURAPONNA, in *Ancient Geography*, a town of India, on this side of the Ganges. Ptolemy.

CURARAY, in *Geography*, a river of South America, which runs into the river of the Amazons.

CURASSAW, CRYING, in *Ornithology*, the PENELOPE *vociferans* of Gmelin; which see.

CURASSO, or CURASSOW. See CRAX.

CURATAS. See CAZIC.

CURATE is properly a parson, or vicar of a parish, who hath the charge or cure of the parishioners' souls.

CURATE is now more generally used for a deputy, or substitute of the parson; or one who officiates in the place of the incumbent, or beneficiary. And in case of plurality of livings, or where a clergyman is old and infirm, it is requisite there should be a curate to perform the cure of the church. He is to be licensed and admitted by the bishop of the diocese, or by an ordinary, having episcopal jurisdiction; and when a curate hath the approbation of the bishop, he usually appoints the salary too; and in such case, if he be not paid, the curate hath a proper remedy in the ecclesiastical court, by a sequestration of the profits of the benefice: but if he hath no licence from the bishop, or hath no such salary appointed, or hath made a special agreement with the rector, he is put to his remedy at common law, where he must prove such special agreement, or leave it to a jury to give damages upon a *quantum meruit*. (*Rights of Clergy*, 127.) By stat. 28 Hen. VIII. c. 11. those who serve a church, during its vacancy, shall be paid such stipend as the ordinary thinks reasonable, out of the profits of the vacancy; or, if that be not sufficient, by the successor, within fourteen days after he takes possession. By stat. 12 Anne, st. 2. c. 12. where curates are licensed by the bishop, they are to be appointed by him a stipend not exceeding 50*l.* nor less than 20*l. per annum*, according to the value of the livings; to be paid by the rector or vicar: and the same may be done, on any complaint made; and on failure of payment, they may sequester the profits of the benefice. But by stat. 36 Geo. III. c. 83. the bishop or ordinary may appoint a stipend to curates of 75*l. per annum*, on livings where the rector or vicar does not personally reside four months in the year at least, together with the use of the rectory or vicarage-house, and the garden and stable belonging to it, or 15*l. per annum* in lieu of it: the grant of the house, however, may be revoked; and the curate is required peaceably

to surrender the possession of it, under a penalty of forfeiting to the rector or vicar all such parts of his stipend as shall then be unpaid, or thereafter become due; and also the sum of 50*l.* to such rector or vicar, recoverable in an action of debt. By the same statute it is enacted, that churches augmented by queen Anne's bounty shall be deemed benefices presentative; and the officiating curate shall have the same stipend, under similar regulations, as in the former case. It is further enacted, that the bishop or ordinary may apportion the stipend to officiating curates of perpetual curacies that are not augmented: and the ordinary may license curates employed, though no nomination shall have been made to him by the incumbent, and may revoke any licence, subject to appeal to an archbishop of the province.

By a bill now (May, 1808) before parliament, it is proposed to be enacted, that where spiritual persons shall be non-resident, the bishop shall assign to the curate a stipend, which, with any former stipend payable in respect of such cure, shall not exceed one-fifth of the annual value of the benefice, &c. if the annual value shall exceed 400*l.* clear of all expences, the payment of such curate excepted; and, in case of neglect on the part of the spiritual person to nominate a fit curate, the bishop may appoint one, assign him his stipend, together with a residence in the parsonage or vicarage house, or in lieu of it a sum not exceeding 30*l.* a year. But the stipend to be assigned to any curate shall in no case exceed 250*l. per annum*, unless with the consent of the incumbent. The bishop in certain cases may nominate more than one curate and allow them stipends. The incumbent is required to deliver a statement of the annual value of his benefice, on which the bishop shall adjudge the stipend with regard to benefices, &c.: under 400*l.* a year, the regulations of the statute 36 Geo. III. continue in force.

One person cannot be curate in two churches, unless such may satisfy the law, by reading both morning and evening prayers at each place: nor can he serve one cure on one Sunday, and another cure on the next; for he must not neglect to read morning and evening prayers in his church every Lord's day: if he doth, he is liable to punishment. (*Comp. Incumb.* 572.) But it is otherwise where a church or chapel is a member of the parish church; and where one church is not able to maintain a curate. (*Can.* 48.) A curate, having no fixed estate in his curacy, not being instituted and inducted, may be removed at pleasure by the bishop or incumbent. (*Nov.*) But there are perpetual curates as well as temporary, who are appointed where tythes are impropriate, and no vicarage endowed. These are not removeable, and the impropriators are obliged to find them, some whereof have certain portions of the tythes settled on them. *Stat.* 29 Car. II. c. 8.

It was provided in 1693 by can. 33. that if a bishop ordain any person, not provided with some ecclesiastical preferment, except a fellow or chaplain of a college, or a master of arts of five years standing, who lives in the university at his own expence, the bishop shall support him till he prefer him to a living. The bishops, before they confer orders, require either proof of such a title as is described by the canon, or a certificate from some rector or vicar, promising to employ the candidate for orders *bona fide* as a curate, and to grant him a certain allowance till he obtains some ecclesiastical preferment, or shall be removed for some fault. No curate, or minister, ought to perform the duties of any church, before he has obtained a licence from the bishop. The bishop cannot increase the salary of the curate, if there be a specific agreement between the incumbent and the curate. (*Freem.* 70.) Curates must subscribe the declaration, according to the act of uniformity, or are liable to imprisonment, &c.

CURATELLA, in *Botany*, Linn. Gen. 679. Schreb. 921. Willd. 1056. Juss. 282. Class and order, *polyandria digynia*. Nat. Ord. *Magnolia?* Juss.

Gen. Ch. *Cal.* Perianth expanding, hairy on the outside, deeply divided into four or five rounded segments; in the former case, two larger than the others; in the latter, only one. *Cor.* Petals four or five, roundish, concave, attached to the receptacle by a short claw. *Stam.* Filaments about sixty, in several rows, a little shorter than the petals; anthers egg-shaped. *Pist.* Germs two, superior, hairy, connate at the base; styles simple; stigmas capitate. *Peric.* Capsules two, united at the base, somewhat fleshy, roundish, hairy, one-celled, two-valved, opening on the interior side. *Seed.* in pairs, oblong, shining, brown. La Marck, from a dried specimen in flower.

Ess. Ch. Calyx deeply divided into four or five segments. Petals four or five. Styles two. Capsules two, united at the base, one-celled. Seeds two in each capsule.

Sp. C. *americana*. Aubl. Guian. 1. 579. tab. 232. Lam. Ill. Pl. 479. Leaf. It. 260. A tree with the habit of coccoloba. Trunk seven or eight feet high, from eight to ten inches in diameter, crooked; with a thick, wrinkled, cracked bark, which falls off in pieces of various sizes; wood reddish, compact; branches crooked, rugged. Leaves alternate, large, almost sessile, oval or oval-oblong, edged with large shallow crenatures, green, very rough, furnished underneath with lateral prominent nerves and intermediate reticular veins. Flowers in compound racemes, situated below the leaves, on the naked parts of the branches, and from the axils of the leaves which have already fallen; white, numerous, with two narrow acute bracts at the foot of each peduncle, and at each ramification of the raceme. A native of South America, in Guiana, &c.

CURATIVE INDICATION, among *Physicians*, that which directs what is to be done for the cure of a disease. See **SYMPTOM**, and **INDICATION**.

CURATOR, among the Romans, an officer under the emperors, who regulated the price of all kinds of merchandize and vendible commodities in the cities of the empire.

They had likewise the superintendence of the customs and tributes; whence also they were called *logijla*.

CURATOR, in *Civil Law*, a trustee, or person nominated to take care of the affairs and interests of a person emancipated, or interdicted.

In countries where the Roman law prevails, between the age of fourteen and twenty-four years, minors have curators assigned them; till fourteen, they have tutors.

CURATOR of an University, in the United Provinces, is an elective office, to which belongs the direction of the affairs of the university; as, the administration of the revenues, the inspection of the professors, &c.

The curators are chosen by the states of each province: the university of Leyden has three; the burghermasters of the city have a fourth.

CURB, in the *Manege*, the designation given by horsemen to the *bit*, or mouth piece, that is provided with a branch and chain. See art. **BITTS**. *Kirble* was the ancient word, and *kih* should, we apprehend, be the proper mode of spelling it now where any restraint is signified; on the contrary, where any curvature or inflexion is intended, the present is the proper mode of spelling it, as in the following article, for they appear to us of different origins and meanings, and from different languages, and ought not to be confounded as they are at present.

CURB, a disease of the lower part of the hock of the horse, derived from *course*, French, and *curvus*, Latin,

distorted or bent from their proper figure. The back part of the hock of the horse, seen in profile, is nearly straight or a little bending inwards, that is, from the point of the os calcis to the head of the mesocynium, or shank where the disease appears. If the hock be exerted beyond its strength, this part is apt to swell and form a curved line outwards, or rather backwards, more or less elevated according to the injury sustained. The advantageous purchase of the gastrocnemii muscles upon the os calcis seems to be the principal cause of this mischief, the parts being unable in violent and sudden action to sustain their effect, though the tendons of this part are singularly wrapped round and strengthened, obviously to enable them to sustain these shocks, by the flattened or sheath-like expansion of the perforatus tendon. In leaping, violent riding, in hunting, drawing, and especially in the military charges of the cavalry, where they are suddenly stopped at full gallop, and often with injudicious and unnecessary suddenness, and without previous preparation, the horses are thrown on their haunches, and thus continually get diseased in this part, and often totally ruined. Nothing but imperious necessity, or the actual combat, one should suppose, could justify the frequent repetition of such a dangerous manœuvre; much depends, however, upon the hand of the rider, in not making it injurious, as a very slight preparation or warning given to the horse is sufficient. These curbs often grow hard, lose all the active inflammation which attends their first production, and seem hardly to affect the horse's going; at other times they are attended with considerable tenderness and lameness, and it most frequently happens, that the other parts of the hock suffer at the same time, and spavin very frequently, and sometimes thorough pain, accompany it.

After the gastrocnemii muscles have attached their tendon strongly to the os calcis, they appear to send portions for a second attachment to the head of the shank, and there it is the injury is sustained.

In recent cases the cold bathing of the parts is the best remedy, and rest till the inflammation is subdued, with a dose or two of physic if there is occasion; in more confirmed cases blistering, or in more desperate cases firing, is the best remedy: a straight line in this case is drawn by the iron down the back of the calcis and head of the shank, feathered on each side by diagonal lines at proper distances; and as the inside of the hock is apt to partake of the mischief, it may be well to draw a straight line down its middle, forming an angle to the former opening upwards, and closing pretty much as the figure of the hock itself does, the diagonal lines from this meet the diagonal lines from the former line, forming with them a double feathered figure: the same also may be done to the outside, if the case shall appear to demand it.

CURCAS, in *Botany*, a name given in Egypt to an esculent root, approaching to the taste and virtues of the *colocasia*.

It is also a name used in Malabar for a small fruit of the shape and size of a hazel nut. Both these things have the credit of being great provocatives; and it is very probable, that the curcas of the East Indies may be the fruit called *lel* by Avicenna, and said to possess the same famous virtues. Garcias has been led into a very great error by this similarity of names and virtues, and supposes the curcas of Egypt the same with the curcas of the East Indies.

CURCO, in *Geography*, a town of Asiatic Turkey, in the province of Caramania; 35 miles S.W. of Tarsus.

CURCULIGO, in *Botany*, (from *Curculio*, one of the coleopterous insects.) Gært. 72. Mart. Class and order, *hexandria monogynia*.

Gen. Ch. *Cal.* none. *Cor.* petals six, oblong, spreading,

ing, withering. *Stam.* Filaments six, very short; anthers linear, erect. *Pyl.* Germ sessile, lanceolate; style very short; stigma large, tapering, with a three-cleft tip. *Peric.* Capsule, when immature, three-celled, with the rudiments of six or eight seeds in each cell; finally appearing one-celled. *Seeds* one to four, shining, black, with a horny, somewhat incurved beak resembling the rostrum of a curculio.

Eff. Ch. Calyx none. Corolla six-petalled. Filaments six. Pistil one. Pericarp a capsule. Seeds beaked.

Sp. C. orchinoides. Mart. *Gært.* tab. 16. fig. 11. Plant. *Coromand.* 14. tab. 13. *Root* tuberous, with many fleshy vermicular fibres. *Leaves* numerous, all radical, petioled, sword-shaped, nerved, slender, beset with a few soft white hairs when young, from six to eighteen inches long, half or three quarters of an inch broad; petiole channelled, sheath-shaped below, and embracing the inner ones. *Raceme* solitary, axillary, two-ranked, its top just appearing above the earth; scape about an inch long, compressed, clubbed; lower bractes remote, upper ones nearer, spathe-like, pointed, decreasing in length towards the top, so that they become nearly horizontal like a corymb, one-flowered. *Flowers* pretty large, yellow, only one or two of the lowest fertile, the others abortive from the want of a pistil; peduncles so long that they elevate the flower above the earth more than an inch, hairy, three-sided. A native of shady uncultivated places about Samulcotah on the coast of Coromandel, but not common. It is the Nallatady of the Telingas.

CURCULIO, in *Entomology*, a genus of the coleoptera order. The antennæ are clavated or terminated in a club, and feated on the snout, which is horny and prominent; feelers four, and filiform.

The curculioncs, in a state of larva, subsist chiefly on the seeds of various kinds of plants; many of them infest granaries, and commit vast depredations, devouring the ripened cotyledons, and leaving only the husk. The larvæ have six scaly legs, and the head also protected with a scaly covering. The perfect insects are, in general, of an elegant form; and some of the species infinitely more remarkable for the splendour and beauty of their colours, than almost any other of the insect race. The species are very numerous, and are divided into a number of distinct families, or sections. Fabricius divides them into three genera, as curculio, anthribus, and brachycerus. Some other continental naturalists divide them into a still greater number of genera.

Species.

Section 1st. * *Snout longer than the thorax; Thighs unarmed.*

GIGAS. Thorax and wing-cafes scabrous; antennæ white at the tip. Olivier.

Native of Japan. Described from a specimen in the British Museum.

PALMARUM. Deep black; thorax flat above; wing-cafes short, and striated. Linn. *Donov. Inf. Ind.*

Lives on the palm-trees in India.

CRUENTATUS. Black; lines on the thorax, and two dots on the wing-cafes ferruginous. Olivier.

Inhabits Carolina. Bankian Cabinet.

LONGIPES. Blackish; wing-cafes ferruginous; snout emarginate; anterior legs long. *Vdet.*

Inhabits the Cape of Good Hope.

COLOSSUS. Blackish; wing-cafes brown or cinereous; legs elongated. *Ouv.*

An East Indian species, the *curculio longipes* of Drury.

INDUS. Black; thorax subovate, excavate, punctured; wing-cafes with rugged grooves; flanks spinous. Linn.

A species of large size, found in India.

PAGANUS. Greyish; thorax brown on the back, with cinereous curves; snout with two grooves. Fabr.

The snout of this insect is thick, and twice as long as the head; the antennæ grey, with the base black.

A native of India.

FERRUGINEUS. Dull-purplish; wing-cafes abbreviated; thighs ciliated in the middle. Oliv.

Inhabits Brasil. Sulzer.

HEMIPTERUS. Dull-purplish; wing-cafes abbreviated and spotted. Linn. *Curculio rufo-fasciatus*, Degeer.

Native of South America, chiefly Cayenne.

VARIEGATUS. Rufous and black varied; snout at the tip black. Olivier.

From the Cape of Good Hope.

LIMBATUS. Blackish; thorax, and wing-cafes at the margin rufous.

Described by Olivier as a native of Senegal.

CRUCIATUS. Black; thorax sub-spinous; lines on the posterior end of the wing-cafes cruciform. Fabr.

A New Holland species, in the Bankian Cabinet.

SANGUINOLENTUS. Deep black; wing-cafes marked with a sanguineous band at the base. Oliv.

Inhabits the American island Tobago.

FASCIATUS. Deep black; wing-cafes striated, with a sanguineous band in the middle. Fabr.

STRIATUS. Black; wing-cafes marked with silky stripes. *Curculio striatulus*, Oliv.

Described from a specimen in the Bankian cabinet. Found in the island of Terre Neuve.

RUBETRA. Deep black; antennæ griseous; thighs fulcated. Fabr. *Curculio gagates*, Oliv.

Native of Cayenne.

GAGATES. Deep black, and glabrous; snout somewhat compressed. Fabr.

Inhabits Cayenne.

MENDICUS. Ovate, greyish; wing-cafes striated. Oliv.

Described from a specimen in the cabinet of the late king of France. It is a native of the island of Madagascar.

PINETI. Black; wing-cafes striated, and spotted with white. *Curculio confusus*, Paykull.

Found on the pine in Sweden.

PINI. Wing-cafes reddish, with clouded bands. Linn. *Curculio castaneus*, Degeer.

Also inhabits the pine in Sweden.

ONOPORDI. Black, with cinereous hairs; snout deep black, with an abbreviated groove on each side at the base.

Native of Africa.

URBUS. Ferruginous-brown, lineated with white; snout black, with an abbreviated groove each side at the base. *Curculio vittatus*, Mant. Inf.

Found in Italy. The snout is cylindrical; wing-cafes smooth.

PLANUS. Black, and without spots; snout cylindrical; wing-cafes striated. Fabr.

Native of Germany.

PUNCTULATUS. Yellow, varied with brown; abdomen cinereous, dotted with black. Fabr.

Inhabits America. The antennæ are black; legs cinereous.

OCULARIS. Greenish-black; snout ferruginous; orbits of the eyes snowy. Fabr.

A native of Barbary, in the museum of M. Desfontaines.

CURCULIO.

CYNARAE. Black, sprinkled with greenish; snout black, and somewhat carinated. *Curculio cardui*, Rossi.

According to Dr. Vahl, a native of Africa.

COLON. Greyish; wing-cafes marked with a white dot. Paykull. *Curculio palustris*, Scop.

Inhabits Germany.

2-MACULATUS. Fuscous, with a cinereous dot on the wing-cafes; snout and legs deep black. Fabr.

Native of Saxony. The snout is curved, and deep black; legs the same colour.

PUNCTUM. Deep black; wing-cafes striated, with a white spot in the middle; antennæ and legs red. Fabr.

Inhabits the same country as the last.

BICUTTATUS. Deep black; wing-cafes with elevated dots; abdomen and posterior legs yellow. Fabr.

From the cabinet of Dr. Hunter. This species inhabits America.

BILINEATUS. Fuscous; two lines and dot on the wing-cafes white. Fabr.

Native of Germany.

SORDIDUS. Dull-black, and without spots; wing-cafes striated. Fabr.

Found in the islands of South America.

SUILLUS. Thorax rough; wing-cafes marked with pilous striæ. Fabr.

Inhabits the same places as the preceding.

TESSELLATUS. Cinereous; white striæ at the tip of the wing-cafes dotted with black. Fabr.

Found in Germany. Hattorf.

ABBREVIATUS. Deep black; thorax flat and dotted; wing-cafes abbreviated, and sub-striated. Fabr.

Inhabits Saxony. Hybner.

NITENS. Deep black and glossy; thorax flat and smooth; wing-cafes striated. Fabr.

Native of the south of France.

EQUISETI. Thorax smooth; wing-cafes muricated and black; two dots, and tip white. Herbst. Arch. *Curculio scaber*, Linn. *Curculio nigro-gibbosus*, Degeer.

Feeds on the *equisetum arvense*, and inhabits England.

DIMIDIATUS. Deep black; wing-cafes somewhat striated and rufous. Oliv.

Native place unknown.

BUFO. Fuscous; wing-cafes sub-reticulated, with a white band in the middle. Oliv.

Described from a Siberian insect in the Bankian cabinet.

ATRIROSTRIS. Cinereous; snout arched, and deep black. Paykull. Monagr.

Found near Leipsic.

BRUNNIROSTRIS. Griseous; snout and legs ferruginous. Fabr.

Inhabits plants in Denmark.

FESTIVUS. Brassy and glossy; an obtuse angle at the base of the wing-cafes; tip of the snout, and the antennæ fuscous. Fabr.

Native of Surinam.

TRAGIÆ. Brassy; snout and legs of the same colour. Oliv.

Discovered among the seeds of the *tragia volubilis*, brought from Brazil. Bankian Cabinet.

AENEUS. Black; wing-cafes brassy. Fabr. *Attelabus cracca*, Panz. *Apion aeneum*, Herbst.

Described as a native of Britain, from a specimen in the collection of Dr. Hunter. Its haunts are unknown.

CURVIROSTRIS. Deep black; wing-cafes brassy. Oliv. The thorax of this species is dotted; and the wing-cafes striated.

A native of New Holland.

AETHIOPS. Deep black; antennæ and shanks pitchy; wing-cafes oblong and striated. Paykull.

Found in Sweden.

SCIRPI. Fuscous; wing-cafes somewhat striated, and sprinkled with ferruginous. Fabr.

Observed on the scirpus, in France, by Bose.

PRUNI. Deep black; antennæ ferruginous; thorax bituberculate. Linn.

Native of Europe.

ARMENIACÆ. Deep black, and immaculate; wing-cafes with crenate striæ. Fabr.

CAMELUS. Fuscous; thorax and wing-cafes tuberculate; snout rufous at the tip. Fabr.

Found in gardens in Germany.

4-TUBERCULATUS. Thorax with four black tubercles; wing-cafes striated and varied with cinereous. *Curculio quadricornis*, Paykull.

Mus. Daldorff; specimen found near Kiel.

TETER. Depressed, villous, and fuscous; snout deep black. Fabr.

Native of Italy.

CAMPANULÆ. Ovate, and black; wing-cafes striated and obtuse. Paykull.

NIGRIROSTRIS. Green, with the snout black. Paykull.

An example of this species found in England is preserved in the Bankian cabinet.

VARIABILIS. Subtestaceous; thorax green lineated; snout at the tip fuscous. Fabr.

Inhabits Hamburg. Dr. Schulz.

PICIROSTRIS. Oblong, black, silvery-silky; snout half-way, and legs piceous. Paykull.

SALICARIÆ. Deep black; base of the antennæ, disk of the body, and the shanks testaceous. Fabr. *Curculio lythri*, Paykull.

Found in England.

FLORALIS. Dull griseous; future of the wing-cafes pale. Paykull.

Taken on flowers in Sweden.

PSEUDACORI. Above black; thorax at the sides ferruginous; wing-cafes striated; future at the base, white. Fabr.

Inhabits France.

CASTOR. Ovate; thorax tuberculate; body striated; future at the base whitish; legs rufous. Fabr.

Native of Germany.

PERICARPIUS. Subglobose, and clouded; wing-cafes on the future at the base, white. Linn.

Found on the scrophularia in Europe. Herbst.

QUERCICOLA. Deep black; thorax tuberculated; wing-cafes striated; future at the base white; legs black. Paykull, Monogr.

Inhabits the oak in Sweden.

ASSIMILIS. Thorax bituberculate, and canaliculate; wing-cafes striated. Paykull, Monogr.

Inhabits Sweden.

SISYMBRII. White and fuscous varied; wing-cafes with an elevated black dot at the base; snout black. Fabr.

A rare species found near Kiel.

CAPRÆ. Wing-cafes with two abbreviated white bands. Fabr.

Inhabits England, on the willow. Donov. Brit. Inf.

BIPUNCTATUS. Villous, cinereous; wing-cafes with a black spot in the middle; shanks yellowish. Linn.

Native of Sweden.

CARPINI. Villous, greenish; snout black; legs testaceous. Knock.

Inhabits Germany.

CURCULIO.

ERYSIMI. Black; thorax bituberculate and greenish; wing-cafes cyaneous. Paykull.

4-MACULATUS. Blackish, wing-cafes marked with four whitish spots. Linn.

Inhabits various places in Europe.

UNIFASCIATUS. Above fuscous; wing-cafes banded in the middle with cinereous. Fabr.

Found in Saxony by Hybner.

BIFASCIATUS. Black; wing-cafes with two cinereous bands, that at the base larger and waved. Fabr.

This species inhabits Germany; the thorax is rounded, and black, with a paler dorsal line; scutel cinereous.

ACRIDULUS. Black; antennæ and legs pitchy; abdomen ovate. Linn.

Frequent on tetradynamic flowers. Herbit.

SCABRATUS. Fuscous; thorax tuberculated; wing-cafes scabrous; legs pitchy. Fabr.

Native of Germany. Smidt.

LAUDA. Above deep black; thorax bituberculate, and elevated at the anterior edge. Fabr. *Curculio elevatus*, Gmel.

Inhabits same country as the last.

DORSALIS. Wing-cafes red; future half-way black. Linn.

Found on the common pilewort, in Europe.

QUERCUS. Cinereous; back of the thorax fuscous; wing-cafes testaceous. Linn.

A small species found on the oak in Germany and Sweden.

SUTURALIS. Ovate and fuscous, with a longitudinal white line. Fabr.

Feeds on the willow. This kind is found in Germany.

CRUX. Deep black; thorax with two dots at the base; wing-cafes at the future, and sprinkled dots white. Schulz.

LEMNÆ. Deep black; snout flat at the tip; wing-cafes striated. Fabr.

Found on the lemna (Duck weed) in Germany. The species is small.

EXCLAMATIONIS. Deep black; wing-cafes with a white dot in the middle, and small white line at the base. Oliv.

Inhabits New Holland; Banksian cabinet.

VENUSTUS. Fuscous; thorax and elytra lineated with white; legs testaceous. Fabr. *Curculio albo vittatus*, Herbit.

Found in England.

PLANTAGINIS. Wing-cafes cinereous, with a fuscous spot in the middle. Paykull.

Inhabits Saxony.

RUMICIS. Griseous, clouded with black; antennæ fuscous. Linn.

Found in the north of Europe.

ADSPERSUS. Griseous; thorax black lineated with cinereous; wing-cafes tessellated with black dots. Fabr.

GRANARIUS. Pitchy; thorax punctured, and as long as the shells. Linn.

This is the weevil insect so destructive to granaries where corn has been kept for some time. It is destroyed by strewing elder or henbane among the corn.

ORYZÆ. Pitchy; thorax dotted, and length of the wing-cafes; the latter with two rufous dots. Linn.

Found in rice imported from the East Indies.

2-TUBERCULATUS. Ferruginous; thorax length of the wing-cafes, with two elevated dorsal dots. Fabr.

Native of New Zealand. In the Banksian cabinet.

PARAPLECTICUS. Cylindrical, and subcinereous; wing-cafes mucronated. Linn. Geoffr.

Found in England but rare.

ANGUINUS. Cylindrical, hoary, lineated with fuscous. Linn.

Inhabits Germany.

STRIATELLUS. Oblong, dull; wing-cafes cinereous, and slightly striated with fuscous. Fabr.

Taken on plants in Barbary.

UMBELLATARUM. Thorax black, with cinereous lines; wing-cafes mucronate and greyish. Fabr.

Found on umbelliferous plants in Barbary.

MUCRONATUS. Cylindrical, cinereous, lineated with fuscous; wing-cafes pointed. Fabr.

Inhabits same country as the preceding.

FERRUGATUS. Black, with ferruginous hair; wing-cafes obtuse. Fabr.

Native of Hungary. Hybner.

GAGES. Deep black, and glossy; wing-cafes striated and dusky; snout truncated. Fabr.

Found in Guinea. Dr. Ifert.

8-LINEATUS. Cylindrical, black; thorax and four lines on the wing-cafes white. Oliv.

Described from a specimen in the royal Paris collection. The species inhabits the Cape of Good Hope.

SEMIUNCTATUS. Cylindrical; thorax with white lines; wing-cafes with white dots. *Curculio semipunctatus*, Oliv.

Brentus semipunctatus. Fabr. Mant.

Native of New Holland. Banksian cabinet.

4-PUSTULATUS. Black; wing-cafes with two ferruginous spots. Oliv.

Inhabits the Cape of Good Hope.

MIXTUS. Cylindrical; clouded white and brown; wing-cafes submucronate; club of the antennæ testaceous. Fabr.

Found in Barbary. Desfontaines.

FILIFORMIS. Cylindrical, subcinereous; three brown lines on the thorax. Fabr.

Native of Italy.

CYLINDRICUS. Cylindrical, above black; wing-cafes cylindrical, with a pale band. Oliv.

Inhabits Siberia.

NOTATUS. Thorax fuscous, with four white dots; wing-cafes fuscous, with two testaceous bands, the anterior one abbreviated. Fabr.

Inhabits Barbary, according to Vall.

BARBIROSTRIS. Black, snout bearded; anterior shanks tridentated. Oliv. Donov. Inf. India.

Inhabits India.

ANGUSTATUS. Cylindrical, deep black; wing-cafes obtuse and punctated. Herbit. *Curculio pulverulentus*, Rossi.

Inhabits England. The thorax is rough; wing-cafes striated with dots.

BARDANÆ. Cylindrical, with grey down; anterior legs elongated. Fabr.

Found in Saxony. The wing-cafes are rounded, and obtuse.

ASCANII. Cylindrical, deep black, beneath bluish. Fabr.

Inhabits the South of Europe.

LINEOLA. Cylindrical, black; wing-cafes marked with a testaceous stripe. Oliv.

Native of New Holland, Banksian cabinet.

LINEARIS. Elongated, black; antennæ and legs pitchy; snout attenuated at the base. Paykull.

Inhabits Europe. Found near Strasburg by Hermann.

CRASSIPES. Anterior thighs subclavated; body deep black. Fabr.

CURCULIO.

Same part of Europe as the foregoing.

ATRIPLICIS. Elongated; deep black, thorax glossy; wing-cafes striated and obtuse. Fabr. *Curculio T. album*, Linn. Fn. Suec.

Found on flowers in Europe.

LYMEXYLON. Elongated, griseous; thorax scabrous; wing-cafes striated. Fabr.

On the rotten trunks of oak trees. Dr. Helwig.

Section 2* *Snout long; Thighs dentated.*

CALCARATUS. Black; wing-cafes sprinkled with fuscous; anterior thighs acutely dentated. Fabr.

The largest in this order of curculiones; the native place is unknown.

BIDENS. Posterior thighs dentated and black; wing-cafes armed with a single spine each. Oliv.

Native of New Zealand.

TAURUS. Greyish; thorax and wing-cafes tuberculated; two bent horns on the snout. Oliv.

Inhabits Cayenne.

CORNUTUS. Thorax tuberculated; snout armed on each side with an acute spine. Oliv.

Native of Cayenne. This is a large insect.

MILIARIS. Fuscous, thorax and wing-cafes rough with numerous tuberculations of deep black. Oliv.

Inhabits same country as the last.

CYANICOLLIS. Oblong, blackish; thorax blue; sides scabrous; wing-cafes striated. Oliv.

A large species, in the collection of Dr. Hunter. Its native place unknown.

JAMAICENSIS. Dull, rough; fasciculate tubercle each side the thorax; wing-cafes striated. Oliv.

Native of South America.

SENEGALENSIS. Wing-cafes tuberculated, and pointed, with two spots of golden down. Fabr.

Inhabits Senegal. Paykull.

VALIDUS. Anterior thighs dentated, oblong, rough and black; anterior shanks dentated. Oliv.

Native of Cayenne.

CORONATUS. Black; anterior part of the thorax ciliated with spines; wing-cafes striated. Oliv.

MUCROREUS. Four anterior thighs dentated; wing-cafes covered with yellowish powder, above the tip gibbous. Linn.

Native of the East Indies.

PUSIO. Four posterior thighs dentated; wing-cafes striated, black, with broad repandate grey line. Linn.

An East Indian species.

SPINIPES. Black, two lines on the thorax, and four on the wing-cafes white; anterior shanks spinous. Fabr.

From the Hunterian cabinet; a native of South America.

BOMBINA. Ferruginous fuscous; wing-cafes striated, and beset with white raised tubercles. Fabr.

Native of Cayenne.

SCORPIO. Deep black; thorax flat, at the base cinereous; wing-cafes tuberculated, and pointed, middle cinereous. Fabr.

Same country as the former.

CHIMARIS. Posterior thighs dentated; black spotted with white; anterior legs very long. Fabr.

Native of South America.

GUTTATUS. Thighs subdentated; black; thorax with two spots at the base; wing-cafes tuberculated and dotted with whitish. Oliv.

Native of Cayenne.

Vol. X.

FASCICULARIS. Thighs black; wing-cafes tufted with down; legs varied with cinereous. Oliv.

Native of Cayenne.

HYSTRIX. Thighs black; wing-cafes with crenated striæ, and two white dots.

MARMORATUS. Brown spotted with white. Oliv.

Native of Cayenne.

SCABER. Thorax carinated; wing-cafes grooved, the elevated ridges armed with tuberculated spines. Fabr.

Inhabits Cayenne.

CYLINDRIOSTRIS. Thorax scabrous; wing-cafes bituberculated behind. Oliv.

This is a large species found in New Holland. Banksian cabinet.

STIGMA. Wing-cafes with a large ferruginous spot. Linn.

Inhabits India.

HEBES. Thorax scabrous; wing-cafes sulcated, tuberculate; mouth bearded. Oliv.

Native of Bengal.

ANNULATUS. Thighs dentated, pale; thorax and wing-cafes streaked with black. *Curculio annulatus*, Linn.

Native of India.

CALIGINOSUS. Wing-cafes striated with approximate dots. Fabr.

Inhabits England. The thorax is rounded and carinated; thighs acutely dentated.

DUBIUS. Thighs dentated and black; thorax smooth; wing-cafes striated scabrous. Fabr.

Native place unknown.

ROREUS. Sprinkled with fulvous; anterior legs elongated. Fabr. *Curculio adspersus*, Mant.

Native of Cayenne.

BRUNNEUS. Brown; snout fuscous; wing-cafes testaceous, striated with dots. Oliv.

Banksian cabinet. Inhabits the Cape of Good Hope.

ABIETIS. Black; wing-cafes marked with linear interrupted white lines. Linn.

Found on the pine trees in Europe; rare in Britain.

DENTIPES. Thorax white; wing-cafes black with white lines; shanks dentated. Oliv.

Native of Senegal.

MULTIGUTTATUS. Black; thorax and wing-cafes dotted with white. Oliv.

PUPILLATOR. Thighs dentated tuberculate, and fuscous; wing-cafes with a large grey marginal spot, dotted with black. Oliv.

Native of Cayenne.

RETICULATUS. Oblong, pitchy; wing-cafes reticulatèd, oblique bands pale; anterior shanks spinous. Fabr.

Found at Tranquebar by Dr. Koerig.

LAPATHI. Thighs bidentated, white and black varied; thorax and wing-cafes mucated. Linn.

Inhabits the willow in Europe.

IRRORATUS. Thighs dentated white; above fuscous spotted with white; thighs annulated with white. Fabr.

Native of Cayenne.

TRICINCTUS. Deep black; side of the thorax, with three bands on the wing-cafes white; anterior legs elongated. Fabr.

Inhabits Guadaloupe island.

STATUA. Deep black; wing-cafes sulcated, with a common white spot; posterior thighs elongated. Fabr.

Native place unknown.

6-GUTTATUS. Black wing-cafes with three white dots. Fabr.

An American species in the collection of Dr. Hunter.

CURCULIO.

- LURIDUS.** Thighs dentated ovate, dull black; wing-cafes striated with dots. Oliv.
Native of New Holland.
- STOLIDUS.** Thighs fuscous; posterior sinaks incurvated and toothed. Fabr.
Bankian cabinet. Native of the Cape of Good Hope.
- FRIGIDUS.** Fuscous, wing-cafes striated, slightly tuberculated, and varied with ferruginous. Fabr. *Curculio chinensis*. Oliv.
Native of China and Amhoyna.
- GIBBUS.** Black; wing-cafes with excavated dots, and an abbreviated whitish streak. Oliv.
Inhabits the island of Bourbon.
- OCELLATUS.** Dull, and cinereous; wing-cafes marked with an ocellar black spot. Oliv.
Native of Cayenne.
- MEDITABUNDUS.** Thighs dentated; wing-cafes striated, and acuminate behind. Oliv.
Native of New Holland. Bankian cabinet.
- STUPIDUS.** Thighs black; sides of the thorax rounded; wing-cafes subspinous. Oliv.
Inhabits New Holland.
- MANGIFERÆ.** Dull; thorax scabrous, with a dorsal white line; wing-cafes reticulated. Oliv.
Lives, according to Dr. Koenig, in the nut of the mangifera.
- STULTUS.** Greyish; wing-cafes with a common lunated cinereous spot; snout deep black. Fabr.
Native of Coromandel. Vahl.
- ARANEUS.** Obscure varied with cinereous; thorax rounded at the sides. Fabr.
Native of South America.
- STRIX.** Black; thorax lineated with ferruginous; wing-cafes striated with ferruginous dots. Oliv.
Inhabits Cayenne. The head is ferruginous; wing-cafes short; thighs acutely dentated.
- SQUALIDUS.** Villous-grey, with testaceous snout. Oliv.
Native of Surinam. Bankian Cabinet.
- GERMANUS.** Black; thorax with two testaceous dots. Paykull.
Found in Germany, but not commonly.
- SCROPHULARIÆ.** Thorax whitish; wing-cafes with two black dots connected with white. Paykull, &c.
Native of Europe.
- VERBASCI.** Black; sides of the thorax yellowish; wing-cafes dotted with black and white in alternate striæ. Fabr.
Inhabits near Kiel.
- BLATTARIÆ.** Whitish; wing-cafes varied with black; dorsal spot at the base and tip black. Fabr.
Native of Italy.
- SOLANI.** Dull; wing-cafes with raised lines, black, dotted with cinereous. Fabr.
Inhabits Saxony. The head is black; legs greyish.
- GRAVIS.** Black; wing-cafes varied with ferruginous; thighs grooved. Oliv.
Native of the Cape of Good Hope.
- 5-PUNCTATUS.** Wing-cafes at the suture, and two dots white. Linn.
Found on plants in Europe.
- GUTTULA.** Thorax tuberculated and black; wing-cafes striated, with a white dot behind. Fabr.
Found in Saxony.
- ABBREVIATULUS.** Fuscous, sprinkled with greyish dots; wing-cafes abbreviated. Fabr.
Same country as the preceding.
- ECHII.** Black; thorax and wing-cafes lineated with white. *Curculio geographicus*, Oliv.
Found in Germany.
- DIDYMUS.** Above fuscous; wing-cafes striated, with a transverse white spot at the sides. Paykull.
Inhabits Germany, on the nettle.
- LAMII.** Black; thorax tuberculated; wing-cafes varied with cinereous; snout arched and black. Fabr.
Native of Germany.
- BRASSICÆ.** Villous-grey; snout arcuated and deep black. Fabr.
A small European species. The thorax is smooth, dusky, and greyish; legs blackish.
- BORRAGINIS.** Villous-grey; feet rufous. Oliv.
Inhabits France.
- HÆMORRHOIDALIS.** Thorax fuscous; sides greyish; wing-cafes at the suture and tip ferruginous. Fabr.
Native of New Holland, in the Bankian Cabinet.
- TRIMACULATUS.** Wing-cafes black, with three cinereous spots; the posterior forming a common lunule. Paykull.
Found in Alface by professor Hermann.
- LITURA.** Varied white and black; snout deep black. Paykull.
Lives on the thistle. A native of Europe.
- VILLOSUS.** Villous-grey; scutel, and oblique posterior band on the wing-cafes white. Herbst.
Native of Germany.
- RAPHANI.** Blackish; thorax tuberculated; snout bent and deep black. Fabr.
- VARIANS.** Black; wing-cafes rufous; margin black. Paykull. *Curculio beccabungæ*.
Found on the pine in Sweden.
- TROGLODYTES.** Fuscous; thorax with a dorsal cinereous line; wing-cafes and legs testaceous. Paykull.
Inhabits Europe near Kiel.
- CARBONARIUS.** Oblong, deep black; antennæ club-villous; wing-cafes marked with crenated striæ. Fabr.
Native of Europe.
- ATERRIMUS.** Black; tip of the thorax bidentated; wing-cafes glossy. Fabr.
- CERASI.** Deep black; thorax bidentated at the tip; wing-cafes oblong. Linn.
Native of Europe.
- VIOLACEUS.** Black; wing-cafes striated and violaceous. Linn.
Inhabits the north of Europe, on the pine.
- PROBOSCIDEUS.** Griseous; snout twice as long as the body. Fabr.
Native of North America.
- NUCUM.** Body greyish, and length of the snout. Fabr.
Inhabits Europe, and feeds on the nut.
- GULOSUS.** Dusky-brown; legs testaceous. Fabr.
Found near Paris.
- PARASITA.** Ferruginous sprinkled with cinereous; thighs with a black spot. Fabr.
Native of Cayenne.
- ESURIENS.** Griseous; scutel, dorsal line on the thorax, and common spot on the wing-cafes behind whitish. Fabr.
Inhabits France.
- NASUTUS.** Brown; wing-cafes striated, cinereous, with the tips brown. Oliv.
Described from a specimen in the British Museum. Its native place unknown.
- HAUSTELLATUS.** Chestnut; wing-cafes striated; snout four times the length of the body. Oliv.
Native

CURCULIO.

- Native of the Cape of Good Hope.
VARIUS. Grey and black varied; snout and legs rufous. Fabr.
 Inhabits Cayenne.
CERASORUM. Fuscous, scutel and wing-cafes with obsolete cinereous bands. Paykull.
 An European species.
AMOENUS. Deep black; two dots on the thorax and five on the wing-cafes snowy. Oliv.
 Native of New Holland.
METALLINUS. Brassy-black; thorax dotted; wing-cafes striated with dots. Fabr.
 Inhabits South American islands.
BICORNIS. Griseous; head bidentated. Fabr.
 Native of New Zealand.
TENUIROSTRIS. Black, with numerous white waves; antennæ rufous.
 Native of Europe. The club of the antennæ is grey, as is also the scutel.
DRUPARUM. Wing-cafes testaceous, obsoletely fasciated. Linn.
 Native of Europe.
FRAXINI. Ferruginous-brown; head and back black. Paykull.
 Found on the ash in Sweden.
MELANOCEPHALUS. Brown; head fuscous; snout deep black. Fabr.
 Native of Saxony.
DEPRESSUS. Thorax depressed; sides obtusely angulated. Linn.
 Inhabits South America.
POMORUM. Body grey clouded. Linn.
 Found on the flowers of fruit-trees.
VORAX. Grey and fuscous spotted; snout bent and deep black. Fabr.
 An Italian species.
TORTRIX. Body testaceous; breast fuscous. Linn. *Curculio ferrugineus*, Geoffr.
 Native of Europe.
TREMULÆ. Blackish; wing-cafes striated, and sprinkled with grey. Paykull.
 Found on the poplar in Sweden.
ÆSTUANS. Fuscous, lineated with cinereous; legs pale. Fabr.
 Native of South America.
TENIATUS. Thorax black; anterior and posterior margin rufous; wing-cafes pale, spotted with black. Paykull.
 Native of Europe. Snout black; mouth sanguineous.
ELONGATUS. Thorax elongated; anterior shanks bidentated. Fabr.
 Native of Jamaica.
- Section *** *Snout long; posterior Thighs formed for leaping.*
- ALNI.** Wing-cafes testaceous, with two dusky spots. Paykull.
 Inhabits England and other parts of Europe.
PILOSUS. Black, varied with cinereous. Fabr.
 Native of England, in the Banksian Cabinet.
HORTORUM. Deep black; band and half band, with the legs, testaceous. Fabr. *Curculio mutillatus*, Laichart.
 Native of Germany.
SALICETTI. Deep black; shanks testaceous. Fabr.
 Found on the willow in Sweden.
SALICIS. Wing-cafes deep black, with two white bands. Linn.
 A native of Europe; found on the willow.
- VIMINALIS.** Body testaceous. Paykull. *Curculio quercus*, Linn. *Curculio ulmi*, Degeer. *Curculio rufus*, Geoffr.
 Inhabits same country as the former.
ILICIS. Blackish; wing-cafes striated, varied with cinereous; future at the base white. *Curculio roboris*, Bonfd. Curcul.
 Feeds on the oak.
FRAGARIÆ. Fuscous; antennæ and feet testaceous. Fabr.
 Native of Germany.
POPULI. Deep black; scutel white; antennæ and legs testaceous. Fabr.
 Found on the poplar.
- **** *Short snouted; Thighs unarmed.*
- ARGYREUS.** Body silvery-green, spotted with gold. Linn.
 Native of India.
SPLENDIDUS. Wing-cafes striated, and spotted with gold; base gibbous, tip pointed. Fabr.
 Native of Brasil. Size of the diamond beetle, and far less common.
SUMPTUOSUS. Wing-cafes greenish, with raised black dots; base gibbous. Oliv.
 Found in Cayenne.
IMPERIALIS. Deep black, with alternate longitudinal black raised lines, and streaks of green-golden spots; tip of the wing-cafes pointed. Fabr.
 This is the resplendently coloured insect, known by the name of the diamond beetle. The species inhabits South America, chiefly Brasil.
CHRYSIS. Whitish; wing-cafes pointed; two bands and two dots of gold. Fabr.
 Described by Olivier, from a specimen in the collection of the late French king.
REGALIS. Body silky green, with broad golden bands. Linn. Donov. Inf. India.
 An extremely rich and elegant species. This beetle is so very scarce in India, that the wing-cafes, or sometimes the whole insect, is mounted like a gem on rings, and worn by the great as an ornament on the finger. *Vide* Donovan's Insects of India.
MARGINATUS. Fuscous; wing-cafes at the future, and the margin of the abdomen golden. Fabr.
 Native of Cayenne. Dr. Hunter.
19-PUNCTATUS. Whitish-hoary; thorax with four black spots; wing-cafes with nineteen. Oliv.
 Same country as the last.
16-PUNCTATUS. Blueish; four spots on the thorax, and twelve on the wing-cafes black. Oliv.
 A Brasilian species. The head is sulcated.
DECORUS. Above fuscous; thorax and wing-cafes marked with two green-gold stripes. Fabr.
 Native of Brasil.
NITIDULUS. Covered with green scales; wing-cafes dotted. Fabr.
 A Cayenne species.
CANDIDUS. Wing-cafes spinous and white; with a lateral fuscous spot. Fabr.
 Native of Cayenne.
NIVEUS. Snowy; thorax and back of the snout fuscous; wing-cafes spinous and pointed. Fabr.
 Native of Cayenne.
LACTEUS. White, with a golden gloss; wing-cafes sulcated and pointed. Fabr.
 Native of Jamaica.

CURCULIO.

- PULVERULENTUS.** Cinereous; head flat and grooved. Fabr.
Inhabits Tranquebar.
- SMARAGDULUS.** Greenish; wing-cafes dotted, with a strong erect spine before, and another behind. Fabr.
Native of Cayenne.
- OCTOTUBERCULATUS.** Varied fuscous and cinereous, dotted, and gibbous behind; tubercles eight. Fabr.
Native of Cayenne.
- MODESTUS.** Cinereous; thorax and wing-cafes spotted with brown. Fabr.
Inhabits New Zealand. Banksian Cabinet.
- FLAVESCENS.** Dull; thorax and wing-cafes acumined, the sides yellow. Fabr.
Native of South America.
- LATERALIS.** Covered with green scales; sides of the thorax and wing-cafes yellow. Fabr.
Native of India.
- VERIDIS.** Green; sides of the thorax and wing-cafes yellow. Linn.
Found on the plumb in Europe.
- AURIFER.** Body ferruginous, spotted with gold. Oliv.
Native of South American islands.
- SPLENDIDULUS.** Shining-green; wing-cafes in the disk cinereous, banded with black. Fabr.
A Siberian species.
- MORBILLOSUS.** Thorax and wing-cafes fuscous and grey varied, with numerous elevated dots of deep black. Fabr.
Inhabits France and Barbary.
- NEBULOSUS.** Hoary; wing-cafes banded obliquely with black. Linn.
Native of Europe.
- MARMORATUS.** Black, and rough with white lines; wing-cafes white, sprinkled with black squarish spots. Fabr.
Inhabits Germany.
- SULCIROSTRIS.** Oblong, cinereous, and somewhat clouded; snout trifurcated. Linn.
Found on plants in Europe.
- PORCULUS.** Blackish, varied with cinereous; head retuse, and with the snout carinated. Linn.
Native of Hungary.
- PERLATUS.** Black; abdomen white, with raised glabrous black dots; snout grooved. Fabr.
Native of China.
- GLAUCUS.** Snout carinated; thorax unequal and dull; wing-cafes glaucous; an elevated dot behind. Fabr.
- DISPAR.** Oblong, fuscous, with villous grey spots. Fabr.
Native of the East Indies.
- VETULA.** Griseous; wing-cafes rugged, black, with cinereous spots; snout deep black. Fabr.
Inhabits Tranquebar.
- CRENULATUS.** Cinereous, with three crenulated waved lines on the wing-cafes. Oliv.
Native of New Holland.
- INCANUS.** Oblong, and fuscous; thorax flat on the back. Linn.
Found on plants in Europe.
- COSTATUS.** Cinereous; thorax black, with four cinereous lines. Fabr.
Native of the south of France.
- LONGIMANUS.** Fuscous, margin of the thorax, and two dots ferruginous; anterior legs long. Oliv.
Native of Brasil.
- SPINIFEX.** Cinereous sprinkled with brown; thorax acutely spined. Fabr.
- MICANS.** Brown-golden, legs ferruginous. Fabr. *Curculio pyri*, Paykull.
Found in gardens in Denmark.
- MURINUS.** Fuscous, with the thorax trilineated; wing-cafes with alternate pale and dusky lines, and dotted with black. Fabr.
Native of Europe.
- POLYGONI.** Thorax lineated; wing-cafes cinereous, marked with three fuscous lines, and dotted with black. *Curculio polygoni*, Linn., &c.
Inhabits Europe. The snout is grey, with a longitudinal white line.
- 3-GUTTATUS.** Blackish; wing-cafes grey, with two white dots; the posterior one large and common. Fabr.
Native of Britain.
- ARUNDINIS.** Yellowish; two dorsal fuscous lines on the thorax. Paykull. *Curculio luteus*, Knoch.
An European species.
- GRESSORIUS.** Griseous; head and thorax black, with a white dorsal line. Fabr.
Native of Italy.
- GRAMINEUS.** Black; wing-cafes striated; antennæ and legs ferruginous. Fabr.
Found on graminiferous plants in Germany.
- CORYLI.** Cinereous and fuscous varied; wing-cafes at the future half way down black. Fabr.
Inhabits England.
- LINEATUS.** Fuscous, with three paler streaks on the thorax. Linn.
Found on plants in Europe.
- FUNDASCENS.** Cinereous; back fuscous. Fabr.
Native of Italy.
- FULVIPES.** Downy greyish; legs testaceous. Paykull.
Inhabits Saxony. Hybner.
- RUFICOLLIS.** Testaceous; head and wing-cafes striated, cinereous brown. Fabr.
- FULVICORNIS.** Brown; wing-cafes with undulated bands of cinereous. Fabr. *Curculio ruficornis*, Paykull.
Found on trees in Europe.
- HIRSUTULUS.** Cinereous, and hispid; wing-cafes striated; antennæ and legs yellowish. Fabr. *Curculio echinatus*, Bonf.
- SCABRIUSCULUS.** Cinereous; head and thorax canalliculated; wing-cafes hispid. Linn. Bonf.
Found in sandy places in Europe.
- LIMBATUS.** Deep black; marginal stripe down the wing-cafes, and the scutel golden. Fabr. *Curculio lateralis*, Paykull.
Inhabits Europe.
- PARVULUS.** Green; antennæ and shanks testaceous. Fabr.
Native of Italy.
- VRIDICOLLIS.** Thorax green and scaly; wing-cafes striated and black. Fabr.
Inhabits Germany, on the oak.
- STRIATUS.** Fuscous; wing-cafes striated, cinereous, with black dots. Fabr.
Native of Barbary.
- LACERTA.** Griseous; wing-cafes striated; antennæ black at the tip. Fabr.
An East Indian species, in the Banksian Cabinet.
- RUFICORNIS.** Deep black, with rufous antennæ; thorax on each side bituberculated. Linn.
Found

CURCULIO.

Found on plants in Europe. The wing-cafes are striated.

CANALICULATUS. Cylindrical, deep black, with the legs rufous; thorax canaliculated. Fabr.

A small species, and inhabits American islands.

CLOROPUS. Cylindrical, black; wing-cafes striated; antennæ and legs rufous. Linn. *Curculio piniperda*, Herbit.

Native of Europe; found on the oak.

TRISTIS. Black; wing-cafes grooved, cinereous. Fabr.

Native of Sweden and England.

RAUCUS. Black; wing-cafes striated, fuscous, with cinereous spots. Paykull.

Inhabits Saxony.

ADSPERSUS. Deep black; wing-cafes behind spotted with white. Oliv.

Described from a New Holland species in the Banksian Cabinet.

PUNCTATUS. Fuscous; wing-cafes with elevated silky dots. Paykull.

Native of Sweden.

MAXILLOSUS. Ovate, black; jaws exerted and bent. Fabr.

Native of Hungary. Hybner.

ROTUNDATUS. Black; wing-cafes with dotted striæ; antennæ and shanks rufous. Fabr.

Native of Germany.

VARIOLOSUS. Black; thorax carinated, and variolous; wing-cafes striated. Fabr.

Found in Saxony.

SUCCINCTUS. Deep black; margin of the wing-cafes, and two small lines white. Fabr.

Native of the Cape of Good Hope.

CAMELEON. Brassly; future of the wing-cafes, and abbreviated stripe green-gold. Oliv.

Inhabits Jamaica.

VITTATUS. Deep black; wing-cafes marked with abbreviated white and red lines. Linn.

An elegant species, found in Jamaica.

SPENGLERI. Wing-cafes yellow, with very glabrous abbreviated lines of black. Linn.

Native of American islands.

BIVITTATUS. Wing-cafes with striæ of dots, and a marginal and an interrupted dorsal band of yellow. Fabr.

Inhabits the island of St. Thomas.

LIVIDUS. Griseous; thorax and wing-cafes cinereous and black spotted. Oliv. *Curculio hisfrionicus*, Sparmann.

An insect of large size, found in South America.

FESTIVUS. Wing-cafes yellowish, with abbreviated black streaks, and a marginal one sanguineous. Fabr.

Native of South America.

IMPRESSUS. Black; thorax and wing-cafes with impressed dots of white. Fabr.

Inhabits Jamaica.

RIVULOSUS. Black; thorax spotted with rufous; wing-cafes with three impressed cinereous lines. Fabr.

Native of the East Indies.

VERRUCOSUS. Brassly-black, with raised dots; wing-cafes warted behind. Fabr.

Native of the Cape of Good Hope.

CAPENSIS. Black; thorax with elevated dots; wing-cafes with crested striæ. Linn.

Inhabits same country as the former; the snout is sulcated.

6-VITTATUS. Black; thorax rough and lineated with white; the wing-cafes pointed. Oliv.

Native place unknown.

INÆQUALIS. Thorax unequal, prominent in front; wing-cafes grooved, and fulcated behind; snout tri-fulcated. Fabr.

An African species, in the Banksian cabinet.

ACUMINATUS. Cylindrical, fuscous; wing-cafes pointed at the tip. Fabr.

Native of New Zealand.

EMERITUS. Black; thorax and wing-cafes spinous; front excavated. Linn.

Native of India.

CULTRATUS. Cinereous; thorax with two compressed tubercles; wing-cafes tuberculated, the posterior part cinereous. Fabr.

Inhabits New Holland.

TRIBULUS. Cinereous; thorax scabrous, the anterior part impressed; wing-cafes spinous. Fabr.

Inhabits same country as the last.

4-DENS. Cinereous; thorax scabrous; wing-cafes spinous; four posterior spines longest. Fabr.

Native of New Holland.

CLAVUS. Whitish; thorax canaliculated; wing-cafes spinous; three small red lines at the base. Oliv.

Inhabits New Holland.

RUBIFER. Cinereous; thorax scabrous; wing-cafes with sanguineous spines. Fabr.

Native of the Cape.

GLOBIFER. Thorax scabrous; wing-cafes spinous, acumined behind. Fabr.

Inhabits the Cape of Good Hope. The snout is smooth and thick at the tip; legs black.

PILLULARIUS. Thorax armed each side with a nodulous spine; wing-cafes with tuberculated striæ; tip acumined.

Native of the Cape of Good Hope.

GLANDIFER. Dull; thorax scabrous; wing-cafes with three elevated spinous lines. Fabr.

Inhabits the Cape of Good Hope.

Section ***** *Snout short; Thighs dentated.*

SPECTABILIS. Body black, varied with green spots. Oliv. *Donov. Inf. New Holland.*

This is the elegant insect known by the name of the diamond beetle of New Holland, to which part of the world this species is peculiar.

PINGUIS. Anterior thighs toothed; gibbous, and blackish; throat with yellowish lines; wing-cafes with two yellowish streaks, and a small line at the tip. Fabr.

Native of Cayenne.

TRIBENS. Cinereous; wing-cafes emarginate at the tip, with three teeth. Fabr.

Native of New Zealand, in the Banksian cabinet.

FUSCO-MACULATUS. Black; thorax and wing-cafes smooth, and spotted with brown. Fabr.

Found in the north of Germany.

ZEBRA. Black; wing-cafes variegated with white. Fabr.

Native of Saxony.

LIGUSTICI. Body dusky; thorax rough and cinereous. Oliv.

Found on the *ligusticum levisticum*.

NUBILUS. Gray; wing-cafes with numerous darker, and nearly square spots. Fabr.

Inhabits Hamburg. The antennæ are black, with the club pointed.

CURCULIO.

CALCARATUS. Black; antennæ and legs rufous. Fabr. Native of Austria.

GEMMATUS. Black; wing-cafes with green dots. Oliv.

Inhabits Europe.

PICIPES. Grey; wing-cafes clouded, striated with subocellate dots. Fabr.

BISULCATUS. Black; thorax and wing-cafes rough; snout with two grooves. Fabr.

Native of Italy. The snout marked with impressed grooves; thorax subcinereous at the sides.

PYRI. Bronzed, changeable to yellow, red, brown, or green; legs rufous. Linn. Donovan. Brit. Inf.

Not uncommon. Inhabits Britain, and most other parts of Europe.

DENTIFER. Cinereous; snout grooved before; posterior thighs tridentated. Fabr.

Native of the East Indies.

CURVICORNIS. Grey, with the sides white; middle pair of thighs bidentated. Fabr.

Inhabits same country as the former.

ARGENTATUS. Covered with fine green bronzed scales; antennæ and legs brown. Linn.

Very abundant in May and June on the birch and alder, in Britain. Donovan. Brit. Inf.

ALBO-LINEATUS. Cinereous; thorax and wing-cafes with white lines; snout black beneath. Fabr.

Native of Saxony.

ATELLAHOIDES. Snout and wing-cafes with a single tubercle. Fabr.

Inhabits Brasil.

ÆRUGINOSUS. Green; thighs ferruginous; antennæ long. Bonfd.

Native of Sweden.

ANTHRACINUS. Black; wing-cafes with striate dots; thighs single toothed. Fabr.

Found by Scopoli in Carniola.

LUGUBRIS. Brown; wing-cafes rough, substriated, rather downy and connected. Fabr.

Native of Italy.

CÆLESTRINUS. Blue; antennæ and legs sanguineous. Scopoli.

Native of Germany.

ROESELII. Thorax dull green, with a longitudinal white line; wing-cafes fulvous, brown with raised lines. Fabr.

Inhabits same country as the preceding.

ARGENTEUS. Silvery green; antennæ and shanks rufous; thighs brown and clavated. Fabr.

Native of Europe.

HÆMORRHODUS. Brown; antennæ, legs, and tip of the abdomen rufous; wing-cafes greenish brown.

Native of Europe.

Section **** Lip bifid; Jaws bifid and short; snout short. *Anthribus*, Fabricius.

ALBINUS. Black front, and tail white. Degeer.

Inhabits Europe; rarely found in Britain. Donovan. Brit. Inf.

LATIROSTRIS. Snout very broad and flat; tip of the wing-cafes white, with two black dots. Fabr.

Native of Saxony; scarce in England. Donovan. Brit. Inf.

ALBIROSTRIS. Snout very broad, flat, and white; wing-cafes black, white at the tip, with a palmated black spot. Herbit.

Inhabits Saxony.

MACROCEROS. Grey; wing-cafes cinereous behind. Fabr.

Native of New Holland.

SCABROSUS. Black; wing-cafes with raised striæ, rufous with scattered black dots. Fabr.

Native of Europe.

UNDATUS. Black; wing-cafes brown, with white wavy streaks. Fabr.

A species of middle size, found on flowers in Africa.

VARIUS. Wing-cafes striated with alternate white and black dots. Paykull.

SEPICOLA. Varied with cinereous and brown, and raised hairy dots. Fabr.

Inhabits Germany, and is found in hedges.

Section ***** Lip rounded, horny; Feelers very short.—*Brachycerus*, Fabricius.

APTERUS. Thorax spinous, with an impressed cross; wing-cafes dotted with ferruginous. Fabr.

Inhabits India.

OCELLATUS. Thorax spinous, excavated before; wing-cafes cinereous, with black subocellate dots. Fabr.

Native of Madagascar.

SCALARIS. Thorax spinous, unequal; body black; wing-cafes with rufous denticulated striæ. Fabr.

Inhabits the Cape of Good Hope.

OBESUS. Thorax spinous and unequal; body black; wing-cafes red, with clouded black dots. Fabr.

Inhabits the Cape of Good Hope.

GLOBOSUS. Thorax spinous, and marked with five grooves; wing-cafes smooth.

Native of India.

ROSTRATUS. Brown; head and thorax cylindrical and narrow; wing-cafes spinous behind. Fabr.

Inhabits the warmer parts of Africa.

INEQUALIS. Thorax rough; wing-cafes with raised crimped lines; head bidentated. Fabr.

This is of a large size, and inhabits the Cape of Good Hope.

CRISPATUS. Black; thorax spinous and grooved; wing-cafes cinereous, the outer angle crimped and toothed. Fabr.

A native of Barbary. The head is black; thorax punctured.

CORNUTUS. Cinereous; thorax and wing-cafes subspinous; spines of the wing-cafes with fasciculate hairs. Olivier.

Native of India.

ALGIRUS. Cinereous; thorax spinous, grooved; wing-cafes with two raised spinous lines, and between these two raised dots. Fabr.

Native of Africa.

RETUSUS. Grey-brown; wing-cafes retuse, and toothed behind. Oliv.

Inhabits the Cape of Good Hope.

SPECTRUM. Brown; thorax and wing-cafes globular. Oliv.

Inhabits same country as the last.

MURICATUS. Thorax spinous, grooved, black, opaque; wing-cafes with three raised crenated lines. Oliv.

Native of Hungary.

UVA. Thorax spinous, and unequal; wing-cafes with numerous raised obtuse tubercles. Oliv.

This is of the middle size, and inhabits the Cape of Good Hope.

CURCUM, in *Ancient Geography*, a town placed by Ptolemy in the interior of Libornia.

CURCUM, in the *Materia Medica of the Arabians*, the name of the largest celandine; the roots of which, when dried, were used by the dyers of those times as a yellow colour, and by the physicians as deobstruents.

CURCUMA, in *Botany*, (from the Arabic name curcum, or hercum.) Roscoe. Linn. Transf. 8. 354. tab. 20. fig. 12.

Ess. Ch. Anther double, two-spurred. Filament petal-shaped, three-lobed; middle lobe bearing the anther.

Cafs and order, *monandria, monogynia*. Nat. Ord. *Scitamineæ*, Linn. Rosc. *Cannæ*, Juss.

Obs. As Mr. Roscoe, in his reformed arrangement of the plants belonging to this natural order, has stated that the calyx, corolla, and nectary differ greatly in the different species of the same genus, we have not attempted a detailed natural character of curcuma. He observes that this genus is not less distinguished from amomum and zingiber by its general habit and inflorescence, than by the parts of its fructification. In all the species the leaves are radical; but amomum and zingiber are both caulescent. Curcuma has a simple scapus and the flowers are enveloped in large loose bractes, not in compact scales as in zingiber. From some circumstance not easy to be accounted for, Linnæus has characterized this genus as having four barren stamens, besides the fertile one, which no subsequent observer has been able to discover. Mr. Dryander supposes that the generic character of Linnæus was derived from his *C. rotunda*, now referred to *Kämpferia*.

Sp. 1. *C. Zedoaria*. Rosc. 1. (*Amomum zedoaria*; Mart. Willd. *A. latifolium*; Lam.) "Leaves egg-shaped, acuminate; bractes emarginate." See **AMOMUM Zedoaria**.
2. *C. montana*. Rosc. 2. Roxb. Pl. corom. 2. tab. 151. "Leaves egg-shaped, acuminate; bractes lanceolate, coloured at the tip." 3. *C. longa*. Turmeric. Rosc. 3. Linn. Sp. Pl. 2. Mart. 2. Willd. 2. Woodv. med. bot. tab. 132. Lam. 2. (*Amomum curcuma*; Jacq. Hort. Vind. 3. tab. 4. *Curcuma radice longa*; Herm. Ludg. tab. 209. *Curcuma*; Rumph. Amb. 5. 162. tab. 67. *Manjella-kna*; Rheed. Mal. 11. 21. tab. 11. *Cannacorus radice crocea*, five *curcuma officinarum*; Tournef. 367.) "Leaves ovate-lanceolate, bractes spatulate." Root perennial, creeping, fleshy, palmate with cylindrical branches, and jointed with parallel rooting circles; bark thin, pale; flesh saffron-coloured, with a bitterish taste, and a somewhat fragrant smell. Stem none. Leaves broad-lanceolate, large, quite entire, smooth, annual, pale-green, densely furrowed with oblique slender lines; petioles long, erect, dilated at the base, mutually supporting and clasping each other. Scape external, three inches long, slender, nearly erect, almost naked, approximating to the cluster of leaves. Spike thick, somewhat egg-shaped, three inches long; scales membranous, a little acute, whitish, half-spreading, united laterally below the middle. Flowers sessile, white, with a yellow nectary, one within each scale of the spike. Calyx. Perianth superior, bifid; segments oblong-egg shaped, erect, concealed by the scales of the spike. Corolla monopetalous, funnel-shaped; tube slender, equal to the perianth, dilated towards the top; border four-parted; segments nearly equal in length; two lateral ones obtuse, undulate-plaited; uppermost acute, incurved; lowest broader, bifid, with roundish segments. Nectary large, incurved, three-lobed and the middle lobe emarginate, adnate at the base to the exterior segment of the corolla. Stamen. Filament one, broad, flat, short, rounded at the top, standing on the uppermost segment of the corolla; anther not closely adhering to the filament (exortica), somewhat cubical, bifid, with an awl-shaped appendage standing out on each side.

Pistil. Germ roundish; style capillary, equal to the stamen, included in the groove of the anther; stigma concave. *Pericarp*. Capsule roundish, smooth and even, three-valved, three-celled. Seeds round, few. We have literally translated the above description from Loureiro, because it was taken from a recent plant which grew in its native soil, though it does not accord with Mr. Roscoe's ideas concerning the anther. Loureiro seems to have confined the term to the upper or middle lobe of what Mr. Roscoe calls the anther, and to have considered all the lower part, with its two lateral lobes, as one of the segments of the border of the corolla; but in this case he must, through an oversight, have committed an error in his description of the situation of the filament, and have written *lacinia summæ corollæ inflexens*, instead of *lacinia infimæ*, &c. We are rather confirmed in our conjecture by an attentive consideration of Koenig's description, as published by Retzius and translated by professor Martyn (for we have not the original at hand); and which Mr. Dryander assures us belongs to the present plant. See Linnæan Transactions, vol. ii. p. 212. It stands thus: Tube of the corolla erect, or a little bent in, round, smooth, stiffish, white, above the middle bell-shaped, somewhat compressed, keeled at the back; border double, each three-parted. Filament single, erect, lanceolate-ovate, between the two dorsal segments growing to the dorsal border, flatish, somewhat convex in front, marked with a line behind half the length of the approximating segments, stiffer than they, but of the same colour. A native of the East Indies, China, and Cochinchina, where also it is generally cultivated for the sake of its root, which is the turmeric of the shops. See **TURNERIC**. 4. *C. pallida*, Mart. 3. Loureiro Coch. 1. 9. (*Curcuma agreftis*; Rumph. Amb. 8. p. 164.) "Leaves lanceolate; bractes short; bulbs knotty." Roots perennial, horizontal, creeping, oblong, cylindrical, twisted, knotty, pale within and without, fleshy, with little smell and taste. Plant annual, three feet high, stemless, erect. Leaves lanceolate, large, with numerous oblique slender furrows; petioles dilated at the base, embracing the inner ones. Scape external, eight inches long, clothed with short bractes; spike oblong; scales ovate-lanceolate, lax, reflexed, reddish, one-flowered; corolla yellowish white, four-cleft; nectary three-lobed; stamen one. A native of China about Canton and Cochinchina. The pounded root is used externally in cases of contusion and local pains. Loureiro has given no description of the filament and anther: but its want of a stem and general habit seem to indicate that it really belongs to this genus as it is settled by Mr. Roscoe.

CURD, in *Rural Economy*, is the coagulum, or whitish solid substance produced from milk, from which cheese is formed. See **CHEESE** and **DAIRYING**.

CURD-Mill, is a kind of mill contrived for the purpose of reducing and breaking down the coagulum or curd, in making cheese. It consists of two cylinders or rollers of about six inches in diameter, and fifteen inches long; one being placed above the other in a thin deep chest, as in the common cyder mill of the more southern districts. The superior upper roller is studded with iron spikes an inch in length, and an inch and half asunder, while the lower one is closely beset with bevil-headed nails, rising with a sharp angle about a tenth of an inch out of the surface of the roller. The curd, after being partially broken over, is put into a hopper, the bottom of which is formed by the upper roller, which, by working against the side of the box, prepares the curd for the lower roller, which being finer, and working closer, reduces it to small particles or granules. The rollers are turned by a crank placed on one end of the

axle of the upper one; the opposite ends of them having each a wooden-toothed wheel, which wheels work in each other, by which means the lower one is turned with facility. This is a sort of machine which must be highly useful in large cheese dairies, where the breaking of the curd by the hand is a business of vast labour, and which requires much time. It is principally employed in the final breaking down of the curd, by which it is rendered more fine and equal than could be done by the hand.

CURDISTAN, or **KURDISTAN**, in *Geography*, a mountainous country of Asia, whence issue the different branches of the Tigris, which, surrounding the upper part of the great Zab, passes to the southward, as far as the frontiers of the Irak-Aojemi, or Persian Irak. Some geographers consider it as one of the divisions of the Turkish province of Diarbekir, anciently known by the name of Assyria. It lies on the east side of the Tigris, towards Persia, being bounded by that kingdom on the east, and by the Tigris on the west, by Irak on the south, and Turcomania on the north. Towards the south it is narrow, scarcely exceeding 90 miles in breadth; but northwards it stretches near 300 miles from east to west, that is, from the 41st to the 47th degree of east longitude; and from north to south it reaches from 35° 30' to 37° 20' N. latitude. The mountain of Costras separates it from Persia on the E., and the Tigris on the W., from Mesopotamia and Chaldæa. According to ancient accounts this country was rich and fertile; but it is now desolate and barren, abounding with deserts, except in those few parts which lie near towns, and which are somewhat better cultivated. It was in former ages the constant field of battle between the Parthians and Romans, and at a later period between the Turks and Persians, which served to depopulate it, and to render it waste and unproductive. Its chief towns and hamlets are Belis, the capital, Scheresal, Arbela, Harpel, Nineveh, Rehobo, Rhesen, Van, and Holwan. It is inhabited by the *Curds*, who are divided into tribes, which are dispersed over the Lower Asia, and have widely extended themselves, especially within the last hundred years. Volney suggests that *Gord* and *Curd* are the same, and that the habitations of the Curds are among the Gordæan mountains, or the *Gord-ouai*, where, according to the Chaldæan Berofus, and the Armenian Maribas, cited by Moses Chorenensis, Xisuthrus landed, after escaping from the deluge. They are supposed to be the same people who are mentioned by Xenophon under the denomination of *Curd-uchi*, and who opposed the retreat of the ten thousand. This historian observes, that though shut in on all sides of the Persian empire, they had constantly braved the power of the "Great King," and the arms of his "satraps." In their modern state they are little different from what they were formerly; for though they are apparently tributaries to the Porte, they pay little respect to the orders of the grand signior, or his pachas. According to the account given of them by Niebuhr, who travelled in these countries in 1767, they are subject, in their mountains, to a sort of feudal government, similar to that which is observed among the *Druzes*. Each village has its chief, and the whole nation is divided into different and independent factions. The disputes inseparable from this state of anarchy have detached from the nation a great number of tribes and families, which have adopted the wandering life of the Turkmans and Arabs. These Curds are dispersed in the Diarbekir, and over the plains of Arzroum, Erivan, Sivas, Aleppo, and Damascus; and all their tribes are estimated to exceed 140,000 souls, that is, 140,000 armed men. Like the Turkmans, these Curds are pastors and wanderers; they are often shifting their position in search of pasture for their numerous flocks and herds; and whilst the men roam in

quest of plunder, the women are occupied in making butter and cheese, and training up the children to the trade of the fathers. Their tents are large, and formed of a sort of coarse brown cloth, which serves as a covering to their houles, which are constructed for temporary use of cane hurdles, disposed in a square form, and having the floor matted, so as to answer the purposes both of bed and board. When they dislodge in order to migrate, they take their huts to pieces, and load their oxen and cows with them, and also with their children, and household utensils. The children are used to go almost naked in the coldest weather. The men are generally well mounted, and take great care of their horses, which are commonly very swift in their motion; the lance is their chief weapon. The women ride either on horses or on oxen. Both men and women are naturally stout and nimble, but not at all agreeable in their persons, having very small eyes, wide mouths, bad complexions, very black hair, and a very fierce and forbidding aspect. The Curds differ from the Turkmans in some particular customs. The latter give their daughters a marriage portion; the former receive a premium for them. The Turkmans pay no respect to nobility or antiquity of extraction; the Curds highly honour it. The Turkmans do not steal; the Curds are almost every where considered as plunderers; and they are therefore much dreaded in the neighbourhood of Aleppo and Antioch, where they occupy, under the name of "Bagdashlia," the mountains to the E. of Beilam, as far as near Kles. In this pachalic, and in that of Damascus, their number exceeds 20,000 tents and huts; for they have also fixed habitations. They are reputed Mahometans; but they never trouble themselves about religious rites or opinions. Several of them, distinguished by the name of *Yezdia*, worship "Shaitan" or Satan, according to the ancient system of the *good* and *evil* principles, which has more or less prevailed in the Diarbekir, and the frontiers of Persia. The language of the Curds is divided into three dialects. It has neither the aspirations nor the gutturals of the Arabic, and Mr. Volney says that it does not resemble the Persian; and, if this be the case, it must be an original language. Considering the antiquity of the people who speak it, and that they are related to the Medes, Assyrians, Persians, and even the Parthians; Volney conjectures, that a knowledge of this tongue might throw some light on the ancient history of these countries. See Volney's *Travels*, vol. i. sect. 2.

CURDLING, the coagulating or fixing of any fluid body; particularly milk, by means of rennet. See **CHEESE**.

Pausanias says, that Aristæus son of Apollo, and Cyrene daughter of the river Peneus, were the first who found the secret of curdling milk.

At Florence they curdle their milk for the making of cheese with artichoke flowers; in lieu of the rennet used for the same purpose among us.

The Bisaltæ, a people of Macedonia, Rochfort observes, live wholly upon curdled milk, *i. e.* on curds. He adds, that curds are the whole food of the people of Upper Auvergne in France, and wher they only drink.

Women newly delivered are subject to have their milk curdled, converted into little grumæ, in their breasts, which occasion violent pains, with a shivering in the back. It is owing to the want of being sucked; whence the method of remedying, and preventing it, is apparent.

CURE, in *Geography*, a small town of France, in the department of the Yonne, on the river Cure, which falls into the Yonne at Cravan.

CURE, in *Medicine*. See **PALLIATIVE cure**.

CURE of souls, a benefice, the incumbent whereof has the charge

charge and guidance of the souls of the people within a certain extent of ground, called a *parish*.

Such are a vicar, a rector, &c. in contradistinction to a prebend, a dean, a chanter, &c.

CURES, *fine*. See SINE.

CURE, in *Falconry*, the same with *Casting*; which see.

CUREL, in *Geography*, a town of France, in the department of the Upper Marne, one league N. of Joinville.

CUREMA, in *Ichthyology*, the name of a fish of the mullet kind, but of a remarkable size, growing to two feet long, and having a very large moveable upper lip; the under one being small, triangular in figure, and scarcely visible, being something shorter than the upper. Its eyes are large, and its fins of a fine silvery white; in all other respects it resembles the common mullet. See MULLUS.

CUREMONTE, in *Geography*, a town of France, in the department of the Correze, and district of Brives, $4\frac{1}{2}$ leagues S.E. of Brives.

CURENA, or CURNA, in *Ancient Geography*, a town of Asia, in Media.

CURENSE, or CORINSE LITTUS, a place on the coast of Spain, with a gulf over against the town of Gades, according to Pliny: supposed by Hardouin to lie between the Guadalquivir and the Guadalate.

CURES, or CURIS, a town of Italy, which was anciently the capital of the Sabines, who from hence assumed the name of "Quirites." After the treaty concluded between Romulus and Tatius, which produced a coalition of the two nations, the Sabines were called Romans, and the Romans Quirites, or Sabines. However, that name, as well as *Tribus Quirina*, was applied, with the greatest propriety, to that canton of the Sabines inhabiting Cures, and the district appertaining to it. The principal deity worshipped here seems to have been Juno Quiris, or Curis. She was represented with a spear or lance in her hand; from which circumstance she received the appellation of "Quiris or Curis," a word in the Sabine language equivalent to the Latin "hasta." Macrobius mentions a Sabine deity under the name of Janus Quirinus, supposed to be the "Pater Curis," held in high veneration among the Falisci.

Cures was situated in the territory now called Correze, or Cureze, upon a small river of the same name, which falls into the Tiber above La Farfa. In the days of Strabo it was a poor mean village, and was afterwards so totally destroyed, that its situation cannot now be ascertained. Cluverius, however, believed, that the ruins of it were to be seen in his time, about a mile from the town of Salici. If this be admitted, it stood near the banks of the river Heinella, the *P'Alia* of the moderns. Holstenius thought that Cluverius was mistaken in fixing upon a place now called "Il Vescovio" as the site of the ancient Cures. The abbé Chauppy, availing himself of some circumstances, which we need not recite, discovered on the Salar way, where the church of St. Anthime stood in the midst of a wood, very considerable ruins of Cures. These ruins were found in the territory of Fare, at a place called "Arcei," on the left bank of the river Correze.

CURETES, in *Antiquity*, a sort of priests, or people of the isle of Crete; called also *corybantes*.

The name Curetes, according to Strabo, was given them because of their cutting off the hair before, to prevent the enemy's taking hold thereof: the word being Greek, *κρυπτες*, of *κρυπ*, *tonsure*, from *κρυω*, *to*nd. Others derive it from *κρηστροφια*, the *feeding* or *educating* of a child; because they are said to have educated Jupiter.

The Curetes are said to have been originally of Mount

Ida, in Phrygia; for which reason they were also called *Idæi Daçtyli*. Ovid says, they had their origin from a huge shower of rain: Lucian and Diodorus Siculus represent them as very expert in casting of darts; though other authors give them no weapons but bucklers and pikes: but all agree in furnishing them with tabors and castanets; and relate, that they used to dance much to the noise and clashing thereof.

These Curetes are said to have inhabited the mountains, under the shade of thick trees, caves, and other places, which naturally afforded shelter and covering, as the art of building houses was not then practised. They were very ingenious, and invented a variety of things that proved highly useful to mankind; they first taught how to manage flocks, to gather honey, to tame horses, to hunt, and to cast darts. They formed men into societies and communities, and shewed them, by their example, the happiness of a peaceable and orderly life. They are likewise said to have invented swords and helmets, and to have introduced the custom of dancing in armour. By the noise they made in these dances, they prevented Saturn from hearing the cries of Jupiter when he was an infant, and, by that expedient, saved him from being destroyed by his father. The Curetes described by Diodorus Siculus (lib. v.) were, according to Herodotus, (lib. v. c. 58.), and Strabo, (lib. x. p. 464.); originally Phœnicians, who accompanied Cadmus out of Phœnicia; some of them settling in Phrygia, where they were called "Corybantes;" some in Crete, where they were known by the name of "Idæi Daçtyli"; and some in Rhodes, where they bore the name of "Telchines." Accordingly, Vossius (*De Idololat.*) distinguishes three kinds of Curetes; those of Ætolia, who inhabited Pleuron, those of Phrygia, and those of Crete, who were originally derived from the Phrygians.

The first, he says, took their name from *κρυπ*, *tonsure*; because, from the time of a combat wherein the enemy seized their long hair, they always kept it cut; but they are said to have suffered the hinder part to grow, that they might be caught by it if they offered to run away: those of Phrygia and Crete, he supposes, were so called from *κρηστρος*, *young man*; because they were young; or because they nursed Jupiter when he was young.

Clemens Alexandrinus (*Stromat. lib. i.*) calls the Idæi Daçtyli barbarians, that is, strangers; and says that they were the first who brought letters into Greece, Phrygia, and Crete; adding, that by their assistance Minos built a fleet, and gained the sovereignty of the sea. According to the authors now cited, the Curetes and Idæi Daçtyli were the same people, and did not settle in Crete till the time of Minos. Bochart (*Canaan, lib. i. c. 15.*) traces them to Palestine, alleging the similarity of their name to that of the Crethins or Cerethites, a Philistine tribe. See CRETE.

Some authors, however, give a different account of the Curetes: according to Pezron, and others, the Curetes were, in the times of Saturn, &c. and in the countries of Crete and Phrygia, and among the Titanic Celtes, what the druids and bards were afterwards among the Gauls, &c. *i. e.* they were priests who had the care of what related to religion, and the worship of the gods.

Hence, as in those days, it was supposed there was no communication with the gods but by divinations, auguries, and the operations of magic; the Curetes passed for magicians and enchanters: to these they added the study of the stars, of nature, and poetry; and so were philosophers, astronomers, &c.

Such were the Curetes, and after them the druids; with

this difference, that the Curetes, in the time of the Titans, went to the wars; for which reason they were armed, and were wonderfully dextrous in dancing cap-à-pie, shaking their bucklers and javelins: from which action, Pezron conjectures, they took their name Curetes; *curo*, in the Celtic, being the same with *κέρω* in the Greek; *q. d. I strike, or beat*.

It is uncertain, however, whether they went to the wars, and encouraged the combatants with their noise and dances, or were exempt from that duty as the druids were; but they must have been different from the bards, who, though of the same order, were, nevertheless, obliged to excite and encourage the people to war with their poetic compositions and musical performances.

According to Kircher, the Curetes were what the *spirits* are among the Cabbalists, the *powers* in Dionysius, the *demons* among the Platonists, and the *genii* among the Egyptians.

CURFEU, *q. d. couvre-feu*, a signal of retreat, given in cities taken in war, &c. to advertise the inhabitants to go to bed, and not to stir out any more.

The *curfew-bell*, wherewith the signal was anciently given, was sometimes hung up as a punishment of sedition. Pasquier says, it was called *carfou*, and *garefou*; as being intended to advertise the people to secure themselves from the robbers and debauchees of the night.

The most ancient curfew was that established in England by William the Conqueror; who appointed, under severe penalties, that, at the ringing of a bell at eight o'clock in the evening, every one should put out their lights, cover, or rake up their fires, and go to bed. Whence, to this day, where a bell is accustomed to be rung about bed-time, it is called *curfew-bell*. It was abolished by Henry I.

In reference to this subject, we may observe, that William of Malmesbury says, in his account of Henry I., "that he restored, in his court, the use of lamps in the night, which had been intermitted in the time of his brother." This is the single passage in any historian before Polydore Vergil, which seems to allude to the curfew, supposed by that author (lib. ix.) to have been introduced by an ordinance of William I., and mentioned by some later writers, as a mark of the slavery, in which he held the conquered English. It is plain, however, from these words, says lord Lyttelton, (Hist. Henry II. vol. i. p. 473.) that William of Malmesbury thought it was introduced by William Rufus, and extended to the whole court, that is, to the Norman nobles, as well as to the English, and, consequently, was no proof of the servitude of the latter. M. Voltaire says (Univ. Hist. t. i. p. 240.) "that the law, far from being tyrannical, was only an ancient *police*, established in almost all the towns of the North, and which had been long preserved in the convents." He adds this reason for it, "that the houses were all built of wood, and the fear of fire was one of the most important objects of general *police*." From the expression of William of Malmesbury, above cited, one should think that, in England, it had only been practised in the king's court, or was taken off *only there* by Henry I. And the foregoing words, *effeminatos curia propellens*, which introduce the whole sentence, and have a connection with it, appear to imply, that some unnatural crimes had been committed in the court, under the cover of the darkness; on which account the use of lamps was *there* restored by that prince. Upon the whole, as Polydore Vergil is too modern a writer to be of any authority, and all the ancient historians are silent about it, lord Lyttelton thinks there is reason to doubt, whether the law, or regulation he mentions,

was made by William I., or was ever so general as he represents it. The curfew-bell may have been only rung in the convents, and probably took its name from an old practice there, of putting out their fire and candles at 8 o'clock every night. In the "Leges Burgorum" of David I., king of Scotland, mention is made of it as marking the time when the watch should go out. As, therefore, the practice of it existed in Scotland, no less than in England, and as it was also a law of police, which William had previously established in Normandy, it could be no badge of a *conquest*, nor any evidence of a nation being enslaved.

CURFEU, Fr. An alarm bell. Formerly in strong, enclosed and fortified places, and particularly in frontier towns, it was customary to have a high tower or steeple, from which they could discover the movements of the enemy. He who observed, or kept a look-out, rung the large bell in it as soon as he discovered or saw from it any thing extraordinary. If he saw infantry coming towards the place he hoisted colours on the side by which it was approaching; but a standard, if he perceived cavalry; and both, if he observed infantry and cavalry. The moment he perceived fire in any place he also rung it. It was by the *beffroi*, or the large bell in the said tower or steeple, that they rung the curfew, when an officer went immediately to see the gates shut. In the morning the same bell was rung for the opening of them. After the founding or ringing of the curfew, the inhabitants were not permitted to leave or go out of their houses.

CURGIA, in *Ancient Geography*, a town of Spain, in Bætica. Ptol.

CURGIE, in *Geography*, a village of Scotland, with a small harbour, on the coast of the county of Wigton, in Luce bay; 3 miles N. from the Mull of Galloway.

CURGOS, or KURGOS, a large island of Egypt, situated on the Nile, several miles long, full of villages, trees, and corn, opposite to which is the mountain Gibbainy, a scene of ruins consisting of broken pedestals, plainly designed, says Bruce, for the statues of the dog, and some pieces of obelisk, with hieroglyphics, almost totally obliterated: this is conjectured by the same traveller to be the ancient city of Meroë, whose latitude should be 16° 26', and in this island, as he conceives, was the observatory of that famous cradle of astronomy. Curgos, he says, should, probably, be Purgos, the Ethiopians not being able to pronounce P, and not having such a letter in their alphabet; and Purgos was the tower or observatory of that city. Travels, vol. iv. 539.

CURIA, in our *Ancient Customs*, was sometimes used for the persons, as feudatory and other customary tenants, who did their suit and service at the court of the lord. And it was usual for the kings of England to summon the bishops, peers, and great men of the kingdom, to some particular place, at the chief festivals in the year; and this assembly is called, by our historians, *curia*; because they were consulted about the weighty affairs of the nation: whence it was sometimes also called *solemnis curia*, *generalis curia*, *Augustalis curia*, and *curia publica*, &c.

CURIA, in *Ancient Geography*, Coire, a considerable town of Rhætia.

CURIA, FRANCESCO, in *Biography*, a Neapolitan painter, was born about the year 1538, and studied under Lionardo da Pistoja. The churches of Naples possess many of his works, which, although they somewhat partake of the mannered style introduced by Vafari and the Zuccheri, are much esteemed for the spirit with which they are composed, the beauty of character in the heads, and truth of colouring.

His

His altar-piece of the circumcision in the church of the Pieta, was, by the common consent of Spagnoletto, L. Giordano, and Solimene, ranked amongst the finest productions of the pencil which Naples could boast. He died about the year 1610. Dominici.

CURIA, among the Romans, denoted a portion, or division of a tribe.

In the time of Romulus, a tribe being the third part of the 3000 foot of which his columns consisted, comprehended ten curiæ, besides 300 horsemen, each curia being 100; so that this legislator made the first division of his people into thirty curiæ or wards. These curiæ were again subdivided into 10 decuriæ.

Over the curiæ were appointed officers, called *curiones*, and over the decuriæ, others called *decuriones*: each curia and decuria having its peculiar commander. Romulus afterwards divided his small territory, which was not above five or six miles in extent, into three unequal parts; one of which was appropriated to the expences of religious worship, another reserved for the king's revenue and the exigencies of the state, and the third, which was the most considerable, divided into 30 portions, corresponding to the 30 curiæ. In the forming of a senate, consisting of 100 persons, each tribe named three senators, and each of the curiæ the like number, amounting in all to 99, and Romulus named the 100th, who was the head or prince of the senate, and the chief governor of the city, when the king was in the field. (See SENATE.) Romulus also ordered the curiæ to choose for him a guard of 300 young men, ten out of each curia, who were called *celeræ*, which see. In regulating the concerns of religion, he ordained, that each curia should have its own temple, and its peculiar gods and priests. He who presided over each curia was called CURIO, and he who presided over them all CURIO MAXIMUS.

Afterwards, *curia*, or *domus curialis*, became used for the place where each curia held its assemblies for performing divine service.

Hence, also, curia passed to the senate-house; and it is from hence the moderns come to use the word *curia*, court, for a place of justice, and for the judges, &c. there assembled. See COURT.

Varro derives the word from *cura*, *care*, *q. d.* an assembly of people charged with the care of public affairs: others deduce it from the Greeks; maintaining, that at Athens they called *κῦρια* the place where the magistrate held his assizes, and the people used to assemble: *κῦρια*, again, may come from *κῦρος*, *authority*, *power*; because it was here the laws were made.

CURIA *Curfus Aquæ*, in *Law*, a court held by the lord of the manor of Gravesend, for the better management of barges and boats using the passage on the river Thames from thence to London, and plying at Gravesend bridge, &c. mentioned in stat. 2 Geo. II. c. 26.

CURIA *Domini*, the lord's-house, hall, or court, where all the tenants attend at the time of keeping courts.

CURIA *militum*, a court so called; anciently held at Carisbrook castle, in the isle of Wight.

Et idem dominus Willielmus de insula facere debet scētam ad curiam domini castri de Carisbroc, de tribus septimanis in tres septimanas, in curia quæ vocatur curia militum.

CURIA *Penticiarum*, a court held by the sheriff of Chester, in a place there called the "Pentice," or "Pentice;" probably deriving its denomination from its being originally kept under a pent-house, or open shed, covered with boards. Blount.

CURIA, *Rectus in.* See RECTUS.

CURIA *Maria*, in *Geography*, an island in the Arabian Sea, near the SE. coast of Arabia; 40 miles long, and 16 broad. N. lat. 17° 20'. E. long. 55° 14'.

CURIA *Auxilium*, in *Law*. See AUXILIUM.

CURIACO, in *Geography*, a bay in Terra Firma, S. America, on the N. Sea.

CURIALITAS *Angliæ*. See CURTESY of England.

CURIAM, *Accedas ad*, in *Law*. See ACCEDAS.

CURIANUM, in *Ancient Geography*, a promontory of Gallia Aquitania, according to Ptolemy; supposed by M. D'Anville to be Cape Fernet, between the Adour and the Garonne.

CURIAS, *Cape Cavati*, or *Delle Gatti*, a promontory of the isle of Cyprus, at the extremity of the most advanced peninsula to the south of the island.—Also a town situated on the above-mentioned promontory.

CURIATA, *Comitia*. See COMITIA *curiata*.

CURIATII, in *Roman History*, three brothers, selected by the Alban general as champions for a contest with three other brothers, named Horatii, chosen by Tullus Hostilius, king of Rome, in order to decide the difference subsisting between Alba and Rome. A. U. C. 87. B. C. 667. On an interview between the two commanders of the hostile armies, the Alban general, declining to terminate the dispute by a single combat with Tullus Hostilius, according to the proposal of the latter, suggested that three champions should be chosen out of each camp for determining the quarrel. As soon as the agreement was known in the two armies, it excited a strong emulation among the young warriors for the honour of being chosen to this important combat. During the intermediate suspense, Fuffetius cast his eyes upon three Albans, of the circumstances of whose birth, Dionysius Halicarnassensis (lib. iii.) has given the following account: Sequinius, an illustrious citizen of Alba, had two daughters; one married to Curiatius, a citizen of Alba, and the other to Horatius, a citizen of Rome. These two sisters were brought to bed on the same day, each of three male children, who were at this interesting period in the flower of their age, and remarkable for their strength and dexterity. The Alban general having fixed on the three Curiatii, the king of Rome having his attention directed to the three Horatii, proposed the matter to them, who consulted their father on the occasion. The father, dreading the event, and apprized of the betrothment of one of his daughters to one of the Curiatii, hesitated for some time in complying with the wishes of his sons; but the love of his country ultimately prevailing over every other consideration, he left his sons to their own choice. When he was informed that in imitation of the Curiatii, they preferred a glorious death, or an important victory, to an inglorious life, he lifted up his eyes to heaven, and, embracing his children, exclaimed, "I am a happy father!" and then commanded them to announce to the king his consent.

The combat of the Horatii and the Curiatii being proclaimed in both camps, Tullus led the former, and Fuffetius the latter, whilst the people srewed the way, as they passed, with flowers, and put garlands on their heads; for they were considered as victims, who had voluntarily devoted themselves for their country. A plain lying between the two camps was chosen for the place of combat; and the two kings advanced with their champions and *feciales* to the middle, where, before the combat began, they concluded a treaty which served as a pattern for most of the treaties that were ever after made by the Romans. When this solemnity was finished, the champions advanced with a slow pace towards each other; and before they com-

menced the hostile attack, they embraced each other with all the expression of the most tender and sincere friendship. The spectators shed tears at the sight, and muttered complaints against the kings for causing such affectionate relations to shed the blood of one another. The tenderness of the young heroes, however, did not abate their courage; each of them resumed his arms, and selected his adversary. The combat then began with great impetuosity; the noise of their arms was heard at a great distance; and the air resounded with a confused mixture of shouts and acclamations from both camps, as either of the combatants appeared to have the advantage. The victory was long held in suspense, by the skill and valour of the combatants. At length the eldest of the Horatii received a mortal wound, and fell. At this fight the Albans triumphed, and the Romans were thrown into great consternation, which was soon followed with despair when they saw the second Horatius, pierced through by another of the Curiatii, expire on the body of his brother. However, the three Alban brothers were wounded, and the surviving Horatius appeared unhurt and vigorous. Thinking he was an unequal match for the three brothers together, he had recourse to a stratagem, and retreated as if he fled: Upon this the Curiatii pursued him at different distances as their respective strength allowed; Horatius, perceiving the success of his stratagem, and that they were separated from each other, hastily returned, and slew them all singly, before one could advance to the assistance of the other; and, elated with his victory, seized the spoils of the vanquished:—the Roman camp in the mean while resounding with joyful acclamations in honour of their hero. Thus Rome gained the superiority over Alba, its mother-city; which Fuffetius acknowledged on the field of battle, saluting Tullus as his sovereign, and asking him what were his commands. Tullus replied; “I command you to keep the Alban youth in readiness to march at my orders, in case I make war with the Veientes.”

As Horatius was returning to the city, he was met by his sister, who, perceiving him loaded with the spoils of the three brothers, among which was a military robe which she had wrought with her own hands for the Curiatius to whom she had been betrothed, could not forbear tearing her hair, beating her breast, and reviling her brother with the most reproachful and provoking words, for imbruing his hands in the blood of his relations. Horatius, flushed with his late victory, and enraged at his sister's unseasonable grief, killed her upon the spot, and then proceeded to the house of his father; who not only approved the action, but would not allow his daughter to be buried in the sepulchre of the Horatian family. However, upon the return of Tullus to Rome, Horatius was brought by some illustrious citizens before the tribunal, to take his trial. Thinking it dangerous to relax the rigour of the laws in favour of conquerors, they insisted on his being tried, and condemned, if found guilty. Tullus, anxious to manifest his regard for the laws, and at the same time solicitous for saving young Horatius, and also foreseeing that he would be censured by some for condemning, and by others for acquitting the criminal, dextrously changed the affair into a state crime, the cognizance of which did not belong to him, but to two commissioners, or duumviri, whom the king was to name. The crime was notorious, nor was it disowned by the prisoner; the duumviri, therefore, without delay, pronounced sentence against him, in these words: “We judge you to be guilty of treason; go, dictator, and tie his hands.” As soon as judgment was given, Horatius, by the king's advice, appealed to an assembly of the people, who revoked the sentence of the

duumviri, rather through admiration of his courage, says Livy, than for the justice of his cause. However, that the crime might not escape wholly unpunished, Horatius was condemned to pass under the yoke, an ignominy with which it was usual to treat prisoners of war, who had surrendered their arms. The king also appointed expiations to pacify the anger of the gods, provoked by this violation of the laws. Besides, the pontifices erected two altars, one to Juno, and the other to Janus, which were still remaining in the time of Augustus, together with the yoke, known by the name of “*Sorum tigillum*,” under which they made the criminal pass. Liv. lib. i. cap. 25, 26. Dionys. Hal. lib. iii.

CURICACA, in *Ornithology*, the name of a Brazilian bird, the wood-pelican of Catesby, and wood ibis of Pennant. See *TANTALUS loculator*.

CURICTA, in *Ancient Geography*, an island of the Adriatic Sea, on the coast of Illyria, according to Pliny and Ptolemy; called by Strabo *Cyralica*; the present isle of Vegia.

CURICUM, a town of the fore-mentioned island, now called *Vegia*.

CURICUM, a town of Asia, in Isauria.

CURIGLIANO, in *Geography*, a river of Naples, which runs into the gulf of Tarento; 5 miles N.E. of Corigliano.

CURIMATA, in *Ichthyology*, a name by which some authors have called the lavaretus, a small fish, of a sort of middle nature, between truttaceous and the herring kind, and caught in the American and German lakes.

CURING, is used for preserving fish, flesh, and other animal substances, by means of certain additions of things, to prevent putrefaction. One great method of doing this, is by smoking the bodies; that is, the making them to imbibe a great quantity of vegetable fumes: for this is usually done where wood is burnt. The reason of this sort of preservation is easily seen by the curious enquirer, since wherever wood, or any vegetable of the acid tribe is burnt, the acid particles go off with the smoke, and in this form penetrate into, and lodge themselves in animal substances exposed thereto; by which means this smoke acts upon them in the same manner that the fumes of spirit of nitre would do: and whether it be not a nitrous acid that tinges hams, herrings, &c. to a redness in the drying, is a subject worthy of enquiry. Shaw's Lectures, p. 152.

CURINI, in *Botany*, or Curiginil. Lam. Enc. Rheed. Mal. 7. 47. tab. 45. Baccifera indica; Rai. Hist. iii. 357. A plant little known, which has somewhat of the habit of a menispermum, and seems to have some affinity to cissus. Stems cylindrical, farmentous, somewhat woody, leafy. Leaves opposite, petioled, oval-acute, entire, soft, smooth, whitish-green above, deeper green underneath, with somewhat projecting nerves. Flowers small, yellowish-white, axillary, forming branched corymbs shorter than the leaves; petals five, green without, white and woolly within, a little hooked at the tip; stamens five, small; germ superior, roundish. Fruit. Drupe oval-oblong, bright green, with whitish and rather bitter flesh; nut hard, whitish; kernel white, slightly bitter, and astringent. A native of the East Indies.

CURIO, CAIUS SCRIBONIUS, in *Biography*, a Roman orator, distinguished for the part which he took in the civil war between Pompey and Cæsar. He was at first a partizan of Pompey, and selected to oppose the ambitious designs of Cæsar: but being of licentious manners, and overwhelmed with debts, he could not withstand the temptation of a high bribe

bribe offered him, and became the opponent of him in whose cause he had joined. In battle, with the troops of Pompey, he fought with vigour and success, but being afterwards led into an ambuscade, his troops were cut to pieces, and he himself fell either by his own hand, or in the general slaughter. This happened B. C. 48. By the poet Lucian, Curio is spoken of in extravagant terms of applause, but, by the historian Velleius Paterculus, he is described as "a man of noble birth, an accomplished speaker, bold, lavish alike of his own fortune and person, and of those of others, most ingeniously profligate and mischievously eloquent, one whose lust for money and for pleasure, no wealth, no enjoyments could satiate." By Plutarch, Curio is represented as the friend and associate of Cato in his early years. Plutarch. Univers. History.

CURIO, COELIUS SECUNDUS, was born at Chericco, in Piedmont, in the year 1503. He was educated at Turin, and made great proficiency in polite literature. He had not attained his 20th year, when he became attached to the doctrines of Zuinglius and Luther, and his zeal in their defence caused him to be thrown in prison, where he was confined for several months. Persecution did not in the least abate his ardour; his disposition being frank and engaging, he was dismissed the place of confinement, with recommendations that might have promoted his worldly interests; but having access to the relics of the monastery in the abbey of St. Benigno, he conceived and executed the plan of carrying away the holy shrine, and leaving in its place what to him was more holy and estimable, the Bible, inscribed with these words, "Hæc est arca fœderis, ex qua vera sciscitari oracula liceat, et in qua veræ sunt sanctorum reliquiæ." The day, however, was approaching, when the fraud would be discovered, and when, he was aware, the fury of the populace would not permit him to escape with his life, if he were even suspected of it; he, therefore, thought it prudent to retire, and we find him afterwards at Milan, and other cities of Italy. At the former place he resided many years, employed in the arduous and honourable task of education: but what raised his reputation the highest, were the courage and humanity which he displayed during a dreadful plague which ravaged that city. Neither dread of danger, nor the disgusting nature of the duties prevented him from visiting the sick, and supplying the various wants of the poor and the dying. In 1530, he married, and afterwards met with very unhandsome treatment from his own relations. At Turin he was, after the lapse of many years, arrested, on account of the shrine, and imprisoned. It was supposed that the most rigorous punishment would befall him, but he contrived to escape, went first to Milan, and afterwards to Pavia, where he gave lectures on the belles lettres: but his enemies were ever on the alert, and the inquisitors had orders to seize him; his scholars, however, and the people, in general, entertained for him so high a respect, that they formed for his defence a sort of body-guard; and thus he lived three years, when the pope himself interfered, and he was obliged to seek a retreat in Venice, and from thence he went to Lucca, where he not only met with a favourable and kind reception, but was appointed professor. Scarcely had he been at Lucca a single year, when orders were sent to the senate to arrest him; from them he received intimation of the design, and he determined to quit Italy for ever. He went to Lausanne, and was chosen principal of the college: his wife and children he had left at Lucca, till he knew whither he might conduct them in safety. When he thought himself secure, he went to Pisa, in order to bring his family to his

new residence; here, while he was at dinner in a public inn, he was arrested; the officer, out of respect probably, came alone into the room, to make known his business: Curio, advancing with his knife in his hand, so alarmed him, that he fainted, and the professor, who ever possessed great presence of mind, walked down stairs, through the attendants, who were not acquainted with his person, and escaped. He got to Lausanne in safety, and had the satisfaction of taking with him his wife and family, whom he met with on his road. He resided at Lausanne four years, and in 1547 he removed to Basil, where he held the office of professor of eloquence and the belles-lettres with the highest reputation for more than twenty years. He died, Nov. 24, 1569, in the 67th year of his age. He was author of many works written and published in the Latin, Italian, and French languages. On theological subjects, the most important were "Christiænæ religionis institutio, et de liberis educandis:" and "De amplitudine Regni Dei;" in the latter he endeavoured to prove that the number of the elect was greater than that of the reprobated: for this, one might suppose, harmless doctrine, he was denounced; and submitted to write an apology, which was published in the 12th volume of the *Amœnitates Literariæ*. Franc. 1730. Gen. Biog.

CURIO, the chief and priest of a curia.

Romulus, upon dividing the people into *curiæ*, gave each division a chief, who was to be priest of that *curia*, under the titles of *curio*, and *flamen curialis*.

His business was to provide and officiate at the sacrifices of the curia; which were called *curionia*; the curia furnishing him with a sum of money on that consideration: which pension or appointment was called *curionium*.

Each division had the election of its curio; but all these particular curiones were under the direction of a superior, or general, called *curio maximus*; who was the head of the body, and elected by all the curiones, assembled in the *comitia curialis*.

All these institutions were introduced by Romulus, and confirmed by Numa, as Halicarnassens informs us. Godwin will have two curiones in each *curia*.

CURIOSOLITES, in *Ancient Geography*, an ancient people of Gaul, in Armorica, so called by Cæsar, and placed by M. D'Anville N.W. of the Redones.

CURIOSI *Naturæ*, *Academy of the*. See ACADEMY.

CURIOSUS, an officer of the Roman empire, during the middle age, appointed to take care that no frauds and irregularities were committed; particularly no abuses in what related to the posts, the roads, &c. and to give intelligence to the court of what passed in the provinces. This made the curicfi people of importance; and put them in a condition of doing more harm than they prevented: on which account, Honorius cashiered them, at least in some parts of the empire, anno 415.

The curiosi came pretty near to what we call controllers: they had their name from *cura*, *care*; "quod curis agendis & evectionibus cursus publici inspiciendis operam darent."

CURIRI, in *Ornithology*, a variety of the *Todus paradisiæus*; which see.

CURISCHE-HAF, in Latin *Lacus* or *Sinus Curonicus*, in *Geography*, a lake, bay, or inland sheet of water formed at the estuary of the river Memel, in Prussia, joining the sea near Memel, and separated from the Baltic by a narrow ridge of land. It is 60 English miles in length, and about 30 in its greatest breadth, and derives its name from its situation in the ancient duchy of Curland or Courland. The coasts

crafts are inhabited by fishermen, who still go by the name of Cures, or Curen.

The Curische-Haf is full of dangerous sand-banks, and exposed to frequent and violent storms.

CURISCHE-NEHRUNG, that tongue or narrow ridge of land which separates the Curische-Haf from the Baltic Sea.

CURIUM, in *Ancient Geography*, a town and also a mountain of Greece in *Ætolia*.—Also, a town which, according to Strabo, was near the promontory of Curias, in the isle of Cyprus, lying to the N.E.; but, according to Ptolemy, it was separated from the promontory by the river Lycus. Curium was also the name of one of the small kingdoms into which the isle of Cyprus was divided. Strabo mentions an altar of Apollo, situated in this canton, so that any one who approached it risked being precipitated into the sea. The town is now called Piscopia; and the promontory Cape Cavati. See CURIAS.

CURIUS, DENTATUS MANLIUS, in *Biography*, an ancient Roman, who raised himself from almost the lowest rank, to the highest and most important offices in the state. He attained the rank of consul, B. C. 299, and shortly put an end to the long war that had been carried on between his countrymen and the Sannites: his courage and prudence fitted him for the difficult times in which he flourished. In some instances, the enemies of his country who were unable to conquer, or to cope with him, attempted, what has often proved a safer and a shorter enterprise, namely, to bribe him. The persons once employed to assail his virtue, found him cooking his humble meal with his own hands: he heard their offer, and manfully replied, “the man that could dine as he did had no occasion for gold:—that he accounted it more honourable to command the possessors of wealth, than to be rich himself; and that they might assure their countrymen, they would find it as difficult to corrupt as to conquer him.” Inflexible as the integrity of this patriot was, still he had his enemies: jealous of his superior talents, and envious of his well-earned fame, they accused him of converting, to his own purposes, part of the spoil taken from the enemy. He was examined on the subject, and confessed the fact—he had retained for his own use, a wooden oil-vessel for the purpose of making libations to the gods. On many occasions after this, he conferred on his country the most signal benefits; and on the defeat of Pyrrhus he had a magnificent triumph, exhibiting not only a vast quantity of rich spoils, but several captured elephants, animals that had never before been seen in Rome. The senate, on this occasion, offered him fifty acres of land, which the virtuous and self-denying consul refused, saying, that seven acres, the common share of every citizen, was enough for any man to live on. Of the latter days of this citizen we have no account: it is, however, recorded, to his honour, that he expended a large part of what he gained from the enemy in bringing the water of the river Anio to Rome. Plutarch. *Univerl. Hist.*

CURL, in *Agriculture*, is a vegetable disease which frequently attacks potatoe crops, producing a sort of crimped-up or curled appearance in the leaves. It is an affection which has been ascribed to various causes, by writers on vegetation; but the real nature of which does not seem to be well understood. Some situations are more exposed to the attacks of it than others; and in some it is said not to occur at all. This is the case, according to Mr. Headrick, in the little island of Arran in Scotland. It is likewise found by experience to be more common in such lands as have been long in the state of tillage, than in those which

have been newly broken up, or brought into the state of cultivation; and in grounds of the fenny and mossy kinds less frequently than in those of the more dry descriptions.

It has been stated in an interesting paper, inserted in the second volume of “Communications to the Board of Agriculture,” as having generally been supposed to be a specific disease, produced solely by contagion, not being conceived capable of arising without it; and that this contagion of necessity produces the disease in all crops with which it is permitted to come in contact. But this opinion is suggested, as appearing not to be well founded; as the disease does not necessarily propagate itself, which is sufficiently evident, it is imagined, both from observation and the result of experiment: for it is often found in fields of this sort of crops, that the most healthy plants are surrounded with those which are in the curled state; and that they not only continue in a state of health and vigour, while the crops remain on the land, but may even be afterwards mixed with them for a considerable length of time, without suffering any contamination. It is likewise ascertained, that healthy potatoes are afforded not only from such as have been thus mixed with those which were curled, but that it has been shewn by experiment, that they may be obtained from curled potatoes themselves, as will be seen below. It is also well known to farmers, that the curl often occurs where not any thing of contagion was communicated, nothing being more common than abundance of curled plants from roots selected with the greatest circumspection; from lands as well as districts, in which the disease has never been perceived. A farmer, whose potatoes had for two or three years been greatly injured by this disease, conceiving that it happened from infected seed, procured a large supply for himself, as well as some of his friends, from a district on the Tweed, where the disease at that time had never been seen: but it so happened, that, while some of the crops from these potatoes were entirely free from the curl, others, and particularly those planted by the farmer himself, were more injured by it than they had ever been before; which should not have been the case, if the common opinion were well founded, that the disease arises from an affection in the original set or root. Other causes must of course be sought for; and it is suggested, that those who take notice will find that whatever renders a crop poor and weakly is the most apt to produce the disease, and that it proceeds in a great measure, if not entirely, from this cause: and it is added, that the weakly state which affords it may be caused by a variety of circumstances, among which the following are the most frequent.

“I. In this district, the most frequent cause of it, perhaps, is the planting potatoes on ground altogether unfit for them. Potatoes require a light pervious or open mould, their germs not being of a nature that can penetrate a stiff soil. This, for a great length of time after potatoes first appeared in this country, met with such marked attention, that they were never planted but in the lightest spots upon the farm, and with such care that the plough was never employed for them: they were planted entirely with the spade, by which the soil was completely broken; hence they had vigorous plants, and rarely any appearance of curl. But on farmers wishing to extend the culture of potatoes, and being thereby induced to plant them on every variety of soil, as they now frequently do, the crops became weak, and the curl frequent. In the culture of every other crop, farmers take care to appropriate particular soils to each; for they know that they commonly fail, if this necessary piece of attention be overlooked. Those who have light sand only do

CURL.

not sow beans; while, on stiff clay soils, the culture of turnips is never attempted. In like manner, potatoes require a peculiarity of soil; and in so far as this is deviated from, the crop is commonly weak, and liable to curl. In a field of several acres, which every fourth year was planted with potatoes, about half an acre, or thereabouts," the writer says, "was stiff clay, while the rest was a free dark coloured loam, rather tending to sand than clay. On all this part of the field the crop was uniformly strong, and free of curl; while on the half acre of clay, although manured with the same quantity of dung, planted with the same seed, and in every circumstance managed in the same manner, the plants were all weak, and a great proportion of the whole curled.

"II. But imperfect culture is perhaps the most frequent cause of curl. This will be found to hold with such uniformity, that a crop of potatoes is commonly strong, abundant, and free of curl, in proportion to the previous culture given to the soil, and care taken to keep it clean after they are planted. This indeed is so remarkably the case, that, excepting in very kindly soils, the additional produce from trenching and planting with the spade is commonly more than sufficient to repay all the difference of expence between this mode of culture and that of planting with the plough. On a large scale, indeed, the spade cannot be employed, and plentiful crops are no doubt often obtained with the plough; but many are not sufficiently aware of the full necessity of ploughing and cleaning their grounds well before the crop is planted: for if the mould is not previously well broken, it cannot be done afterwards, so that the plants are weak from their first appearance, and a great proportion of the whole curled. The effect of complete previous tillage, in the culture of potatoes, is indeed so remarkable, that there is reason to believe, that the amount of our potatoe crop, in a great proportion of cases, would be more than double of what it commonly is, if the ground on which they are planted was previously put in better order. Of this many proofs might be given, but the writer only mentions two. A farmer, who every year planted several acres of potatoes with the plough, allowed his servants to plant nearly two acres for their own use; but these last, being commonly on spots of difficult access, could not easily be managed with the plough, and, being always in bad order, they were planted with the spade, in the form of what is usually termed lazy beds. The effect of this uniformity was, that although the crops, even of those planted with the plough, were always good, being sometimes at the rate of three hundred Winchester bushels on the Scotch acre, and weighing from eight to ten tons; the others, in different instances, weighed more than the double of this, and for the most part were entirely free of curl. And the writer soon after getting possession of a farm, being late in overtaking his potatoe crop, a considerable part of a field, which happened to be both full of root weeds and not sufficiently broken, was in that situation planted by his servants, before he knew of it; but half an acre, or thereabouts, being still worse than the rest, it was kept either with a view to give it a complete fallow, or to sow it with tares. The season, however, being dry, which favoured the cleaning of ground, this piece was three times ploughed, well harrowed after each ploughing, and the root weeds gathered and carried off. Being now in fine order, it received the same quantity of dung which was given to the rest; it was planted with potatoes taken from the same quantity, and in every other circumstance managed in the same manner: but the event was widely different. Although a week later in planting,

the crop was sooner above the surface; the plants were stronger from their first appearance, and scarcely a curled stem to be met with: while in every row of the others the curl was frequent. The ground was kept clean with less than a fourth part of the expence and trouble, the produce was more than double, the ensuing crop of wheat was considerably better on this piece, and the ground continued in every respect in better condition till the third crop, when more pains were taken with the rest of the field.

"III. The writer has reason from experiment to think, that small roots, or too small a portion of strong roots, being given to each set, has an influence in producing a weak crop, and curled plants. It is perhaps equally necessary, in the culture of potatoes, as in that of wheat, or any other crop, to make a choice of healthy full-grown seed; but this is not always done. Small potatoes are often indeed purposely kept for planting, instead of those that are full grown, and therefore more capable," the writer supposes, "of producing a vigorous progeny. In like manner, there is cause to suspect," he says, "that our frequent attempts of late years to discover new varieties of potatoes, by raising them from seed instead of the root, have had some influence in rendering the curl more frequent; plants raised from the seed being commonly, for the first two or three years, very weak and feeble. Sixty-four sets were planted: sixteen of which were full-grown potatoes; sixteen from small roots, in which no curl appeared when in the field; sixteen from roots raised from the feeds two years before; and sixteen from roots of plants strongly curled. They were all planted in the same manner, in a light soil, and in furrows parallel to each other, with a moderate quantity of dung to each, and covered to the depth of three inches. Of those taken from large potatoes, none were curled, and the plants were all strong and healthy. Some good plants appeared in each of the other rows, but nearly a half of the whole was curled. The proportion of curled plants was greatest in those lately raised from the seed; in the other two rows, they were nearly the same. The row planted with curled potatoes had seven curled plants, and the other only six; but in this last row, the other three were so weak from the first, that, although not obviously curled, they soon began to shrivel, and, in the course of two or three weeks, disappeared entirely.

"IV. It has," the writer says, "been mentioned by a noted planter of potatoes, that sets taken from roots that have sprouted early, and from which the germs have been rubbed, as is commonly done, with a view to the preservation of the sets, never fail to produce curl. The plants which succeed to the second production of germs are always very weak, and with such certainty produce curl, that he is induced to consider this as the only cause of it; but this attentive observer will find, that whatever tends to render a crop, or even particular plants in the crop, weak and delicate, will in like manner seldom fail to produce curl.

"V. Too much as well as too little dung appears," the writer says, "to have influence in producing curl: the first may probably act by corrupting the germ of the young plant; the latter, by not being sufficient to produce vigorous plants. This effect, resulting from an unequal application of dung, may perhaps be considered as the most frequent cause of that partial appearance of the curl, that we often meet with in fields managed all apparently in the same manner: for dung is often spread in such a careless slovenly manner, that, while some of the plants have none, others have it in too great a proportion, being sometimes covered with it to the depth of several inches.

“ VI. Too deep as well as too shallow planting,” he thinks, “ are both apt to produce the curl ; but the first of these errors is perhaps the most frequent. The sets should never be placed deeper at first than three inches, however useful it may afterwards prove to lay the earth up to the stems ; but instead of this, by the usual method of planting in drills, or ribs, as they are termed, and throwing two deep furrows over the plants, they are frequently covered to the depth of nine or ten inches : by which, from a total exclusion of air, and perhaps from other causes, the crop is always late in piercing the surface, and many of the plants are weak and curled. These ridges are indeed commonly harrowed down at last, but often not till it is too late. And where the plants are placed too near the surface, if the ground itself is dry, they rise in weak feeble stems ; and many are curled from want of moisture alone. With a view to ascertain the best depth for sets of potatoes, twelve were planted at eighteen inches deep, the same number at the depth of sixteen inches, fourteen, twelve, ten, eight, seven, six, five, four, three, and two inches ; and twelve were so lightly covered, that they were not perhaps at the depth of one inch. The sets were all from large roots of the same crop, and all as nearly as possible cut of the same size. They were all planted at the same time, in the first week of April, in a light dry soil ; and they all got the same quantity of dung ; and in every other circumstance were managed in the same manner. The plants at the depth of one and two inches appeared first ; but they were weak, and some of them curled. Those at three, four, and five inches were all strong, healthy, and entirely free of curl. At six and seven inches, they were also healthy and free of curl ; but they were three weeks later in getting above the ground than those that were thinly covered, and the plants neither so strong, nor the roots so large. Those planted at the depth of eight inches were still later in piercing the surface ; they were all weak, and nine out of the twelve were curled. Only four ever appeared of those planted ten inches deep ; and they were so weak, that they very soon withered and died. Of those placed at the depth of twelve, fourteen, sixteen, and eighteen inches, none ever appeared ; and on digging them up at the end of two months, those at sixteen and eighteen inches deep were found jult in the state in which they were planted, without any appearance of vegetation on any part of them ; while some of those at the depth of twelve and fourteen inches had put forth some feeble germs, none of them exceeding the length of an inch. Those planted at the depth of three and four inches were evidently the strongest plants during the whole season, and their roots largest. Those at five inches deep were nearly equally good ; but they were ten days later in appearing above the surface, and the stems never became so strong, nor the roots so large, as the others not so deeply covered. The writer is therefore convinced, from the result of this, as well as other experiments on the same subject, that about three inches is the best depth at which potatoes can be planted ; that the crop will be more or less early, abundant, and, in general, more or less injured with curl, according as the roots are placed at a greater or less depth than this. The result even of the same experiment, upon this point, may indeed be different in different sorts and seasons ; but he has much reason to think that in general it will be nearly the same.

“ VII. Whatever injures the new planted sets, or the germs afterwards, may produce curl : such as the sets being trampled upon and broken by the horses’ feet, in the time of planting ; particular sets being partially covered with

stones, or impenetrable clods of earth ; severe and deep harrowing, when the young shoots are advancing ; and grubs, snails, and other insects, destroying the germs at first, or the stems afterwards.

“ VIII. Some years ago, when on a journey, the writer observed a field with a greater proportion of curled potatoes than he had ever before seen, by which he was induced to inquire into the culture of the crop. The ground he found was stiff, and not having been sufficiently broken before the crop was planted, the farmer had passed a roller over it, about a fortnight after planting : the effect of which was, that many of the plants did not appear at all, and a very uncommon proportion of those that came forward were curled. This might in part be owing to the state and nature of the soil ; but, in a great measure, it seemed to depend upon the solidity given to it by the roller : for in the contiguous field, where the soil was exactly similar, the plants were more vigorous, and the curl not so frequent.

“ IX. The state of the weather, while the crop is young, has an obvious effect in rendering the curl more or less frequent. It does not appear that rain, in whatever quantity it may fall, has any effect, if it be not allowed to lodge, and if the soil is such as potatoes ought to be planted in, that is, a light pervious loam, with little or no tendency to clay. But we frequently find that a long continuance of dry weather, when the shoots first come forth, particularly when accompanied with severe cold winds, is very apt to produce curl. In the early state of the crop, too, frost seldom fails to produce it, particularly hoar-frost. This should lead farmers,” the writer thinks, “ to fix on that season for planting, in which they find from experience that their district of country is least liable to be injured by these causes, and chiefly by cold winds, frost, and a long continuance of dry weather. So far as the writer has observed, the first, second, or third weeks of April answer best for the south of Scotland, and north of England. Potatoes planted at this period do not appear till the middle or end of May ; after which, if it be not in low fields, contiguous to rivers or marshy grounds, in which hoar-frosts are frequent, they seldom suffer from frost ; at the same time that dry weather does not hurt them so much as it commonly does, when they do not appear till the middle of June, when, the heat and evaporation being more considerable, any scarcity of rain proves more particularly hurtful to all such plants as require a full supply of moisture, and which certainly is the case with potatoes, while the plants are young, and do not cover the ground. For although good potatoes cannot be raised on soils naturally wet, every farmer may observe, that nothing tends with more certainty to prevent curl, and produce vigorous perfect roots, than frequent showers in the early state of the crop. As a proof of the influence of winds on crops of potatoes, and in the production of curl, may be mentioned what the writer of this paper has several times observed, that, in the district of country in which he resides, where easterly winds commonly prevail during the months of April, May, and June, all such fields as are sheltered from this wind by high walls and hedges do not so readily produce curled potatoes as others commonly do. In two instances, in his own fields, it has happened, that the plants on these ridges immediately west of a stone-wall have been strong, and entirely free of curl, while the rest of the crop was poor, with several curled plants in every ridge, although the seed and culture were the same over the whole. The general result of all these observations,” the writer says, “ is, therefore, that the curl is not a disease, but only an accidental debility of those plants in which it occurs. We are not,” he thinks,

“ therefore,

“ therefore, to seek for a cure, or preventative, in a change of seed alone, as many have all along done, but in complete attention to all that experience shews to be necessary for an accurate culture of the crop; from which alone there is much reason to think, that this very useful article of life may be cultivated with the same success as before this dreadful enemy, the curl, made such havock in our crops. By proper attention to these observations, it is probable that this troublesome disease may in a great measure be removed.”

It has, however, lately been contended by others, that this affection of the leaves of the potatoe plant may proceed from the attacks of insects on the nutritive part of the set under ground, soon after it has been put in. This has been suggested as a cause, from the circumstance of having found some of the stems which came from a potatoe set very weak, and their leaves affected with the curl, while others from the same set were strong, vigorous, and free from the disease; and on the set being examined, its being discovered that the part from which the curled stems proceeded was wholly excavated, and the substance consumed by insects, while that portion from which the healthy stems came was perfectly free from their depredations. And in some cases it is imagined that the disease may arise from the leaves only, being attacked by numerous minute *animalcule*, without the substance of the set being hurt. The former is, however, suspected to be the much more general cause. The substance of the sets is found to be destroyed by insects of the snail, centipede, and beetle kinds.

And it has still more lately been supposed, by Mr. Knight, to be occasioned by moulding the plant; and that the method of preventing it is by permitting the potatoes to remain in a moderate state of heat, during the winter; and that the young shoots which appear in the spring should be taken off, when two or three inches in length, from the tuber, and planted out as sets, the plants from which will be perfectly free from the disease. From whatever cause this disease of the potatoe plant may, however, have its origin, there cannot be any doubt but that great benefit in preventing it may be derived, from having a nice attention to the preparation of the land on which it is to be planted, to the proper season of planting, and to having the culture of the crop afterwards well executed, as upon these much in all situations is found to depend. See POTATOE.

CURLEW, in *Ornithology*, the English name of the *arquata* or *numenius*, or *SCOLOPAX arquata*; which see. See also *SCOLOPAX phaeopus* and TANTALUS.

CURLEW *Mountains*, in *Geography*, are situated in the county of Sligo, Ireland, between Loughs Gara and Arrow, on the borders of the county of Roscommon.

CURLEW, *stone*, in *Ornithology*, a species of the *charadrius edicnemus* of Linnæus and Gmelin, the *pluvialis major* of Brisson, the thick-kneed bustard of Latham, and the Norfolk plover of Pennant. It is called *edicnemus* from its thick legs, with a remarkable swelling below the knee. Its specific character is, that it is grey, its two primary wing-quills are black, in the middle white; its bill is sharp, and its feet are cinereous. It is a migratory bird, appears in England about the middle of April, and retires in autumn. It is remarkable for a piercing shrill noise, which it begins in the evening, repeating the cries *túrrlui, túrrlui*, which re-echoe from hill to hill, during the months of September, October and November, in the provinces of Picardy, Orleans, Beauce, Champagne and Burgundy, in France; and as these resemble the articulated sounds of the curlew, it has hence been called the land-cowlew, or coulis de terre. It breeds in rabbit-burrows, and also lays its eggs, which

are two, of a copper colour, among the stones on the bare ground. It feeds in the night on worms and caterpillars, and it is said they will catch mice. Its flesh is esteemed very delicate food. In habit, make, and manners, this bird approaches near to the bustard. See OTIS.

CURLIGNANO, in *Geography*, a town of Naples, in the province of Otranto, 8 miles W. of Otranto.

CURMI, a name given by the ancients to a sort of malt liquor or ale. It was made of barley, and was drank by the people of many nations instead of wine, according to Dioscorides's account. He accuses it of causing pains in the head, generating bad juices, and disordering the nervous system. He also says, that in the western part of Iberia, and in Britain, such a sort of liquor was in his time prepared from wheat instead of barley.

CURMILIACA, in *Ancient Geography*, a place of Belgic Gaul, situated, according to the itinerary of Antonine, between Samacobriva and Cæsaromagus; corresponding to the present Corneille D'Anville.

CURNOCK, a measure of corn, containing four bushels or half a quarter. *Fleta*, l. ii. c. 12.

CURNONIUM, in *Ancient Geography*, a town of Spain, placed by Ptolemy in the Tarragonenian territory, in the country of the Vasconi.

CUROBIS or CURABIS, now *Gurba*, a town of Africa in Zeugitania, 7 leagues from Clybea, or ancient Clypea or Clupea. This is the Curobus of Ptolemy, who places it on the sea-coast near the promontory of Mercury, between the towns of Clypea and Neapolis, over against Sicily. It was formerly episcopal, and a considerable place; but at present the ruins of a large aqueduct, with the cistern that received the water, are the only antiquities which it affords.

CUROPALATA, or CURAPALATI, in *Antiquity*, an officer of the palace of Constantinople, to whom the care and ceremonies of the palace were entrusted. This officer occupied an illustrious rank in the age of Justinian, but was supplanted by the “Protovestiare,” whose primitive functions were limited to the custody of the wardrobe, from whence his jurisdiction was extended over the numerous menials of pomp and luxury; and he presided with his silver wand at the public and private audience.

CUROPOLIS, a town of Asia Minor in Caria.

CURRADI, CAV. FRANCESCO, in *Biography*, a Florentine painter, who was born in the year 1570, and studied under Batista Naldini. The churches and palaces of Florence possess many of his works, which, as he lived to the great age of 91, differ much from each other in point of style. One of his best altar-pictures is that of S. Saverio in the church of S. Giovanni. His works upon a smaller scale are much admired. Of this kind the gallery of Florence exhibits stories of Mary Magdalen, and the Martyrdom of S. Tecla, executed in his best style. Lanzi Stor. Pitt.

CURRAGH, *the*, in *Geography*, a celebrated common in the county of Kildare, Ireland, where there is a remarkably fine race course, and which is also used occasionally for encampments. It consists of above three thousand acres of a soft and verdant turf composing one uninterrupted lawn, varied only by the pleasing undulations of a few gentle hills. It was formerly covered with wood, and was sacred to religious purposes. It is near the town of Kildare, and affords pasture to an immense number of sheep. Beaufort. Robertson.

CURRAGHROE MOUNTAINS are situated in an angle of the county of Tyrone, Ireland, adjoining Donegal.

CURRAN, a town of Hindoostan, in the country of Allahabad; 30 miles N.W. of Allahabad.

CURRAN-Lough, a lake of the county of Kerry, Ireland, in the wild barony of Inveragh, the river issuing from which falls into Ballinaskellig's bay. It is of an oval form, 3 miles in length and about half as broad, and abounds with white trouts and salmon. There are some small islands, one of which are the ruins of a church and other buildings. Smith's Kerry.

CURRANT, in *Botany*, See RIBES.

CURRANT-Tree, in *Gardening*, is a small well known fruit tree or shrub, of which there are different species and varieties. See RIBES.

This useful fruit-shrub is said to have been brought from the isle of Zant, and planted in this country about the year 1533; and different sorts have since been introduced from Holland. In the different sorts of these kinds of fruit-bushes, there are different colours in the fruits which they afford; thus we have red, white, and black currants, as well as various shades of the red, from which circumstance, when the two first sorts are used at the table in mixture well arranged, they produce a very pleasing effect. From the juice of the red kind a jelly is prepared by boiling with lump sugar, which is much employed in sauces and other culinary purposes. And from the black kind a rob is frequently made, which is in high estimation by some as a simple remedy in cases of sore throat, and from the great use of the fruit in quinties, the produce has sometimes been denominated squinancy berries.

The produce of the red and white currant, besides being much esteemed as a table fruit, and for kitchen uses, is likewise valuable in febrile complaints from its grateful cooling effect on the stomach, and quenching thirst. It has also considerable restraining property; and the black sort is highly astringent; from which circumstance, and its strong disagreeable flavour, it is more rarely admitted to the table.

All the different kind of these trees are propagated with much facility by planting out cuttings made from the strong straight shoots, as well as by layers from the side branches; which, when they have become well rooted, should be removed in the autumn, or early spring months, into nursery rows, where they should be properly managed till they have attained a proper growth for being placed out where they are to remain for fruiting. In doing this they may either be put out as standards in rows, at four or five feet distance from each other, and six, eight, or ten feet apart in the rows, or be set out against walls or palings, to which they may be nailed, or trained as espaliers, in which latter methods they occupy less room, and afford finer fruit. Being trained horizontally they will require to have nearly the same distances as in the standard method, in these modes of planting them; the best season of doing which is in the early autumn. And they succeed the best in soils of a rich sandy quality which has been well trenched over to the depth of two feet, and well rotted dung put in, and where the situation is open.

These sorts of fruit bushes stand in need of a regular annual pruning, after they have arrived at the state of bearing fruit. They produce their fruit on the preceding year's wood as well as on studs or spurs. Therefore all the last year's lateral shoots should be cut off so as to leave only an eye or two on each, being careful not to rub off or injure the spurs; and the young leading shoot of each bearing branch should be shortened generally to about one-third of its length, but more or less according to the strength of the bearing branches in general. From the general luxuriant growth of the shoots of the currant, they mostly re-

quire considerable shortening. When the bearing branches become weak and unfruitful, they should be cut out, and strong young shoots be let come from the stem or roots to supply their places.

Thus, in the standards, by permitting the bushes to extend in height, only in a gradual manner, and keeping the bearing branches sufficiently thin, they produce better fruit, and in greater abundance; besides, the bearing branches become strong, and are not liable to be forced down to the ground by its weight. This way of pruning has also the advantage of enabling the bearing branches to throw out spurs on every part of them, so that fruit is afforded on every part of the bushes from the stem near the surface of the ground to the very extremities of the shoots, scarcely any portion being naked of a supply. See RIBES.

This is a sort of fruit which, by proper management in respect to situation, may be preserved much longer upon the plants than most others. In this view some should be planted against pales or walls which have a southern aspect, by which the fruit may become ripe more early, as in June; and others against northern fences of the same kinds, which, by being well protected from the early autumnal frosts, and well secured from birds by being covered with mats, may have their fruit continued hanging upon them until the end of October or longer; which is an advantage in respect to its culinary as well as other uses.

CURRANTS, in *Commerce*, a kind of little raisins, or dried grapes of different colours, black, white, or red; brought from several places of the Archipelago, and among others, from the isthmus of Corinth; whence their name, *currants*, q. d. *Corinths*.

They must be chosen new, small, and in large masses; and care be taken, that the little Spanish currants be not soiled in their room. When made up in bales, they may keep two or three years, without stirring, or giving them air. Their use is in seasoning several viands, and in some medicinal compositions; where they serve in lieu of raisins. Sir George Wheeler's account of these fruits, and the manner of preparing them, is very curious. The island of Zant, he observes, is the chief place whence currants are brought: the Morea, or the isthmus of Corinth, which was anciently the principal plantation, and whence the Latins denominated them *uvæ Corinthiaca*, now produces no more, as having been much neglected; the jealousy of the Turks not allowing large vessels to enter the gulph to take them off their hands.

They do not grow on bushes, like our gooseberries, though that be the common opinion, but on vines, like other grapes; except that the leaves are somewhat thicker, and the grapes somewhat smaller; they have no stone, and, in this country, are all red, or rather black.

They gather them in August, dispose them in couches on the ground till they be dry, clean them, and lay them up in magazines, which the natives call *seraglios*; pouring them in at a hole, till the magazine be full. They cling so fast together by their own weight, that they are forced to be dug out with iron instruments.

To barrel them for sending abroad they have people who grease their feet and legs, and tread them close, that they may keep the better. They are sold for about twelve crowns the thousand weight; and pay as much custom to the state of Venice.

Zant produces enough yearly to load five or six vessels; Cephalonia three or four; and the other islands one. The English have a factory at Zant; the Dutch two or three merchants, and the French one: the English consuming more than six times the quantity that both France and Hel-

land do together. Those of Zant know but little of the use we make of them; being persuaded they only serve in dyeing of cloth; and being entirely ignorant of the luxury of Christmas pyes, and English puddings.

CURRENT, COURANT OF CURRENT money, good money, or that which passes in commerce from one to another. See **COURANT**.

CURRENT accounts. See **BOOK, COIN, and PRICE**.

CURRENT, Currenato, also denotes a sort of running French dance; sometimes, a musical air in triple time. See **COURANT**.

CURRE, an English name for the fish called by authors *euculus*, and by us more frequently named the red gurnard. See **TRIGLA Cuculus**.

CURRENCY, in *Commerce*, denotes the coin or paper used in any country as a circulating medium for the purposes of commercial intercourse. See **CIRCULATION and PAPER-Money**.

CURRENT, Substantive, (from the Latin *currans*, running) denotes the progressive movement of any thing; but it is chiefly applied to the progressive movement of fluids, especially of air, of electricity, and of water.

Currents of Air.—The various movements of the air have obtained a variety of specific names under the generic appellation of winds, and these names are principally derived from the velocity, direction, and duration of the movements. Hence we have the names breezes, gales, trade winds, monsoons, &c. A peculiar movement of the air is likewise the principal propagator of sound; though not the only one; for sound is also propagated through solids. But the difference between wind and sound is, that the former consists in a progressive motion of the air from one place to another; whereas sound is propagated and conveyed from the sonorous body to the ear, by means of a vibratory motion of the air, the particles of which, in that case, move a very little way backwards or forwards, from their situations, and at the end of every other vibration, are to be found precisely at their original places. See the article **SOUND**.

The winds generally owe their origin to the rarefaction or condensation of the atmospherical fluid; and, in the strict sense of the word, they actually are currents of air; yet the last denomination has been peculiarly applied to a constant and general movement from east to west, which the air of our atmosphere has been observed to have; but the nature of this current, as well as the probability of other aerial currents, being intimately connected with the common winds, the whole will be examined under the article **WIND**.

Currents in Electricity. The extensive and wonderful phenomena of electricity exhibit two powers diametrically opposite to each other; and it seems, that if it were not for the mutual opposition of those two powers, hardly any electrical effect would take place. By friction and other means several bodies are electrified, or have an electric power excited in them, which power is conveyed from the excited body to another, through certain substances, which are therefore called *conductors*; but it is not conducted by other substances, which, therefore, are called *non-conductors* of electricity. When glass is thus excited by friction with the human hand, and a pointed metallic wire is presented to it in a dark room, a small luminous spark, nearly globular, will appear on that point. When a lick of sealing-wax, or of resin is excited by the like means, and the pointed wire is presented to it, a pretty long luminous brush, nearly of a conical form, will be seen with its apex touching the point of the wire. These appearances are the distinctive characteristics of the two electric powers, one of which has thereby

been called the *vitreous*, and the other the *resinous* electricity. Another very remarkable distinction is, that if two or more bodies are possessed of the same kind of electricity, viz. either of the vitreous or of the resinous, and are freely suspended by means of flexible nonconductors within a certain distance of each other, they will manifest a considerable degree of repulsion; but if one or more bodies be electrified with the vitreous, and an equal number of similar bodies be equally electrified with the resinous electricity, and all these bodies thus differently electrified be brought within a certain distance of each other, a powerful attraction will be observed between the same, which brings them into contact, and as soon as they touch, every appearance of electricity will vanish. It is farther to be observed, that these two opposite electrical powers always appear together, or the one cannot exist without the other; for instance, if a body be electrified with the vitreous electricity, then the other bodies, or the air which is contiguous to it, will of course acquire the resinous power, and *vice versa*. If one of these powers be communicated to one side of a plate of glass, the other side will naturally acquire the other power. Upon an attentive consideration of these phenomena, and of others of a similar nature, two principal theories have been formed, besides several others, which, being evidently defective or absurd, are at present entirely disregarded. One of these theories supposes that there are two distinct electric fluids; viz. the vitreous and the resinous. Each of these fluids is attractive of the other, but itself elastic, that is, its own particles repel each other, hence bodies possessed of different electricities attract each other. The other theory, which goes under the name of the Franklinian theory, supposes that there is only one electric fluid whose particles repel each other, but they attract every other kind of matter; in consequence of which this fluid is dispersed throughout the universe, and every body possesses a certain quantity of it. According to this hypothesis, when a body is excited, either an additional quantity of electric fluid is accumulated upon it, which must have been taken away from other bodies, or a portion of its natural quantity has been abstracted from it. In consequence of this supposition the two electric powers have been called the *positive* and the *negative* electricities; the positive answering to the vitreous, and the negative to the resinous powers. Now both these theories have been so well adapted to the phenomena as that either of them is sufficient to account for the phenomena of electricity, excepting, however, those of one kind; namely, of those experiments which manifest an evident current from the positive or vitreous, to the negative or resinous power; for these results can only be explained upon the Franklinian hypothesis of a single electric fluid. Therefore, in the present article it is incumbent upon us to point out the nature of electrical currents, briefly describing the principal of those experiments which shew the direction of these currents in a clear and decided manner; and it is for the purpose of elucidating the nature or the dependance of these currents, that the above short statement of the leading phenomena of electricity has been premised.

Two sorts of electrical currents must be remarked. One sort consists of those which move in the same direction, whether they be caused by the vitreous or by the resinous electricity. The currents of the other sort are those which always proceed from the vitreous or positive, and run towards the resinous or negative power.

If a pointed metallic body proceeds from an electrified prime conductor of an electrical machine, and the face or the hand be presented to it at the distance of a few inches, a slight but perceptible wind will be found to proceed from the

point; and this is the case whether the prime conductor be electrified positively or negatively. The cause of this result is, that bodies possessed of the same kind of electricity, repel each other; for as soon as each particle of air, contiguous to the pointed body, has received some electricity from the point, it is immediately repelled by it, and other particles succeed, which are electrified in their turn, and are immediately repelled; hence a continual current or wind proceeds from the point. This effect may be rendered still more evident by presenting the flame of a candle to the point, for this will be always blown from it. The same effect takes place when the electrical fly (*viz.* a little apparatus of metallic wires, see *Electrical Fly*) is used; *viz.* the fly will always turn the same way, whether it be electrified with the vitreous or with the resinous electricity; for the wind which proceeds from each point of the fly, produces a counterpressure which impels the fly the contrary way.

If the wire at the end of the prime conductor be furnished with a brass ball of about three quarters of an inch in diameter, and whilst the machine is in action, the flame of a candle be presented to it, this will be blown from the ball when the prime conductor is electrified with the vitreous or positive electricity, and towards the ball when the prime conductor is electrified with the resinous or negative power. The result of this experiment is evidently in favour of the Franklinian theory of a single electric fluid. It may, however, be asked why the flame of the candle is blown towards the wire when the ball is upon it in the latter case, and from it when it terminates in a point? The answer is, that the electricity which proceeds from the point, being incomparably more copious than that which proceeds from the ball, electrifies the air contiguous to it, and produces a current of it which counteracts the direction in which the mere afflux of electric power would impel the flame. In the performance of this experiment care must be had not to use a ball too large or too small; the action of the machine must, likewise, be regulated in a manner suitable to the size of the ball. But with respect to these particulars, experience alone can instruct the operator.

Place a lighted piece of wax-candle between the knobs at the ends of the wires of the universal discharger, (see *Universal Discharger*) so that the flame may stand midway at the distance of about one inch from each knob. Then connect one of those wires with the outside coating of a charged electrical jar, and touch the other wire with the knob which communicates with the inside-coating of the jar; and thus on making the discharge which must pass from one wire to the other, through the flame of the candle, it will be found that the flame is always driven in the direction of the electric fluid, that is, it will be blown upon the knob of that wire which communicates with the negative side of the jar. For this experiment the jar must contain an exceedingly small charge, *viz.* just sufficient to pass through the interval in the circuit, which experience will readily determine; otherwise the experiment will not succeed. If it be asked why this experiment does not succeed with a great charge as well as with a very small one? The answer is, that when the jar is highly charged, and is brought near one of the wires of the universal discharger, it creates an atmosphere about the knob of that wire which disturbs the flame of the candle, before the discharge actually takes place. Besides, the electric fluid in a great explosion, being actuated by its great elasticity, which is proportionate to its condensation, passes through the flame of the candle too swiftly to communicate any distinct motion to it, in the same manner as when a bullet is discharged from a gun against an open door,

which makes a hole through the door without shutting it.

Bend a card in the form of a half cylinder, *viz.* so as to form a semi-circular groove. Lay it upon the circular board of the universal discharger, and place a pith-ball of about half an inch in diameter in the middle of it. Let the two brass knobs on the wires of the universal discharger be disposed so as to stand on each side of the pith-ball at the distance of about three quarters of an inch from it. The card must be perfectly dry and rather hot. Now, if you connect one of those wires with the outside of a charged jar, and touch the other wire with the knob of the jar, the charge will be sent from one wire to the other, along the channel in which the pith-ball is situated, and this will be found to be driven from the positive to the negative side. In this experiment, also, the charge of the jar must be very low, the card must be very clean and dry, also the distance of the brass knobs from the pith-balls must be nicely adjusted, otherwise the experiment is apt to fail.

Let a card be laid upon the circular board or tablet of the universal discharger, and place the pointed wires of the same so that one point may touch the upper, and the other may touch the lower surface of the card. Let the interval between these extremities of the two wires be about one inch; then send the charge of a pretty powerful jar through those wires, in the same manner as directed in the preceding experiment, and it will appear from the luminous track, that the electric fluid runs over that surface of the card which touches the wire that communicates with the positive side of the jar, and in order to pass to the extremity of the other wire, it breaks a hole through the card just over the extremity of that other wire, which is connected with the negative side of the jar.

The last experiment which we shall mention must be performed with an electrical battery, or at least, with three or four large jars connected together. When the charge of such a battery is sent through a slender wire of any metallic substance, and of a considerable length; *viz.* of a foot or upwards, the discharge generally melts and disperses either part of the wire, or the whole of it; but if the charge of the said battery be diminished, so that the discharge be just able to render the wire red-hot, without actually melting it, then it will be found that the redness appears first at one end of the slender wire; *viz.* that which communicates with the positive side of the battery, and thence proceeds successively to the other end of the wire. This result is an ocular demonstration of the theory of a single electric fluid. Indeed the wire is not rendered red-hot at one end before the other, in consequence of the electric fluid passing first through the former, and then through the latter; that difference of time being by far too small to be observed; but, because the electric fluid loses part of its impetus or velocity, in going through the wire; so that the extremity of the wire which the electric fluid enters at, suffers the greatest effect of the shock, and, of course, becomes red-hot sooner, in a greater degree than the rest.

CURRENTS, in *Hydrography*. Two movements of different kinds have been observed, by which the waters of the sea are impelled in some horizontal direction from one spot towards another; namely, *tides* and *currents*. The motion of the waves when the wind prevails, seems to urge the water in the direction of the wind; but in truth they do not; they only raise and depress the water of the same spot alternately. (See *WAVE*.) The action of the wind, however, undoubtedly urges the waters in its direction; but that movement is so very slow, as hardly to be perceived,
even

CURRENT.

even in a pretty hard gale; for instance, if a man on shore fixes his sight on a piece of wood floating at the distance of about a mile, he will find that the piece of wood rises and falls alternately, according as the waves do; but its motion from that spot will perhaps not exceed a quarter of a mile in an hour; and such is nearly the motion of the waters which surround the floating piece of wood.

The difference between tides, and currents properly so called, is, that the former follow, with alternate rising and falling, the daily motion of the moon, and, likewise, in some measure of the sun; whereas the currents continue in one direction much longer. As both the tides and the currents are matters of the utmost consequence in navigation, no pains have been spared to examine, and to investigate the causes of all the various phenomena which attend them; such as, their periods, their velocities, their directions, the places in which they prevail, and so forth. The observations of navigators, the experiments and the calculations of philosophers, on this interesting subject, are very numerous; and, though they have not as yet been able to form a general theory sufficient to account for all the phenomena; yet it must be acknowledged, that they have furnished the present generation with much useful information, which is daily deriving additional lights from the assiduity of numerous able and industrious observers.

The tides, which are rendered more apparent on the coast, by their flowing and ebbing, depend principally on the attraction of the moon, but in some measure also upon the attraction of the sun; for when those two celestial bodies happen to be in the same direction, the tides are sensibly greater than when the moon alone acts upon the waters of the sea, which is the case when the sun is at some apparent distance from it. "Every day, about the time of the moon's passing over the meridian, or a certain number of hours later, the sea becomes elevated above its mean height, and at this time it is said to be high water. The elevation subsides by degrees, and in about six hours it is low water, the sea having attained its greatest depression; after this it rises again when the moon passes the meridian below the horizon, so that the ebb and flood occur twice a day, but become daily later and later by about $50\frac{1}{2}$ minutes, which is the excess of a lunar day above a solar one; since $28\frac{1}{2}$ lunar days are nearly equal to $29\frac{1}{2}$ solar ones." Thus much concerning the tides has been thought necessary to be inserted in this place, for the purpose of making a proper discrimination between them and the currents; but the full account of the numerous and interesting particulars relative to the former, will be found under the article *TIDE*.

CURRENTS at Sea, are progressive movements of the waters, which carry vessels, or any thing floating upon them, in their directions, and precisely with their own velocity, when no wind prevails; or, if any wind acts upon the vessel, the current will increase or check its rate of going, according as the wind happens to blow with, or contrary to its direction. Hence, in reckoning the ship's run, due allowance must be made for the action of currents.

The currents do not, like the tides, change their directions after the lapse of a few hours; yet some of them run one way during a few days; others continue a few months in one direction, and then alter their course, or vanish altogether, whilst others run continually the same way. The extent of currents, their breadths, their depths, and their velocities, are also various, and often fluctuating. Some, for instance, run along immense tracts, and spread a vast way, whilst others are observed close to some particular coast or strait, and not farther. Some reach very deep, and others are very superficial. The velocities of some cur-

rents are remarkably great; but in general when the periodical currents are near the period of their termination, they generally slacken their pace.

Currents are either *general*, *particular*, or *variable*.

General currents are those which are always directed towards the same point of the compass.

Particular currents shift from one direction to its opposite in the course of about six months.

And variable currents are those which have no stated period, and are generally affected by the wind; one twentieth part of the velocity of the wind being equal to that of the current.

There are also upper and under currents; that is, the waters at the surface move in a contrary or oblique direction to those at the bottom. And there are currents at the surface, at no great distance from each other, which move in opposite directions.

The principal current of the aqueous part of our globe is observed in its broader and more exposed surface. Its general direction is from the east towards the west; viz. contrary to the motion of the earth in its diurnal revolution. This current comes from the Pacific and Indian oceans, round the Cape of Good Hope, along the coast of Africa; thence it passes over to America, where it divides itself into two branches, one of which is reflected southward, toward the coasts of the Brazils, and the other northward, into the gulf-stream (see *GULF-STREAM*), which proceeds round the Mexican gulf, advances north-eastward in the vicinity of Newfoundland, after which it probably returns eastward and south-eastward, crossing the Atlantic once more. "The atmosphere also seems affected by a general current from east to west, like that of the sea; and there is reason, from astronomical observations, to suppose that a similar circumstance happens in the atmosphere of Jupiter, on account of the actions of his satellites, which must be considerably more powerful than that of the moon."

"These currents," Dr. Th. Young observes, "as well as the general current of the sea, have been attributed, by some astronomers, to the immediate attractions of the sun and moon, and of the satellites of Jupiter, which they have supposed to act in the same manner as the attraction of the sun operates in retarding the lunar motions. But the fact is, that according to Mr. Laplace, the disturbing force of the sun produces this effect on the moon only in proportion as it increases her distance from the earth; consequently, no such retardation can possibly be produced by the force of gravitation in the rotation of the sea, or of the atmosphere, and the whole effect must be attributed to the operation of meteorological causes, producing first the trade winds, and secondly occasioning, by means of the friction of those winds, a similar motion in the sea."

Another remarkable constant current is that which runs from the Atlantic into the Mediterranean, through the straits of Gibraltar; a channel of about seven leagues. The velocity of this current is in some measure influenced by the state of the winds, according as they may either conspire with, or blow against it. However, its ordinary velocity, at the narrowest part, is about two miles an hour; but this velocity slackens as soon as the channel becomes wider, and soon after disappears. It is said that at the sides, and especially on the south side of the Straits, there is a current outwards. (Phil. Trans. vol. xxxiii.) It has likewise been asserted that the currents run in contrary directions on the opposite coasts. (Phil. Trans. for 1762.) And Mr. Robison says that the current sometimes runs outwards in the middle of the Straits. It appears, however, from the constant observations of mariners, that if any such outward currents do

really

really exist, the breadth of that which runs into the Mediterranean is incomparably larger than the former. Now the question is, what becomes of that immense quantity of water which thus continually runs into the Mediterranean, which sea has no other visible communication with the ocean? A variety of conjectures have been offered in explanation of this remarkable phenomenon; and though some of these conjectures are attended with an appearance of probability, yet we are by no means possessed of a clear and satisfactory theory concerning it. We shall briefly state the principal hypotheses respecting this question, together with the reasons by which they seem to be supported or invalidated. But previously to this, it will be necessary to mention certain facts of importance in the present case. The straits of Gibraltar are unfathomable; hence the depth of the water must at least exceed one mile. The surface of the Mediterranean seems to have remained at the same level during at least a century or two; nor are the low lands on the coast of Africa, or elsewhere, ever overflowed. But between the present time and a remote antiquity, *viz.* a period of about 2000 years, the rising of the water a few feet has been deduced from the following documents. The floor of the cathedral of Ravenna is at present several feet lower with respect to the sea, than it is supposed to have been formerly. Some steps have been found in the rock of the island of Malta, apparently intended for ascending it, which at present remain under water. In the bay of Naples, and on that part of the coast which is nearest to the famous grotto of Posilipo, vestiges of several ancient houses are at present visible under water, which formerly must undoubtedly have been out of it. The like thing is also to be observed on several other parts of the coast. Yet a considerable degree of uncertainty is thrown upon the evidence of these documents, by other observations. Thus in the bay of Puzzuoli, near the city of Naples, the ancient piers of massive stone which have resisted the efforts of about 2000 years (whether they belonged to the bridge of Caligula, as tradition says, or to a mole which was intended for the protection of the Roman galleys) seem at present to remain at such an height above the surface of the water, as might have answered either of those purposes. Since the rising of the level of the water in the Mediterranean has not been perceived within this century or two, and considering all the above-mentioned facts, it will be difficult to determine whether the level of the sea has risen a few feet in the course of eighteen or twenty centuries; or the ground has subsided in some parts of the coast in consequence of earthquakes, and other causes. It is lastly to be observed, that the specific gravity of the Mediterranean waters is a little greater than that of the Atlantic water, indicating the presence of a little more salt in the former than in the latter, which may be naturally expected, considering that the waters of the Mediterranean are surrounded by a proportionably greater extent of coast than those of the Atlantic.

One of the conjectures concerning the disposition of the water, which is continually brought into the Mediterranean by the current of the Straits, is, that there is an aperture, or passage, at a considerable distance below the surface of the ground, which joins the Mediterranean with the Red Sea; so that the water, which enters the Mediterranean through the Straits, runs out of it through the above-mentioned passage. This conjecture, however, being not established upon any actual facts, is not likely to prove very satisfactory. Another conjecture is, that the influx of water is carried away by evaporation, considering the solar heat to which the Mediterranean is exposed; and so Dr. Halley is inclined to think. It has been calculated, that in one

summer's day about 5280 millions of tons of water are, in all probability, evaporated from the surface of the Mediterranean. It has also been calculated, (admitting the great uncertainty to which such calculations are liable,) that all the rivers, or at least the nine principal ones, which discharge their water into the Mediterranean, do not furnish more than 1527 millions of tons of water a day. (Phil. Trans. N^o 212.) The deficiency then is supposed to be supplied by the rain, and by the current from the Atlantic. But, since the vapour of sea-water does not take up any saline particles, it follows that the Mediterranean sea, after so many centuries of evaporation, which leaves the saline particles behind, and of influx by the current, which introduces salt and water, would by this time have almost been converted into a solid rock of salt; which is by no means the case. The last hypothesis we shall mention, and which, upon the whole, seems to be the most probable, is, that at the Straits of Gibraltar there are two currents in different directions, one above the other; *viz.* that a current runs into the Mediterranean at the surface, and to a certain depth, whilst another current runs out of it near the bottom; which, considering that the evaporation continually tends to increase the specific gravity of the Mediterranean waters, may take place in consequence of that circumstance; "for the same reason," Dr. Thomas Young observes, "as the air, when it is denser in a passage than in the adjoining room, blows a candle towards the room at the lower part of the door, and draws it towards the passage at the upper."

The probability of the existence of two opposite currents, one above the other, in the Straits, is corroborated, first, by this hypothesis answering to the phenomena better than any other supposition; and, secondly, by the observation, that opposite currents, one below the other, have been actually found to exist in other parts of the sea. Thus, in support of the above-mentioned lower current, Dr. Smith, in the 14th volume of the Philosophical Transactions, relates an experiment made in the Baltic Sound, which was communicated to him by an able seaman, who was present at the making of it. Being at that place with one of the king's frigates, they went with their pinnace into the mid-stream, where they were carried away violently by the current. Whilst thus running with the current, they sunk a basket with a large cannon-ball to a certain depth of water, by which means the boat's motion was checked; but by sinking the basket still lower and lower, the motion of the boat was checked more and more, until at last it was driven a-head to the windward, against the upper current, which seemed to reach not lower than about four or five fathoms. He added, that the lower the basket was sunk, the stronger the under-current seemed to be. Dr. Smith derives another argument in favour of an under-current at the Straits, from the ebbing between the north and south Foreland, where it runs tide and half tide; *viz.* it is either ebb or flood in that part of the Downs three hours before it is so off at sea: a certain sign that, though the tide of flood runs above, the tide of ebb must run below, *viz.* close to the ground; and so at the tide of ebb it will flow close to the ground.

A remarkable current exists in the Atlantic, about the coast of Guinea, which runs from the west towards the east, in a direction contrary to the general motion of the sea, from Cape Verd towards the curvature or bay of Africa. This current, which is known by the name of "Fernando Poo," is said to be so strong as to impel vessels powerfully towards the bay, when they happen to come too near the coast. Its strength is such that a vessel may, in two days, go from Mavra to Rio de Beuin, distant 150 leagues; and the time required

CURRENT.

required to return is often about six weeks. From Cape Spartelle to Sallee a current sets nearly according to the trend of the coast; and from thence it inclines towards the west.

Of the currents, which may be properly called partial and shifting, a vast number have been observed, and new ones are met with in different parts of the world, by attentive navigators. They are generally occasioned by the monsoons and other winds, or by the peculiar configurations of promontories, straits, coasts, gulfs, &c.: for the water, which, by the continuance of the wind in a certain quarter, is driven against bays, gulfs, straits, and the like, must run off some way or other, and must thus produce a current or two, which last no longer than the cause continues to act.

“At Java, in the straits of Sunda, when the monsoons blow from the west, *viz.* in the month of May, the currents set to the eastward, contrary to the general motion.

“Also, between the island of Celebes and Madura, when the western monsoons set in, *viz.* in December, January, and February, or when the winds blow from the north-west, or between the north and west, the currents set to the south-east, or between the south and east.

“At Ceylon, from the middle of March to October, the currents set to the southward, and in the other parts of the year to the northward; because at this time the southern monsoons blow, and at the other the northern.

“Between Cochinchina and Malacca, when the western monsoons blow, *viz.* from April to August, the currents set eastward, against the general motion; but the rest of the year set westward: the monsoon conspiring with the general motion. They run so strongly in these seas, that unexperienced sailors mistake them for waves that beat upon the rocks, known by the name of *breakers*.

“So, for some months after the 15th of February, the currents set from the Maldives towards India on the east, against the general motion of the sea.

“On the shore of China and Cambodia, in the months of October, November, and December, the currents set to the north-west, and from January to the south-west, when they run with such a rapidity of motion about the shoals of Parcel, that it seems swifter than that of an arrow.

“At Pulo Condore, upon the coast of Cambodia, though the monsoons are shifting, yet the currents set strongly towards the east, even when they blow to a contrary point.

“Along the coasts of the bay of Bengal, as far as the cape Romania, at the extreme point of Malacca, the current runs southward in November and December.

“When the monsoons blow from China to Malacca, the sea runs swiftly from Pulo Cambi to Pulo Condore, on the coast of Cambodia.

“In the bay of Sans Bras, not far from the Cape of Good Hope, there is a current particularly remarkable, where the sea runs from east to west to the landward; and this more vehemently as it becomes opposed by the winds from a contrary direction. The cause is undoubtedly owing to some adjacent shore, which is higher than this.” Varenus.

It is said that a current runs towards the east in St. George's Channel, in consequence of which some ships have been driven by it so far from their intended course, as to enter the English, instead of the Bristol, Channel. (Phil. Trans. vol. xxii.) There is reason, however, to suppose, that this mistake arose from their not accurately knowing the variation of the magnetic needle in those parts.

A current is said to prevail on the western coast of Scilly, which is supposed to come out of the Bay of Biscay, to-

wards the N.W. by W., in consequence of the westerly winds of the Atlantic.

Near Sumatra there are some rapid currents, which run from south to north, and which, according to Buffon, have probably formed the gulf which is between Malay and India. Between the eastern coast of Africa and the island of Madagascar, particularly between Terra de Natal and the Cape of Good Hope, upon the African coast, there are very considerable currents. In the Pacific ocean, on the coast of Peru, and other parts of the American coast, the current sets from south to north: a direction which appears to be occasioned by a wind which constantly blows from the south. This is also the case with the current upon the coast of Brazil, from Cape St. Augustine, as far as the Antilles.

In the sea bordering on the Maldivé islands, and between them, there are very strong currents, which run constantly during six months from east to west. They follow the course of the winds, and are probably produced by them. See Buffon's Nat. Hist.

Between Jamaica and Cuba the currents run towards the W.; and at Cape de Croix, towards the N.W.; but on the Caimanes, towards the N. and N.E., to fall in with the small channels of the Jardines; and by the Isle of Pines, they set to the S.W., till they come to Cape de Corrientes; and from thence to the W.N.W. and N.W., and by the coast of Apalachi, they return to the E. and E.S.E. and S.E., at the edge of the Soundings, near Tortugas; and from thence run towards the E. to fall into the channels of Bahama, according to their situation.

The strongest currents of the waters are in the gulf of Florida, where they run to the N., until they come out at the cape of Canaveral; and from thence they set towards the N.E., losing much of their force and strength near Bermudas.

By the north side of Cuba the current sets from Cape Mayfi, towards the N.W., and through the old straits of Bahama, to the W.N.W. with a small stream; but coming to the point of Hicacos, it runs to the N. and N.E. to fall in with the other channels; and from the port of Cavannas it runs to the E. and E.N.E., sometimes violently into the said channels; but from Cavannas, towards the west part of the coast, the current alters its course, and runs to the S.W. to fall in with the little channels of St. Isabel or Colorados. With the north and land winds the current sets into the aforesaid gulf, and along the coasts of Havana and Florida, in the same manner as with the trade-winds. Upon the coasts of Caraccas, Venezuela, Maracaiibo, and St. Martha, the currents set with the trade-winds, towards the W. and W.N.W. With the land winds the currents are in general strong, especially on the coast of St. Martha; but during the time of the north wind, the currents become weak. In the channel between Cape St. Nicholas, in the island of Hispaniola, and Cape Mayfi, in the island of Cuba, the current sets towards the N.W. and W.N.W.; and those currents that fall in with the south coast of the above-mentioned cape run along it, towards the west, by the coast of Cuba; and those that take their course by Cape St. Nicholas, on the land side, run towards the east, and fall in between the coast and the island Tortugas. From thence they steer a course between the N. and N.W., in order to fall into the channels formed by the islands and shoals to the northward of the islands of Cuba and Hispaniola, &c. In the bay of Piliquao, the current runs in eddies with a slow motion; and along the north and south coasts of Hispaniola, the current sets with the trade-winds towards the west; and on the north coast, its direction is towards

towards the north-west. On the eastern side of the above-mentioned islands, the currents run in very contrary directions, particularly in the bay of Samana; on the Virgin islands, and Porto Rico, the current sets towards the west with the trade-winds; and along Puffin, runs towards the N.W.; and in the westernmost part of the island of Porto Rico, the currents are changeable, inclining more towards the W.N.W. as they run to the bay of Samana.

Captain Vancouver observes, that from the island of St. Antonio, one of the Cape Verd islands, till crossing the latitude of St. Augustine, (perhaps the cape so called on the coast of Brazil, in lat. $8^{\circ} 48' S.$) were material currents; and from 6 degrees of N latitude to the equator, strong ripplings. But they were irregular in direction, and not uniform, as Mr. Nicholson states in his Indian Directory of 1787. Our current was not northward, as he states, but southward, or south-east. Mr. Vancouver also disapproves his notion of finding longitude by the variation of the compass: for these observations, though made with the greatest care, says he, differ from one to three, or even four degrees from each other.

Other authorities state, that in the long. $26^{\circ} 16' W.$ upon the line, a current has been found to set N. by E. half a knot an hour, and to continue nearly so for a month's sail or more to the northward. It afterwards begins to set to the southward of west. But in the long. of $9^{\circ} 25' W.$, scarce a degree N. of the line, a current has been found setting N.E. eight knots in 24 hours, making an error in reckoning from St. Jago of 3° more to the east than by account. After crossing the line, the S.E. trade-wind seems to set the current westward, as a ship will then outstrip her reckoning. Perhaps these currents have been less attended to, because, in this track, they commonly balance each other to the Cape of Good Hope.

M. de la Perouse remarked, after leaving Easter island, in April, 1786, that a current set toward the Sandwich islands, at first about 3 leagues in 24 hours, making a degree to S.W. It then changed to east at the same rate, till in $7^{\circ} N.$; after that to the westward. Hence the longitude by account was 5° too far east, on arriving at those islands; and hence the Los Mejos, La Mafa, La Diogra, Ciada, &c. of the Spanish charts, probably no other than the Sandwich islands, have from these currents been laid down too far easterly. He found also on the North American coast uncommonly strong currents, about the latitudes of 46 and 47 degrees.

The following notices of currents were also made in the course of captain Vancouver's voyage. He found that in passing through the Atlantic ocean, in going towards the equator a current set 6 miles to E.N.E. in 24 hours, when he was arrived in lat. $42^{\circ} 34' N.$ and long. $12^{\circ} 31' W.$ After passing the island of St. Antonio, the currents became extremely variable and uncertain. After passing the southern tropic, he found, on arriving at the parallel of $38^{\circ} 26'$ of S. lat. and in long. $43^{\circ} 43' E.$, that a current had set the ships 26 miles to the north of their reckoning. When he was on the coast of New Holland, near King George's Sound, in lat. $35^{\circ} 5' S.$ and long. $118^{\circ} 17' E.$ he concluded that the current set eastward. When he had entered the North Pacific ocean, and had reached the north-west American coast, he observed that a current set northward half a league in an hour, (perhaps a mistake in printing, or transcribing, for half a mile,) which set the ship 10 or 12 miles daily to the north of her reckoning. On returning southward, he noted also that a current set westward, when he was in latitude $9^{\circ} 27' N.$ and long. $96^{\circ} 24' W.$

Captain Cook observes as follows: "From the time of our leaving that island (Teneriffe) till the 15th August, being then in lat. $12^{\circ} N.$ and long. $24^{\circ} W.$, the ship was carried $1^{\circ} 20'$ of longitude to the westward of her reckoning. At this station the currents took a contrary direction, and set to E.S.E. at the rate of 12 or 14 miles a day, or 24 hours, till we arrived in the latitude of $5^{\circ} N.$ and longitude of $20^{\circ} W.$, which was our most easterly situation after leaving the Cape Verd islands, till we got to the southward. For in this situation the wind came southerly, and we tacked, and stretched to the westward, and for two or three days could not find that our reckoning was affected by any current; so that, I judged, we were between the current that generally, if not constantly, sets to the east upon the coast of Guinea, and that which sets to the westward of the coast of Brasil.

"The westerly current was not considerable till we got into $2^{\circ} N.$ and $25^{\circ} W.$ From this station to $3^{\circ} S.$ and $30^{\circ} W.$ the ship, in the space of four days, was carried 115 miles in the direction of S.W. by W. beyond her reckoning: an error by far too great to have any other cause than a strong current running in the same direction. Nor did its strength abate here: but its course was afterwards more westerly, and to the north of west; and off Cape Augustine, north, as I have already mentioned. But this northerly current did not exist at 20 or 30 leagues to the southward of that cape, nor any other, that I could perceive, in the remaining part of the passage." He farther observes, (vol. iii. p. 479.) "that from the 21st of March, when we were in latitude $27^{\circ} 22' S.$ long. $52^{\circ} 25' E.$, to the 5th of April, when we got into latitude $36^{\circ} 12' S.$ long. $22^{\circ} 7' E.$, we were strongly affected by the currents, which set to the S.S.W. and S.W. by W., sometimes at the rate of 80 knots a day."

It was also observed by sir Erasmus Gower, captain of the Lion, on an embassy to China, which left England in September, 1702, that all vessels from England to Madeira will discover their way is affected by a current from the western ocean into the bay of Biscay, and also into the Mediterranean. He supposed, on an estimate from five voyages, that it set S.E. about 11 miles in 50 leagues. From the Madeiras to the Canaries a current was observed to set southward, about 22 miles in the whole run of 66 hours, or 1 mile in 3 hours. But captain Mackintosh of the Indostan, on an estimate of 20 voyages, states a current from the 39° of latitude to the Canaries, which sets $3^{\circ} 25'$ E.S.E. It is strongest opposite the Straits of Gibraltar, and it once appeared to set 40 miles a day. Near the Canaries it was more southerly; but on the coast of Africa, near Cape Bajadore, in lat. $26^{\circ} N.$, it strikes the shore, and goes one way northward for the Mediterranean, and the other southward for the coast of Guinea. From Rio Janeiro, on the coast of Brazil in South America, a small current sets all the way towards the S.E. till it comes within about 4° of longitude W. from the Cape of Good Hope; but from about $3^{\circ} W.$ to $3^{\circ} E.$ of the same cape, a counter current sets strongly to the westward. On the coast of Cochinchina a current constantly sets from the eastward, or eastern Indian ocean, towards the land, between the Paracel's islands and the large island of Hai-nan, into the gulf of Tonquin. Whilst the ships, after leaving Turon, ran 100 miles to the N.E. in 24 hours, a current drove them 30 miles to the N. $67^{\circ} W.$ The water which returns to those shores is too weak to counteract the constant eastern tide, and is consequently forced northward along the coast into that gulf. Here the tides are, from these causes, very strong and high. Farther to the northward, the reflux from

CURRENT.

the east coast of the island of Hai-nan occasions a current to the N.E.; but still farther to the northward, it again sets in from the eastward, nearly in the parallel of the northern channel of Hai-nan, about 13 miles in 24 hours. But about the lat. of 22° N. in the long of 114° , or upwards, not far from the coast of China, a current was found to set N. by E., about a mile an hour for 24 hours.

Having thus stated the most known currents, it now remains for us to shew how the existence of a current, and the velocity of it, may be ascertained; for though the time of the setting in and duration of most currents have been examined by various attentive navigators, yet both their durations and their velocities are influenced by a variety of meteorological circumstances. Besides, it frequently happens that a new current is met with in particular seas, of which no mention is made in any book on navigation. Hence it is highly necessary for the mariner to know the best method of observing the existence and the velocity of a current, in which he actually is, or expects to be. If the ship is near the coast, so as to ride at anchor, both the direction and the velocity may be readily ascertained by casting the log, and looking at the compass. But when the sea is too deep, and the ship is under fail, the method which has been found more efficacious by the mariners is as follows: a common iron pot, capable of containing four or five gallons, is fastened to a small rope, which must be tied to its handles, so that, when suspended, the aperture of the pot may remain upwards and horizontal. The rope, which may be from 70 to 100 fathoms in length, is to be coiled in the boat, which is hoisted out of the ship at a convenient opportunity; *viz.* when there is little or no wind to ruffle the surface of the sea. The pot then being thrown overboard into the water, and immediately sinking, the rope is slackened until about 70 or 80 fathoms have run out, after which the rope is fastened to the stern of the boat, which is by it restrained, and rides as it were at anchor. The velocity of the current is then easily tried by means of the log and half-minute glass, in the same manner as the ship's rate of sailing is usually ascertained. It is evident, however, that this method is grounded upon the supposition that the current does not reach so low below the surface of the sea as the place to which the iron pot has been sunk; which, though perhaps mostly true, cannot be always so. Therefore, when the iron pot is not out of the influence of the current, or when it happens to come within an under-current, the result of the above-described method must unavoidably prove fallacious: nor does the present knowledge of navigation afford any other safer method for the purpose.

When the direction and velocity of a current has been ascertained, the application of it to the purposes of navigation is easy and evident: for if the ship sails along the direction of the current, its progress is the sum of the current's velocity and the rate given by the log; if the ship sails directly against the current, then its real progress is the difference of the two above-mentioned particulars, and is directed the same way with the strongest: hence it may happen that a vessel, which appears to proceed in full sail towards the north, may actually go backwards towards the south, in consequence of a strong current. If the current runs assant to the direction of the ship, then, since the ship is impelled by two forces, *viz.* by the force of the wind in one direction and by the current in another direction, its real course must be in the diagonal of a parallelogram, of which the sides are the velocity of the current and the velocity with which the wind impels the ship. See Varenus' Geography, Naval Gazetteer, &c.

CURRENT Island, in Geography, a small island in the

Pacific ocean, discovered by captain Carteret, in October, 1767, and so called on account of the strong southerly current which set the ship, in this part of the ocean, from 24 to 30 miles southward every day, besides the difference it might make in its longitude. N. lat. $4^{\circ} 40'$. E. long. $134^{\circ} 3'$. Near this island are two other small islands, which captain Carteret called St. Andrew's islands, in N. lat. $5^{\circ} 18'$. E. long. $133^{\circ} 40'$.

CURRENT Sailing, is the method of resolving those problems in navigation, in which the effect of a current is taken into consideration.

That point of the compass to which a current runs, is called its *setting*, and the rate of its motion *per* hour is called its *drift*.

In a calm, it is evident, a ship will be carried in the direction, and with the velocity, of the current.

Hence, if a ship sails in the direction of the current, her rate will be augmented by the velocity of the current; but if sailing directly against it, the distance made good will be equal to the difference between the rate of the ship as given by the log, and that of the current; and the absolute motion of the ship will be a-head, of her rate exceeds that of the current; but, if less, the ship will make sternway. If the ship's course be oblique to the direction of the current, her true course and distance will be compounded of the course and distance given by the log, and of the setting and drift of current; and the distance made good in a given time, will be represented by the third side of a triangle, of which the distance given by the log and drift of the current in the same time, are the other two sides. The two first cases are evident, and the last may be illustrated as follows.

In the parallelogram ABCD, (*Plate I. Navigation. fig. 3.*) let AB be the distance run by the ship, in the same time that a current sets from B to C, and AM a meridian; then AC being joined, will be the distance made good; the angle MAB the course *per* compass, and MAC the true course, or that resulting from the combined motions of the ship and current. For since the current neither assists nor prevents the ship from approaching the line BC, the wind will bring it there, in the same time as if no current existed; and as the wind has no tendency on the current, and the direction of the ship being in the line AB, the current will bring the ship to the line CD, in the same time as if in a calm; therefore, the ship will be found to be at C, the point of intersection of the lines BC, CD; and, consequently to have sailed in the direction AC, the diagonal of the parallelogram contained between the distance run, and the drift of the current in the same time.

The setting and drift of the principal currents, are in general known nearly, but with respect to unknown or doubtful currents, the following method is usually employed to ascertain their setting and drift.

In the open ocean, in calm weather, the setting and drift of a current are easily found by taking a boat to some little distance from the ship, which being brought up, by sinking from the stern a heavy iron pot or loaded kettle, to the depth of about 100 fathoms; then, the log being hove, its bearing will be the setting of the current, and the number of knots run out in half a minute will be its drift. See CURRENT.

When in sight of land, the setting and drift of a current may be found by observing some remarkable place, or places on shore, at certain intervals of time.

Examples.

I. A ship sailed S. by W. 21 hours, at the rate of 8 knots an hour, in a current that set E.N.E. 3 miles an hour, required the course and distance made good in that time.

CURRENT.

By Construction.

Describe the circle N.E., S.W., (*fig. 4*) in which N.S. represents the meridian of the place sailed from, and E.W. the parallel of that place, these lines being at right angles to each other; from the centre C, draw the S. by W. line CB, equal to 168 miles ($= 1 \times 8$) the distance run in a given time; and from B, draw BD in an E.N.E. direction, which make equal to 63 miles ($= 21 \times 3$); join CD, which will be the distance made good, and will measure 143 miles, and the measure of the angle SCD being applied to the line of chords, will be found to be S. $10^{\circ} 15'$ E.

By Calculation.

In the triangle CBD, are given the sides CB, BD, equal to 168 and 63 respectively, and the included angle CBD equal to five points, the supplement of the number of points contained between the E.N.E. and S. by W. rhumbs; to find the angles C and D, and the side CD.

To find the angles.

Distance	BC = 168	
Distance	BD = 63	
Sum	231	
Difference,	105	
Angle CBD =	5 points,	
Sum of C and D =	11 points,	
Half	$5\frac{1}{2}$ points =	$61^{\circ} 52'$
As the sum of the sides	231	2.36361
Is to the diff. of the sides	105	2.02119
So is the tang. of half sum angles	$61^{\circ} 52'$	10.27189
To tangent of half diff. angles.	$40^{\circ} 22'$	9.92947
Angle D	- - - $102^{\circ} 14'$	
Angle BCD	- - - $21^{\circ} 30'$	
Angle BCS	- - - S. $11^{\circ} 15'$ W.	
True course SCD	- - - S. $10^{\circ} 15'$ E.	

To find the distance CD.

As the sine of BDC	- - $102^{\circ} 14'$	9.99002
Is to the sine of CBD,	- - $56^{\circ} 15'$	9.91985
So is BC	- - 168	2.22531
To the distance CD	- - 142.9	2.15514

Remark.

The most expeditious method of performing questions of this kind, is by inspection; by this method of operation, the preceding example is resolved as follows.

Courses.	Dist.	Diff. Lat.		Departure.

II. A ship from a certain headland in the latitude of $34^{\circ} 00'$ N., sails S.E. by S. 12 miles in three hours, in a current that sets between N. and E., and then the same headland is found to bear W.N.W., and the ship to be in the latitude of $33^{\circ} 52'$ N., required the setting and drift of the current?

By Construction.

Having drawn the compass N.E.S.W., (*fig. 5*) let A represent the place of the ship, and draw the S.E. by S. line AB equal to 12 miles, also the E.S.E. line AC.

Set off from A upon the meridian AD, equal to 8 miles, the difference of latitude, and through D draw DC parallel to the E. and W. line W.E., meeting AC in C. Join C and B with the right line BC; then C will be the ship's place, the angle ABC the setting of the current from the S.E. by S. line, and the line BC will be the drift of the current in three hours.

By Calculation.

In the triangle ADC, right-angled at D, are given the difference of latitude AD, equal to eight miles, the angle DAC equal to $67^{\circ} 30'$. Whence for AC the distance the ship has sailed, it will be:

As radius	- - -	10.00000
Is to the secant of the course DAC	$67^{\circ} 30'$	10.41716
So is the difference of latitude	8	0.90309
To the distance	20.9	1.32025

Again, in the triangle ABC, are given AB, equal to 12 miles, AC equal to 20.9, and the angle BAC equal to $33^{\circ} 45'$, the distance between the S.E. by S. and E.S.E. lines: Whence for the angle at B, it will be,

As the sum of the sides AD and AB	32.9	1.51720
Is to their difference	- - 8.9	0.94939
So is the tangent of half the sum of the angles B and C	- - } $73^{\circ} 7'$	10.51806

To the tangent of half their diff. $41^{\circ} 43\frac{1}{2}'$ 9.95025

Consequently, the angle B is $114^{\circ} 51'$, and, therefore, the setting of the current will be N. $81^{\circ} 6'$ E. or E. by N. $2^{\circ} 21'$ E. Then for BC, the current's drift in three hours, it will be,

As the sine of B	- - - $114^{\circ} 51'$	9.95780
Is to the sine of A	- - - $33^{\circ} 45'$	9.74474
So is the distance run AC	20.9	1.32025

To BC 12.8 1.10719
the current's drift in three hours, and consequently the current sets E. by N. $2^{\circ} 21'$ E. 4.266 miles an hour.

III. A ship at sea in the night has sight of Scilly light, bearing N.E. by N. distant four leagues, it being then flood tide, setting E.N.E. 2 miles an hour, and the ship running at the rate of five knots an hour; what course and distance must the ship fail to make the Lizard, which bears from Scilly E. $\frac{1}{2}$ S. distance 17 leagues?

By Construction.

Draw the N.E. by N. line AS = 12 miles, (*fig. 6*); hence S will represent Scilly. From S draw SL = 51 miles, and parallel to the E. $\frac{1}{2}$ S rhumb; then L will represent the Lizard; draw LC parallel to the E.N.E. rhumb, and equal to two miles, and make CD equal to five miles; or, because these numbers are too small to determine the triangle with precision, let equimultiples of them be taken, as 10 and 25. From A draw AB parallel to CD, meeting LC,

J. C produced in B, then AB will be the distance, and the angle S A B the course; the first of these applied to the scale will measure nearly 45 miles, and the course will be about S. 88° E.

By Calculation.

In the triangle S A L, are given the sides A S, S L, equal to 12 and 51 respectively, and the angle A S L equal to 10½ points, to find the other angles and distance A L.

To find the Angles.

Distance	S L = 51	
	A S = 12	
Sum	- - -	63
Difference	- - -	39
Angle	- A S L	10½ points.
Sum of	S A L, S L A	5½
Half sum	2¾ = 3	56'
As the sum of the sides	- - -	63° - 1.79934
Is to the difference of the sides	- - -	39° - 1.59105
So is the tangent of half sum of the angles	- - -	30° 56' 9.77763
To the tangent of half diff. angles	- - -	20° 21' 9.56735
Angle S A L	- - -	51° 17'
N A S = 3 points	- - -	33° 45'
N A L	- - -	85° 2'
L A E = F L A	- - -	4° 58'
T L B = 2 points	- - -	22° 30'
A L B = D L C	- - -	17° 32'

To find the distance A L.

As the sine of S A L	- - -	51° 17'	9.89223
Is to the sine of A S L	- - -	10½ points.	9.94543
So is the distance S L	- - -	51	1.70757

To the distance A L	- - -	57.65	1.76077
---------------------	-------	-------	---------

In the triangle D L C, are given D C = 5 miles, the hourly rate of sailing, L C = 2 miles, the drift of the current in the same time, and the angle D L C = 17° 32', to find the angle L D C = L A B.

As distance D C	- - -	5	0.69897
Is to the distance L C	- - -	2	0.30103
So is the sine of L D C	- - -	17° 32'	9.47894

To the sine of L D C	- - -	6° 55'	9.08100
Angle N A L	- - -	85° 2'	°

N A B	- - -	91° 57'
Course	- - -	S. 88° 3' E.

Lastly, in the triangle A B L, the side A L, together with the angles are given, to find the distance A B.

As the sine of A B L	- - -	155° 33'	9.61689
Is to the sine of A L B	- - -	17° 32'	9.47894
So is the distance A L	- - -	57.65	1.76077

To the distance A B	- - -	41.96	1.62282
---------------------	-------	-------	---------

For more examples on this subject the reader is referred to Dr. Mackay's "Treatise on Navigation."

CURRER, in *Geography*, a town of Hindoostan, in the country of Viliapour; 60 miles W. of Vissapour.

CURRESO, in *Ornithology*, a name given by Dauphin to the CRAX *lector*, which see.

CURRICULUS, in our *Ancient Writers*, denotes the year, or course of a year.

"Actum est hoc annorum Dominicæ incarnationis quater quinquagenis & quinquies, quinis latus, & tribus *curriculis*;" i. e. in the year 1028; for four times fifty makes two hundred, and five times two hundred makes one thousand; five lustres are twenty-five years, and three *curriculi* are three years.

CURRIED HIDE. See HIDE.

CURRIERS are those who dress and colour leather, after it comes from the tan-yard. No currier shall use the trade of a butcher, tanner, &c. or shall carry skins insufficiently tanned, or gash any hides of leather, on pain of forfeiting for every hide or skin 6s. 8d. Curriers not carrying the leather sufficiently shall forfeit the ware or the value, &c. Stat. 1 Jac. I. c. 22. If curriers do not carry leather that is sent to them, within six teen days between Michaelmas and Lady-day, and in eight days at other times, they are liable to a forfeiture of 5l. on conviction before a justice, to be levied by distress, &c. but subject to a mitigation. 12 Geo. II. c. 25. Curriers and such as deal in leather, may cut and sell it in small pieces in their shops, to any persons whatsoever. Stat. Id.

CURRIER'S *Shaves*, or *paring knives*, in *Heraldry*, instruments used by the curriers, and borne in the arms and crest of their company.

CURRITUCK, in *Geography*, a county of America, situated on the sea-coast of Edenton district, N. Carolina, and forming the N.E. corner of the state. bounded E. by Currituck sound, N. by Virginia, S. by Albemarle Sound, and W. by Camden county, containing 6928 inhabitants of whom 1530 are slaves. *Dismal* swamp lies in this county, on the S. side of Albemarle Sound, and is now supposed to contain one of the most valuable rice estates in America. In the midst of this Dismal, which contains upwards of 350,000 acres, is a lake about 11 miles long, and 7 miles broad. A navigable canal, 20 feet wide, and 5½ miles long, connects the waters of the lake with the head of Skappernong river. Several saw-mills are erected about 500 yards from the lake; and as the water of the lake is higher than the banks of the canal, the company can at any time lay under water about 10,000 acres of rich swamp, which is admirably fitted for the culture of rice. See GREAT DISMAL.

CURRITUCK, or CARATUUK, a settlement in Maine, 28 miles above Norridge-walk. In 1792 this was the uppermost settlement on Kennebach river, and then consisted of about 20 families, and in 1800 of 136 inhabitants. Morse.

CURRODREPANUS, formed of *currus*, chariot, and *ῥεπανον*, scythe, or sickle; in *Antiquity*, a kind of chariot armed with scythes. The driver of these chariots was obliged to ride on one of the horses, as there was no other seat for him; the usual place for him being all armed with knives, as was likewise the hinder part of the chariot. There were no scythes pointing down to the earth, either from the beam or axle-tree; but these were fixed at the head of the axle-tree in such a manner as to be moveable by means of a rope, and thereby could be raised or let down, and drawn forward or let fall backward, by relaxing the rope.

CURRUCIA, in *Ornithology*, a name given by Frisch. Av. t. 24. to a variety of the MUSCICAPA *Atricapilla* of Cme in: which see;—and also to varieties of the MOTACILLA *Atricapilla* of Gmelin; and also to the MUSCICAPA *grifola* of Gmelin, which see respectively.

CURRUCIO, Gainer's name of the *MUSCICAPA* *9-1* *fol.*

CURRUS TRIUMPHALIS, triumphal chariot. See **TRIUMPH**.

CURRY-COMB, in *Rural Economy*, is an implement of the comb kind, thickly set with small teeth, which is used in the operation of currying animals.

CURRYING, the operation of combing and dressing any sort of domestic animal by means of a curry-comb, in order that the dust may be removed from their coats, and they may have a sleek appearance.

CURRYING is the art of dressing cow-hides, calves-skins, seal-skins, &c. principally for shoes; and this is done either upon the flesh or the grain.

In dressing leather for shoes on the flesh, the first operation is soaking the leather in water, until it be thoroughly wet; then the flesh-side is shaved on a beam, about seven or eight inches broad, with a knife of a peculiar construction, to a proper substance, according to the custom of the country, and the uses to which it is to be applied. This is one of the most curious and laborious operations in the whole razzery of currying. The knife used for this purpose is of a rectangular form, with two handles, one at each end, and a double edge. They are manufactured at Cirencester, and composed of iron and steel; the edge is given to them by rubbing them on a flat stone of a sharp gritty substance, till it comes to a kind of wire; this wire is taken off by a fine stone; and the edge is then turned to a kind of groove wire by a piece of steel, in form of a bodkin, which steel is used to renew the edge in the operation.

After the leather is properly shaved, it is thrown into the water again, and scoured upon a board or stone commonly appropriated to that use. Scouring is performed by rubbing the grain or hair-side with a piece of pumice-stone, or with some other stone of a good grit, not unlike in thickness and shape to the slate with which some houses are covered. These stones force out of the leather a white sort of substance called the bloom, produced by the oak-bark in tanning. The hide or skin is then conveyed to the shade or drying-place where the oily substances are applied, termed stuffing or dubbing; the oil used for this purpose is prepared by the oil leather-dressers, by boiling sheep-skins or doe-skins in cod-oil. This is put on both sides of the leather, but in a greater and thicker quantity on the flesh than on the grain or hair-side.

Thus we have pursued the currying of leather in its wet state, and through its first stage, commonly called getting out.

When it is thoroughly dry, an instrument with teeth on the under-side, called a graining board, is first applied to the flesh side, which is termed graining; then to the grain-side, called bruising; the whole of this operation is intended to soften the piece of leather to which it is applied. Whitening or pring succeeds, which is performed with a fine edge of the knife already described, and used in taking off the grease from the flesh. It is then boarded up or grained again, by applying the graining board, first to the grain and then to the flesh.

It is now fit for waxing, which begins with colouring. This is performed by rubbing with a brush dipped in a composition of oil and lamp-black on the flesh, till it be thoroughly black; it is then sized, called black sizing, with a brush or sponge, dried, tallowed with a woollen cloth; and sleeked upon the flesh with a broad smooth piece of glass, sized again with a sponge; and when dry this sort of leather, called waxed or black on the flesh, is curried.

Currying leather on the hair or grain-side, termed black

on the grain, is the same in the first operation with that dressed on the flesh, till it is scoured. Then the first black is applied to it, while wet; which black is a solution of copperas in fair water, or in the water in which the skins, as they come from the tanner, have been soaked; this is first put upon the grain, after it has been rubbed with a stone; then rubbed over with a brush dipped in stale urine; sleeked out with an iron slicker, in order to make the grain come out as fine as possible; and then stuffed, in the manner already described among the first operations of currying; and when dry it is seasoned, *i. e.* rubbed over with a brush dipped in copperas water on the grain, till it be perfectly black; then sleeked with a stone of a good grit, to take out the wrinkles and coarse grain as much as possible: after this the grain is raised with a fine graining board, by turning the skin or piece of leather in various directions; and when a little dried, it is bruised in order to soften it. When it is thoroughly dry it is whitened, bruised again, and grained in two or three different ways; and when oiled upon the grain with a mixture of oil and tallow, it is finished.

Bull and cow-hides are sometimes curried for the use of saddlers and collar-makers; but the principal operations are much the same as those we have already described. It should, however, be observed, that only a small portion of flesh is taken from hides designed for these purposes. Hides for the roofs of coaches, &c. are shaved nearly as thin as shoe-hides, and blacked on the grain.

CURSED. See **ACCURSED**, and **CORSEID**.

CURSHUND, in *Zoology*, the name given by Ridia-ger to the greyhound, *Canis Curforius*. See **GREYHOUND**.

CURSING. See **SWEARING**.

CURSITORS, officers or clerks belonging to the court of chancery, who make out original writs.

These are also called *clerks of the court*, (*clerici de curfu*, 18 Ed. III. stat. 5.) and are twenty-four in number; making a coporation of themselves. To each of them are allotted several shires; in which shires they exercise their functions (2 Inst. 670.) This coporation consists of a principal, two assistants, 21 cursitors, and a bag bearer.

CURSITOR-Baron, an officer in the court of Exchequer, who administers the oath of all high-sheriffs, under-sheriffs, bailiffs, auditors, receivers, collectors, controllers, surveyors, and searchers of all the customs in England.

CURSOLI. See **CURZOLA**.

CURSOR, a little ruler, or label of brass, divided like a line of lines, and sliding in a groove, or notch, along the middle of another label, or ruler, representing the horizon, and always at right angles to it. It is used in the analemma.

CURSOR is also used for a point screwed on the *beam compass*; and which may be moved, or slidden along the beam thereof for the striking of greater or less circles.

CURSULA, in *Ancient Geography*, a town of Italy, in Latium, situated 80 stadia from Rieti, near mount Coreto, called *Corfula* by Tacitus; and supposed to be the present town of Cassia, in Umbria.

CURSUS, a town of Spain, in Bætica, placed by Ptolemy in the country of the Turdetani.

CURSUS Achilles, a point of land lying to the left of the Borysthenes, at its mouth. *Achilles* is said by Mela to have celebrated games in this place, when he was entering into the Pontic sea.

CURTA, a town of Lower Pannonia, situated on the banks of the Danube; marked in the Itinerary of Antonine

nine between Arrabonæ and Alicanum; supposed to be *Buda*.

CURTAILING, in the *Manege*, the docking, or cutting off a horse's tail.

The practice of curtailing is no where in vogue so much as in England; it being a popular opinion, that the cutting off the tail renders the horse's chine or back the stronger, and more able to bear burdens.

The amputation is usually made between the fourth and fifth joints of the tail; a ligature being first tied tight about the place, to prevent the flux of blood; and the raw stump afterwards seared up with a hot iron, till the extremities of the vessels be all stopped.

This absurd and barbarous custom is now in great measure out of fashion; and horses are allowed to enjoy the use, and retain the beauty of their tails, as given to them by nature.

CURTAIN, in *Fortification*. See **CURTIN**.

CURTAINS, in a *Fire-ship*, are pieces of a coarse canvas, about three quarters of a yard wide, and a yard long, thickened in a melted composition of pitch, sulphur, rosin, tallow, and tar, and covered with saw-dust on both sides.

CURTATE DISTANCE, in *Astronomy*, the distance of a planet's place from the sun or earth, reduced to the ecliptic; or, the interval between the sun or earth, and that point where a perpendicular, let fall from the planet, meets with the ecliptic.

CURTATION, in *Astronomy*, the interval between a planet's distance from the sun, and the curtate distance.

From the preceding article it is easy to find the curtate distance; whence the manner of constructing tables of curtation is obvious.

The quantity of inclination, reduction, and curtation of a planet, depending on the argument of the latitude; Kepler, in his Rudolphin Tables, reduces the tables of them all into one, under the title of *Tabulæ Latitudinariæ*.

CURTESY of England, *jus curialitatis Angliæ, Tenant by*. See **COURTESY** and **TENANT**.

CURTEUS FALCATUS, Lat.; a chariot armed with scythes. The ancients made use of them in war; and the invention of them, according to Diodorus, goes back to the highest antiquity. Ninus used them against the Bactrians; and the nations that opposed the Israelites also fought in them.

CURTEYN, CURTANA, a name given to king Edward the Confessor's sword, which is the first sword that is carried before the kings of England at their coronation.

It is said, the point of it is broken, as an emblem of mercy.

CURTI, GIROLAMO, in *Biography*, a Bolognese painter, called Il Dentone, from the circumstance of his carrying his mouth half-open, so as to discover two large front teeth. He was born in the 16th century of very poor parents, who had him taught the business of a thread-spinner. At the age of 25, however, he began to practise design in company with Lionello Spada; but finding the study of the human figure too arduous an undertaking, he determined to confine his exertions to the attainment of perspective, and the practice of that species of decorative painting which the Italians term *quadratura*. He accordingly received some instructions in this way from Baglione, and grounded himself in architecture by studying Vignola and the finest remains of the ancients at Rome. Curti soon acquired the reputation of being one of the best artists in his line, and was eagerly employed in many great works in Rome, Bologna, Parma, and other parts of Italy,

and in particular in the first-mentioned city, where he painted a hall in the palace of prince Lodovisi, which was extremely admired, and judged far to surpass the hitherto unrivalled works of Gio. Alberti in the Sala Clementina in the Vatican. He died at Parma in 1631. Lanzi. Stor. Pitt.

CURTI, FRANCESCO, an engraver, born in Bologna, who flourished in the 17th century. His style seems formed on that of Cherubino Alberti, though the execution is less masterly, and the extremities of the figures drawn with less correctness. He engraved after Guercino, Parmigiano, Guido, and other celebrated masters. The following are amongst the best of his works.

"The Virgin teaching the Child Jesus to read; from Guercino. A drawing-book from the designs of the same artist. A set of 16 portraits, 1633. Two heads of the Virgin and St. Catherine, upon the same plate." Heineken. Strutt.

CURTI, BERNARDINO, probably a relation of the preceding, and also an engraver. This artist executed a great number of portraits, besides other works, which, however, are not much esteemed. We shall only notice the following:

"An emblematical subject from Luc. Ferrar, a middling sized plate, lengthways. The Virgin, a half figure, with the Infant Jesus and the Child St. John, 1640." Heineken. Strutt.

CURTICONE, in *Geometry*, a cone whose top is cut off by a plane parallel to its basis; called also *truncated cone*.

CURTILAGE, CURTILAGIUM, in *Law*, a yard, backside, or piece of ground, lying near a dwelling-house.

CURTILES TERRÆ. See **COURT-lands**.

CURTILLA, in *Ornithology*, a name given by some to the *CORVUS sylvaticus* of Gesner, which see.

CURTIN, CURTAIN, or COURTINE, in *Fortification*, is the part of a work which joins the flank of one bastion or demi-bastion to that of the bastion or demi-bastion next to it, whether it be in the body of the place, or in a crown-work, horn-work, &c. The curtains, with the flanks and faces of the bastions, form the *encinte* of the body of a place.

Do-Cange derives the word from the Latin *cortina, quasi minor cortis*, a little county-court, inclosed with walls: he says, it was in imitation hereof, that they gave this name to the walls and parapets of cities, which inclose them like courts: he adds, that the *curtains* of beds take their name from the same origin; that *cortis* was the name of the general's, or prince's tent; and that those who guarded it were called *cortinari* and *curtisani*.

The *curtin* is usually bordered with a parapet five feet high; behind which the soldiers stand to fire upon the covert-way, and into the moat.

Besiegers seldom carry on their attacks against the *curtin*, because it is the best flanked of any part.

CURTIN, angle and complement of the. See **ANGLE** and **COMPLEMENT**; see also **MILITARY CONSTRUCTION**.

CURTIS, WILLIAM, in *Biography*, an eminent botanist and entomologist, was born at Alton in Hampshire, in 1746. His family were quakers, and his father a tanner; but he was at the age of fourteen bound apprentice to his grandfather, an apothecary in his native town. It happened that the ostler of an adjoining inn was a practical botanist, versed in the study of Gerard and Parkinson's herbals. Such an intimacy for their son's sober parents might have deprecated, and ambitious ones have contemned; yet hence the youthful Curtis imbibed that taste for natural knowledge

know which proved the source of his future fame and merit, and above all, of which is not always justly appreciated, his happiness. Some more systematic works falling in his way soon after, infused into his apt and ardent mind principles or method, and of Linnæan philosophy, which neither his original preceptor, nor the books he studied, could ever have taught. At the age of twenty Mr. Curtis came to London, in order to finish his medical education, and to seek an establishment in the line to which he was destined. He was associated with a Mr. Talwin of Gracechurch street, to whose business he at length succeeded; but not without having from time to time received many reproofs and warnings, respecting the interference of his botanical pursuits with the more obviously advantageous ones of his profession. Nor were these warnings without cause. The street-walking duties of a city practitioner but ill accorded with the wild excursions of a naturalist; the apothecary was soon swal-owed up in the botanist, and the shop exchanged for a garden. Mr. Curtis therefore became a lecturer on the principles of natural science, and a demonstrator of practical botany. His pupils frequented his garden, studied in his library, and followed him into the fields in his herborizing excursions. His first garden was situated at Bernoldsey; afterwards he occupied a more extensive one at Lambeth Marsh, which he finally exchanged for a more salubrious and commodious spot at Brompton. This last garden he continued to cultivate till his death.

Mr. Curtis was very early led to combine the study of insects and their metamorphoses with that of plants, and his various gardens were furnished with accommodations for this pursuit. Hence he became an author; his first publication being a pamphlet entitled, "Instructions for collecting and preserving Insects; particularly Moths and Butterflies, illustrated with a copper plate," and printed in 1771. In the following year he published a translation of the *Fundamenta Entomologie* of Linnæus, entitled, "An Introduction to the Knowledge of Insects," many valuable additions being subjoined to the original treatise. These two pamphlets have contributed more than any similar works to diffuse a knowledge of scientific entomology in England, and to engraft on the illiterate illiberal stock of mere collectors, a race of enlightened and communicative observers of nature: who no longer hoard up unique specimens, and selfish acquisitions, but contribute their discoveries and their experience for the benefit of the agriculturist, the manufacturer, or the physician.

The celebrity which these publications procured for their author was soon altogether eclipsed by what arose from his botanical labours, which have placed him in the very first rank of English writers in that department of science. In 1777 appeared the first number of his *Flora Londinensis*, containing 6 folio plates, with a page or more of letter press consisting of a description in Latin and English, with synonyms, of each plant, and copious remarks on its history, uses, qualities, and the insects it nourishes. Each number was sold at half a crown plain, 5 shillings coloured, and some copies, finished with extraordinary care, were sold at seven shillings and six pence. The first artist employed in making the drawings for this work was Mr. Kilburn, who used a *camera obscura* for the purpose; his sketches were shaded with Indian ink, before the colours were laid on. The performances of this artist have not been excelled in any similar work. When from other engagements Mr. Kilburn was obliged to relinquish his task, Mr. Sowerby was employed, and maintained undiminished the perfection of the figures. After him Mr. Sydenham Edwards has

been engaged by Mr. Curtis, with no less credit, both in the publication of the *Botanical Magazine*; hereafter mentioned. Of the plates of the *Flora Londinensis* too much cannot be said; their beauty and botanical accuracy are alike eminent, and it is only to be regretted that the manufactory of paper, as well as the typographical art, were in so degraded a state when this book first appeared. For this its author cannot be responsible, nor are these defects of any moment in the eyes of learned or scientific readers. To them the *Flora Londinensis* is a mine of original, solid, practical information, conveyed in a style of candour and unalloyed love of science, by which the author, as well as his subject, steal the hearts of his readers. It has already been observed, (*Transactions of the Linnæan Society*, v. iv. p. 280.), that the work in question, "independent of its excellent figures, ranks next to Ray's *Synopsis*, in original merit and authority upon English plants." It may be added that the works of Curtis have tended, more than any other publications of their day, to give that tone of urbanity and liberality to the science, which every subsequent writer, of good character, has observed. Wherever their author swerved in any degree from this candour, which was very seldom, and not always without provocation, it was always to his own loss, and he was thus led into some of the very few mistakes that he has committed; but these we shall consign to oblivion. His mention of Mr. Hudson's "usual inaccuracy" is most reprehensible. The author of the *Flora Anglica* was indeed blameable for treating the infant publication of Curtis with lofty neglect, but it is not true that he was "usually inaccurate" in his own labours. Mr. Curtis conducted himself rather more uncandidly towards the work entitled *English Botany*, because he conceived it an encroachment on his own botanical domain, of which a narrative is given in the preface to its seventh volume, unnecessary to be repeated here. His fame and his work were superior to all rivals, and the object of his unjust displeasure is proud to bear testimony to his merit, with which no person was better acquainted. The *Flora Londinensis* was extended to six fasciculi, of 72 plates each. It is to be regretted that the feelings above alluded to occasioned its author in the latter part to describe, from garden specimens, several plants out of his originally intended limits, respecting which he could give no particular information; while numerous species growing near London remained unexplained and ill-understood. A botanist who had like him so admirably illustrated the genera *Polygonum*, *Rumex*, *Chenopodium*, and several others, makes us regret that his genius was ever diverted from its original bent. On another occasion however we rejoice that it was otherwise employed. Ten years after the beginning of his *Flora*, Mr. Curtis undertook a new publication, the *Botanical Magazine*, a work whose sale has been extensive beyond all former example, and which is in every respect worthy of its author. No book has more diffused a taste for unostentatious nature and science. It rewarded its contriver with pecuniary emolument as well as with merited celebrity, and is still continued with unabated utility. It is designed to be a general repository of garden plants, whether previously figured or not in other works, but it has often had the advantage of giving entire novelties to the public.

In the year 1782, Mr. Curtis published a history of the brown-tailed moth, an insect confounded by Linnæus under his *Phalena Cbrysoforrhoea*. The design of this pamphlet was to allay the alarm which had been excited in the country round the metropolis, by an extraordinary abundance of the caterpillars of this moth, and which was so great, that the parish officers offered rewards for collecting these caterpillars,

pillars, and attended in form to see them burnt by bushels at a time. It was one of those popular alarms which every now and then arise among the ignorant multitude, and which vanish before the first ray of common sense. When the natural history of the insect was inquired into, and compared with that of others, no cause for any great apprehension could be discerned; and, indeed, the subsequent years were not more abundant in this species than usual.

Besides the above works, Mr. Curtis published "Practical Observations on the British Grapes," in 8vo.; his truly praise-worthy aim being to direct the farmer to a knowledge and discrimination of the species and their qualities. He also, from time to time, printed catalogues of his garden. He was induced, by the unfortunate alarm which he conceived at the publication of "English Botany" above-mentioned, to put forth diminished figures in octavo of his great *Flora*; but these met with no approbation nor success, and were soon discontinued. His "Lectures on Botany," rendered needlessly expensive by superfluous coloured plates, have appeared since his death; but for this publication he is not responsible. Two admirable entomological papers of Mr. Curtis are found in the "Transactions of the Linnæan Society; of which society he was one of the original fellows. The first of these is an account of the *Silpha Grisea* and *Curculio Lapathi*, two coleopterous insects very destructive to willows. The other paper is intended to shew that the *Aphides*, or lice of plants, are "the sole cause of the honey-dew;" a new theory on the subject, and perfectly just, as far as concerns the most common kind of honey-dew. This paper was digested by the president from the unfinished materials of its author, and communicated to the society after his death, which happened on the 7th of July, 1799, after he had for near a twelvemonth laboured under a disease in the chest, supposed to be of a dropsical nature; but which was rather, perhaps, an organic affection of the heart, or of the great vessels immediately connected with it. His remains were interred at Battersea church. He left behind him the character of an honest friendly man, a lively and entertaining companion, and a good master. He was ever ready to encourage and assist beginners in his favourite science, and always endeavoured to render that science as attractive as possible. It must not be forgotten that he was one of the first who, in spite of authority, contributed to remove some reproaches to which it was justly liable on the score of indelicacy. His example has been followed by other writers (see CLITORIA); and its salutary effects have only in one disgraceful instance, which we shall not drag forth from its merited obscurity, been attempted to be counteracted. This last praise is justly paid to Mr. Curtis by an excellent and very eminent friend, who has given the world a history of his life and merits in the Gentleman's Magazine for 1799, whence we have derived many of the above particulars. S.

CURTISIA, in *Botany*, (named in honour of William Curtis, author of *Flora Londinensis*, &c.) Hort. Kew. 3. 507. Schreb. 1729. Lam. Ill. 186. Willd. 247. Class and order, *tetrandria monogynia*.

Gen. Ch. *Cal.* Perianth one-leaved, four-parted; segments egg-shaped, acute. *Cor.* Petals four, egg-shaped, obtuse, sessile, longer than the calyx. *Stam.* Filaments four, inserted into the receptacle, awl-shaped, shorter than the petals; anthers egg-shaped. *Pist.* Germ' superior, egg-shaped; style awl-shaped, the length of the stamens; stigma four or five-celled. *Peric.* Drupe somewhat globular, succulent, smooth. *Seed.* Nut roundish, boney, four or five-celled; kernels solitary, oblong.

Ess. Ch. Calyx four-parted. Petals four. Drupe superior, roundish, succulent; nut four or five-celled.

Sp. C. *faginea*. Thunb. Prod. 28. Lam. Ill. Pl. 71. (*Relbania faginea*; Gmel. Syst. Veg. 247. *Junghansia faginea*; Gmel. Syst. Veg. 259. *Sideroxylon foliis acuminatis dentatis, fructu monopyrens flavo*; Burm. Afr. 235. tab. 82.) One of the largest trees in the African woods. Younger branches pubescent. *Leaves* opposite, on short petioles, ovate-lanceolate, sharply toothed, entire at the base, smooth above, pubescent underneath. *Flowers* very small, in a terminal panicle. The Hottentots and Caffres make the shafts of their javelins or assaguays from its wood. It is called in Dutch wite-esse, stink-hout, and assaguay-hout, or assaguay-tree.

CURTIVS, M., in *Biography*, a Roman whose patriotism has been celebrated by Livy; and though the fact, which is recorded in connection with his name, and by which he is rendered illustrious, has been the subject of much discussion and doubt, yet there was unquestionably some foundation for the story, which is thus recorded by the historian. "In the year 392 of the city, the ground in the midst of the forum, either from an earthquake, or some similar cause, opened and left a vast chasm, which could not be filled by any human art. The oracle was consulted, who declared that the Roman state would endure for ever, provided they threw that into the gulf in which the Romans were most powerful. Curtius heard the answer, and asked if his countrymen possessed any thing so valuable as their arms and courage? The courage of the hero was well known; his question caused the most profound silence: Curtius turned his eyes towards the Capitol, and the temples of the gods overlooking the forum, and stretching his hands first towards heaven, and next towards the bottom of the gulf, solemnly devoted himself. He then, fully armed, mounted his horse decorated in all his caparisons, and plunged into the chasm; the applauding people of both sexes throwing after him flowers and fruit." This was afterwards called the Curtian lake, in memory of the deed. Livy, tom. ii. p. 67, 68. Mattaire's edit.

CURTIVS, QUINTUS RUFUS, a Roman historian, who is known now only for his history of the reign of Alexander the Great, is supposed to have flourished in the reign of Vespasian or Trajan; but many doubts have been entertained on the subject. No notice is taken of his work till the twelfth century, though it is thought that Suetonius refers to the author as one among the eminent rhetoricians of those times. This history was divided into ten books, of which the first two, the end of the fifth, and the commencement of the sixth are lost: it has ever been esteemed for the elegance, purity, and floridness of its style. It is, however, vastly defective as a history, abounding with anachronisms, and various geographical mistakes. The Elzevir edition of this work, and also the Delphin editions of 1678 and 1724, and the Variorum of 1708, are highly regarded by critics. See Preface to the Delph. edit.

CURTIVS, MATTHEW, a native of Padua, acquired considerable reputation for his skill in medicine, which he taught in succession at Padua, at Florence, at Bologna, and at Pisa. From Pisa he was called to Rome by the pope Clement VII., and appointed his physician. From an inscription on his monument, erected to perpetuate his memory, by Cosmo de Medicis, it appears that he died in 1564, aged seventy years. His works, several of which passed through many editions, and appear to have been in great vogue, are, "De Vera sectione cum in aliis affectibus, tum vel maxime in Plenitudine," Lugd. 1532, 8vo. "In Mundini Anatomien explicatio," 1550, 8vo. "De curandis

eurandis febribus *Ars Medica*, 1561, Svo. For the remainder, see Haller *Bib. Med.* Another Italian physician of the name, probably of the family, Nicholas Curtius, taught medicine at Padua for twenty-six years. He left "*Methodus consultandi, Venetiis*," 1603, folio. "*Libellus de Medic. lenientibus, purgantibus, &c.*" and "*Consilium adversus pestem*," 1615, in 2mo. These, however, were not published until several years after his death, which took place in the year 1576. Haller *Bib. Med.*

CURTOLONE, in *Geography*, a town of Italy, in the duchy of Mantua, four miles W. of Mantua.

CURVAT, a small town of France, in the department of the Tarn, 15 miles E. of Alby.

CURVATAPINIMA, in *Ichthyology*, a name by which Marcgrave and Piso call the fish named by English writers the scad and horse-mackrel, the SCOMBER *Trachurus*, which see.

CURVATOR COCCYGIS, in *Anatomy*, a name given by Albinus to a muscle of the coccyx discovered by himself, and not described by any other author. It is an oblong, thin, and small muscle, and for the most part tendinous. It arises with a double head, one from the inner, and the other from the lower and lateral part of the *os sacrum*; and descending, terminates in three extremities. He calls it the curvator coccygis, from its office, which is the bending the coccyx; and says, that he found it in different states, in three subjects: one very perfect and entire; in a second, more imperfect and degenerating; and in the third, resembling a ligament rather than a muscle.

CURVATURE, in general, means any deviation from straight. The word is commonly used in mathematics, in philosophy, in mechanics, and other subjects. In mathematics there are several species of curvature (*viz.* of bending or flexure) either of lines or of surfaces, the nature of which is particularly examined under various articles. Thus the curvature of a circular periphery is different from that of a parabola, and different from that of a cycloid; the curvature of a globular surface is different from that of a spheroid, and so forth. And all these peculiar curvatures, together with their origin and properties, are described under the articles CIRCLE, PARABOLA, SPHERE, &c.

In philosophy there are several cases of curvature, which demand particular notice and attentive examination; but most of these cases are treated of under those articles to which they more immediately belong. Thus the curvature of the images of objects, formed by the transmission of light through lenses, or by the reflection of the same from mirrors, will be noticed under the articles LENS, OPTICS, and MIRROR. The curvature of the rays of light, occasioned by their passing by the surfaces of solids, will be found under the article INFLECTION of light, and so forth. Hence in the present article we shall only take notice of those cases of curvature, which are not so obviously sought for under other denominations; and these are the curvature of the surfaces of liquids, and the apparent curvature of the sky.

However the particles of liquids may appear to be moveable with respect to one another, it is certain that they are in a considerable degree possessed of the attraction of aggregation, *viz.* a mutual attraction of the particles; and this attraction differs in different liquids. It is owing to this attraction, that when a separate quantity of a liquid is not under the influence of other forces, it always tends to assume a globular form; which shape is the natural consequence of a mutual attraction amongst the particles of the liquid. Thus a very small drop of water dropped through the air, and especially when the air is much rarefied, assumes a form

so very nearly globular, that the eye cannot perceive its deviation from a perfect sphere. Such is likewise the case with oils, spirits, mercury, and other fluids. But in their usual states of existence, liquids are acted upon by other forces, which may either conspire with, or oppose their attraction of aggregation, according to a variety of circumstances; whence they are obliged to assume shapes different from those which they would assume in consequence of their aggregation only. The other forces are their gravitating power, or the force by which they are drawn towards the centre of the earth; the attraction of affinity, and the attraction of cohesion, *viz.* the peculiar degree of attraction which every liquid has for other bodies. Thus, if a small drop of water be placed upon a dry and clean plate of glass, it will remain nearly of a globular form; its attraction of aggregation, which draws every particle of it towards its centre, being stronger than its gravity, and likewise more powerful than its cohesion or attraction towards the glass, which it touches in a very small spot. This attraction, however, is sufficient to retain the drop of water, when the glass is turned downwards. But if the drop be spread over the surface of the glass, then the film of water will adhere to the glass with much greater force, nor will it recover its globular shape, because by spreading the drop, its particles have been brought nearer to the surface of the glass, and in contact with a far greater extent of it. They have also been removed farther from each other, which has weakened the attraction of aggregation in a very great degree. When a pretty large drop of water is placed upon the glass, the upper middle part of it will be nearly horizontal, its gravity being more powerful than its aggregation. If the water be in considerable quantity, and it be put in a cup, or glass, then the attractions of aggregation and cohesion being much weaker than the gravitation, the surface of the water will be horizontal, excepting that part of it which lies nearest to the sides of the cup, which will be attracted, and ascending a little way will draw part of the contiguous fluid above the horizontal level, in consequence of its attraction of aggregation, so as to form a concave surface to a certain extent. If, by a little care, more water be added, so that the fluid may project above the edge of the cup or glass, then the water close to the edge will assume a surface visibly convex; it being to a certain degree prevented from running over, both by the attraction of aggregation, and the attraction towards the sides of the cup or glass. The like experiments repeated with other fluids, will be attended with results of the same species, but differing in degree, according to the nature of the fluid, and its attraction towards the other substances concerned in the experiments. Thus, if a small drop of mercury be placed upon the flat surface of a piece of glass, it will assume a globular form, in consequence of its attraction of aggregation; and it will adhere to the glass, when this is turned upside down, on account of its attraction of cohesion. But it will be found impossible to spread it over the surface of the glass, like water, because its attraction of aggregation is much more powerful than its cohesion to the glass. And it is for the same reason that if a glass or china cup be partly filled with mercury, this fluid will not rise, like water, towards the sides of the cup; but it will form a convex curve of considerable extent.

The different degrees of attraction between a given fluid and other substances, is easily shewn by the effects of contact. Thus a small globule of mercury laid upon paper will adhere to glass when the latter is brought into actual contact, and is drawn by the glass from the paper; and in the same manner if a larger quantity of quicksilver be brought in contact with it, the small globule will leave the glass,

CURVATURE.

glass, and will incorporate with the larger quantity of the same fluid metal.

The curvature of fluids round the bodies which float in them depends likewise upon the same causes, and hence that curvature is sometimes convex, and at other times concave. Its extent also varies considerably; it being influenced, besides the nature of the body and of the fluid, by heat and cold, and often by the interposition of a little unctuousity, or such minute bodies, as elude the strictest examination. It appears, therefore, from the above experiments and observations, that in a variety of cases fluids assume a curvature of surface which depends on the circumstances already enumerated; but those circumstances being very fluctuating, and often unperceived, it becomes extremely difficult, or rather impracticable, to determine in most cases the nature of the actual curvature, any more than to pronounce it in general terms either *convex* or *concave*. See *CAPILLARY Attraction*.

With respect to the curvature of the sky, an obvious phenomenon has been remarked from time immemorial, and several theories have been formed in explanation of it. The phenomenon is, that the starry heavens, or the ideal vault, upon which the stars seem to be fixed, has the appearance, not of a spherical surface, but of a flattened vault, having its upper part nearer to us, than its lower edge, *viz.* the sides which stand towards the horizon. And the same constellation appears to be much larger when it approaches the horizon, than when it stands nearly overhead. Yet when measured with a quadrant, its dimensions are the same in either situation. This is likewise the case with the sun and the moon. See *HORIZONTAL Moon*, and *Sun*.

In explanation of this phenomenon, several conjectures have been made, and most of them may be seen in Dr. Priestley's *History of Optics*. But it would be needless to place before our readers any other hypothesis, besides that which seems to be by far the most rational and satisfactory. According to this hypothesis, the phenomenon is considered as a deception of our sight, or rather of the judgment formed on the perception of our eyes. And this supposition is grounded upon the following well known facts, and obvious deductions. In judging of the distances of objects, we are assisted by four circumstances; *viz.* the adjustment of the axes of our eyes; the comparison of the situation of the object in question with others which stand at known distances; the angle under which a known object is seen; and the degree of distinctness with which the object appears to us.

In looking at an object, we naturally move our eyes so that their axes produced may meet at that object, and according as that object is removed farther and farther from us, so the angle made by the axes of the two eyes becomes smaller and smaller; hence by this motion of our eyes we are enabled to judge with sufficient accuracy of the distance of the object within certain limits. But when the object is removed a vast way from us, then the adjustment of the eyes becomes insensible, and of course the distance cannot be determined from it. Hence it is, that when we look at an object with only one eye, we form a very imperfect judgment of its distance. The effect arising from the situation amongst other known objects does not require any farther explanation. When the object is familiar to us, such as a man, a horse, &c. the angle under which we see it, is sufficient to inform us of its distance; for the farther the object is from us, the smaller must the angle be under which we see it. The last circumstance is the distinctness of the appearance; and since small objects become invisible to us be-

yond a certain distance, it follows, that by losing sight of the minutest parts of a large object, we see the latter more and more confused and indistinct, in proportion as it is removed farther and farther from us. Hence, by a natural association of ideas, when we see an object indistinctly, we are led to suppose, that its situation is far from us. The effect of all these circumstances may be observed in the practice of landscape-painting; for when the artist means to represent a man at a great distance, he paints him very small, and indistinct, placing him amongst such objects, or in such a spot, as may, from other circumstances, appear to be far distant from us. With respect to the celestial objects, it is evident, that the first three of the above-mentioned circumstances cannot be concerned; hence the distinctness or indistinctness of the object is the only one which can influence our judgment.

It is to be remarked, that since the earth is surrounded by an atmosphere which is loaded with vapours in various states of existence, the same object, at the very same distance, will appear to be farther from us when its situation is near the horizon, because in that case the visual rays pass through a great portion of the atmosphere, or partially-obstructing medium, and the object appears indistinct; than when it stands near the zenith, where it looks brighter, and more distinct, because the visual rays pass through a smaller portion of the atmosphere. And our judgment is led to make the same conclusion with respect to that part of the apparent vaulted heavens upon which we see the stars. But independent of the stars, or sun, and moon, the colour itself of the sky, being a more determined azure towards the zenith, and more diluted towards the horizon, is sufficient to impress us with the idea of the sky being more extended towards the horizon, than overhead.

CURVATURE, in *Mathematics*. A straight line drawn through any point of a curve-line in such a manner that no other straight line can be drawn through the same point, so as to pass between the first line and the curve on either side, is called a tangent of the curve-line. In like manner, of all the circles that can have a common tangent with a curve line at any proposed point, that one, which coalesces so intimately with the curve, that none of the rest can pass between it and the curve on either side, is said to have the same curvature as the curve at the proposed point: or it is called the circle of equal curvature, or the osculating circle.

Of all curves, the circle is that which is the most simple in its nature. It depends only on one arbitrary quantity: for when the radius of a circle is given, or found, the whole figure is determined. The periphery of a circle, too, being perfectly uniform, has an equable curvature throughout. For these reasons, it seems natural to compare curve-lines with the circle, next after the straight line. The tangents mark the directions of the several parts of a curve-line; the circles of equal curvature enable us to judge of the deviations from the rectilinear course.

It will readily be allowed, that the greater the radius of a circle is, the less is the curvature of its periphery. This is not an inference deduced from mathematical principles; it is a proposition, of which we have a general conception, and which seems to flow naturally from the notion we have of a curve-line. There can be no measure of curvature fit to be the basis of scientific reasoning, independent of definition. No part of the mathematics has been treated more vaguely, or has been obscured by more paradoxes, than the consideration of curvature. The exploded mysteries about the angle of contact, once so much agitated, deserve not to be drawn out of merited oblivion. The obscurities and inconsistencies that occur in such discussions, arise solely from the

CURVATURE.

want of due care in laying down precise definitions. After having reflected on this subject, it appears most convenient to measure the degrees of the curvatures of different circles by the inverse proportions of the radii. Thus a circle, that has a radius twice as great as another, will, according to this definition, have only half the curvature. Having thus fixed what is meant by the proportions of the curvatures of different circles, we can compare the degrees of curvature of all other curves by the help of the osculating circles.

It is to be remarked, that the definition of the equicurve circle, which we have laid down, is independent of any assumed measure of curvature. It supposes that, when an indefinite number of circles have a common tangent with a curve-line, some of them coalesce with the curve more intimately than others: and that there is one which coalesces with the curve more intimately than all the rest. This is the equicurve circle: and the degree of curvature is considered to be sufficiently determined, when we have ascertained the circle which has the closest possible contact with the proposed curve. What is really useful in this inquiry depends upon the magnitude and the position of the equicurve circle, and not upon any nice and subtle disquisitions concerning the nature and the degrees of contact. There are cases of continued curvature, where a less circle approaches nearer to a curve line than a greater, without any limit; and there are other cases where a greater circle approaches nearer to a curve line than a less, without any limit: in the former instances, the curvature is said to be infinitely great; and in the latter, the curvature is said to be infinitely small. In all other cases of continued curvature, the degree of curvature is finite, and is measured by the equicurve circle.

The determination of the osculating circles of curve-lines is a subject that has been much treated of by mathematicians; and it is important on account of its usefulness in the doctrine of central forces. In order to lay before our readers a succinct view of what is most valuable in this research; we shall first treat of the osculating circles of the conic sections in a geometrical manner: and, in the second place, we shall give some account of Mr. Huyghens's Theory of Evolute and Involute Curves, with its application to the present subject.

Of the Osculating Circles of the Conic Sections.

PROP. I.

Let BD , (*Analytis*, Plate III. *fig. 1* and *2*) be ordinately applied to the axis of a parabola, or to the transverse axis of an ellipse, or hyperbola; and let BA and DA , drawn perpendicular to the lines touching the curve at B and D , meet in A : then are BA and DA (which are manifestly equal to one another) less than any other line drawn from A to the curve. And, in the ellipse, if BE be an ordinate to the conjugate axis; and if BE and EK , perpendicular to the tangents at B and E , intersect in K ; then are BK and EK (equal to one another) greater than any other line drawn from K to the periphery of the ellipse.

Let the lines touching the conic section at B and D meet in F , and draw the diameter DC : let M be any point in the curve, and draw MN , terminated by the curve, parallel to DF , and let MN cut CD in O , and BF in L . also draw OR parallel to DA , and let it cut BA produced in R . It is manifest that $BF = FD$, and, because,

$$BF^2 : FD^2 :: BL^2 : ML \times LN.$$

Therefore, $BL^2 = ML \times LN$. Consequently, if a circle be described through the points B , M , and N , (*5. 4. E.*)

BH will be a tangent of that circle, (*37. 3. E.*): therefore, the centre of that circle is in the line BR , perpendicular to BH , (*19. 3. E.*): but the same centre is in the line OR , (*7. 3. E.*): for MN is bisected in O , and OR (parallel to DA) is perpendicular to MN , (parallel to DF): therefore, R is the centre of the circle described through the points B , M , and N . But AB is the least of all the lines that can be drawn from A to the periphery of the circle, whose centre is R , and the radius RB , (*7. 3. E.*): therefore, AB is less than AM . In like manner, it may be shewn, that AB is less than any other line drawn from A to the curve.

And the like reasoning will equally apply in the case of the ellipse, when BE is ordinately applied to the conjugate axis: but, in this case, the point R , which is the centre of the circle that passes through the points B , M , and N , will fall between the points K and B : therefore KB is the greatest line that can be drawn from K to the circumference of that circle, (*7* and *8. 3. E.*): therefore, KB is greater than KM . Therefore, KB and KE are greater than any other line drawn from K to the periphery of the ellipse.

Cor. 1. In all the conic sections, the periphery of a circle described from the centre A , with the radius AB , will touch the curve at B and D , (that is, it will touch the tangents of these conic sections at these points), and, every where else, will be wholly contained within the conic section. And, in the ellipse, the periphery of a circle, described from the centre K , with the radius KB , will touch the ellipse at B and E , and, every where else, will be wholly without the ellipse.

Cor. 2. In the parabola and hyperbola, a circle, touching the curves internally at B (not the vertex of the axis), and having a greater radius than AB , will necessarily meet the curve again in another point different from B .

For such a circle will wholly include the circle described with the radius AB ; and, consequently, it will include the point D : and, because the parabola and hyperbola are continuous curve-lines, extending to an indefinite distance both ways, therefore, they will necessarily cut the circle in two points at least, one on each side of the point D .

Cor. 3. And if a circle be described to touch an ellipse at the point B (not the extremity of either axis), with a radius that is greater than AB , but less than KB , that circle will necessarily meet the periphery of the ellipse again in another point, different from B .

For the circle described with the radius, AB , will be wholly within such a circle, and the circle described with the radius, KB , will be wholly without it: consequently, the point, D , will be within such a circle, and the point E will be without it. And, because the periphery of the ellipse is a continuous curve-line returning into itself, therefore it will necessarily meet the circumference in two points, at least, one on each side of the point D .

Lemma. Let A , B , C , and D , be four right lines, such that $A \times B = C \times D$; and let the sum of A and B be likewise greater than the sum of C and D : then the greater of the two lines, A and B , is the greatest, and the other is the least, of all the four lines.

Let A be greater than B , and E greater than D ; and, if it be possible, let C be greater than A : then, because $A \times B = C \times D$, therefore

$$C : A :: B : D.$$

Consequently, the sum of C and D is greater than the sum of A and B , (*25. 5. E.*) contrary to the hypothesis. Therefore A is greater than C and D , and B is less than C and D .

PROP. II.

CURVATURE.

PROP. II.

Let BD , (*fig. 3* and *4.*) be ordinately applied to the axis of a parabola, or to the transverse axis of an ellipse, or hyperbola; and let a circle, which touches the conic section at B , cut the curve again in M (*Cor. 2* and *3* of *PROP. I.*): then, if MN be drawn parallel to the tangent DF , the circumference of the circle will pass through N ; and, the part of the circumference of the circle that is on one side of MN will be within the conic section, and the other part of the circumference will be without the conic section.

Produce MN to meet the tangent of the curve, drawn from B , in L . Because the tangents drawn from B and D are equal to one another, therefore, $ML \times LN = BL^2$: therefore the circle which touches the conic section at B , and passes through M , will likewise pass through N , (*37. 3. E.*)

Draw the diameter DC , cutting MN in O , and make RO perpendicular to MN . Let a line, drawn parallel to MN , or DF , cut the circle in P and Q , the conic section in T and S , the diameter DC in G , the line RO in I , and the tangent BF in K . It is manifest, that MN is an ordinate of the diameter DC : and, because RO bisects MN , one chord of a circle, at right angles, it will bisect all the chords parallel to MN . Thus $PI = IQ$, and also $TG = GS$; consequently, $KP + KQ = 2KI$, and $KT + KS = 2KG$. Since the line, RO , crosses the diameter of the conic section at the point of intersection, O , it is plain that KG is greater than KI , when the parallel is on one side of MN ; and, on the contrary, KI is greater than KG , when the parallel is on the other side of MN . Therefore, in the former case, $KT + KS$ are greater than $KP + KQ$; but, in the latter case, $KP + KQ$ are greater than $KT + KS$.

Because the tangents, BD and DF , are equal to one another, therefore $KT \times TS = KB^2$: but $KP \times KQ$ is also $= KB^2$; therefore, $KT \times TS = KP \times KQ$.

From what has now been shewn, it follows that KS is greater, and KT less than KP or KQ , (*Lem.*), when the parallel is on one side of MN ; and, on the contrary, that KQ is greater, and KP less, than KS , or KT , when the parallel is on the other side of MN . Therefore, the part of the circumference of the circle, on one side of MN , is included within the conic section; and the part of the circumference, on the other side of MN , is without the conic section.

Cor. 1. When the two points B and D are on opposite sides of the line MN , the circumference of the circle falls within the conic section on both sides of the point of contact B : but when the points B and D are on the same side of the line MN , the circumference of the circle falls without the conic section on both sides of the point of contact B .

This is manifest, when it is considered that the point D is always included within the conic section.

Cor. 2. When one of the extremities of the line MN , falls on the point of contact B , the circumference of the circle meets the curve of the conic section only in two points.

PROP. III.

Let BD (*fig. 5* and *6.*) be ordinately applied to the axis of a parabola, or to the transverse axis of an ellipse or hyperbola; and let BM be ordinately applied to the diameter of the curve drawn through D : then the circle which touches the conic section at B , and passes through the point M , is the osculating circle at the point B ; and it will cut

off, from the diameter drawn through the point of contact, a chord that is equal to the parameter of that diameter.

For the circle so described will meet the curve of the conic section only in the points B and M , (*Cor. 2. 2.*); and it will be wholly without the conic section on that side of BM on which the point D is, and wholly within the conic section on the other side of BM . And if another circle be described so as to touch the conic section at B ; then this second circle may be wholly included within the conic section (*Cor. 1. 1.*): or it may cut the curve of the conic section on the same side of BM as the point D ; in which case the circumference will likewise fall within the conic section on both sides of the point B , (*Cor. 1. 2.*): or the second circle may cut the curve of the conic section on the opposite of BM to the point D , in which case the circumference will fall without the conic section on both sides of the point B , (*Cor. 1. 2.*): or lastly, in the case of the ellipse, the second circle may be wholly without the ellipse, so as to include it. (*Cor. 1. 1.*) Now, in none of all these cases does the circumference of the second circle pass between the circumference of the first circle and the curve of the conic section on either side of the point B . Therefore the latter circle is the osculating circle, or the circle of equal curvature, at the point B .

Again, let the diameter drawn through D meet BM in O , and the diameter drawn through B meet the osculating circle in L : join ML and draw the tangents BH and DF .

Then, in the parabola, having joined LO , (*fig. 6.*); because BO , an ordinate to DO , is parallel to DF , therefore the angle $FDO =$ the angle $DOB =$ the angle OBL ; it is also manifest that the angle $FDO =$ the angle $HBL =$ (because BH touches the osculating circle) the angle BML , (*32. 3. E.*); therefore the angle $OBL =$ the angle BML ; and the triangle BLM is isosceles; and LO , which bisects the base BM , is perpendicular to BM . Hence the two triangles BOL and BDL , right-angled at O and D , are equiangular: therefore

$$LB : BO :: BO : OD,$$

consequently $BO^2 = LB \times OD$. Therefore LB is equal to the parameter of the diameter drawn through D , or to that of the diameter drawn through B .

And, in the ellipse and hyperbola, from the centre C , (*fig. 5.*) draw CP parallel to ML , and CQ perpendicular to BM : because BH touches the osculating circle, therefore the angle $CBH =$ the angle BML , (*32. 3. E.*) = the angle BPC : also, the angle $CBH =$ the angle $CDF =$ (because BM is parallel to DF) the angle MOC : therefore the angle $BPC =$ the angle MOC ; and the triangle OCF is isosceles; and CQ bisects OP . It is manifest that $BC^2 - CO^2 = BQ^2 - QO^2$, (*47. 1. E.*): but $BC^2 - CO^2 = DC^2 - CO^2 = DO \times OG$, (*5. 2. E.*): and $BQ^2 - QO^2 =$ (because $OQ = QP$) $OB \times BP$, (*5. 2. E.*): therefore $DO \times OG = OB \times BP$. Therefore

$$DO \times OG : OB^2 :: OB \times BP : OB^2, \text{ or } BP : OB.$$

Because CP is parallel to ML , therefore

$$BP : BM :: BC : BL,$$

and, $BP : \frac{1}{2} BM$, or $BO :: 2 BC$, or $DG : BL$,

$$\text{therefore } DO \times OG : OB^2 :: DG : BL.$$

Therefore the chord BL is equal to the parameter of the diameter drawn through D , or to that of the diameter drawn through B .

The preceding propositions apply only to such points of a conic

CURVATURE.

conic section as are without an axis: for this reason it is necessary to add the following proposition to complete the theory of the osculating circles of the conic sections.

PROP. IV.

If in AB , (*figs.* 7, 8, and 9.) the axis of a conic section, a line AP be taken adjacent to the vertex, and equal to the parameter of the axis; then a circle having that line for its diameter will be the osculating circle at the vertex of the axis.

In the parabola, let HM , (*fig.* 7.) an ordinate of the axis, meet the circle upon the diameter AP in L : from the natures of the parabola and the circle. $HM^2 = PA \times AH$, and $HL^2 = PH \times HA$: hence, it is manifest that HL is less than HM : therefore the circle falls wholly within the parabola. Take AQ greater than AP and describe a circle upon the diameter AQ : make $QR = AP$; assume any point as H between A and R , and let an ordinate of the parabola drawn from H , meet the circle upon the diameter AQ in L : then, as before, $HM^2 = PA \times AH = QR \times AH$ and $HL^2 = QH \times HA$: hence it is obvious that HL is greater than HM : therefore the circumference of the circle upon the diameter, AQ , falls without the parabola on both sides of the vertex. Hence it is plain that no circle upon a diameter, such as AQ , that is greater than AP , can be the osculating circle: for, if a circle be described upon a diameter less than AQ , but greater than AP ; it will follow, from what has been proved, that the periphery of such a circle will be without the parabola on both sides of the vertex, while it will be within the circle upon the diameter AQ : that is, it will be between the two curves. And it is manifest that a circle upon a diameter less than AP , is not the osculating circle; for the periphery of such a circle will be equally within the parabola and the circle upon the diameter AP . Therefore the circle upon the diameter AP , equal to the parameter, is the osculating circle at the vertex of the parabola.

Next, let AB , (*fig.* 8.) be the transverse axis of an ellipse or hyperbola, and let HM , an ordinate of AB , meet the circle upon the diameter AP in K . Then, from the nature of the conic section,

$$BH \times HA : HM^2 :: BA : AP,$$

but also

$$BH \times HA : PH \times HA :: BH : HP.$$

Now, it is plain, that the ratio of BH to HP is greater than the ratio of BA to AP (8. 5. E. *et componendo*): therefore (10. 5. E.) $BH \times HA$, or HL^2 , is less than HM^2 ; therefore the circle falls wholly within the conic section. Take AQ greater than AP , (and, in the ellipse, less than the axis AB ;) and describe a circle on the diameter AQ : make as BP to PA , so BQ to QR ; and, it is plain that QR will be less than QA : draw an ordinate of the conic section from any point H between A and R , and let the ordinate meet the circle upon the diameter AQ in L . Then, as before,

$$BH \times HA : HM^2 :: BA : AP, \text{ or } BR : RQ,$$

$$BH \times HA : QH \times HA :: BH : HQ.$$

But the ratio of BR to RQ is greater than the ratio of BH to HQ : therefore HM^2 is less than $QH \times HA$, or HL^2 : therefore the periphery of the circle upon the diameter AQ falls without the conic section on both sides of the vertex of the transverse axis. Hence, it is manifest, as in the case of the parabola, that the circle upon the diameter AP is the osculating circle.

And, in the case of the conjugate axis of the ellipse, it may be shewn, by similar reasoning, (*fig.* 9.) that the circle upon a diameter equal to the parameter, falls wholly without the ellipse; and that a circle upon a less diameter falls within the ellipse on both sides of the vertex. Therefore, in this case also, the former circle is the osculating circle of the ellipse.

Thus have we investigated two of the most remarkable properties of the osculating circles of the conic sections, by the help of which the circles in question may be determined in every case. For, in the first place, we have proved that the osculating circle at the point B passes through M (*figs.* 5 and 6.), where BM drawn parallel to the tangent of the circle at D , cuts the conic section; and, in the second place, we have shewn that the same circle, in all cases, cuts off, from the diameter drawn through the point of contact, a part equal to the parameter of that diameter.

Huyghens's Theory of Evolute.

We shall now proceed to explain the theory of evolute and involute curves, invented by Mr. Huyghens, which will enable us to determine the osculating circles of any proposed curves. Let ABC , (*fig.* 10.) be any curve line whatsoever, having its curvature all turned one way; for the sake of assisting the imagination, the curve ABC may be conceived to be a mould of wood, or any solid materials; and let a thread, perfectly fine and flexible, be adapted to, or lapped round, the convexity of the curve, or mould; and, while one end of the thread remains immovable on the curve, let the other end, after having been stretched to any proposed point D , be moved so as to keep the thread always tight, and to unlap it gradually from the curve; then the moveable end of the thread will describe a second curve, the nature of which will depend on the given curve, and the position of the initial point D .

Mr Huyghens calls the curve ABC , from which the thread is unlapped, the evolute or *curva evoluta*; the curve, described by the moveable end of the thread, he calls *linea ex evolutione descripta*, and it is sometimes termed the evolutrix, but more commonly the involute. This last name seems to have originated from a procedure directly opposite to evolution, for if the end of the thread be moved backward on the involute, the thread will be again lapped up on the mould.

The geometrical relation, that subsists between the evolute and involute curves, when abstractly enunciated, is this; that every tangent of the evolute curve cuts the involute curve at right angles. Mr. Huyghens demonstrates this property in the following manner. Let BE , touching the evolute at B , meet the involute at E , and draw EL perpendicular to EB : let G and H be two points of the evolute on opposite sides of the point B , and HL and GK the tangents of the evolute drawn from G and H , meeting the involute at L and K ; join KB and GB , and let EB and EI intersect HL in N and I . While the thread is unfolding from the evolute, the parts of it that are detached from the curve, coincide successively with the tangents KG , EB , and HL . Hence $EB = KG + \text{curve } GB$; therefore EB is greater than $KG + \text{chord } GB$; and consequently it is greater than BK . (20. 1. E.); therefore all the part of the involute, on the same side of BE as the point G , falls within the circle described with the radius BE : consequently it falls within IE a tangent of that circle. Again, $EB + \text{curve } BH = LH$; therefore $EN + NH$ are greater than LH ; and NE greater than NL ; but NI is greater than NE , (19. 1. E.); therefore it is greater than NL ; therefore all the part of the involute, on the other

side

C U R V A T U R E.

side of BE , likewise falls within the line IE . Therefore IE touches the involute at E ; that is, the tangents of the evolute cut the involute at right angles.

From this demonstration it is easily inferred, that the circle described with the radius BE from the centre B , falls within the involute on the one side, and without it on the other side. It has already been shewn, in the preceding demonstration, that the arc EK of the evolute is within the circle. Let the circle meet HL in R , and join RB and BH ; then HR is less than $RB + \text{chord } BH$; therefore it is less than $RB + \text{curve } BH$, that is, than HL ; therefore the arc EL of the evolute is without the circle.

It is next to be proved, that the same circle is the osculating circle of the involute at the point E . It has been shewn that EN is greater than NL ; therefore, if a circle be described with a radius EQ , greater than EN , the arc of the involute between E and L will fall within that circle, (7. 3. E.); but the part of the involute between E and K is also within the same circle; for it has been shewn above, to be within the circle described with the less radius BE ; therefore the circle described with the radius BE , as well as the axes EL and EK of the involute, fall within a circle described with any radius, as EQ , greater than EN . Again, let KG meet EB in M ; it is manifest that KM is greater than ME ; therefore, if a circle be described with a radius EP less than EM , the arc EK of the curve will be without that circle, (7. 3. E.); but the part of the curve between E and L , is also without the same circle; for it has been shewn to be without the circle described with the greater radius BE , therefore the circle described with the radius BE , as well as the arcs EK and EL of the involute, fall without a circle described with any radius, as PE less than ME . Now, however little EQ exceeds EB , or however little EP falls short of EB yet the tangents HL and GK may be drawn so near to BE , as that the point N shall be between the points Q and B , and the point M between the points P and B . Therefore no circle described to touch the involute at E , with a radius either greater or less than BE , will pass between the involute and the circle described with the radius BE ; therefore this last circle is the osculating circle of the involute at the point E .

In the course of the last demonstration it has been shewn that, a circle which touches the involute will fall within that curve on both sides of the point of contact, if it be less than the osculating circle; but, it will fall without the same curve on both sides of the point of contact, if it be greater than the osculating circle.

The view that we have taken of the subject of curvature makes it necessary to prove that the rectilinear deflections from the common tangent are equal in the involute and its osculating circle. By the rectilinear deflections of an arc from the tangent, we mean the perpendicular drawn from one extremity of the line upon the line that touches it at the other extremity. The proposition that we here propose to demonstrate, does not necessarily follow from any thing before proved: and it is too important to be left undemonstrated; for, on it, hinges the whole of the application of this subject to the doctrine of central forces. The proposition may be thus enunciated: "If two arcs, $E\beta$ and $E\gamma$, (fig. 11.) equal in length, be taken on a curve and its osculating circle, the limit of the ratio of the rectilinear deflections from the common tangent is the ratio of equality." Let BE be the radius of the osculating circle, and EL the common tangent of the curve and the circle: take EP less, and EQ greater, than EB ; and with these radii let two circles be described touching EL

at E : then, as has been shewn, part of the circle whose radius is EP , will fall within both the curve and the osculating circle on either side of E , and part of the circle whose radius is EQ will fall without both the same curves on either side of E : Take EL , upon the tangent, so small that a perpendicular, drawn from L may cut the four curves in such a manner that the points p and q , when it cuts the curve and the osculating circle, may be between the points m and n when it cuts the two other circles. Then the less EP and EQ differ from EB , and the smaller EL is taken, the nearer will the points m and n come together; and the nearer will the ratio of the chords of the arcs Em and En , or the ratio of the arcs Em and En themselves, approach to the ratio of equality; and likewise, in the same circumstances, the nearer will the ratio of the deflections Lm and Ln approach to the ratio of equality: and, by taking EP and EQ nearer and nearer to EB , and EL smaller and smaller, it is plain that both the ratios just mentioned will approach to the ratio of equality without any limit. But what is true of these ratios is much more true of the ratio of the arc $E\beta$ to the arc $E\gamma$, and of the ratio of Lp to Lq : because these two last ratios are always nearer to the ratio of equality than the two first ratios. Thus, then, as the arcs $E\beta$ and $E\gamma$ are diminished, their ratio, as well as the ratio of the deflections Lp and Lq , approach continually to the ratio of equality without any limit.

The effect of every central force is to deflect the moving body from the tangent: hence it follows, from this last proposition, that it is indifferent whether we suppose the momentary motion to be performed in any curve, or in the osculating circle of that curve; because the deflections from the tangent are the same in both.

If the arc $E\gamma$ of the osculating circle be so small, that it may be considered as equal to its chord; then, from the nature of the circle, $2EB \times Lq = E\gamma^2$, or $2EB \times Lp = E\beta^2$: therefore $EB = \frac{E\beta^2}{2Lp}$; that is, the radius of curvature is directly as the square of the arc, and inversely as the deflection from the tangent, where the arc is indefinitely diminished. Hence it likewise follows, that the curvature at two points of different curves, or at two different points of the same curve, are proportional to the deflections from the tangents in very small arcs of equal length: for such deflections are inversely proportional to the radii of curvature at the two points.

The method of generating one curve by unlapping a thread from another curve, is certainly very ingenious: and it is well calculated to assist the imagination in forming clear and precise notions in a matter of no little subtilty. It demonstrates in the clearest manner this curious property of two curves, one of which cuts all the tangents of the other at right angles; viz. That the difference of two tangents bounded by the curves is precisely equal to the arc intercepted between the two points of contact. We shall now add some inferences from what has been demonstrated.

If any number of points, as R, E, L , (fig. 10.) be assumed in any curve, and if RG, EB, LH be drawn perpendicular to the several tangents, these perpendiculars will be all tangents of the evolute of the proposed curve. The point N , in which two of the perpendiculars intersect, is always without the evolute, but is the nearer to it, the less is EL the portion of the curve intercepted between the two perpendiculars: and if we suppose the arc EL to be continually diminished, while one of the perpendiculars, as EN , retains its position, the point, N , will continually approach to the point B , which will be the ultimate place of N . Thus, we see that, in any proposed curve, the positions

CURVATURE.

of the centres of the osculating circles, and the lengths of their radii, may be deduced from the curve itself, without any consideration of the evolute: and this shews that, for any given curve, it is always possible to find a corresponding evolute.

Only one tangent can be drawn to the evolute from a point assumed in the curve: and hence, from such a point, only one perpendicular can be drawn to the involute. From a point on the convex side of the evolute, two tangents of that curve can be drawn (for the sake of simplicity we confine our attention to one branch of the evolute, having a continued curvature all turned one way): therefore, from such a point, two perpendiculars can be drawn to the involute. But, from a point on the concave side of the evolute, no tangent at all can be drawn: therefore, from such a point, no perpendicular can be drawn to the involute. Thus the evolute divides the whole plane which contains the involute into two distinct spaces; if a point be assumed in the one, two perpendiculars can be drawn from that point to the involute; if a point be assumed in the other, no perpendicular at all can be drawn; and if a point be assumed in the line of separation, then only one such perpendicular can be drawn.

We will now inquire how the length of the radius of the osculating circle, and the position of its centre, are to be determined for a curve whose equation is known. Let DA (fig. 12.) be the axis of the curve; EH, an ordinate, = y; DH, the corresponding absciss, = x; EB, the radius of the osculating circle, = R: draw BN parallel, and BK perpendicular, to DA: let ER be a small arc of the curve, and draw RS perpendicular to EH. Suppose \dot{x} and \dot{y} to denote the corresponding fluxions of the absciss

and ordinate; then $\dot{x} = RS$ and $\dot{y} = ES$: put $\frac{\dot{x}}{\dot{y}} = \frac{RS}{ES} = \tau$; and τ will be the tangent of the angle RES (radius 1), or the tangent of the angle EBN, which is plainly equal to RES; then the fluxion of that angle, or the length of the

little arc that measures the angle EBR, = $\frac{\tau}{1 + \tau^2}$: and the length of the like arc, when the radius is R, = $R \times \frac{\tau}{1 + \tau^2}$: but, from the nature of the equicurve circle, the last arc is plainly equal to the little portion of the curve

$ER = \sqrt{\dot{x}^2 + \dot{y}^2} = \dot{x} \sqrt{1 + \frac{\dot{y}^2}{\dot{x}^2}} = \frac{\dot{x}}{\tau} \sqrt{1 + \tau^2}$; therefore

$R \times \frac{\tau}{1 + \tau^2} = \frac{\dot{x}}{\tau} \sqrt{1 + \tau^2}$; whence,

$$R = \frac{\dot{x}}{\tau\tau} \times (1 + \tau^2)^{\frac{3}{2}}; \text{ where } \tau = \frac{\dot{x}}{\dot{y}}.$$

Again, the sine of the angle EBN = $\frac{\tau}{\sqrt{1 + \tau^2}}$;

And the cosine of the same angle = $\frac{1}{\sqrt{1 + \tau^2}}$;

Hence BN = EB \times cosine of EBN = $\frac{\dot{x}}{\tau\tau} \times (1 + \tau^2)$;

And EN = EB \times sine of EBN = $\frac{\dot{x}}{\tau} \times (1 + \tau^2)$;

Therefore,

$$DK = BN + DH = x + \frac{\dot{x}}{\tau\tau} \times (1 + \tau^2).$$

$$BK = EN - EH = -y + \frac{\dot{x}}{\tau} \times (1 + \tau^2).$$

The symbol τ (which is the tangent of the angle that the radius of curvature makes with the axis of the curve (radius 1) is purposely introduced, in the above expressions, to avoid second fluxions: because we are thus left at liberty to make any one of the variable quantities we please, to flow uniformly.

To illustrate these formulas, let the proposed curve be the conic parabola, of which the equation is, $4 p x = y^2$.

Then $y = 2 p^{\frac{1}{2}} x^{\frac{1}{2}}$; and $\frac{\dot{y}}{\dot{x}} = \frac{p^{\frac{1}{2}}}{x^{\frac{1}{2}}} = \frac{1}{\tau}$; hence $\tau^2 = \frac{x}{p}$,

and $\frac{\dot{x}}{\tau\tau} = 2 p$: therefore the radius of curvature = $\frac{\dot{x}}{\tau\tau} \times$

$(1 + \tau^2)^{\frac{3}{2}} = 2 p \times (1 + \frac{x}{p})^{\frac{3}{2}}$. At the vertex of the

curve, where $x = 0$, the radius of curvature is $= 2 p = \frac{1}{2}$ of the principal parameter.

To investigate the nature of the evolute, we have DK

$$= x + \frac{\dot{x}}{\tau\tau} (1 + \tau^2) = x + 2 p \times (1 + \frac{x}{p}) = 3 x + 2 p:$$

let the evolute meet the axis of the parabola at A; then DA = radius of curvature at the vertex = $2 p$; therefore AK = DK - DA = $3 x$.

Again, BK = $-y + \frac{\dot{x}}{\tau} (1 + \tau^2) = -y + 2 p^{\frac{1}{2}}$

$x^{\frac{1}{2}} (1 + \frac{x}{p}) = -y + 2 p^{\frac{1}{2}} x^{\frac{1}{2}} + \frac{2 x^{\frac{3}{2}}}{p^{\frac{1}{2}}}$ (because

$$y = 2 p^{\frac{1}{2}} x^{\frac{1}{2}})$$

Draw AM perpendicular to AD, and put AM = BK = z ; and BM = AK = u : then $u = 3 x$, and

$z = \frac{2 x^{\frac{3}{2}}}{p^{\frac{1}{2}}}$: hence the equation of the evolute is $u^3 =$

$\frac{27}{4} \times p z^2$; which shews that the curve sought is a semicubical parabola.

The arc AB of the evolute, according to what has been taught, is equal to BE - AD, or in symbols, to $2 p \times$

$$(1 + \frac{x}{p})^{\frac{3}{2}} - 2 p. \text{ Thus it appears, that any proposed}$$

arc of the semicubical parabola may be exactly rectified. The investigation we have here given is due to Mr. Huyghens; but this curious discovery was first made by Mr. Will. Neil, an Englishman and a pupil of Dr. Wallis, and from him the curve to which it relates is sometimes called *Parabola Neiliana*. The same discovery seems also to have been made, very little later in point of time, and without any knowledge of what had been done in England, by Van Heuraet, a Dutch mathematician.

Let there be proposed the equation $p^n x^{m-n} = y^m$, which comprehends all curves of the parabolic kind:

then $y p^{\frac{n}{m}} x^{\frac{m-n}{m}}$; and $\frac{\dot{y}}{\dot{x}} = \frac{m-n}{m} \cdot p^{\frac{n}{m}} x^{-\frac{n}{m}} = \frac{1}{\tau}$;

hence

CURVATURE.

hence $\tau^2 = \frac{m^2}{(m-n)^2} \times \frac{x^{\frac{2-n}{m}}}{p^{\frac{2-n}{m}}}$; and $\frac{\tau^2}{x} = \frac{m n}{(m-n)^2} \times$

$$\frac{x^{\frac{2-n-m}{m}}}{p^{\frac{2-n-m}{m}}}. \text{ Thus } R = \frac{x}{\tau} \times (1 + \tau^2)^{\frac{3}{2}} = \frac{(m-n)}{m n} \times \frac{p^{\frac{2-n}{m}}}{x^{\frac{2-n-m}{m}}} \times \left\{ 1 + \frac{m^2}{(m-n)^2} \times \left(\frac{x}{p} \right)^{\frac{2-n}{m}} \right\}^{\frac{3}{2}}.$$

In the cubical parabola, whose equation is $p^2 x = y^3$, we have $m = 3$ and $n = 2$, and $R = \frac{p}{6} \times \left(\frac{p}{x} \right)^{\frac{1}{3}} \left\{ 1 + 9 \left(\frac{x}{p} \right)^{\frac{4}{3}} \right\}^{\frac{3}{2}}$. Now, in this case, the less x is taken, or the nearer we approach the vertex of the parabola (the point where the ordinates begin), the greater does R become: so that R is infinitely great at the vertex. This is an instance of curvature infinitely small: and the same thing will plainly happen whenever the equation of the curve is such that $2n$ exceeds m .

In the semi-cubical, or Neilian, parabola, whose equation is $p x^2 = y^3$, we have $m = 3$, and $n = 1$: and $R = \frac{3p}{4} \times \left(\frac{x}{p} \right)^{\frac{1}{3}} \left\{ 1 + \frac{9}{4} \left(\frac{x}{p} \right)^{\frac{2}{3}} \right\}^{\frac{3}{2}}$. In this case, the less x is taken, or the nearer we approach the vertex of the curve, the smaller does R become; and, at the vertex, it is infinitely small. This is an instance of curvature infinitely great; and the case will be the same whenever the equation of the curve is such that $2n$ is less than m .

Thus, then, in the whole series of parabolas, comprehended in the equation $y^m = p^n x^{m-n}$, the conic parabola, which answers to the case $m = 2n$, is the only one that has a finite curvature at the vertex. In all the rest the curvature at the vertex, when compared with the circle, is either infinitely small, or infinitely great. And these several curvatures can as little be compared with one another as they can with the curvature of the circle. They form a scale of infinitely varied gradation, every step of which furnishes a new curvature, *sui generis: neque novit natura limitem*. Princ. Math. Lib. 1. Lem. ii. Schol. But this is a subject on which we must not enter; our present purpose being exclusively confined to the comparison of curve lines with the circle.

If we examine the varied curvature of one leg of the semi-cubical parabola, by means of the general expression of the radius of curvature, it will be found to pass through all possible degrees of finite curvature, constantly decreasing the farther the curve is continued. But in the cubical parabola, the case is different; for the curvature is infinitely small both at the beginning of the ordinates and when they are infinitely great. Therefore, in this parabola, the curvature must first increase and then decrease again; and there will be some point where the curvature is a maximum, or the radius of curvature less than at any other point of the curve. This point of greatest curvature will be found by treating the expression for the radius of curvature according to the rules for finding the maxima and minima of quantities.

Sir Isaac Newton has given the name of "variation of curvature" to the proportion which the fluxion of the radius

of curvature bears to the fluxion of the curve; and the logarithmic spiral, in which this ratio is every where the same, he calls a curve "equably variable." Newton's Fluxions.

We shall conclude this subject with investigating a formula for finding the osculating circles of the curves that are generated by the revolving of a "radius vector" about a fixed centre, or pole, such as the spirals. Let A (fig. 13.) be the pole, M a point in the curve, and O the centre of the osculating circle; let MN be a very small part of the curve, and join MA , NA , MO , NO ; draw MR , AP , and AQ , perpendicular to AN , MO and NO respectively. The nature of such curves is most commonly defined by assigning the relation that subsists between the radius vector AM and the angle which it makes with a line AB given by position. Put $AM = \rho$, and let the arc that measures the little angle MAN on the circle whose radius is $1, = \phi$: then $NR = \rho \phi$, and $NR = \rho$, and $MN = \sqrt{\rho^2 + \rho^2 \phi^2}$: It is plain that the triangles MNR and MAP are equiangular; hence MP (for which we shall write p) =

$$\frac{AM \times MR}{MN} = \frac{\rho^2 \phi}{\sqrt{\rho^2 + \rho^2 \phi^2}}; \text{ again, because } AM^2 = MO^2 + OA^2 - 2MO \cdot OP^2 \text{ and } AN^2 = NO^2 + AO^2 - 2NO \cdot OQ; \text{ therefore, since } MO = ON, NA^2 - MA^2 = 2MO \times (OP - OQ) = 2MO \times (NQ - MP); \text{ that is, in symbols, writing } R \text{ for } MO, 2\rho \xi = 2R p: \text{ Hence}$$

$$R = \frac{\rho \xi}{p}, \text{ a formula of easy application.}$$

The nature of the evolute will be known from the values of the radius vector AO , and the perpendicular upon the tangent AP . Now $AP = \sqrt{\rho^2 - p^2}$: and $AO = \sqrt{MO^2 - 2MO \cdot MP + MA^2} = \sqrt{\frac{\rho^2 \xi^2}{p^2} - 2 \frac{\rho \xi}{p} \rho + \rho^2} = \rho \sqrt{\frac{\xi^2}{p^2} - 2 \frac{\xi}{p} + 1}$.

In the logarithmic spiral, all the radii vectores cut the curve in the same angle: let this constant angle be denoted by m ; then, in this curve, $\frac{p}{\rho} = \sin. m$, and $\frac{\xi}{\rho} = \frac{1}{\sin. m}$: whence

$$AO = \rho \times \sqrt{\frac{1}{\sin.^2 m} - 1} = \rho \times \frac{\cot. m}{\sin. m}; \text{ therefore } MAO$$

is a right-angled triangle; and the angle $AO M$, which the radius vector of the evolute makes with the curve of the evolute, is constantly equal to the given angle m , or to the angle which the radius vector of the involute makes with the curve of the involute. Thus it appears that, in the instance of the logarithmic spiral, the evolute is not only similar to the involute, but it is precisely the very same curve in a different position. James Bernoulli first discovered this curious property; and, admiring the constant reproduction of the same curve by repeated evolutions, he desired that a logarithmic spiral should be engraved on his tomb-stone, with the inscription *eadem mutata refurgo*.

CURVATURE, *Variation of*. See VARIATION.

CURVATURE, *Double*, is used for the curvature of a line, all the parts of which are not situated in the same plane.

CURUCHE, in *Geography*, a town of Portugal, in the province

province of Alentejo, district of Aviz, with a population of 2400 inhabitants.

CURUCUI, in *Ornithology*, a name given to several species of TROGON; which see.

CURVE, in *Geometry*. The original idea, from which all our notions of geometrical magnitudes are derived, is that of a solid. From the idea of a solid, we get the notion of a surface, which is the boundary of a solid; and in like manner, from the idea of a surface, we derive the notion of a line, which is the boundary of a surface, and possesses length only without breadth or thickness.

Straight Line.

The simplest sorts of lines are those which are called straight, or right, lines. The idea of a straight line is of so simple and uncompounded a nature, that it appears difficult, if it be possible, to make it clearer by any description or definition. It will certainly not be maintained that Euclid has succeeded in his attempt to define a straight line, when he says that it is such a line as "lies evenly between its extreme points:" for the phrase here used does not convey a more clear and precise meaning than the word *straight*, which it is intended to define. We apprehend that the most philosophical course to pursue in this case is to omit defining what cannot be made clearer by definition; and fairly to take it for granted that whoever understands the English language must have a distinct idea of the meaning which the word *straight* is intended to convey. All the purposes of geometry will be answered by stating as an axiom, or self-evident inference from the idea of a straight line, that particular property which is selected to be the foundation of scientific reasoning. And this is in effect what Euclid has done; for none of his conclusions are drawn from his definition, but they all hinge on the 10th axiom, which is an inference obviously flowing from the notion we have of straight lines.

Curve Line.

It is no less difficult to give a direct definition of a curve line than of a straight line. The ancient geometers seem to have extended the appellation of a curve line (*καμπύλη γραμμή*) not only to lines, such as the circle and the conic sections, that have a regular and continued curvature, but also to lines made up of several contiguous straight lines in different directions; and even to mixed lines composed partly of straight, and partly of curve lines. We shall exclude such singular combinations from the class of curves by defining a curve line to be "that which is neither a straight line, nor composed of straight lines."

The straight line and the circle, the simplest of all the curves, are the subjects of the plane geometry. Next after the plane geometry, the ancient geometers ranked the theory of the conic sections, of which we have treated in its proper place. These two branches comprehend nearly the whole of the ancient geometry; a very few curves, devised for the solution of particular problems, and forming no connected theory, do not deserve to be distinguished as a separate branch. The most noted of the curves here alluded to are the following: the spiral of Archimedes; the conchoid of Nicomedes; the cissoid of Diocles; and the quadratrix of Dinostratus.

It may not be amiss to notice in this place a classification of lines laid down by the ancient mathematicians in their treatises on geometrical loci. The most simple of the local propositions, comprehending such as related to the circle,

they called *loci plani*; the more complex propositions, depending on the conic sections, they termed *loci solidi*; and all other local propositions, which they could not reduce to one or other of these two classes, they comprehended under the generic name of *loci lineares*, in the investigation of which they had made no advances. Pappus, lib. vii.

The instance of the "*Locus ad rectas*" will serve to illustrate what is here said. In this locus, a certain number of straight lines, as four or six, are supposed to be given by position; it is supposed too that straight lines are drawn from a point to cut each of the lines given by position in a given angle; further, in the case of four lines given by position, the ratio of the rectangle contained by two of the lines drawn from the point to cut the lines given by position, to the rectangle contained by the other two, is to be a given ratio; and, in the case of six lines given by position, the ratio of the solid contained by three of the lines drawn from the point to cut the lines given by position, to the solid contained by the other three, is to be a given ratio; then the question is to investigate from these data the nature of the line that the point will touch. The case of four right lines given by position (*locus ad quatuor rectas*) fell within the compass of the ancient geometry, and it was shewn in general to be a *locus solidus*; but, in particular states of the data, it might become a *locus planus*; that is, in this case, the point touched a conic section, and in particular circumstances, a circle, or a right line. But, in the case of six right lines given by position (*locus ad sex rectas*), the investigation surpassed the limits of the ancient geometry; and the proposition fell into the unknown class of *loci lineares*.

It is not till the time of Des Cartes that the general properties of curve lines can be considered as forming a separate branch of the mathematical sciences. This celebrated philosopher and mathematician first pointed out the application of algebra to geometry; and, by this happy thought, laid the foundation of the great modern improvements in analysis. For it requires only a superficial view of the history of the mathematics to shew that the chief modern discoveries have originated from researches into the properties of curve lines.

Let A B (*Analysis*, Plate VI. fig. t.) be a right line given by position, and A a given point in it; from A draw A C making a given angle with A B, and let P M, drawn from the point P, be parallel to A C. Then the position of the point P will be perfectly ascertained when we shall have determined these four things: *viz.* the length of the line A M; the length of the line P M; whether A M lies on the right or the left of the point A; and whether P M is above or below the line A B.

A mathematical curve line may be considered as a series of points, all of which are possessed of some common property. What is called the *equation of the curve* is merely the algebraical expression of the relation that must necessarily subsist between the lengths of the lines A M and M P, in order that the point P may have the property which is characteristic of the curve line. This equation puts it in our power to find the length of one of the lines, as M P, when the length of the other, A M, is given; and, the several points of the curve, that correspond to any proposed portions of the fixed line A B, are by this means determined, as far as the two first of the conditions enumerated above are concerned.

The line A B is called the axis of the abscissas.

The

The portion of the axis, AM , is called an abscissa; and the fixed point, A , is called the origin of the abscissas.

The line PM , parallel to AC , is called an ordinate of the curve. The ordinates are understood to be at right angles to the axis, unless the contrary be expressly mentioned.

A point of a curve is sometimes determined by two lines, as PM and PN , drawn from it parallel to two axes, AB and AC : in this case, PM and PN are called co-ordinates; and the point A , where the axes cross, is called the origin of the co-ordinates.

We shall denote the abscissa, AM , by the algebraical symbol x , and the corresponding ordinate by the symbol y .

The next thing to be considered regards the position of the abscissas in respect of the point A ; and the position of the ordinates in respect of the axis AB . On this head the rules of analysis are clear and explicit; and there is no doubt that they are just and accurate. But although these rules suggest themselves readily enough in the application of algebra to geometry, and there has been no difference of opinion about them, yet no author, that we know of, has succeeded in deducing them, in a perspicuous manner, from first principles. The doctrine of negative quantities comes into play here; a doctrine concerning which much has been written that is vague, much that is subtle, nothing that is very clear and satisfactory. The author that appears to have approached nearest to the unravelling of this part of the theory of curve lines is M. Carnot, in his "Geometrie de Position;" (See particularly the Discours Preliminaire); to which treatise we refer such of our readers as are pleased with disquisitions of this kind.

Adopting the received doctrine of positive and negative quantities, as laid down by the writers on algebra; all the positive abscissas are to be set off on one side of the point A , *Fig. 1.* as on the right-hand side; then it will follow of course, that the negative abscissas, which are of an opposite nature to the positive ones, must be set off on the left-hand side of the same point. In like manner, all the positive ordinates, whether they correspond to positive abscissas or to negative ones, are to be drawn on one side of the line AB , as on the upper side of it: and, then, all the negative ordinates, whether they correspond to positive abscissas or negative ones, must necessarily be drawn below the line AB . Thus a positive ordinate, that corresponds to a positive abscissa, will be placed above the line AB , on the right hand of the point A , as MP ; and a negative ordinate, that corresponds to such an abscissa, will be placed below the line AB , on the right hand of the point A , as MP' : and, again, a positive ordinate, that corresponds to a negative abscissa, will be placed on the left-hand of the point A , above the line AP , as mp ; and a negative ordinate, that corresponds to such an abscissa, will be placed on the left-hand of the point A , below the line AB , as mp' . Thus the equation of the curve, which expresses the relation of the lengths of the abscissas and the corresponding ordinates, is, at the same time, sufficient, with the help of the directions just laid down, to fix the relative positions of the same lines; because the rules for resolving algebraic equations not only investigate the numerical values of the unknown quantities, but likewise determine the signs that must be prefixed to these values.

It is to be remarked that what are called impossible, or imaginary, roots in algebra, have no place in the theory of curve lines. These mysterious quantities have no correspondent expression in geometry. When a known value,

positive or negative, is given to the abscissa, then every real value of the ordinate deduced from thence, whether positive or negative, will determine a point in the curve by being placed in its proper position; but the impossible values of the ordinate only mark that we are past the limits of the curve, and that we have been seeking for it, where it is not to be found.

Figure of Curve Lines.

The connection between the algebraic values of the abscissas and ordinates, and their different positions, being a capital point in the geometry of curve lines, we shall endeavour to illustrate it by a few examples.

1. *Fig. 2.* Let the equation of the curve be $p x = y^2$. The general value of y , in this equation, is $= \pm \sqrt{p x}$. And here we see that there are no ordinates corresponding to the negative abscissas; for, when x is made negative, the value of y becomes impossible; there will, then, be no part of the curve on the negative side of the origin of the abscissas. It appears also that, for every positive abscissa there will be two ordinates, both equal in length, the one positive, and the other negative. Hence, it is plain, that this curve will be one continuous line, having two legs uniting in the origin of the abscissas, extending indefinitely on both sides of the positive part of the axis, and receding constantly from it.

This curve is no other than a conic parabola, of which p is the principal parameter. The same observations will equally apply to all curves included in the general equation $p x^n = y^m$, when n is an odd, and m an even number, and m is greater than n ; such as, $p x^3 = y^4$, $p x^3 = y^6$, &c.

For the greater precision it may be proper to remark, that a curve, whose equation is $p x^n = y^m$, will be concave, or convex to the axis, according as m is greater or less than n . When m and n are equal, the equation belongs to a straight line.

2. *Fig. 3.* Let the equation of the curve be $p^2 x = y^3$; the general value of y is $= \sqrt[3]{p^2 x}$. It appears, from this expression of the value of y , that there is only one positive ordinate for every positive abscissa; and only one negative ordinate for every negative abscissa. Therefore this curve will consist of two branches, uniting in the origin of the abscissas, and extending indefinitely in opposite directions; the one above the axis of the abscissas, and the other below it.

The same will be the case with every curve included in the general equation $p x^n = y^m$, when n and m are both odd numbers.

Point of contrary Flexure.

It is plain that curves of this kind have their curvatures turned in opposite directions; for if the concavity, or convexity, of one branch be toward the right, the concavity, or convexity of the other branch, will be toward the left. In this case, the curve is said to undergo a contrary flexure; and the point, where the change takes place, is called a point of contrary flexure.

3. *Fig. 4.* Let the curve be expressed by the equation $p x^2 = y^3$. The general value of y is $= \sqrt[3]{p x^2}$. In this instance the ordinates are all positive whether x be positive or negative; and thus there is no part of the curve below the axis of the abscissas. This curve will consist of two branches diverging from the origin of the abscissas, and both on the same side of the axis.

A like figure belongs to all curves included in the equation

tion $p \cdot x^n = y^m$, when n is an even, and m an odd number, and m is greater than n .

Cuspid.

When a curve is reflected back, as happens in the present instance at the origin of the abscissas, the point where the change in the direction of the curve takes place is called a cuspis, or point of reflexion. The marquis de L'Hopital distinguishes points of reflexion into two kinds; the first kind is when the convexities of the curve, before and after the cuspis, are turned toward each other, as in the instances we have just been considering; the second kind (fig. 5.) is when the convexity of the part of the curve on one side of the cuspis is turned toward the concavity of the part on the other side of the cuspis. The second kind of cuspis was disputed by some mathematicians; but instances where it actually takes place were produced by D'Alembert, and it must now be admitted. The equation $(ay - x^2)^2 = \frac{x^5}{b}$

is an instance of a curve having a cuspis of the second kind at the origin of the abscissas.

The several cases which we have gone through deserve particular notice; and indeed they ought to be considered as elementary propositions in the theory of curve lines. For, by proper transformations, they will enable us to examine the nature of the curvature at any proposed point in any curve. To do this, we must make the point of the curve the origin of the abscissas, and take, for the axis, the line drawn perpendicular to the tangent of the curve; then the relation that subsists between the abscissas and the ordinates, when both are very small, or in a nascent state, will, for the most part, coincide with one or other of the cases above enumerated; and thus we shall discover whether the curvature is continued without interruption, or a contrary flexure, or a cuspis, takes place at the proposed point.

Conchoid.

4. As an instance of a more complex figure, let there be proposed the conchoid (fig. 6.) of the ancients, of which the equation is, $x^2 y^2 = (a^2 - x^2) \times (b - x)^2$. The general value of the ordinate is, $y = \pm \sqrt{a^2 - x^2} \times \frac{b - x}{x}$. Here,

when $x = 0$, the ordinate is infinitely great; therefore, if A K be drawn through the origin of the abscissas parallel to the ordinates, that line will no where meet the curve. But, for every positive value of x how small soever, it is plain that there correspond two equal ordinates, one positive and the other negative; therefore the curve will consist of two equal branches, one above and the other below the axis of the abscissas, which approach nearer to the line A K than any assignable distance, but no where meet it. A right line, such as A K, to which a curve continually approaches but never meets, is called an asymptote.

The points, in which a curve will cut the axis of the abscissas, will be determined by putting $y = 0$, and seeking the values of x in the resulting equation. In the present instance, when $y = 0$, then $(a^2 - x^2) \times (x - b) = 0$, whence $x = \pm a$, and $x = b$: therefore, supposing a to be greater than b , make A D and A E each $= a$, and A B $= b$; and B, D, E, will be the points in which the curve will meet the axis. It is plain that the two branches of the curve both pass through the point B, and meet again at the point D, beyond which there is no part of the curve on the positive side of A: for the ordinates change their signs when x , from being less than b , becomes greater than b ; and they

are impossible when x is taken greater than a . To examine the figure of the curve on the negative side of the origin of the abscissas, write $-x$ for $+x$ in the expression for y , then

$$y = \pm \sqrt{a^2 - x^2} \times \frac{b + x}{x}$$

: whence it is easy to infer that the curve will consist of two infinite branches, uniting at E, and extending on opposite sides of the axis along the same asymptote as before.

The part of the curve between B and D is called a *nodus*.

A point, such as B, where two branches of a curve intersect, is called a *punctum duplex*. In like manner, when three branches of a curve pass through one and the same point, that is called a *punctum triplex*. When a *punctum multiplex* takes place, there is always a certain number of equal values of y corresponding to one value of x : but the converse must not always be inferred. Thus, when two points of section coalesce into one point of contact, there is no *punctum duplex*: but if the equality of the ordinates still remains, however the equation of the curve be transformed, or to whatever axis the ordinates be referred, then we may conclude with certainty that there is a *punctum multiplex*, according to the number of equal ordinates.

When $a = b$, then the points B and D (fig. 7.) come together, the *nodus* disappears, and there is a *cuspid* at B.

When a is less than b , the curvature at D (fig. 8.) is continued without interruption, and there is neither a *nodus* nor a *cuspid*.

5. Let there be now proposed the curve whose equation is $ay^2 = (x + b)(x^2 - a^2)$. The general expression of the

ordinate is $y = \pm \frac{\sqrt{(x + b)(x^2 - a^2)}}{\sqrt{a}}$. The values of x ,

corresponding to $y = 0$, are $+a$, $-a$, and $-b$ (fig. 9.): therefore make A B and A C each equal to a , and A D $= b$, (which is supposed to be greater than a): then the curve will cut the axis at the points B, C, and D. There are no ordinates corresponding to such abscissas as are less than a : therefore there is no part of the curve between A and C, nor between A and B. When x is positive and greater than a , the corresponding ordinates will increase as x increases; and the curve, on the positive side of A, will consist of two infinite legs uniting at B. When x is negative,

then $y = \pm \frac{\sqrt{(b - x)(x^2 - a^2)}}{\sqrt{a}}$: whence it appears that

there will be an oval, or a curve enclosing space, corresponding to the part of the axis between C and D.

An oval, such as that just mentioned, which is placed apart from the other branches of the curve, is called an *ovalis conjugata*.

As b approaches nearer to a in value, the part of the axis C D, to which the oval corresponds, becomes less and less; and when b is exactly equal to a (fig. 10.), then the oval contracts into a single point; which is, nevertheless, to be reckoned a part of the whole curve belonging to the equation $ay^2 = (x + a)(x^2 - a^2)$. A single point of this sort, which, though it is detached from the other parts of the curve, yet satisfies the equation of the curve, is called a *punctum conjugatum*.

Classification of Lines.

In the course of the examples that have been adduced, the most remarkable circumstances respecting the figure of curve

C U R V E.

curve lines have been briefly noticed. To the reader, who is pleased with this speculation, and wishes to pursue it further, we recommend the perusal of sir Isaac Newton's "Enumeratio Linearum tertii Ordinis." When the scope of this doctrine is considered, it is plain that a curve line may be employed to exhibit the correlative magnitudes of any two indeterminate quantities, which depend upon one another in such a manner, that, when any values of the one are assumed, the corresponding values of the other may be thence computed. For this purpose, the given values of one of the indeterminate quantities must be made the abscissas of the curve; and then the corresponding values of the other will become the ordinates. Thus the number of curve lines is infinitely great. Hence it is necessary to introduce order into the study of this subject, by proper classification.

The great division of lines is into geometrical and mechanical.

Geometrical Lines.

The class of geometrical lines comprehends all those in which the relation between the abscissas and the corresponding ordinates is expressed by a finite algebraic equation: such are all the curves in the preceding examples. This class comprehends the straight line.

Mechanical Curves.

The mechanical curve lines are all those in which the relation of the abscissas and ordinates cannot be expressed by a finite algebraic equation. The most remarkable quantities, which cannot be algebraically expressed in finite terms, are the lengths of circular arcs and logarithms; and it is on these quantities that the most noted of the mechanical curves depend. The cycloid and the spiral of Archimedes are instances of mechanical curves derived from the circle: the logarithmic curve is an instance of one derived from logarithms; and the logarithmic spiral is an instance of one depending equally upon circular lines and logarithms. It has not been found requisite to subdivide the mechanical curves into subordinate classes.

Algebraic and Transcendent.

Many authors use the words *algebraic* and *transcendent*, in place of *geometrical* and *mechanical*, introduced by Des Cartes: and, when it is considered that the distinction signified refers solely to the nature of the equations which characterize the curves, it must be allowed that the former terms seem to be more appropriate than the latter. Leibnitz gave the name of *curvæ interscendentes* to a class which he considered as holding an intermediate rank between the algebraic and transcendent curves. This class comprehended such as had surd exponents in their equations: as, for instance, $y = x\sqrt{2}$.

Orders of Algebraic Lines.

The class of algebraic lines, which, on account of their mutual affinity, are alone capable of general discussion, are subdivided into orders according to the degrees of their equations. It hardly requires to be remarked, that the degree of any term of an equation depends only on the exponents of the indeterminate quantities, and not at all upon the invariable or given coefficients; but it must be carefully observed, that the degrees of such terms, as involve the two indeterminate quantities, are to be reckoned by the sums of the exponents of both. Thus all the terms, x^2, xy, y^2 , are homogeneous, and equally of the second degree; all these,

x^3, x^2y, xy^2, y^3 , are of the third degree; all these, $x^4, x^3y, x^2y^2, xy^3, y^4$, are of the fourth degree. When the equation of a line is freed from rational fractions, and from surds, then its order, or genus, is to be reckoned by the exponent of the homogeneous terms of the highest degree contained in it.

Complete Equation.

The equation of a line is complete when it contains all the homogeneous terms that characterize its order, and all those of all the inferior degrees. Thus the complete equations of the first, second, and third orders of lines are as follow:

1st order, $ax + by + c = 0$.

2d order, $ax^2 + bxy + cy^2 + dx + ey + f = 0$.

3d order, $ax^3 + bx^2y + cxy^2 + dy^3 + ex^2 + fxy + gy^2 + hx + ky + l = 0$.

These equations plainly comprehend all the possible varieties of one order; and what can be proved to be true of a line expressed by a complete equation, must be admitted to be a general property of all lines of that order. This distribution of lines comprehends the straight line, which forms the first order. Some authors, excluding the straight line, give the name of curves of the first order to the same class which have been ranked as lines of the second order; and, in like manner, they call curves of the second order what have been ranked as lines of the third order.

Number of Terms of a complete Equation.

It is important to know the number of terms that an equation will contain when it is complete: because this alone is sufficient to determine the number of points through which it is possible to describe a curve line of any proposed order. Now the number of homogeneous terms of the n th degree is plainly $n + 1$; and because a complete equation of the n th order contains all the homogeneous terms of all the degrees that can enter into it, therefore the number of the terms must be equal to the sum of the arithmetical series, $(n + 1) + n + (n - 1) + (n - 2) \dots + 1$; which sum is equal to $(n + 1) \times \frac{n + 2}{2}$. The number of

the coefficients of a complete equation is apparently the same as the number of the terms: but it is to be observed, that one of the coefficients may be made to disappear by division; so that, in reality, the number of arbitrary coefficients is one less than the number of the terms, and it is

therefore equal to $\frac{n^2 + 3n}{2}$. And if as many points be pro-

posed as there are arbitrary coefficients in a complete equation of any order, then the curve of the same order that will pass through all these points will be determined. For, let any line at pleasure be drawn for an axis, and let any point in it be assumed for the origin of the abscissas, and let ordinates be drawn to this axis in any given angle; then there will be as many known abscissas, with a known ordinate corresponding to each, as there are given points; and these, being respectively substituted in the equation of the curve, will furnish an equal number of equations, in which every thing is known, excepting the coefficients of the several terms. Therefore, by proceeding according to the rules for resolving simple equations in algebra, the several coefficients will be found in terms of the known abscissas and ordinates: and hence the equation of the curve sought will be completely determined. In this manner it is proved that a

C U R V E.

line of the second order may be described through five points; and one of the third order through nine points.

Change of the Axis.

When the equation of a curve is found for any one axis, it may be transformed into another equation, in which the indeterminate quantities shall denote the abscissas and ordinates of a new axis drawn at pleasure. As this is an operation continually wanted in the theory of curve lines, it must not be passed over without explanation. Let P, (fig. 11.) be a point, the position of which is determined by the abscissa AM = x, and the ordinate MP = y: and let AM' = z, and PM' = u, be the abscissa and ordinate of the same point referred to a new axis AC, it is required to express the first abscissa and ordinate, x and y, by means of the new abscissa and ordinate, z and u. Draw A'N and M'H parallel to AM; and A'B and M'K parallel to PM: put AB = b, and A'B = k: let the angle AMP, in which the first ordinate cuts its axis be = m, and the angle MPM', contained between the first and the new ordinates be = n, and the angle M'AN, between the two axes be = v: then, observing that the sine of the angle PM'H = sin. (m + n), and the sine of the angle AM'K = sin. (m + v), the following determinations are readily derived from the theorem in trigonometry that the sides of a triangle are proportional to the angles opposite to them; viz.

$$\begin{aligned} PH &= \frac{\text{Sin. } (m + n)}{\text{Sin. } m} \times u \\ M'K &= HN = \frac{\text{Sin. } v}{\text{Sin. } m} \times z \\ AK' &= \frac{\text{Sin. } (m + v)}{\text{Sin. } m} \times z \\ M'H &= KN = \frac{\text{Sin. } n}{\text{Sin. } m} \times u. \end{aligned}$$

Hence, because AM = AB + A'K + KN, and PM = PH + HN + A'B, we have in symbols,

$$\begin{aligned} x &= \frac{\text{Sin. } (m + v)}{\text{Sin. } m} \times z + \frac{\text{Sin. } n}{\text{Sin. } m} \times u + b \\ y &= \frac{\text{Sin. } (m + n)}{\text{Sin. } m} \times u + \frac{\text{Sin. } v}{\text{Sin. } m} \times z + k. \end{aligned}$$

If the ordinate PM' is to cut its axis at right angles, the values of x and y become,

$$\begin{aligned} x &= \frac{\text{Sin. } (m + v)}{\text{Sin. } m} \times z + \frac{\text{Cof. } (m + v)}{\text{Sin. } m} \times u + b \\ y &= \frac{\text{Cof. } v}{\text{Sin. } m} \times u + \frac{\text{Sin. } v}{\text{Sin. } m} \times z + k. \end{aligned}$$

And, if both the first and the new ordinates are perpendicular to their axes, then

$$\begin{aligned} x &= \text{Cof. } v \times z - \text{Sin. } v \times u + b \\ y &= \text{Cof. } v \times u + \text{Sin. } v \times z + k. \end{aligned}$$

If these values of x and y be substituted for them in the equation of any curve, the result will be a new equation of the same curve referred to a new axis drawn at pleasure. But however the axis of the curve may be changed in this way, yet it is plain that the order of the curve will remain unalterably the same. The two last expressions for x and y are the most useful; they contain three arbitrary quantities, viz. Sin. v, b, and k, which may be determined so as best to suit the purpose in hand.

Subordinate Species.

We are now to consider the complete equations of the se-

veral orders, with the view of classing the subordinate species contained in each.

First Order of Lines.

The complete equation of the first order of lines is $ax + by + c = 0$; which, by changing the coefficients may be brought to this form, $y = \frac{a}{b}x + c$. Here there is plainly no variety; for whatever changes be made in the coefficients or the signs, the locus of the equation is equally in all cases a right line. It is thus constructed. Fig. 12. From the origin of the abscissas A, draw AB parallel to the ordinates, and equal to c; draw BN parallel to the axis, take Bn = a, and make mn parallel to the ordinates, and = b: then the line drawn through B and m is the locus of the equation, as is manifest.

Second Order of Lines.

The second order of lines will require more discussion. The complete equation, when the arbitrary coefficients only are retained, is

$$\begin{aligned} y^2 + 2axy + bx^2 + 2cy + 2dx + e &= 0. \\ \text{This equation may be thus written,} \\ (y + ax + c)^2 - (a^2 - b)x^2 - 2(ac - d)x &= e^2 - e. \end{aligned}$$

And there are three cases to be distinguished; when $a^2 - b$ is a positive quantity; when it is negative; and when it is equal to nothing.

Hyperbola.

I. Let $a^2 - b$ be positive, and = p^2 ; and let $p^2q = ac - d$: then the equation (A) becomes, by substitution, $(y + ax + c)^2 - p^2(x + q)^2 = e^2 - e - p^2q^2$: let the left-hand side of this equation be resolved into its factors, and, for the sake of brevity, put $m = p + a$, $n = p - a$, $r = pq + c$, $s = pq - c$; and the result will be, $(y + mx + r) \times (y - nx - s) = e^2 - e - p^2q^2$, an equation which may be thus constructed: Fig. 13 and 14. Draw cde parallel to the ordinate PM, and make cd = n × Ad, and ce = m × Ad; and draw the lines AcQ, and AeR: make AH parallel to the ordinate PM, and = s, also AK = r; and draw HL and KN, intersecting in O, parallel to AQ, and AR. Then PN = PM + MR + RN = y + mx + r, and PL = PM - MQ - QL = y - nx - s: therefore PL × PN = $e^2 - e - p^2q^2$; whence it is manifest that the curve, which is the locus of the point P, is a conic hyperbola, of which OL and ON are the asymptotes. When $e^2 - e - p^2q^2$ is a positive quantity, the point P will be without the angle LON: and, in this case, if OS be drawn parallel to PM and = $\sqrt{e^2 - e - p^2q^2}$; then P will be a point in the hyperbola. But when $e^2 - e - p^2q^2$ is a negative quantity, then P will be within the angle LON: and if FG be interposed between OL and ON, so as to be parallel to PM, and = $2\sqrt{p^2q^2 + e - e^2}$; then S, the middle of FG, will be a point in the hyperbola. Thus, in every case, the general equation, when $a^2 - b$ is positive, belongs to a conic hyperbola, which passes through a given point, and has two given lines for its asymptotes.

The complete locus, in the former case, consists of the two opposite hyperbolas, lying in the angles, adjacent to the angle LON; and, in the latter case, it consists of the two opposite hyperbolas contained in the angle LON, and the angle opposite to it.

If $e^2 - e - p^2q^2 = 0$, the equation resolves itself into these two, $y + mx + r = 0$, and $y - nx - s = 0$; which are the

C U R V E.

the equations that determine the position of the right lines O I, and O N.

Under this head are comprehended all cases of the general equation where either y^2 , or x^2 , or both of them, are wanting.

Ellipse.

II. When $a^2 - b$ is a negative quantity; put $p^2 = b - a^2$, and $p^2 q = ac - d$, and the equation (A) will become $(y + ax + c)^2 + p^2(x + q)^2 = c^2 - e - p^2 q^2$. Because the left-hand side of this equation is essentially positive, consistency requires that the other side of it should likewise be positive; and if this condition be wanting, the inference is, that the equation is absurd, and cannot be constructed at all.

Fig. 15. Draw de parallel to the ordinate PM, and make $de = a \times Ad$; and draw AeH : make AR parallel to PM, and $= c$, and draw ROG parallel to AH: take $AK = q$, and draw KL parallel to AR. Then $PO = PM + MH + HO = y + ax + c$: also $KM = AM + AK = x + q = \frac{Ad}{Ae} \times LO$: therefore $PO^2 + \frac{Ad^2}{Ae^2}$

$p^2 \times LO^2 = c^2 - e - p^2 q^2$: make $LN = \sqrt{c^2 - e - p^2 q^2}$; and $LG = \frac{Ad}{Ae} \cdot p \times LN$: then $PO^2 + \frac{LN^2}{LG^2} \times LO^2$

$= LN^2$; whence it is manifest that the locus of the point p is a conic ellipse, of which the lines LG and LN, given in magnitude and position, are two conjugate semi-diameters.

Parabola.

III. The remaining case to be considered is, when $a^2 - b = 0$: the equation (A) becomes $(y + ax + c)^2 - 2(ac - d)x = c^2 - e$; and, by putting $2q = ac - d$, and $4qr = c^2 - e$, it is changed into $(y + ax + c)^2 = 4q(x + r)$, an equation belonging to a conic parabola.

Fig. 16. Draw de and AR parallel to PM; and make $de = a \times Ad$, $AR = c$, and $AK = r$: draw RO parallel to AeN , and KL parallel to PM: then $PO = y + ax + c$, and $KM = x + r = \frac{Ad}{Ae} \times LO$: therefore PO^2

$= 4 \frac{Ad}{Ae} q \times LO$; whence the locus of the point p is a conic parabola, having LO for one of its diameters, and the parameter of that diameter $= 4 \cdot \frac{Ad}{Ae} \times q$.

As every possible case of the complete equation of lines of the second order falls under one or other of the three heads we have separately examined, it follows that the three curves, known by the name of the conic sections, comprehend all the varieties of this order of lines. The same curves which the Greek geometers, nearly two thousand years before the time of Des Cartes, derived from the sections of a solid cone, present themselves here, under a new aspect; and their mutual affinity, as well as their characteristic differences, are as strongly marked by the varied signification of the same algebraic expression, as they are by the changes of position in a geometrical construction. It may be proper to observe that the nature of the highest member of the equation, and the species of the curve to which that equation belongs, both depend on the same quantity $a^2 - b$: for when $a^2 - b$ is positive, the highest member of the equation, or $y^2 + 2axy + bx^2$, has two real binomial factors; and the curve to which the equation, in this case belongs, is the hyperbola: when $a^2 - b$ is positive, the highest member has no real binomial factors; and the curve to which it belongs is the ellipse: and when

$a^2 - b = 0$, the highest member is a complete square, or has two equal binomial factors; and the curve is the parabola.

Third Order of Lines.

Lines of the third order are divided by sir Isaac Newton, first into four principal divisions, or genera; and these are again subdivided into no less than seventy-two different species. The purpose of classification is, in some measure, defeated, when the number of subordinate species becomes so excessively great. It will not be expected that we can enter into any detail concerning a subject occupying so large a field, and which, after all, must be allowed to be more curious than useful. The enumeration of the illustrious author is founded on the varieties of figure that result from all the possible cases of the general equation. This principle of classification is certainly not a little arbitrary. Perhaps there is less reason to be surpris'd that a few cases have been omitted, than that so complete an enumeration was made with so unsure a guide. Mr. Stirling, who has commented on the treatise of sir Isaac, has added four species to those of his author: and who will say that the enumeration is at last complete?

Some mathematicians have advanced a different principle for subdividing the orders of curves, which, they think, is less precarious than the consideration of figure. It is founded on the number of branches which run out to an infinite distance. And, as the number of such branches depends on the number of real binomial factors of that member of the equation, where the indeterminate quantities rise to the highest dimensions, it cannot be denied that there is here an analytical character fit to be the basis of a systematic arrangement. This new principle has the more imposing an aspect, as it succeeds completely for lines of the second order; where the number of different curves, as has already been noticed, corresponds exactly with the varieties of the highest member of the equation in regard to binomial factors. M.M. Euler and Cramer have both given a classification of lines of the third order founded on the number of infinite branches; and although they agree in the first or principal divisions, yet they differ from one another in subdividing these; for the former classes the whole order in sixteen genera, while the latter enumerates only fourteen. We may therefore conclude that there is something arbitrary in all the classifications of curve lines hitherto proposed; and that mathematicians have not clearly pointed out the route which is to be followed, at least in what regards the minutest subdivisions.

General Properties of Curves of all Orders.

Newton has remarked that all geometrical curve lines have properties analogous to those which the ancient geometers have demonstrated of the conic sections. In treating of so extensive a subject, the nature of our work necessarily confines us to a general view only; but as it is in tracing the properties of curve lines common to all the orders, that the superior power and excellence of the algebraic method is most to be admired, we must not pass over so interesting a part of the theory of curve lines with a general remark.

Refusing the general equation of lines of the second order, viz.

$$y^2 + 2axy + bx^2 + 2cy + 2dx + e = 0:$$

Let the position of a point, situated any where in the same plane, and referred to the same axis as the curve, be determined by the abscissa p and the ordinate q ; let a right line (making an angle denoted by m with the ordinate

q) be drawn to cut the curve, and let ξ denote the segment of this line between the point and the curve; let x and y be the abscissa and ordinate of the curve drawn from the extremity of ξ ; then, supposing the ordinates to be perpendicular to the axis, it is plain that $\xi \text{ Sin. } m = q + y$, and $\xi \text{ Cof. } m = p + x$; whence $y = \xi \text{ Sin. } m - q$ and $x = \xi \text{ Cof. } m - p$; let these values of x and y be substituted in the equation of the curve, and, for the sake of brevity, put,

$$A = \text{Sin.}^2 m + 2 a \text{ Sin. } m \text{ Cof. } m + b \text{ Cof.}^2 m$$

$$B = \text{Sin. } m p + a \text{ Cof. } m p + a \text{ Sin. } m q + b \text{ Cof. } m q - c \text{ Sin. } m - d \text{ Cof. } m$$

$$C = p^2 + 2 a p q + b q^2 - 2 c p - 2 d q + e$$

then the equation of the curve will be transformed into the following

$$A \xi^2 - 2 B \xi + C = 0.$$

And if the same substitutions be made in an equation of any order, as the n th order, that equation will be transformed into another of this form

$$A \xi^n - B \xi^{n-1} + C \xi^{n-2} \pm N = 0.$$

Now three of the terms of the transformed equation deserve particular attention. The first is the term that contains the highest power of ξ ; the coefficient of which depends only on the angle m , in which the line cuts the ordinates of the curve, and not at all upon the quantities p and q that determine the position of the point through which the line is drawn: the second is the last term, which, on the contrary, depends upon the quantities p and q , and not at all upon the angle m ; and the third is the second term, the coefficient of which involves the quantities p and q simply, without any of their powers, or products. From these observations, some general properties of curve lines may be readily deduced.

1. A right line cannot meet a curve line in more points than there are units in the number which denotes the order of the curve. For, in the transformed equation, if the quantities p and q , and the angle m , which determine the position of the cutting line, be supposed to be given, then ξ will be the unknown quantity; and every value of ξ , which satisfies the equation, will give a point common to the right line and the curve; but the number of such values cannot be greater than the exponent of the highest power of ξ , which, it is plain, is the same as the number that denotes the order of the curve.

2. If there be any number of parallel straight lines, every one of which cuts the curve in as many points as there are units in the number which denotes the order of the curve, then a straight line may be drawn to cut all the parallels in such a manner, that the sum of the segments of each of the parallels on one side of the line shall be equal to the sum of the segments of the same parallel on the other side of the line. Let the coefficient of the first term of the transformed equation, containing the highest power of ξ , be taken away by division, then

$$\xi^n - \frac{B}{A} \xi^{n-1} + \frac{C}{A} \xi^{n-2} \pm \frac{N}{A} = 0:$$

an equation which, in the present hypothesis, has all its roots real; for they are manifestly the segments that lie between the point through which the line is drawn and the several points where it cuts the curve; it follows, from what has already been noticed, that the coefficient of the second term, $\frac{B}{A}$, will be of this form $a + b \times p + c \times q$, when a , b , and c , are quantities that depend on the angle m ;

and if we suppose the angle m to be given, then we may determine p and q so that $a + b \times p + c \times q = 0$; in which case, the second term of the above equation will be wanting; but when the second term of an algebraic equation is wanting, then the sum of the positive roots is equal to the sum of the negative ones; that is, in the present instance, the sum of the segments, on one side of the point through which the line is drawn, is equal to the sum of the segments on the other side of it: now the equation $a + b \times p + c \times q = 0$ belongs to a right line, the position of which depends on the quantities a , b , and c , that is, on the angle m ; therefore, the property in question will take place for every line drawn to make an angle equal to m with the ordinates of the curve, provided it cut the curve in the requisite number of points.

The property which is here demonstrated of all geometrical curves, is analogous to what is proved of lines ordinately applied to the diameters of the conic sections; and thus the right line, determined by the equation $a + b \times p + c \times q = 0$, may, in general, be called a diameter; and the parallels which it cuts may be said to be ordinately applied to that diameter.

3. If a point be assumed in the plane of a curve, and two right lines be drawn through it, so as to be parallel to two lines given by position, and both to cut the curve in as many points as there are units in the number which denotes the order of the curve; then the continued product of all the segments of one of the right lines, between the assumed point and the several points where the line cuts the curve, will have, to the like product under the segments of the other right line, the same constant ratio, wherever the point through which the two lines are drawn, is assumed. Let p and q denote the abscissa and ordinate that determine the position of the assumed point; and let m be the angle which one of the two right lines, drawn through the assumed point, makes with q ; then the segments of this line, between the assumed point and the several points of section of the curve, will be the roots of the equation

$$\xi^n - \frac{B}{A} \xi^{n-1} + \frac{C}{A} \xi^{n-2} \pm \frac{N}{A} = 0;$$

which roots, in the present hypothesis, will be all real; therefore the continued product of the same segments will be equal to $\frac{N}{A}$, the last term of the equation; and, it is to be recollected, that N depends only on p and q , and A , only on the angle m . In like manner, if m' denote the angle which the other right line makes with q , then the continued product of the segments of this line will be equal to $\frac{N}{A'}$; where N is the same as before, and A' is derived from the angle m' , in the same manner that A is derived from the angle m ; therefore the first product is to the second product as $\frac{N}{A}$ to $\frac{N}{A'}$, or as $\frac{1}{A}$ to $\frac{1}{A'}$; a ratio which plainly depends only on the angles m and m' , and remains the same so long as the two lines are drawn parallel to two lines given by position.

Many other general properties of curve lines might be deduced from the transformation we have here used; but we have already enlarged on this subject as far as our limits will permit. The application of fluxions to the drawing of tangents, determining the points of contrary flexure, and other important parts of the theory of curve lines, will engage our attention in other parts of our work. Such of our

C U R V E.

our readers as wish to acquire a profound and critical knowledge of this part of the higher geometry, may consult Stirling's "Lineæ tertii ordinis Newtonianæ;" Maclaurin's "Geometria Organica;" and his other works; the second volume of Euler's "Introductio in Analysin infinitorum;" and Cramer's "Introduction a l'Analyse des lignes courbes Algebriques."

CURVE of equable Approach. See APPROACH.

CURVE of a double curvature. or *CURVE having a double curvature,* is used for a curve, all the parts of which do not lie in the same plane; that is, such as cannot be described on the same plane.

The curves commonly treated of in geometry, are supposed to be described, or to have all their points placed in the same plane; but if a curve be supposed to be described on a curve surface, in such a manner that all the points of that curve cannot lie or be situated in one and the same plane, then will the curve so described have a *double curvature*.

Monsieur Clairaut has published an ingenious treatise on curves of a double curvature. See his "Recherches sur les Courbes, à double Courbure," Paris, 4to. 1731. Mr. Euler has also treated this subject in the "Appendix to his Analysis Infinitorum," vol. ii. p. 323.

CURVE, Inflection of a. See INFLECTION.

CURVE, Quadrature of a. See QUADRATURE.

CURVE, caustic, in the higher geometry, a curve formed by the concurrence, or coincidence of the rays of light reflected, or refracted from some other curve.

Every curve has its twofold caustic; accordingly, caustics are divided into *catacaustics* and *diacaustics*; the one formed by reflection, the angle of reflection being equal to that of incidence, the other by refraction.

The genesis of these curves may be thus conceived; let $AB, A'B, \&c.$ *Plate. II. Analysis, fig. 24.* represent an infinite number of incident rays, that he all in one plane of incidence; it is evident, that after reflection or refraction, they will not belong to a single point or focus, but cut one another in an infinite number of points: then, if a curve be supposed of such a shape as to touch every one of the reflected or refracted rays $BF, B'F, \&c.$ produced, if need be, in the points $F, F, \&c.$ the curve FFF is called a caustic by reflection or refraction, as the name is applied to reflected or refracted rays. It is plain, that if two tangents $BF, B'F$ intersect one another in G , and be supposed to approach one another till they coincide, the points of contact and of intersection will also coincide; and therefore the reflected or refracted ray touches the caustic in that point of the ray, where its intersection with the next ray vanished, when they were supposed to coincide. And if two incident rays infinitely near to each other be conceived to revolve about their focus A , in the plane of incidence, the focus F or point of intersection of the reflected or refracted rays will describe the caustic above defined; which is real or imaginary, as F is the focus of converging or diverging rays.

Or, a caustic by refraction, called a diacaustic, may be supposed to be thus generated. Imagine an infinite number of rays, as $BA, BM, BD, \&c.$ (*fig. 25.*) issuing from the same luminous point, B , to be refracted from, or to, the perpendicular MC , in the curve AMD ; and so, as that CE the sines of the angles of incidence CME be always to CG , the sines of the refracted angles CNG , in a given ratio; then the curve line, which touches all the refracted rays, is called the diacaustic.

M. Bouguer observes, that there are two caustics formed at the same time, by convex and concave surfaces; and that they occasion two different images of objects seen by re-

flection from them. See his *Traité d'Optique*; or Priestley's *Hist. of Vision*," p. 233. See also on this subject, Smith's *Optics*, p. 171—181.

Caustic curves have this remarkable property, that when the curves that produce them are geometrical, they are equal to known right lines.

Thus, the caustic formed by reflected rays from a quadrant of a circle, which came at first parallel to the diameter, is equal to three-fourths of the diameter; which is a sort of rectification of curves that preceded the invention of the new doctrine of infinites, on which most of our rectifications are built.

Caustic curves are usually supposed to be the invention of M. Tschirnhausen; but it is only the name he invented. The first mention he made of them was in the year 1682, when he produced no instance but that of the caustic in a circle, which he might have learned from Dr. Barrow's *Lectiones Opticæ*, published in 1669. It would have been easy for him to have done the same for any curve, by the help of the radius of curvature published by Huyghens in his *Horologium Oscillatorium*, in 1673. It is certain this had been done by sir Isaac Newton as early as the year 1669, as appears from his *Lectiones Opticæ*, which were read that year at Cambridge, though not published till after his death, *viz.* in 1728. *Act. Erud. Lupl. ann. 1682*, p. 364. *Newt. Lect. Opt. sect. 4. Pref. Stat. Rep. Lett. tom. i. p. 50, seq.*

CURVE, Harmonical. See HARMONICAL CURVE.

CURVE Refleatoire, in *Optics*, so called because it is the appearance of the plane bottom of a basin covered with water to an eye perpendicularly over it. In this position, the bottom of the basin will appear to rise upwards from the centre outwards; but the curvature will be less and less, and at last the surface of the water will be an asymptote to it. M. Mairan, who first conceived this idea from the phenomena of light, found also several kinds of these curves; and he gives a geometrical deduction of their properties, shewing their analogy to caustics by refraction. *Ac. Par. 1740. H. 121. M. 1.* Dr. Priestley's *Hist. of Vision*, p. 752.

CURVES by the Light, or *COURBES a la Lumiere,* a name given to certain curves by M. Kurdwanowski, a Polish gentleman. He observed, that any line, straight or curved, exposed to the action of a luminous point, received the light differently in its different parts, according to their distance from the light. These different effects of the light upon each point of the line, may be represented by the ordinates of some curve which will vary precisely with these effects. Dr. Priestley's *Hist. of Vision*, p. 752.

CURVE, Exponential, is that defined by an exponential equation; that is, by an equation, wherein is an exponential quantity, *v. gr.* $x^x, a^x, \&c.$

The properties, geneses, &c. of particular curves, *v. gr.* the cycloid, conchoid, &c. See under their proper heads, CYCLOID, CONCHOID, &c. See also the preceding article CURVE.

CURVE, Logarithmic. See LOGARITHMIC.

CURVES, Radial, is a denomination given by some authors to curves of the spiral kind, whose ordinates, if they may be so called, do all terminate in the centre of the including circle, and appear like so many radii of that circle; whence the name.

CURVE, Rectification of a, denotes the finding a right line equal to a curve. For the praxis hereof, see RECTIFICATION OF CURVES.

CURVES, Regular, are such whose curvity proceeds continually in the same uniform geometrical manner. Such are the perimeters of the conic section, &c.

Such as have a point of inflection, or regression, and which being continued to a certain point, turn themselves a contrary way, are called irregular curves. Such are the conchoid, and the solid parabola, which has a square for its parameter. See FLEXION and RETROGRESSION, and CURVE *supra*.

CURVE, *Tractory*. See TRACTRIX.

CURVE, *Characteristic triangle of a*, in the higher geometry, is a rectilinear right-angled triangle, whose hypothenuse makes a part of the curve, not sensibly different from a right line. It is so called, because curve lines are used to be distinguished hereby.

Suppose, *e gr.* the semiordinate pm (*Plate Analysis, fig. 11.*) infinitely near another PM : then will Pp be the differential of the absciss: and letting fall a perpendicular, $mR = Pp$, RM will be the differential of the semi-ordinate. Draw, therefore, a tangent TM : and the infinitely small arc Mm will not differ from a right line: consequently, MmR is a rectilinear right-angled triangle, and constitutes the characteristic triangle of that curve.

CURVET, in the *Manege*. See CORVET.

CURVICAUDA, in *Natural History*, the name of a species of bee fly, very common in England, and very troublesome to horses, commonly known by the name of the *wrangle-tail*.

CURVILINEAR, or CURVILINEAL *Figures*, in *Geometry*, are spaces bounded by crooked lines; as the circle, ellipsis, spherical triangle, &c.

CURVILINEAR *Angle and Superficies*. See ANGLE and SUPERFICIES.

CURVIROSTRA, in *Ornithology*, a species of *loxia*; which see.

CURVIROSTRA *Fossilis*, in *Natural History*, the name of a species of fossil shell, found very frequently in the stone quarries of Northamptonshire, and the neighbouring counties. It is a species of cockle, and is distinguished by its beak not standing in the middle, but always inclining to one or the other side. The shell is sometimes found remaining entire, and in its native state and condition, but more frequently there is stony matter deposited in its place.

CURULE CHAIR, *Sella CURULIS*, in *Antiquity*, a high ivory chair, wherein certain of the Roman magistrates had a right to sit.

The curule magistrates were, the ædiles, prætors, censors, and consuls. The senators, who had borne these charges, were carried to senate on curule chairs, as also those who triumphed: the chair being fitted into a kind of chariot, currus; whence the origin of the word curulis.

The curule chair is used, on medals, to express a curule magistracy: when traversed by a halberd, it is the symbol of Juno, and serves to express the conservation of princesses.

CURULE *Statues*. See STATUE.

CURUPA, in *Geography*, a town of South America, in the Brazils, seated on the south side of the river of the Amazons; built by the Dutch, but now possessed by the Portuguese.

CURURUS, in *Botany*. Plum. See PAULLINIA *curura*, and *pinnata*.

CURURU *pala*, Rheed. See TABERNÆMONTANA *alternifolia*.

CURURUCA, in *Ichthyology*, the name of an American fresh-water fish, of an oblong, and not flattened body. It grows to a foot and a half in length; its mouth is very large. It is eaten in the Brazils.

CURWILLET, in *Ornithology*, the sanderling, or CHARADRIUS *Culidris*; which see.

CURZA, or CURSA, in *Geography*, a town of France, in

the department of the Golo, in the island of Corsica. It is the chief place of a canton, in the district of Corte, and contains 3407 inhabitants.

CURZAY, a small town of France, in the department of the Vienne, on the river Vone; 15 miles S.W. of Poitiers.

CURZOLA, CURSOLI, or CORCYRA *Nigra* (which see), a small island of Dalmatia, in the gulf of Venice, ceded by Ragusa to the Venetians in the year 1386. It abounds in wood, which makes the situation convenient for the building of ships, and produces good wine. It is about 30 miles long, and 8 broad, and contains one city, and several villages. N. lat. 43° 17'. E. long. 17° 4'.

CURZOLA, a town of European Turkey, at the east end of the island of the same name; the see of a bishop, and residence of a governor. It is fortified with strong walls and towers, and has a good harbour. The Turks attempted to make a descent here in the year 1507, but were repulsed by the women, after the men had fled.

CURZOLARI, an island, or rather five small islands, which are little more than rocks, in the Mediterranean, near the coast of Greece; 12 miles E. of Cephalonia.

CUSA, NICHOLAS DE, in *Biography*, sometimes styled *Cusinnus*, was born of obscure parents, at Treves, in the year 1401, but who, by his talents, attained to the high office of cardinal. On account of the severe treatment which he met with in his father's house, he entered, at an early age, into the service of the count de Manderscheidt, who, struck with his natural capacity and good talents, was at the expense of his education. He studied in the most celebrated universities of Germany and Italy, and took the degree of doctor in canon law at Padua, when about 23 years of age. He now attained to considerable preferments in the church, and was employed by pope Eugenius IV. on some very important missions, which he executed with so much satisfaction to his employer, that he was, in 1448, raised to the purple, and appointed bishop of Brixen in the Tyrol. In the year 1450, he was sent by the pope into Germany, with a view of composing the differences between the princes of that empire, and of engaging them to unite their efforts against the Turks under Mahomet II.: and, on the capture of Constantinople by that sovereign, in 1453, cardinal Cusa renewed his efforts with additional zeal to unite the Christian princes against the Turks, and addressed to pope Pius II. a refutation of the Koran, which has been mentioned with great respect as a learned and judicious performance. By this pope he was sent again into Germany, to maintain the rights of the holy see, against the claims of the secular princes; and on his return was constituted papal legate at Rome, and governor of the city. He was afterwards imprisoned by Sigismund, duke of Austria, in resentment for some of his reforms; but the duke being threatened with excommunication, was glad to release the cardinal on any terms. Cusa died in his 63d year, at Todi, a town in Umbria, in 1464, leaving behind him a high character for prudence and moderation which were ever exhibited in the undertakings devolved upon him. As an author, he was diligent and very learned on various topics; his works were published in different places where he happened to reside, but they were collected in 3 vols. fol. in 1565. The first volume is on theological subjects; the second contained his controversial pieces; and the third is devoted to mathematics, astronomy, and geography. Moreri.

CUSA, in *Ancient Geography*, a river of Africa, in Mauritania Tingitana; supposed to be the present *Ommirabâ*.

CUSANO, in *Geography*, a town of Naples, in the province of Lavora; 22 miles N.E. of Capua.

CUS-BEHAR. See COOCH-BAHAR.

CUSCASOW. See COOSCOOSOW.

CUSCO, or Cuzco, in *Geography*, the most ancient city of Peru, in South America, and still the second of that viceroyalty, Lima being the first. It was founded by the first Inca, Manco Capac (*i. e.* rich in virtue) who is supposed to have reigned in the 12th or 13th century, as the seat and capital of his empire. Having peopled it with the first Indians, who voluntarily submitted to him, he divided it into two parts, which he called high and low Cusco; the former having been peopled by Indians assembled by the emperor himself, and the latter by those whom his consort (his sister) Mama-Oello had prevailed upon to leave their wandering mode of life. Previously to his marriage, he declared himself and his sister to be children of the sun. The first part forms the north, and the latter the south division of the city. Here he founded the temple of the sun, and appointed virgins of the royal blood to serve that divinity. The houses were originally low and small, like cottages; but as the empire increased, they assumed a new appearance; so that when the Spaniards landed in these parts they were astonished at the extent and splendour of the city, especially at the magnificence of the temple, the grandeur of the palaces of the Inca, and the pomp and richness becoming the seat of so vast an empire. In October, 1534, Don Francisco Pizarro entered and took possession of it in the name of Charles V. emperor, and king of Spain. This was followed by a siege of the Inca Manco, who laid great part of it in ashes, but without dislodging the Spaniards. Here Manco Capac was crowned with the permission of Pizarro; but being afterwards defeated by the Spaniards, he retired to the mountains, and is supposed to have died about the year 1553. This city stands in a very uneven situation on the skirts of mountains, which are watered by the little river Guatanay. On a mountain contiguous to the north part of the city are the ruins of that famous fortress built by the Incas for their defence; from which it appears, that they intended to inclose the whole mountain with a prodigious wall, so constructed as to render the ascent of it impracticable to an enemy, and capable of being easily defended within. It was strongly built of free-stone, and remarkable for its dimensions and the magnitude of the stones, as well as the art with which they are combined. The internal works of the fortress, consisting of apartments, and two other walls, are chiefly in ruins, but the outward wall is standing. A subterranean passage, of singular construction, led from the palace of the Incas to the fortress: and these ruins, together with the fragments of a pavement of stone, which led to Lima, are no mean monuments of ancient art. The city of Cusco is nearly equal to that of Lima; and the latter may be called the maritime capital of Peru, whilst the former may be considered as its inland metropolis. Proudly situated amongst the surrounding Andes, and boasting its origin from the first of the Incas, Cusco still retains the majesty of a capital. Its north and west sides are surrounded by the mountain of the fortress, and others called "Sanca;" on the south it borders on a plain, which has several beautiful walks. Most of the houses are of stone, covered with red tiles; the apartments are spacious, and finely decorated; the mouldings of the doors are gilt, and the other ornaments and furniture correspond to the elegance of the buildings and taste of the inhabitants. The population of Cusco is estimated by Alcedo at 26,000; but it suffered greatly by a pestilence in 1720, and has of late years very much declined. Three-fourths of its inhabitants are said to be Indians, who are very industrious in the manufacture of baize, cotton, and leather; and they have also a taste for

painting, in which they are said to excel. Cusco is episcopal, and its bishop is suffragan to the archbishop of Lima. The cathedral is a large, rich, and handsome edifice, and, though smaller, preferred by some to that of Lima: it is served by three priests, one for the Indians of the parish, and the other two for the Spaniards. Cusco has also eight other parishes; a convent of Dominicans, the principal walls of which were formerly those of the temple of the sun; and eight others of Franciscans, Augustines, Jesuits, &c. The government of the city consists of a corregidor, and two alcaldes, chosen out of the chief nobility, according to the custom of all the cities in South America. Here are three colleges, one of which has a seminary for the cathedral, in which are taught Latin, the sciences, and divinity. The members of the cathedral chapter, besides the bishop, are the dean, archdeacon, chanter, rector and treasurer, canons, and prebendaries. There are four hospitals, one of which is supported by the tolls of the neighbouring bridge, on the Apurimac. The courts of justice are those of the revenue, consisting of two judges, a court of inquisition, and of the crossade. The diocese of Cusco comprehends 14 different jurisdictions; the first of which is that of Cusco, extending two leagues. In this district the temperature of the air is various, but in some parts the cold is intense, though both heat and cold are generally tolerable: the coldest parts produce good pasture for all sorts of cattle, and the valleys afford plenty of grain and fruits. In the "Intendancy" of Cusco, as this district is now called, with its dependency of Carahuasi, the only mines mentioned in the "Mercurio Peruano," are those of silver; 19 in number, which were successfully wrought. S. lat. 13° 25'. W. long. 71° 15'.

CUSCOWILLA, the capital of the Alachua tribe of Indians, pleasantly situated in East Florida, upon a high swelling ridge of sand hills, within 300 or 400 yards of a large and beautiful lake, abounding with fish and wild fowl. The lake is terminated on one side by extensive forests, consisting of orange groves, overtopped with grand magnolias, palms, poplar, tilia, live oaks, &c.; and on the other side by green plains and meadows. The town is composed of 30 habitations, each consisting of two houses, large and convenient, and closely covered with the bark of the cypress-tree. Each has a little spot for a garden, containing corn, beans, tobacco, and other vegetables. In the great Alachua Savanna, at the distance of about two miles, is an excellent plantation, cultivated by the whole community, of which each family has its appropriate part. Each family collects and deposits in its granary its proper share, setting apart a small contribution for the public granary, which is situated in the midst of the plantation.

CUSCUTA, in *Botany*, Dodder, (*κυστάνθη*, or *κυστάνθη*, Mod. Greek, a name applied to some parasitical plant, but it is not determined what particular one was intended, and it is equally uncertain whence the name was derived: some suppose from *κυστάνθη*, *confus*; others from the Arabic *chafsub*, or *chafsub*.) Pourn. 652. Linn. Gen. 170. Schreb. 227. Willd. 262. Gært. 376. Juss. 135. Vent. 4. 2. Class and order, *tetrandria digynia*. Linn. Wulst. Lam.. *Pentandria*. Smith. Flor. Brit. Nat. Ord. *Convolvuli*? Juss. Undetermined. Vent.

Gen. Ch. *Cal.* Perianth one-leaved, four or five-cleft, fleshy at the base. *Cor.* monopetalous, egg-shaped, or somewhat campanulate, longer than the calyx, four or five-cleft. *Stam.* Filaments four or five, awl-shaped, the length of the calyx; anthers roundish. *Pist.* Germ. superior, globular; styles two, erect, short; stigmas simple. *Peric.* Capsules globular, its lower part covered by the fleshy calyx,

lyx, two-celled, dividing horizontally. *Seeds* in pairs, somewhat globular.

Ess. Ch. Calyx four or five-cleft, inferior. Corolla monopetalous, four or five-cleft. Capsule two-celled, dividing horizontally. *Seeds* in pairs.

Obs. The number of parts varies in different, and sometimes in the same species, but is most frequently five.

So. 1. *C. europea*. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Gert. tab. 62. Flor. Dan. tab. 199. Eng. Bot. 378. (*C. major*; Bauh. Pin. 219. Cassutha; Fuchs. Hist. tab. 348.) "Flowers nearly sessile; corolla without scales; stigras acute." *Root* annual, small, soon perishing. *Stems* red, filiform, twining, parasitical, leafless, smooth, throwing out small tubercles by which it roots itself into the bark of other plants, and derives nourishment from them after its proper root has withered away. *Flowers* in fascicles, lateral, somewhat transparent, reddish, generally five-cleft; corolla bell-shaped; stamens inserted into the throat of the corolla, alternate with its segments; styles divaricated. A native of Great Britain, on thistles, nettles, and other plants, but rare. Found near Aberdeen and in Cambridgeshire. 2. *C. epithymum*. Lesser dodder. Mart. Lam. Ill. Smith Fl. Brit. Eng. Bot. 55. (*C. europæa* β; Linn. Sp. Pl. Lam. Enc. Willd. Epithymum, five *Cuscuta minor*; Bauh. Pin. 219.) "Flowers sessile, with a fringed scale inserted into the corolla at the base of each stamen; stigras acute." Less than the preceding. *Stems* twisted. *Flowers* clustered; corolla white, funnel-shaped, with a short tube, generally four-cleft; calyx red; stamens inserted into the throat of the corolla, alternate with its segments, having at the base of each a crescent-shaped scale incumbent on the germ; styles elongated, acute. Common in Great Britain, especially in the southern counties of England, on beans, grass, and various other plants, to which it is so pernicious that it is called by the common people Devil's-guts, or hell-weed. Dr. Smith, we believe, is the first botanist who has pointed out the true specific difference between these two plants. Professor Martyn and La Marck had previously separated them, but without being aware of their distinguishing characters. La Marck, in particular, questioned whether they are sufficiently distinct, and has even figured epithymum under the name of europæa. 3. *C. americana*. Linn. Sp. Pl. 2. Mart. 3. Lam. Ill. 4. Willd. 2. (*C. floribus pedunculatis*; Jacq. Amer. 24. *C. inter majorem & minorem*; Sloan. Jam. Hist. t. 201. tab. 120. fig. 4. *C. ramosa repens*; Brown. Jam. 149.) "Flowers peduncled, five-cleft; corolla tubular; border small, spreading." *Stems* much branched, leafless, twining, parasitical, tender, shining, yellowish. *Flowers* greenish, inclining to yellow, small, clustered, scentless; common peduncles very short; calyx withering; the colour of the corolla, egg-shaped, five-cleft; segments roundish, blunt, concave, short, converging; corolla cylindrical; tube the length of the calyx; scales five, fringed, converging, attached to the petal below the stamens; filaments always five, upright, from the upper part of the tube, the length of the corolla; anthers oblong, erect; styles little longer than the corolla; stigmas capitate. *Seeds* convex on one side, flattish on the other, one, two, or three often abortive. A native of North America and the West Indies, on shrubs and trees. According to Sloane, the stems are very strong, stretching themselves over very large trees, and whole fields and pastures. 4. *C. africana*. Willd. 3. (*C. americana*; Thunb. Prod. 32.) "Peduncles one-flowered; corollas five-cleft." *Stem* filiform, more slender than in the preceding species. *Flowers* smaller; peduncles with a lanceolate bracte at the base. A native of the Cape of Good Hope,

on trees. Linnæus found this species growing on a dried specimen of *myrica æthiopica*, and described them both together as one plant in the first edition of his *Species Plantarum*, under the name of *scinus myricoides*; and in the appendix to the second, under the name of *schrebera schiroides*. 5. *C. monogyna*. Willd. 4. Vahl. Symb. 2. 32. (*C. lupuliformis*; Mart. 5. Krock. Siles. tab. 36. *C. orientalis viticulis crassissimis*; Tourn. Cor. 45. *C. major caulibus lupuli*; Buxb. Cent. 1. 15. tab. 23.) "Flowers peduncled, monogynous." The habit of *Cuscuta americana*, but twice the size. Segments of the calyx egg-shaped, shining. *Corolla* twice the length of the calyx, narrowed above, permanent, edged with lanceolate teeth. *Style* single, thicker, and shorter than in the other species. *Stigma* thick, somewhat globular. *Pericarp* the size of a pepper-corn, mucronate with the permanent style and stigma. *Seeds* compressed, somewhat kidney-shaped. Vahl. Willdenow observes that Vahl and Krock's plants are certainly the same; for, in the figure of the latter, the flowers are peduncled, and the permanent single style is conspicuous on the fruit. According to Krock, the stem is round, branching, very thick like hop-binds, with reddish-green or brown-purple bark, rough, and studded with purplish stiff rising grains resembling millet. *Flowers* in racemes coming out laterally, an inch or two in length, sometimes branched, scattered, solitary, or only two or three together, not glomerate; corolla four-cleft, reddish-white; calyx covered with a fleshy skin, green, or tinged with purple. *Capsule* large, covered with the same skin. *Seeds* wrinkled, rounded. A native of Silesia and the Levant. 6. *C. chinensis*. Lam. Enc. 2. Ill. 1718. Willd. 5. "Flowers panicled, five-cleft; calyx angular, nearly the length of the corolla." *Root* annual. *Stem* pale or yellowish green, a little thicker than in *C. europea*. *Flowers* white, in lax fascicles, on short branched peduncles, forming a kind of irregular panicle; calyx of the same colour as the corolla; corolla oval, almost globular, narrowed at the mouth, with five acuminate horn-like segments; stamens five, small; germ large, globular; styles very short, revolute, and reclining on the germ; stigmas somewhat capitate. This plant was seen in flower by La Marck in the royal garden at Paris, in 1784, twined about an ocymum, the seeds of which had been sent from China, and with which its seeds must have been intermixed.

Ventnat observes that it is not easy to determine to what natural family this singular genus belongs, on account of the difference which prevails among botanists with respect to the structure of the embryo of its seeds. Linnæus pronounces it acotyledonous; Adanson and Gærtner consider it as monocotyledonous; and Jussieu presumes it to be dicotyledonous.

CUSE, in *Geography*, a small town of France, in the department of the Doubs; 15 miles S.E. of Vesoul.

CUSH, or as some write it CHUS, in *Biblical and Ancient History*, was the eldest son of Ham and grandson of Noah; and,

and, according to Josephus, the father of the Ethiopians, who were, in his time, called Cushians, not only by themselves, but by all the inhabitants of Asia. Others conceive it to be more probable, that he seated himself in the south-eastern part of Babylonia, and in the adjoining part of Susiana, still called Khuzestân or Chusitan, the land of Chus; from whence his posterity, in the succeeding generations, might have passed into other countries. It appears from Scripture, that a part of Arabia, near the Red Sea, was named Cush. Cushan and Midian are joined together, as the same or neighbouring people, dwelling in tents; and, in other places, the Arabs are made to border on the Cushites, who, therefore, cannot be the Ethiopians: in a word, by Cush in Scripture is always to be understood Arabia. As for those texts which are alleged to prove that Cush is sometimes taken for Ethiopia, they may also be expounded of Arabia. Cush, according to the Arabian and Persian traditions, which name him Cutha, was king of the territory of Babel, and resided in Irak, where two cities existed of his name; and hence Dr. Hyde concludes, that Cush reigned in Babylonia, and that his descendants removed into Arabia, though it is difficult to assign the peculiar habitations of any of them: and this uncertainty has given occasion for supposing Cush to be Ethiopia, and for spreading these people all along the coast of Africa to the extremity of Mauritania.

Among the Abyssinians, as Bruce informs us in his *Travels* (vol. i. p. 376.) it is a tradition, derived, as they say, from time immemorial, and equally received among Jews and Christians, that almost immediately after the flood, Cush, grandson of Noah, with his family, passing through Atbara from the low country of Egypt, then without inhabitants, came to the ridge of mountains which still separates the flat country of Atbara from the more mountainous high-land of Abyssinia. This tradition says, that terrified with the apprehension of another deluge, that awful event being recent in their minds, they chose for their habitation caves in the sides of these high mountains, where they might be secure, and where the adjacent country was fertile and pleasant. Whatever might be their motives, here, it is said, the Cushites, with unparalleled industry, and with instruments now unknown, formed for themselves commodious habitations in mountains of granite and marble, several of which remain entire to this day, and promise to be of much longer duration.

As the Cushites became populous, they occupied habitations in the neighbouring mountains, and gradually extended the industry and arts which they cultivated, as well to the eastern as to the western ocean; but they never descended from their caves, nor chose to reside at a distance on the plain. Many of their descendants still occupy the same mountains and houses of stone, similar to those which their ancestors made for themselves in the beginning of their settlement. The Abyssinian tradition further says, that they built the city of Axum at an early period, in the days of Abraham. Soon afterwards they extended their colony to Atbara, where, as Herodotus informs us (lib. ii. c. 29.), they successfully pursued their studies, from which Josephus says (*Antiq. Jud.*) they were called "Meroëtes," or inhabitants of the island of Meroë. From Meroë they probably, in process of time, stretched on to Thebes. While these improvements were advancing in the central and northern territory of the descendants of Cush, their brethren to the south extended themselves along the mountains that run parallel to the Arabian gulf, in the country called "Saba," or "Azabo;" which was the principal mart and source of supply for the Abyssinian myrrh and frankincense. The

northern colonies of Cushites, proceeding from Meroë to Thebes, were intent upon the improvements of architecture, and building of houses; and substituting these for their caves, became traders, farmers, and artificers of various descriptions, and even practical astronomers, from having a meridian night and day free from clouds, such as that of the Thebaid. Letters too, at least one sort of them, and arithmetical characters, we are told, were invented by the Cushites of the middle regions; while trade and astronomy, the natural history of the winds and seasons, necessarily employed that part of the colony that was established at Sofala, moved to the southward. The nature of the commerce of the Cushites, the collecting of gold, the gathering and the preparing of their spices, necessarily fixed them perpetually at home; but their profit lay in the dispersion of these spices through the continent; otherwise their mines, and the trade produced by the possession of them, would be of little avail. The Cushites of course needed carriers; and such were presented to them among their neighbours, who lived in plains, having moveable tents or habitations, attended their numerous herds, and wandered from the necessities and particular circumstances of their country. These people were in the Hebrew language called "Phut," and in all other languages "Shepherds," a name they still bear, subsisting by the same occupation. (See SHEPHERDS.) The whole employment of the shepherds had been the dispersion of the Arabian and African commodities all over the continent; by which employment they became a great people: as that trade increased, their cattle increased also, and consequently their number, and the extent of their territory.

The learned Bryant traces the appellation *Chus*, by the aid of etymology, through a variety of ramifications and changes; and discovers traces of it in the names of places, and the manners and rites of their inhabitants, through various and very remote regions of the globe. Chus, he says, in the Babylonish dialect, seems to have been called "Cuth;" and many places where his posterity settled were styled Cutha, Cuthaia, Cutaëa, Ceuta, Cotha, and Cothon. Thus Chusitan, east of the Tigris, which was the land of Chus, was likewise called Cuthæ and Cissia by different writers. Chus was the father of those nations, denominated Ethiopians, who were more truly called Cuthites and Cushians; and who were more numerous and more widely extended than persons have imagined. The author to whom we now refer traces the origin of the Cushites or Cuthites to the first settlement of the descendants of Noah soon after the deluge. Their several abodes were assigned them, as he conceives, by the immediate appointment of God. The children of Shem were particularly regarded in the general distribution; and they were fixed near the place of their separation. They had in general Asia for their lot, as Japhet had Europe, and Ham the large continent of Africa. The children of Chus, however, would not submit to the divine dispensation; and his son, Nimrod, who first assumed regal state, drove Ashur, one of the sons of Shem, who had been settled on the western side of the river Tigris, from his demesnes, and forced him to take shelter in the higher parts of Mesopotamia. The sons, disobeying the divine order, which arranged the habitations of the posterity of Noah, went off under the conduct of the arch-rebel Nimrod; and, after having remained for a long time in a roving state, arrived at last in the plains of Shinar. These they found occupied by Ashur and his sons, who had been placed there by divine appointment. Him they ejected, and seized upon his dominions; which they immediately fortified with cities, and laid the foundation of a great monarchy. This ejection of Ashur, as Mr. Bryant thinks, happened after the general migration;

migration; and when the Cuthites had ejected Ashur, they afterwards trespassed upon Elam, in the region beyond the Tigris. The dispersion from Babel, according to this writer, did not include the whole of mankind, but related chiefly to the sons of Chus; whose intention it was to have founded a great, if not an universal, empire: which was frustrated by this event. The Cuthites had many associates, probably out of every family, who were apostates from the truth, and had left the stock of their fathers and the worship of the true God, in order to follow the rites and worship of the Cuthites. These were the persons who, fearing that they might be separated and scattered abroad, built the tower of Babel, as a land-mark to which they might repair; and Mr. Bryant suggests, that it was probably an idolatrous temple, or high altar, dedicated to the host of heaven, from which they were never long to be absent. That the sons of Chus, who wished to remain where they first settled, instead of occupying the countries to which they were appointed, were the chief agents in erecting the tower of Babel, and in prosecuting these rebellious principles, is plain from the passage, in which it is said of Nimrod, the son of Chus, that "the beginning of his kingdom was Babel." The defection, as our author imagines, was not general, nor the judgment universal; for it is not likely that all mankind should co-operate with this tyrant. The confusion of speech and consequent dispersion related merely to the Cuthites of Shinar and Babylon, and to their adherents, who seem to have been a very numerous body. The dispersion of the Cuthites is an event referred to, directly or indirectly, by many ethnic writers: and our author says, that it is manifestly to be discovered under the fable of the flight of Bacchus; and the disunion of that moveable body, which made so bold a stand, and the scattering of them over the face of the earth, are represented under the fable of dismembering the same person. Our author discovers traces of the rebellion of the Cuthites in the wars of the giants and Titans, described by ancient writers, and of their appellation in the people called Scythians. As these people were the first apostates from the truth, they introduced the worship of the sun, and paid similar reverence to the stars, and the whole host of heaven. They regarded them as fountains, from whence were derived to men the most salutary emanations. This worship was styled the fountain worship. One of the titles of the Cushan shepherds, who came into Egypt, was deduced from this worship, and derived from "El-Ain," the fountain of light, which they worshipped. The golden age of the poets was, according to our author, the age of Chus, denominated by the Greeks Chusos, and Chrusos.

These Cuthites, the sons of Chus, who seized upon the region of Babylonia and Chaldæa, and constituted the first kingdom upon earth, and who were called by other nations Cushan, Cushans, Arabians, Oreitæ, Erythreans, and Ethiopians, were an ingenious and knowing people, and at the same time very prolific. They combined with others of the line of Ham; and were enabled, at a very early period, to carry on an extensive commerce, and to found many colonies; so that they are to be traced in the most remote parts of the earth. A large body of this people invaded Egypt, in its infant state, when it was composed of small independent districts, artless and unformed, without any rule or polity. They seized the whole country, and held it for some ages in subjection, and from their arrival the history of Egypt commences. The region between the Tigris and Euphrates, where they originally resided, was styled the country of the Chusdim or Chaldim: but by the western nations Chaldæa. It lay towards the lower part of the Tigris, to the west, and below the plain of Shinar. On

the opposite side to the east was the province of Elam, which country they seem soon to have invaded, and to have occupied the upper part. This country consisted of that fine region called afterwards Susiana, and Chusistan, which was watered by the Ulai, Chobar, and Choaspes, and by other branches of the Tigris. When the Persians gained the sovereignty of Asia, it was from them denominated Persis, which was only another name for Cutha: for the Persians were the Cuthites of that country, under a different appellation. This Cutha was by the Grecians called Scythia. It extended far towards the east, and was in great measure bounded by Media to the north. This is one of the countries called Cuthan in scripture; and by other people it was rendered Ethiopia. The Ethiopians were, therefore, Cuthites or Cushans. Accordingly Eusebius says (Chron. p. 11.) that Chus was the person from whom came the Ethiopians; an appellation formed from $\alpha\delta\delta\alpha$ and $\sigma\lambda$, and derived from their complexion. This was a sacred term, a title of the chief deity, whence it was assumed by the people, who were his votaries and descendants. The sons of Chus came into Egypt under the name of Auriæ and shepherds, and also of Ethiopians, whence Egypt inherited the name. The Cuthites also settled at Colchus, the Colchis of the Greeks, whence it was called Cutaia and Ethiopia. They likewise came under the titles of Casus and Belus into Syria and Phœnicia, where they founded many cities; and we are informed by Strabo (l. 10) that this country was called Ethiopia. Eubæa and Samothræe were distinguished by a similar appellation. The extreme settlement of this people was in Spain, upon the Bœtis, near Tartessus and Gades; some of whom traversed a great part of Africa, and others gained possession of different parts of the sea-coast. Some of the same family were found on the coast of Mauritania. The original Ethiopia was the region of Babylonia and Chaldæa, where the first kingdom upon earth was formed, and the most early police instituted. Here also the first idolatry began. And as the Scythæ, or Cuthites, were the same people, it is no wonder that they are represented as the most ancient people in the world; even prior to the Egyptians. Another title by which the Cuthites were distinguished was that of Erythreans; and the places where they resided received it from them. The Cuthite Erythreans, who settled near Midian, upon the Sinus Elanitis, conferred this name upon that gulf, and the Persian sea was distinguished by the same denomination. Upon the whole, our author concludes by reciprocal evidences from the most genuine history, that the Cuthites, Ethiopians, and Erythreans were the same people; and that they had a more general name of $\Sigma\upsilon\theta\alpha\iota$, Scythai. Mr. Bryant farther undertakes to shew, that not only the Scythæ of Colchis, Mœsia, and Thrace, with those upon the Palus Mœotis, were in great measure of the race of Chus; but that all nations styled Scythian were in reality Cuthian or Ethiopian. Having seized upon the province of Susiana, and Chusistan, they possessed the navigation of the Tigris downwards; and probably commenced a very early trade. They obtained footing in India, where they extended themselves beyond Gedroña, and Carmania, upon the chief river of the country. They also occupied various parts of India; and the same people who imported their religious rites and science into Egypt, carried the same to the Indus and Ganges, and still farther into China and Japan. Some colonies undoubtedly came from Egypt; but the arts and sciences imported into India came from another family, even the Cuthites of Chaldæa; by whom the Mizraim themselves were instructed, and from Egypt they passed westward. Hence we need not be surpris'd, if we find the same customs in India, or the same names of places as are to be met with in Egypt, or

Colchis, or the remotest parts of Iberia. Many instances of this kind are produced by the learned etymologist.

The sons of Chus, however distinguished, whether they be called Oritæ, Arabians, Ethiopians, or Erythreans, were in all places celebrated for science. They were sometimes called Phoinices, and those of that name in Syria were of Cuthite extraction. The Mizraim, who settled in Egypt, before the dispersion of the Cuthites and their adherents, had no share in their rebellion, nor in the Titanic war, which ensued. Their country was that which in aftertimes was known by the name of Upper Egypt. When the Cuthites, or Titanic brood, were driven from Babylonia, they fled to different parts; and a large body of them betook themselves to Egypt. Confederate and well-disciplined, they easily overcame a nation so rude and unexperienced as the Mizraim. They soon took Memphis, the frontier town of Egypt, and afterwards over-ran the whole region above, and kept it in subjection. The Cuthites or Ethiopians were also called Arabians, and the province of Cushan in Egypt, the same as the land of Goshen, was denominated the Arabian nome, which was the best of the land of Egypt. They were also styled Hellenes, Phœnices, and Auritæ. The people so called were the first who reigned in Egypt; and with them, as we have before observed, the history of the people must commence. Manetho informs us, that the whole body of this people had the appellation of royal shepherds; a title which Bryant conceived was more particularly given to their kings. They borrowed this mark of distinction from their ancestors in Babylonia; among whom it seems to have been common. It is somewhat remarkable that Nimrod, the first tyrant upon earth, should have masked his villainy under the meek title of a shepherd. From him it was derived, and transferred to other kings, in Chaldæa, and afterwards in Egypt. At the time when the Cuthite Ethiopians arrived, Lower Egypt was very much a kind of morass; but under their direction it was drained by numerous canals, and rendered the most beautiful country in the world. They carried a sluice from the Pelusian branch of the Nile to the western gulf of the Red Sea. The chief of the pyramids at Cochoe are said to have been erected by them. They raised the most ancient obelisks in Egypt, which were marked with hieroglyphics, curiously wrought, and these were the sacred characters of Egypt, known only to the priests, and which had been introduced by the Cuthite Ethiopians. After the Cuthites had drained Lower Egypt, and had built cities there, every city had probably some sacred emblem, as the goat, hawk, ibis, crocodile, or dog, represented in sculpture, either upon the gates, or upon the entablature of their temples. This characteristic denoted its name as well as the title of the deity, to whom the place was sacred; and the deity in those cities was often worshipped under such particular symbol. Some of the poets allude to this. They have represented the dispersion of the sons of Chus from Babel as the flight of the gods into Egypt; where they are supposed to have sheltered themselves under the form of these sacred symbols. After the Cuthite shepherds (see SHEPHERDS) had been in possession of Egypt about 260 or 280 years, they were obliged to retire to the amount of 240,000 persons. The Egyptians succeeded to the Cuthites in their cities and temples; and having been initiated in their rites never forsook them. When the Cuthites were ejected from Egypt, they withdrew to many parts; and particularly to the coast of Syria; which they occupied under the titles of Belidæ, Cadmians, and Phœnices. Hence they went to Hellas, to Etruria, and Iberia, and the coast of the great Atlantic. A colony also settled at Colchis, and upon different parts of the Pontic region. Where-

ever they came they were in every respect superior to the natives; they were skilful in physic, and the knowledge of the properties of herbs; they cultivated the vine; and taught the composition of fermented liquors. They opened roads, formed causeways, and drained stagnant waters in the countries, whither they migrated; but their achievements in these ways have been attributed to some one hero, either Oloris, Hercules, or Bacchus. Their religion consisted in the worship of the sun, under various titles; to this were added divine honours, paid to their ancestors, the Baalim of the first ages, which was attended with particular mysterious rites. In these were commemorated the circumstances of the deluge, and the history of the great patriarch, through whom mankind was preserved. The Cuthites who settled in Sicily seem to have been a very powerful and intelligent people; but those of Etruria were far superior. The two most distant colonies of the Cuthite family westward were settled upon the Atlantic ocean; the one in Europe to the north; the other opposite at the extreme part of Africa in the country called Mauritania, inhabited by the Atlantic Ethiopians. They considered themselves as of the same family with the gods: and they were undoubtedly descended from some of the first deified mortals. Those who occupied the provinces of Iberia and Bœtica, on the other side, were distinguished by the same title, and preserved the same histories. They were of Erythrean and Ethiopic race; and gave name to the island Erythra, or Erythia, which they occupied for the sake of trade, and where stood the city Gadara, said to be of high antiquity.

Mr. Bryant has shown, that a great resemblance once existed between the numerous colonies of the same family. They carried the art of weaving, first practised at Arach in Babylonia, and thence extended to other neighbouring cities, and in process of time to the most remote parts of the world, to a high degree of excellence. The people of Egypt were famous for this manufactory. They were famous for their flax and linen at Colchis, Campania, Bœtica, and other parts of Spain. The Indi were also noted for this manufacture. The art of dyeing was also discovered by people of this family. The wonderful art of managing silk, and of working up cotton, was found out by the Indian Cuthites, and from them it was transferred to the Sere. To them are also attributed the game of chess; and the use of those cyphers, or figures, commonly called Arabian. They are said to have written letters *εσσιςσι*; but whether by this was meant really linen; or whether we are to understand a kind of paper manufactured from it, is uncertain. (See PAPER). Those who cultivated the grape brought it to the highest degree of perfection. The Mareotic wine, produced in Scythia Ægyptiaca, is well known, and has been highly celebrated. Calybon in Syria, Cyprus, Crete, Cos, Chios, and Lesbos, were famous on the same account. The fine wine of Sicily, of Thrace, and of Campania, in which country were the Falernian and Formian grapes, was in high repute among the ancients. In Iberia and Mauritania they had some of very noble growth. (Strabo, l. xvii. p. 1182.) There was also wine among the Indian Ethiopians, particularly in the country of the Oxydrace, who were supposed to be the descendants of Bacchus. (Strabo, l. xv. p. 1108.) They had also a strong drink made of rice, which was used in their sacrifices. The people of Latitania and Bœtica made a fermented liquor called "Zuth," the knowledge of which was derived from Egypt, in which they were supposed to have been instructed by Oloris. Hesychius calls it wine, and says it was made of barley. It is also mentioned by Strabo, (lib. iii. p. 233.) In short, all of the Cuthite family were renowned for their wisdom.

The

The natives of Colchis, who were of the Cuthite race, were devoted to magic, and had their nightly orgies in honour of the moon: and among the different branches of this family we discover an extensive acquaintance with the properties and uses of different herbs. But they were pre-eminently distinguished by the mighty works and edifices, which they carried on and erected in the different parts where they settled. All those mounds and canals, the high roads and stately structures, which have been attributed to Semiramis of Babylon, were the works of these people. They formed vast lakes, and carried on canals at a great expence; and they opened roads over hills, and through forests, which were before impassable. (Strabo, lib. xvi. p. 1071.) The stately structures of various kinds erected in Egypt were the works of the Cuthites; those Arab shepherds, who built Heliopolis or Balbec, and who were the γίγαντες, the giants and Titans of the first ages. The pyramids of Egypt are also ascribed by Mr. Bryant to these people. (See PYRAMID.) The buildings, which the Cuthites erected, were in many places styled Cyclopiæ, from a title given to the architects. Many ancient edifices in Sicily were of their construction; for they seem to have been the first inhabitants of this island. They were called Læstrygones and Lamii; and resided chiefly in the Leontine plains, and in the regions near Ætna. They erected many temples; and likewise high towers upon the sea-coast, and founded many cities; some of the ruins of which are still extant.

The noble character of the Cuthites, who by their extraordinary inventions and improvements were regarded as general benefactors to mankind, was, however, greatly tarnished by their cruelty; for which they seem to have been infamous in all parts, and which seems to have been derived from their rites and religion, that had always a tendency to blood. The Cuthæ upon the Mæotis, and in the Tauric Cherfoneus, are described as very inhospitable; and all those in their vicinity were of a savage cast, and guilty of great barbarity. In various parts they also contracted a habit of robbery and plunder; so that they lived in a state of piracy, making continual depredations.

We have already hinted, that one of the most considerable colonies which went from Babylonia, was, that of the Indi, or Sindi, called Eastern Ethiopians. They settled between the Indus and Ganges, and one of their principal regions was Cuthaia, rendered by the Grecians Cathaia. They traded in linen and other commodities, and carried on an extensive commerce with the provinces to the south. A large body of them passed to the north, under the name of Siceæ and Sacæans, who ranged very high, and got possession of Sogdiana, and the regions upon the Iaxartes. From thence they extended themselves quite to the ocean. These sent out large bodies into different parts; and many of the Tartarian nations are descended from them. They gained possession of the upper part of China, which they denominated Cathaia; and Japan was probably in some degree peopled by them. Their religion also extended far; and many noble edifices in various parts of the East afford evidences of their original. Near Syriam in Pegu are two temples, built after the same model; and other temples and pagodas in India, together with the deities to whose service they were consecrated, and the rites of worship practised in them, testify their original. For other particulars relating to the sons of Cush or Chus, or the ancient Cuthites, see the "Analysis of Ancient Mythology," in 3 vols. 4to. *passim*.

CUSHAI, in *Geography*, a small river of America, which discharges itself into Albemarle sound, between Chowan and the Roanoke, in N. Carolina.

CUSHENDEN BAY, a small bay on the east coast of

the county of Antrim, Ireland, where there is pretty good anchorage when the wind does not blow on shore. Long. 5° 23' W. Lat. 55° 7' N.

CUSHETUNK MOUNTAINS, mountains of America, in Hynterton county, New Jersey.

CUSHING, a township of America, in Lincoln county, Maine, separated from Warren and Thomallow by St. George's river, incorporated in 1789, containing 1415 inhabitants, and lying 216 miles E by N. of Boston. The E. part of this township is now "St. George's," 35 miles S. E. of Wiscasset.

CUSHION, LADIES, in *Botany*. See SAXIFRAGA *hypnoides*.

CUSHION, SEA. See STATICE.

CUSHION, a rubber, in *Electricity*. See ELECTRICAL machine.

CUSHION, in *Engraving*, is a bag of leather filled with sand, commonly about nine inches square, and three or four thick, used for supporting the plate to be engraved.

CUSHION, in *Gilding*, is made of leather, fastened to a square board, from fourteen inches square to ten, with a handle. The vacancy between the leather and board is stuffed with fine tow or wool, so that the outer surface may be flat and even. It is used for receiving the leaves of gold from the paper, in order to its being cut into proper size and figures.

CUSI, in *Ancient Geography*, a town of Lower Pannonia, 16 miles from Bononia, according to the Itinerary of Antonine, supposed to be the present Cudelaf.

CUSI, in *Ornithology*, a name given by the people of the Philippine islands to a very small and very beautiful species of parrot.

CUSIGHE, SIMONE DA, in *Biography*, so called from the place of his nativity, a small town near Cadore, in the Venetian state, a painter who flourished in the 14th century. Some of his madonnas of considerable merit are still to be seen at Cusighe, and bear date from 1382 to 1409. Lauzi. Stor. Pitt.

CUSP, CUSPIS, properly denotes the point of a spear, or sword; but is used in astronomy to express the points, or horns of the moon, or any other luminary.

CUSP, in *Astrology*, is used for the first point of each of the twelve houses, in a figure, or scheme, of the heavens. See HOUSE.

CUSP of a Curve, in *Geometry*. See CURVE.

CUSPIDATED, in *Botany*, is when the leaves of a flower end in a cusp, or point, resembling that of a spear.

CUSPIDATED hyperbola, &c. See CURVE.

CUSPIDATUS DENS, in *Anatomy*, the canine tooth of the human subject. Mr. Hunter assigns the former name to it.

CUSPIDIA, in *Botany*, Gært. See GORTERIA *cernua*.

CUSSAC, in *Geography*, a small town of France, in the department of the Upper Vienne, six miles S. of Roche Chouart.

CUSSÆIM, in *Ancient Geography*. See COSSÆI.

CUSSAMBIUM, in *Botany*; Lam. Encyc. Rumph. amb. 1. 154. tab. 57. A tree hitherto but little known, which seems to have some affinity with the ponga of Rheede, and the tataiba of Piso, but differs in having a one-seeded drupe for its fruit; it is rather lofty, but not very spreading; its wood hard and heavy; the bark brown, rugged, and very brittle. Leaves generally opposite, oval-lanceolate, entire, on short petioles. Flowers small, in slender lateral racemes. Fruit roundish or egg-shaped, commonly rough, with pointed caducous tubercles; flesh rather thin, of a pleasant acid taste; kernel of the nut white, tender, oily.

A native

A native of the Molucca islands. The ripe fruit is eaten raw. A yellowish oil is expressed from the kernels, which having a pleasant smell, and not growing rancid, is used for lamps, and as an ingredient in various odoriferous preparations.

CUSSENS, in *Geography*, a small river of America, in Cumberland county, Maine, which runs a S.E. course to Casco bay, between the towns of Frankfort and North Yarmouth.

CUSSET, in Latin *Cussetum*, a town of France, in the department of the Allier, 21 miles N. of Roanne, and 255 S.E. of Paris. It is the chief place of a canton, in the district of La Palisse, with a population of 3945 individuals. The canton has 12 communes, and 14,443 inhabitants, upon a territorial extent of 180 kilometres.

CUSSIE, a town of Egypt, 15 miles S. of Ashmunein.

CUSSITAH, an Indian town, in the western part of Georgia, 12 miles above the broken Arrow, on Cattaheooc river.

CUSSONIA, in *Botany*, (named by the younger Linnaeus in honour of M. Cusson of Montpellier, a botanist who paid particular attention to the family of umbelliferous plants) Linn. jun. Supp. 1378. Schreb. 455. Willd. 517. Juss. 218. Class and order, *pentandria digynia*. Nat. Ord. *Aralia*; Juss.

Gen. Ch. *Cal.* Perianth five-toothed, permanent, superior, formed by the dilatation of the edge of the receptacle. *Cor.* Petals five, trigonous, acute, sessile. *Stam.* Filaments five. *Pist.* Germ inferior, top-shaped; styles two; stigmas simple. *Peric.* two-celled or two-coccos, two-valved, roundish, angular, crowned with the styles. *Seeds* one in each cell.

Fl. Ch. Petals five, trigonous. Calyx formed by the dilatation of the edge of the receptacle, five-toothed.

Sp. 1. *C. thyriflora*. Linn. jun. 1. Mart. 1. Lam. 1. Willd. 1. Thunb. Aët. Nov. Upsal. 3. tab. 12. "Leaves digitate; leaflets sessile, ridge-shaped, truncated, three-toothed; flowers in racemes." A shrub. *Stem* scabrous towards the bottom, unequal, simple, the thickness of a finger. *Leaves* on the upper part of the stem, near together, alternate, petioled; leaflets scarcely emarginate, sometimes, but rarely five-toothed; teeth remote, small; petioles long; stipules intrafoliaceous. *Flowers* in terminal cylindrical racemes, forming an umbel; rays four, quite simple, naked towards the bottom, bearing racemed flowers towards the top. There is a variety with jointed leaflets, the lowest joint dilated at the end into smaller lobes, so as to appear proliferous. 2. *C. spicata*. Linn. jun. 2. Mart. 2. Lam. 2. Illus. Pl. 187. Willd. 2. Thunb. Aët. Nov. Upsal. 3. tab. 13. "Leaves digitate in fevens; leaflets somewhat pedicelled, simple, and lanceolate, or ternate; flowers spiked." Whole plant smooth. *Flowers* in a single terminal spike about two inches long. Both species are natives of the Cape of Good Hope. Jussieu observes that this genus is scarcely distinct from panax; but that, if kept separate, the shrubby species of panax should be removed to it with *P. undulata* of Aublet, *unjala* of Rheede and perhaps *aralia umbellifera* of La Marck.

CUSTARD APPLE. See ANNONA.

CUSTINES, ADAM PHILIP DE, in *Biography*, one of the French generals in the revolutionary wars, was born at Metz, on the 4th of February 1740 of a noble family, and served in the seven years' war against Prussia. Having obtained the command of a regiment of dragoons, he exchanged this regiment against another which was ordered to America, and fought for American independence. On his

return to France, he was promoted to the rank of *maréchal de camp* (major general). In 1789, the nobles of Metz named him one of their deputies at the first national assembly, where he embraced the popular party, and moved the issuing of the assignats, (paper money) the dismissal of the ministers, and the abolition of the military establishments of the French princes.

In 1792 Custines was appointed commander in chief of the troops collected in the camp of Soissons, and afterwards of the army of the Rhine. He took possession of Spire, Mentz, and Frankfort on the Mayne; but a furious and impolitic proclamation against the princes of Germany made them unite their forces to oppose him. He was driven from Frankfort by the Prussians, from Worms by the Austrians, and obliged to retreat into Alsace.

Denounced by the jacobins as a traitor, he appeared at the bar of the convention to defend himself, but was condemned and executed on the 27th of August 1793. He went weeping to the scaffold, and died with cowardice. His son, who had been appointed French minister at Berlin, and whom the king of Prussia would not receive, showed much more firmness when, at the age of 25, he suffered death in January 1794, for having been a bad jacobin.

The military talents of general Custines were never held in great estimation; the soldiers under his command detested him for his pride and stern severity. *Nouv. Dict. Historique.*

CUSTODE. Fr. A holster cap. See CHAPERON.

CUSTODE *admittendo*, and *CUSTODE amovendo*, in *Law*, are writs for the admitting, or removing, of guardians.

CUSTODES *libertatis Anglie auctoritate parlamenti*, was the style, or title, in which writs, and other judicial proceedings, did run in the time from the death of Charles I. till Oliver was declared protector, &c. Stat. 12 Car. II. c. 3.

CUSTODIA. See RECTO *de custodia terre et hereditis.*

Hærede deliberando alii qui habet CUSTODIAM terre. See HÆREDE.

CUSTODIA *militaris*, Lat.; a military guard. Military prisoners at Rome, and in the provinces, were guarded in the following manner, particularly if guilty of serious offences or crimes. The guilty person had a chain fastened to his right hand, and to this chain was equally fastened the left hand of him who guarded him. Sometimes, for greater security, the criminal was confined under the guard of two persons tied with him. The chain was long enough for both the guards and the criminal to walk freely. This sort of confinement, however, which must have been attended with much inconvenience and have withdrawn from useful and more important duty a great number of soldiers, did not exist at all periods of the Roman government.

CUSTODIO, HIERONYMUS, in *Biography*, a painter born in Antwerp, who resided in England in the reign of queen Elizabeth. There is at Wooburn (the seat of the duke of Bedford) a portrait of Elizabeth Bruges, daughter of lord Chandos, with the following inscription, *Hieronymus Custodio Antverpiensis, fecit 1589.* Walpole.

CUSTODY of IDIOTS and LUNATICS, used formerly to be committed by the king himself to proper committees, in every particular case; but now, to avoid solicitations and the very shadow of undue partiality, a warrant is issued by the king under his royal sign manual to the chancellor or keeper of his seal, to perform this office for him; and if he acts improperly in granting such custodies, the complaint must be made to the king himself in council. (3 P. Wms. 108. Reg. Br. 267.) But the previous proceedings on the commission are on the law side of the court of chancery, and can only be redressed (if erroneous) by writ of error in

the regular course of law. See IDIOT, LUNATIC, and MAD-HOUSE.

CUSTODY of the *temporalities of bishops*, or of all the lay revenues, lands, and tenements (in which is included his barony), which belong to an archbishop's or bishop's see, forms the first branch of the king's ordinary revenues. Upon the vacancy of the bishopric, these are immediately the right of the king, as a consequence of his prerogative in church matters; by which he is considered as the founder of all archbishoprics and bishoprics, to whom during the vacancy they revert. The policy of the law hath vested this custody in the king, partly because before the dissolution of abbeys, he had the custody of the temporalities of all such abbeys and priories as were of royal foundation, on the death of the abbot or prior, and partly because, as the successor is not known, the lands and possessions of the see would be liable to spoil and devastation, if no one had a property in them. The law, therefore, has given to the king, not the temporalities themselves, but the custody of them till such time as a successor is appointed; with power of taking to himself all the intermediate profits, without any account to the successor; and with the right of presenting (frequently exercised by the crown) to such benefices and other preferments as fall within the time of vacation (stat. 17 Edw. II. c. 14. F. N. B. 32.) This revenue could not formerly be granted out to a subject; but now by stat. 15 Edw. III. ff. 4. c. 4 and 5, the king may, after the vacancy, leave the temporalities to the dean and chapter; saving to himself all advowsons, glebes, and the like. For the prevention and remedy of irregularities which anciently occurred with regard to these temporalities, it was one article of the great charter (9 Hen. III. c. 5.) that no waste should be committed in them, nor the custody of them be sold. The same is ordained by the statute of Westminster, 3 Edw. I. c. 21; and also 14 Edw. III. ff. 4. c. 4. The statute 1 Edw. III. ff. 2. c. 2. guards against the king's seizing the temporalities of bishops, during their own lives. This revenue, formerly considerable, is now reduced almost to nothing: for, at present, as soon as the new bishop is consecrated and confirmed, he usually receives the restitution of his temporalities quite entire, and untouched, from the king; and at the same time does homage to his sovereign; and then, and not sooner, he has a fee simple in his bishopric, and may maintain an action for the profits. Co. Litt. 67. 341.

CUSTOM is used to denote the manners, ceremonies, or ways of living of a people, which in time have turned into habit, and by usage obtained the force of laws.

In this sense, custom implies things that were at first voluntary, but are become necessary by use.

CUSTOM. *Consuetudo*, in *Law*, is a law not written, established by long usage, and the consent of our ancestors. No law can oblige a people without their consent; so wherever they consent, and use a certain rule or method as a law, such rule, &c. gives it the power of a law; and if it is universal, then it is common law; if particular to this or that place, then it is *custom*. 3 Salk. 112. And as to the rise of customs, when a reasonable act once done, was found to be good, and beneficial to the people, then they used it often; and by frequent repetitions of the act, it became a custom; which being continued without interruption time out of mind, it obtained the force of a law, to bind the particular places, persons, and things concerned therein. Thus a custom had beginning, and grew to perfection; and a good custom must be grounded on antiquity, continuance, peaceable acquiescence, reason, certainty, and mutual consistency.

As to the antiquity of any custom, it must have been

used so long, that the memory of man runneth not to the contrary; so that if any one can shew the beginning of it, it is no good custom. On this account no custom can prevail against an express act of parliament; since the statute itself is a proof of a time when such a custom did not subsist. Co. Litt. 113. As to *continuance*, any interruption would cause a temporary ceasing; and the revival gives it a new beginning, which will be within time of memory, and thus the custom will be void. But we must distinguish between an interruption of the *right*, and an interruption merely of *possession*, which, though it takes place for 10 or 20 years, will not destroy the custom. (Co. Litt. ibid.) *Peaceable acquiescence* is such as has not been subject to contention and dispute: for as customs owe their original to common consent, their being immediately disputed, either at law or otherwise, is a proof that such consent was wanting. Moreover, customs must be *reasonable*; or rather, taken negatively, they must not be unreasonable. This Sir Edward Coke explains (1 Inst. 62.) as referring to artificial or legal reason, warranted by authority of law; on which account a custom may be good, though the particular reason of it cannot be assigned; for it is sufficient, if no good legal reason can be assigned against it. With reference to the *certainty* of custom, it is observed, that a custom, limiting the descent of lands to the most worthy of the owner's blood, is void; for how shall it be determined? but a custom to descend to the next male of the blood exclusive of females, is certain, and therefore good. (1 Rol. Abr. 565.) A custom to pay a year's improved value for a fine on a copyhold estate is good, though the value is uncertain; for the value may at any time be ascertained: and the maxim of law is, "id certum est, quod certum reddi potest." Again, customs, established by consent, must be, when established, *compulsory*, and not left optional. Customs must be *consistent* with each other; one custom cannot be set up in opposition to another. For if both are really customs, then both are of equal antiquity, and both established by mutual consent; which it would be absurd to say of contradictory customs.

If it be asked, how are those customs and maxims which lie at the foundation of common law to be known, and how is their validity to be determined? The answer is, by the judges in the several courts of justice. They are the depositories of the laws, the living oracles, who must decide in all cases of doubt, and who are bound by an oath to decide according to the laws of the land. Such judicial decisions are the principal, and most authoritative evidence, that can be given, of the existence of such a custom as shall form a part of the common law. These are registered and preserved under the name of *records*, explained in our *reports*, and digested for use in the authoritative writings of the venerable sages of the law. See RECORDS and REPORTS, and AUTHORITIES.

The effect of a custom thus circumstantiated, is, that in popular states, and limited monarchies, it serves to interpret the written laws: for, in absolute monarchies, it is the king alone who has the power of interpreting laws. Hence, the word custom is still retained, and serves to express the particular rights, and municipal laws, established by usage in particular provinces, &c. after they are reduced into written laws.

In this sense, most of the common law of England is *lex non scripta*; being originally no more than the customs of our forefathers.

The Romans were governed by customs, or unwritten laws, after the expulsion of their kings.

Lex non scripta, in this sense, is used in opposition to statutes,

statutes, or acts of parliament; which commence laws at once. See COMMON LAW.

Another branch of the *lex non scripta*, or the unwritten laws of England, consists of particular customs, or laws which affect only the inhabitants of particular districts. These, or some of them at least, are undoubtedly the remains of that multitude of local customs, out of which the common law, as it now stands, was collected at first by king Alfred, and afterwards by king Edgar, and Edward the Confessor; each district mutually sacrificing some of its own special usages, in order that the whole kingdom might enjoy the benefit of one uniform and universal system of laws. But, for reasons that have been now long forgotten, particular counties, cities, towns, manors, and lordships, were, at a very early period, indulged with the privilege of abiding by their own customs, in contradistinction to the rest of the nation at large; which privilege is confirmed to them by several acts of parliament. Magn. Chart. 9 Hen. III. c. 9. 1 Edw. III. st. 2. c. 9. 14 Edw. III. st. 1. c. 2. 2 Hen. IV. c. 1. See BOROUGH-ENGLISH, GAVEL-KIND, DOWER, &c.

As to the *allowance* of special customs, it is observed, that customs, in derogation of the common law, must be construed strictly. Thus, by the custom of gavel-kind, an infant of 15 years may, by one species of conveyance, (called a deed of feoffment) convey away his lands in fee-simple, or for ever. Yet, this custom does not empower him to use any other conveyance, or even to lease them for seven years; for the custom must be strictly pursued. (Co. Cop. § 33.) And, moreover, all special customs must submit to the king's prerogative. Therefore, if the king purchases lands of the nature of gavel-kind, where all the sons inherit equally; yet upon the king's demise, his eldest son shall succeed to these lands alone. (Co. Litt. 15.) As general customs are determined by the judges, *particular* customs, such as are used in some certain town, borough, city, &c. shall be determined by a jury. (1 Inst. 110.)

For the difference between custom and prescription, see PRESCRIPTION.

CUSTOM of London. The principal local customs of this city are the following: if a citizen and freeman dies, leaving a widow and children, his goods and chattels, (deducting for the widow her apparel, and the furniture of her bed-chamber, called the "widow's chamber,") shall be divided into three parts; the widow shall have one part, the executor or administrator another, to discharge legacies, &c. and the children the other third part. If he leaves only a widow, or only children, they shall respectively, in either case, take one moiety, and the administrator the other. (2 P. Wms. 341. Salk. 246.) If he leaves neither widow nor child, the administrator shall have the whole. (1 Show. 175.) This portion, or "dead man's" part, the administrator was wont to apply to his own use, (2 Freem. 85. 1 Vern. 133.) till the statute 1 Jac. II. c. 17. declared that the same should be subject to the statute of distribution. So that if a man dies worth 1800*l.* personal estate, leaving a widow and two children, this estate shall be divided into 18 parts; of which the widow shall have eight, six by the custom and two by the statute, and each of the children five, three by the custom and two by the statute:—if he leaves a widow and one child, she shall still have eight parts, as before; and the child shall have ten, six by the custom and four by the statute:—if he leaves a widow and no child, the widow shall have three-fourths of the whole, two by the custom and one by the statute; and the remaining fourth shall go, by the statute, to the next of kin. It is also to be observed, that if the wife be provided for by a jointure before mar-

riage, in bar of her customary part, it puts her in a state of non-entity, with regard to the custom only (2 Vern. 665. 3 P. Wms. 16.); but she shall be entitled to her share of the "dead man's" part under the statute of distributions, unless barred by special agreement. (1 Vern. 15. 2 Chan. Rep. 252.) And if any of the children are advanced by the father in his life-time with any sum of money, (not amounting to their full proportionable part,) they shall bring that portion into hotchpot with the rest of the brothers and sisters, but not with the widow, before they are entitled to any benefit under the custom. (2 Freem. 279. 1 Equ. Caf. Abr. 155. 2 P. Wms. 526.); but, if they are fully advanced, the custom entitles them to no further dividend. The custom of London extends also to the province of York, and also to the kingdom of Scotland, and probably also to Wales; inasmuch, that the effects of the intestate, after payment of his debts, are, in general, divided according to the ancient universal doctrine of the *pars rationabilis*, in the manner above stated. However, in order to favour the power of bequeathing, and to reduce the whole kingdom to the same standard, three statutes have been provided; the one 4 and 5 W. & M. c. 2, explained by 2 and 3 Ann. c. 5, for the province of York; another, 7 and 8 W. III. c. 38, for Wales; and a third, 11 Geo. I. c. 18, for London;—by which it is enacted, that persons within those districts, and liable to these customs, may (if they think proper) dispose of *all* their personal estates by will; and the claims of the widow, children, and other relations, to the contrary, are totally barred. There are two principal points, besides other less material variations, in which the customs of London and of York considerably differ. One is, that in London the share of the children (or orphanage part) is not fully vested in them till the age of twenty-one, before which they cannot dispose of it by testament (2 Vern. 558.); and if they die under that age, whether sole or married, their share shall survive to the other children; but after the age of twenty-one, it is free from any orphanage custom, and in case of intestacy, shall fall under the statute of distributions. (Prec. Chanc. 537.) The other is, that in the province of York, the heir at common law, who inherits any land either in fee or in tail, is excluded from any filial portion or reasonable part. (2 Burn. 754.) But, notwithstanding these provincial variations, the customs appear to be substantially one and the same.

A woman in London that uses a trade, without her husband, is chargeable without him, as a *feme sole* merchant; and if condemned may be put in prison till she pay the debt; and her bail are liable, if she absents herself, and the husband shall not be charged. It is the custom of the city of London, that a person educated in one trade may set up in another. See APPRENTICE. A person may acquire the freedom of London either by the servitude of an apprenticeship, by birth-right, as the son of a freeman, or by purchase, under an order of the court of aldermen. (1 Mod. 145.) In London every day, except Sunday, is a market overt, for the buying and selling of goods and merchandise. (5 Rep. 85.) But no person, not being a freeman of London, shall keep any shop, or other place to put to sale by retail any goods or wares, or use any handicraft trade for hire, gain, or sale, within the city, upon pain of forfeiting 5*l.* (8 Rep. 124. Chart. Car. I.)

If a debtor be a fugitive, he may be arrested before the day to find better security. See FOREIGN ATTACHMENT. Every tenant at will of a house above 40*s.* *per ann.* in the city, ought to give and receive half a year's warning on leaving it. An arrest may be made in London, on the plaintiff's entering his plaint in either of the compters, and a serjeant of London need not shew his mace when he arrests a person;

and the liberties extend to the suburbs and Temple-Bar. Jenk. Cent. 201.

If the existence of any custom in London be questioned, it shall not be tried by a jury, but by a certificate from the lord mayor and aldermen by the mouth of their recorder (Cro. Car. 516.); unless it be such a custom as the corporation itself is interested in, as a right of taking toll, &c.; for then the law permits them not to certify on their own behalf; but it must be determined by a jury (Hob. 85.) It is said (1 Ro. Rep. 106.) that the courts at Westminster take notice of the customs of London, and not of any other place. But this is only where they have been certified. The customs of London are confirmed by act of parliament. 8 Rep. 126. Cro. Car. 347.

CUSTOM of Merchants. lex mercatoria, a particular system of customs used only among one set of the king's subjects; which, however different from the general rules of the common law, is yet ingrafted into it, and made a part of it (Winch. 24.); being allowed, for the benefit of trade, to be of the utmost validity in all commercial transactions; for it is a maxim of law, that "*Cuilibet in sua arte credendum est.*" This custom of merchants is so far considered as law, that it affords the rule of construction, in cases of contracts, agreements, &c. and other commercial transactions. The *lex mercatoria*, like the *lex et consuetudo parliamenti*, describes only a great division of the laws of England. The laws relating to bills of exchange, insurance, and all mercantile contracts, are as much the general law of the land, as the laws relating to marriage or murder. And it is the opinion of Mr. Justice Foster, that the custom of merchants is the general law of the kingdom, and, therefore, ought not to be left to a jury after it has been settled by judicial determinations. 2 Barr. 1226.

CUSTOM-Heriot. See HERIOT.

CUSTOM-Suit. See SUIT.

CUSTOMS, in *Commercium*, the duties, tolls, or taxes, paid upon merchandize when brought into or carried out of a country. They appear to have been called customs, as denoting customary payments, which had been in use from time immemorial; and began to be imposed as soon as commerce became an object of public attention. Such princes as wished to encourage foreign trade, found that it brought some additional expences upon them, as it became necessary to maintain ambassadors or other public agents in most of the countries to which their subjects resorted; to negotiate treaties for the regulation of commercial intercourse; to establish courts for deciding maritime causes; and to maintain a navy for protecting merchant vessels at sea from enemies and pirates. In order to indemnify themselves for these charges, they demanded of the merchants tolls, tributes, or customs, by authority of the royal prerogative, which continuing to be paid as customary dues, came to be considered as part of the inheritance of the crown. The considerations (says judge Blackstone) upon which this branch of the revenue (or the more ancient part of it, which arose only from exports) was invested in the king, were said to be two (Dyer. 165): 1. Because he gave the subject leave to depart the kingdom, and to carry his goods along with him. 2. Because the king was bound of common right to maintain and keep up the ports and havens, and to protect the merchant from the pirates.

The ancient customs in England, consisted of small sums paid by the merchants for the use of the king's warehouses, weights, and measures. About the year 979, king

Ethelred established duties on ships and merchandize, to be paid at Billingsgate in the port of London. In Magna Charta it was stipulated that merchants were to come into the kingdom to buy and sell *per antiquas consuetudines*, which proves that some customs had been usually paid long before that time. And some have imagined, that they are called with us customs, because they were the inheritance of the king by immemorial usage, and the common law, and not granted him by any statute (Dyer, 43. pl. 44); but sir Edward Coke hath clearly shewn (2 Inst. 58, 59.), says judge Blackstone, that the king's first claim to them was by grant of parliament (3 Edw. I. A.D. 1274), though the record thereof is not now extant. And indeed this is in express words confirmed by statute 25 Edw. I. c. 7. A.D. 1297, wherein the king promises to take no customs from merchants, without the common assent of the realm, "saving to us and our heirs, the customs on wool, skin, and leather, formerly granted to us by the commonalty aforesaid." These were formerly called the hereditary customs of the crown; and were due on the exportation of the said three commodities, and of none other; which were styled the "staple" commodities of the kingdom, because they were obliged to be brought to those ports where the king's staple was established, in order to be there first rated, and then exported. These customs, granted by the act of 3 Edw. I. consisted of a duty of six shillings and eight-pence for every sack of wool, containing twenty-six stone; six shillings and eight-pence for every three hundred woolfells; and thirteen shillings and four-pence for every last of hides; a last containing twelve dozen. These duties, with some others of inferior importance which were then levied, were afterwards denominated *custuma antiqua sive magna*. They were payable by every merchant, as well native as stranger: with this difference, that merchant-strangers paid an additional toll, *viz.* half as much again as was paid by natives. The appellation *custuma* seems to be derived from the French word *coustum*, or *coitum*, which signifies toll or tribute, and owes its own etymology to the word *coust*, denoting price, charge, &c. as we have adopted it in English, *cost*. By an ordinance of 31 Edw. I. certain new duties of customs were established, to be paid by alien merchants only; these were called *custuma nova* or *custuma parva*, and aliens' duty, and consisted of an additional duty of two shillings for every hoghead of wine imported; additional duties of forty pence for every sack of wool; six shillings and eight-pence for every last of hides, and forty pence for every three hundred woolfells, exported; two shillings for every piece of cloth dyed in grain; eighteen pence for every piece of cloth, in which part of a grain colour was intermixed; and twelve pence for every other cloth without grain; twelve pence for every quintal of wax; and three-pence in the pound on all other kinds of merchandize. The duty on wine, which was at first called *butlerage*, because paid to the king's butler, exchanged for *prifage*, or a right of taking two tons of wine from every ship importing into England twenty tons or more, being afterwards imposed at so much a ton, was called a *tonnage*; and the duty on goods not specified being imposed at so much in the pound of their estimated value, was called a *poundage*. In the 47th year of Edward III. a duty of sixpence in the pound was imposed upon all goods exported and imported, except wool, woolfells, leather, and wines, which were subject to particular duties. In the 14th of Richard II. this duty was raised to one shilling in the pound; but three years afterwards, it was again reduced to sixpence. It was raised to eight-pence in the 2d year of Henry IV.; and in the fourth year

year of the same price to one shilling. From this time, to the 9th year of William III., this duty of poundage continued at one shilling in the pound. The duties of tonnage and poundage were generally granted by one and the same act of parliament, and were called the subsidy of tonnage and poundage. These duties were at first granted, as the old statutes (and particularly 1 Eliz. c. 19.) express it, for the defence of the realm, and the keeping and safeguard of the seas, and for the intercourse of merchandize safely to come into and pass out of the same. They were at first granted only for a fixed term of years, as for two years in 5 Rich. II.; but in the time of Henry VI. they were granted him for life by a statute in the 31st year of his reign; and again to Edward IV. for the term of his life only;—since which time they were regularly granted to all his successors for life, sometimes at the first, sometimes at other subsequent parliaments, till the reign of Charles I.; when, as lord Clarendon expresses it (Hist. Rebell. b. iii.) his ministers were not sufficiently solicitous for a renewal of this legal grant. And yet these imposts were imprudently and unconstitutionally levied and taken, without consent of parliament, for fifteen years together; which was one cause of the subsequent troubles. However, the king, previous to the commencement of hostilities, passed an act, with a view of correcting past errors and appeasing prevalent discontents, by which he renounced all power in the crown of levying the duty of tonnage and poundage, without the express consent of parliament; and also all power of imposition upon any merchandizes whatever. Upon the restoration this duty was granted to king Charles II. for life, and also to his two immediate successors; and by three several statutes, 9 Ann. c. 6, 1 Geo. I. c. 12, 3 Geo. I. c. 7, it was made perpetual, and mortgaged for the debt of the public.

The subsidy of poundage having continued for so long a time at one shilling in the pound, or at five per cent., a subsidy came, in the language of finance, to denote a general duty of this kind of five per cent. This subsidy was afterwards called the old subsidy, and was levied according to a book of rates established in the 12th year of Charles II. The new subsidy imposed by the 9th and 10th William III., was an additional five per cent. upon the greater part of goods. The one-third and the two-thirds subsidy, made up together another five per cent. of which they were proportionable parts. The subsidy of 1747, made a fourth five per cent. upon the greater part of goods; and that of 1759, a fifth upon some particular sorts of goods. The old subsidy was imposed indifferently, upon exportation as well as importation; but the four subsequent subsidies, as well as most of the duties which have since been occasionally imposed on a great variety of goods, have been laid almost wholly upon importation: other ancient duties which had been imposed on the exportation of the produce or manufactures of the country, have either been reduced or taken off altogether. The customs thus imposed by parliament were, till the stat. 27 Geo. III. c. 13, contained in two books of rates, set forth by parliamentary authority, stat. 12 Car. II. c. 4, 11 Geo. I. c. 7. One of these was signed by sir Harbottle Grimston, speaker of the house of commons in the time of Charles II.; and the other, an additional one signed by sir Spencer Compton, speaker in the reign of George I., to which also subsequent additions have been made.

The book of rates, established in 1660, has been considered as the foundation of the present mode of levying

the duties of customs, as it contained the rate of duty payable both by denizens and aliens, and the value to be set upon different descriptions of merchandize, and specified the articles which were custom free. Some new duties on importation were afterwards imposed, and at the revolution the duties of customs consisted of the following branches.

1. Tonnage and poundage granted to Charles II. for life, and to James II. for his life; which, by an account laid before parliament in the first session after the revolution, produced on a medium of four years, 577,507*l.* 12*s.* 10½*d.*; but, according to Dr. Davenant, it produced 600,000*l.* clear of all charges and deductions.
2. Duties on wines and vinegar imported, granted in 1685, which by the same account produced 172,900*l.* 11*s.* 8½*d.*
3. Duties on tobacco and sugar imported, likewise granted in 1685, and which by the same account produced 148,861*l.* 8*s.* per annum.
4. Duties on the importation of French linens, wrought silks, brandies, and East India manufactures, which were also established in the same year, and produced 93,710*l.* 8*s.* 1*d.* per annum.

The total produce of the customs in 1688 was therefore about 992,980*l.*, being more than double their amount twenty years prior to that period.

A considerable increase in the public expenditure, with the introduction of the funding system, occasioned very frequent impositions of new duties, which were generally adjusted on the principles of the old subsidy; that is, the value of the goods was ascertained by a book of rates, and the amount computed by the quantities of the goods, either with respect to gauge, to weight, or to tale; the duty was, therefore, not a certain proportion of their real value, but of an arbitrary value, agreeing, perhaps, with the current value at the time of imposing the duty; but which must, from the natural fluctuations of trade and manufactures, be necessarily liable to many changes and alterations. The consequence of this mode of fixing duties was, that when they were laid on by bulk on goods of one general description, the duty was always the same, whether upon the finer or the coarser manufacture; by which means it either operated as a prohibition to the latter, or was not at all felt by the former. There was also another mode by which duties were imposed; this was by a proportion to the value on goods not rated, being the real and actual value of the same as sworn to by the importer. These principles of taxation, being once adopted, were pursued in all the new and additional duties of customs which were imposed for payment of the interest on the various loans which were raised from time to time for the public service. In some instances the additional duties were calculated by a percentage on the duties previously paid; in others a further duty was laid on a different denomination of the commodity, either with respect to its value, its bulk, its weight, or its number; and by proceeding gradually in this manner, from period to period, the numerous additions made had at length become such a mass of confusion as produced an infinity of inconvenience and delay in business, and became the subject of universal complaint among mercantile persons. The perplexity arose in a great degree from almost all the additional duties having been appropriated to some specific fund, for the payment of certain specific annuities, in consequence of which it was necessary that a separate calculation should be made at the custom-house for each of the different duties. From the great complexity of the whole of this branch of the revenue, scarcely any one merchant could be acquainted by any calculations of his own, with the exact amount of what he was to pay; nor could much assistance in this respect be derived from the va-

rious books which had been published for the purpose of furnishing a general view of the customs, as in every session of parliament some alteration or another was made in several of the duties, and each of these alterations, following the old principle, totally unlinged and overturned the use of every preceding printed calculation; the officers of the customs, therefore, who from constant practice had acquired some facility in making the necessary calculations, were the only persons to whom the merchants could apply for assistance and direction: thus the merchant was not only in a great degree left at the mercy of the officers, but the officers themselves, who were intended to be a check upon the merchants, were forced to become their agents.

In order to remedy these inconveniences, Mr. Pitt proposed, in the beginning of the year 1787, to abolish all the duties then subsisting, and to substitute in their stead one single duty on each article, amounting as nearly as possible to the aggregate of all the various duties then payable; only in general where a fraction was found in any of the sums, to charge the nearest integral number, usually taking the higher rather than the lower, which made a small addition to the revenue. The series of resolutions submitted to the house of commons, for the purpose of carrying this measure into effect, but of which the house chose to waive the formality of reading, amounted to upwards of three thousand in number. A systematic simplicity and uniformity was at the same time introduced into the custom-house accounts, by which a more distinct view has been since obtained both of the total amount of this important branch of the revenue, and of the various sources from which it arises. These beneficial regulations were the result of the laborious investigation and judicious remarks of the commissioners of public accounts, who in their 13th, 14th, and 15th reports, had fully explained the constitution of this department, the duties of its several officers, and the mode of collecting the customs both in London and the out-ports. They also pointed out many other important regulations for the reduction of expence, or the accommodation of merchants, most of which have been since carried into effect. The statute 27 Geo. III. c. 13. called "the consolidation act," repeals all former statutes imposing duties of customs and excise, with regard to the *quantum* of the duty; and the two books of rates above-mentioned were declared to be of no avail for the future; but all the former duties were consolidated, and were ordered to be paid according to a new book of rates annexed to that statute.

Statement of the gross and nett Revenue of the Customs, with the Rate per Centum of the Expence of Collection.

Years.	Gross Receipt.	Rate per Cent. thereon.	Nett Produce.	Rate per Cent. thereon.
	£	£ s. d.		£
1789	5,417,333	6 7 0	4,050,003	8 9 10
1790	5,349,478	6 17 6	3,976,808	9 5 0
1791	5,587,853	7 3 8	4,193,817	9 11 6
1792	6,045,818	6 9 7	4,407,837	8 17 6
1793	5,574,708	6 19 7	4,221,832	9 4 8
1794	5,841,840	7 1 8	3,821,216	10 16 8
1795	5,776,058	6 19 5	3,959,462	10 3 5
1796	6,381,902	6 2 6	4,533,489	8 12 6

The total gross receipt accounted for, falls short of the whole sum raised upon the public in consequence of the duties constituting this branch of the revenue, as there are fees paid to the various officers, in part sanctioned by law, but chiefly claimed on the ground of ancient usage, which

are a very considerable charge to the merchant. In the year 1788, the opinions of the merchants resident in London, and in most of the out-ports, were collected, upon the expediency of abolishing or regulating these fees, and of providing compensations to the officers by a tonnage duty. The merchants of London declared their wishes for a total abolition; and the various communications received from the merchants and traders at the out-ports, rendered it evident that it would be impracticable to form a general table of fees to suit all places. With a view, therefore, to ascertain the amount of the fees for which it would be proper, that a compensation should be provided, if the fees themselves were abolished, an act was passed, authorizing the treasury to appoint two commissioners of the customs in England, and one in Scotland, to enquire on oath into the emoluments of all persons employed in the service of the customs. In January 1790, these commissioners, having visited thirty-four out-ports, made their first report, recommending certain measures for relief of the coasting-trade; and in the same year an act of parliament was passed for the relief of that trade, at a considerable loss to the revenue. In March 1791, the commissioners made a second report, by which it appeared that the total of the fees received, exclusive of allowances from the crown and shares of seizures, amounted, in the year 1788, to 133,805*l.* 6*s.* 3*d.* In May 1791, they made their third report; in which, after stating and discussing the various opinions communicated to them by the merchants, they declared themselves to be decidedly of opinion, that an entire abolition of custom-house fees, and the payment of every person in that department wholly by the crown, would be a measure highly beneficial both to the commerce and to the revenue of the country: and they further gave their opinion, that if an entire abolition was deemed inexpedient, great advantages might still accrue to commerce, and much security to the revenue, by abolishing the fees paid to the persons usually called out-door officers; the annual amount of which was about 45,000*l.*; and that this measure, though of a more limited extent, would place the out-door business at the several ports of the kingdom, on an equal footing. In consequence of these representations, a bill was prepared in 1792; but the apparent difficulty of the subject, and the expence of providing a compensation upon the principle and to the extent suggested, prevented any further proceedings upon the subject; thus a very laborious investigation was rendered of no benefit, and the mercantile interest is still burthened with this highly improper mode of remunerating the servants of government. It cannot be doubted that if fixed and nett salaries could be given to every officer of the customs, proportionate to his services, instead of leaving their compensation to depend upon having additional places or employments in other situations, it would contribute greatly to the independence of the officers, to the relief of the trader, and to the security of the revenue.

Any article of commerce liable to a custom duty upon importation, must, to secure the payment of the duty, be watched from the time the ship enters the port, until the duty is paid; and as it becomes forfeited by evading the duty, it may be pursued and seized. Any article liable to a duty upon exportation, must, to prevent its being changed or altered, be guarded from the time the duty is paid, until the ship has quitted the port: and an article entitled to a drawback or bounty upon exportation, must likewise, to prevent the re-landing of it, be guarded from the time the merchant delivers it to the officer, until the ship has quitted the port. Hence arises the necessity for different

C U S T O M.

different classes of officers, to attend upon and examine these articles, at different stages, in their passage between the ship and the merchant; and to pursue them if they escape the duty. The total number of officers, clerks, and assistants, employed in the management of this branch of the public revenue, was, in the year 1784, 1606, with an indefinite number of inferior attendants; since that period several useless offices have been suppressed, but the great increase in the duties has rendered it necessary to augment the number of persons employed in collecting them very considerably.

The laws relating to the customs are voluminous in bulk, and intricate in their details, comprehending not less than twelve hundred articles upon which duties are levied; about nine hundred of these are subject to rated duties, and the rest are charged *ad valorem*. The statutes relative to the customs alone fill six very large volumes in folio; they are unprovided with any printed index; and the compilation, even in this state, is not published, nor can it be commonly obtained by purchase. This circumstance induced the Committee on Finance, in 1797, to recommend strongly the consolidation and simplification of the laws of the customs, by which means the revenue officer would be enabled to execute his duty with more promptitude and safety; the merchant would better know how to transact his commercial concerns with the revenue; and the foreign trader would have the means of avoiding those errors which, at present, so frequently expose his property to seizure, for the omission of forms which it is almost impossible that he should know to be necessary. At some future period of peace this very useful measure will probably be accomplished.

In the year 1803, another consolidation of the duties was effected by 43 Geo. III. c. 68; but the new duties, which have been since imposed, have again destroyed, in some degree, the simplicity then established, and will render it necessary, at no great distance of time, to recur again to the same principle.

The extraordinary system of warfare adopted in the succeeding contest between France and Great Britain, in which unprecedented decrees were attempted to be enforced, for excluding the latter country from every species of commercial intercourse with other nations, rendered necessary some measures of retaliation; with this view, new duties on exportation, commencing from 5th February 1808, were imposed on all the principal articles of foreign merchandize, with the exception of the produce of the British colonies, and of articles which had been imported by the East India Company.

The total nett produce of the customs, after deducting re-payments, drawbacks, bounties, and the charges of management, has been as follows:

In 1802	£7,415,726	19s. 3 $\frac{3}{4}$ d.
1803	7,776,775	2 7 $\frac{3}{4}$
1804	9,060,297	8 2 $\frac{1}{2}$
1805	9,825,037	15 9 $\frac{3}{4}$
1806	10,553,293	19 9 $\frac{3}{4}$

Total Gross Receipt of the Customs of Great Britain, for the Year ending 5th January 1807.

Balance in the hands of the different collectors, on 5th January 1806	£50,843	16s. 3d.
Balance in the hands of the receiver-general of Scotland, on 5th January 1806		
1806	54,657	3 8 $\frac{1}{2}$
Carry over	£105,500	19 11 $\frac{1}{2}$

Brought over	£105,500	19 11 $\frac{1}{2}$
Bills arising and remitted out of the revenue of 1805, but not brought to account till 1806		
- - - - -	283,759	1 3 $\frac{3}{4}$
Gross receipt within the year, including permanent and annual duties, and war taxes		
- - - - -	12,379,983	19 1 $\frac{1}{4}$
Total	£12,769,244	0 4 $\frac{1}{2}$

The various payments to which this receipt was subject, including the nett payment into the exchequer, were as follow:

Drawbacks of duty on exportation	£162,119	11s. 0 $\frac{1}{4}$ d.
Repayments on over-entries and damaged goods	79,781	0 5 $\frac{1}{2}$
Bounties on exportation	1,318,446	0 2
Bounties for promoting national objects	307,864	3 1 $\frac{1}{4}$
Imprest money granted to out-port collectors, &c.	34,989	13 3
Paid towards the expenses of the civil government of Scotland	76,445	18 6 $\frac{5}{8}$
Charges of management	655,603	8 10 $\frac{1}{2}$
Payments into the exchequer, on permanent and annual duties, and war taxes	9,733,813	12 1 $\frac{1}{2}$
Balance in the hands of the different collectors, on the 5th January 1807	58,594	11 6 $\frac{1}{2}$
Balance in the hands of the receiver-general of Scotland, on the 5th January 1807	61,542	8 7 $\frac{1}{2}$
Bills arising and remitted out of the revenue of 1806, but not brought to account till 1807	280,043	12 7 $\frac{1}{2}$
Total	£12,769,244	0 4 $\frac{1}{2}$

Deducting from the gross receipt within the year, of 12,379,983*l.* 19*s.* 1 $\frac{1}{4}$ *d.*, the sums paid for drawbacks on exportation, and in bounties for promoting national objects, the total nett amount of the year's duties will be 11,910,000*l.* 4*s.* 11 $\frac{1}{4}$ *d.*, arising as follows:

From duties inwards	£10,166,561	13s. 4 $\frac{3}{4}$ d.
Duties outwards	621,566	16 5 $\frac{1}{4}$
Duties coastways	1,035,988	17 8
Remittances from the plantations	26,061	16 7 $\frac{3}{4}$
Quarantine tonnage duty	13,370	14 7
Condemned tobacco, rent of tobacco warehouses, &c.	17,570	5 11 $\frac{1}{2}$
Imprest money repaid	28,880	0 3
Total	£11,910,000	4 11 $\frac{1}{4}$

Total Gross Produce of the Customs of Ireland for the Year ending 5th January 1807.

From duties inwards	£1,889,462	15s. 5 $\frac{1}{2}$ d.
Duties outwards	20,129	11 9 $\frac{1}{2}$
Storage	1,951	10 11 $\frac{3}{4}$
Light money	6,114	8 1 $\frac{1}{2}$
Irish spirits	959	4 3
Fines and seizures, surecharges, &c.	16,923	7 2 $\frac{1}{2}$
Total	£1,920,359	16 4 $\frac{3}{4}$
Deduct appropriated duties	15,181	1 5
Total	£1,920,359	16 4 $\frac{3}{4}$

The

The total expence of collecting the revenue of the customs, in the year above-stated, was, in England, at the rate of *5l. 1s. 3d. per cent.* on the gross receipt, or *6l. 1s. 3d. per cent.* on the nett produce; in Scotland it amounted to *5l. 17s. 7d. per cent.* on the gross receipt, or *7l. 18s. 4d. per cent.* on the nett produce. In Ireland the expences of this branch of the revenue being in a great measure blended with the excise, cannot be separately stated, but they considerably exceed the rate of collection in Great Britain.

The statutes for preventing frauds in this branch of the revenue, and for directing and regulating the conduct of merchants and of the several officers of the customs are much too numerous to be here recited. Some of the principal are as follow:

In case goods and merchandize are brought to a port, and part of the goods are sold there, but never landed, they must pay the customs. Ships outward bound, and coming from beyond sea, having goods and merchandize on board, are to be entered at the custom-house, and the customs paid or agreed for under the penalty of 100*l.* and forfeiture of the goods; one moiety to the king, and another to the seisor, &c. and if any concealed goods are found after clearing, for which the duties have not been paid, the master of the vessel shall be subject to the like penalty. 13 and 14 Car. II. c. 11. Officers of the customs may search ships; and having writ of assistance search houses. By other statutes, foreign goods, taken in at sea by any coasting vessel, shall be forfeited and treble value: and for prevention of clandestine running of goods, if any foreign brandy, &c. is imported in vessels under forty tons, the importer shall forfeit the vessel and brandy. Run goods concealed or offered for sale, are liable to forfeiture and treble value. 8 and 11 Geo. I. When three persons are assembled and armed with fire-arms, &c. to be assisting in running goods, they shall be adjudged guilty of felony: and 50*l.* be paid for apprehending such offenders, &c. And two or more found in company within five miles of the sea-coast, with any horses, carts, &c. on which are put above six pounds of tea, or five gallons of brandy, or other foreign goods of 30*l.* value, landed without entry, and not having permits, who shall carry any offensive weapons, &c. or assault any officer of the customs, shall be deemed runners of goods, treated as felons, and the goods shall be seized and forfeited. If any person offers any tea, brandy, &c. to sale, without a permit, the persons to whom it is offered may seize and carry it to the next warehouse belonging to the customs or excise, and be entitled to a third part of the produce on condemnation. And persons offering any bribe to officers of the customs to connive at the running of goods are liable to a forfeiture of 50*l.*; obstructing such officers in entering and searching ships, incurs a forfeiture of 100*l.*; and if the officers are wounded or beaten on board any ship, the offenders incur the penalty of transportation, &c. 9 Geo. II. If any persons, three or more, armed with weapons, shall be assembled in order to aid in the illegal exportation of goods to be exported, or the running of uncustomed goods, or the illegal relanding of any goods, or rescuing the same after seizure, or the person apprehended for a felonious act relating to the customs or excise, or preventing a guilty person from being apprehended; or if such persons shall so assist, or have their faces blacked, or wear a mask, or other disguise, when passing with such goods, forcibly obstruct or resist, any revenue officer in seizing such goods, or shall maim or dangerously wound, &c. such officer, in his attempt to go on board any vessel, or shoot at or dangerously wound any such person when

on board, and in the execution of his office; every such person shall be guilty of felony, and suffer death. On information on oath of any persons being guilty of any of the above offences, the justice may certify the information to one of the secretaries of state, who is to lay it before his majesty: and his majesty may order the offender to surrender himself in 40 days after publication of the order in the Gazette; and in default thereof the order being published twice in the Gazette, and proclaimed in two markets near the place where the offence was committed, and a copy of it being affixed in some public place there, the offender shall be attainted of felony, and suffer death. Any person harbouring or aiding any such offender after the expiration of the time of his surrender, knowing that he has been required to surrender, being prosecuted within a year, shall be transported for seven years. If any officer, &c. in the seizing, &c. of such goods, or the attempt for apprehending such offender, shall be lost, wounded, maimed, or killed, or the goods be rescued, the inhabitants of the hundred, &c., unless the offender be convicted within six months, shall forfeit 100*l.* to the executors of any officer killed, and pay damages to any officer beat, &c. not exceeding 40*l.*, and for any goods rescued, not exceeding 200*l.* A reward of 500*l.* for apprehending any offender, a person wounded in apprehending any offender to have 50*l.* extraordinary, and the executors of a person killed to have 100*l.* 19 Geo. II. c. 34.

By stat. 14 Ric. II. c. 10.; no customer or comptroller of the customs shall have any ships of his own, or meddle with the freight of ships. By stat. 10 Hen. VI. c. 5. no searcher, surveyor, &c. or their clerks &c. may have any such ships of their own; nor shall use merchandize, keep a wharf, inn, or tavern, or be factor, attorney, &c. to a merchant, under the penalty of 40*l.* By stat. 3 Hen. VI. c. 3.; customers, collectors, or comptrollers, shall not conceal customs duly entered and paid, on forfeiture of treble value, and payment of fine and ransom to the king. By stat. 13 and 14 Car. II. c. 11.; if any persons employed about the customs and subsidies take a bribe, or connive at any false entry, they shall forfeit 100*l.* and be incapable of any employment under the king: and the person who gives the bribe shall forfeit 50*l.* By stat. 5 Geo. I. c. 11.; if an officer of the revenue shall make any collusive seizure of foreign goods, to the intent that the same may escape payment of the duties he is to forfeit 500*l.* and be incapable of serving his majesty; and the importer and owner shall forfeit treble value of the goods so collusively seized. By stat. 12 Geo. I. c. 28; officers of the customs, &c. shall not trade in brandy, coffee, &c. on pain of 50*l.* and forfeiture of offices. For other particulars, see DRAWBACK, EXCISE, and SMUGGLING.

CUSTOMARY FREEHOLDERS, are a species of copyholders, of free or privileged tenure, who are derived from the ancient tenants in villein-socage, and are not said to hold "at the will of the lord," but only "according to the custom of the manor." These may be allowed, without absurdity, to be capable of enjoying a freehold interest; and therefore the law doth not suppose the freehold of such lands to rest in the lord of whom they are holden, but in the tenants themselves; who are sometimes called customary freeholders, being allowed to have a freehold *interest*, though not a freehold *tenure*. See COPYHOLD.

CUSTOMARY Land, in Agriculture, is that description of land which is granted by the lord of a manor to a tenant under certain restrictions, in respect to fines, quit rents, &c. according to the particular rules and regulations of the manor.

manor. The author of *Modern Agriculture* has remarked, that a considerable portion of the lands of this country are held under lords of manors by copyhold or customary tenures, subject to the payment of fines on the alienation of the property, the death of the lord or of the tenant, and also to the payment of certain yearly rents, and the performance of various services. That this sort of tenure, says he, should be considered not only as a grievance, but also as an obstacle to agricultural improvement, cannot appear surprising, when it is remarked that the lord of the manor is entitled to two years' improved value of the copyholds on the death of the copyhold tenant, or on the alienation of the property. Under such circumstances it is not probable that the possessors will be disposed to a liberal expenditure of money on the improvement of lands held by a tenure of this restricted kind. Besides, says he, the services performable by the proprietors of copyhold or customary lands, in the north-west of England in particular, are disgraceful in the extreme, and such as in a free country ought to be for ever abolished. They consist of cutting, drying, and loading the lords' peats, ploughing and harrowing his land, reaping his corn, making his hay, carrying his letters, &c. whenever and how often his lord's services are demanded. It could not, he supposes, be a matter of much difficulty to arrange general terms, on which copyholders might have it in their power to enfranchise the estates, by payment of a certain sum to the lords of manors for the total abolition of this remain of the feudal system. So far as he is informed, lords of manors may, as the law now stands, make any arbitrary demand they please on their vassals for the enfranchisement of their lands; and if not complied with, they must remain in the state above described. Whereas, were an equitable mode established, whereby the copyholder could purchase his independence on reasonable terms, few would continue, he thinks, in a state of bondage, nor would the improvement of the country be obstructed by the arbitrary exactions of the superiors and great landholders. As manorial rights have been handed down from father to son for many generations; and as by the law of the country, the present possessors have as good a title to exercise these rights as any of their predecessors, it would, he says, be unjust to deprive them of the privilege, without giving them an equitable compensation; but when the exercise of these rights stands in the way of improving the national territory, and of supplying the public markets with provisions, it must be deemed impolitic in the legislature to permit them to exist. It is very generally known, he adds, that one great obstacle to improvement, arises from a laudable anxiety in the customary tenants, to have their little patrimony descend to their children. These small properties (loaded with fines, heriots, &c. joined to the necessary expence of bringing up and educating a numerous family) can only be handed down from father to son by the utmost thrift, hard labour, and penurious living: and every little saving being hoarded up for the payment of the eventful fine, leaves nothing for the expence of travelling to see improved modes of culture; to gain a knowledge of the management and profits of different breeds of live stock, and to be convinced, by ocular proofs, that their own situations are capable of producing similar advantages: and even should they be half inclined to adopt a new practice, prudence whispers, that should the experiment fail, it would require the savings of many years to make good the deficiency. Customary tenures are therefore allowed on all hands, he thinks, to be a great grievance, and a check to improvement. This, he thinks, might be done away on

the division of common rights. The yearly value of the various customs, fines, &c. might be settled by commissioners, and twenty five, or any reasonable number of years' purchase, on this yearly value, be the price of the enfranchisement, which might be paid in money or in land, at the option of the copyhold or customary tenant. It is impossible, says this writer, that any solid argument can be urged against the propriety of abolishing, without delay, every remain of the feudal system, where it tends, in the smallest degree, to obstruct the general improvement of the country. This may, it is supposed, be accomplished with very little trouble. All that appears necessary, in regard to customary or copyhold lands, for instance, is, either to adopt the plan delineated above, or to pass one general act of parliament, empowering those who hold their estates only mediately of the crown, but immediately of a subject or superior, to demand of that superior, that, by means of a legal proof, he shall ascertain the actual yearly value in money or grain of the fines payable on the alienation of the property, the death of the superior or lord, or of the copyholder. Where personal services are payable, as mowing peats, carrying letters, &c. the value of these should also be ascertained, and the proprietors, so situated, have it in their power to become independent, by paying a reasonable number of years' purchase, or by making payment annually of the sum thus ascertained to be the value of these fines and services. Were such an arrangement to be made, customary tenants or copyholders would, says he, have an inducement to cultivate their lands in the best possible manner; because they, not the superiors, would reap the profits arising from improved cultivation.

Whether the methods here proposed by Mr. Donaldson be the most proper and convenient or not, there cannot be any doubts, but that all those obstacles and restraints which have the operation of retarding and preventing the improvement of the soil, should be removed as speedily as the different nature of their circumstances will permit. See **COPYHOLD and LAND.**

CUSTOMARY Tenants, are those who hold their estates, in consequence of the kindness and indulgence of successive lords of manors, according to particular customs established in their respective districts; and therefore, though such estates are still held at the will of the lord, and are in general so expressed to be held in the court-rolls, yet that will is qualified, restrained, and limited, to be exercised according to the custom of the manor. This custom, being suffered to grow up by the lord, is looked upon as the evidence and interpreter of his will, which is no longer arbitrary and precarious, but fixed and ascertained by the custom to be the same, and no other, that has time out of mind been exercised and declared by his ancestors. A copyhold tenant is therefore now full as properly a tenant by the custom, as a tenant at will; the custom having arisen from a series of uniform wills. And therefore it is rightly observed by Calthorpe (on Copyholds, 51. 54.) that copyholders and customary tenants differ not so much in nature as in name; for although some be called copyholders, some customary, some tenants of the verge, some base tenants, some bond tenants, and some by one name and some by another, yet they all agree in substance and kind of tenure;—all the said lands are holden in one general kind, that is, by custom and continuance of time; and the diversity of their names doth not alter the nature of their tenure. See **COPYHOLD.**

CUSTOM-HOUSE, an office established on the frontiers of a state, or in some chief city, or port, for the receipt of the customs and duties of importation and exportation,

tion, imposed on merchandizes, by the authority of the sovereign, and regulated by tariff, or books of rates.

There are several custom-houses in the several ports of England: the most considerable is that of London. It is under the direction of nine commissioners appointed by patent; who have the charge and management of all the customs (the petty farms alone excepted) in all the ports of England.

Other officers are, a secretary, solicitors, receiver-general, comptrollers of the issues and payments of the receiver-general, comptroller-general, patent comptroller, patent collector, inspector of the out-port collectors' accounts, inspector-general of the exports and imports, register-general of all ships of Great Britain, surveyors-general, surveyors of the out-ports, register of the seizures, receivers, collectors and surveyors, in various departments, searchers, &c. all holding their places by patents: with other inferior officers, appointed by warrant from the board of treasury.

CUSTOMS and SERVICES. See CONSUETUDINIBUS, &c.

CUSTOR, in *Geography*, a river of Hungary, which runs into the Theis near its conflux with the Danube.

CUSTOS, PETER, in *Biography*, a painter, born in Antwerp, sometimes also called Peter Balthasar, and more commonly Balthus. He was received into the company of painters at Antwerp, in the year 1579, and excelled in his representations of fairs, village feasts and landscapes, in the style of Peter Breughel. According to Heineken, he published, under the name of Balthasar, a book of the Geologies of the Counts of Flanders, enriched with forty portraits and figures—The arms and devices of the knights of the golden fleece, &c.

CUSTOS, DOMINICUS, the son of the preceding Custos, who was also a native of Antwerp, and at first called Balthus, but being afterwards established as an engraver and printseller at Augsbouurg he resumed his real name *Custos*. He died in 1612, leaving three sons, Raphael, David, and Jacob, who were also engravers. The plates of this artist are neatly executed, but they discover a want of taste, and a stiffness which renders them disagreeable to the eye. The following are amongst his best works: "Fuggerorum et Fuggerarum Imagines," a book in folio, containing 64 portraits, 1593, very rare. A second edition was afterwards published at Augsbouurg, augmented by others of Lucas and Wolfgang Killian to the number of 127. "Effigies pictorum ac doctorum aliquot Virorum, ad vivum delineatæ, et æri incisæ per Dom. Custos, 1594," 12 pieces. "Tyrolensium Principum Comitum genuinæ Eicones, 1599," containing 28 plates, full lengths, folio. He also engraved after Baroccio, Paul Brill, Bassan, the Caracci and other masters. His mark is composed of the letters D. C. united with an A and an F. Strutt. Heineken.

Custos Brevium, the name of an office belonging to the court of common pleas, executed by four persons, and two deputies, &c. who receive and keep all the writs, and put them upon files, every return by itself; and at the end of each term, receive of the prothonotaries all the records of the *nisi prius*, called the *postas*.

The writs are first brought in by the clerks of assize of every circuit to the prothonotary, who enters the issue in the causes, to enter judgment. Four days after the return, the prothonotary enters the verdict, and judgment thereupon, into the rolls of the court; and then delivers them over to the *custos brevium*.

The *custos brevium* also makes entry of writs of covenant,

and concords on fines; and makes copies and exemplifications of all writs and records in his office, and of all fines levied: the fines, when engrossed, are divided between the *custos brevium* and chirographer; the former keeping the writ of covenant and the note, the latter the concord and foot of the fine. This officer is made by the king's letters patent.

In the court of king's bench there is likewise a *custos brevium & rotulorum*, who files such writs as are there used to be filed, and all warrants of attorney; and transcribes or makes out records of *nisi prius*, &c. This office is held by two persons.

Custos placitorum coronæ, in our *Ancient Writers of Law*, seems to be the same with him we now call *custos rotulorum*, which is mentioned in the writ *de odio & alio*.

Custos rotulorum, an officer who has the custody of the rolls, or records of the sessions of peace; and, some say, of the commission of peace itself.

He is always a justice of the peace and quorum, in the county where he hath his office; and being the principal civil officer in the county, as the lord lieutenant is the chief in military command, he is generally selected on account of his wisdom, countenance, or credit. By the 37 Hen. VIII. c. 1. (altered by 3 and 4 Edward VI. c. 1, but restored by 1 Will. c. 21.) no person shall be appointed to the office of *Custos rotulorum*, but such as shall have a bill signed with the king's hand for the same; which shall be a sufficient warrant to the lord chancellor to make a commission, assigning and authorizing thereby the same person to be *custos rotulorum*, until the king hath by another bill with his own hand appointed one other person to have the same office, by himself, or his sufficient deputy, learned in the laws, and meet and able to supply the said office. By his office he appears to be rather a minister than a judge: because the commission of the peace, by express words, lays this special charge upon him; *Quod ad dies & loca prædicta, brevia, præcepta, processus, & indictamenta prædicta coram te & dictis sociis tuis venire facias*. It is his province to appoint the clerk of the peace.

Custos spiritualium, the person who exercises spiritual or ecclesiastical jurisdiction in any diocese, during the vacancy of the see.

This, by the canon law, belongs to the dean and chapter; but, in England, to the archbishop of the province, by prescription: though divers deans and chapters do challenge it, by ancient charters, from kings of this land.

If the archiepiscopal see be vacant, the spiritual jurisdiction is committed to the dean and chapter. (2 Ról. Abr. 22, 223.) The guardian of the spiritualities may be either guardian in law, *jure magistratus*, as the archbishop is of any diocese in his province; or guardian by delegation, being the person whom the archbishop or vicar-general doth for the time appoint. The *Custos spiritualium* hath all manner of ecclesiastical jurisdiction of the courts, power of granting licences and dispensations, probate of wills, &c. during the vacancy, and of admitting and instituting clerks presented; but such guardian cannot, as such, consecrate or ordain, or present to any benefices. Stat. 13 Eliz. c. 12. Wood's Inst. 25, 27.

Custos temporalium, the person to whose custody a vacant see was committed by the king as supreme lord; who, as a steward of the goods and profits, was to give an account to the escheator, and he into the exchequer.

His trust continued till the vacancy was supplied by a

successor, who obtained the king's writ *de restitutione temporalium*; which was commonly after consecration, but sometimes before. See *CUSTODY of temporalities*.

CUSTREL. The shield bearer among the ancients was so called.

CUSTRIN, or **KUSTRIN**, originally *Köstryn*, in *Geography*, from a large lake of that name between Custrin and Sonnenburg, is a handsome and strongly fortified town of Prussia, in the Newmark of Brandenburg, on the confluence of the rivers Oder and Warther, surrounded on all sides by marshes and morasses, 21 miles N.E. of Frankfort on the Oder, and 65 miles east of Berlin. The approach to Custrin on the side of the middle mark is by a causeway of nearly four miles in length, which has not less than thirty-six bridges; and on the side of the Newmark by another causeway, which has seven bridges.

In 1758 the Russians under general Fermor reduced Custrin to a heap of ruins by means of bombs and red-hot bullets: but the fortifications commanded by the brave Prussian colonel Shack de Wuthenow held out against their attempts; and the great Frederick having raised the siege and beat the Russians at Zorndorf, lodged the Russian officers his prisoners along with the common soldiers in the casemates, and pointing at their uncomfortable quarters, observed that they were indebted to their own cruelty for the badness of their accommodations.

Different, however, has been the fate of Custrin in 1806. Panic-struck at the rapid advances of the French after the memorable battle of Jena, or confident that there was no Prussian army near to relieve the town, colonel Ingersleben, who commanded at Custrin in October 1806, surrendered on capitulation to marshal Davoust, on the 31st of the same month. The garrison, which consisted of 4000 men, were made prisoners of war, and marched to France. The officers were permitted to return to their respective homes on parole. When the French entered the town on the first of November, they found 90 cannons on the ramparts, and immense magazines in the place.

CUT, in *Inland Navigation*, denotes the same with canal, branch, or arm. See **CANAL**.

CUT, in *Agriculture*, is a term often used to signify the operation of castrating or gelding young animals, as lambs, calves, fowls, &c.

CUT. There are six cuts established for the use of the cavalry to be made with the broad sword or sabre, for which see **SWORD-EXERCISE**.

To cut off, is to intercept or separate a party, detachment, or convoy from the army, corps, or place it belongs to or is destined for; or to separate one part of an army from the rest, and either take them prisoners, or destroy them. It is a phrase variously applied and in familiar use.

To cut off an enemy's retreat, is to manœuvre in such a manner, as to prevent an hostile army or body of men from returning when closely pressed, either to their entrenchments or to a fortified town, which they had sallied or marched out from; or to prevent a detachment, advanced corps, or part of an army from leaving a position they have occupied, and retiring to another position in order to effect a junction with the main body of their army; or to prevent an hostile army or corps, that enters a country for the sake of making incursions, or for the purpose of conquest, whether the attempt be made by land or water, from returning within their own frontiers or on board their ships; or to reduce them to such difficulties without both sustaining a great loss of men and leaving many things behind them, and thereby to force them for the sake of re-embarking without molestation into a convention on terms neither very advantageous nor very ho-

nourable, as happened last war at the Helder. Armies may be cut off either in toto, or in part, through the ignorance, timidity, or mismanagement of those who command them, or through the superior talents and skill of an enemy's general, who amidst the hurry, confusion, noise, and defolation, that generally attend pitched battles, suddenly takes advantage of some opening in the wings or centre of his enemy's army, or of those favourable incidents which occur in every engagement. When an army is superior in numbers to another, provided it be not too numerous for all its parts to be easily managed for the purposes of co-operation, and is commanded by a skilful and intelligent officer, it may always cut off a part at least of the forces opposed to it when they come into action.

To cut short, a sort of cant phrase among military people; as when they say, that soldiers are cut short of their pay, or their allowances, &c.

To cut up, to kill or destroy: When we say that the cavalry went in pursuit of a flying enemy, and cut the most of them up, we mean, that the cavalry killed or destroyed the most of them.

To cut through, to penetrate, to open a passage or cut a way through. A small body of resolute and brave men, will sometimes, when surrounded or in difficulties, extricate itself from apparent captivity or destruction by opening or cutting a passage for themselves through superior force. The Roman history affords many, and the British several instances of this nature.

CUT a feather, in *Sea Language*, is when a well-bowed ship so swiftly presses the water, that it foams or froths.

To cut the sail, is to unfurl it, and let it fall down.

To cut and run, is to cut the cable and make sail instantly, without waiting to weigh anchor.

CUT-bastion. See **BASTION**.

CUT-purse, in *Law*; if any person *clam & secreté*, and without the knowledge of another, cut his purse, or pick his pocket, and steal from thence above the value of twelve pence, it is felony excluded clergy. 8 Eliz. c. 4. 3 Inf. 68.

Cut-purses or *saccularii* were more severely punished than common thieves, by the Roman and Athenian laws.

CUT-roof. See **ROOF**.

CUT-water, the sharp part of the head of a ship below the beak. It is so called because it cuts or divides the water before it comes to the bow, that it may not come too suddenly to the breadth of a ship, which would retard her. See **SHIP**.

CUT-water, in *Ornithology*, the Sea-crow of Edwards, Black-skimmer of Latham, and *RYNCHOPS nigra* of Gmelin; which see.

CUTACIUM, in *Ancient Geography*, a town of Asia, in Armenia.

CUTAMBULI, in *Medicine*, a name given by the old writers to certain worms bred under the skin, and causing by their creeping a very uneasy sensation. Afterwards the same word was used to express certain uneasy itchings caused by a scorbutic habit, and resembling the crawling of worms.

CUTANEOUS, from *cutis*, the skin, belonging or relating to the skin. Thus we say cutaneous disease, cutaneous eruption, &c.

CUTANEOUS diseases, or *eruptions*, comprise all the variety of discolorations, spots, and excrescences, which arise on the skin, and which have obtained various appellations, according to the difference of their forms; such as pimples, pustules, vesicles, scales, rashes, tubercles, &c. (which see respectively.) The modifications of these, again, constitute

the different *genera* of cutaneous disease; as the small-pox, measles, itch, leprosy, &c.; some of which are accompanied with fever, and complete their course in a stated time, and by regular stages; others, in much greater number, are chronic diseases, and are irregular and various both in appearance and duration. The chronic diseases of the skin are often tedious and difficult of cure; and the utility of the remedies, recommended by physicians and surgeons, has been considerably diminished by the inaccuracy with which the diseases have been described, so that medicines, which had been found efficacious in one form of disease, have been misapplied to others, and their efficacy denied. Many modern writers, indeed, have contented themselves with one or two general terms, such as *scorbutic*, *herpetic*, and *leprosy*, by which they have indiscriminately designated all cutaneous eruptions. So long as this inaccuracy of language is continued, little improvement can be expected in our knowledge of the nature and treatment of these diseases. It is fortunate, therefore, that we have now an arrangement of cutaneous diseases, in which each is considered according to its external character, as consisting of one or other of the simple forms above-mentioned, viz. of pimples, scales, &c. This arrangement was devised by Dr. Willan: the following is an outline of it.

Orders and Genera of Cutaneous Diseases.

Order I. Papulæ (*Pimples.*)

Genera.

Strophulus (Red gum, tooth eruption, &c.)
Lichen (Spring eruption, scorbutic pimples, &c.)
Prurigo (Gratelle, or universal itching of the skin.)

Order II. Squamæ (*Scaly diseases.*)

Lepra (Leprosy of the Greeks.)
Pсориазис (Dry or scaly tetter.)
Питириазис (Dandriff.)
Иктыозис (Fish-skin.)

Order III. Exanthemata (*Rashes.*)

Rubeola (Measles.)
Scarlatina (Scarlet fever.)
Urticaria (Nettle rash.)
Roseola (Rose rash.)
Purpura (Purple or scorbutic rash.)
Erythema (Red rash.)

Order IV. Bullæ (*Large irregular Bladders.*)

Erysipelas (St. Anthony's fire.)
Femphigus (Vesicular fever.)
Pompholyx (Water-blebs.)

Order V. Vesiculæ (*Vesicles.*)

Herpes (Ring worm, shingles, wild fire, &c.)
Varicella (Chicken pox, and swine pox.)
Vaccinia (Cow-pox.)
Miliaria (Miliary eruptions.)
Eczema (Heat eruption.)
Apthæ (Thrush.)

Order VI. Pustulæ (*Pustules.*)

Impetigo (Running tetter.)
Ecthyma (Large inflamed pustules.)
Variola (Small pox.)
Scabies (Itch.)
Perri'o (Cold head, honey-comb-scab, &c.)

Order VII. Tubercula (*Tubercles.*)

Phyma (Boils, carbuncles, &c.)
Verruca (Warts.)
Molluscum (Small soft wens.)
Vitiligo (White smooth tubercles.)
Aene (Stone pock, red tuberculated face, &c.)
Lupus (or Noli me tangere.)
Elephantiasis (Arabian leprosy.)
Frambæsiâ (Yaws.)

Order VIII. Maculæ.

Ephelis (Sun spots.)
Nævus
Spilus, Moles, and other original marks.

Every one of these *genera* is subdivided into *species*, so as to include all the modifications of cutaneous disease.

There is a simplicity, and, comparatively speaking, a facility of discrimination, connected with this arrangement, as founded exclusively on external character, which render it worthy to be studied; and it is only by the use of one common nomenclature, like this, that writers on diseases of the skin will be enabled to make themselves intelligible, or to understand each other. See each *Genus* in alphabetical order. See also Willan's Description and Treatment of Cutaneous Diseases, &c.

CUTANEUS COLLI, in *Myology*, a name given to the platysma myoides.

CUTANEUS externus nervus, in *Neurology*, is the same with the musculo-cutaneous nerve of the upper extremity.

CUTANEUS internus nervus, is a superficial nerve of the upper extremity. See NERVE.

CUTCH, in *Geography*, a territory of considerable extent in Hindoostan, situated in the S.E. of Sindy;—the eastern branch of the Indus separating the two countries. It extends along the northern coast of the gulf of Cutch, and is separated from Guzerat by the Puddar river, or one of its branches. The present capital and residence of its rajah is *Boodge-boodge*, which see. Cutch is composed chiefly of hills, woods, and sandy wilds, but its interior part is very much unknown. The mouths of several rivers appear in the map of its coast; and the ancient maps describe the Puddar river as discharging itself into the gulf of Cutch, through these openings. Major Rennell thinks it possible, that the river formed by the Coggar, and other streams, may discharge itself by one of these openings: unless it loses itself in the sand of the desert, which borders on the north of Cutch. On the S. coast of the gulf of Cutch is a district inhabited by a piratical tribe, named "Sangarians," who cruize for merchant ships as far to the west as the gulf of Persia. The capital of this state is Noanagur; Bate or Bait, and Aramroy, are its principal ports. The Ayin-Acharee takes notice of the founding of Noanagur by a rajah, who was driven out of Cutch about 300 years ago; and says, that the territory in which it is situated is named "Little Cutch."

The province of Cutch, as well as the western parts of the peninsula of Guzerat, are governed by rajahs of their own; and do not seem to have undergone much change by the late revolutions in Hindoostan. Cutch is not only a barren country, but in its nature too strong to be easily attacked. And the western part of Guzerat is mountainous and woody; and inhabited by a wild, hardy race; and therefore, on both accounts, unfavourable to the progress of a Mahratta army.

CUTHA, in *Ancient Geography*, a country of Asia, in Assyria. See CUSH.

CUTHBERT,

CUTHBERT, St. the 6th bishop of Durham, who died A.D. 686, in a hermitage upon the Farne islands, having resigned the bishopric of Lindisfarne, or Holy island, about two years before. His body was brought to Lindisfarne, where it is said to have remained until a descent of the Danes, about 763, when the monastery was nearly destroyed. The monks on this occasion fled to Scotland, with the relics of St. Cuthbert, which they deemed their chief treasure. Many fabulous stories are recorded with regard to the migrations and miracles of the body of this saint through various parts of Scotland and the north of England: at length, however, the saint is said to have chosen for his place of residence a place named Wardlaw or Wardilaw, in a forest called Danholeme near Chester-le-Street, whither the bishop's see had been transferred. It is said that the Northumbrian catholics keep secret the precise spot of the saint's sepulchre, which is only entrusted to three persons at a time. When one dies, the survivors associate to them, in his room, a person judged fit to be the depository of so important a secret. The Entrochi found among the rocks of Holy island, are denominated "St. Cuthbert's beads." While forming these beads he is supposed to sit during the night upon a certain rock, and use another as his anvil. This saint's legend contains many other stories not more probable.

CUTHBERT'S Beads, in *Natural History*; these Mr. Walcott has shewn to be separated joints of the Entrochus, of which he has figured several in his "Petrifications found near Bath," *fig. 61*. These abound in some of the Bath free-stone strata, particularly in the stone-pits used for making of the new road leading from King's-down to Bradford; where also pundibs, both smooth and striated, high-waved cockles, and two other curious fossil shells (*figs. 32 and 37.*) are found in abundance.

CUTHBERT duck, in *Ornithology*. See ANAS.

CUTHITES. See CUSH.

CUTICLE, in *Vegetable Anatomy*. See BARK, CORTEX, and EPIDERMIS.

CUTICULA, in *Anatomy*, is the inorganic, and insensible covering, which universally invests the surface of the cutis, or true skin. See SKIN.

CUTICULAR GLOVE, in the Phil. Transf. denotes a separation of the *cuticle* from the *cutis*, from the writ to the finger-ends, &c. in the form of gloves, occasioned by a singular kind of fever. See the case and history related, *ibid.* vol. lix. N 38. an. 1769.

CUTILLÆ, or **CUTILA**, in *Ancient Geography*, a town of Italy, in the country of the Sabines, E. of Reate. It is spoken of by the ancients as a considerable city, famous for its sulphurous waters. This country, and that of Reate, were, according to Varro, the most elevated part of Italy, and called *Umbilicum*, or the "the navel" of Italy. The town was situated on the banks of a lake called *lacus Cutillensis*. In this lake were floating islands, and Pliny relates that a kind of moving forest was observed in it. The waters were reckoned salubrious, and used for fortifying the stomach and nerves. Suetonius says, that the emperor Vespasian resided here during the summer, and according to Xiphilinus, this was the place in which he died.

CUTINA, a town of Italy, in the country of the Vestini.

CUTIS, in *Anatomy*, is the strong, vascular, and sensible membrane; which every where covers the surface of the body, and constitutes the organ of touch: it is also called dermis and true skin. See SKIN.

CUTLER, a military artificer, whose business is to forge, temper, and mount all sorts of sword-blades.

CUTLERIAN LECTURES, lectures on mechanics founded in 1664 by sir John Cutler, who appointed a salary of 50*l.* a year, and settled it upon Mr. Hooke for life; the president, council, and fellow of the royal society, being entrusted to appoint both the subject and number of the lectures.

CUTLERY. Under this head we shall comprise the articles knives, forks, razors, and scissors. They are all either made of steel or of iron, with steel to form the edge.

Three kinds of steel are made use of in the manufacture of different articles of cutlery, *viz.* common steel, shear-steel, and cast-steel; these different kinds are made from what is termed blistered steel, which has hitherto been obtained of good quality only from certain kinds of bar iron brought from Sweden and Russia.

The bar iron is stratified with powdered charcoal in a furnace termed a converting furnace, within a recess termed a pot, from 7 to 14 feet long, 3 feet broad, and 2½ feet deep, the whole covered close up with a mixture of clay and sand, so as to prevent the access of atmospheric air. A strong heat is applied for about 8 days; as soon as the pot is cooled, which is in about 8 days more, the bars are taken out, and the iron is found to be converted into steel; it always appears blistered upon the surface, and hence is termed blistered steel. When these bars are taken to the tilt, and drawn into rods of various dimensions, it is called common steel. All the cheaper cutlery are made of this steel, and also all kinds of forks.

When a number of bars of blistered steel are laid together, heated to a welding heat in a forge furnace, and drawn down into bars under a forge hammer, they constitute what is termed shear steel. It has received this name from its being made use of to make wool shears. It is also termed Newcastle steel, from having been first made at that place.

Shear steel is exceedingly kind and tough. All the edge tools which require great tenacity without great hardness, are made of it, such as table-knives, scythes, plane-irons, &c. It is also freer from flaws, on account of the welding heat which has been given to it.

Cast-steel is formed by melting blistered steel in covered crucibles, and pouring it into cast-iron moulds, so as to form it into ingots: these ingots are then taken to the tilt and drawn into rods of suitable dimensions. No other than cast-steel can assume a fine polish, and hence all the finer articles of cutlery are made of it, such as the finest scissors, pen-knives, razors, &c.

Formerly cast-steel could only be worked at a very low heat; it can now be made so soft as to be welded to iron with the greatest ease. Its use is consequently extended to making very superior kinds of chisels, plane-irons, &c.

Forging of Table Knives.

Two men are generally employed in the forging of table knives, one called the foreman or maker, and the other the striker.

The steel called common steel is employed in making the very common articles; but for the greatest part of table knives which require a surface free from flaws, shear-steel is generally preferred. That part of the knife termed the blade, is first rudely formed and cut off. It is next welded to a rod of iron about ½ inch square, in such a manner as to leave as little of the iron part of the blade exposed as

C U T L E R Y.

possible. A sufficient quantity of the iron now attached to the blade, is taken off from the rod to form the bolster, or shoulder and the tang.

In order to make the bolster of a given size, and to give it at the same time shape and neatness, it is introduced into a die, and a swage placed upon it; the swage has a few smart blows given it by the striker. This die and swage are by the workmen called prints.

After the tangs and bolster are finished, the blade is heated a second time, and the foreman gives it its proper anvil finish; this operation is termed *smithing*. The blade is now heated red-hot and plunged perpendicularly into cold water. By this means it becomes hardened. Being thus hardened, it requires to be tempered regularly down to a blue colour: in this state it is ready for the grinder. Forks are generally a distinct branch of manufacture from that of knives, and are purchased of the fork makers by the manufacturers of table knives, in a state fit for receiving the handles.

The rods of steel from which the forks are made, are about $\frac{3}{4}$ inch square. The tang and shank of the fork are first roughly formed. The fork is then cut off, leaving at one end about 1 inch of the square part of the steel. This part is afterwards drawn out flat to about the length of the prongs. The shank and tang are then heated, and a proper form given to them by means of a die and swage. The prongs are afterwards formed at one blow by means of the stamp; this machine is very similar to that used in driving piles, but it is worked by one man. It consists of a large anvil fixed in a block of stone nearly on a level with the ground. To this anvil are attached two rods of iron of considerable thickness fixed 12 inches asunder, perpendicularly to the anvil, and diagonally to each other. These are fastened to the ceiling. The hammer or stamp, about 100 lbs. in weight, having a groove on either side corresponding to the angles of the upright rods, is made to slide freely through its limited range, being conducted by its two iron supporters. A rope is attached to the hammer which goes over a pulley on the floor of the room above, and comes down to the person who works the stamp: two corresponding dies are attached, one to the hammer, and the other to the anvil. That part of the fork intended to form the prongs, is heated to a pretty white heat and placed in the lower die, and the hammer containing the other die, is made to fall upon it from an height of about 7 or 8 feet. This forms the prongs and the middle part of the fork, leaving a very thin substance of steel between each prong, which is afterwards cut out with an appropriate instrument called a *file-pres*. The forks are now annealed by surrounding a large mass of them with hot coals, so that the whole shall become red-hot. The fire is suffered gradually to die out, and the forks to cool without being disturbed. This process is intended to soften, and by that means to prepare them for filing. The inside of the prongs are then filed, after which they are bent into their proper form and hardened. When hardened, which is effected by heating them red-hot and plunging them into cold water, they are tempered by exposing them to the degree of heat at which grease inflames.

Penknives are generally forged by a single hand with the hammer and the anvil simply. The hammer in this trade is generally light, not exceeding $3\frac{1}{2}$ lbs. The breadth of the face, or the striking part, is about one inch, if broader it would not be convenient for striking so small an object. The principal anvil is about 5 inches, and 10 upon the face, and is provided with a groove into which a smaller anvil is wedged. The smaller anvil is about 2 inches square

upon the face. The blade of the knife is first drawn out at the end of the rod of steel, and as much more is cut off along with it as is thought necessary to form the joint. The blade is then taken in a pair of tongs, and heated a second time to finish the joint part, and at the same time to form a temporary tang for the purpose of driving into a small haft used by the grinder. Another heat is taken to give the blade a proper finish. The small recess called the nail hold, used in opening the knife, is made while it is still hot by means of a chisel, which is round on one side, and flat on the other.

Penknives are hardened by heating the blade red-hot and dipping them in water up to the shoulder. They are tempered by laying them side by side, with the back downwards upon a flat iron plate laid upon the fire where they are allowed to remain till they are of a brown or purple colour.

The blades of pocket knives, and all that come under the denomination of spring knives, are made in the same way.

The forging of razors is performed by a foreman and striker as in making table knives.

They are generally made of cast-steel. The rods as they come from the tilt are about $\frac{1}{2}$ inch broad, and of a thickness sufficient for the back of the razor.

There is nothing peculiar in the tools made use of in forging razors: the anvil is a little rounded at the sides which affords the opportunity of making the edge thinner, and saves an immense labour to the grinder.

Razors are hardened and tempered in a similar manner to penknives. They are however left harder, being only let down to yellow or brown colour.

The forging of scissors is wholly performed by the hammer, and all the sizes are made by a single hand. The anvil of the scissor-maker weighs about $1\frac{1}{2}$ cwt.; it measures on the face about 4 by 11 inches. It is provided with two gates or grooves for the reception of various little indented tools termed by the workmen *bosses*; one of these bosses is employed to give proper figure to the shank of the scissors; another for forming that part which has to make the joint; and a third is made use of for giving a proper figure to the upper side of the blade. There is also another anvil placed on the same block containing two or three tools called *beak irons*, each consisting of an upright stem about 6 inches high, at the top of which projects a horizontal beak; one of these beaks is conical, and is used for extending the bow of the scissors, the other is a segment of a cylinder with the round side upwards containing a recess for giving a proper shape and smoothness to the inside of the bow.

The shank of the scissors is first formed by means of one of the bosses, above described, leaving as much steel at the end as will form the blade. A hole is then punched about $\frac{1}{2}$ inch in width a little above the shank. The blade is drawn out and finished, and the scissors separated from the rod a little above the hole. It is heated a third time, and the small hole above mentioned is extended upon the beak-irons so as to form the bow. This finishes the forging of scissors. They are promiscuously made in this way without any other guide than the eye, having no regard to their being in pairs. They are next annealed (for the purpose of filing such parts of them as cannot be ground) and afterwards paired.

The very large scissors are made partly of iron, the blades being of steel.

After the forging, the bow and joints, and such shanks as cannot be ground, are filed. The rivet hole is then bored, through which they are to be screwed or riveted together. The common kind of scissors are only hardened up to the joint. They are tempered down to a purple or blue colour. In this state they are taken to the grinder.

Grinding

CUTLERY.

Grinding and polishing of Cutlery.

The various processes which come under this denomination are performed by machinery, moving in general by the power of the steam engine or a water wheel.

Grinding wheels or grinding mills are divided into a number of separate rooms; every room contains six places called troughs; each trough consists of a convenience for running a grindstone and a polisher at the same time, which is generally occupied by a man and a boy.

Two of the above troughs are represented in *Plate I. Cutlery*: *A* is a wooden wheel, called a drum, the axis of which run through the whole length of the room. On the same axis are placed three other drums, one of the same length with the above, and two of half the length. Each of the large drums carries four straps, which give motion to the two stones *c, c*, and to the polishers *b* and *e*, by passing round their respective pulleys *g, g, g, g*: *d, d, d, d*, are the places where the workmen sit, and as he sits astride for the purpose of leaning over the stone, the seat is termed a horse.

The business of the grinder is generally divided into three stages, viz. grinding, glazing, and polishing.

The grinding is performed upon stones of various qualities and sizes, depending on the articles to be ground. Those exposing much flat surface, such as saws, fenders, &c. require stones of great diameter, while razors whose surface is concave, require to be ground upon stones of very small dimensions. Those articles which require a certain temper, which is the case with most cutting instruments, are mostly ground on a wet stone; for which purpose the stone hangs within the iron trough *H*, filled with water to such a height that its surface may just touch the face of the stone.

In the manufactories of Sheffield not less than five various qualities of stone are employed. The most valuable of the five is termed the Wickersley stone, from its being brought from a village of that name, about nine miles east of Sheffield.

It is of the sandstone kind, rather firmly indurated, of a compact texture. It appears to consist of very hard silicious particles cemented together with a softer medium. Both in the wet and dry state, it cuts with great facility, and is particularly adapted for grinding razors, penknives, table knives, and the inside of the blade of scissors.

Another very useful stone is termed the whitening stone. It is of a bluish white colour, exceeding the Wickersley stone in hardness, in firmness, and in closeness of texture. It is particularly employed for grinding the outside of the blade of scissors, and other articles requiring great smoothness and neatness of shape.

Forks, and the shanks of some scissors, are ground upon a dry stone, termed the fork-stone. It is a very sharp grit stone of a whitish colour, very similar to that of which millstones are formed. The stones employed for grinding saws and files are of a similar quality with the fork-stone, of a yellowish grey colour.

It is necessary that the stones move with a certain velocity, in order to produce a maximum of effect.

If the velocity be too great, two evils are generally to be expected: the first (which is most to be dreaded) is the breaking of the stone, the second is the stone almost ceasing to cut; this is also the case with drills, files, and other similar instruments; if they move too rapidly over the surface they are cutting, they generate much heat, but do not cut so well.

The surfaces of all stones are contrived to move with about the same velocity. This is effected by means of different sized pulleys. The drums above described are

four feet in diameter, and make from 120 to 140 revolutions in a minute, and the pulley on the axis of the stone must be of such diameter as to cause the surface of the stone to move at the rate of from 600 to 700 feet per second.

We cannot wonder at the dreadful effects of the breaking of a stone when we consider the great velocity with which they move. The horse or seat of the workman projects over the centre of the stone, and is secured to a beam of wood on a level with the ground by means of a strong chain. This in some measure secures the workman from those pieces of the stone, which might be projected upwards against the under side of the horse. But as it is quite uncertain what direction the fractured parts may take, the above contrivance is only a partial defence against these shocking accidents. It sometimes happens that the chain is broken, and the man and horse together projected to a considerable distance.

Means have been recently adopted by some of the grinders to prevent, in a great measure, the breaking of stones, which consist in a different method of fastening the stones upon the axis. The old method consists in wedging on the stone by means of wooden wedges. The improved method is to secure the stones to the axis by means of two circular plates, which are screwed firmly against the sides of the stone. By this means the parts of the stone are kept together. On the contrary, when the wedges are employed, a force is constantly exerted to break the stone; this effect is increased when the stones are used wet, from the circumstance of the wood absorbing moisture.

Glazing is a process following that of grinding: it consists in giving that degree of lustre and smoothness to an article which can be effected by means of emery of the various degrees of fineness. The tool on which the glazing is performed, is termed a glazer. It consists of a circular piece of wood, formed of a number of pieces in such a manner that its edge or face may always present the endway of the wood. Were it made otherwise the contraction of the parts would destroy its circular figure. It is fixed upon an iron axis similar to that of the stone: some glazers are covered on the face with leather, others with metal consisting of an alloy of lead and tin; the latter are termed caps. In others the wooden surface above is made use of. Some of the leather-faced glazers, such as are used for forks, table knives, edge tools, and all the coarser polished articles, are first coated with a solution of glue and then covered with emery. The surfaces of the others are prepared for use by first turning the face very true, then filling it with small notches by means of a sharp-ended hammer, and lastly filling up the interstices with a compound of tallow and emery.

The pulley of the glazer is so much less than that of the stone, that its velocity is more than double, being in general at the surface that of 1500 feet in a second. The glazer and its pulley are seen at *e* and *l*.

The process of polishing, consists in giving the most perfect polish to the different articles. Nothing is subjected to this operation but what is made of cast-steel, and has been previously hardened and tempered.

The polisher consists of a circular piece of wood covered with bull leather, the surface of which is covered from time to time, while in use, with the crocus of iron, called also co-leather of vitriol.

The polisher requires to run at a speed much short of that of the stone, or the glazer. Whatever may be its diameter, the surface must not move at a rate exceeding

CUTLERY.

70 or 80 feet in a second. This diminished velocity is effected by causing its stop to pass over the rounded part of the axis of the drum as shewn at B.

Grinding of Table Knives.

The stones made use of are from 35 to 45 inches in diameter, and about six inches broad upon the face. This stone is a species of sand stone, before termed the Wickersley stone. It is first turned, or raised exceedingly true, and then notched upon the face with a sharp-edged tool to make it cut faster. This species of stone cuts astonishingly fast, and has the peculiar property of not heating to a great degree any substance ground upon it. It is valuable on that account for grinding those articles which have been previously hardened. Table knives are ground first upon this stone, and afterwards upon one of finer texture, called the whitening stone. This prepares them for the glazing. The glazer is about 20 inches diameter and 5 inches broad, covered on the face with thick leather. This leather is thinly coated with glue, and is rolled in a quantity of emery. As soon as the glue is set the glazer is fit for use. It runs upon an iron axis, in the same manner as the stone. The bolster of the knife, when plane, is also ground and glazed in a similar way.

Forks.

The stone on which forks are ground are from 18 to 24 inches in diameter and about $2\frac{1}{4}$ inches broad. It is a very sharp grit, something harder than that last mentioned. The face of the stone is a little rounded, for the purpose of meeting hollow parts, which are observed in all forks. The grinder holds the fork crosswise on the stone, and very dexterously gives it a kind of circular motion; by this means he makes the shank very round. The shank and neck of the prongs are ground upon this stone. The stone being dry, a profusion of sparks is given out, and the fork becomes heated with the great friction, till it is blue. The prongs are afterwards ground upon a wet stone, from 14 to 18 inches diameter and about 7 inches broad. The shank and neck of the prongs are finished upon a glazer of a similar shape to that of the stone on which they are ground; this glazer is of wood covered with leather, and prepared upon the surface with glue and emery, in the same manner as that for table knives. The prongs are finished upon a glazer of the same materials, but flat upon the face, about 8 inches both in diameter and breadth. The insides of the prongs are dressed by means of thin leather straps about 2 inches broad and 18 inches long; they are first coated with glue and then covered over with emery: as soon as the glue is set the stop is introduced between the prongs of the fork, and is drawn backwards and forwards till the part becomes sufficiently clean.

Grinding of Penknives.

The stone made use of for penknives is the Wickersley stone, about 16 or 18 inches in diameter when new, and is worn down to about 9 or 10 inches; the breadth is about $4\frac{1}{2}$ or 5 inches. This stone, as has been before observed, having so little tendency to heat the substances ground upon it, is generally made use of dry for grinding penknives. There are several advantages in grinding upon the dry stone. It does not wear so fast. The edges of the stone are kept sharper and the surface even; but the great advantage is, that the stone cuts much faster. When the surface of a dry stone becomes clogged with the particles of steel adhering to it, a piece of soft iron is always at hand, which

being rubbed over it soon clears it of its incumbrance, and a fresh cutting surface is presented.

All the finer penknives, after being ground the first time, go back to be hanoled or hafted. The handles are wrapped in paper to keep them from being soiled, and the knives thus hafted are again returned to the grinder. The blades are all slightly ground over again upon a stone kept for the purpose of one determinate size. The flat parts of the blade are next glazed upon a glazer or lap made of lead, and for common articles of wood. After the lap is turned perfectly true, and a number of notches are made in the face; the surface is rubbed over with emery and grease. If it is found to cut too keen it is slightly rubbed over with bees wax. This process would finish the common sort of knives, but the finer blades are afterwards polished upon the polisher already described.

Grinding of Razors.

Razors are generally ground upon the stones which are laid aside by the grinders of penknives and scissors. They take them when about the diameter of 8 inches, and wear them down to 4 or 5 inches. These small stones are highly proper for razors, in order to give to the blade a requisite degree of concavity and corresponding thinness to the edge. The razors are next glazed upon laps of metal, of a size corresponding with the size of the stone, and afterwards polished upon a polisher of wood covered with leather, similar to those used for penknives. The process of polishing, indeed, is always performed on the same kind of tool, differing only in size.

Grinding of Scissors.

The stones made use of by the scissor-grinder are of two kinds; the one of the same size and quality with that used for penknives, and the other of the same nature with that used in the grinding of table-knives, and which the workmen term a whitening stone. The first is employed to grind the inside of the blades, and the latter for grinding the outside. Scissors, the blades of which alone are hardened, are never sent to the grinder before they are hardened and tempered. After the blades of the scissors are ground they are returned to the maker, and are fitted and screwed together, and properly adjusted for cutting. This being done, they are taken to pieces and returned to the grinder. The scissors being slightly ground over again are finished upon their appropriate glazer. The insides of the blades, and all the other parts which are not rounded, are glazed upon a glazer of metal, of a size corresponding to the stone on which they were ground; for the inferior articles the glazer is of wood.

When the shanks of scissors are sufficiently plane to admit of grinding, they are sent to the shank-grinder, a workman solely employed in grinding the shanks and in dressing those parts of the scissors which have been filed, and which cannot be touched by the glazer.

The shanks of larger and commoner sorts of scissors are ground upon a stone similar to that used for grinding the shanks of forks, but the finer kinds are ground upon the Wickersley stone already described. Being ground, they are glazed upon a glazer of wood faced with leather, of the same size and shape with the shank of the scissor. The remaining parts of the scissors, which have been only filed and rubbed with sand but are still destitute of polish, are finished by brushing.

The brush is an instrument consisting of a circular piece of wood set upon the face with very hard bristles. Two brushes are generally employed in succession. The first

CUTLERY.

is made use of with grease and emery, which gives a coarser sort of polish. The second is used with crocus and water to give the proper finish to the surface. If the blades of the scissors are required to be polished, which is frequently the case, they are again sent to the first grinder, who polishes them upon a polisher similar to those described for razors and penknives. It will be here proper to remark that the shanks of the above kinds of scissors, being soft, cannot assume the polish with crocus, as nothing but cast-steel in the hardened state is susceptible of that peculiar lustre. An imitation of polishing is, however, given to the soft shanks by means of a burnisher of polished hardened steel.

The more delicate and finer sorts of scissors, in order to render all the parts susceptible of polishing, are hardened quite up to the bow, in consequence of which the order of manufacturing is a little varied, from that of the scissors having soft shanks. After being forged, filed, and having the hole drilled for the screw, the insides of the blades are ground, and they are fitted and screwed together. They have next to be hardened and tempered, and as it is a common property of steel to warp during that process, the two sides of the scissors are firmly bound together by means of iron wire. The screw being withdrawn, which would be liable to be hardened along with the scissors, they are heated red-hot all over, and immersed in water up to the bow.

After being thus hardened they are heated, for the purpose of tempering them till the blades appear of a purple and the shanks of a blue colour. The wire is then taken off, and the scissors are finished by processes similar to those above described, with the difference of the shank being polished with crocus along with the blades. After the scissors return the last time from the grinder they only require to be sharpened, wiped clean and screwed together. Previous to wiping, however, they are generally put into pulverized quick-lime, which greatly tends to the preservation of their lustre by absorbing the moisture from the surface; the presence of which is well known to facilitate the rusting of polished steel.

Some of the very fine scissors are elegantly and variously ornamented. Formerly they used to be ornamented with studs of gold or polished steel, arranged round the joint of the scissor or along the shank.

The studs are each furnished with a small tang, by which they are inserted into small holes made in the scissors. The holes are made while the scissors are soft, and the studs are inserted after the scissors are polished.

More recently the same parts are inlaid with circular bits of gold, which are polished along with the scissors and afterwards ornamented on the surface by engraving. Scissors are also ornamented by means of gilding, bluing, and etching. The gilding is performed in two ways; the first by dipping the finished article into a solution of muriate of gold in alcohol; the second with metallic gold laid on by means of heat. The first kind of gilding has been rejected on account of its want of permanency. The second, though very durable, is objectionable on account of the heat employed in the process, which is so great as to make the scissors too soft.

Various devices, such as letters, coats of arms, &c. are sometimes put upon scissors, but more frequently upon razors and swords, by means of etching. The figures are drawn upon the polished surface with a varnish, made by dissolving resin in oil of turpentine. Every other part of the articles is covered with the same varnish, excepting what is to form the ground of the picture. The exposed part

is then covered with dilute nitric acid, which is suffered to remain upon it till it is supposed to be sufficiently corroded. It is then rinsed in water to take away the acid, and the varnish is removed by means of oil of turpentine. The ground of the picture appears of a dead white, while the figure, and other parts of the article, display their original polish.

Cutlery made of Pig-Iron.

Great quantities of various kinds of cutlery have been made of pig-iron, by means of casting, particularly forks and scissors. The models are made of lead, alloyed with a little antimony. The articles are cast in sand, in flasks similar to those used in casting small articles of brass. The metal employed is of that sort of pig-metal known by the name of N^o 1, from the large quantity of carbon contained in it. It fuses at a lower temperature, and becoming more liquid on that account, it is the only kind which can be used for small articles.

The metal is fused in crucibles of Stourbridge clay, in the common air furnace employed in iron founderies. The articles, when cast, are almost as brittle as glass. This, in a great measure, is occasioned by the moisture in the sand, which effects this change upon the metal in a manner similar to that by which steel becomes hardened. In order to obviate this hardness, the castings are cemented with ashes or sand, for the purpose of annealing them. Cast-iron pots of a cylindrical shape are employed for this purpose. They are about 12 inches diameter, and about the same depth. A number of these pots are filled nearly to the top with the goods to be annealed: a quantity of fine sand or ashes is then employed to fill up the interstices, and to cover them completely, so as to exclude the air. The pots are placed in a furnace, and are surrounded with small coaks, for the sake of carrying on slow combustion. They are heated very gradually to a temperature little short of fusion, and they are as gradually allowed to cool. The whole time occupied in heating and cooling is from 24 to 30 hours. They are found, after this process, to have become very soft, and to be capable of bending a little without breaking. They afterwards are finished in a manner similar to those which are forged, with the exception that they are not hardened and tempered: were they subject to that process, they would return to the same state as before annealing.

Notwithstanding the great demand which has been for cast cutlery, on account of their very low price, they are so completely destitute of utility, that ultimately they cannot fail to disgrace both the merchant and manufacturer. If a preference can be given to any of them, it is in favour of the scissors. The knives and forks are not only liable to break, but they soon turn black, and can be very little improved by the common mode of cleaning, as by the best means they are only susceptible of a miserable polish.

Various attempts have been made with a view to improve the cast cutlery, the most successful of which is by Mr. Lucas of Sheffield; and for his method he some time ago obtained a patent. By Mr. Lucas's process, the cast metal articles are converted from their brittle and crude state into malleable iron or steel at pleasure, without injuring the surface, or distorting the figure of the article. Nails of various kinds have been made in this way, more flexible and equally tenacious with those of wrought iron. This method consists in stratifying the articles, in pots similar to those employed for annealing, with an oxyd of iron. Calcined iron-stone pulverized was first made use of, but was found to make the surface of the metal so rough as to render those articles useless. This inconvenience was in some measure obviated by laying

CUTLERY.

A thin stratum of sand between the metal and oxyd of iron. Any sort of earth, containing a portion of the oxyd of iron, is capable of bringing about this change. The red sand which abounds in some countries, or loam, or clay, containing oxyd of iron, would answer very well. The theory of this process is obvious. The cast-iron consists of iron and charcoal, or carbon; and it is to the presence of the carbon that we attribute the peculiar qualities of cast-iron different from those of a malleable iron and steel. The oxyd of iron, with which the cast-iron articles are stratified, consists of iron combined with oxygen. During the process of cementation, the oxygen of the oxyd combines with the carbon of the cast iron, forming carbonic acid, which is dissipated in the form of air. For the particulars of the process, see the articles IRON and STEEL.

Specimens of scissors, table knives and forks, and even penknives, have been made so complete by the above process, that the best judges could not distinguish them from those made of the best steel. An insurmountable objection, however, still remains, which will preclude the application of this important discovery in the manufacture of those articles which require a fine edge, and every other article which requires to be hardened and tempered.

This metal, previous to hardening and tempering, is equally tough with the best steel or iron, but afterwards becomes very brittle, at least much more so than we should expect from steel so apparently good. The reason of this will be explained under IRON and STEEL.

Handling of Table Knives.

The handles of table knives are made of ivory, bone, horn, and wood. They are formed in two different ways: one, by drilling a hole into the handle, and cementing into it the tang of the knife. This kind is by the manufacturers termed round tangs. The other kind of handle consists of two sides, which, when laid on each side of the tang, and paired together, form the handle. The two sides are termed scales, and knives of this kind are called scale tangs.

Iron handles are the most valuable, and in the greatest repute. The greatest part of them is made for the round tangs. These are of various patterns, such as octagon, oval, and fluted. The octagon and oval handles are filed into the intended form, and afterwards rubbed first with fine sand and water, and afterwards with powdered chalk and water. The fluting of the handles is performed by means of a sharp tool of the scraping kind, having the figure of the flutes upon its face.

The tangs are cemented into the handles with rosin mixed with whitening.

A very convenient and durable handle is made of stag horn. The round parts of the horn which are of proper thickness are selected for the round tangs. The outsides of the other parts of the horn are cut into scales, which make the scale tang handles. The surfaces of the stag-horn handles are invariably left in their natural state.

The small end of the ox-horn, termed the tip, is generally employed for making the handles of table knives. The tips are formed into hafts of a great variety of patterns, by means of pressing between two dies. This advantage is obtained from the well known property of horn being so soft and ductile when hot, as to admit of considerable extension. The dies employed for pressing the horn are represented in *fig. 2.* A and B, the upper and lower dies, are made to form the bits of a pair of tangs, on the even faces of which the exact figure of the handles is formed, as represented in the figure.

The pieces of horn intended to be pressed are first softened

in hot water, and then cut to the size deemed requisite exactly to fill the mould. The dies are heated to the temperature of about 400° Fahrenheit, or something short of the heat required to burn oil. The horn, with a little oil, is then laid between the dies, which are placed in the pressing vice, *fig. 3.* consisting of a compound lever, acting with a screw at A, and turning round the handle B, similar to the common vice. The force required to be given at the handle is not more than what a man may perform with ease. The motion being now reversed, the tangs are withdrawn, and the horn is found to have received the full impression of the die.

If the handles are plain, and the horn be native black, the first pressing is sufficient; if, however, they are not sufficiently black, they are dyed after the first pressing in a liquid, containing logwood and green vitriol. The process of dyeing takes off that smooth glossy surface given by the dies, which is restored by pressing them a second time in dies a little less than those employed for the first pressing. If the handles require to be fluted, or otherwise ornamented, they are pressed a second time in dies containing the intended figure.

The above handles, after they come from the press, require only to have blades inserted, and to be polished by means of rotten stone or chalk and oil.

The handles of bone are made from the shank of the ox. The thickness of the solid parts of the bone is never sufficient to make the handles equally thick with those of ivory. Some of the bones are very dense and hard, but can always be distinguished from ivory by the colour. Such handles, in order to correct their defect in colour, are dyed green in liquid, consisting of the oxyd of copper dissolved in aqua ammonia. The hartshorn of the shops, being the cheapest preparation of ammonia, is always used. The proportions are about seven ounces of the oxyd of copper to one gallon of hartshorn.

After dyeing, the blades are cemented into the handles, which are afterwards polished. When the dye does not contain any substance capable of rusting the blade, the handles are dyed after the blades are inserted.

Various kinds of wood are employed in making the handles of table knives. The very common articles have handles of birch wood, which are expeditiously made by being turned in an oval lathe. They are afterwards dyed black or red. After this they only require the blades to be put into them, and to be furnished with a smooth stone, termed blood-stone. A superior kind of wood handles are made of various foreign wood, such as lignum vitæ, ebony, &c. Handles are sometimes made of very thin silver in the sheet, and of plated copper. The thin metallic shells, which form the outside of the handle, are made in two laits, by being forced into a steel dye, by means of lead; the two sides are afterwards soldered together, and the hollow part filled up with a cement of rosin and pulverized brick. The cement serves to give firmness to the thin shell of metal, and at the same time to secure the blade.

Handling of Penknives.

The handles of penknives in general consist of three parts, *viz.* the outer scales, the inner scales, and the spring. The outer scales, which are only ornamental to the knife, are made of various substances, such as horn, stag-horn, ivory, bone, tortoise-shell, and pearl. The two latter substances are employed for the most valuable knives. The beautiful variegated horn stands the next in estimation. But the most durable scales are made of stag-horn.

The inner scales, which serve to give firmness and durability

CUTLERY.

bility to the knife, and to which the outer scales are attached, are made of iron, brass, and sometimes of silver: the ends of the inner scales intended to receive the blade is in general made thicker, and is termed the bolster of the knife. The scales of those knives having no bolsters are cut out of thin plates of the metal of which they are made. Iron scales with bolsters are forged with the hammer.

The spring is of steel, running along the back (and in single blade knives round the end) of the handle, and serves to separate the scales from each other; and by its elasticity exerted upon the tang of the blade, it secures the knife in the situations of being shut or open. The inner scales and the spring being forged, and the outer scales being provided, they are put into the hand of a workman, who finishes the whole of the handling department.

His tools consist of a vice, a small anvil, and hammer, a variety of files, steel burnishers, a breast-plate, drill-bow, and drills of various kinds; a glazer coated on the face with emery and glue, to polish the different parts; and a buff, which is an instrument similar to a glazer; but instead of being coated with emery and glue, it is used with oil, and fine sand, and rotten-stone. It is employed to polish the surface of the outer scales. The buff and the glazer are turned by the foot, in a manner similar to that of the common street-grinder. He is also provided with a number of hardened steel plates, about one-twelfth of an inch thick, and in shape corresponding to the different patterns of the handles: each plate contains holes in situations answering to the holes in the handle, by which the spring and blade are secured in their places. The inner scales are each secured to one of the plates above, for the sake of drilling holes through them opposite to the holes in the plate. The scales are then fastened on each side of the plate by temporary pins, and the edges are filed down to the plate. By this means the handles are made exactly of the pattern required. The spring is next drilled, placed between the scales, and secured in its proper situation by temporary pins, till it is filed quite level with the edges of the scales. A hole being drilled through the tang of the blade, one of the above pins is taken out, and the spring thrown back, so as to allow the blade to pass between the bolsters, in which situation it is fastened by means of a temporary pin. The tang is then filed square, to correspond with the bolster and the spring.

The blade, the spring and the scale being properly adjusted to each other, the different parts are separated by taking out the pins.

All the visible parts of the spring are next filed smooth, and the spring bent a little inwards, for the sake of giving it greater power when placed in its intended situation. The spring is then hardened, by heating it red-hot and immersing it in water; it is afterwards tempered, by rubbing it over with grease, and heating it till the grease inflames: the visible parts being glazed and burnished, the spring is deemed finished.

Our next process is to place the outer scales of horn or other substance upon the inner scales.

Scales of horn or tortoise-shell are heated, and exposed while warm to the action of a screw-press, for the purpose of making them flat.

The scales are then made of uniform thickness, by means of filing. In the next place, the shield of tin or silver is introduced.

As this is a process of some ingenuity, at least so far as concerns the forming a recess for the different shaped shields, we shall describe the tools employed, with the assistance of the following figures.

VOL. X.

Fig. 2. is a plate of hardened steel, about one-twelfth of an inch thick, and of breadth and length suitable to the size of the shield. A hole is made through the plate exactly of the figure of the shield; and every different pattern of course requires a different plate. *Fig. 3.* represents the drill employed to cut the intended figure in the horn or other substance.

This differs from the common drill, in having the springs fastened into the part B. by means of two screws, A, A. The ends, b, b, are made sharp like the points of a drill, and are capable of boring up to the shoulder a a. The plate, *fig. 2.* is placed upon the scale, and fixed in the vice; the springs of the drill are then pressed till the ends, b, b, enter the hole of the plate. It is plain that if the drill be pressed and turned round, that the force of the spring will cause the cutting parts to make a figure the same as that of the plate. The depth of the recess is limited by the shoulders, a, a. The silver shields are cut out of the sheet by means of a punch; those of tin are first cast, and afterwards struck into a recess made in a die by means of the plate and drill above mentioned.

The shield being secured in its proper place, the outer scales are pinned upon the inner ones; the compound scales are next pinned together with the temporary pins, and both their edges are filed and finished together. They are again separated, and the insides of the inner scales polished; after which the blades, spring, and scales are all riveted together. The next thing is to file and burnish the joint and bolster; and lastly, to finish the outer scales. This is performed by filing, scraping, and buffing, first with fine sand, and lastly with rotten-stone.

Handling of Razors.

After the blades of razors are ground and polished, they only require to be handled and set or sharpened.

The handle of a razor consists of two sides, called scales, which are made of various substances. The most valuable are made of pearl, tortoise-shell, ivory, and native horn. The handles of the greatest quantity of razors, however, are made of pressed horn, some of which are dyed black, and others spotted to imitate tortoise-shell, and hence are termed mottled shell. Pearl is a substance very seldom made use of for the handles of razors. In the first place, they are very expensive, on account of the very high price of the shells; and secondly, they are very liable to be broken, as well in manufacturing as when in use. Ivory makes a very neat handle; but their very great expence in manufacturing, added to the great price of the raw material, renders their price very high. In the opinion of most, they are not neater, nor by any means so durable, as the handles of pressed horn. Tortoise-shell makes a beautiful handle, when used in the state in which it is cut from the shell; but on account of its high price, it is used with more economy by pressing it in a manner similar to that of horn. The pressing, however, deprives it of a great part of its beauty. No handles for elegance and durability can exceed those of native horn, when the specimens are properly selected for the purpose. Since, however, the handles of pressed horn are in no way objectionable, but, on the contrary, are the most generally preferred, we shall be more particular in the description of this branch of manufacture.

Having already described the process of pressing the handles of table knives, and since the scales of razors are pressed by a method strictly similar, it will be unnecessary to give a separate description.

The dies in which the scales of razors are pressed are made to press one pair at a time. The pieces of horn intended

C U T L E R Y.

tended for pressing are in the process sometimes extended as much as two inches.

The handles of pressed horn are divided into three varieties, *viz.* the native black, consisting of horn which is black previous to being pressed; those of the second variety are such as are dyed black, or other colour, after being pressed; and handles of the third kind are those destined for mock shell, for which the most clear and colourless scales are selected.

Those of the first kind, after pressing, retain their native black, and are much esteemed for their permanent colour. The scales, which are partially coloured, are generally dyed black with a dye made of logwood and sulphat of iron: some are dyed red, and others green. The former are dyed with archill, and the latter with indigo dissolved in the sulphuric acid.

The imitation of tortoise-shell is performed by a process called spotting, which consists in the application of a composition to the surface of the horn, by which it becomes irregularly coloured.

The compound consists of one part of minium, four parts of common pot-ash, and ten parts of quick-lime: as much water is added as will give it a pulpy consistence. It is then laid upon the upper surface of the scale with a stick as carelessly as possible, and is spread thicker in some parts than in others, for the purpose of giving a variety of shades. The substance is allowed to remain upon the surface for six or eight hours; and the latter part of the time they are placed before the fire. After the composition is removed, the surface exhibits a striking imitation of tortoise shell. The singular effect of this substance is evidently the result of some chemical change. The lime appears to answer two purposes: it takes the carbonic acid from the pot-ash, and at the same time serves to give a proper consistence to the mass. The lead and the pure pot-ash together are essential to producing the effect; though, when separately applied, no change is observed. The fact is, that the colour is produced by the dissolved oxyd of lead in the alkali. A colourless solution of this kind may be advantageously used for the spotting of horn. May not this compound be found of use in giving colour to other animal substances, such as hair, leather, &c.?

The handles of razors are frequently ornamented by means of shields of various figures, some of which are of silver, others of yellow metal, and of an alloy formed of lead and tin. The silver and yellow metal shields are pressed into the substance of the horn by means of a press similar to a fly-press. The scale and the shield are placed between the two dies of a figure corresponding with the shape of the scales, the dies being previously heated to a temperature something short of that employed in the first pressing. A sufficient force is then exerted upon the screw to force the metal into the horn. Figures, letters, and other ornaments, are introduced by the same method.

The shields of lead and tin are put in by first making in the scales a proper recess, by means of the spring-drill described in *figs.* 2. and 3., and afterwards filling it with the melted metal. The greatest number of shields are of this kind.

The handles of pearl, ivory, &c. which cannot be made by pressing, have the proper shape given to them by means of the file. The shields are then introduced by first making the proper recess with the spring-drill, and afterwards securing the shield by means of rivetting, but more completely by the following method. After the shield is cut out to its proper shape, it is made concave on one side, and convex on the other; at the same time the edge is a little

bevelled towards the convex surface. The cutting part of the spring must be so formed as to make the bottom of the recess to receive the shield a little larger than at the top. The shield being then introduced with the concave side downwards, and hammered upon the convex side, becomes firmly secured.

The scales of the handle in the state already described are now fit for the reception of the blade. A piece of white metal, an alloy of lead and tin, called the bead, is next placed between the scales at one end, to allow the blade to go between when the razor is shut; the blade is then screwed in its place, and the scales fastened together by means of rivets, which are of iron, brass, and sometimes of silver. Zinc wire has been recently used for the purpose, and receives a good polish. The handles of razors in the state left by the press and the file are first scowered with sand and water, and afterwards polished upon a buff.

A superior kind of fine cutlery is manufactured in London, chiefly by the surgical instrument-makers; the excellence of which consists in the great attention paid to its fabrication; the quality of the steel, and above all to the correctness of the several temperatures under which it is hardened, and the reduction of this by the process called tempering.

The estimation these articles are held in, allows the manufacturer to employ the superior workmen, and also to reject, during any part of the process of manufacture, such articles as from slight flaws, cracks, or even any inferior quality in the steel, may be objectionable.

The process of the manufacture differs also from the circumstance of the same workman beginning and completing the article. Engines and complicated machinery are never used: therefore his skill and abilities being exerted, greater perfection is obtained. The hardening of steel depending on the quick abstraction of the heat given, different mediums are made use of, as quicksilver, water, oil, &c. The tempering, or reduction of the hardening, is not governed by the colour only, but by a more accurate method (proposed by Hartley); the exact variations of temper are given in a fluid, into which a Fahrenheit's thermometer graduated to the boiling point of mercury is immersed, and the delicacy of this operation may be sufficiently understood, from the various colours produced on the steel, at the various temperatures shewn by the thermometer. The change of scale takes place at 430, and finishes at nearly 600. Nine changes of colour are observable at about 20 degrees distance of each other, *viz.*

430 Slight colour inclining to yellow.

450 Straw colour, pale.

470 Yellow.

490 Brown.

510 Brown with purple spots.

530 Purple.

550 Bright blue.

560 Blue.

600 Blackish blue inclined to scale or oxyd.

From 430 to 470 is chiefly employed for razors, and some of the finer edged surgical instruments.

470 and 490 for penknives, and some pointed instruments.

From 510 to 550 includes pocket-knives, table-knives, carvers, scissors, &c. &c.

The experience of the workman is much required, and also a knowledge for what purpose the edge is to be employed; during these three ranges of temperature.

550 and 560 Spring temper.

Setting.

Setting.

The operation of setting an edged instrument, is the giving it a more permanent, or lasting edge, by means of a hone, or any other fine cutting stone. Every article is left from the wheel with a thin wiry or notched edge. This must be removed, and one substituted of an angular form; the more obtuse the angle, the stronger the edge, and *vice versa*. This angular edge is obtained in several ways; sometimes by the thickness of the back of the instrument, but more generally by the elevation of the back from the stone.

Razors are set upon a stone brought from Germany. Their backs being thick, they are laid perfectly flat, and rubbed backward and forward on each of their sides, till the wire or notched edge gives place to a fine smooth one. The use of a small quantity of oil on the surface of the stone is requisite.

Penknives are set upon a stone brought from Turkey, and from its property of absorbing oil, it is called an oil-stone. They are held at an elevation of the back just sufficient to keep it from touching the stone; and the greatest attention is here requisite, to give them the same exact elevation, during the removal of the wire edge. They have also a few strokes given them as a finish, upon a hard kind of green stone.

Scissors are set upon the oil-stone; they are held nearly upright, that their edges may be turned toward their inner side.

Pocket-knives, carving, and table-knives, are set at an elevation, upon a stone, called a rag-stone, of a fine sandy texture, and without the use of oil.

CUTRIGURI, in *Ancient Geography*, a people who inhabited the district adjoining to the Palus-Mæotis; and formed a part of the Huns.

CUTTABUNK, in *Geography*, one of the *Elizabeth Islands*, which see.

CUTTER, in *Sea Language*, denotes a small vessel commonly navigated in the English Channel, furnished with one mast, and rigged as a sloop. Many of these are used in an illicit trade; and others employed, under the direction of the admiralty or custom-house, by government to seize them.

CUTTER is also the name of a small boat belonging to ships of war. It is broader, deeper, and shorter than the barge or pinnace: fitter for sailing; and usually employed in carrying stores, provisions, &c. to and from the ship. Clincher-work is used in the structure of these boats.

CUTTER of the tallies, an officer of the exchequer, who provided wood for the tallies, and cut the sum paid upon them. See TALLY.

CUTTER, in *Mechanics*, is a circular piece of well tempered steel, varying in diameter, from the dimensions of a shilling, to the size of a crown-piece, and having notches cut on its edge generally of the shape of saw-teeth, but sometimes finer, like the indentations of a coarse file; when fixed, by means of a central hole, on the revolving arbor of an engine for cutting the teeth of a wheel, it forms the spaces between the teeth of a breadth equal to its own thickness, and when its sides are flat the space so formed is a small parallelogram, pointing to the centre of the wheel. It is therefore necessary that every engine should have a variety of cutters, differing in thickness as well as shape, to form the teeth of wheels, that require different degrees of strength, and forms adapted to particular purposes. The reader will see in our subjoined account of CUTTING-ENGINE, a reference to the plates in which some of the varieties of cut-

ters may be seen both in a detached state, and also attached to the engine of which they form a constituent part.

CUTTER-GAUGE is a contrivance for ascertaining and expressing the exact thickness of a cutter, such as is described in our preceding article. The workman who is in the constant habit of using a cutting engine will, indeed, generally guess what cutter is proper for any wheel, of which he knows the diameter and number of teeth wanted, particularly when it is of ordinary dimensions; but still it is necessary to verify his conjecture, by a previous partial trial on a piece of useless metal of similar radius, or by marking only with the cutter, or a marking knife, the edge of the wheel itself, till he is satisfied that the teeth and spaces, when cut of the requisite depth, will be reciprocally of due dimensions. To avoid such previous trial, Mr. Robert Hynam of St. Petersburg invented an instrument for gauging and expressing the thickness of cutters, which was laid before the Society of Arts at the Adelphi, and honoured with a reward. [See vol. xvii. of their Transactions, 1799.] The instrument here alluded to manifests considerable ingenuity, but in our opinion is too complex and expensive to become of general use. An ordinary wire-gauge, or plate of steel with notches, having parallel sides of various dimensions, would, we think, be found equally serviceable in practice. The method is simply this; when the wheel is ready for cutting, describe a circle on its plane to represent the pitch-line, more or less distant from its extreme edge, according as the teeth are to be fine or coarse, and measure the diameter of this circle in inches and tenths of an inch, for the practical diameter of the wheel; in the next place, multiply this diameter by 3.1416, or otherwise multiply it by 22, and divide the product by 7, and the inches thus obtained will be the circumference of the pitch-line of the wheel, by which, if the number of teeth proposed for the wheel be divided, the result will be the number of teeth per inch that the wheel is to be cut into; but as there are as many spaces as teeth in every wheel, it must be recollected, that both a tooth and a space go in this calculation for one tooth only; hence, when the teeth and spaces are respectively of equal dimensions, the cutter that makes the space ought to be only one half of the calculated dimensions; that is, a wheel found to be of six inches circumference at the pitch-line, in order to be cut into sixty teeth, or ten per inch, will require a cutter of only one twentieth of an inch thick, to make the tooth and space equal to each other. Suppose now the gauge-plate to have a dozen notches, of $\frac{1}{16}$ th, $\frac{1}{8}$ th, $\frac{1}{4}$ th, &c. up to $\frac{3}{4}$ th of an inch breadth respectively, these notches will be proper gauges for cutters to use for 5, 6, 7, &c. up to 17 teeth per inch, on a supposition that the plane of the cutter is precisely at right angles to the arbor on which it revolves in action; but as it is found in practice, that most cutters, however carefully made, cut notches or spaces broader than the thickness of the cutter, particularly when the cutter has been newly sharpened, it may be a necessary precaution, after the cutter, chosen by the gauge, has formed one space in the wheel, to compare that space with the gauge rather than the cutter itself, as determined by calculation of the wheel's diameter, and requisite number of teeth, taken conjointly. In this way a suitable cutter for any practical number of teeth in a given wheel may be readily determined without previous trial. In those cases, however, where it is deemed desirable to have the teeth larger than the spaces in any wheel, its fellow, or corresponding wheel of the pair, must have its

teeth smaller than the spaces; so that one of the two wheels must be cut with a cutter thicker than a mean cutter and the other with one thinner. We have given a table of diameters in our article *Clock-making*, where the workman will find the various dimensions and corresponding number of teeth per inch already calculated for him, which therefore he may take by inspection, and choose his cutters, accordingly, (as we have there directed in the uses of the table) by the mere help of his gauge-plate, or even without, provided the cutters once gauged were marked agreeably to the number of teeth per inch they have been gauged for; and also provided the original thickness at the cutting part be not altered by the act of sharpening.

CUTTERS, a term with *Miners*, for joints or partings in a vertical direction, or nearly, between the different blocks of coal, as they lie in the seam; these are crossed again, nearly at right angles, by other vertical joints called backs, and these together much facilitate the getting of the coal in a mine.

CUTTERAH, in *Geography*, formerly a town, now a ruined village of Hindoostan, in the country of Oude; remarkable for being the scene of the decisive battle of 1774, in which Sujah Dowlah defeated the Rohillas, by which action the fate of that brave people was determined; for Hafez-Rhanut, their chief, was slain, and our army penetrated their country as far as Loll Dong at the foot of the mountain. This place is now a motley assemblage of ruinous mud houses, not a tenth part of which are inhabited: 20 miles S.S.E. of Bereilly.

CUTTING, a term used in various senses, and various arts; in the general it implies a division or separation.

CUTTING, in *Coinage*. When the laminæ, or plates of the metal, be it gold, silver, or copper, are brought to the thickness of the species to be coined, pieces are cut out of the thickness, and nearly of the weight, of the intended coin; which are now called *planchets*, till the king's image hath been stamped on them.

The instrument wherewith they cut, consists of two pieces of steel, very sharp, and placed over one another; the lower a little hollow, representing a mortar, the other a pestle. The metal put between the two, is cut out in the manner described under *COINAGE*.

Note. Medallions, where the relieve is to be great, are not cut but cast, or moulded.

CUTTING is particularly used in *Heraldry*, where the shield is divided into two equal parts, from right to left, parallel to the horizon, or in the fesse-way.

The word is also applied to the honourable ordinaries, and even to animals and moveables, when they are divided equally the same way: so, however, as that one moiety is colour, the other metal. The ordinaries are said to be *cut*, *couped*, when they do not come full to the extremities of the shield.

CUTTING, in the *Manege*, is when the horse's feet *interfere*; or when with the shoe of one foot he beats off the skin from the joint of another foot.

The part most frequently bruised is the side of the fetlock joint, where the toe of the hoof is turned out, the inner quarters of the shoe or hoof are more frequently the parts that do the mischief; but when the toe is turned in, the injury is done by the anterior part of the shoe. If the toe is turned out, the inner quarter of the crust is most frequently lower than the outer. This condition of the hoof necessarily inclines the fetlock joint of the foot that supports the weight, nearer to

the foot in motion. Farriers, says Mr. Coleman, in his "Observations on the Structure, &c. of the Foot of the Horse" (vol. i.) generally attend to the hoof that cuts, and not to the hoof of the injured leg; but while the leg is in the air, no shoe can alter its direction; and the small quantity of horn, or iron, that can be removed from the hoof and shoe, very rarely prevents cutting. But it is very practicable to alter the position of the leg, that supports the animal; and thus the foot in motion may preserve the same direction without being liable to cut. The outer quarter of the crust should be lowered, and the inner quarter preserved. This operation will tend to make the bottom of the hoof the reverse of its former state, that is, the inside quarter higher than the outside, and this will throw the fetlock joints farther from each other. Where the sole is thin, very little of the crust can be removed from the outside; and thus it will be necessary to attend to the shoe. The inner quarter should be thickened, and the outer quarter made thin, which will produce the same effect, as altering the horn; or, if the hoof be sufficiently strong, both these remedies may be applied at the same time.

When the toe inclines inward, says Mr. White, in his "Compendium of the Veterinary Art" (vol. i.), it renders a horse liable to cut on the inside of the knee, at the lower part of the joint: this is sometimes termed the "speedy cut," from its happening upon the trot or gallop, and is considered as a dangerous failing in a horse:—the pain occasioned by it sometimes causing him to fall very suddenly. The remedy for this is to keep the toe as short as possible, that being the part which inflicts the wound, and to alter the improper position of the foot. Cutting frequently depends upon weakness or fatigue, and is therefore liable to happen to young horses when rode very hard over deep heavy ground. The only remedy in this case is to avoid the cause till the legs acquire more strength, and to protect the wounded part with leather, or a boot, as it is termed. Whenever a horse cuts, it is desirable to ascertain what part it is that inflicts the wound; and this may be often done by applying tar to the wounded part, which of course will adhere to the part of the hoof or shoe that comes in contact with the wound.

CUTTING, in *Surgery*, denotes the operation of extracting the stone out of the bladder by section. See *LITHOTOMY*.

CUTTING-glass, in *Surgery*. See *CUPPING-glass*.

CUTTING-Engine, in *Mechanics*, is the name of an engine, which divides and cuts a wheel, pinion, or rack, into any assigned number of teeth, which office it performs both with accuracy and expedition. While the art of constructing wheel-work was yet in its rude state, the dividing of a wheel into the requisite number of circular parts, and cutting away the notches or spaces by a manual operation with a file, was not only a tedious but an imperfect way of proceeding, which left such inequalities in the size and shape of the tooth, as were but ill suited to transmit any applied force in an equable manner, or to perpetuate the duration of the parts once made. To facilitate such manual operation by a file, the simple platform was invented, described by father Alexander, in his book on clock-making, which was a circular plate of brass, from ten inches to a foot, or more, in diameter, with as many concentric circles thereon, as the usual numbers of teeth in the wheels and pinions of clock-work required to be divided into corresponding parts of a circle. In the centre of this platform was fixed a stem, or fast arbor, round which an alidade, ruler, or index, with a straight edge, pointing to the centre, turned freely into

CUTTING-ENGINE.

any given point of a required circle, by means of which the divisions of any given circle were transferred to a wheel, placed on the said stem under the said index, by a marking point. This mode of dividing a wheel is still imitated by the enamellers and engravers of clock-faces, and is certainly an easy way of transferring divisions from a larger to a smaller circle for various purposes, where the accuracy of an astronomical instrument is not required; but still the spaces were required to be cut by hand with a file; at length a little frame was mounted on the index, which was contrived to direct and confine the file in such a way as to cut the notches of a wheel, placed over the index, with less deviation from the truth than could be managed by mere manual dexterity; this addition, no doubt, led to the adoption of a circular file, or cutter, and of such other appendages as completed the construction of a simple cutting-engine; and it is asserted [“*Etreintes Chronometriques*” par M. le Roy] that Dr. Hook was the first person who contrived such an arrangement, as could merit the name of a cutting-engine, [machine a fendre.] The doctor’s invention, which, like many other of his inventions, has proved to be of permanent and great utility in mechanics, consisted of an entire transmutation of the old stationary platform, with its moveable appendages, into a moveable platform inserted into a strong metallic frame with stationary and additional appendages; the machine thus converted into an engine, or self-acting piece of mechanism, consisted of the strong frame; the sliding supporting bars of the platform, or plate, with an horizontal screw of adjustment for distance from the circular file; the divided plate with a revolving arbor to receive the wheel to be cut; and the alidade fixed to the great frame, in the position of a tangent line to any of the divided circles, and applying its bent and rounded point to the punched marks of division on the circle successively, as the plate revolved, in the act of cutting the successive teeth of a wheel. This construction of the engine is very nearly the same that remains in the tool shops of the present day. The original divisions of the circles, viz. 360, 300, 150, 90, 60, &c. are also retained in the ordinary engines, though many of the smaller numbers are included in the larger ones, and are therefore superfluous; for taking every fourth hole of 360, is the same as using the circle of 90, or every sixth the same as using the circle of 60; also taking every other hole of 300 is the same as using the circle of 150. As these ordinary engines are very limited in their operations, by reason of their powers extending only to the numbers marked on the divided circles; and as the prime numbers are not usually inserted, we find that different ingenious men, both in France and England, have contrived additional apparatus to render the engine more perfect. Indeed so long ago as the year 1716, Henry Sully brought into England, among his collection of new tools, a superb engine, made by M. de la Faudière, which has been mentioned by Julien le Roy, and described by Thiout in his “*Traité d’Horlogerie*.” About 1730, M. Taillemard made further improvements in the cutting-engine, particularly by introducing a tubed arbor instead of an arbor with a square hole, which had been usual before. After Taillemard, his apprentice Hulot continued to construct engines in a superior way in France, and is succeeded by his son Hulot the younger, whose execution is deemed equal to that of his father.

M. Fardoil, another French mechanist, contrived a plate to his engine, which afforded the means of cutting any number of teeth in a wheel, prime or composite, by a circular rack and endless screw, the latter of which is fixed in a stationary position. The description of this engine is

given in Thiout’s work which we have already mentioned, to which the curious reader is referred for a full account. The number of notches on the circumference of the plate, which has no divided circles, is stated to have been 420, so that one revolution of the screw answered to a tooth, where the wheel was required to be cut into 420 teeth, and in proportion as the micrometer-head of the screw was turned more or less than an entire revolution, were the teeth reciprocally fewer or more numerous than 420. This number seems to have been chosen in preference to any other, by reason of the many composite parts it is capable of being divided and subdivided into. In practice it was necessary to divide the number 420, and also the number of teeth of the proposed wheel by some common divisor, in order to reduce the terms into their lowest denomination; then the quotient arising from the number of the wheel’s teeth, in using the common divisor, was made the number for the divisions of the micrometer-head, and the larger quotient coming from the term 420, was the proper number of divisions of the said divided micrometer-head necessary to pass the index after cutting each tooth. An example will render this mode, which was certainly ingenious, intelligible to any ordinary reader, who has seen an engine. Let the number of teeth to be cut be 249, then the common divisor will be 3, and $\frac{420}{3} = 140$, likewise $\frac{249}{3} = 83$; the smaller quotient therefore 83 is the number of divisions proper for the micrometer-head, fixed to the axis of the endless screw, and 140 of those divisions must pass the index after each cutting operation; the result in this case will be the same as if the micrometer had had 249 divisions, and 420 of these had passed the index after the cutting of each tooth. The micrometer-head had a ratchet wheel and contrivance for making number *one* of the divisions come back to its original situation after each operation, like the contrivance in the engine for dividing sextants and nautical circles, which engine will be seen in another place. This mode of cutting all kinds of numbers, ingenious as it is, requires, however, various micrometer-heads to suit such prime number, which prime numbers themselves require dividing previously; consequently the real advantages of this contrivance are by no means adequate to its professions. Berthoud has given a description and drawing of a French machine for cutting the teeth of wheels and pinions, in his “*Essai sur l’Horlogerie*,” and also in his “*Histoire de la Mesure du Temps*,” such as he considers of the best construction; and in his “*Traité des Horloges Marines*,” he has described an apparatus for forming the ends of the teeth by means of a concave file confined in a frame, which makes it move in a given direction; which description, together with the drawing, is copied into his “*Histoire de la Mesure du Temps*.” We satisfy ourselves with a reference to these contrivances, in order to describe two engines of English construction, which have not been previously described, and which, we think, merit a particular notice, both as specimens of ingenuity, and as engines of great utility in daily practice. These engines we have already referred to under our article *CLOCK-MKING*; one as being used by the late Brown of King-street, Seven-Dials, London, which we learn was projected, and partly made between the years 1770 and 1780, by Hindley of York, when in London; and the other, as being contrived by the late Rehé, mechanist to the naval board of works, and purchased by Troughton for the use of a relative, who is since dead, and who is succeeded by James Fayer of No. 35, White Lion-street, Pentonville, who now uses it. On a reference to Mr. Troughton’s books, we find, that his late brother divided Rehé’s engine-plate in

CUTTING-ENGINE.

the year 1783, which fixed the date of its construction; and from this as a model it was, that the inventor constructed a similar one for Dr. Milner, the dean of Carlisle, of the expense of which that gentleman had not formed a competent judgment at the time he gave his order, to make as good an engine as could be constructed, which occasioned some demur about the payment. The worthy dean little suspected that the engine he had ordered would cost him three hundred pounds or guineas; and the reader will not be less surpris'd to be told, that Rehé's engine, with its apparatus, was sold at his sale for 700*l*.

Cutting-Engine by Hindley.

The cutting-engine contriv'd by Hindley is represented in *Plate II. of Engines. Fig. 1.*, is a perspective view of the entire engine in a state proper for cutting, with the exception of the foot-wheel surrounded by the cord that gives motion to the revolving cutter, and of the bench to which that wheel is attached, and on which the engine rests; but the reader who has seen a common turning-frame, or other mechanism turned by the foot, can readily conceive how a similar motion may be given to the cutting-engine by a lever, placed nearly horizontally under foot, and connected with the crank of the large wheel's arbor: *figs. 2 and 3.* shew the cutter frame detached from the engine, the first of which supposes the eye placed over it, and the other at one end when viewing it; we shall speak of them more minutely, and also of some figures in *Plate III.*, when we have described the engine in its entire state.

A B C D E F is a strong iron frame, fixed by the end pieces at E and F to a steady bench, to which also the large wheel for the cord is fast, but not seen in the drawing; the side-pieces of the frame, A B and C D, are exactly parallel to each other, and their upper edges are terminated by two slopes that form an oblong and obtuse wedge, on which the sunk base of the cutter-frame, G H I K, rests, and slides smoothly when one of the handles and micrometer head at L turns the horizontal screw, between B and D, that is tapped into a piece of metal behind the cutter-frame and attached thereto. M is a strong tube of brass fixed to the side of A B by four screws seen to the right and left in the square part to which the tube is fast: within this fixed tube M there is another tube N seen above it, which constitutes the revolving arbor of the large circular plate O, under the frame; the annular shoulder-piece, P, resting on the top of tube M, and pinned or screwed fast to the interior tube N, bears the whole weight of the plate O: a section of these tubes, containing another tube and arbor of a pinion to be cut, is given in *fig. 1. of Plate II.* The plate, O, is about a foot in diameter, and marked into a number of divided circles, with holes drilled through at each divided point, the use of which will be explained presently. Through the inner tube N, or axis of the plate O, passes a solid arbor on which the plate, Q, is fixed, with a few notches cut on one side; this solid arbor is fixed by a screw, under the centre of the plate O, as seen in *fig. 1. Plate II.*, and may be taken out at pleasure, and a projecting pin fixed in this solid arbor, below the wheel, takes into a corresponding notch made in the tube N, which contrivance makes the solid arbor and tube, N, rest or revolve together, as circumstances require, and also along with them the circular piece of metal Q, placed fast to the solid arbor by a collet and tapped nut screwing down upon the superior end of the arbor, formed into a screw, as seen in the figure. Of these solid arbors there is a variety belonging to the engine, with their superior ends varying in thickness to suit the different holes of different plates Q, or in other words, to suit the central

holes of different wheels previously turned and fitted to their respective arbors; but it is not necessary to introduce those different arbors into our drawing, as their shape is common, and their dimensions vary only at the superior end, where the wheel fits. In consequence of the connection of the solid innermost arbor with the tube N attached to the platform or divided plate O, whenever this plate revolves a given quantity, or division of one of its circles, the wheel fixed to the solid arbor, above the frame, moves with it precisely the same portion of a circle, and presents itself to the cutter or revolving circular saw R, borne by the moveable frame G H I K, and having a small pulley round the posterior end of its arbor, which is seen embraced by the cord that puts it in motion. Whenever the handle S, attached to the cutter-frame, as may be seen more clearly in *fig. 2.*, is lowered by hand, the cutter, R, descends with it till meeting with the edge of the plate, or wheel Q, it cuts a notch through it, while the moving pulley gives motion to the said cutter; as soon as this notch is cut, the depth of which is regulated by the screw of the handle L, that moves the whole cutter-frame, the handle, S, is permitted to ascend, which it does by means of a spiral spring seen in the middle of the cutter-frame pressing under the top portion in *fig. 2.*; the cutter is then free from the notch of Q, and the latter is at liberty to advance round whenever the plate, O, is moved; during this time an index, with a fixing point, T, called by the French an alidade, holds the plate in a firm position, in consequence of the point, T, penetrating one of the drilled holes of the divided circle, made choice of for the operation; this point, T, is next raised by the right thumb pressing on its opposite end at U, while the fingers of the same hand turn the plate, the space of one division or more as may be required; the left hand in the mean time grasping the handle S, and the foot continuing to turn the large wheel, that is the first mover; the motion of the large plate has now brought Q, the wheel to be cut, a corresponding space round, to the situation required for cutting another notch, which the cutter immediately does on being brought down by S, the handle for the left hand, into contact; the operation of raising the fixing point T, and of moving the large plate O, another division, is repeated, and the wheel, Q, is again in a situation to have its third notch cut; and thus the operations of moving the large plate and lowering the revolving cutter are alternately repeated till there are as many notches cut in the edge of the wheel, as the divided circle contains drilled holes of division, provided the plate is turned only the space of a single division; but when the plate is moved two divisions of the circle every time the point, T, is raised, then the number of notches cut in the wheel will be only half the number of such divisions; so that any divided circle on the plate will serve for a wheel that is either the whole number, or any exact aliquot part of that number. For the ordinary engine this description would have been sufficient to have conveyed to the reader an adequate idea of the operation of cutting a wheel fit for all common purposes; but the engine before us is comprehensive in its uses, and takes in all numbers prime and composite, whether divided on the plate or not, which lie under 360, its greatest number of divisions in one circle; nay, it will go even beyond this number if found necessary, as will appear from a little closer inspection. In an ordinary engine, the fixing-index, or alidade, is made elastic, and placed on the side of the principal frame, and is moveable on the end opposite to the fixing point, so as to be capable of being placed as a tangent line to any one of the divided circles, but has no screw or micrometer to alter its length or position when once fixed, on which account a wheel cannot be cut into any other number of teeth, but

such

CUTTING-ENGINE.

such as are laid down on the plate, or such as are derived from those, by taking every second, third, or fourth, &c. hole of the divisions; whereas in the engine before us the fixing index, U T, is not attached to the frame, but to the four-armed piece of brass V W X Y, that is moveable round the inferior end of the fixed tube M at V, and connected with a worm-screw by means of teeth cut on its branch Y, as shewn in the figure; the worm near Y is fixed by a cock to the end-piece E of the large frame, and has a micrometer head, Z, divided into sixty notches, instead of dividing lines, that the elastic index *f*, above Z, seen screwed to the said end-piece of the frame, may make such a noise in passing the said notches of the micrometer-head as are audible to the workman, who therefore has no need to examine the dividing marks by the eye in the act of cutting. The branch, X, has an oblong hole in it, that the contiguous end of branch Y may be adjusted in it, by fixing the racked end near Y in a proper situation to act freely with the worm screw when wanted; the piece of brass *a*, with a long open in the middle, and screwed at *g* to the side, A B, of the principal frame, has the screw, *d*, passing through it to fix the branch X, whenever the worm-screw is not required to be in use, which in this case fixes the index, T U, to the frame A B, but when the worm is used, as hereafter described, the thumb-screw, *d*, is turned back. The arm W b, to which the index and fixing point, T, are attached, slides, in the adjustment for a given circle to be used on the plate O, along an under bar of similar dimensions, which it covers, and which is a part of V continued; the interior end of W b is kept to its direction by the fixed clamp, *b*, that moves on pivots near the letter *b*, at one side, and has a fixing point that penetrates the holes of division made and numbered, along the upper or sliding bar, with figures that indicate the divisions of any given circle to which the fixing point, T, of the fixing index is at any time placed; therefore, when a wheel is required to be cut into any number of teeth, found upon the divided bar W b, this bar is slid in or out, while the fixing point of clamp *b* is held up, till the hole designated by the required number falls under the said point, in which situation it is made fast by the thumb-screw *e*, and the point, T, then falls into one of the drilled holes of the proper circle of plate O, which in ordinary engines contains the numbers itself. The index, T U, of the fixing point of the plate O, turns on pivots above *b* when pressed by the thumb at U, and has a spring underneath that makes it return, and holds it fast in any assigned hole of a given circle of the plate during the cutting of a space in the wheel required to be cut; but when the plate is wanted to be at liberty to move a large portion of a revolution for any purpose, the spring just mentioned can be locked, so as to hold the point, T, above the plane of the plate, till the act of cutting commences. By the help of this appendage to the engine a wheel may be cut into a number of teeth not divided on the plate in the following manner; suppose a wheel of 62 teeth were required to be cut, and that there were no divided circle on the plate nearer than one divided into 60 holes, to cut it from; then having fixed the wheel on the solid arbor by the fixing nut, in the situation of Q, and having slid the divided bar W b till the fixing point of *b* falls into the hole designated by 60 on the said bar, let it be fixed there by the thumb-screw *e*, and let the point T fall into any one of the holes drilled in the circle 60, which will now be exactly under it; also let the thumb-screw *d* be turned back to set the four-armed piece at liberty to move by the worm-screw Y attached to the micrometer-head Z; in this situation of the apparatus cut a notch in the wheel, then press on the end U of the index and carry the plate in the direction from O towards T, the quantity of two divisions,

which will be two teeth in the wheel if they were cut, the cutter in the mean time being raised from the wheel, as in the drawing; turn in the next place the micrometer screw, and count the turns and parts of the micrometer until the wheel is brought back to its original situation; that is, till the cutter on trial is found to drop easily into the notch before cut without rubbing on one edge of the notch more than on the other. Let the turns of the micrometer thus counted be 7, and 14 notches or marks out of 60 over, for the measure of two teeth in case 60 teeth had been the number to be cut, which will be 434 notches on the micrometer-head passed over by the index *f*; then if these notches be divided by 62, the teeth to be cut there will be $\frac{434}{62} = 7$, for the number of notches that the large plate O ought to be turned back after each tooth is cut, in a direction opposite to that of the plate's motion, when made to revolve after the fixing point, T, is raised; the process therefore now to be used in cutting, is to raise the point T in the first place, then to move the plate from O towards T, one division or $\frac{1}{60}$ of the circle, after that to turn the micrometer back 7 notches of the 60, which carries the plate back again from T towards O, a small quantity, so as to form a tooth of $\frac{1}{62}$ instead of $\frac{1}{60}$, of the whole number to be cut. Lastly, let the notch be cut, and repeat the same process at every cutting, and it will be found at last that a wheel of 62 teeth has been cut instead of one of 60, on account of there being 62 times 7 notches in the 434, that have in the whole passed the index *f*, during the time that the wheel has been under the act of cutting. Should it happen, as will generally indeed be the case, that there is a remainder in the division of the notches by the teeth of the wheel to be cut, the remaining numbers may be intercalated thus: as a second example, let the number of teeth be 61 to be cut from the same circle of 60, and let the turns of the micrometer, as before, be 3, with 37 notches over, out of 60, for the space of a single division on the plate O; in this case there will be only 217 or half the former number of notches in the whole, to be divided by 61, the quotient arising from which is three, with a remainder of $\frac{3}{61}$, so that, properly speaking, $3\frac{3}{61}$ notches of the micrometer ought to be drawn back after every shifting of the fixing point T, but this is not practicable without a ratchet, and returning back to the micrometer, which the engine has not got; therefore as 34 is only 3 more than half of 61, and as one notch on the micrometer does not affect the motion of the plate O in a sensible manner, the notches may be taken alternately 3 and 4 in succession, except in three equidistant points of the wheel, where 4 may be taken twice in succession, which mode of interpolation of the notches belonging to the remainder, as they accumulate, may be practised with any other numbers, and the difference thus occasioned among the teeth will not be sensible even under a magnifying glass. The writer of the present article has seen and examined a wheel of 126 teeth cut from a circle of only 100 divisions in this manner, which appeared as evenly divided, as if it had been cut from a circle drilled or punched into 126 divisions.

If the number of teeth to be cut had been taken fewer than the divisions in the circle used on the plate, the micrometer-head must, in that case, have been turned the contrary way, to augment the divided spaces of the plate, and to enlarge the size of the teeth in proportion as their number is decreased, which effect can now be readily apprehended without further detail.

But this property of being capable of cutting wheels into all assigned practical numbers of teeth, is not the only advantage that this engine possesses over the common engines seen in the tool-shops: when the cutters of these engines require

CUTTING-ENGINE.

require to be changed, the arbor, on the middle of which they are fixed, requires to be taken out of its frame, and to be replaced and adjusted to the centre of the plate, or middle of the solid arbor, as frequently, which is troublesome: also as the cutter-arbor revolves round stationary pivot-holes, the bottom of each notch cut in a wheel is necessarily a portion of the circumference of a circle, which in a thick wheel requires to be filed into a straight line after the cutting is finished. Both these inconveniences are obviated in our present engine. To avoid the first inconvenience, the cutter, R, is put on the projecting end of its arbor, and can be taken off and put on without displacing the arbor from its moveable frame. When, however, the cutters vary in thickness, they require an adjustment of their middle part to the middle of the solid arbor that bears the wheel to be cut, which is done by a contrivance seen best in *fig. 2*; where R, as before, is the cutter, and H I an arbor, round the pivots of which the top of the frame, to which the handle, S, is attached, revolves, and, to which the said top is united by a small handle *i*; when the screws, *k* and *l*, are loose, the top of the frame, *k l m n*, is at liberty to have a motion in the direction from H to I, or the contrary; but the small handle, *i*, is screwed at the middle to the arbor H I, and at the interior end to the top of the frame, near the fork of the large handle S; so that, as the bearing parts H and I, beyond the two ends of the arbor, have no lateral motion, whenever the screws, *k* and *l*, are loose, and the end, *i*, of the small handle is moved towards H, the whole top, *k l m n*, and cutter, R, are carried towards I, and the contrary when the end, *i*, of the small handle is moved towards I; this side motion of the cutter, and of its arbor, affords the ready means of adjustment for cutting the spaces, and consequently of forming the teeth of any wheel with a given cutter, in a direction tending exactly to the centre of the said wheel; and when the adjustment is made, and examined by the notch in gauge *p*, *fig. 1*, which ought to fall on the middle of the cutter, when turned round its centre of motion at its lower extremity, the tightening screws, *k* and *l*, may be turned home again, and the cutter will remain adjusted. With respect to the other advantage of cutting the bottom of each space in a straight line, however thick the required wheel may be, *fig. 3* will furnish an explanation; here is a side view of the cutter seen less obliquely than in *fig. 1*, and detached from the other mechanism; H, as before, is the place, where the proper centre of motion of the arbor H I, in *fig. 2*, is, and R again is the cutter; the arbor of the cutter is hid, but can easily be apprehended to be admitted to pass up and down the opening *s*, of the part, K, of the frame, as seen in *fig. 1*; while a roller or friction-wheel, surrounding the said arbor, touches the interior sides of the fork *s t*; this property of the cutter's ascending and descending in a straight line, when the handle, *s*, is raised or lowered, would however be checked by the limit of distance from R, the centre of the cutter, to H, the centre of motion; but the pieces, H and I, have also each a centre of motion at their lower extremities, as at *r*, which allow the centre H, and its corresponding one at I, to approach to, and recede from, the oblong aperture, *s*, twice in each ascent and descent of the cutter; namely, once above its present horizontal position, and once below. The perpendicular screw at *u*, forms a stop to the ascent of the arbor, and a corresponding one below at *r*, forms a similar stop to its descent; the latter of which is also used as a limit for the depth of a contract wheel's teeth, during the operation of cutting. When a very large wheel is to be cut, there is a part of the cutter frame behind G, not seen, which is tapped, to receive the screw of the handle L, in

fig. 1, one half of which tapped piece is cut away, and allows the other semicircular part to be set at liberty from the screw, by turning on a hinge, to enable the frame to slide freely to the rough distance, without turning the screw, which contributes to expedition in the adjustment of the cutter's distance from the solid arbor that bears the wheel. In common engines it may be proper just to mention the large plate O, together with its secondary frame that supports its lower pivot, is adjusted by the horizontal screw to the cutter, the frame of which cutter remains always fixed to the principal frame.

Besides the parts above described, the engine before us has got two appendages, that render its uses still more comprehensive, namely, a contrivance for cutting pinions on the arbor, and an apparatus for cutting straight racks, with which we will finish our account of this engine.

Fig. 1. of Plate III. (of ENGINES), is an elevation of the appendage for holding a pinion on its arbor, together with a section of the concentric tubes above the large plate referred to above, but not seen. In *fig. 1. of Plate II.* A B is a portion of the principal frame, denoted by the same letters as before, M and N, a section of the fixed tube M. In *fig. 1. of Plate II.*, N and N, a section of the revolving tube N, or axis of the plate, P and P, its bearing shoulder, and Q R, a third tube, instead of the solid arbor, holding the pinion arbor fast, and fixed by the milled nut, R, under the plate O, seen now as a straight line: the stage of the innermost tube at Q, has many holes drilled into it, tapped so that not only a pinion, but a wheel also, may be attached to it, and cut, after it is fast to its arbor; of these tubes, Q, R, there are many varieties, differing in bore and size of the stage, to suit different purposes. The piece *a b*, attached to the frame A B, by two screws at *a*, has an oblong opening, receiving the sliding piece *c*, that can be fixed by a thumb-screw behind, at any height, and that admits the horizontal bar *d*, to slide through it, before it is fixed; at the part *e*, of *a b*, is a hole with a slit, that allows it to open or close by the action of the screw *f*; through this hole *e*, the steel wire, *g*, passes, and forms a bearing for the upper pivot of the arbor, *p*, of the pinion, which otherwise would yield to the cutter, while the bar *d*, pressing against the said arbor near the pinion, prevents its bending during the operation of being cut, or *slit*, as this operation is usually called, which is performed like the cutting of a wheel, already described.

Fig. 2. of Plate III. is a plan of the upper side of a small plate of brass, and of its appendages, for holding a rack during the act of cutting, and for limiting the size of the teeth to any given dimensions; *a b*, is the plate in question, mounted over the frame of the engine, near the cutter, by means of a strong bar, like *a b*, in *fig. 1*, and placed in the same situation, as may be seen in *fig. 3*, which is an end view of *fig. 2*; the two little screw-holes at each side of the letter *b*, in *fig. 2*, shew the place of attachment; and a strong screw, passing through the larger hole at *c*, enters the superior end of the main arbor of the engine plate, and fixes this mechanism steady enough to bear the action of the cutter, applied in the usual way. The bar to be cut into a straight rack lies upon this plate *a b*, from *d* to *e*, between the cocks *d* and *e*, on one side, and the adjustable bar *f*, on the other, which bar sliding in the two oblong openings, may be fixed at the required distance from the said cocks, by means of the two screws at its opposite ends taking into two nuts, beneath, while a couple of thumb-screws *g, h*, seen in *fig. 4*, which is a side view, press above the said bar intended for the rack, and keep it firmly down. The pinion *i*, with twenty teeth, is used as the head of a micro-

CUTTING-ENGINE.

meter serew, which the elastic index, *k*, rests upon, so as to make an audible sound, to serve as a reporter of each twentieth part of a revolution; it is seen in the *figs.* 2, 3, and 5, the last of which is the plane of the inferior side of the plate *ab*, and without which the whole contrivance could not well be explained in an intelligible manner: on the arbor of the pinion, *i*, is an endless serew or worm, seen in *fig.* 5, into the spiral space of which a single tooth, *l*, is inserted; the bar, *l*, which is seen pressing against the cock *e*, as a thin bar in *fig.* 2, has a joint near the pinion *i*, on which the catch, *m*, turns, when lifted by the lever *n*, which lever itself turns on a pin in the bar *l*, as a fulcrum. The catch *m*, as represented in *figs.* 2 and 5, is raised a little from the bar *l*, and has a spring, attached to the bar *l*, pressing it back again into contact with this bar; consequently the end, *n*, of the lever is now nearer to the pinion, *i*, than it would be, if the end, *m*, of the catch were not removed, in opposition to its spring, from the excavated part of the plate. The catch, *m*, which is seen covering the bar, *l*, in the side view in *fig.* 4, has an oblong opening, through which the fixing thumb-serew, *o*, passes, as well as through an opening in *l*, not seen, into the cock *e*, in *fig.* 2; and the bar, *l*, is itself attached to the plate by a sliding cock *p*, in *fig.* 5, and also by a dove-tailed piece attached to the cock *e*, in *fig.* 2, on which piece the concealed dove-tailed opening of *l* slides, when the worm is in motion. From this detail of the different parts of action, it may now be conceived, that when the pinion, *i*, is turned, its worm actuates the single tooth attached to the bar *l*, and consequently moves this bar, together with the lever *n*, and catch *m*, a quantity in or out, that depends on the direction and quantity of the pinion's revolution, after which motion, it may be fixed to the cock *e* of the plate, by the fixing serew *o*; and as the edge of this cock *e* is divided into inches and tenths, a stroke made on the contiguous edge of the bar, *l*, serves as an index to measure the tenths passed over; the thread of the worm-serew is so cut, that one revolution of the pinion draws the bar *l*, and its appendages, just one-tenth of an inch; consequently, one tooth of the said pinion, counted by the noise of the elastic index *k*, measures $\frac{1}{20}$ of $\frac{1}{10}$, or $\frac{1}{200}$ of an inch. As the same letters of reference apply to all the four *figs.* 2, 3, 4, and 5, a further description, it is presumed, is unnecessary. In using this apparatus, the cutter-frame of the engine is adjusted so, that the cutter intended to be used is brought into contact with the edge of the bar to be cut, at the excavation near the end, *m*, of the catch, and is made to cut a notch, as though a wheel were to be cut; the cutter is then raised out of the notch thus cut to a proper depth, and the pinion, *i*, is turned, so as to make the end, *m*, of the catch fall into and till the said notch, the rack being in the mean time pressed fast by the serews *g* and *h*, seen in *fig.* 4; the lever, *n*, is then depressed, which takes the catch, *m*, out of the notch; and supposing $\frac{1}{5}$ of an inch to be the thickness of the tooth to be cut, the pinion is turned back again two entire revolutions, one for the space, and the other for the tooth, in which new situation the bar, *l*, is set fast, by the fixing serew *o*; the rack is now set at liberty, by turning back the pressing serews *g* and *h*, and the rack is moved gently by hand, towards the pinion *i*, until the catch *m*, in its adjusted and fixed situation, falls again, by means of its spring, into the same notch which it occupied before it was moved by the worm-serew; the rack is a second time pressed by the serews *g* and *h*, and a second notch is cut as before, which now forms the tooth of a requisite thickness; again the catch, *m*, is lifted by the lever *n*, the rack set at liberty, and moved till the second notch is

caught by the catch, where it is in a situation to be fixed for the cutting of the third notch, or second tooth; and thus the alternate process of raising the catch, and moving the bar of the rack, till it is caught in the next succeeding notch, is repeated before each cutting, till as many teeth are cut as are wanted; the pinion and its worm serew having performed their whole office before the second notch was cut. When the rack is required to be cut into teeth on nearly its whole length, it is usual to begin about the middle, and to cut one half first, and then to reverse for the other half, and begin again from the notch first cut, which mode of operation requires not only the ends of the rack, but the surfaces also, to be reversed, after the first half of the work is performed.

On the plate of this engine there are thirty divided circles, with the points of division drilled quite through; numbered thus; 365, 360, 144, 100, 60, 30, 96, 90, 80, 78, 72, 54, 48, 62, 54, 92, 64, 59, 86, 88, 84, 82, 76, 74, 70, 68, 58, 56, 52, and 49, which divisions include all the usual numbers introduced in the wheels of clock-work; and such as are not found here may be obtained by the help of the micrometer, when wanted for planetary motions, or other extraordinary purposes.

Cutting Engine by Rehe.

Plate IV. of Engines exhibits a general perspective view of the engine for cutting the teeth of wheels, as originally made by Rehe for his own use, and which, we have said before, is now the property of Mr. Troughton of Fleetstreet. It is drawn to one-fourth of the real size. AABCDE is one solid mass of cast-iron, formed into a frame in the mould, of which AA is the upper horizontal part, B and C the ends of the said frame, and DE its base, fixed with four strong serews (the heads of which are visible) to a wooden frame, to which the large wheel is appended, that gives motion to the revolving cutter and some intermediate pullies placed over the head to give a due direction to the moving cord: this large wheel and these pullies are purposely omitted in the drawing to give room for the engine itself to be taken on a good scale. F and G are a pair of cheeks forming a part of HI, which is another piece of cast-iron of the shape of a parallelogram, having an oblong aperture through the greatest part of its length, along the middle. KL is the platform, or large plate, of the engine, in which are drilled the dividing holes of a variety of circles; its diameter is nineteen inches; the arbor of this plate is a strong brass tube, MN, resting in a hole on the base, DE, of the large frame, and having a serew formed on its circumference at N, with a corresponding tapped nut, that has got a handle to turn it by; it has also a slit cut through it to admit a wedge under the nut, as may be seen without further description; the upper part of the arbor is supported by a hole in the top part of the frame AA, and passes freely through the oblong aperture of HI. The tubed arbor, MN, of the large plate will receive a variety of arbors successively, each of which has a slit to receive the wedge already named, near N, while the nut N, turned firmly down on the wedge, sets the interior arbor, that carries the wheel to be cut, fast at the shoulder O, on below its superior end. The interior arbor is, however, composed of two pieces, of which the upper part bears the wheel and is serewed fast into the lower part between M and O. There is a great variety of the upper parts of the interior arbor to suit different central holes of different wheels, as well as different shoulders, or resting places, for the wheels to lie upon in a steady manner, all which

CUTTING-ENGINE.

would take several plates to represent, but may be easily conceived to be only different sizes and shapes of the same thing; it may, notwithstanding, be right just to remark, respecting these bearing pieces of the arbor, that the centering of the wheel does not depend on the screw part that enters the concealed arbor, but on a circular bed, M, made at the top of the lower half of the arbor, which a corresponding circular piece of metal of the upper half, under the bearing shoulder that holds the wheel, near O, exactly fits, by which means the wheel is certain to be placed in the centre of the large plate, which is an essential condition. The wheel, which is seen with a few notches cut, is fastened by a collet pressed down on its plane, by a tapped nut screwed from above the arbor. P Q is a brass frame, embracing the solid cheeks G and F, and bearing the cutter and its arbor R, that has got a pulley on its posterior end, round which the cord of the first mover goes, and to which it gives the motion at first produced by the foot; when the cutter is taken out to be changed, the end piece S, and a circular piece concealed at the opposite pivot of the cutter arbor, are set at liberty, by the tightening screws, T and T, being turned back *pro tempore*; a plan and side view of one of the cutters, of which there is a great variety of sizes and shapes, may be seen in *fig. 2*, of *Plate VI.*, and the arbor dismounted and separated into its parts in *fig. 5*, of *Plate V.*, of one half its real size, both which may be understood by inspection of the figures, in the latter of which *a* is the pulley on the end of the arbor, *b* the part where the cutter is fixed by pressure of the tubed part *e*, urged by the nut *f*, when screwed home. When the hand U, in *Plate IV.*, is turned, which has a pinion on its arbor taking into a straight rack, fixed to the part embracing the cheek C, out of sight, the whole brass frame has a motion, up or down, as the handle may direct, which is always given it in the operation of cutting each notch. This motion of the whole cutter frame is made easy and smooth by eight sectoral pieces of hard polished steel acting as friction wheels against parallel bars, attached to the cheeks, both within and without the said cheeks; of these sectoral pieces 1, 2, 3, and 4 are seen, but the others, placed in their opposite and corresponding places, are concealed from the view, by the intervening parts of the mechanism. Behind Q, on the posterior part of the cutter frame, is a box containing a spring, with a chain fixed at its lower end to a piece of metal, not seen, between the cheeks and behind the cutter frame, which spring balances the weight of the frame in any position, and renders the working pleasant. Near the character 3 is a perpendicular screw seen, the lower end of which bears against a solid piece fixed between the cheeks, when the frame is lowered so much that the cutter is free from the wheel it is cutting; which screw is also the part of adjustment for the exact depth of a space in a conuate wheel, while the barrel and chain limit the ascent. The whole of this cutter frame is attached to the horizontal parallelogram HI, and is moved to or from the wheel to be cut, by a horizontal screw on the arbor of handle V, which enters a tapped part of the metal under the cutter frame, and when the due distance for making the teeth of a proper depth is ascertained, the whole of the moveable part of the engine is fixed fast in its given position, by the clamping piece W, and crossed nut, that takes the screw on the upper end of a bolt, passing up from below the top, A A, of the large fixed frame; the clamping piece, W, has a dove-tailed projection under it, that enters and fills the breadth of the oblong aperture of HI, and

keeps the piece at right angles thereto. X is the fixing index, or index-bar with a fixing point, that holds the large plate in a given position: this index-bar slides into an octagonal socket Y, to which it is firmly fixed, when necessary, by the thumb-screw seen under it; and near Y is a micrometer head divided into 30 divisions, for which a pin behind it forms an index; by means of this micrometer screw the fixing index can be made to protrude, or retire, any given small quantity, and when its fixing point rests in one of the drilled holes of the large plate, it consequently takes the plate along with it, and also the wheel fixed at the top of the plate's solid arbor. The socket Y has another octagonal hole at right angles to the former one, which enables it to slide along the octagonal axis Z, so that the fixing point of X may approach to or recede from the centre of the plate, and be made to fall into any given divided circle; the numbers of each circle are laid down on the small oblong plate *a*, for which a line on the moving socket, Y, forms an index. This part of the apparatus belonging to the plate would have been sufficient, if the operator were to take the trouble of counting the holes of division on the plate as he turns it in the act of cutting; but in those cases where every second, third, or fourth, &c. hole only is taken by the fixing point, in order to cut a wheel into one half, one third, one fourth, &c. part of the number laid down in any circle, such counting is very troublesome; therefore a curious addition of a moving index *b*, *c* is introduced to be a substitute for the counting. This index turns on the arbor of the large plate, and has a sliding point and thumb-screw *e*, to fix it in any given hole of the circle chosen for the fixing point of X to rest in: *d e* is a sliding stop, passing through a cock fixed to the part, A A, of the principal frame, and is held in any given situation by the thumb-screw over it; and *f g* is another stop attached to a second cock, fixed in like manner to A A; which second stop can be placed in various positions, by means of its own slit and two thumb-screws, and also of the two slits in the cock at right angles to the length of the stop. The use of the moving index is this; when the fixing point of X is fast in its proper hole of any given circle, the moving index is brought so near to it, that its point will fall into the next contiguous, or second next hole, in which situation the inner stop, *d e*, is brought to bear against it and fixed, then the moving index, *b c*, is removed back over two, three, four, or as many holes as are to be counted at each act of cutting a notch of the wheel, from the index X, and is put into the hole so counted, in which situation the outer stop, *f g*, is brought to bear against it and made fast; now it is easy to conceive, that if one hand were to raise the fixing index, X, out of its hole, whilst the other hand were to bring the moving index together with the large plate into which it is inserted, until it meets with the inner stop *d e*, the point of X would then cover the hole counted, into which it might be permitted to fall at random, and it would find its own proper hole under it; then raising the moving index from its hole, and moving it to the outer stop, would place it over the hole to be next counted, into which it might also fall at random. Thus the operation might be repeated all round any given circle, while the stops would act as counters, and the moving index as a handle to move the plate by; but this mode of using the indices would occupy both the hands of the operator, and would require a second person to turn the handle U, and to attend to the cutter; an appendage therefore to the moving index is added, which connects the

CUTTING-ENGINE.

the moving with the fixing index in such a way, that one hand is competent to manage the whole operation even without the eye being directed to the part, after the stops are properly set, and the indices adjusted; thus, at the part *b* of the moving index is a milled head, like a thumb-screw in appearance, placed on the perpendicular small rod *k*, that passes through this index freely, and attached to a lever *i*, that is moveable on a pin or centre of motion, at the inferior end of the cock *k*, placed fast to the moving index; this lever, *i*, passes on, beyond its centre of motion, till it meets with a long lever under the plate, lying in the direction of the dotted lines passing by *K* on the plate; this second or long lever is fast to the octagonal axis of socket *Y*, which, it has been said, is also the axis of motion of the fixing index *X*; it is easy then to see, that, when lever *i* lies under the lever of the axis *Z*, pushing down the milled head, *b*, over the moving index, will raise the fixing index out of its hole, on the large plate, and set the plate at liberty to move; and also when the said milled head, *b*, is quitted, the fixing index will fall again into the hole that may happen to be under it, and will be kept close by the screw *l*, pressing the long lever down by the intervention of the pin *m*, at its extreme end; all therefore that is necessary to be observed in moving the plate, after the indices and stops are properly adjusted, is, to press with the thumb of the left hand on the nut *b*, before the moving index is carried forwards with the plate, and to let it go before the said index is made to return without the plate, for an attention to this particular raises and lowers the fixing index alternately in the way, and at the times required. When however a wheel is required to be cut into a number of teeth, not to be obtained from one of the divided circles alone, another operation becomes necessary, to take or give a tooth or teeth to complete the number desired; this is done by the micrometer head of the socket, *Y*, of the fixing index, which will push the index out, or draw it in, any small assignable quantity, and will consequently push on or draw back the whole plate a corresponding quantity, provided the micrometer be turned when the fixing point of *X* is in its hole of the divided circle that is used; when this operation is necessary at the cutting of every tooth, the moving index does not fall into a hole, but gradually advances to, or recedes from, its original situation, till it arrives at the next contiguous hole, when one tooth only is to be added or subtracted: but when more than one are required to complete the required number of teeth, the point of the moving index will gradually pass over as many divided spaces of the plate, from its original situation, as there are teeth required to be added or subtracted; so that, if four teeth are to be gained or lost by means of the micrometer, the moving point will traverse one divided space of the plate during the cutting of each quarter of the wheel, and in the same proportion for any other number to be taken or given; whence, at any period, during the act of cutting a wheel into a number not inserted on the plate, it may be seen by inspection of the moving point, at what rate the gain or loss is proceeding upon, which indication forms a good check upon the original calculation by which the micrometer is guided. This advantage, arising from the point of the moving index having a progress or regress over the supplementary divisions, is the more desirable in this engine; because, the fixing index which ought to be always a tangent to the divided circle used, and to have its point at a right angle to the central arbor of the plate, does not preserve the latter condition rigidly, when pushed out or drawn in; which deviation renders the reading of the micrometer in practice, less accurate than

the theory supposes; an objection from which the more complex mechanism of Hindley's engine is free. When a wheel of 142 teeth was cut on our present engine, in our presence, from a divided circle of 140, nineteen turns of the micrometer were found equal to a motion of two divided spaces, as compared with the moving point, when left stationary against the outer stop: therefore, as there are 30 divisions on the micrometer head at *Y*; 19×30 , or 570, were the whole divisions to be divided by the number 142, and gave a quotient of 4, with a remainder of $\frac{2}{7}$; consequently, after every moving of the plate for a new cutting, four divisions of the micrometer head were turned in a backward direction, to lessen the size of the teeth, and to increase their number in the proportion 142:140; but at two opposite points of the wheel, the remaining two were interpolated, by giving five divisions instead of four at each place; the additional division on the micrometer, however, made at each of the said two places, made no sensible difference in the size of those teeth, nor would it have been of any importance, if the remainder, which was so small, had been neglected altogether. A similar process, as explained more fully in our account of Hindley's engine, must be adopted agreeably to a similar calculation, for any other number of teeth to be taken in or left out by the aid of the micrometer. The original circles of the large plate were divided by Troughton's dividing-engine into the following numbers, *viz.* 720, 580, 504, 396, 365, 364, 300, 276, 228, 192, 186, 170, 162, 156, 140, 128, and 118; to which have been since added, at different times, the numbers 274, 260, 206, 148, 136, 130, 111, 103, 101, 87, 83, 74, 65, 47, 43, 41, and 37, so that, by this engine, all numbers under 100 can be cut without the help of the micrometer, except 97, 95, 89, 88, 79, 77, 61, 53, and 49.

When our present engine is used to cut pinions on their arbors, a steel perpendicular bar descends from a beam in the room directly over the centre of the plate, and holds the upper end of the arbor steady, while the lower end is made fast to the revolving arbor. There are also many other useful appendages to the engine, some of which merit a particular description and corresponding drawings, which we have obtained.

Fig. 1, of Plate V. is a detached cutter frame of one-fourth of the real size, to be used occasionally when a wheel is wanted to act with a worm-screw, in which case the teeth are required to be a little inclined from the axis to the right or left, accordingly as the screw is a right or left-handed screw. When this cutter frame is used, it is attached to the cheeks *G, F*, in *Plate IV.*, without disturbing the frame already attached. *A B* is a strong brass plate with two forked pieces, *C, D*, projecting back from its posterior plane near the top; these forks enter over the sliding frame *S Q*, in *Plate IV.*, and embrace the two tapped studs *n* and *p* not seen, within the cheek, by which they are held fast when pressed by the tapped nuts of the said studs; at *A*, the bottom of the plate *A B*, in *fig. 1, of Plate V.*, is a screw which enters the small tapped hole, near *I*, on the sliding piece *H I*, in *Plate IV.*, and a corresponding screw at the other side, out of sight, holds the fourth or concealed corner of the said plate *A B*, so that this plate, when thus attached, may be considered as a part of *H I*, in *Plate IV.*, behind which additional plate the common cutter frame is concealed, and remains useless for the time. *E F* is a second plate of brass of nearly a semicircular shape and graduated on its periphery; this second plate is attached to the former one, *A B*, by two tapped bolts passing through the long opening *G*, and made fast with nuts at *E* and *F*, by which

CUTTING-ENGINE.

means this second plate can be placed at any given height on A B, and a motion, which it has round E, as a centre, allows of its being placed to any angle of obliquity marked on its periphery; the circular slit at E, allowing the upper or fixing bolt to pass along it to any required position, before it is fixed by the nut: the cutter frame, H I K L, moves on pivots in the feet of E F, near A and K, which pivots are turned out of an horizontal line to the right or left, by the obliquity given to the plate E F, and consequently the cutter arbor, L I, has also an obliquity, which makes the cutter at the middle of it cut the notches in an oblique direction; this cutter, however, having but one centre of motion, or rather one pair of centres, cuts the bottom of the notches of a wheel in a circular direction. The arbor of the cutter has a pulley which gives it motion, and the two pulleys, *a* and *b*, over it have no other use, but to direct the cord to the larger distant pulleys, not shewn in the drawing. When the plate, E F, is adjusted to zero, or horizontal line, it may be used for cutting ordinary wheels, but is liable to be displaced by accident or jerks in cutting; therefore is used only for wheels with oblique teeth. The French engine recommended by Berthoud, as made by Hugot has, notwithstanding, no other cutter frame but that which is adjustable for obliquity. The vertical screw, *d*, is a rest for limiting the depth of the spaces of contrate wheels in cutting, and also for stopping the descent of the frame further than is necessary in cutting other wheels: the opening B of the plate A B seems to have no other use, except for the eye to look through at the cutter, when the workman stands behind the cheeks to turn the first moving wheel of the cord, which wheel, we remarked, is not very conveniently placed to consult the easy position of the body, during the act of cutting. This frame being attached to the sliding part H I, of *Plate IV.*, is of course capable of the adjustment for distance from the arbor of the plate, on which the wheel is placed, that requires to be cut.

Fig. 2, of Plate V. is a representation of the apparatus for cutting the interior edge of an annular wheel, such as is used in a theodolite, and solar microscope, &c. of $\frac{1}{2}$ of the actual size. A B is the ring or annular wheel to be cut, which is fixed to the top of the arbor by means of the wooden chuck, on which it was turned in the lathe, and *a b c d* is a short frame for the cutter *e*, and cutter-arbor, seen detached in two pieces in *fig. 3* of $\frac{1}{2}$ the real size. This small frame is attached to the face of the cutter frame in *Plate IV.*; its arbor, *ab*, enters the hole of the arbor at S, and an opposite hole not seen in *Plate IV.*, after the arbor, R, has been previously removed, and is made fast by the two screws *x* and *x*, entering the holes *e* and *d*, of *fig. 2. Plate V.*; the interior teeth are then formed by the small cutter, by a process similar to that of cutting the exterior teeth of a wheel in the ordinary way.

Fig. 4, of Plate V. is a contrivance of $\frac{1}{4}$ of the real size, for cutting a rack into any number of teeth per inch, by the aid of the engine plate and common cutters, thus; A and B are two strong cocks screwed fast to the opposite sides of H I, already described in *Plate IV.*; C is a piece of metal forming a bed for the oblong bar, D E, to rest on; this bar, which is a rack already cut, is placed with its teeth in action with a wheel of 74 teeth nicely rounded, that is attached to the arbor of the plate in the usual way; under the bar D E, and fast to it, is a rib parallel to its sides, moving easy in a corresponding long groove made in the bed, C, to receive it, the motion of which is made smooth by friction wheels interposed and borne by the bed;

the bar, D E, has a great number of holes drilled and tapped in it, that the moveable corks or clamping pieces, F, F, and F, may fix any bar, G, to be cut into the requisite rack; when the mechanism is thus arranged and properly fixed, the motion of the wheel, caused by moving the subjacent plate, a given number of holes of any circle fixed on, will carry the racked bar D E, and bar G along with it, over the bed a certain distance, between the cutting of each space of bar G, and this distance may be made $\frac{1}{10}$ th, $\frac{1}{12}$ th, or $\frac{1}{20}$ th of an inch, according to the number of divided holes on the plate, passed over by the moving index, between each operation of cutting.

These three appendages render the engine competent to cut teeth in all ways, and on all wheels and bars that are in use in mechanical contrivances; but the teeth thus formed with ordinary cutters, are in the shape of parallelograms, and require to be rounded by hand with a file or files of different coarseness and shape; the contriver, in common with other workmen, had experienced the inconvenience attending the finishing, both as it was a laborious operation, and liable to produce irregularities in the shape of the tooth, on which the equable transmission of power and velocity entirely depend, in clocks, watches, and other delicate machines; he therefore constructed his cutters in such a way, that they rounded the teeth at the same time that they cut the spaces; this invention is very important to the successful application of racks and wheel-work in many cases, where a good shape of the tooth is indispensable, and has been claimed by both Rehe and the late ingenious Merlin; but which of the two, if either, was the real inventor, remains to be decided.

Plate VI. of Engines, contains the drawings of some cutters to answer the purpose of rounding the teeth during the act of cutting, and also the apparatus for forming the cutting edges and for sharpening them when blunt, which apparatus is indispensably necessary to accompany the engine when *finishing cutters*, as we shall henceforth call them, are adopted in practice.

A A, in *fig. 1*, is the front side of a wooden bench, to which a foot wheel, as a first mover, is fixed out of the drawing, and B B is a small frame attached to its inferior plane; C C C is a species of small lathe, with a three-grooved pulley revolving on a solid arbor, together with the arbor itself; this lathe is attached to the brass plate D D, and by means of it screwed fast to the wooden bench A A; at the exterior end of the arbor that bears the pulley, is fixed a circular copper plate, E, with its plane at right angles to the said arbor, which plate consequently revolves with the pulley, when the foot wheel gives motion to the cord that embraces it: just above the brass plate, D D, of the small lathe, lies parallel thereto another stronger but smaller plate, F F, attached to and borne by a side plate, G G G G, that fits the frame under the bench, and slides up or down to nearly the height required in use, in which it is fixed by the thumb screw at H, under the bench; at the ends of the plate F F, which we will call the bed of the cutter frame, or frame for holding the cutter while grinding, are two cross bearing pieces near F and F respectively, on each of which are cut three semi-circular notches, some of which are seen at *a, a,* and *a*; I I is the horizontal plate of a cutter frame resting on the horizontal tapped wire, K, that has got a milled nut screwing upon the tapped part beyond the bed F F, and has its opposite bearing end concealed under the other parts; this plate, I I, may be fixed to any part of the bearing wire, K, by the thumb screw *b*, and will have a little circular motion round the wire, to the right or left, when not held in the

CUTTING-ENGINE.

band, or nicely balanced; above this plate, II, lies a still smaller plate, L, that bears the cock M, and another similar one concealed, but opposite to it; which small plate, L, is moveable round a centre of motion under it, on the next subjacent plate II, but can be fixed in any given position by the thumb-screw at L, agreeably to the graduations marked near its extreme end, beyond the circular groove penetrated by the thumb-screw, for which graduations a line on the small cock, *d*, constitutes an index; into the cock M, and the one concealed, passes an arbor not seen, that may be called *e*, which is capable of being fixed by pressing screws at the exterior sides of the said cocks; across this arbor, *e*, at right angles, is a long hole, or tube, into which the cutter arbor is inserted, and fixed by a pressing screw N; so that the plane of the cutter may be made either horizontally parallel to the copper circle E, or to stand in an inclined direction; accordingly as the arbor, *e*, is turned more or less round before it is fixed by its pressing screws at M, and at the opposite pivot; while the thumb-screw at L, by the help of the graduations near it, fixes the planes of the cutter and circular plate, E, vertically parallel, or at any given angle of reclination to each other, as the shape of the acting faces of the tooth may require; the nut at D limits the proximity of the cutter to the circle E. In the present position of the cutter, its plane is smoothed by emery smeared over the copper circle, as the arbor revolves, and while the plate, II, has a circular motion given it backwards and forwards by hand, round the bearing wire K, which alternate motion carries the cutter across the plane of the grinding circle E, and assists the grinding; upon the arbor *e*, not seen, is a second divided scale of a circular shape, like a micrometer head, by means of which the situation of this arbor, and consequently of the cutter's plane, is adjusted before the pressing screws are made quite fast; and a small gauge, near *f*, like a small leg and foot, moveable at its knee, on the cock, presents its heel to a tooth of the cutter, and limits its position in such a way, that each succeeding tooth to be sharpened may be fixed, by the pressing screws, in precisely the same situation while they are respectively sharpened. By the help of these various adjustments of the plane of a cutter, such, for instance, as is seen in two views in *fig. 2*, the preceding or cutting part of each tooth is made thicker than the following part, and also the part at the periphery thicker than the part nearer to the centre, which shape makes the cutter clear itself in the space it cuts as it advances, a condition that experience has proved to be necessary in forming or sharpening a cutter. When one plane of each tooth of a cutter has been gone round, the planes are reversed, and the cutter fixed as before by the help of the scales, gauge, and screws, and then the former process of grinding the teeth singly in succession is repeated.

When the plate II, with its appendage, which together we have called the cutter frame, is lifted out of the semicircular notches or bearings on the ends of the bed FF, and is laid aside; another nearly similar frame, seen in *fig. 3*, is put into its place, with the parallel wires, *a, a*, and *a*, resting in the said semicircular notches, as in *fig. 1*, are denoted by the same characters; in this situation the nut, D, in *fig. 3*, falls in the place of nut D in *fig. 1*, and answers the same purpose of adjustment for proximity of the cutter to the grinding circle E; the small upper plate, L, is also nearly the same as in *fig. 1*, both as to its positions and uses, where also the index line of the small cock, *d*, points out the degree of obliquity on the graduated sectoral part; but here the frame is not a single plate II, resting on the

bed as in *fig. 1*, but has a motion round the pivots *b* and *b*, placed on another plate that bears the wires *a, a*, and *a*, so that the two plates may be made to open, and form a blunt wedge, by turning the screw *k*, which bears on the lower plate with its point, and is tapped into the upper plate, after which adjustment for height, which cannot be made nicely by sliding GGG only, the position is rendered permanent by the fixing nut, *l*, that takes a tapped stud fixed to the lower plate. In this figure, the arbor that holds the cutter is in the situation of the arbor *a*, *fig. 1*, which we said cannot be seen; and the ends of the teeth are presented to the grinding face of E, which position of the cutter could not be attained by the mechanism of *fig. 1*. On the cocks that bear the pivots of the cutter arbor, are fixed two small cannons, on which the bent arms, *m* and *m*, revolve, and are fixed by the pressing screws *n* and *n*; the play of the arbor is limited by the two thumb-screws *o* and *o*, fixing the stops in their respective places; and a wire, *k*, connected with the arms *m* and *m*, forms the centre of motion of the leg or gauge, which is here better seen than in *fig. 1*, and performs a similar office. It is hardly necessary to add, that after each tooth is pointed in this way, the fixing screws *m* and *m*, and also the gauge *f*, are released for the moment, and brought back again to their original situation at the adjustment of every successive tooth to the grinder.

For sharpening the front edge of a tooth, the cutter must be reversed, the bed lowered, and the nut, D, turned back, till the position, represented in *fig. 4*, be obtained; in which the teeth are successively ground as before directed.

The mechanism above described is all that would be necessary, if the tooth of the cutter were made by straight lines to cut teeth of a shape like a parallelogram, but to round them at the same time required another addition, which remains to be described.

In *fig. 5*, are seen two different views of a cutter, such as will round the teeth and cut them at the same operation, by means of the sides of the cutter's teeth being formed into curves; these curves ought to be epicycloids, or involutes of a circle to constitute a tooth of any wheel of the exact shape requisite for the equable transmission of power and velocity, and these curves should vary in shape with the size of the wheel compared with its pinion or fellow-wheel; but such niceties cannot be obtained in practice without almost infinite trouble; therefore the same cutter, once shaped and sharpened, is used for wheels of different diameters, where its thickness is found proper. *Fig. 6*, shows how the side curves of the cutter's teeth are formed, where a cylinder of copper is substituted in the small lathe CCC, *fig. 1*, for the arbor and circular plate E; *fig. 3*, is then applied to the bed FF, and the side of the tooth is adjusted to touch the side of the cylinder as it revolves; this mode of application would make the curve circular if the cutter-arbor were to stand at right angles with the grinding cylinder; but as any degree of obliquity can be given, by undoing the thumb-screw *b*, and moving L, the position ought to be such as to make the tooth rest obliquely against the cylinder, more or less, as the shape may require, in which case an elliptic curve, instead of a circular one, is formed on the edge of the cutter, by reason of the oblique section of a cylinder forming an ellipse, which curve approximates nearly to the shape required in a given degree of obliquity, and may always be used when once determined. When the curves on one side of each tooth of the cutter are thus formed, which are assisted by a motion lengthwise of the frame in the bed, while the wires *a, a*, and *a*, slide in their bearing notches, the planes of the cutter

CUTTING.

cutters are reversed and the opposite corresponding curves are formed in a similar manner. Cutters of this kind not only facilitate the labour of making wheels, but render them more perfect than manual filing can possibly do; and it is to be regretted that clockmakers in general will not go to the additional expence of having them thus formed. Thus, each of the two engines we have described, have appropriate advantages; and we think it would not be difficult to construct one that would unite the advantages of both, and be preferable to either.

CUTTING-off, in *Military Language*. See **RETRENCHMENT**.

CUTTING, in *Inland Navigation*, signifies the same with digging or excavating; and thus they say, such a part of the canal is in level-cutting, or in deep-cutting, according as the surface of the water is nearly level with, or considerably sunk below, the natural surface of the ground. Several of the most remarkable instances of deep-cutting upon the British canals, are mentioned in our article **CANAL**. See *Plate 1. Canals, fig. 6*.

CUTTING, in *Painting*, the laying of one strong lively colour over another, without any shade or softening. The cutting of colours has always a disagreeable effect.

CUTTING in wood, a particular kind of sculpture, or engraving; denominated from the matter wherein it is employed.

It is used for various purposes; as, for figured letters, head and tail-pieces of books; and even for schemes, and other figures, to save the expences of engraving on copper: and for prints, and stamps for paper, calicoes, lincens, &c.

The invention of cutting in wood, as well as that in copper, is ascribed to a goldsmith in Florence; but it is to Albert Durer, and Lucas, they are both indebted for their perfection. See **ENGRAVING and PRINTING**.

One Hugo de Carpi invented a manner of cutting in wood, by means whereof, the prints appeared as if painted in *claire-obscur*. In order to this, he made three kinds of stamps for the same design; which were drawn, after one another, through the press for the same print: they were so conducted, as that one served for the grand lights, a second for the demi-tints, and a third for the outlines and the deep shadows.

The art of cutting in wood was certainly carried to a very great pitch above two hundred years ago; and might even vie, for beauty and justness, with that of engraving in copper. It was reduced however to a low condition, as having been long neglected, and the application of artists was wholly employed on copper, as the more easy and promising province: not but that wooden cuts have the advantage of those in copper on many accounts; chiefly for figures and devices in books; as being printed at the same time, and in the same press, as the letters: whereas, for the other, there is required a particular impression. In the representation of plants and flowers, and in designs for paper-hangings, where the outline only is wanted to be printed, in a bold full manner, this method will be found cheaper and more effectual than the use of copper-plates. It has been lately revived by the Bewicks of Newcastle; and several other persons have applied the art with great success; so that some of their vignettes have a brilliancy and force, which almost rival the first and finest productions on copper.

The cutters in wood begin with preparing a plank or block, of the size and thickness required, and very even and smooth on the side to be cut: for this, they usually take

beech, pear-tree, or box; though the latter is the best, as being the closest, and least liable to be worn-eaten. The wood being cut into a proper form and size, should be planed as even and truly as possible; it is then fit to receive the drawing or chalking of the design to be engraved. But the effect may be made more apparent, and the ink, if any be used in drawing, be prevented from running, by spreading thinly on the surface of the wood, white lead, tempered with water, by grinding with a brush: pencil, and afterwards rubbing it well with a fine linen rag, whilst it is wet; and when it is dry, brushing off any loose or powdery part with a soft pencil.

On this block they draw their design with a pen, or pencil, just as they would have it printed. Those who cannot draw their own design, as there are many who cannot, make use of a design furnished them by another; fastening it upon the block with paste made of flour and water, with a little vinegar, or gum tragacanth; the strokes or lines turned towards the wood.

When the paper is dry, they wash it gently over with a sponge dipped in water: which done, they take off the paper by little and little, still rubbing it a little first, with the tip of the finger; till at length there be nothing left on the block, but the strokes of ink that form the design, which mark out so much of the block as is to be spared, or left standing. Figures are sometimes cut out of prints, by taking away all the white part or blank paper, and cemented with gum-water to the surface of the wood.

The rest they cut off, and take away very curiously with the points of very sharp knives, or little chisels, or gravers, according to the bigness or delicacy of the work; for they need no other instruments.

It differs from engraving in copper, because in the former, the impression comes from the prominent parts, or strokes left uncut; whereas in the latter, it comes from the channels cut in the metal.

The manner of printing with wooden prints is much more expeditious and easy than that of copper-plate: because they require only to be dipped in the printing-ink, and impressed on the object in the same manner, and with the same apparatus as the letter printing is managed; and for purposes that do not require great correctness, the impression is made by the hand only, a proper handle being fixed to the middle of the print, by which it is first dipped in the ink, spread by means of a brush, on a block of proportionable size covered with leather; and then lifted up instantly, and dropped with some little force on the paper, which is to receive the impression. *Handmaid to the Arts, vol. ii. p. 222.*

CUTTING, in *Gardening*, a small portion of a branch, twig, shoot, or other part of a plant, cut off for the purpose of planting, with a view of increasing the kind of tree, shrub, or plant from which it is taken.

There are numerous trees, shrubs, and plants which are capable of being propagated with facility in this way; but in some, the young tender shoots or branches of one or two years growth can only be employed with success; while in others, the large boughs, or even poles, may be made use of with the greatest certainty of their growing. This is the case with most of the aquatic kind of plants; as the willows, poplars, &c. And there are still others in which the leaves can be had recourse to, as the agave and aloe kinds.

For the most part in the herbaceous and succulent plants, cuttings of one or two years growth are commonly used; but

C U T T I N G.

but in those of the tree sort, those of one year; and in those of the hard wooded kind, those of the same year's growth.

The most proper lengths for making the cuttings are different in different sorts, according to the nature and habits of growth of the plants; but in common, from three or four inches to a foot, or a foot and a half; the strongest requiring in general the most length to be left to them.

In the business of the choice of shoots, branches, or other parts for this use, those of the firmest and most even growth, and the freest from lateral shoots, should be fixed upon. In most strong-shooting trees and shrubs, and all the more succulent plants, the cuttings should be taken from the lateral or terminal shoots. The cuttings in the herbaceous are usually made from the stems that support the flowers, which should be cut off from the bottoms, and afterwards divided into suitable lengths for the purpose.

In some particular sorts, as those of the tree and shrub kinds, it is found advantageous in some cases to take them off with an inch or more of the former year's wood, as in the vine, laurel, and some others of a similar nature.

In the mode of preparation of cuttings for planting, the only thing necessary is that of trimming of such side-shoots as may be present, and occasionally the crooked straggling tops in the deciduous kinds; but this should not be done in the evergreen or herbaceous succulent sorts. Where the shoots are of considerable length, the lower parts should principally be employed for the purpose of cuttings.

The proper seasons for planting out cuttings are, according to their kinds, either the spring, summer, or autumn. The first and the last are in general the best for most sorts of trees and shrubs. Those of the herbaceous and flowering kind mostly succeed best when planted in the spring and summer months; but those of the luxuriant and more succulent sort answer best when put into the earth in the summer season.

In the business of planting the cuttings of different sorts of plants, such as those of the tree, shrub, and other kinds that are not succulent, they should be put nearly two-thirds of their lengths into the ground; but those of the succulent sort should only be put lightly into the soil, so as just to support them in their proper position, as when put in too deep they are apt to rot, and do not take root so readily. The cuttings of most of the tree, shrub, and plant kinds should be put into the soil as soon as possible after they are made; but those of the succulent tribe are better to remain out of the earth till the cut parts be fully incrustated or healed over, as when put in while the moisture is oozing out, they are apt to rot and be destroyed. In all the sorts the mould should be well pressed about them, and in the former kinds be kept properly cool by watering. It is also of great use to keep them perfectly steady in the earth when they are first put into it.

In the management of cuttings after being planted out, different methods must be pursued according to circumstances; some succeed perfectly in the open ground, others in sheltered shady situations; some require to be placed in pots, for the convenience of occasional protection in severe weather, and others to be plunged in hot-beds in order to promote their striking root, as is fully explained under the culture of each particular sort of plant.

The length of time which is necessary for striking root is also different in the different sorts. In many of the tree, and some of the herbaceous, shrubby, and succulent kinds, it will be perfectly effected in the course of one or

two months; and in almost all the sorts in the course of a twelvemonth. When assisted by artificial heat, it is always effected in a more expeditious manner than where the contrary is the case.

In this method of propagation, the varieties of all the different curious species which are capable of being increased in this way, may be equally preserved and kept distinct, as in the practices of budding, grafting, and layering.

In order to raise plants of many sorts in this manner, much attention is not only necessary in regard to season, but great care required in their management.

CUTTING-Box, in *Rural Economy*, is a contrivance of the box kind constructed for the purpose of cutting different sorts of materials, as straw, hay, and the haulm or stems of various plants, as those of the pea, bean, and other similar kinds by the hand, into a small state, or what is usually denominated chaff, to be employed as cattle fodder.

It is a sort of tool which has undergone various alterations and improvements since it was first invented; but it is only necessary to notice those which have more lately been made, for the present purpose. The first of which consists in the addition of what is termed a *presser*, to the original long, narrow box, which is open on the upper part. This is formed of a piece of wood of the same length with the width of the box, having a number of upright tongues or tines somewhat similar to those of the prongs of the hay-fork. These tongues are passed through the materials to be cut, and by means of a rope or thong of leather, fastened thereto, and extending below the box, the presser is forced down by the left foot of the person employed in cutting, and the bundle, of course, kept light. By this means the materials are cut into chaff with great ease and facility, the operator raising his left foot after every cut, pushes his sheaf or bundle forward, with his left hand, then presses it down again with his foot, and makes another cut, continuing to work in this manner, till the whole of the bundle is finished.

Since this, more simple contrivances have been introduced for effecting these different purposes; and lately a *lever-handle* has been added, with some other alterations, by which it is supposed that the materials are cut with greater convenience and facility.

In the midland counties, according to Mr. Marshall, a "chaff box" is made use of, which is somewhat peculiar in its construction, uniting in some measure "the old single-handed machine and the more modern one with a wheel of blades." It has a long upright knife, but feeds itself, in consequence of which the cutter is left with both hands at liberty for the knife. It is suggested as being however somewhat complex, and more suited for a person who makes "straw-cutting" his employment, than for the servant of the farmer. See *CHAFF-Cutter*.

CUTTING-Knife, a tool used by the patten-makers and borne in their armorial ensign.

CUTTING-Over, in *Gardening*, the operation of thinning and shortening the branches of different sorts of fruit trees, as the currant, gooseberry, &c. It is necessary to the proper bearing of such shrubby fruit trees, that this sort of cutting *in* or *over* should be annually performed.

CUTTING-Teeth, in *Anatomy*. See **CRANIUM**.

CUTTLE-fish, *Sepia*, in *Zoology*, a genus of the *Vermes Mollusca*. (See **SEPIA**.) The *Sepia officinalis*, or common cuttle-fish, when it is in danger of being taken, is said to emit a black liquor like ink, contained in a bag near the cœcum, in considerable quantities, whereby the water being obscured, it finds an opportunity of escaping; and from this.

this property it has got the name of the *ink-fish*. It is not wholly a stranger to our seas, as appears from its bone being found on our shores. It is occasionally caught on the southern coasts of England, but more frequently on those of Italy.

CUTTLE-fish bone, *Sepia os*, or *testa*, is a white, spongy, testaceous substance, growing on the back of the cuttle-fish, and seeming almost to be calcined by the sun.

From some experiments lately made by the ingenious Mr. Hatchett upon the cuttle-bone of the shops, he infers, that the term bone is here misapplied, if the presence of phosphate of lime is to be regarded as the characteristic of bone (see *BONE*): for this substance, in composition, is exactly similar to *shell* (which see), and consists of various membranes, hardened by carbonate of lime, without the smallest mixture of phosphate. This substance is rough and absterfve, and chiefly used in medicine as a dentrifice. It is hard on one side, but soft on the other, so as to receive neat impressions from medals, and to serve as a mould for the casting of metals, which thus take the figure of the original. It is likewise used for polishing or cleansing silver. (Lewis's Com. P. T. p. 333, & seq.)

M. Chaptal says (*Elem. Chem.* vol. iii.) that the eggs, the scales, and the black fluid of the cuttle-fish, are still used in medicine. The eggs deterge the kidneys, and excite urine and the courses. The scales and bones are applied to nearly the same uses; they are likewise used as an astrigent, and enter into the composition of dentrifice powders, collyria, &c.; the goldsmiths likewise use them to make their moulds for casting spoons, forks, toys, &c., because their spongy part easily receives the impression of metals. The black humour of the cuttle-fish may be used instead of ink. We read in the fables of Perius that the Romans used it as an ink; and Cicero calls it "atramentum." It seems that the Chinese use it as the basis of their famous ink. "Sepia pifeis est qui habet succum nigerrimum instar atramenti, quem Chineses cum brodio orizæ, vel alterius leguminis, inspissant et formant, et in univfersum orbem transmittant, sub nomine atramenti Chinesis," (Pauli Hermani *Cynofura*, t. i. p. 17, par. 2.). Pliny was of opinion that the black humour of the cuttle-fish was its blood. Rondelet has proved that it is the bile. This liquor is dried in the bladders, then separated from the membrane, and ground with gum-water. It is used by the Italian artists for tinted drawings, and is in many respects preferable to China-ink. Sonnini informs us, (*Travels in Greece*, &c. p. 416.) that the Greek women use the back-bone as a pin-cushion; and that, in the isle of Seio, they calcine it, and reduce it to a fine powder, with which they blacken their eyebrows. The solid and almost ossaceous part is the bait with which the Greek fishermen usually garnish their lines, in order to take the eight-armed cuttle-fish (*Sepia octopus*).

CUTTOFOE, in *Botany*, a name given by the people of Guinea to a plant which they esteem greatly for its medicinal virtues. They boil it in water, and give the decoction in all cases of the colic, in which it proves a cure. It is the *Hedyfarum hamatum* of Linnæus, but was formerly supposed to be a species of *ononis* or *anonis*; and is well figured and described by sir Hans Sloane, under the name of *anonis non spinosa minor glabra procumbens flore luteo*, the yellow-flowered, small, procumbent, smooth *anonis*, without thorns.

It is found in vast abundance on the banks of the Rio Cobre, near the city of St. Jago de la Vega, or Spanish Town. *Phil. Trans.* N^o 232.

CUTTS, flat-bottomed boats, built low and commodi-

ously, used in the channel for transporting horses. *Stow, Annal.* p. 412.

CUTT'S-Island, in *Geography*, a small island of America, on the coast of York county, in the state of Maine.

CUTTUPIEA, an island in the N.E. part of the bay of Bengal, N. lat. 21° 53'. E. long. 92°.

CUVAGNA, a town of Italy, in the territory of Friuli, belonging to the state of Venice; five miles N. of Udina.

CUVES, a small town of France, in the department of La Manche, 12 miles N.E. of Horanches.

CUVETTE. See *CUNETTE*.

CUVIERA, in *Botany*, *Rosl.* See *ELYMUS Europeus*.

CUVILLER, FRANÇOIS, in *Biography*, an architect, who was born in 1698 at Soissons in France. He was educated at Paris, and afterwards went to Munich, whither he was invited by the then elector, who succeeded to the imperial crown by the name of Charles VII. Cuviller was employed by the elector in many public buildings. He continued in the service of the court until his death, which happened in the year 1760; leaving behind him many plans and designs, which were afterwards engraved by different artists, and published by his son, François Cuviller, who was born at Munich in 1734, and succeeded his father as architect to the court. Heineken.

CUVILLY, in *Geography*, a small town of France, in the department of the Somme, nine miles S.E. of Mont Didier.

CUXHAVEN, a small town of Germany, in the district of Ritzebuttel, to which it is so contiguous that it appears the same place, is situated on the mouth of the river Elbe, and belonged formerly to the city of Hamburg, but is at present in the possession of the French. It has a small but convenient harbour, and affords a safe retreat, or a good anchorage in the roads, to vessels outward-bound detained by contrary winds. After the conquest of Holland by the French, regular English packets used to sail betwixt Harwich or Yarmouth and Cuxhaven, until the latter place fell likewise into their hands at the renewal of the war in 1803.

CUYABA, a mining station in the interior of Brazil, seated on a river of the same name, which joins the river Paraguay beneath the marsh of Xaraes.

CUYCK, a town of Brabant, in a small territory of the same name, of which Grave is the capital; four miles E.S.E. of Grave, and twelve W. of Cleves.

CUYLENBURG, in *Biography*, a painter of the 17th century, who is said by some to have been a disciple of Cornelius Poelemburg, whom he appears to have imitated as well in the choice of his subjects as in the manner of executing them. He is, however, inferior to his model. A brown tint too generally pervades his pictures, which are upon a larger scale than those of Poelemburg, and are deficient in that correctness of design, and delicacy of finish, which characterize the genuine productions of that esteemed artist. Pilkington.

CUYO, in *Geography*, a province of South America, in the viceroyalty of La Plata, or Buenos Ayres, situated amidst the mountains which extend from the great chain towards Cordova, but having many fertile vallies; as it is separated from Chili on the west by the Andes, the administration is annexed to that of Cordova. Its chief town is St. Juan de la Frontera. This province produces in great abundance grapes, figs, pears, apples, and most kinds of European fruits, which form the chief articles of its trade. Wines, brandy, and dried fruits, are also carried to Buenos Ayres, Cordova, and other parts of the four intendancies.

The

The mountains of Cuyo and Rioja abound in metals; but the passes are difficult, so that there is no inducement to work them. In the northern part of the same chain are many flocks of vicunas, whose wool is sometimes wrought in the country, but chiefly sent to Europe, where it is celebrated as the first of all in broad cloths, uniting the gloss of silk, with the firmness and warmth of woollen, while the native fawn-colour can scarcely be exceeded in beauty.

CUYP, in *Biography*. See КУУР.

CUZCATLAN, in *Geography*, a river of New Spain. See ST. SEBASTIAN River.

CUZCO. See CUSCO.

CUZEAU, a small town of France, in the department of Saône and Loire; 15 miles S.E. of Louhans, and 36 of Châlons.

CUZUMEL, an island of America, in the province of Yucatan, and audience of Mexico, situated in the bay of Honduras; 15 leagues long and five broad: its principal town is Santa CRUZ, which see. N. lat. 19°. W. long. 87°.

CYALOS, in *Ancient Geography*, a town of Asia Minor, in Lydia. Steph. Byz.

CYAMEA, in *Natural History*, the name by which the ancients call the black flinty eagle-stone. Pliny describes its blackish colour, and says, that when broken, there was found within it another stone of the bigness of a horse-bean. This is what rattles in it when shaken.

CYAMON, in *Ancient Geography*, a promontory of Crete, according to Ptolemy, thought to be the present *Capo Spada*.

CYAMOSORUS, a river of Sicily, in the environs of the town of Centuripa, according to Polybius; supposed to be the present *Traina*.

CYAMUS, in *Botany*, (*κυμαος*, originally the Greek name of a plant, which appears to be not specifically different from our common cultivated bean, afterwards extended by Theophrastus and other writers to the plant now before us, on account of a fancied resemblance in the seeds.) Smith Exot. Bot. p. 59. Salisbury in *Annals of Botany*, vol. ii. p. 75. (Nelumbo; Gært. 85. Nelumbium; Juss. 68. Vent. ii. 216. and iv. 32. Poir. in *Encyc. Willd.* 1075.) Class and order, *polyandria polyandria*; Nat. Ord. *Succulentæ*; Linn. *Hydrocharidæ*; Juss. *Nymphææ*; Salisb.

Gen. Ch. *Recept.* inversely conical or top-shaped, truncated, honey-combed or hollowed into numerous cells, which are open at the top. *Cal.* Perianth four or five-leaved, inserted into the receptacle, permanent. *Cor.* Petals generally numerous, inserted into the receptacle. *Stam.* Filaments very numerous, inserted into the receptacle, much shorter than the corolla, curved. *Pistl.* Germs solitary in each cell of the receptacle; styles single, very short; stigmas simple. *Seeds* solitary, attached by a short umbilical cord to the bottom of each cell, and appearing above the top, globular or oblong, resembling nuts, fleshy within, terminated by the permanent style.

Eff. Ch. *Calyx* of four or five leaves. *Seeds* half immersed in a cellular receptacle, each crowned by its own style.

Sp. 1. *C. Nelumbo*. Smith Exot. Bot. tab. 31. 22. (*C. mytilicus*; Salisb. Ann. Bot. i. *Nelumbo nucifera*; Gært. tab. 19. fig. 2. *N. javonica*; Poir. Enc. *Nelumbium speciosum*; Willd. 1. Bot. "Leaves peltate, orbicular, undulated; petioles and peduncles prickly." Dr. Smith. "Anthers rising above the cells, club-shaped." Mr. Salisbury.

Vol. X.

"Leaves peltate, orbicular, quite entire; peduncles and petioles mucronate; corolla polypetalous." Willd. "Leaves lobed, undulated, plaited, nerves underneath umbellate." Poir. β . *Nelumbo indica*; Poir. Lam. Ill. Pl. 453. *Tamara*; Rheed. Mal. 11. 59. tab. 30, and Bern. *Tamara*, 11. 61. tab. 31. "Leaves flat, quite entire, with two opposite indentures, each of which has a mucronate projection in the middle." Poir. *Root* perennial, large, tuberous, black without, white within, throwing out numerous long fibres. *Stem* none. *Leaves* radical, smooth, rather glaucous, with many concentric radiating ribs; when young, floating on the water; when full grown, rising three or four feet above it, and becoming two or three feet in diameter, concave, variously waved, twisted or torn by the wind; petioles long, cylindrical, prickly, upright. *Flowers* on simple naked peduncles, resembling the petioles, but rather taller; solitary, upright, very handsome and fragrant, eight or ten inches wide when fully expanded, lasting for several days; calyx-leaves four or five, green, egg-shaped, concave; petals numerous, in several ranks, differing in size, sometimes white, but most commonly of a delicate pale rose-colour, white, marked with many crimson longitudinal ribs, which drawing nearer together as they approach the point, render that part of a deeper hue; stamens numerous, yellow, filiform, knobbed; anthers oblong, lateral, germ protruding through the orifice of the cell; stigma oblong, obtuse, perforated, yellow. *Receptacle* finally coriaceous, separating from the stalk, and floating down the water, laden with ripe oval nuts or seeds, which vegetating, render it a cornucopia of young sprouting plants, till at length breaking loose from their confinement, they take root in the mud. The petioles are divided internally into several longitudinal tubes, containing a thick, whitish, gummy fluid, which condenses when exposed to the air, and draws out into long threads, like those which are spun by a spider. The variety β is considered by Poiret as a distinct species; but appears to differ chiefly, if not entirely, in the shape of the leaves. A native of the East Indies, Cochinchina, China, Java, &c.; in many parts of which it is esteemed a sacred plant, and makes a conspicuous figure in their mythology as the symbol of fertility. It was known to the Greeks; and is said by Herodotus, Theophrastus, and others, to be a native of Egypt: but no modern traveller has observed it in that country. There can, however, be no doubt of its having actually existed there, since the terms in which it is described by those authors, are too clear and decisive to be mistaken; and their accounts are confirmed by ancient Egyptian sculptures and mosaics which are still preserved, and testify that from the earliest times, it, as well as the proper lotus, has obtained a religious reverence. It is remarkable that neither Herodotus nor Theophrastus, the most ancient Greek writers, by which it is described, have attributed to it a sacred character; but only speak of it as used by the Egyptians for food. The former distinguishes it by no particular name, but gives both to it and the lotus the common denomination of lily, a term which appears to have been applied by the Greeks to various plants with large specious flowers. Having observed that a paste is made of the pith of the lotus, and baked into bread, he adds, there are also in the river other lilies, resembling a rose and bearing a fruit very like a wasp's nest, which contains numerous esculent seeds about the size of the stone of an olive, that are eaten both raw and roasted. A total want of botanical knowledge has caused both our English translators, Littlebury and Beloe, to mistake the meaning of the original with respect to the situation of the fruit. Littlebury places it at the foot of the stem: Beloe,

by a still greater biunder, says, it grows from the bottom of the root, where we believe no proper fruit ever grew. The words of Herodotus are, ἡ καρπὸς ἐ ἀλλήν' καὶ οὐκ ἀπὸ τοῦ ἑστέως ἑστῆς ῥίζης ἔσται; meaning, no doubt, that the *stalk* of the flower, as well as of the leaves, springs directly from the root, without the intervention of a *stem*; though it is expressed too concisely to be easily understood, by those who are not acquainted with the plant. Theophrastus describes the plant more fully in the beginning of the tenth chapter of his fourth book, and calls it simply *κυμαίος* without any discriminating epithet; but he could not have confounded it with the well known *κυμαίος* or bean of his own country, which he mentions in various parts of his work, and particularly describes in his eighth book; and which appears by unequivocal characters to be of the leguminous kind, and not essentially different from our common cultivated bean. To prevent confusion the exotic plant was generally called by subsequent authors *κυμαίος αἰγυπτίος*, the Egyptian bean, and is expressly said by Strabo to be so called, because in its fruit it resembles the Grecian bean, differing only in size and taste; καὶ καρπὸς ὁμοίος τῷ παρ' ἡμῶν κρεῖσσιν, μεγέθει μόνον καὶ γούσῃ διαλαττόντα. According to Dioscorides it was sometimes called the Pontic bean, and is said to be a native not only of Egypt, but also of Asia Proper and Cilicia. Theophrastus had said before him that it grew, though it did not attain to its proper perfection, in Syria and Cilicia; and had even added, that it completely ripened its fruit in a lake near Torone in Chalcis. But in all these situations some species of *nymphaea* must certainly have been taken for it.

Dr. Smith has started an ingenious, and we believe, perfectly original, conjecture, that the plant before us is the real mystical bean of Pythagoras, concerning the prohibition of which to his followers so much has been written and so little determined. He supposes that this celebrated philosopher imbibed the notion of its sacred character during his travels in India, if he actually went thither, or else in Egypt at second hand from India, and that afterwards, when he propagated his acquired philosophy in Samos, Greece, and Italy, he took as a substitute for it, since it did not grow in his own country, a common seed resembling it, which the common horse bean does very nearly. He consequently understands the famous prohibition in a literal, not in a figurative sense. The total disappearance of the plant from modern Egypt favours the idea that it was not indigenous there, but brought from India. And we should find but little difficulty in acceding to the opinion of our learned friend, if we had not very strong doubts concerning the truth of the modern doctrine which derives the mythology of Egypt from that of India: but after all we have read on the subject, we do not scruple to confess that this doctrine appears to us to be in all its parts unfounded.

However that may be, we entirely agree with him in preferring the classical *cyamus* to the barbarous *nelumbo* or *nelumbium*; as the former name has not hitherto been appropriated in modern botany, and as it is certainly applied to our plant, by the Greek writers, though not in an exclusive, or as a primary sense. The root and the seeds are now used in the East Indies as articles of food, in the same manner as they formerly were in ancient Egypt. The root, having been called *colocasía* by some Greek writers, has sometimes been mistaken for the modern *colocasía* of the shops, which is the root of *arum colocasia*. 2. *C. luteum*. Salisb. Ann. bot. 2. (*Nelumbium luteum*; Willd. 2. *Nymphaea Nelumbo*. β. Linn. Sp. Pl. N. glandulifera virginiana; Moris. hist. 3. 514. Pluk. Alm. 567.) "Anthers rising above the cells, linear." Salisb. "Leaves peltate,

orbicular, quite entire; peduncles and petioles smooth; corolla polypetalous." Willd. *Flowers* pale yellow. Mr. Salisbury asserts that the petioles are prickly and not smooth, as Willdenow describes them. A native of the rivers in Virginia, Carolina, and Florida. 3. *C. pentapetalum*. (*Nelumbium*; Willd. 3. *Nymphaea*; Walt. Car. 155.) "Leaves peltate orbicular, quite entire; calyx five-leaved; corolla with five petals." A native of Carolina. Mr. Salisbury thinks that the genus of the last two species is not sufficiently ascertained.

Propagation and Culture.—The first species has flowered lately in several of our collections, but though it bears the severe cold of Pekin, it has not hitherto been successfully cultivated with us out of the stove. It requires a deep cistern with a considerable depth of mud for its roots. The seeds preserve their vegetative life for many years.

CYANA, Reneal. See *GENTIANA pneumonanthe*.

CYANA, in *Ancient Geography*, a town of Asia Minor, in Lycia, according to Pliny. It has been episcopal.

CYANEÆ, or CYANEAN *Islands*, islands or rather islets of the Euxine sea, at the mouth of the Bosphorus of Thrace, one lying on the coast of Europe, another on the coast of Asia, at the distance of about 20 stadia. At present they are very small rocks, so that their size has probably been diminished by the attrition of the waters. These rocks were also called "Symplegades," because they appeared to be united or joined, according to the place from which they were viewed. Being more or less visible, as the north or south wind raises or lowers the waters in this part, the Greeks, always inclined to the marvellous, have supposed that these islands were floating, and very dangerous to imprudent or inattentive mariners. On one of these rocks, that near the coast of Thrace, the Romans erected an altar to Apollo; which, at Constantinople, is improperly called "Pompey's pillar."

CYANECULA, in *Ornithology*, a name given by Brisson to the blue-throated warbler, or *MOTACILLA Suecica*; which see.

CYANELLA, in *Botany*, (diminutive of *κυανος*, blue, alluding to the colour of the flowers.) Linn. Gen. 420. Schreb. 568. Willd. 641. Gært. 79. Juss. 53. Vent. 2. 164. Class and order. *hexandria monogynia*. Nat. Ord. *Coronarie*. Linn. *Aphodeli*. Juss. *Liliacea*, Vent.

Gen. Ch. *Cal.* none. *Cor.* Petals six, cohering by their claws, oblong, concave, spreading; the three lower ones hanging forwards. *Stam.* Filaments six, contiguous at the base, very short, somewhat spreading; the lower one declined, and twice the length of the others; anthers oblong, erect, dehiscent at the tip, with four obtuse teeth. *Pist.* Germ. trigonous, obtuse; style trifid, declined, the length of the lowest stamen; stigma rather acute. *Peric.* Capsule roundish, three-turrowed, three-celled, three-valved. *Seeds* several, oblong.

Ess. Ch. Corolla with six petals, three lower petals hanging forward; lowest stamen declined, longer than the others.

Sp. 1. *C. capensis*. Linn. Sp. Pl. Mart. 2. Lam. 1. Willd. 1. Jacq. Hort. 3. 21. tab. 35. Gært. tab. 17. fig. 7. Lam. Ill. Pl. 239. Bot. Mag. 568. Bot. Rep. tab. 141. (*Phalangium*; Pluk. tab. 434. fig. 2.) "Stem leafy, panicled; racemes divaricated; leaves lanceolate, undulated." Root a bulb. *Leaves* chiefly from the root, acute, smooth, sheathing the stem. *Stem* six or seven inches high, almost naked, branched, with a short lanceolate acute leaf at the foot of each branch. *Flowers* purple, with a tinge of violet, in short lax racemes; pedicels rather long, almost

almost horizontal; anthers yellow, five very short, erect, incurved, the sixth longer, grooved; style incumbent on the longer anther. The bulbs, which are about the size of those of *crocus verna*, are said to be esculent when roasted. A native of the Cape of Good Hope, at the foot of the Table mountain. 2. *C. orchidiformis*. Willd. 2. Jacq. Ic. Rar. 2. tab. 447. "Stem branched; racemes erect; stem-leaves sword-shaped, stiff and straight; root ones egg-shaped." Leaves glaucous, cartilaginous, and finely toothed at the edges. *Flowers* violet-purple; three of the petals and three of the stamens erect, the three others of each deflexed. A native of the Cape of Good Hope. 3. *C. lutea*. Linn. jun. Supp. 205. Mart. 1. Lam. 2. Willd. 3. Thunb. Act. Holm. 1794. tab. 7. fig. 1. "Scape somewhat branched; racemes erect; leaves linear-lanceolate, flat." *Flowers* yellow, larger than those of *C. capensis*, with longer peduncles; filaments united at the base, as in that species, but three of them erect, and three, one of which is longer, deflexed. A native of gravelly inundated fields at the Cape of Good Hope. 4. *C. alba*. Linn. jun. Supp. Mart. 3. Willd. 4. Thunb. Act. Holm. 1794. tab. 7. fig. 2. "Scape one-flowered; leaves filiform." A filiform bract at the middle of the scape. All the stamens erect, except the larger one. A native of the Cape of Good Hope.

CYANELLA, in *Entomology*, a species of CRYPTOCEPHALUS.

CYANELLA, in *Ornithology*, a species of EMBERIZA.

CYANEUS, in *Ancient Geography*, a river of Asia, in the territory of Colchis, now called *Clanis*.

CYANEUS, in *Zoology*. See COLUBER.

CYANOIDES, in *Botany*, Dod. See CENTAUREA *muricata*, n. 125.

CYANOMETER, (from *κυανός*, *cæruleus*, *azure*, and *μέτρον*, *mensura*, *a measure*.) is the name given by M. de Saussure to an instrument which he contrived, for the purpose of estimating the intenseness of the blue colour of the sky. This instrument is nothing more than a circular band of paper, or paste-board, divided into 51 parts, each of which is painted with a different shade of blue; beginning with the deepest, which is mixed with black, and gradually proceeding to lighter and lighter shades, as far as the lightest, which is mixed with white. By alternately looking at the sky and at the different shades of blue on this instrument, one may easily determine which shade of the latter agrees with the actual colour of the sky; and thus the various intenseness of the aerial blue, as it appears at different times, or from different altitudes above the surface of the earth, may be ascertained, compared, &c.

That the blue colour, which we observe in the heavens, belongs to the atmosphere of the globe we inhabit, is easily proved from evident facts; the principal of which are, that the higher the observer is situated, the darker does the colour of the sky appear to be. M. de Saussure finding that it corresponded with a deeper shade of blue on his cyanometer, the higher he ascended above the surface of the earth; hence concludes, that, at a certain height, the blue will disappear altogether, and the sky will appear black, *viz.* it will reflect no colour whatever.

Another proof of the blue colour being reflected by something below the moon, (and that something can be nothing else besides the air of our atmosphere,) is that when the moon is in her quadratures, or nearer to the sun, that part of it which is not illuminated by the sun will appear blue like the rest of the sky, to an observer who directs his eye to it in the day-time; whereas, if the blue was reflected by

something beyond the moon, the above-mentioned part of the moon would not appear of that colour.

This blue colour of the sky is supposed to be produced by the blue, indigo, and violet rays being more easily reflected than the other component rays of white or solar light. And it has been observed, that the colour of the sky becomes always lighter, in proportion to the quantity of aqueous vapour that happens to be mixed with the air: whence it evidently appears, that the colour of the sky is owing to the reflection from those vapours. And it also appears, that, by the use of the cyanometer, an attentive observer may be enabled to guess pretty nearly at the quantity of water actually dissolved in the air; on which account, the cyanometer ought to be added to the barometer, thermometer, and other instruments of a meteorological observatory.

CYANUS, in the *Natural History of the Ancients*, is used to express two different substances. The one, the *lapis lazuli*; the other, the *lapis armenus*, a substance used by the painters in its native state, and very improperly called *azilone*, being a mere earth, and being truly to copper, what yellow ochre is to iron.

CYANUS, in *Ornithology*, a name given by Bell., Gessn., Aldr.,

Aldr., Ray, and Will., to the solitary sparrow of Edwards, and blue thrush of Latham; the *Turdus cyanus* of Gmelin; which see.—Also, a species of *PARUS*; which see.

CYANUS, in *Zoology*. See *MUS*.

CYARDA, in *Ancient Geography*, a town of Asia Minor, in Caria. Steph. Byz.

CYATHEA, in *Botany*, (from *κύπελος*, a cup,) Smith A&T. Taurin. 1793, vol. 5. 414. Tracts, 251. Clafs and order, *cryptogamia filices*. Nat. Ord. *Filices*, Linn. Juss.

Gen. Ch. Fructification scattered, roundish, standing in an hemispherical calyx, which bursts at the top without an operculum.

Eff. Ch. Involucrum going under the receptacle of the capsules, either entirely like a cup, or partially on one side.

Sp. 1. *C. horrida*. (*Polypodium horridum*; Linn. Sp. Pl. 57. *Filix ramosa*; Pet. Fil. 50. tab. 5. fig. 1. *F. latifolia ramosa*; Plum. Amer. 3. tab. 4.) "Trunk thorny; frond bipinnated and pinnatifid; segments acuminate, serrated at the tip, flowering near the margin, furnished with interramifying veins at their base. A native of Hispaniola and Jamaica. 2. *C. multiflora*. "Trunk unknown; frond bipinnated and pinnatifid; segments obtuse, serrated; stalk winged; flowers scattered; calyx torn." A native of Jamaica, communicated by sir Joseph Banks. 3. *C. arborea*. (*Polypodium arboreum*; Linn. Sp. Pl. 55. *Filix arborescens*; Plum. Fil. 1. tab. 1. Am. 1. tab. 1, 2. Pet. Fil. 41. tab. 1. fig. 1, 2.) "Trunk arborescent, scaly; frond bipinnated; leaflets sessile, serrated, with many flowers at their base; calyx entire." A native of Jamaica. 4. *C. capensis*. (*Polypodium capense*; Linn. jun. Supp. 445.) "Frond tripinnated; leaflets sessile, acute, serrated, bearing a solitary flower at their base; calyx torn." A native of the Cape of Good Hope. 5. *C. fragilis*. Smith Flor. Brit. 1. Eng. Bot. 1587. (*Polypodium fragile*; Linn. Sp. Pl. 51. Bolt. Fil. 50. tab. 27. and 46.) "Frond bipinnated; leaflets pinnatifid, sharply and deeply serrated; fructifications a little distant; calyx torn; common stalks winged." Root perennial, tufted, crowned with brown scales. Fronds from four inches to a foot high, delicate and tender, lanceolate, acute, smooth, bright green; stalk blackish, smooth, brittle; leaflets alternate, cut, most frequently pinnatifid, sometimes inversely egg-shaped, more generally lanceolate, pointed, with more or less zig-zag nerves; dots of fructification numerous, alternate, brown or black, not confluent except when old. Involucrum cup-shaped, bursting laterally, jagged, at length reflexed and obliterated. No fern varies more in the number, form, and breadth of its subdivisions. When large, most compound and finely cut, it is the *polypodium rheticum* of British writers, but not of Linnæus. When smaller and less compound, it is the *P. ilvense* of Ray's Synopsis. Dr. Smith. A native of rocky places and buildings in the mountainous parts of Britain, and the continent of Europe. 6. *C. regia*. Smith Flor. Brit. 2. (*C. incisa*; Eng. Bot. 163. *Polypodium regium*; Linn. Sp. Pl. 52. *Adiantum nigrum*, *pinnulis cicutarie divifura*; Rai. Syn. 126.) "Frond bipinnated; leaflets lobed, obtuse, without a bristly point, quite entire at the edges; calyx torn; stalk slightly winged." Root perennial, scaly. Fronds four or five inches long, lanceolate, smooth, fine green; dots of fructification nearly as in the preceding species, but smaller. A native of France and Britain, on walls and alpine rocks, but rare. 7. *C. dentata*. Smith Flor. Brit. 3. Eng. Bot. 1588. (*Polypodium*; Dickf. Crypt. Fasc. 3. 1. tab. 7. fig. 1.) "Frond generally bipinnated; leaflets egg-shaped, obtuse, deeply

and bluntly toothed, pointless." About the size of the preceding. Fronds lanceolate, acute, smooth; leaflets with zig-zag nerves; common stalk winged only towards the top; dots of fructification numerous, approximate, some becoming confluent; involucrum half way round, fringed. Rocks in Wales, and the Highlands of Scotland. 8. *C. montana*. (*Polypodium*; Allion. Ped. 2410.) "Frond in three divisions, each bipinnated and pinnatifid; segments slightly crescent-shaped, toothed at the tip; stalk winged; flowers scattered; calyx torn." A native of the Alps of Europe.

Obs. We are authorised by Dr. Smith to state, that his idea of this genus has not been understood by some German botanists, who have taken the less certain species (*fragilis*, *regia*, &c.) as examples of the genus, and thence made a new genus of the primary cyatheæ (*arborea*, &c.). We are happy to add, that Dr. Smith has in contemplation a full investigation of the subject, which will be presented to the Linnæan Society, and doubtless in due time be published in their Transactions.

CYATHODES, Rudge, Linn. Transf. 8. 293. See *STYPHELIA*.

CYATHUS, from *κύειν*, to pour out, in *Antiquity*, a liquid measure among the Romans, being the twelfth part of the sextarius. It only held as much as a man could easily drink at one draught, and was divided into twelve parts, called uncie.

CYATHUS, in *Botany*, Hall. Juss. See *NIDULARIA*.

CYATHUS, in *Ancient Geography*, a river of Greece, in Ætolia, near the town of Arfinoë.

CYAXARES I., in *Biography*, king of the Medes, who succeeded his father, Phraortes, B. C. 635, was a prince of great courage, extraordinary abilities, and devoted to the military profession. In the preceding reigns, much of the kingdom had been conquered by the Assyrians; but, by the prowess and skill of Cyaxares, it was retaken. He not only defeated his enemies in a battle, on which almost every thing depended, but laid siege to Nineveh their capital. Scarcely, however, had he attained this object, when the Scythians successfully invaded his country, and made themselves masters of Media, and a great part of Upper Asia, which they held for nearly 30 years. Wearied of their oppression, Cyaxares resolved to free himself from them by stratagem. He accordingly invited them to a general feast, which was given in every family; and when they were off their guard by intoxication, he caused a massacre to take place, and thus freed himself from his enemies. He then attacked the Lydians for having aided or succoured the fugitive Scythians. These, however, were not easily subdued; and after five years' war, which was carried on with various success, a most obstinate engagement took place: but a total eclipse of the sun, which happened during the heat of battle, had so powerful an effect on the superstition of both parties, that with one accord they retreated: peace was concluded, and a marriage was brought about between the daughter of the Lydian king and Alyages, the eldest son of Cyaxares. This business being settled, Cyaxares entered into a strict alliance with Nebuchadnezzar, king of Babylon; and, in conjunction with his new friends, he resumed the siege of Nineveh, slew Sarac the king, and levelled that proud metropolis with the earth. This important circumstance gave rise to the great successes of the allied monarchs, and laid the foundation of the collateral empires of the Medes and Babylonians. Enriched with the plunder of very many subjugated nations, they divided their forces, Nebuchadnezzar pursuing his conquests in the west, and Cyaxares falling upon the provinces of Armenia, Pontus,

and Cappadocia, which he subdued with great slaughter of the inhabitants. After these achievements, the armies united again, and completed the conquest of the Assyrian empire. Cyaxares died in the 40th year of his reign, and was succeeded by Astyages; upon whose death, in 560 B. C.,

CYAXARES II., son of Astyages, and uncle to Cyrus, succeeded to the throne. This prince is supposed to be the same with "Darius the Mede," mentioned in the Old Testament. In concert with his nephew, Cyaxares, after the reduction of Babylon, arranged the affairs of the new empire, and divided it into 120 provinces, which were entrusted to the care of those persons who had distinguished themselves during the war, over whom three presidents were appointed; the prophet Daniel, on account of his age, experience, and great wisdom, being the chief. Cyaxares reigned in conjunction with Cyrus till the year 536 B. C., when he died. *Univ. Hist. Xenoph.*

CYBEA, in *Antiquity*, a kind of ship used in commerce, of a roundish form.

CYBASSUS, in *Ancient Geography*, a town of Asia Minor, in Caria. *Steph. Byz.*

CYBATE, **WASITH**, a town of Asia, upon the right bank of the Tigris, S.E. of Seleucia, and N.W. of Apamea.

CYBELE, in *Mythology*, a heathen goddess; who, according to the Roman mythology, was the daughter of Cælus and Terra, or heaven and earth, wife of Saturn, and mother of the gods.

The Greek mythologists pretend that she sprang from one of the stones used by Deucalion and Pyrrha for re-peopleing the earth after the deluge. The Phrygians affirm that she was daughter of their first king Meon, debauched by Attys, whom her father caused to be put to death; and that she afterwards wandered with Apollo to the country of the Hyperboreans. Cybele, as the Phrygian fable reports, on occasion of the death of Attys, was seized with phrenzy, and filled the woods and mountains, wherever she went, with her lamentations. A plague soon after laying waste the country, the oracle, which was consulted, advised to bury Attys with great pomp, and worship Cybele as a goddess; but his body, which had been thrown to wild beasts, not being found, they made a statue of him, which they attended with howlings and funeral ceremonies. A magnificent temple was erected to Cybele in the city of Pessinus; and lions were placed at her feet, in commemoration of her having been nursed by these animals, when exposed in her infancy on mount Cybelus. The worship of the earth was very ancient, and the origin of it has been sought in Phrygia; for it was not received in Europe till the time of Cadmus, who transferred it from Asia; and Dardanus, it is said, who was contemporary with Cadmus, repaired with Cybele, represented as his filter-in-law, and Corybas his nephew, into Phrygia, where they introduced the mysteries of the goddess Earth, or great mother goddess, to whom was given the name of Cybele, as was that of Corybas to the Corybantes, her priests. In Italy this deity was unknown till the time of Hannibal; when the Romans, consulting the Sibylline oracles, found that this formidable enemy could not be expelled unless they brought the Idæan mother, or Cybele, to Rome. The senate, therefore, dispatched ambassadors to Attalus, king of Phrygia, and obtained from him the statue of this goddess, which was of stone, at the city of Pessinus, in Galatia. Accordingly she was brought to Rome, with singular ceremonies, and introduced, according to the Sibylline order, by the best man of the city, whom the senate adjudged to be Publius Scipio.

Cybele, besides other appellations by which she was distinguished, was named Cubebe, because her priests, when seized with their frantic fits, used to throw themselves on their beads; from the Greek verb *κυβηβαιν*, in caput pro- volvi.

She was also adored under the names of Ops, Rhea, Vesta, the Good Goddess, Dydime, Berecynthia, &c. and was called Cybele from mount Cybelus in Phrygia. She is represented in a chariot drawn by four lions, her garments flowered, a key in her hand, and a turret on her head.

Allegorists by Cybele mean the earth, and her crown of towers they consider as an emblem of the towns and cities built upon it; the key held in her hand denotes that the earth, which the winter, as it were, locks up, begins to open in the spring; and her garment, variegated with different flowers, is a symbol of the earth beautifully enamelled with these productions; the lions that draw her chariot signify her empire over all sorts of animals which she produces and cherishes; she rides in a chariot, because, as it is fancifully said, the earth is suspended in the air; and the chariot is supported by wheels, because the earth is a revolving body. Under the character of Vesta, she is generally represented upon ancient coins in a sitting posture, with a lighted torch in one hand, and a sphere or drum in the other. Varro, cited by St. Austin, (*De Civ. Dei*) gives the following explanation of the appellation and attributes of Cybele: she is called the mother of the gods; the drum, which is ascribed to her, represents the globe of the earth; the turrets, its towns and cities; the seats that surround her shew, that she only stands still when all things are in motion around her; her eunuch priests denote, that the earth must be manured in order to produce corn; their agitations before the goddess teach husbandmen, that they must not lie still; the sound of cymbals denotes the noise of the instruments of husbandry; and the tame lions intimate, that there is no soil so wild and barren, that may not be manured. Eusebius and some others are of opinion, that Cybele was a woman famous for her skill in remedies against distempers to which young children are subject, and that all the stories relating to her are grounded on this faculty which she possessed.

Cybele had her peculiar priests, ceremonies, and sacrifices. Her priests were called, in the Phrygian language, Cubeboi; the Greeks and Latins named them Cabiri, Curetes, Corybantes, and Galli, from the river Gallus, which flowed through Pessinus above mentioned. They were also styled Idæi Dactyli. The ceremonies performed by these priests in honour of the goddess were these: at stated times they carried her statue about the streets, dancing and skipping round it; and after having by violent gesticulations worked themselves into a kind of phrenzy, they began to cut and slash their bodies with knives and lancets, in commemoration of the grief of Cybele at the loss of her beloved Attys. The victims immolated in honour of the Phrygian goddess were bulls, or she-goats, whence the sacrifice was called "Taurobolium," or "Criobolium." At Rome a sow was annually sacrificed to her; and the ceremony was performed by a priest and priests sent for out of Phrygia on that occasion. Her priests (at least those designated by the name of Galli) were all eunuchs, in memory of Attys, who was said to have deprived himself of his virility; and the waters of the river Gallus were supposed to inspire them with such frantic enthusiasm, that they unreluctantly performed the necessary operation on themselves. They were forbidden wine, because Attys, overcome with it, disclosed his amours with Actæis, which he had before carefully concealed.

concealed. They abstained from bread, in commemoration of the long fast which Cybele kept after the death of Attys. They held all oaths to be unlawful; and after their death, these priests were placed on a stone 10 cubits high. The rites of Cybele were not less infamous for their lewdness than for their cruelty. Her festivals were celebrated with a confused noise of timbrels, pipes, and cymbals; and accompanied with howlings, and obscenity both of language and gesture. The animals sacrificed to her were the bull, goat, and sow, as symbols of fecundity; and the box and pine were sacred to her:—the former, because the pipes used at her festival were made of that wood; and the latter, for the sake of Attys, or Atys, the Phrygian youth, already mentioned, who was beloved by her, and made president of her rites, but who, having violated a vow of chastity, was turned by her into the pine-tree.

Cybele was one of the chief goddesses among the ancient Gauls, and particularly venerated in the city of Autun, where her priests were castrated in honour of her, and hence called Galli. However, if the worship of Cybele was introduced into Gaul, it was either by force, or in servile imitation of that of the Greeks and Romans. Such was the abhorrence with which the Gauls regarded all mutilations, that they would never voluntarily have adopted a kind of worship, which required every priest, and encouraged every votary of the goddess, to become an eunuch. Besides, the Galli were held in such abhorrence, that no other people would maintain any intercourse with them; and they were placed on a level with forcerers, gladiators, and executioners; so that they subsisted merely by carrying about their goddess, and begging charity for her sake:—a discipline which was entirely opposite to the genius of the Gallic nation. Indeed, St. Jerome intimates, that the Romans forced this emasculated priesthood upon the Gauls, and called these eunuchs Galli, in order to fix a perpetual ignominy upon that nation, for having taken their metropolis, and besieged their capitol.

CYBELE, *Mons*, in *Ancient Geography*, a mountain of Phrygia, which gave name to Cybele, the mother of the gods. We may infer that this mountain was not far from Cœlœne, towards the source of the Meander, from a verse of Ovid:

“—Viridem Cybelan atlasque Cœlœnas.”

CYBELEIA, a town of Asia Minor, in Ionia; probably the same with *Cybellia* of Strabo.

CYBELICUM ΜΑΡΜΟΡ, a name given by the ancients to a species of marble, dug in a mountain of that name in Phrygia. It was of an extremely bright white, with broad veins of a blueish black.

CYBISTRA, in *Ancient Geography*, a town of Asia, in Lesser Armenia, reckoned by Hierocles in the number of episcopal cities in the second Cappadocia. It was situated south of mount Argeus.

CYBOMANTIA, a species of divination performed by lots.

CYBRASA, in *Ancient Geography*, a town of Asia Minor, in Caria. Steph. Byz.

CYBUS, a town of the Phœnician Libya, belonging to the Ionians. Steph. Byz.

CYCAS, in *Botany*, (κυκας; Theoph. the name of a palm, said to grow in Ethiopia.) Linn. Gen. 1222. Schreb. 1699. Juss. 16. Vent. 2. 68. Class and order, *palmæ pinnatifolia*, Linn.; but afterwards removed by him to filices. *Diacia polyandria*, Jacq. Nat. Ord. Filices, Juss. Vent. *Palmæ*, Lam.

Gen. Ch. *Male flowers* in a terminal oval-oblong catkin,

resembling a strobile. *Cal.* Scales imbricated, fleshy, spatulate or oval, ending in a weak point. *Cor.* none. *Stam.* Filaments none; anthers numerous in each scale. *Female flowers* on a separate plant. *Fronds* numerous, terminal, somewhat compressed below, dilated above, clustered. *Pist.* Germs sessile, on the edges of the frond; style short; stigma simple, permanent. *Peric.* Drupe egg-shaped; outer coat fleshy; nut woody, one-celled; kernel rounded, firm.

Ess. Ch. *Male catkin* resembling a strobile. *Anthers* numerous, sessile. *Females.* *Fronds* numerous, terminal, somewhat compressed below, dilated above. *Drupes* sessile, on the edges of the frond.

Obs. This genus and zamia seem to constitute an intermediate order between the ferns and the palms. They resemble the former in the mode of their foliage; but, in other respects, have all the proper characters of a palm. Linnæus erroneously describes the pollen of cycas as naked, i. e. not enclosed in an anther.

Sp. 1. *C. circinalis*. Linn. Sp. Pl. Mart. 1. Lam. 1. Ill. Pl. 891. (Toda-pana; Rheed. Mal. 3. 9. tab. 13—21. Rai Hist. 1360. Oius calappoides; Rumph. Atob. 1. 86. tab. 22, 23. Arbor zagoe amboinensis; Seb. Thes. 1. 39. tab. 25. fig. 1.) “Leaves pinnated; leaflets linear, flat, not pungent at the tip, slightly curved outwards; common petioles prickly beneath the leaflets.” *Trunk* thick, generally short, scaly; sometimes from fifteen to twenty feet high, with numerous annular protuberances, and divided at the summit into a very few short branches. *Leaves* crowning the trunk, three feet long or more; leaflets numerous, very near together. *Male catkins* terminal, within the leaves, solitary, sometimes very large, fleshy, having some resemblance to a large pine-apple. *Fronds* bearing the *females* numerous, terminal, within the leaves, coriaceous, woolly, sword-shaped, expanded upwards, indented at the edges about the middle, jagged near the summit, and ending in a long sharp point. *Fruit* about the size of a small orange, reddish-yellow, slightly compressed. A native of the East Indies, and of the islands in the South Sea. 2. *C. revoluta*. Mur. Syst. Veg. 2. Mart. 2. Lam. 2. Thunb. Flor. Jap. 229. Smith. Linn. Trans. 6. 312. tab. 29, 30. (Tessio; Kœmpf. Amœn. 897. Arbor calappoides titsjin dicta; Rumph. Amb. 1. 92. tab. 24.) “Leaves pinnated; leaflets narrow, revolute at the edges, slightly curved inwards, pungent at the tip; common petioles prickly underneath the leaflets.” *Trunk* cylindrical, branched, five feet high or more, nine or ten inches in diameter, brown, very scaly with the remains of old petioles. *Leaves* four or five feet long, crowning the trunk, and forming a magnificent bason ten or twelve feet broad at the top. *Fruit-bearing fronds* numerous, terminal, within the leaves, forming a kind of strobile or cone, at first hollow like a bird’s-nest, finally rather convex; from six to eight inches long, fleshy, entirely covered with a pale brown woolly down; flattish and stalk-like towards the bottom; bearing on each edge about the middle a row of three or four sessile drupes; dilated at the extremity into a pinnatifid, or rather palmate many-fingered leaf, whose lobes are generally turned inwards, and tipped with a spine. *Fruit* nearly as large as an apricot, of a rich orange hue, and clothed with a woolly down which easily rubs off, somewhat obovate or elliptical, a little compressed, tipped with a minute rigid point formed of the permanent stigma; outer coat coriaceous; nut elliptical, hard, whitish, tipped with a point connected with the stigma, and internally lined with a loose brown membranous integument, closely enfolding a white, firm, uniform kernel, which completely occupies the shell, and consists entirely of albumen. A native of Japan. This species

Species produced fruit, for the first time in England, in the autumn of 1799, at Farnham castle in Surrey, the seat of the honourable and right reverend Dr. North, bishop of Winchester, where it was seen by Dr. Smith, from whose accurate description the preceding one is abridged. The kernels of both these species are eaten in their native countries; and from the pith of both a kind of fago is made, which is said to be very nutritive, but not equal to that which is produced by the tree fagoe palm, metroxylon of Rottböll, and fagus of Gärtner, La Marek, and Ventenat. Linnæus confounded the two plants. 3. *C. inermis*. Lour. Cochin. p. 632. "Leaves pinnated; common petioles without prickles." *Trunk* five feet high, the thickness of the human thigh, quite simple, brown, rugged. *Leaves* five feet long, ascending; leaflets linear-lanceolate, six inches long, smooth, dull green, flattish, sessile. *Male catkin* strobile-shaped, four inches in diameter, terminal, solitary, erect, oval-oblong, brownish-yellow, imbricated, rather close; scales oblong-top-shaped, thick, fungous; anthers more than a hundred in each scale, the size of rape-seed, globular, dehiscant at the tip. *Fruits of the female flowers* various, linear, reflexed, few-flowered, nearly terminal, simple, dilated and jagged near the top. *Fruit* an inch and half long, egg-shaped, somewhat compressed, smooth and even, red. Found wild and cultivated for its beauty in Cochinchina and China, but no part of it used for food. In Tonquin a tolerable fago is said to be obtained from the pith.

CYCEON, from *κράσιον*, to mix; a name given by the *Ancient Poets and Physicians* to a mixture of meal and water, and sometimes of other ingredients. These constituted the two kinds of *cyceon*; the coarser being of the water and meal alone; the richer and more delicate composed of wine, honey, flour, water, and cheese. Homer, in the eleventh Iliad, talks of *cyceon* made with cheese and the meal of barley, mixed with wine, but without any mention either of honey or water; and Ovid, describing the draught of *cyceon* given by the old women of Athens to Ceres, mentions only flour and water. Dioscorides understood the word in both these senses; but extolled it most in the coarse and simple kind: he says, when prepared with water alone, it refrigerates and nourishes greatly.

CYCESIUM, in *Ancient Geography*, a town of Greece, in the Peloponnese, plac'd by Strabo near the fountain Bifa.

CYCINNIS, a Grecian dance, so called from the name of its inventor, one of the satyrs belonging to Bacchus. It consisted of a combination of grave and gay movements.

CYCLADES, from the Greek word *κύκλος*, a circle, in *Ancient Geography*, a cluster of islands in the Ægean sea, forming a kind of circle round Delos, though this is not strictly the case, as most of them lie S. of Delos: called *Minioides* by Apollonius. The number and order of these islands, according to Strabo, are as follow: Helena, Ceos, Cythnus, Seryphus, Melo, Siphnus, Cimois, Prepeinthus, Olearus, Naxus, Parus, Syrus, Myconus, Tenus, Andrus, Gyarus, which see respectively.

CYCLAMEN, in *Botany*, (*Κυκλαμίνος*: Diosc. From *κύκλος*, circular; referring to the round form either of the leaves or of the roots.) Sowbread. Linn. gen. 201. Schreb. 262. Willd. 293. Lam. Ill. 281. Juss. 97. Vent. 2. 290. Class and order, *pentandrii monogynia*. Nat. Ord. *Preciæ*, Linn. *Lyfsmachia*, Juss. *Primulaceæ*, Vent.

Gen. Ch. *Cal.* half five-cleft; segments egg-shaped. *Cor.* monopetalous, wheel-shaped; tube very short, somewhat globular, border very large, bent backwards, five-

parted, segments linear-lanceolate; orifice of the tube prominent. *Stam.* Filaments five, very small, within the tube of the corolla; anthers straight, acute, converging, *Pist.* Germ superior, roundish; style filiform, straight, longer than the flaments; stigma acute. *Peric.* Berry capsular, globular, one-celled, dehiscing at the top in five directions. *Seeds* numerous, somewhat egg-shaped, angular, attached to an egg-shaped free receptacle.

Eff. Ch. Corolla wheel-shaped; tube very short, with a prominent orifice; border reflexed. Stamens within the tube. Berry covered with a capsule.

Sp. 1. *C. coum*. Hort. Kew. 1. Mart. 1. Bot. Mag. 4. "Leaves orbicular, heart-shaped, quite entire." *Leaves* flat, smooth and of a lucid green above, very red underneath in the beginning of winter, but the colour goes off gradually in the spring; petioles short, weak. A native of the South of Europe. 2. *C. europæum*. Hort. Kew. 2. Mart. 2. Willd. 2. Jacq. Antl. 5. 1. tab. 401. Scop. Carn. 2. 211. Smith. Prod. Flor. Græcæ. 442. (*C. orbiculato folio inferne purpurascens*; Bauh. pin. 308. Tourn. 154) "Leaves orbicular, heart-shaped, crenate." *Root* tuberous. *Stem* very short, within the ground. *Leaves* deep green and spotted above, commonly reddish purple underneath, smooth, on very long red petioles. *Flowers* drooping, purple, sweet-scented; peduncles resembling the petioles, erect with the flower, spiral with the fruit. *Capsular berry* coriaceous, purple, opening first at the top, and then entirely. *Seeds* large, rufous, kidney-shaped. A native of Austria. 3. *C. persicum*. Hort. Kew. 3. Mart. 3. Willd. 3. Prod. Fl. Græc. 443. Bot. Mag. 44. "Leaves oblong-ovate, heart-shaped, crenate." *Leaves* stiff, with purple veins underneath; petioles near six inches long, purple, strong, fleshy. *Flowers* pure white, with a bright purple bottom; sometimes entirely white and very fragrant. A native of Greece, frequent about Athens. 4. *C. hederifolium*. Hort. Kew. 4. Mart. 4. Willd. 4. Bot. Mag. 1001. Bauh. pin. 308. Flor. Græc. tab. 185. (*C. europæum*; Mill. Diet. Smith Eng. bot. 548. Flor. Brit. 1. 224.) "Leaves heart-shaped, angular, finely toothed." *Root* a large roundish knob, throwing out several branched fibres. *Leaves* veined, smooth, stained above with white sinuated spots, purplish underneath; petioles long, cylindrical, zig-zag, slender at the base. *Flowers* drooping, either white or purplish; segments upright, twisted; peduncles longer than the petioles. After impregnation the peduncles curl in a close spiral manner, and bury the ripening fruit in the ground, or lay it close to the surface among the leaves. A native of Italy and Greece. It has been found growing, apparently wild, on a bank in the parish of Bramfield, Suffolk, and has been admitted by Dr. Smith into the British Flora, but, as he himself observes, it can scarcely be thought really indigenous. 5. *C. repandum*. Smith Prod. 445. Flor. Græc. tab. 186. (*C. radice calliææ magnitudinis*; Bauh. pin. 308. Tourn. 155.) "Leaves heart-shaped, repand." A native of the country about Constantinople. 6. *C. inlicum*. Linn. Sp. Pl. 2. Mart. 5. Lam. Enc. 2. Ill. 1561. Willd. 5. "Border of the corolla drooping." Border of the corolla not completely reflexed, but only inclined outwards. A native of the isle of Ceylon.

Propagation and Culture.—The plants of this genus admit of but little increase by the roots; the best method of propagating them is by seeds, which should be sown soon after they are ripe, in boxes or pots, and covered about half an inch deep, placing them where they may have only the morning sun, till the beginning of September, when they may

may be removed to a warmer exposure. The first, second, and fourth species may be plunged into the earth close to a south wall in a mixture of bog-earth and loam, and will stand common winters with out covering, but in very severe frosts should be sheltered by mats or straw. If the season be mild the first species will flower as early as February, or much earlier by artificial heat. The third species is more tender, and requires to be treated rather as a green-house plant. None of the species should have much water after the leaves have died down.

CYCLAMEN, in *Gardening*, contains plants of the low, herbaceous, flowery, perennial tuberous-rooted kind; of which the species cultivated are: the common cyclamen (*C. Europeum*), the round-leaved cyclamen, (*C. coum*), the Persian cyclamen, (*C. Persicum*), and the fig-leaved cyclamen, (*C. hederifolium*).

Method of Culture.—All these plants may be increased by sowing the seeds in large wide pots, tubs, or boxes filled with good light mould mix'd with a little sand, in the latter end of summer or the beginning of autumn, covering them to the depth of about half an inch, exposing them at first in situations that have only the morning sun, but afterwards removing them into more warm and sunny exposures; and as the winter approaches, placing them under the protection of frames and glasses, or some other contrivance, fresh air being admitted when the weather is mild and suitable. In this way some plants of the hardy sorts will appear about the beginning of the following year, and of all the kinds in the spring. During the beginning of summer, when the weather is hot and dry, slight waterings should be given occasionally; but when their leaves begin to decline in the latter end of it, they should be removed to an eastern aspect, with only the morning sun; and as their roots are then in an inactive state, have little or no water. They should be kept free from weeds in the autumn, and have some fresh mould applied over the surfaces of the pots or tubs in which they grow, protecting them again in the winter as before, continuing the same management as in the preceding year, till the decline of the leaves in the latter part of the summer, when they should be carefully taken up, and the more hardy sorts planted out in the situations where they are to remain, as those of a warm, dry border; and the tender kinds removed into pots to have protection from frosts in winter.

As the Persian sort is the most impatient of cold and moisture, it should constantly be kept in pots filled with light sandy earth, or a compost of loam and lime-rubbish, and be placed in such situations in the frame or green-house, as to have as much free air as possible in mild weather in winter. Some of the sorts will generally begin to flower in the course of one or two years after being thus planted out; the first kind often about Christmas, which is succeeded by those of the Persian sort.

The plants in the borders should have the protection of mats, or other contrivances, in severe winters, as by such means they produce a greater abundance of flowers, and these more fair and beautiful.

The varieties of the different sorts are best preserved and continued by planting pieces of the divided roots, immediately after they have been separated in the summer season, in pots, tubs, or other places, as above: but in this mode they do not increase in an expeditious manner.

These plants are very ornamental though of small growth, in their variegated large foliage, as well as their elegant flowers, which in some of the sorts are fragrant, as those of the spring kinds.

The hardy sorts produce a fine effect in the fronts of bor-

ders, or clumps in pleasure-grounds, and those of the tender kinds among other potted plants in the green-house.

The most proper period for removing these plants for any purpose is about the beginning of June, when the leaves decline, but they should not be often removed, as the roots do not lose their fibres, as in some others of the tuberous and bulbous rooted kinds of flowers.

CYCLAMINUS SINUS, in *Ancient Geography*, a gulf of Asia Minor, in the Thracian Bosphorus, N. of the gulf *Castaneus*.

CYCLAS, in *Botany*, Schreb. Mart. See **CRUDIA**.

CYCLAS, in our *Old Writers*, a long garment, close upwards, and open, or large below. Matt. Paris, speaking of the citizens of London, tells us they were *cericis agstimentis ornati, cycladibus auri textis circumdati*. Anno 1226.

CYCLE, ($\kappa\upsilon\kappa\lambda\omicron\varsigma$, a circle of time) a periodical portion of time, constantly renewed after the expiration of the proper interval, in which certain phenomena, or events, complete their courses.

We shall here recite some of the principal cycles, with their defects and improvements. The first we shall mention is the

CYCLE, Calippic. See **CALIPPIC Period**; and **Metonic Cycle**.

CYCLE, Canicular. See **CANICULAR Year**.

CYCLE, Chinese, a period of 60 years, or of 720 revolutions of the moon, which, with the settled intercalation of 22 lunations, were at first supposed to bring a perfect coincidence of the relative positions of the sun and moon:—however, even according to this period, every new year was made constantly to recede, in a very small degree, which the Chinese afterwards, from time to time, corrected. This cycle answered a double purpose; one as an era for chronological reckoning, and the other as a regulating period for a luni-solar year. Each year of the cycle is distinguished by the union of two characters, taken from such an arrangement of an unequal number of words placed in opposite columns, that the same two characters cannot be found again together for 60 years. The first column contains a series of ten words; as, *kia, y, ping, ting, ou, ki, kong, sin, yen, koui*; the other of twelve words, *viz t'fée, tehou, yn, mao, tchen, fée, ou, ouei, chen, yeou, kiu, hui*; which last are, in reality, the same that denote the twelve hours or divisions of the day; each being double the European hour. The first word or character of the first series or column of ten words, joined to the first word of the second series or column of twelve, marks the first year of the cycle; and so on until the first series is exhausted; when the eleventh word of the second series combined with the first of the first series, marks the eleventh year of the cycle; and the twelfth or last of the second series joined with the second of the first series, serves for denoting the twelfth year. The third of the first series becomes united in regular progression with the first of the second series to mark the thirteenth year; and proceeding in this order, the first character in the first and second series cannot come again together for sixty years, or until the first year of the second cycle. Guabil says, that the year 1723 was reckoned the 40th year, or the year *koui-mao*, of the 74th sexagenary cycle, so that it is easy to ascend backwards to the commencement of the Chinese era. For 73 cycles of 60 years and the odd 59 years of the 74th cycle, amount to 4419 years, which will bring us to the year 2695 before the Christian era, or 347 years before the deluge, according to the chronology of the Hebrew text. But if, with sir George Staunton, in his "Embassy to China," (vol. ii. p. 555.) we reckon the year

CYCLE.

1797 the 54th year of the 68th Chinese cycle, its commencement must have been 2277 years B. C., or about 71 years after the deluge. The institution of this Chinese cycle is commonly ascribed to Hoang-ti, who lived above 300 years before Yao, the commencement of whose reign is dated by Du Halde, in the year 2357 B. C.

Cycle of *Cleostratus*, a period of eight years, or 2292 days, distributed into 99 lunations, viz. 96 of 29 and 30 days alternately, and three complete intercalary months. (Herod. l. i. c. 32 Gemin. Elem. Astr. c. 6.) This cycle was formed by Cleostratus, an astronomer of Tenedos, who flourished after Thales about the year 532 B. C. He observed, that one revolution of the sun being completed in 365 days 6 hours, was $11\frac{1}{4}$ days greater than 12 lunations of $29\frac{1}{2}$ days. These $11\frac{1}{4}$ days multiplied by 8, amount to 90 days, which are equal to three months of 30 days each. Hence he formed his cycle. This cycle, by which the Olympic games were regulated, would have been very exact, if a lunar year had consisted of $354^d 4^h 18'$; but, in reality, it consists of $354^d 8^h 48' 34''.7052$. The difference, viz. $4^h 30' 34''.7052$, in the space of eight years, would amount to $36^h 4' 37''.6416$; so that 99 lunations contain $2923^d 11^h 40' 45''.3179$. The moon, which should have been renewed at the conclusion of this cycle, was observed to be $1^d 13^h 10' 41''.3179$ distant from the time of conjunction. This error must have exceeded three days in 16 years, and 30 days in 160 years. The correction of it was attempted by succeeding astronomers. The addition of three days, which was made at the conclusion of two periods, corresponded nearly to the course of the moon, but not to that of the sun. Hence arose a confusion and perplexity, which excited the raillery of Aristophanes, in his comedy of the "Clouds." The partiality which many of the Greeks retained in favour of the cycle of Cleostratus induced Eudoxus to attempt the correction of it. He observed, that eight solar years of 365 days contained 2922 days, and that 99 lunations contained $2923\frac{1}{2}$ days. In the course of every period, therefore, the moon varied from the sun a day and a half, which amounted to a month of 30 days, in 20 periods, or in 160 years. The subtraction of this month from every 160 years constitutes the cycle attributed by Scaliger to Eudoxus. (De Emend. Temp. l. ii. p. 69.)

Cycle, *Metonic*, or lunar cycle of Meton, is a period of 6940 days, in which are very nearly completed 19 tropical revolutions of the sun, or solar years, and 235 lunations, or revolutions of the moon, with regard to the sun. After the completion of this cycle, the conjunctions of the sun and moon take place in the same degrees of the ecliptic, and consequently the new moons fall on the same days of the year as they did 19 years before.

Livy seems to ascribe the invention of this cycle to Numa Pompilius, and Geminus to Euctemon and Philippus; but the honour of it has been generally attributed to Meton, an Athenian astronomer, about 432 years before our era, for the purpose of regulating the festivals of the Greeks, which, on account of the imperfection of the calendar of that people, had gone into great confusion. The Greeks denominated it *ἑννεαδικαίτηρις*, *enneadikæteris*. It was published at the general meeting of the Greeks, assembled for the celebration of the Olympic games; and it was received with so much applause, that a statue was decreed to the inventor, and he was declared victor in the first department. The scheme of the festivals, arranged according to the new cycle, was publicly proposed, inscribed on a marble pillar in letters of gold; and hence the number which expresses the order of the current year in this cycle

is usually called the golden number. This cycle was adopted on July 16th, B. C. 433; and the new moon which happened P. M. $7^h 43'$, was the precise era of its commencement. The first day was reckoned from sun set.

The year of the Greeks consisted of 12 months of 29 and 30 days alternately; making in all a period of 354 days, which comprises very nearly 12 lunations, or full moons. This year corresponds to the mean conjunctions of the sun and moon within something less than nine hours. The great difficulty was to connect this lunar year with the revolution of the sun, so as to make the several months fall nearly in the same seasons. The Olympic games were celebrated every fourth year, during the full moon next after the summer solstice; and the year of the Greeks was so regulated as to make this the full moon of the first month. This purpose was effected by intercalations; but these were managed so injudiciously, that, in the time of Meton, the calendar and the celebration of the sacred festivals had fallen into great confusion. In the "Clouds" of Aristophanes, Diana, the goddess of the moon, is introduced greatly displeased that her course was no longer the standard by which the disposition of the festivals and the sacrifices to the gods was regulated: she complains bitterly that the deities were often disappointed of the repasts, which, on the return of the due times, they expected to receive from the devotion of their worshippers. This clearly shews the height to which the evil had reached, and proves that the necessity of mending the calendar was generally perceived; a circumstance which, while it would stimulate the exertions of ingenious men to find a remedy, would, at the same time, secure a favourable reception to a proper plan of reformation.

The Metonic cycle is recommended by its great simplicity: in this respect it is much to be preferred to any other period hitherto proposed for reconciling the motions of the sun and moon. Although it is possessed of considerable accuracy, it is yet far from being perfectly exact. An interval of 6940 days is neither precisely equal to 19 tropical years, nor to 235 lunations; it exceeds the former about $9\frac{1}{2}$ hours, and the latter about $7\frac{1}{2}$ hours. In four cycles these errors would accumulate to more than a day; and the several phases of the moon, which are very remarkable appearances, would be really observed to happen a day sooner than the times computed by the calendar. To remedy this defect, Calippus, who lived about a century posterior to Meton, proposed to cut off a day in four periods of 6940 days; and for this purpose he contrived a new cycle of 27,759 days, in which were contained 76 solar years, and 940 months or lunations. This new cycle is, in a considerable degree, more accurate than that of Meton; for it supposes the tropical year to consist of 365 $\frac{1}{4}$ days, and it is anticipated by the full moons only $5^h 53'$ in 76 years.

It is in the manner we have just been describing, that the primitive astronomy was first improved, and that a tolerably exact knowledge of the mean motions was first acquired. When the solstice, or the full moons, actually observed in the heavens, had separated from the calculated times by an interval too great to escape notice, the errors were cut off so as to bring the computations to correspond more nearly with the phenomena. And it is not difficult to conceive that, by repeated corrections of this kind, the mean motions might at length be determined with very great accuracy, without the help of nice and delicate observations, and even although astronomy, in other respects, should still continue in a rude state. This seems to be exemplified in the astronomy of the Hindoos, in which the mean motions are ascertained with great precision; at least the na-

ture of the methods employed in the astronomy of that people, favours this opinion.

The civil year, according to the calendars now in use, is entirely regulated by the motion of the sun; but certain festivals of the Christian church, such as that of Easter, do still depend upon the full moons that happen at determinate seasons of the year. The celebration of Easter, as laid down by the council of Nice in 325, is fixed for the first Sunday after the next full moon following the 21st of March; and thus our calendars, as well as that of ancient Greece, require a method of reconciling the motions of the sun and moon.

At the time this rule was established, the vernal equinox really happened on the 21st of March, and the framers of it seem to have imagined that this would always continue to be the case. The intention certainly was to make the Paschal moon depend on the vernal equinox: and if the Nicene decree mentions the day on which the equinox then happened, and not the equinox itself, without making any provision for the separation of these two events, this can only be accounted for from its not being adverted to that such a separation might possibly take place. The fathers of the council of Nice made no change in the civil year, which continued to be regulated by the Julian calendar as before. All that was then thought to be necessary for introducing into the church an uniform practice in regard to the times for celebrating the festivals was, to lay down a general rule for determining the Paschal full moon, and of course Easter Sunday. For this purpose the ancient cycle of Meton was adopted. If it be supposed that 235 lunations are precisely equal to 19 Julian years, it is plain that the Paschal full moons would happen on the same days of the month in the corresponding years of every cycle. For instance, if the Paschal full moon should fall on the 17th day of April of the fourth year of the current cycle, the same event would take place on the same day of the same month of the fourth year of all the following cycles. According to this supposition, it was only necessary to determine the Easter Sundays for one complete cycle, in order to have a perpetual table for all succeeding ages. Such was the simple scheme adopted by the church after the council of Nice; and this practice continued to be universally followed till the reformation of the calendar in 1582, and, by some of the Protestant churches, for a long time after.

But in process of time two things happened, which had not been provided for by the council of Nice, and which introduced confusion into the calendar, and a departure from the rule laid down for the celebration of Easter. The first of these was the separation of the vernal equinox from the 21st of March. In the 16th century the first full moon after the 21st of March was frequently not the first full moon after the vernal equinox, which it ought to be, according to the intention and spirit of the Nicene decree. In fact the vernal equinox, which in 325 fell on the 21st of March, in the 16th century actually happened on the 10th of the same month. This anticipation was owing to the excess of the Julian year, of 365 days 6 hours, above the actual time of a tropical revolution of the sun, which is only 365^d 5^h 48' 48". In an interval of 1300 years the 4th had anticipated the Julian calendar 10 complete days.

The second thing that happened was owing to the inaccuracy of the supposition on which the scheme for determining the Paschal full moons was founded; namely, that 235 lunations are exactly equal to 19 Julian years. The error of this supposition was precisely the same as that of the ancient period of Calippus, introduced to correct the

cycle of Meton; and it amounted to something less than a day in 304 years. In 1300 years, that elapsed between the council of Nice and the end of the 16th century, the full moons calculated by the rules of the church were later than the true full moons by nearly four days: and hence arose a distinction between the ecclesiastical full moons and the true ones.

The defects of the calendar, both in regard to the seasons and to the full moons, had been frequently the subject of discussion before the 16th century, and many plans of reformation had been proposed at different times. At last pope Gregory XIII., in 1582, accomplished the great work of reforming the calendar. As far as regarded the civil year the undertaking was neither very difficult nor very complicated. In order to bring the 21st of March to the equinox, as it was at the time of the council of Nice, 10 days were cut off, by calling the 5th day of October, 1582, the 15th of that month; and, in order to fix the equinox for the 21st of March in all time coming, three days were directed to be left out in every period of 400 Julian years, by making three consecutive centennial years common years, and the fourth a bissextile year; whereas, according to the old calendar, every centennial year was a bissextile year. This is equivalent to the supposition that 400 tropical revolutions of the sun are performed in 146,097 days; which, although it is not perfectly exact, is very near the truth. The error is in excess, and it amounts to a day in 36 centuries: and, on this account, a day extraordinary must be left out in that period of years. The first correction for this error will fall in the year 5203, which must be made a common year, although, in the general tenor of the calendar, it should be a bissextile year.

A more difficult part of the reformation of the calendar, was to connect the motions of the moon with the solar year, so as to lay down a rule sufficiently simple for determining the Paschal full moons. The scheme to which the preference was given is still founded on the Metonic cycle of 19 years, although a new set of numbers, called epacts, was introduced. By the epact of any year is understood the age of the moon on the first day of January of that year; or, it is the number of days elapsed since the last new moon. The epacts, it is evident, will be regulated by the excess of the solar year above 12 lunations, which are completed in it. Supposing a full moon to fall on the first day of January, the epact for that year would be 0; but next year it would be 11, which is the number of days that the solar year exceeds 12 lunations: the third year it would be 22: the fourth year it would be 3, namely, the excess of 33 above 30, the number of days that suffice for a lunation. In this manner the epacts for a complete cycle of 19 years are continued, by constantly adding 11 and dropping 30, when the sum exceeds that number: after which the series of numbers again recommences with a new cycle.

If 235 lunations had corresponded exactly to 19 Julian years, the series of epacts would have been perpetual, or constantly the same for every cycle: and the new calendar would have been in substance the same as the old method by the golden numbers. But this regularity of the epacts is disturbed by two causes; by the omission of the intercalary days in the secular years; and by the error of the cycle of 19 years, which amounts to a day nearly in three centuries. On the former account a day must be subducted from the series of epacts at the commencement of every century, whose first year is a common year; and on the latter account a day must be added to the same numbers after every interval of 300 years. In the language of the calendar,

C Y C L E.

the first correction is called the solar equation, and the latter the lunar equation. It thus happens that every century, for the most part, requires a new set of epacts; at the same time it is not difficult to infer from what has just been said that the same set will sometimes continue in use for two, and even for three centuries together. If we consider further that every set of epacts is derived from the epact of the first year of the cycle, and that this is necessarily a number less than 30, it will plainly appear that all the possible sets are limited to 30. In the scheme of the Gregorian calendar, the 30 sets of epacts are arranged in a table, and they are distinguished by as many letters of the alphabet, which serve as indexes: in another table the several secular years are contained, each having the letter annexed to it, which is the index of the set of epacts to be used for the following 100 years.

According to the Gregorian calendar, the series of epacts for 1800, which is to continue in use for the 19th century, is

1,	2,	3,	4,	5,	6,	7,	8,
*,	XI,	XXII,	III,	XIV,	XXV,	VI,	XVII,
9,	10,	11,	12,	13,	14,	15,	16,
XXVIII,	IX,	XX,	I,	XII,	XXIII,	IV,	XV,
XXVI,							
18,	19,						
VII,	XVIII,						

The figures denote the golden numbers, or the rank in the cycle of 19 years, and the Roman characters the epacts: the asterisk denotes either 0 or 30. In the year 1900, which is a common year, the epacts must be all carried back a day; thus,

1,	2,	3,	4,	5,	6,	7,	8,
XXIX,	X,	XXI,	II,	XIII,	XXIV,	V,	XVI,
9,	10,	11,	12,	13,	14,	15,	16,
XXVII,	VIII,	XIX,	*,	XI,	XXII,	III,	XIV,
17,	18,	19,					
XXV,	VI,	XVII,					

And this set of epacts will remain in use for the next 300 years: for the year 2000 being a bissextile year, there is no solar equation; and the year 2100 being a common year, and at an interval of 300 years from 1800, the solar and lunar equations both take place, and, being contrary to one another, they produce no change in the epacts.

It is to be remarked that the new moons do not anticipate the cycle of 19 years quite so much as a day in 300 years. The anticipation is very nearly only 8 days in 2500 years: and hence, after having applied the lunar equation

of the epacts seven times successively, at intervals of 300 years each time, it must be applied the eighth time at an interval of 400 years.

At the time of the council of Nice, when the lunar cycle of 19 years was adopted for computing the church festivals, it would have been most convenient to have made the series of cycles to commence with the era of Christ. Had this been done, the golden number of any proposed year, or its rank in the current cycle, would have been the remainder of the division when that year was divided by 19. But this consideration was neglected in preparing the table of the Paschal full moons, which was accommodated to the state of the heavens at its formation: and, on reckoning back, it was found that the first year of our era corresponded not to the first, but to the second year of the cycle of 19 years. Hence the golden number for any proposed year will be found by this rule: "Add 1 to the year and divide by 19; the remainder of the division is the golden number sought; if there be no remainder, the golden number is 19." The only use of the golden number, in the new or reformed calendar, is to find the epact.

If it be proposed to find the golden number for the year 1808: then 1809 being divided by 19 the remainder of the division comes out to be 4, the golden number for that year. In the set of epacts in use for the 19th century, it will be found that III corresponds to the golden number 4; this then is the epact for 1808, or the age of the moon on the first of January 1808, according to the calendar: whence all the full moons for that year may readily be found.

The calendar is entirely founded on the mean motions of the sun and moon, and the new moons computed by it would have coincided with the mean conjunctions of the sun and moon, if its epoch had coincided with the astronomical epoch. This, however, is not the case: the astronomical epoch is earlier than the epoch of the calendar, and the mean conjunctions of the sun and moon precede the new moons of the calendar.

As the lunar cycle of 19 years sometimes includes five leap-years, and sometimes four, it is impossible to have a correct table of all the numbers, unless it be extended to four times 19, or 76 years, in which there are 19 leap-years without a remainder. In this case, however, it must be adapted to the old style, because, in every customary year not divisible by 4, the regular course of leap-years, is interrupted in the new style, as was the case in the year 1800. Mr. Ferguson, in his "Astronomy," (p. 264—5.) has given a table, computed upon the regular old style plan, of the mean times of all the new moons to the nearest hour for 76 years, from the year of Christ, 1724, to the year 1800, inclusive: and he has also shewn how to make this table perpetual. The table is here subjoined.

CYCLE.

A TABLE, shewing the Times of all the Mean Changes of the Moon, to the nearest Hour, through four Lunar Periods, or 75 Years. M signifies Morning, A, Afternoon.

The year 1800 begins a new Cycle.

C Y C L E.

This table may be made perpetual, by deducting six hours from the time of new moon in any given year and month from 1724 to 1800, in order to have the time of new moon in any year and month 76 years afterward; or, deducting 12 hours for 152 years, 18 hours for 228 years, and 24 hours for 304 years; because, in that time the changes of the moon anticipate almost a complete natural day. And if the like number of hours be added for so many years past, we shall have the mean time of any new moon already elapsed. This table may be easily adapted to the new style, for any time to come. Thus, because the year 1724 in this table is the first year of the cycle for which it is made; if, from any year of Christ after 1800, you subtract 1723, and divide the excess by 76, the quotient will shew how many entire cycles of 76 years are elapsed since the beginning of the cycle here provided for; and the remainder will shew the year of the current cycle answering to the given year of Christ. Hence, if the remainder be 0, you must instead of it put 76, and lessen the quotient by unity. Then, look in the left-hand column of the table for the number in your remainder, and against it you will find the times of all the mean new moons in that year of the present cycle. And whereas, in 76 Julian years, the moon anticipates 5 hours 52 minutes, if these hours and minutes be multiplied by the quotient above found; the product subtracted from the times in the table will leave the corrected times of the new moons to the old style; which may be reduced to the new style, thus:—

Divide the number of entire hundreds in the given year of Christ by 4, multiply this quotient by 3, to the product add the remainder, and from their sum subtract two:—this last remainder denotes the number of days to be added to the times above corrected, in order to reduce them to the

new style. The reason is this; because every 400 years of the new style gains 3 days upon the old style, one of which it gains in each of the centenary years succeeding that which is exactly divisible by 4 without a remainder: but then, when you have found the days so gained, 2 must be subtracted from this number, on account of the rectifications made in the calendar by the council of Nice, and since by pope Gregory. It must also be observed, that the additional days found, as above directed, do not take place in the centenary years, which are not multiples of 4 till February 29th, Old Style, for on that begins the difference between the styles; till which day, therefore, those that were added in the preceding years must be used. *E. G. Required the mean time of new moon in April, A. D. 1808, N. S.*

From 1808 take 1723, and the remainder 85, divided by 76, gives a quotient 1 and remainder 9; against which, in the table, is April 13^o 8^h A: and subtracting from it 5^h 52' × 1, the above quotient, the remainder will be 13^d 2^h 8', the mean time, according to the old style; then the quotient of the entire hundreds in 1808 divided by 4 being 4, and the remainder 2, multiply 4 by 3; add the product 12 to the remainder 2, the sum will be 14, from which subtract 2, and the remainder 12, added to the above time, old style, viz. 13^d 2^h 8' gives 25^d 2^h 8' A. Hence, it appears, that the mean time of new moon in April, 1808 New Style, is the 25th day at 8 minutes past 2 in the afternoon.

If 11 days be added to the time of any new moon in this table, it will give the time, according to the new style, till the year 1800. And if 14 days, 18 hours, 22 minutes, be added to the mean time of new moon, in either style, it will give the mean time of next full moon according to that style.

This Table is adapted to the New Style.

Use of Table I. Find the even hundreds of any given year at the left hand, and take the odd years in the columns at the head of the table; and where the horizontal and vertical column meet, you will have the golden number (which is the same both in old and new style) for the given year. *E. G.* Let the year be 1808; and having found 1800 at the left hand of the table, look for 8 at the top; under this number, and even with 1800, we find 4, which is the golden number for that year. See **GOLDEN NUMBER**, and preceding part of this article.

To find the *Epact*; see **ΕΡΑΚΤ**, and the preceding part of this article.

CYCLE of the Moon, or Lunar CYCLE, a period of 19 solar years; equivalent to 19 lunar years, and 7 intercalary months, which was thought to contain exactly 6940 days, or 235 synodical months; in which time the new and full moons and her other aspects, are supposed to return to the same day of the Julian year.

This is also called the *Mutonic period*. (See the preceding article.)

CYCLE of the Sun, or Solar CYCLE, is a period of 28 years, after which the days of the month return to the same days of the week.

In order to connect the days of the week with the days of the year, the first seven letters of the alphabet are chosen to mark the several days of the week: and they are disposed in such a manner for every year, that the letter A shall stand for the 1st day of January; the letter B for the second day; the letter C for the third; and so on; the seven letters being constantly repeated in their order through all the days of the year. It is plain, from this disposition, that the same letter will answer to Sunday, or any other day of the week, throughout the whole year. The letter which stands for Sunday, in any year, is called the dominical letter for that year.

This cycle has no reference to the motion of the sun, as its name would seem to import. It has derived its appellation from the Latin name of Sunday, *Dies Solis*; the chief use of this cycle being to find the dominical letters, or the days of the year that answer to Sunday.

A common year of 365 days contains 52 weeks and 1 day: hence it follows, that the first and last days of a common year fall on the same day of the week, and answer to the same letter. Because the first day of every year is represented by the letter A, it is plain that if the first day of a common year be Monday, the seventh day will be Sunday, and the dominical letter for that year will be G: the following year will begin with Tuesday, and the sixth day of the year will be Sunday, to which the letter F corresponds:

if this second year be a common one, the third year will begin with Wednesday, and the fifth day of the year will be Sunday, and the dominical letter will now be E. Thus, if all the years were common ones, the several letters, taken in a retrograde order, would successively stand for Sunday, and the cycle of the dominical letters would be completed in seven years, after which the letters would return again in the same order. But this simple arrangement is disturbed by the bissextile, or leap years, each of which contains 52 weeks and two days. In order to correct the effect of the intercalation, and to cause the same letters to fall on the same days of the month, after the 29th of February, that they would have done if no intercalation had taken place, the whole series of letters must be shifted forward a day after the 29th of February: and thus every leap year has two dominical letters; the one to be used before the intercalary day, and the other, which always stands before the first in the order of the letters, to be used for the rest of the year. It now appears that there are five different dominical letters, all standing next one another in a retrograde order, required for every period of four years: and as it is easy to prove that no more than seven such combinations of five letters can possibly be formed, it follows that, in 28 years, all these combinations will be exhausted, the dominical letters will be again renewed in the same order as before, and the days of the month will return to the same days of the week.

If the contrivers of this cycle had consulted simplicity and convenience, they would have made the series of cycles to commence with the Christian era. This consideration has been neglected, and the first year of our era is found to correspond to the 10th of the solar cycle. Hence is derived this rule for finding the rank of any proposed year in the current cycle of 28 years. "Add 9 to the proposed year, divide the sum by 28, and the remainder of the division is the year of the solar cycle; if there be no remainder, the proposed year is the 28th year of the cycle." It will readily be observed that the first year of every cycle is a leap year, unless in the case of a centurial year, when the intercalary day is omitted.

The following table shews the disposition of the letters in the solar cycle for 100 years, beginning with 1800.

1	E	D	5	G	F	9	B	A	13	D	C	17	F	E	21	A	G	25	C	B		
2		C	6		E	10		G	14		B	18		D	22		F	26		A		
3			B	7		D	11		F	15		A	19		C	23		E	27		G	
4				A	8		C	12		E	16		G	20		B	24		D	28		F

C Y C L E.

The year of the cycle for 1808, found by the preceding rule, is 25; to which the dominical letters C B correspond. Hence, this year, which is a leap year, began on Friday, and will end on Saturday.

There is a peculiarity in the use of this table for the year 1800, which it may be proper to remark: the year of the cycle for 1800 is 17, to which the letters F and E correspond; but 1800 being a common year, the letter E is the dominical letter throughout the whole year.

In the year 1900, the order of the letters will be inter-

rupted by the omission of the intercalary day, and a new table must be constructed. For this purpose, it is only necessary to move the letters in the preceding table one place forward; so that the letters for the four first years of the cycle will be F E, D, C, B: and, because the year 2000 is a bissextile year, the order of the letters will not be again interrupted till 2100, and so long will the new table continue in force.

The dominical letter may be easily found for any year either before or after the Christian era, by the following tables:

Use of the Tables. In Table III. or IV. for Old Style or Table V. for New Style, look for the hundreds of years at the head of the table, and for the odd years, necessary for completing the given year, at the left hand; and where the columns meet, you have the dominical letter desired. Suppose it were required to find the dominical letter for the year of our Lord, 1808, New Style, look for 1800 at the head of Table V. and for 8 at the left hand of the same table; and in the angle formed by the lines of the two columns, we find CB, which are the dominical letters for that year, and shew that it is leap-year; because leap-year

has always two dominical letters, the change taking place at the end of February. If the dominical letters were wanted for the same year, old style, they will be found by Table IV. to be E D. But to find the dominical letter for any year before Christ, subtract 1 from that year, and proceed to find it, as before, by Table III. E. G. Let it be required to find the dominical letter for the 585th year before the first year of Christ, look for 500 at the head of Table III. and for 84 at the left hand; and in the meeting of the columns you find F E the dominical letter, indicating that year to have been leap-year.

The following table serves for finding the day of the month answering to any day of the week; or the day of the week answering to any day of the month, for any year past or to come.

TABLE VI. Shewing the Days of the Months for both Styles by the Dominical Letters.

Week Day.	A	B	C	D	E	F	G
	1	2	3	4	5	6	7
January 31	8	9	10	11	12	13	14

	21	22	23	24	25	26	27
	28	29	30	31			
June 30	4	5	6	7	8	9	10
	11	12	13	14	15	16	17
	18	19	20	21	22	23	24
	25	26	27	28	29	30	

Use of the Table. Having found the dominical letter for the given year, enter Table VI. with the dominical letter at the head; and under it, all the days in that column are Sundays, in the divisions of the months; those in the next column to the right hand are Mondays; those of the next are Tuesdays, and so on to the last column under G; from which go back to the column under A, and proceed as before. Thus, in the year 1808, the dominical letters in

new style are CB; then all the days under C are Sundays, those under D are Mondays, &c. to that year as far as Feb. 28; and those under B are Sundays for the rest of the year, and those under C are Mondays, &c. If it be required to find the day of the week answering to any day of the month, it may be easily had from the same table by the letter that stands at the top of the column in which the given day of the month is found. Thus, the letter that stands over the 28th of May is A, and in the year 585, B. C. the dominical letters were found to be FE, which, being a leap-year, and E taking place from the 24th of February to the end of that year, (see *BISSEXTILE*), shews by the table that the 25th of May was Sunday; and, therefore, the 28th must have been Wednesday. Hence, as it is said that the famous eclipse of the sun, foretold by Thales, by which a peace was brought about between the Medes and Lydians, happened on the 28th of May, in the 585th year B. C., it fell on a Wednesday. See *DOMINICAL LETTER*.

CYCLE of Indiction, or The Indiction, is a period of 15 years, continually renewed like the other cycles.

This cycle is merely chronological, and has no reference to astronomy. It was introduced at Rome under the emperors, and it began in the year 312 of our era. Authors are very much divided in regard to the purpose which this cycle was intended to serve, and even in regard to the time it was first introduced. The times for the payment of certain taxes, or tributes, seem to have been regulated by it.

We may suppose the series of indictions to have commenced three years before our era, and then the rank of any proposed year in the current circle will be found by this rule: "add 3 to the given year, and divide by 15; the remainder of the division is the year of the indiction: if there be no remainder, 15 is the year of the indiction."

Thus, if the year 1808 be proposed, it will be found that the year of the indiction is 11.

The Julian period is a space of 7980 years, obtained by multiplying together the numbers 28, 19, and 15, which are the years in the lunar and solar cycles, and the indiction. This period was first proposed by Joseph Scaliger in 1583, with the view of introducing into chronology a language at once uniform and free from uncertainty. The principle by which these advantages are obtained is simple and not difficult to prove; namely, that there is only one number, less than 7980, which, being separately divided by 28, 19, and 15, will leave three proposed remainders. Hence, it follows, that when the ranks of any proposed year in the three cycles are known, the place of that year, in the Julian period, will be thence determined. Thus, every year in this long period is marked by peculiar characters, that distinguish it from all other years. The chronology of events, prior to the Christian era, is often not a little perplexed; both because authors make use of the Julian years now employed, and because the epochs from which they reckon are, in many instances, arbitrary and hypothetical. On this account, there is much advantage derived from reducing the principal epochs made use of in ancient history to the correspondent years of the Julian period, by which means their relative places are clearly fixed, without danger of ambiguity.

The Julian period has given occasion to the proposing of an arithmetical question, for the purpose of finding the rank which any given year holds in it. To do this, it is necessary to determine a number, which, when separately divided by 28, 19, and 15, shall leave three given remainders: a problem which, in general, is indeterminate, but admits of only one answer, when the restrictions arising from the nature of the case are taken into view. This problem has been often resolved, and is attended with no difficulty: on

this account, we shall be content with inserting a rule, without stopping to give the invelligation of it. Let l denote the rank of the proposed year in the lunar cycle, S its rank in the solar cycle, and i its rank in that of the indictions; then, having found the value of the expression $4200 \times l + 4845 \times S + 6916 \times i$, let it be divided by 7980, and the remainder of the division will be the year of the Julian period required.

For the first year of our era, $l = 2$, $S = 10$, and $i = 4$; and hence that year is found to correspond to the 4714th of the Julian period.

This period commenced 710 years before the supposed year of the creation, or, as Usher states it, 4004 years B. C. At no later period than this could all the cycles begin together, and it is not yet completed; and therefore it includes all other cycles, periods, and eras. At the close of the 4713th year of this period was the Dionysian or vulgar era of Christ's birth; and consequently the first year of his age, according to that account, coincided with the 4714th year of the said period. Therefore, if to the current year of Christ we add 4713, the sum will be the year of the Julian period. And to find the year of the Julian period, corresponding to any given year before the first year of Christ, subtract the number of that given year from 4714, and the remainder will be the year of the Julian period.

CYCLE of Easter, Great Paschal Cycle, called also the *Victorian or Dionysian Period*, is the product of the solar and lunar cycles, or of 28 and 19, comprehending 532 years. If the new moons did not anticipate upon this cycle, Easter-day would be always the Sunday next after the full moon which follows the 21st of March. But on account of this anticipation, which was not duly regarded before the alteration of the style, the ecclesiastical Easter has been several times, within the last century, a week different from the *true Easter*: an inconvenience which is now remedied by making the table which was used for finding Easter for ever, in the Common Prayer Book, of no longer use than the lunar difference from the new style will allow. The earliest Easter possible is the 22d of March, and the latest the 25th of April. Within these limits are 35 days, and the number belonging to each of them is called the *NUMBER of Direction*; because it serves to find the time of Easter for any given year. In order to find this number of direction, according to the new style, first find the dominical letter, and then the golden number for the given year; then enter TABLE II. with the dominical letter at the left hand, and the golden number at the top; and where the horizontal and vertical columns meet is the number of direction for that year: which number, added to the 21st day of March, shews on what day either of March or April Easter Sunday falls in that year. *E. G.* The dominical letters for the year 1808 are CB, and the golden number is 4, and the number of direction, corresponding to these, is 27; which, reckoned from the 21st of March, gives the 17th of April for Easter Sunday.

CYCLES, in *Harmonics*, are certain determinate periods or series of pulses or vibrations, excited in the air by the consonance of two musical sounds.

Dr. Smith (*Harmonics*, p. 56.) distinguishes these, 1st, into *simple cycles*, when the least terms of the ratio expressing a small interval differ but by 1; 2d, *complex cycles*, when the least terms of such a consonance differ by more than unity; 3d, *short cycles*, formed by the pulses of perfect consonances, or such whose ratios are expressed in small numbers; and, 4th, *long cycles*, of the pulses of imperfect unisons, or other consonances, which are not expressible but by high or surd numbers.

In his seventh proposition, Dr. Smith demonstrates, "that in going from either end to the middle of any simple cycle, or period of the pulses of imperfect unisons, the alternate lesser intervals between the successive pulses increase uniformly, and are proportional to their distances from that end; and at any distances from it less than half the simple cycle or period, are less than half the lesser of the two vibrations of the imperfect unisons:" from whence he deduces as corollaries, 1. "That any simple cycle or period of the pulses of imperfect unisons contains one more of the quicker than of the slower vibrations." 2. "The lesser intervals that lie nearest to the periodical points, and the points of coincidence, are less than any of the rest." 3. "Some of the alternate lesser intervals of the pulses of imperfect unisons are the differences of equal numbers of their vibrations, counted from the nearest coincident pulses; and others are the differences of equal numbers of the same part or parts of their single vibrations, counted from the nearest periodical point." 4. "If the vibrations of two couples of imperfect unisons, or of any two consonances, be proportional, the periods and cycles of their pulses, whether simple or complex, will be in the ratio of the homologous vibrations." 5. "The length of the period of the least imperfections, in any consonance of imperfect unisons, is the same as that of the period of its pulses." At page 69, the following is deduced as one of the corollaries to his eighth proposition; viz. "The imperfect short cycle of any imperfect consonance contains equal numbers of the slower and quicker vibrations of the imperfect unisons, from whence it is derived."

If R and r be the least integers in the ratio of the interval between any two sounds, and V and v represent the times of their single vibrations, respectively; then will the length of the cycle of times between the successive coincidences of the pulses of V and v be rV or Rv ; because these multiples of V and v are the least of any which can be equal; R and r being prime to each other.

Also, if S and s be the least integers of another consonance, whose vibrations are V and v ; then the length of its cycle is sV or Sv .

Hence the length of the cycle of V and v , is to that of V and s , as r to s ; that is, consonances which have a common sound or vibration, V , have the lengths of their cycles proportional to the numerators of the fractions $\frac{r}{R}V = v$, $\frac{s}{S}V = v$, expressing the times of the single vibrations of the other sounds. Harm. p. 22.

Supposing the vibrations, V and v , of imperfect unisons to be incommensurable, or $V : v :: \sqrt{p} : \sqrt{q}$; and x to be an indeterminate vibration, and $V : x :: m : n$. Then if the ratios of the indeterminate numbers, m, n , be supposed to approach gradually to the given ratio of \sqrt{p} to \sqrt{q} ; though the length, nV or mx , of the indeterminate cycle of the pulses of V and x increase without limits, nevertheless the length $\frac{n}{m-n}V = \frac{m}{m-n}x$, of the indeterminate period of their pulses tends gradually to a determinate limit,

$\frac{\sqrt{q}}{\sqrt{p}-\sqrt{q}}V = \frac{\sqrt{p}}{\sqrt{p}-\sqrt{q}}v$. And this is the period of the pulses of the incommensurable vibrations, V, v , which excites the determinate sensation of this imperfect unison, be the complex cycle of their pulses ever so long, infinite, or impossible. The doctor adds, at page 102, "I say, determinate sensation; for though the alternate lesser intervals of the pulses in the several successive periods of V and v , even

when commensurate, are not precisely equal, yet it is highly probable that the ear could not distinguish a repetition of any one period from the succession of them all, and seems agreeable to experience, in observing the identity of tone of imperfect unisons held out upon an organ."

CYCLIDIUM, in *Zoology*, a genus of vermes, invisible to the naked eye, of a simple form, pellucid, flat, and orbicular or oval. They are found chiefly in vegetable infusions.

Species.

BULLA. Orbicular and transparent. Müll. *Cyclidium corpore orbiculi sub-fusco*, Hill.

Found in infusions of hay. Its colour is white and pellucid, with the margin rather dark; and its motion slow and circular.

MILIUM. Elliptical and crystalline. Müll.

Observed in vegetable infusions; its texture appears membranaceous, and is marked with a line through the whole length.

PEDICULUS. Oval and convex, beneath flat. Müll. Goetze, &c

Discovered by Trembley on the arms of the hydra fusca; the colour is white and gelatinous; with both extremities depressed and truncated, or sometimes one of them cleft.

NUCLEUS. Oval; posterior part acuminated. Müll.

Resembles a grape-seed; the intestines are visible, and the fore and hind part at each side are dark. Found in vegetable infusions.

ROSTRATUM. Oval; the anterior part ending in a point. Müll. Spallanz.

This species is pellucid and smooth, with a blue canal within branching into two arms, and two transverse blue lines just beneath the middle of the body.

RADIANS. Ovate, with distinctly visible intestines. Hermann. *Cyclidium corpore elliptico*, Hill, Spallanzani, &c.

Pellucid, with a blackish margin, and transparent vesicular intestines enclosed in a blueish pellicle.

GLAUCOMA. Oval, with the intestines hardly visible. Müll.

Found in water which had been kept in a stagnant state for the space of six months; it is pellucid, and membranaceous, with transparent greenish-blue intestines; the margin sometimes blackish.

CYCLIDIUM, a species of *TRICHODA* and also of *CERCARIA*; which see respectively.

CYCLISCUS, (from *κύκλος*, *circulus*;) an instrument in form of a half-moon; used by the surgeons to scrape the skull, in fractures of that part.

CYCLOGASTER, in *Ichthyology*, the *CYCLOPTERUS Liparis* of Gmelin; which see.

CYCLOGRAPH, in *Practical Geometry*, an instrument contrived, as its name imports, for describing the arcs of circles, and applicable to other useful purposes. This instrument (*Plate IV. Geometry, fig. 1.*) is composed of five rulers: four of them, $DE, DF, GE,$ and GF , forming a trapezium, are moveable on the joints, $D, E, F,$ and G ; the fifth ruler, DI , passes under the joint D , and through a socket carrying the opposite joint G . The distances from the centre of the joint D , to that of the joints E and F , are exactly equal, as are the distances from G to the same joints. The rulers, DE and DF , pass beyond the joints, E and F , where a roller is fixed to each; the rollers are fixed upon their axes, which move freely, but steadily on pivots, so as to admit of no shake by which the inclination of the axes can be varied. The ruler, ID , passing beyond

the joint D, carries a third roller A, like the others, whose axis lies precisely in the direction of that ruler; the axes of B and C extend to K and L.

A scale is put on the ruler DI, from H to G, shewing, by the position of the socket, G, thereon, the length of the radius of the arc in inches, that would be described by the end I, in that position of the trapezium. When the socket, G, is brought to the end of the scale near I, the axes of the two rollers B and C, the ruler DI, and the axis of the roller A, are precisely parallel; and in this position, the end I, or any other point in DI, will describe straight lines at right angles to DI; but on sliding the socket, G, towards H, an inclination is given to the axes of B and C, so as to tend to some point in the line ID, continued beyond D, whose distance from I is shewn by the scale.

A proper socket, for holding a pen or tracer, is made to put on the end I, for the purpose of describing arcs; and another is made for fixing on any part of the ruler DI, for the more convenient description of concentric arcs, where a number are wanted.

It is plain from this description, that the middle ruler, DI, in this instrument, is a true *oblique* ruler, by which lines may be drawn tending to a point, whose distance from I is shewn by the position of the socket, G, on the scale; and the instrument is made sufficiently large, so as to answer this purpose as well as the other.

In this instrument the part, intended to be used in drawing lines, lies within the trapezium, which on that account is made large; but this is not necessary. *Fig. 2.* exhibits another instrument of a similar kind, in which the trapezium may be made much smaller, and consequently less cumbersome.

DBEC represents such a trapezium, rollers, socket, and scale as above described, but much smaller. Here the ruler, ED, is continued a sufficient length beyond D, as to A, where the third roller is fixed; a pen or tracer may be fitted to the end E, or made to slide between D and A, for the purpose of drawing arcs. Adams's Geometrical and Graphical Essays, p. 151, &c.

CYCLOID. If a circle, EPF (*fig. 1.*), be made to roll along a right line, AB, in the same plane with the circle, until a fixed point, as P in the circumference, which at first touched the right line at A, comes to touch it again at B, after an entire revolution; then the curve, traced upon the plane by the point P, is called a cycloid. This genesis is familiarly illustrated by the tract made in the air by a nail in a coach-wheel; a tract which would be a perfect cycloid, could we suppose such a motion to be quite free from all the irregularities to which it is subject. The same curve is sometimes called a trochoid; and, by the French mathematicians, a roulette.

The cycloid is not a curve of great antiquity. Cardinal Cusa, about 1454, and a person whom Dr. Wallis names Carolus Bovillus, in 1500, in searching for the quadrature of the circle, both thought of rolling a circle along a right line, with the view of marking off a part equal to the periphery: but as they neither paid any particular attention to the curve traced by a fixed point in the circumference of the circle, nor gave a name to the line so described, their claim to the invention of the cycloid, although it is asserted by Dr. Wallis, seems to rest on very slender foundations. It appears from a letter written by Galileo to Torricelli, that the former of these celebrated men is more justly to be considered as the inventor of this curve, which he began to contemplate about 1559, and to which he gave the name of a cycloid, that it still bears. He informs us, that the shape of the cycloid seemed to him to be very proper for the arches

of a bridge. He likewise made some attempts to discover the proportion of the area of the curve to the area of the generating circle. In these attempts he was not successful; but the method which he employed, as related by Torricelli, if it reflect little credit on the geometrical invention of Galileo, deserves at least to be mentioned on account of its singularity. Having chosen some substance of an equable thickness and uniform texture, he cut it in the shape of a cycloid, and then, by weighing it, he tried to discover the proportion of the surface of the curve to the surface of the generating circle.

The invention of the cycloid is likewise ascribed, by the French writers, to Mersenne, who, without knowing that the same curve had already been noticed by Galileo, is said to have remarked it about 1615, when considering the motion of a wheel. It is certain that Mersenne first drew the attention of mathematicians to this curve. He proposed the problem concerning the area of the cycloid to Roberval, who appears to have discovered, about 1634, that the whole area was equal to three times the area of the generating circle. The determining of the tangents of the same curve, at that time a problem of no little difficulty, was accomplished by Des Cartes and Fermat. Mersenne, who carried on a correspondence with most of the learned men of his time, informed Galileo of the problems concerning the cycloid, which then occupied the attention of the French mathematicians: and, by this channel, the same curve came to be the subject of consideration in Italy. Torricelli resolved the problem concerning the area of the curve; and Viviani found the method of drawing tangents to it: and these discoveries were communicated to the public in an appendix to the works of Torricelli, printed in 1644. On this occasion, a keen contestation arose between Roberval and Torricelli concerning the originality of the discoveries made in Italy. The investigations of the French mathematicians were certainly prior in point of time; but, although they were handed about among the learned in France, they were not given to the public through the medium of the press: and there appears to be no good ground for the charge of plagiarism made by Roberval, which the original term of the demonstrations of Torricelli likewise helps to refute.

Pascal, under the feigned name of Dettonville, in 1658, proposed some problems concerning the cycloid to the contemporary mathematicians; and he engaged to give certain prizes to such as should resolve them against a limited time. In these problems it was required to find the dimensions of the segments of the cycloid, and of the solids generated by the rotation of these segments, and to determine the centres of gravity of the same spaces and solids: all matters of the greatest difficulty, and within the reach of mathematicians of the first rank only. On this occasion, many curious discoveries were made. Huyghens found out the exact quadrature of a definite portion of the cycloid; and Wren discovered the rectification of its arcs. But there were only two competitors, who, having considered all the problems of Dettonville, could have any pretensions to the prize. These were Dr. Wallis and La Louere, a Jesuit of Toulouse; and, on comparing the two performances given in, the superiority of that of the former was undisputed. The prize was not, however, awarded to Dr. Wallis: there were some mistakes in his calculations, and some errors in his results, which, in the opinion of the judges, justified them for withholding it. Dr. Wallis, on the other hand, contended that he had resolved all the proposed problems; and, although he admitted that there were mistakes in his original paper, some of which he had corrected by letters sent subsequent to the delivery of it, he asserted that these mistakes

CYCLOID.

were neither very essential, nor of such a nature as to set aside his claim by the conditions of the proposer. Thus this curve, like the apple of discord, was again the occasion of dispute and dissension.

In proportion as mathematicians advanced in their researches concerning the cycloid, the more interesting and remarkable did it appear for its curious and singular properties. Leibnitz found out another definite portion of the curve admitting an exact quadrature, different from that already discovered by Huyghens; and John Bernouilli shewed how innumerable spaces, all exactly quadrable, may be determined: a discovery that included in it, as particular cases, the two portions of Huyghens and Leibnitz. A still more curious and singular property is due to Huyghens, who demonstrated that the curve produced by the evolution of a semi-cycloid is another semi-cycloid, precisely equal to the first. Nor is the cycloid less remarkable for its mechanical than for its mathematical properties. Huyghens, by his researches concerning pendulum-clocks, was led to investigate the nature of the curve, along the arcs of which, whether great or small, the times of descent, or oscillation, of a heavy body, should be perfectly equal; and he found that the curve possessed of this curious property was no other than the cycloid. In 1697, John Bernouilli proposed the following problem to all the mathematicians of Europe: Suppose a heavy body to fall through a given height, in a direction oblique to the horizon, what is the nature of the curve along which it must descend, that the time of falling may be the least possible? It is extremely natural to suppose, that the time of descent would be least along the right line, which is the shortest distance between the beginning and end of the fall: but a little reflection is sufficient to correct this first suggestion of the kind; and it has been demonstrated, that the cycloid is the curve which, in this instance, likewise answers the required conditions.

In treating of the cycloid, we shall first demonstrate, as succinctly as possible, the geometrical properties on which its mechanical properties depend; these will engage our attention in the second place; and we shall, in the last place, notice the more remarkable propositions concerning the cycloidal spaces.

1. If we suppose the fixed point in the circumference of the circle (*fig. 1.*), or the generating point of the cycloid, to have touched the base-line, first of all at A, it readily follows, from the manner in which the curve is described, that when the circle has arrived at any other position, as FPE, the right line, AE, between A and the point of contact E, is exactly equal to PE, the arc of the circle between the fixed point, P, and the same point, E: and hence, AB, the whole base, is equal to the whole periphery of the generating circle. When the circle has made exactly half a revolution, as in the position CQD, then the describing point will be at C, diametrically opposite to the point D, in which the circle touches the base line; and consequently C will be the point of the curve farthest removed from the base, AB. It is also sufficiently plain, that the same curve will be described, whether the circle be rolled from A to B, or back again from B to A: whence it appears that the part of the cycloid between A and C is similar to the part between B and C.

The line, AB, is called the base of the cycloid.

The point, C, its vertex; the line, CD, bisecting the curve, its axis; the circle, CQD, upon the axis, the generating circle.

A line, as PR, parallel to the base, and bounded by the curve and the axis, is called an ordinate; and CR, the

distance of the ordinate from the vertex, the corresponding abscissa.

2. That part of the ordinate of a cycloid, between the curve and the convexity of the generating circle, is equal to the arc of the generating circle between the ordinate and the vertex; that is, $PQ = \text{arc } CQ$. When the describing point is at P, let the revolving circle touch the base at E; draw the diameter, EF, and join PE, QD. Because the diameters EF and CD, are both perpendicular to AB, it is plain that arcs, EP, and DQ, of equal circles, have equal versed sines; consequently these arcs will be equal to one another, and their chords, which make equal angles with the diameters EF and CD, will be parallel to one another. Hence EPQD is a parallelogram, and $PQ = ED$. Again, the semi periphery CQD = the right line AD, and the arc QD = arc PE = right line AE: therefore the arc CQ = the right line ED = PQ.

The whole ordinate PR is equal to the arc CQ, together with its right line QR.

If the radius of the generating circle be supposed = r , and the length of the arc CQ = x ; then the ordinate of the cycloid $PR = r + \sin. x$, and the correspondent abscissa $CR = r - \cos. x$. Thus it appears that the relation between the abscissa and the ordinate of this curve cannot be algebraically expressed by an equation of a finite number of terms; and therefore the cycloid belongs to the class of transcendent, or mechanical curves.

3. If an ordinate of a cycloid, as PR, cut the generating circle in Q, and QC be drawn to the vertex; then a line drawn through P, (*fig. 2.*) parallel to QC, is a tangent of the curve.

Let a and b be any two points of the curve on opposite sides of P, and from these points draw two ordinates to meet the generating circle in m and n , CQ or the same line produced in H and K, and the line drawn through P in M and N: also let a line touching the circle at Q, meet the two ordinates at S and T, and CE parallel to PR in E. It is plain that CE is a tangent of the circle: therefore $CE = QE$, and consequently, $QS = SH$, and $KT = TQ$. Therefore $mH = HS - Sm = QS - Sm$, is less than the chord Qm , and much more is it less than the arc Qm . But, as has been shewn, PQ , or MH , = arc CQ; therefore $MH - Hm$, or mM , is greater than arc $QC - \text{arc } mQ$, that is, than arc mC , or the right line ma . Again, $Kn = KT + Tn = QT + Tn$, is greater than the arc Qn ; for $QT + Tn$ is greater than the sum of two tangents, $QO + On$, drawn from the extremities of the arc Qn : (20. 1. E.) therefore $KN + Kn$, or Nn , is greater than arc $CQ + \text{arc } Qn$, that is, than the arc Cn , or the right line nb . And because mM is greater than ma , and Nn likewise greater than nb , therefore the right line drawn through P parallel to CQ, will meet the cycloid only in the point P, and, every where else, will be without the curve; therefore it is a tangent.

This demonstration, which is very elegant and geometrical, is due to Wren; it is published in an Appendix to Dr. Wallis's Treatise on the Cycloid. The same conclusion might have been derived from the common method for the tangents of curve lines. Let the tangent of the cycloid at P meet the axis produced in F; then, agreeably to the

general method, $\frac{PR}{RF} = \frac{\text{fluxion of } PR}{\text{fluxion of } RF} = \frac{1 + \text{Cof. } x}{\text{Sin. } x} = \frac{\text{Sin. } x}{1 - \text{Cof. } x} = \frac{QR}{CR}$; therefore the tangent PF is parallel to CQ.

CYCLOID.

4. Let two equal semi-cycloids, ACD and FAE , (*fig. 3.*) be placed in such a manner that their bases may be parallel, and the extremity of the base of the first may be upon the vertex of the second; then will the first be described by the evolution of the second. Let NH , a tangent of the second cycloid, meet the base of the first in H , and describe a circle equal to the generating circles of the cycloids to touch the same base in H , and produce NH to cut this circle in P : draw the ordinate NML , and the chord AM . Because NH is a tangent of the cycloid, it is parallel to the chord AM . And because AH is a common tangent of two equal circles, and the chords AM and PH are drawn from the points of contact to make equal angles with the common tangent, it is plain that these chords will divide the two equal circles into segments that are respectively equal to one another; therefore the arc AM is equal to the arc PH . But the arc AM is equal to MN , or to AH ; therefore the arc PH is equal to AH . Therefore when the revolving circle, by which the cycloidal arc AC is generated, comes to touch the base at H , the describing point will fall upon P , which is consequently a point in the curve. Draw the ordinate PQR , the chords CQ , EM , and ST , touching the cycloid at P : because the arc PH is equal to the arc AM , the chords of these arcs are equal and parallel, and hence $AL = DR$, and $CR = LE$; therefore the chord CQ is equal and parallel to the chord ME : but ST is parallel to CQ , and therefore it is also parallel to ME . Therefore because AM is perpendicular to ME , NP (parallel to AM) is perpendicular to ST (parallel to ME .) Thus all the tangents of the semi-cycloid ANF cut the semi-cycloid APC at right angles; and consequently, by what was proved of evolute and involute curves, under the head *Curvature*, the former semi-cycloid is the evolute of the latter.

5. An arc of a cycloid between the vertex and an ordinate, is double of the chord of the arc of the generating circle, between the vertex and the ordinate; that is, the arc AN is double of the chord AM . For if a thread be lapped up upon the semi-cycloid ANF , and, while the end that falls on F remains fixed, the other end, that falls on the vertex A , be moved so as to keep the thread always tight, and to unlap it from the curve; then, by what has been proved above, the moveable end of the thread will describe the semi-cycloid APC ; and, in every position of the thread, it is plain that the part of it which is detached from the curve, as NP , is equal to the arc AN , from which it has been unapp'd. Now it is manifest, from what has already been shewn, that $PH = AM = HN$; therefore the cycloidal arc AN is equal to the double of the chord AM .

Hence it appears that the whole arc of the semi-cycloid is double of the diameter of the generating circle.

This curious instance of the exact equality of the arc of a curve to a right line, is due to Wren; and it is the second instance of the kind that was discovered, the rectification of the Newtonian parabola having been the first. The demonstration here given of it is taken from Mr. Huyghens's treatise, *Horologium Oscillatorium*. Wren's own investigation is to be found in the Appendix to Dr. Wallis's treatise, *De Cycloide*.

The same conclusion may readily be obtained by the method of fluxions. For, the square of the fluxion of the arc $PC = 2x \dot{x}$; the fluxion of PR + square of the fluxion of $CR = x^2(1 + \cot^2 x)^2 + \dot{x}^2 \sin^2 x = 2x^2 \times$

$\frac{1}{2} + \cos^2 x = x^2 + \dot{x}^2 \cos^2 \frac{x}{2}$; therefore, the fluxion of

the arc $PC = 2x \dot{x} \cos \frac{x}{2}$; and, the arc $PC = 4 \sin \frac{x}{2}$;

but $2 \sin \frac{x}{2} = \text{chord } CQ$; therefore, the cycloidal arc $PC = 2 \text{ chord } CQ$.

Having now noticed the most remarkable geometrical properties of the cycloid, as far as is consistent with our plan, we are next to consider its chief mechanical properties.

6. Let a cycloid be placed with its base horizontal, and its vertex downward, as ABC (*fig. 4.*) then, if a body descend along the cycloidal arc, the increment of the velocity produced by the accelerating power of gravity in some small portion of time, as the 10th or 100th part of a second, at any part of the curve, as M , will be to the increment of the velocity, produced in the same small portion of time, at any other part of the curve, as N , as CM , the arc of the curve between the vertex and the first point M , is to CN , the arc between the vertex and the second point N . It is to be recollected that the force of gravity acts equally on all bodies in all circumstances; that it produces the same augmentation of velocity in a given time in a body descending with the greatest swiftness, as in one just beginning to obey its power. It is to be recollected too, that, when a body is made to descend along an inclined plane, part of the accelerating power of gravity is destroyed by the resistance of the plane, and the remaining part only (which is less than the whole accelerating force of gravity in the same proportion that the length of the inclined plane is greater than its height) is employed in increasing the velocity of the descending body. These things being premised, draw MR and NS tangents of the cycloid; draw also the ordinates MPF and NQG , and the chords of the generating circle CP and CQ . In a very small portion of time, as the 10th or 100th part of a second, the increment of the velocity of a body descending along the cycloidal arc at M , may be considered as equal to the increment of the velocity along the inclined plane MR , which touches the cycloid at M ; but MR is parallel to PC ; and the increment of velocity produced by the whole accelerating power of gravity, is to the increment of velocity produced in the same time on the inclined planes MR or PC , as PC is to CF , or as DC is to PC ; therefore, the increment of velocity produced by the whole accelerating power of gravity, is to the contemporaneous increment of the velocity of a body descending along the cycloid at M , as DC is to PC .

And in the very same manner is it shewn, that the increment of velocity produced by the whole accelerating power of gravity in a very small portion of time is to the contemporaneous increment of the velocity of a body descending along the cycloid at N , as DC is to CQ . Therefore it follows (*ex aequo*) that the increment of velocity in the cycloid at M is to the increment of velocity at N , as the chord PC is to the chord CQ . Now the chord PC is the half of the arc CM , and the chord CQ the half of the arc CN ; whence the proposition is manifest.

7. Supposing a cycloid to be placed as before, the time, in which a heavy body descending along the curve will reach the vertex or lowest point, is the same whatever be the length of the arc, through which the body has fallen. For the sake of presenting a more precise object to the mind we shall suppose that the arc CM is double of the arc CN , *fig. 4.*; and it is to be proved that the times of falling through these arcs are exactly of the same duration. The descending bodies being supposed to be let go from the points

CYCLOID.

points M and N at the same instant, let them arrive at the points $m, m', m'', \&c., n, n', n'', \&c.$ at the end of any very small equal moments of time, as 10th parts or 100th parts of a second. On the supposition that has been made it will follow, from what was proved (art. 6), that the velocity generated in the cycloid at M in one moment of time will be double of the velocity generated at N in the same time: therefore the velocity with which the one body arrives at m , will be double of the velocity with which the other body arrives at n . It is no less evident that the little arc Mm described by the first body is double of the little arc Nn , described by the second body; consequently the arcs Cm and Cn , that remain to be described, have the same proportion as the whole arcs CM and CN ; therefore, in a second moment of time, the increment of velocity at m will be double of the increment of velocity at n (art. 6). And because the whole velocities, already acquired at m and n , are double one of another, and the new increments superadded likewise follow the same proportion, therefore, at the end of the second moment of time, the whole velocity acquired at m will be double of the whole velocity acquired at n , and the space mm' will be double of the space nn' . Again, because mm' is double of nn' , therefore the arcs Cm' and Cn' , that remain to be described, will still have the same proportion as the whole arcs CM and CN , and consequently the increments of velocity generated in a third moment of time, as well as the spaces run through $m'm''$ and nn'' , will be to one another in the same proportion as the arcs CM and CN ; therefore, at the expiration of the third moment, the whole velocities acquired, and the arcs Cm'' and Cn'' that remain to be described, will both have the proportion of 2 to 1. And because the same reasoning may be continued indefinitely, it follows, that at the end of any proposed time from the beginning of the falls, the whole velocities acquired, and the parts of the arcs that remain to be described, preserve invariably the same proportion as the original arcs CM and CN , that is, in the present instance, the proportion of 2 to 1; hence it is manifest, that the falls through the whole arcs are accomplished in the same time.

Although, in this demonstration, the arc CM is supposed to be double of the arc CN , yet the proposition is to be held as proved generally for all proportions of the arcs; for the reasonings do in no respect depend upon the particular proportion supposed, but are equally applicable for all proportions.

Not only are the falls through the whole arcs MC and CN performed in the same times, but the same thing is likewise true of the falls through any proportional parts of the same arcs. For the parts $Mm, m m', m' m'', \&c. Nn, nn', n' n'', \&c.$ of the two arcs that are described in the same moments of time, have been shewn to be respectively in the same proportion as the whole arcs; and therefore any aggregates of those parts will compose like parts of the whole arcs.

When a heavy body has descended through an arc of the cycloid, it will have acquired such a degree of velocity as is sufficient to make it ascend through an arc in the opposite part of the curve equal to that it fell through; it will then be reduced to a state of rest, after which it will fall back to the lowest point of the curve, and again mount up to the same height as at first. A body that thus descends and ascends is said to oscillate or vibrate; and the time employed in one descent and ascent is called the time of an oscillation or vibration. When a body oscillates in a cycloid, placed as has been supposed, all the oscillations will be performed in equal times, whether they

be wide or narrow; for the times of ascent and descent being equal, the time of an oscillation will be double of the time of descent.

Galileo first remarked that the vibrations of a pendulous body, suspended by a string, or chain, were isochronous, or of equal duration; and this discovery had been applied in astronomical observations. Two things rendered the use of such pendulums very imperfect even for the purposes of astronomy; they required the constant attention of the observer to number the vibrations, and to communicate new velocity as the motion was destroyed by the resistance of the air. Galileo had turned his thoughts to remedy these imperfections; but in this research he was not successful. Huyghens first entertained the idea of applying a pendulum to regulate the motion of a piece of mechanism, whilst at the same time the moving power of the machine should act on the pendulum in such a manner as to keep its motion from being spent; and he thus accomplished an invention of the greatest utility in common life, and no less essential to the improvement of some of the sciences, particularly astronomy. Galileo thought that all the vibrations of a pendulum swinging in a circle, whether great or small, were of equal duration; but a little experience was sufficient to correct this erroneous opinion. Huyghens, aware that the narrow vibrations in a circle were performed in shorter times than the wider ones, was led to investigate the curve in which all the oscillations, whether wide or narrow, would be perfectly isochronous; and on this occasion he discovered those curious properties of the cycloid, which he has demonstrated with all the elegance and rigour of the ancient geometry, in his *Horologium Oscillatorium*.

But it was not sufficient to have discovered the curve in which the oscillations would be of equal duration; a method was likewise wanted for making the body oscillate as required. A new research was thus presented to Huyghens, and from this sprung his beautiful theory of evolute and involute curves.

Fig. 5. If two moulds, shaped like a semicycloid, be placed so as to have their bases horizontal and to touch one another in F , from whence a pendulum is suspended by a flexible thread equal in length to the whole semicycloid, or to twice the diameter of its generating circle; it is plain, from what is proved in art. 4, that such a pendulous body will vibrate in a cycloid, and will perform all its vibrations in equal times: for the curve described by the vibrations is made up of the involutes of the semicycloids AF and FP , which taken together compose a cycloid equal to the evolutes, and so placed as to have its base horizontal, (Art. 6.). It is not a little mortifying that the finest inventions, which have cost much pains and ingenuity, are often of little practical utility. This has been the fate of Huyghens's theory in the present instance. The perfect isochronism of the cycloidal vibrations is more than counter-balanced by the unavoidable imperfections of the mechanism which they require, and they are universally rejected in practice for circular oscillations in small arcs.

8. A cycloid being supposed to be placed as before, the time in which a heavy body, that descends through any arc of the curve, will reach the lowest point, is to the time in which a heavy body will fall through the diameter of the generating circle, as half the circumference of a circle is to its diameter.

As the times of descent in all arcs (*Fig. 6.*) of the cycloid are of equal duration, we shall consider the fall through

CYCLOID.

through the half of the curve. Suppose then, that a heavy body, which has begun to fall at B, is come to M; draw the ordinate MQP, and the chords of the generating circles DQ, QC: let Mm be a part of the curve moved through in a very small, but finite, portion of time, as the 10th or 100th part of a second; draw mrrn parallel to MP, and QO to the centre of the generating circle. Because the tangent of the cycloid at M is parallel to the chord QC, therefore $nQ = Mm$. There is no proposition respecting motion more familiar than this; that the velocity acquired by a heavy body in descending from any height is the same, whether the fall be made directly in the perpendicular, or obliquely on an inclined plane, or along any arc of continued curvature; from this it follows, that the velocity acquired by descending through the arc BM is equal to the velocity acquired by falling directly through the height DP; therefore the velocity in the curve at M is to the velocity acquired by falling through the diameter DC (which velocity we shall denote by a) in the subduplicate proportion of DP to DC, or as DQ is to DC; therefore, taking the halves of the consequents, the velocity in the curve at M is to the velocity $\frac{a}{2}$ as DQ is to DO. Because the angles DQC and OQr are right angles, therefore the angle DQO = angle nQr: Also the angle ODQ = PQC = Qnr; therefore the triangles ODQ and nQr are similar; consequently OD is to DQ as nQ or Mm is to Qr. Hence it is manifest that the velocity in the curve at M is to the velocity $\frac{a}{2}$ as Mm is to Qr: therefore a

body moving with the velocity $\frac{a}{2}$ would describe the little arc Qr in the same time that the descending body moves through the little arc Mm. The same thing may be demonstrated of all the little arcs that compose the whole semi-cycloid BMC, and the corresponding parts that make up the whole semi-circle DQC; therefore the whole time of the fall through the semi-cycloid BMC, is equal to the time in which the semi-circumference DQC would be described with the velocity $\frac{a}{2}$. But the time of falling perpendicularly through the diameter DC, is equal to the time in which the same diameter DC would be described with the velocity $\frac{a}{2}$. Hence it follows that the whole time of descent along the semi-cycloid is to the time of falling perpendicularly through the diameter DC, as the semi-circle DQC is to the diameter DC.

The whole time of a complete oscillation in any arc of a cycloid, is to the time of falling perpendicularly through the diameter of the generating circle as the circumference of a circle is to its diameter; for the time of an oscillation is double of the time of descent through the arc.

If a circle be described from F, the point of suspension of a pendulum that vibrates in a cycloid so as to touch the cycloid at its lowest point, (fig. 5.) this circle will be the oscillating circle of the curve (Art. 6.); and the time of a vibration in the cycloid will approach the nearer to an equality with the time of a vibration of the same pendulum in the circle, the less is the arc of the circle the pendulum moves through. The time of vibration in an arc of the circle, how small soever, will indeed be always greater than the time of vibration in the cycloid; but, when the circular arc is very small, the difference of the times is insensible.

Hence we learn the reason of the isochronism of vibrations in small circular arcs.

And hence too it is plain, that the time of a complete vibration in a small arc of a circle, is to the time of falling perpendicularly through half the length of the pendulum, as the circumference of a circle is to its diameter: for the time of vibration in the small circular arc, may be considered as equal in duration to the time of vibration of a pendulum of equal length in a cycloid.

By means of experiments made with pendulums, we can discover with great accuracy, the measure of the accelerating force of gravity, or the space through which a falling body will move in a given time. Thus, suppose l to be the length of a pendulum which has been found by experiment to vibrate once in a second, and let ω be $= 3.1416$ the periphery of a circle whose diameter is unit; then l will be the measure of the velocity acquired in falling through $\frac{l}{2}$ half the length of the pendulum, and $\frac{\omega l}{2}$ will be the measure of the velocity acquired in the time of one vibration of the pendulum, that is, in a second: let x be the space fallen through in the same time, then, because the spaces fallen through are proportional to the squares of the velocities acquired, $\frac{1}{2}l : x :: l^2 : \frac{\omega^2 l^2}{4}$: therefore $x = \frac{\omega^2 l}{2}$. In this manner it is found that a heavy body moves through $16\frac{1}{2}$ feet in the first second of its fall, and acquires a velocity of $32\frac{1}{2}$ feet per second.

We should next shew that the cycloid is the curve of swiftest descent: but this property cannot be clearly demonstrated, without entering upon considerations which would take up too much of our room for a matter of speculative curiosity. We proceed to finish what we have to say of this interesting curve, by noticing the most remarkable things that have been discovered concerning the mensuration of the cycloidal spaces.

9. Let MP (fig. 7.) be an ordinate of the cycloid, and draw the tangents at the extremities of the arc, MF, to meet in N, and also the chord of the generating circle FQ: then is the mixtilineal space bounded by the cycloidal arc MF, and its two tangents equal to the segment of the generating circle cut off by the chord FQ. Divide the circular arc, FQ, into an indefinitely great number of equal parts Qa, ab, &c., and draw the ordinates ac, bd, &c. as also the chords of the generating circle Fa, Fb, &c., and the lines ge, fb, &c., touching the cycloid at c, d, &c. Because the several tangents of the cycloid are respectively parallel to the chords FQ, Fa, Fb, &c., and FN, which touches the cycloid at the vertex, is parallel to MQ, ca, db, &c., therefore FN = MQ = arc FQ; Fe = ca = arc Fa; Ff = db = arc Fb, &c. Therefore, Ne = arc Qa, ef = arc ab, &c. And because what has been shewn is true, whatever be the number of the parts into which the arc FQ is divided, it will still be true when the number of parts is so great that the little arcs Qa, ab, &c. may be regarded as right lines: but when this is the case, the little triangles aFQ, aFb, &c. are plainly equal to the little triangles Nge, ebf, &c. each to each: for the bases of the triangles have been shewn to be equal; and the angles which the chords make with the periphery at Q, a, b, &c. are equal to the angles which the same chords make with the periphery, or with the tangent of the periphery, at F, that is, to the angles which the tangents MN, ge, bf, &c. make with the same tangent FN. Therefore the mixtilineal space included by the cycloidal arc and its two tangents, which is the aggregate of one of the

the sets of triangles, is equal to the circular segment, which is the aggregate of the other set of triangles.

In the case of the semi-cycloid A F, the mixtilineal space, A F T, is equal to the semicircle C Q D; and because the whole rectangle, A T F D, contained by the diameter and the semi-periphery, is equal to four times the same semicircle; therefore the semi-cycloidal space, A F D, is triple of the semicircle, and the whole area of the cycloid is triple of the area of the generating circle.

If M K be drawn perpendicular to F N, then the external space M K F, is equal to the circular space F Q P: for the triangle, M N K, is equal to the triangle F Q P.

10. If the ordinates M P and N Q, (*fig. 8.*) - cut off abscissas from the axis whose sum is equal to the radius of the generating circle, and if the chord, M N, be drawn, the cycloidal segment, M C N, will be equal to the sum of the rectilineal triangles D R Q, and D S P. Let O be the centre of the generating circle, and draw M K, N H, perpendicular to the tangent through the vertex. The trapezoid K M N H is = $KH \times \frac{MK + HN}{2} = \frac{1}{2} CO \times KH$ (hyp.) = $\frac{1}{2} CO \times MP + \frac{1}{2} CO \times QN$. Now, $\frac{1}{2} CO \times MP = \frac{1}{2} CO \times MS + \frac{1}{2} CO \times SP = \frac{1}{2} CO \times \text{arc. CS} + \frac{1}{2} CO \times SP =$ mixtilineal area S D C: and in like manner is it shewn, that $\frac{1}{2} CO \times QN =$ mixtilineal area C D R. Therefore the trapezoid K M N H = mixtilineal area S D R. But the outward spaces M K C and N H C, are equal to the circular areas C S P, and C R Q: therefore the remainders are equal; that is, the segment, M C N, is equal to the sum of the two triangles S P D, and R Q D. This property of the cycloid was discovered by John Bernouilli.

When the ordinates, M P, and N Q, coincide in one, as *mn*, the abscissas cut off will be half the radius C O: then the segment, *m C n*, will be equal to the triangle S D r, which is the equilateral triangle inscribed in the generating circle. The quadrature of this segment of the cycloid was discovered by Huyghens.

On the other hand, when one of the abscissas vanishes, and the other becomes equal to the whole radius; then the cycloidal segment, C l, will be equal to the triangle D O E, that is, to half the square of the radius. The quadrature of this segment was discovered by Leibnitz.

Protracted and Contracted Cycloid.—Supposing a circle, or wheel, to roll along a right line; let a fixed point be assumed, not in the periphery, but within it; then such a point, in one entire revolution, will trace a curve line, the base of which is equal to the whole periphery of the rolling circle, and therefore greater than the periphery of the concentric circle drawn through the fixed point: the curve line, so described, is called a protracted cycloid.

And if a point be assumed without the rolling circle, then such a point will trace a curve line, the base of which will be the same as before, and therefore less than the periphery of the concentric circle drawn through the fixed point; the curve line, so described, is called a contracted cycloid.

Let *m* denote any number, or proportion, then if a curve line be constructed by making the abscissa = $1 - \text{Cof. } x$, and the correspondent ordinate = $m \times x + \text{Sin. } x$: this curve will be a protracted cycloid when *m* is greater than 1: it will be a common cycloid when *m* = 1: and a contracted cycloid when *m* is less than 1. What is here said, is easily deduced from the definitions that have been laid down: and the nature of the curves being now defined by an equation,

their properties may be investigated by the common analytical process so well known.

It is asserted above, that the whole base of a protracted cycloid is equal to the periphery of the rolling circle; and this cannot be doubted: but, because every point of the periphery of the smaller concentric circle drawn through the fixed point, is successively applied to the same base during the description of the curve; it has been contended that the same line is also equal to the periphery of the smaller circle.

By this reasoning, it has been thought the circumference of the nave of a coach-wheel is proved to be equal to the periphery of the outer rim. How is the inconsistency to be explained? This curious mechanical problem was first proposed by Aristotle; and that philosopher himself, as well as many others, have given solutions of it which are not, in every instance, completely satisfactory.

The difficulty will be best unravelled, by separating into its elementary parts the complex motion by which the cycloids are described. It is plain that two motions are combined together in the description of these curves; one of them, an angular motion round the centre of the rolling circle, or wheel; the other, a progressive motion by which the centre is carried forward in a right line. These two motions are perfectly distinct and independent on one another; and the rolling of a circle or wheel along a right line, is to be considered as nothing more than the mechanical means of combining them in the requisite proportion. Instead of a circle rolling on a right line, conceive a wheel turning upon an axle, while the axle itself is made to move in a rectilineal course; it is manifest that the two cases differ in no respect, and are to be considered as equivalent. The two motions being now conceived in a detached and separate manner, the rectilineal space through which the centre is carried, may be supposed to bear any required proportion to the circular arc, that the fixed point moves over in the same time: now if the rectilineal space be exactly equal to the circular arc, we have the case of the common cycloid; if the rectilineal space be greater than the arc, we have the case of the protracted cycloid, where the line moved through by the progressive motion of the centre, by the very supposition made, is greater than the arc described in the same time; and if the rectilineal space be less than the arc, we have the case of the contracted cycloid, where the line moved through by the progressive motion is less than the arc described in the same time.

If a circle be made to roll upon the circumference of another circle, instead of a right line, a new set of curves, called epicycloids, will be generated by a fixed point in the plane of the rolling circle. These curves, which are useful in determining the figure of the teeth of wheel-work, will engage our attention under another head.

CYCLOIDAL SPACE, the space contained between the cycloid and its subtense.

CYCLEMETRY, from κυκλος, *circle*, and μετρο, *I measure*, the art of measuring cycles, or circles.

CYCLOPÆDIA, from κυκλος and παιδεια, *instruction*, the circle, or compass of arts and sciences; more ordinarily called *encyclopædia*.

The word cyclopædia is not of classical authority, though frequent enough among modern writers, to have got into several of our dictionaries. Some have censured us for having called the present work by this name; not considering that names and titles of books, engines, instruments, &c. are in a great measure arbitrary; and that authors make no scruple even of coining new words on such occasions, when there are no old ones to their mind. Thus it is Dr. Hooke calls

calls his fine book of microscopical observations, Micrographia; Wolfius his book on the air, Aerometria; Drake his book of anatomy, Anthropologia, &c.; all of them words of modern, if not of their own fabric; and on no better authority stand the names of half our later inventions, as *microscope, telescope, barometer, thermometer, micrometer, &c.* But it is suggested the word cyclopædia is ambiguous, and may denote the *science of a circle*, as well as the *circle of sciences*: we answer, that as custom, the only sovereign rule of language, has determined the word to the latter sense, it is no more chargeable with ambiguity than a thousand other words of received use; no more, for instance, than *micrometer*, which might either denote a *little measure*, or a *measure of little things*.

CYCLOPES, in *Entomology*, a class of the monocus genus of insect, according to Muller, with two or four antennæ. See MONOCULUS.

CYCLOPES, from *κύκλωρ*, and *ὄψ*, *eye*, in *Mythology*, a people who were said to inhabit the western part of the island of Sicily, in the primitive times, together with the Læstrigones. According to Justin, Pliny, Solinus, and Thucydides, they were the first inhabitants of this island; and they are said to have settled in the territory of Leontium, and the districts in the neighbourhood of mount Ætna. Their origin, however, was unknown; and Thucydides acknowledges, that he knew neither the country from which they came, nor that to which they afterwards removed. According to Hesiod they were the sons of Ouranus and Tellus, or of heaven and earth; but of Neptune and Amphitrite, according to Euripides and Lucian. They were called Cyclopes from their being described with but one eye, placed in the middle of their forehead, and were of gigantic stature: they were said to be the companions of Vulcan. They are represented as a people lawless, savage, and delighting in human flesh; which character arose from the cruel custom of sacrificing strangers whom fortune brought upon their coast. It is related that Apollo killed the principal among them, for having forged the thunder-bolts which Jupiter hurled against his son Æsculapius. The adventures of Polyphemus, the chief of these people, whose residence was near the foot of mount Ætna, with Ulysses and Galatea, are well known.

The explanation of this allegory has been represented to be man in a state of uncultivated nature; unskilled in the laws of civil society, and living in a state of brutal force, having but one sense, which was sight. Him Ulysses overcame by superior knowledge and experience. Homer, in his "Odyssey" (l. ix. v. 106, &c.), describes the Cyclopes as having no laws. Each, he says, governs his family, and rules over his wife and children. They trouble not themselves with their neighbours, and think not themselves interested in them. Accordingly, they have no assemblies to deliberate on public affairs; they are governed by no general laws to regulate their manners and their actions. They neither plant nor sow: they are fed with the fruits which the earth produces spontaneously. Their abode is in the summits of mountains, and caverns serve them for a retreat. Such is Homer's account of them. But though the Greek and Roman poets, and even Strabo, together with other respectable writers, have taken it for granted, that the Cyclopians of Homer were near Ætna in Sicily; the poet does not once mention the island in his whole account of the Cyclopes; nor does Ulysses arrive in Sicily till after many subsequent adventures. His Cyclopians were, therefore, inhabitants of the continent. There were probably people of the same family in many parts of Sicily, who seem to have been of the Anakim race, and worshippers of the sun; espe-

cially about the city Camarina. The fable of their having only one eye, some have explained by observing, that they were the archers of their times, and that they usually shut one eye to take their aim in shooting. (Shuckford's Connection, vol. iii. p. 52.)

The Cyclopes, according to Dr. Bryant, were a tribe of the ancient Amonians, of a size superior to the common race of mankind, who settled in many parts of Greece. They were famous for architecture; and the idea of this people was borrowed from the lofty towers which they erected. As these buildings were often light-houses, and had, in their upper story, one round casement, by which they afforded light in the night, the Greeks made this circumstance a characteristic of the people. They supposed this aperture to have been an eye, which was fiery and glaring, and placed in the middle of their foreheads.

The Cyclopians, says Pausanias (lib. ix. p. 785), were truly wonderful for the temples which they erected to the gods, and for the stately edifices which they built for men. When the Sibyl in Virgil shows Æneas the place of torment in the shades below, and leads him through many melancholy recesses, we find that the whole was separated from the region of bliss by a wall constructed by the Cyclopians. The Sibyl accordingly at their exit tells him:

"Cyclopium educta Carminis
Mœnia conspicio." Æn. l. vi. v. 630.

From hence we find that they were the reputed builders of the infernal mansions: a notion which arose from the real buildings about the infernal regions, and the torments of hell, were taken from the temples in each country; and from the rites and inquisition practised in them. The Cyclopians, however, were more than imaginary operators. They founded several cities in Greece; and constructed many temples to the gods, which were of old in high repute. The Scholiast upon Statius (Thebaid. l. i. p. 26.) observes concerning them, that every thing great and noble was regarded as Cyclopians. These people are said to have built the ancient city of Mycene, which Hercules in Seneca threatens to ruin.

"Quid moror? majus mihi
Bellum Mycenis restat, ut Cyclopea.
Everfa manibus mœnia nostris concidunt."
Hercules Furens, act. iv. v. 996.

They likewise built Argos; which is mentioned by Thyestes in Seneca (Act. ii. v. 406.) as a wonderful performance.

"Cyclopium Sacras
Turres, labore majus humano decus."

They built also several other cities in Greece, as Hermione, an ancient city, which stood near a stagnant lake, called the pool of Acherusia, and a deep cavern, which was supposed to be the most compendious passage to the shades below, near which yawning cavern the Cyclopians chose to take up their habitation (Strabo, lib. viii. p. 573.):—Tiryns, the walls of which were esteemed no less a wonder than the pyramids of Egypt (Pausan. l. ii. p. 147. l. ix. p. 783. Strabo, l. viii. p. 572.):—and they resided at Nauplia in Argolis, near which city were caverns in the earth, and subterraneous passages, consisting of labyrinths cut in the rock, like the Syringes in Upper Egypt, and the maze at the lake Moeris, which were reported to be the work of Cyclopians. Euripides (Herc. Furens, v. 944.) speaking of the walls of ancient Mycene, as built after the Phœnician

Phœnician rule and method, ascertains the country from which the Cyclopians came: the Phœnicians alluded to being the Φαίνοι of Egypt, to which country they are principally to be referred. The seven Cyclopes, who, according to Strabo (l. viii. p. 572.), built Tiryns, were, as Bryant suggests, seven Cyclopians towers built by these people; some of which were situated towards the harbour, to afford light to ships, when they approached in the night. These towers were likewise erected for Purait, or Purathœia, where the rites of fire were performed. Mr. Bryant conceives, that not only the common idea of the Cyclopians was taken from towers and edifices; but that the term Κυκλωψ, and Κυκλωπις, Cyclops, and Cyclopius, signified a building or temple, and from thence the people had their name. They were of the same family as the Cadmians and Phœnicians; and as the Hivites, or Ophites, who came from Egypt, and settled near Libanus and Baul-Hermon, upon the confines of Canaan. They worshipped the sun under the symbol of a serpent: and hence they were styled, in different parts where they settled, Europians, Orpians, Inopians, Afopians, Elopians; all which names relate to the worship of the Pytho Ops, or Opis. Our learned author does not determine the precise etymology of the term Κυκλωψ, Cyclops; but as a perforage, he was said to have been the son of Ouranus and the earth; which Ouranus, among the Amonians, was often styled Coel, or Cœlus, and was worshipped under the emblem of a serpent. Hence the temple of the deity might originally have been called Co-Cœl-Ops, domus Cœli Pythous; and the priests and people Cyclopians. The Cyclopians deity was, therefore, Ouranus, and the Cyclopians were his priests and votaries. Some of the Cyclopians race settled in Thrace, where was a place called Cyclops; and many of the Amonians came thither; so that Thrace seems at one time to have been the seat of science, and the Athenians acknowledged that they borrowed largely from them. The head of Medusa in Argolis is said to have been the work of Cyclopians (Pausan. l. ii. p. 156.) This head seems to have been an ancient hieroglyphical representation upon the temple of Cephissus. The head of Medusa, like other devices upon temples, was esteemed a kind of talisman, and supposed to have an hidden and salutary influence, by which the building was preserved. It is probable that this opinion induced the Athenians to exhibit the head of Medusa upon the walls of their acropolis. The notion of the Cyclopes forming the thunder and lightning for Jupiter, arose chiefly from their engraving hieroglyphics of this kind upon the temples of the deity. Hence they were represented as persons,

“Ὁ Ζηνὶ βροχίαν τ' ἰδρῶσαν, τρυχῶν τε κερῶσιν.”

Hesiod. Theogon. v. 141.

The poets considered them merely in the capacity of blacksmiths, and condemned them to the anvil. This, Mr. Bryant apprehends, arose from the chief Cyclopians deity being called Aemon, and Pyracmon; and under the former title he was worshipped in Phrygia. As the Cyclopians were great artificers, they were probably famous for works in brass or iron; and this circumstance in their history may have been founded in truth. The Idæi Daetyli were Cyclopians; and they are said to have first forged metals, and to have reduced them to common use:—the knowledge of which they obtained from the fusion of minerals at the burning of mount Ida. From this event the Curetes and Corybantes, who were the same as the Idæi Daetyli, are supposed to have learned the mystery of fusing and forging metals. From them it was propagated to many countries westward, particularly to the Pangæan mountains, and the

region Curetis, where the Cyclopians dwelt in Thrace;—and also to the region Trinacia and Leontina near Ætna, which they occupied in Sicily.

After tracing very much in detail the true history and antiquity of the Cyclopians, Mr. Bryant infers from their works, that there was a time when they were held in high estimation. They were denominated from their worship; and their chief deity, among other titles, was styled Aemon, and Pyracmon. They seem to have been great in many sciences; but the term Aemon signifying among the Greeks an anvil, the poets have limited them to one base department, and considered them as so many blacksmiths. And as they resided near Ætna, they have made the burning mountain their forge:

“Ferrum exercebant vasto Cyclopes in antro,
Brontesque, Steropesque, et nodus membra Pyracmon.”
Æn. l. viii. v. 424.

Bryant's Analysis of Anc. Mythol. vol. i.

CYCLOPIS INSULA, in *Ancient Geography*, an island of the Mediterranean sea, upon the coast of Asia Minor, and near the island of Rhodes. Pliny.

CYCLOPS, ROCKS OF, in *Geography*, three rocks of lava, which are termed islands because they are surrounded by the sea, situated about a stone-throw's distance from the shore of Sicily, on which the village of Trezza stands. These rocks, which are mentioned by Pliny, might once have formed a part of the sides of Ætna, and have been separated from them by the sea; or they may have been thrown up out of the water by partial eruptions. Some of these rocks appeared to Spallanzani, who examined them, to consist externally only of prismatic columns, that fall perpendicularly into the sea, in some places one foot long, in others two, and in others more; but other parts of these rocks are only full of irregular fissures, which have divided them into pieces, as we see in common lavas. M. Dolomieu found on the surface of these rocks, and even in the middle of their substance, where are small pores and cavities, various and numerous zeolites of great beauty. This ingenious naturalist thinks, that these stones, after the congelation of the lavas, derived their origin from the waters which filtrated through them, and held in solution the particles proper for the production of zeolites. See Spallanzani's Travels, vol. i.

CYCLOPTERUS, in *Ichthyology*, a genus of branchiostegous fishes, distinguished by having the head obtuse; mouth in the anterior part; tongue short and thick; and the jaws beset with a number of small acute teeth; gill-membrane four-rayed, the cover of one piece; body short, thick, and destitute of scales; ventral fins united into an oval concavity, and forming an instrument of adhesion. The species of this genus are of the marine kind, and subsist on worms, insects, and the fry of other fishes; and they are furnished beneath with an oval or roundish organ of adhesion, by means of which they have the power of fastening themselves to the rocks so firmly, as to require considerable force to remove them. The species of this genus are not very numerous.

Species.

LUMPUS. Body angulated by rows of sharp bony tubercles. Linn. *Lumpus angulorum* Gœfuer. Common lump-sucker, Donovan. Brit. Fishes, &c.

This fish inhabits the northern seas, and grows to the length of eighteen inches or two feet; the body thick and uncouthly formed; its colour variable; the prevailing hue on the upper part of the body is usually blueish, tinged

with purple, and rough with innumerable dusky papillous dots; the sides pale, and the belly vivid scarlet; the pectoral fins are orange radiated with red, and the eyes bright red. Specimens sometimes occur of a fine and tender green, glossed with silvery, the back blue, and the sides pale rosy. This variety we have obtained more than once, (vide *Donov. Tour South Wales*.) and are satisfied it is only a variety of the common fort. Dr. Shaw describes it as a distinct species, under the title of *pavonian sucker*. The pyramidal sucker (*lumpus pyramidatus*) of the latter writer is not a different species, nor even a natural variety, but an example of the common kind capriciously distorted by art, as is sufficiently demonstrated by the specimen from whence Dr. Shaw's description was taken. The specimen alluded to was formerly preserved in the Leverian Museum, and is at present included in the London Museum. A third variety is described as having the dorsal fin very long, examples of which we have not seen.

The common lump-sucker is found on the northern coasts of Britain, during spring, in vast numbers, where they become the prey of seals, who lurk beneath the surface of the water. It is easy to distinguish the place where the seals are devouring these or any other unctuous fish, by the smoothness of the water immediately above the spot. Great numbers of these fishes are found on the coasts of Greenland in April and May, when they resort to the shores to spawn. The natives call them *nipifets* or *cat-fish*, and admire them as an article of food, being of a very unctuous nature. In England it is also sometimes eaten, stewed in the manner of carp, or broiled; in which latter case the head and skin are taken off, and the flesh cut into slices.

MINUTUS. Body naked; snout above the mouth, with three tubercles. Linn.

A species of small size, allied in its general aspect to the former species. The colour is white; the body compressed, with two white unequal bony tubercles on each side. The head is thicker than the body, nearly square, and obtuse in front; the vent placed nearly in the middle of the body, and instead of a dorsal fin, a long and tapering recurvate spine. The pectoral fins are yellow; the tail entire and equal; the organ of adhesion oval, with dilated and seven lobate margin. This fish inhabits the Atlantic sea.

NUDUS. Body naked; head with a single spine each side on the posterior part. Linn.

A native of India, and of small size.

DENTEX. Body naked; head unarmed, very smooth; fins separate. Pallas. *Spicil. Zool.* 7. t. 1. f. 1-4.

This species inhabits the American seas. The head is very large and much broader than the body, depressed and flat beneath; the lips thick, wrinkled, and doubled, with two very soft fleshy caruncles within; the gill-covers large and bony; vent situated near the tail. The general colour reddish.

VENTRICOSUS. Body naked; urinary vessel double, very large, and distending the belly. Pallas. *Spic. Zool.*

Inhabits the sea between Kamtschatka and America. Its length is about twelve inches; the body olive covered, with a thick slimy livid mucus; back flattish, with the tail suddenly tapering behind the vent.

GELATINOSUS. Body gelatinous, and sub-transparent; pectoral fins very broad. Pallas.

Found in the eastern parts of the same seas as the preceding. This fish is about eighteen inches in length; the body very slender, oblong, compressed, thicker towards the head, and gradually tapering towards the tail, of a whitish colour tinged with rosy; the skin smooth and very soft, and when just caught is said to tremble like jelly. The flesh is not

eatable, being refused even by the Kamtschatkan dogs, which are fed during part of the year with fish of various kinds.

LIPARIS. Body naked; dorsal, anal, and caudal fin united. Bloch.

A general inhabitant of the northern seas, and sometimes found on the coasts of Britain. The length is from five to sixteen inches; its shape thick towards the head, and becoming attenuated and compressed towards the tail. *Donov. Brit. Fishes.*

LINEATUS. Body naked, and marked with longitudinal bluish lines; dorsal and anal fins running gradually into the tail. *Lepechin. Nov. Com. Petrop.*

A beautiful species, in its general aspect much resembling the last. *Lepechin* found it in the White Sea, and described it in the *Transactions of the Petersburgh academy*. This rare fish has also once been met with on the British coasts. It is described in *Donovan's Hist. British Fishes*; and the specimen itself, from which the figure and account are taken, is arranged with the other British cyclopteri in the London Museum.

OCELLATUS. Body naked, tapering towards both ends; two large dorsal ocellated spots near the shoulders, and before each eye a bifurcated process. *Donov. Brit. Fishes. Jura sucker. Penn. Lesser sucking fish. Borlase.*

Length four or five inches; a very local species found on the coast of Scotland, and on those of Cornwall and Devonshire in Britain; and in some others of the European seas.

BIMACULATUS. Body naked, attenuated behind, and rosy, with a purple spot surrounded by a white ring on each side the abdomen. *Donov. Brit. Fishes. Bimaculated sucker. Penn.*

A small species, found on the coast of Devonshire.

MONTAGUI. Body naked, lanceolate, diaphanous, tinged with reddish and spotted with fuscous; dorsal, anal, and caudal fin distinct; organ of adhesion oval. *Donov. Brit. Fishes.*

A new and very beautiful species of a small size, discovered lately on the coast of Devonshire.

CYDARA, in *Ancient Geography*, a river placed by *Pliny* in the northern part of the island of *Taprobana*.

CYDARUS, a stream of *Thrace*, in the vicinity of *Constantinople*.

CYDDESES, a people of *Asia*, placed by *Ptolemy* on the confines of *Bithynia*.

CYDER, in *Rural Economy*, is a fruit liquor prepared by means of fermentation, from the expressed juice of different sorts of apples. The process by which this liquor is formed has much similarity in all the different districts where it constitutes an object of the farmer, though there is much diversity in regard to the care and management which are bestowed upon it.

The varieties of apples which are grown and cultivated in the various fruit districts of the kingdom, with this intention, are extremely numerous; but by some it is supposed that all such as have a yellow or light red ground, are tinged with red streaks on the sun side, having a smart acid flavour, with a firm juicy parenchyma and an aromatic flavour, whatever the name may be, are unquestionably proper for cyder. It has, however, been remarked by *Mr. Knight*, that the properties which are essential for cyder and the table are rarely met with in the same fruit. That degree of firmness which is necessary in the eating apple, is useless in the cyder fruit; and colour, which is disregarded in the former, is amongst the most important qualities of the latter. Some degree of astringency, which is prejudicial in the eating fruit,

CYDER.

fruit, is conceived beneficial in that made use of for cyder. In Devonshire, according to Mr. Vancouver's Survey, a rich sweet fruit is generally preferred for the purpose of cyder, while in others those which have more astringency are held in the highest estimation. See APPLE, APPLE-TREE and ORCHARD.

Gathering the Fruit.—In the business of gathering the fruit for this liquor, much care should be taken that it be sufficiently ripe before it is removed from the trees, otherwise the cyder will be harsh, rough, and unpleasant in its taste, in spite of any thing that can be done in the process of making it. The most certain indications of ripeness, according to Mr. Crocker, are the fragrance of the smell, and the dropping of the apples from the trees in a spontaneous manner.

The most early ripe fruits should, of course, be first gathered, but as on the same trees the fruits rarely become equally ripe at the same period of time, it is found necessary to throw them together into large round heaps in the open air, as noticed below, in which state they are suffered to continue for some time, until a sort of sweating or fermentation has been brought on, which induces a similar state of mellowness and fitness for grinding in the whole heap. This method, however, which requires much judgment in directing it, does not, even under the most careful management, always answer the purpose; therefore the nearer the apples approach towards perfect ripeness the better, as their juice is the more rich.

Mr. Crocker advises that in a dry day, when the fruit has acquired such a state of maturity as to be ready to drop from the tree, that the limbs or branches of it should be slightly shaken, and disburthened in a partial manner of its apples, thus taking only such as are in a ripe state, leaving the others to acquire a due degree of maturity. It is indeed suggested as proper to make three gatherings of the crop, keeping each of them by itself.

The latter gatherings, as well as the wind-falls, can, however, only be employed in making inferior cyder: the prime cyder must be drawn from the first gatherings which have been made.

According to Mr. Knight, the merit of cyder will always depend much on the proper mixture, or rather on the proper separation of the fruits. Those whose rinds and pulp are tinged with green, or red without any mixture of yellow, as that colour will disappear in the first stages of fermentation, should be carefully kept apart from such as are yellow, or yellow intermixed with red. The latter kinds, which should remain on the trees till ripe enough to fall without being much shaken, are alone capable of making fine cyder. Each kind should be collected separately, as noticed above, and kept till it becomes perfectly mellow. For this purpose, in the common practice of the country, they are, as stated above, placed in heaps of ten inches or a foot thick, and exposed to the sun and air, and rain; not being overcovered except in very severe frosts. The strength and flavour of the future liquor are however, he says, increased, by keeping the fruit under cover some time before it is ground; but unless a situation can be afforded it, in which it is exposed to a free current of air, and where it can be spread very thin, it is apt to contract an unpleasant smell, which will much affect the cyder produced from it. Few farms are provided with proper buildings for this purpose on a large scale, and the improvement of the liquor will not nearly pay the expence of erecting them. It may reasonably be supposed that much water is absorbed by the fruit in a rainy season; but the quantity of juice yielded by any given quantity of fruit will be found to diminish as

it becomes more mellow; even in very wet weather, provided it be ground when thoroughly dry. The advantages therefore, of covering the fruit, will probably be much less than may at first sight be expected. No criterion appears, the writer says, to be known, by which the most proper point of maturity in the fruit can be ascertained with accuracy; but he has good reason to believe that it improves as long as it continues to acquire a deeper shade of yellow. Each heap should be examined prior to its being ground, and any decayed or green fruit carefully taken away. The expence of this will, he observes, be very small, and will be amply repaid by the excellence of the liquor, and the care with which too great a degree of fermentation may be prevented in the process of making it into cyder.

Mr. Crocker has likewise remarked that the cyderist, who would be particularly curious in his prime liquor, should hand-gather his fruit, and keep the sorts separate one from another: but as this would be troublesome, expensive, and in a full season wholly impracticable, the general crop may, at different times, be shaken down, and collected from the ground. Fruit of equal ripeness, and whose qualities are nearly alike, should be heaped together, to meliorate their juices, or, in other words, to perfect the saccharine fermentation. How this is best done, cyder-makers are not, the writer says, agreed: some, says he, judging it altogether unnecessary to keep them at all, if sufficient time be allowed for perfecting the saccharine fermentation on the tree: some considering it best to sweat them in close lofts, whilst others allege, that the open air is the only place where they ought to be heaped. Experience, however, should, he thinks, teach us that most apples require time for their being mellowed, to attain their highest flavour; and, until this mellowing be perfected, their juices are not in the best state possible for being converted into cyder-liquor.

However, philosophy has shewn, he thinks, that fermentation is never improved by hastening the operation with too much heat; nor perfected in due time under too great an exposure to cold. It would be well, therefore, says he, if apples, when gathered from the tree, were placed in open sheds, having boarded floors, in heaps or layers of ten or twelve inches deep; the hard and harsh fruits might probably, he supposes, be laid in heaps of greater depth; the sorts to be kept separate, as much as the nature and conveniences of the sheds will allow: at any rate there must be a mixture of apples in the same heap; let them, says the writer, be such as are of qualities nearly alike, and which are of equal ripeness at the time of gathering, but on no account should sweet and sour fruit be heaped together. To some cyderists it may, says he, have appeared unnecessary to keep the different sorts of apples separate, but it is of importance so to do: and the trouble is very little, as has been observed, compared to the advantages which will hereafter result from a regular fermentation of the juices. The impropriety of housing and laying apples in very large heaps must, the writer thinks, be manifest to every thinking mind; more especially when in the same room are found all sorts; sweet, sour, harsh, generous, ripe, and unripe, thrown promiscuously together; where some are rotten before others are mellowed. And what must the liquor be, he asks, which is expressed from such an heterogeneous mass?

In respect to heaping, the author of the Survey of Gloucestershire well remarks, that though it may improve unripe fruit, it cannot communicate the richness found in that which is fully ripened. And that the effect which is thus produced on those which are heaped in a very green and

and unripe state, is rottenness, in which condition very few are capable of communicating an unpleasant flavour, even to a very large quantity of the liquor, especially where they have become of a black appearance.

Supposing, says Mr. Crocker, that the fruit, which is of different sorts and qualities, has been kept separate from one another a few weeks, it will be perceived that some of the prime sorts are in a proper state of maturation; that the pulp has acquired its highest degree of richness; the kernels assumed their brownest colour; the rind still free from any appearance of rottenness; and that they readily yield to the pressure of the thumb: then is the time, says he, and such is the fruit to be employed in making prime cyder: every necessary utensil must now be set in order: the mill, press, tubs, casks, pails, and bowls, clean washed, and suffered to dry before they are employed in the business.

The able writer of the Agricultural Report of the County of Gloucester very strongly and very justly reprobates the too common practice of those who indiscriminately, and without any regard to the maturity of the fruit "run over the whole orchard with the beating pole, or 'lug,' and bring down every apple within their reach," as thus beating the trees before the fruit is nearly ripe is not only injudicious in respect to the cyder, but injurious to the succeeding year's crop of fruit; the bearing buds for the next season being formed early in the summer near, and even attached to, the growing fruits. Of course, the beating of the trees, unless where the apples separate with facility, must of necessity bring off the buds which nature had provided for the ensuing year, with them. And he adds that, "after an operation of this kind the ground is strewed with these buds, to an extent scarcely to be conceived by those who have not witnessed it." The practice of the most careful farmer is therefore, he says, to have the trees "shaken limb by limb, by a person up in the tree," only suffering the few that remain to be beaten off, and occasionally even allowing them more time to ripen, which he considers by far the best practice, except that of suffering them to fall of their own accord, as securing a regular fermentation with less keeping.

Grinding the Apples. In the business of grinding the fruit for this use, into what is termed pomage, several different methods are practised: but those most commonly in use are the bruising-stone, with a circular trough, and the apple-mill. In the first of these methods the apples are thrown into the trough, and bruised by the motion of the stone, as it is moved round by a horse, in the usual way that tanners grind their bark. This is a very ancient method, and which is still in use in some parts of Devonshire, and although it has its inconveniences, in bruising some apples too much and some too little, it is not without its advocates in these parts of the country; the inhabitants of which allege, that it bruises the kernels of the fruit better than other machines. Although it must be admitted, that the kernels possess an agreeable aromatic bitter, yet it has been held questionable if they impart any perceivable beneficial quality to the cyder. Be this as it may, certain it is, that this method of converting apples to pomage by the trough and stone has, in the last fifty years, much given way to the apple-mill.

The author of the treatise on the apple and the pear has remarked that when iron mills have been tried, this metal has been found to be soluble in the acid of apples, to which it communicates a brown colour and an unpleasant taste. No combination has, he believes, been ascertained to take place between this acid and lead; but as the oxyd or calx

of this metal readily dissolves in, and communicates an extremely poisonous quality to, the acetous juice of the apple, it should, he thinks, never be suffered to come into contact with the fruit or liquor. In the construction of these mills, there are various methods had recourse to in regard to their motion or moving powers, some being worked by hand, some by horses, and others by water. The horse and water powers have obviously considerably the advantage in the quantity of work that is capable of being performed; but the hand method is supposed capable of reducing the pulp into a state of greater fineness, where the latest improvements in mills of this kind have been adopted. See *CYDER-Mill*.

It has been suggested in the Herefordshire report, that each sort of apples should be ground separately, or at least such sorts in mixture as become ripe at the same time; but on the authority of Mr. Appesley of Withington and other manufacturers, it is stated, that the former practice is that by which "fine cyder of different flavours and degrees of strength is obtained, from the same orchard, the liquors being mixed after they are made." It is however allowed that "in all common cases," the practice of grinding different varieties of fruit equally ripe, together, is found eligible; as it is less difficult to find the requisite degrees of richness, astringency, and flavour, in three varieties, than in one. And hence it is supposed that cyders made from the juice of mixed fruits under common management, generally succeed with greater certainty, than those from only one kind. In the grinding, the fruit should be reduced as nearly as possible to an uniform confistence, in such a manner as that the rinds and kernels may be scarcely discernible from the general mass; the operation proceeding slowly, with a free access of air. The quantity of fruit which is usually thrown into the cistern at one time to be ground, is about two bushels in the large mills.

Pressing the ground fruit.—It is remarked by Mr. Crocker, that cyderists are not agreed in opinion, whether the pomage should immediately after grinding be conveyed to the press, there to be formed into a kind of cake, or what is sometimes called the cheese; or whether it should remain some time in that state before pressing. Some say it should be pressed immediately after grinding; others conceive it best to suffer it to remain in the grinding trough, or in vats employed for the purpose, for twenty-four hours, or even two days, that it may acquire not only a redness of colour, but also that it may form an extract with the rind and kernels. Both extremes are, he thinks, wrong. There is an analogy, he supposes, between the making of cyder from apples, and wine from grapes; and the method which the wine-maker pursues ought, he thinks, to be followed by the cyder-maker. When the pulp of the grape has lain some time in the vats, the vintager thrusts his hand into it and takes some from the middle of the mass; and when he perceives by the smell that the luscious sweetness is gone off, and that his nose is affected with a slight piquancy, he immediately carries it to the press, and by a light pressure expresses his prime juice. In like manner should the cyderist determine the time when his pulp should be carried to the press. If he carry it immediately from the mill to the press, he might lose some small advantage, which may be expected from the rind and kernels, and his liquor may be of lower colour than he might wish. If he suffer it to remain too long unpressed, he will find to his cost, that the acetous fermentation will come on before the vinous is perfected; especially in the early part of the cyder-making seasons. He will generally find, he thinks, that his pulp is in a fit state for pressing in about twelve or sixteen hours. If

C Y D E R.

he must, of necessity, keep it in that state longer, he will find a sensible heat therein, which will engender a premature fermentation; and he must not delay turning it over, thereby to expose the middle of the mass to the influence of the atmosphere. Mr. Knight, however, thinks it should remain twenty-four hours before it is taken to the press. And the writer of the "General view of the state of agriculture in the county of Gloucester," states that there the pulp is either immediately carried to the press, or, which is better, laid up in tubs or open casks for twenty-four hours; by which the colour is improved, and by the digestion which takes place, a more intimate union of the rind, kernel, and stalk juices are produced, especially when again carried to the mill and reground. See *CYDER-Press*.

The ground fruit or pommage being new in a proper state, it is carried to the press, and a square cake or cheese made of it, by placing very clean sweet straw or reed between the various layers of pulp or pommage; or by putting the same into hair-cloths spread upon the vat, and placing them one on another. They are turned up on the sides and corners over the pulp, so as to nearly meet in the centres. They are laid very even, ten or twelve being thus applied over each other in regular layers, the square frame of the press being raised with them, keeping the pile to a uniform size. Upon the whole, a strong board is placed, wider than the pile, on which the blocks of the press rest. It is of importance that the straw or reed, where they are used, be sweet and perfectly free from any fustiness, lest the cyder be impregnated therewith. Particular care ought also to be taken to keep the hair-cloths sweet, by frequently washing and drying; or the ill effects of their acidity will be communicated to the cyder. To this cake or cheese, after standing a while, a slight pressure is at first to be given by lowering the screw of the press, which must be gradually increased as the cakes become dryer, until all the must or juice is expressed, which is usually completed by the long lever and windlafs: after which, the juice must be strained through a coarse hair sieve, to keep back the gross feculencies of the juice, and be put into proper vessels. These vessels may be either open vats, or close casks; but as in the time of a plentiful crop of apples, a number of open vats may by the cyderist be considered an incumbrance in his cyder-rooms, the must should be generally carried immediately from the press to the cask. The pressed pulp or cheeses, as they are termed, on being removed from the press and taken out of the cloths, are thrown away, when not designed for further use; but when the crops are scanty they are sometimes laid by in some places, to be afterwards reground with water, from which is afforded a liquor of weak quality, which is denominated in some places *washings*, but of sufficient strength to render it fit for family use; as notwithstanding the utmost attention in grinding, and the greatest exertion of the press, some portions of the fruit remain unexpressed, which contain juice in an unexpressed state. It is found that the residue of a quantity of fruit, sufficient for making three hogheads of cyder, is capable of yielding about one hoghead of washings.

Fermenting, racking, and casking the liquor.—These are the next operations to be regarded in the manufacture of this liquor. It is suggested by Mr. Crocker, that cyder-making is thus far a mere manual operation, performed with very little skill in the operator; but that now it is that the great art of making good cyder commences: nature soon begins to work a wonderful change in this foul-looking, turbid, fulsome, and unwholesome fluid; and, by the process of fermentation alone, converts it into a wholesome, vinous, salubrious, heart-cheering beverage. He thinks

that philosophy has shown, and that experience justifies the position, that the juices of all vegetables, when exposed to certain degrees of heat and atmospheric influence, are disposed by nature to spontaneous intestine motions of their constituent parts: this is called fermentation.

And it is observed by Mr. Knight, that the juice of the apple in its unfermented state consists of sugar, vegetable mucilage, acid, water, its tingeing matter, the principle of smell, and, he believes, of astringency. Of these component parts, the first only is known to be capable of producing ardent spirit, and it might thence be inferred that the strongest cyders would be afforded by the sweetest fruits: but the juice of these generally remains defective in what is termed "body" in liquors, and it is extremely apt to pass from the saccharine to the acetous state. Much of the strength of cyder is supposed by the Herefordshire farmers to be derived from the rind and kernels of the fruit, and hence arises their great attention to grind it thoroughly; the stalks also are necessarily reduced, when the apples are thoroughly ground, and he suspects that the body of the liquor is strengthened, and its flavour improved by the astringent juice of these: yet it does not appear probable, he says, that either of them contains any saccharine matter.

It is further stated as well-known that there are various kinds of fermentation in the juices of all vegetables, each of which changes the very nature and quality of the fluid; but the principal ones which are to be particularly attended to, in the instance now under consideration, (the must or juice of apples,) are these; namely, the vinous, the acetous, and the putrefactive. The first converts the must from its turbid, fulsome state to a transparent spirituous liquor, lightly piquant on the palate, resembling wine both in its flavour and effects.

The above writer states in addition, that it has been observed to take place in such bodies only as contain a considerable portion of sugar, and that it is always attended with the decomposition of that substance. The liquor gradually loses its sweetness, acquiring an intoxicating quality, and by distillation affords a greater or less quantity of ardent spirit, according to the quantity of sugar it originally contained, and the skill with which the process has been conducted. When this fermentation proceeds with too much rapidity, it is often confounded with the acetous, but the products of that are totally different. A violent degree of fermentation however, though purely vinous, is extremely injurious to the strength and permanence of cyder, probably owing to a part of the ardent spirit being discharged along with the disengaged air or gas.

"If," says the author of the *Treatise on Cyder-making*, "the juice has been expressed from four apples, this fermentation is perfected in two or three days; but if from sweet apples, not under a week or ten days, and sometimes longer."

The next succeeding stage of fermentation gives an acidity to the vinous liquor before spoken of, converting it to a sort of vinegar. This fermentation begins soon (frequently in a few hours) after the vinous is ended, and if the fermentation be improperly hastened by heat, before the vinous can be perfected. And Mr. Knight has remarked that it usually succeeds the vinous; but that it will sometimes precede it, when the liquor is in small quantity and exposes a large surface to the air. In this process, vital air is absorbed from the atmosphere, and the ardent spirits, vegetable acid, and sugar, if any remain, are alike converted into vinegar.

It is also further remarked that in the putrefactive process which follows the acetous, the vinegar loses its acidity,

becomes foul and viscid, and emits air of an offensive smell: an earthy sediment subsides, and the remaining liquid is little but water. But although we cannot, Mr. Crocker thinks, form any clear and distinct knowledge of the precise manner in which nature performs these changes in fermenting liquors, yet the effects are evident; and from a consideration of the different natures and results of the various fermentations, it may be perceived, that the first is the only one useful in making good cyder, and that the others tend to vitiate, and render unwholesome a liquor that would otherwise be highly pleasant, and truly salubrious. To regulate the first and to check the others, is then, says he, the greatest business of that cyder-maker, who would attach to himself the satisfaction and fame which every one is emulous of acquiring and deservng.

In the view of attaining these ends, fermentations should not, he thinks, by too much heat, be carried on rapidly, nor by extreme cold, too slowly; as, in each case, the fermenting body must be injured. Hence (he says) it appears, that a certain degree of warmth, or rather imperceptible heat, conduces best to regulate this operation. This degree of warmth may be understood to rest between forty and fifty degrees of Fahrenheit's thermometer. If then the warmth of the cellar, in which new-made cyder is placed, be between these points (no adventitious cause interfering), we may expect that the vinous fermentation will commence and go on with due regularity, and in a proper manner.

It has been observed above, that fermentation is an intestine motion of the parts of a fermentable body. This motion, in the present case, is always accompanied with an evident ebullition; the bubbles rising to the surface, and there forming a scum, or soft and spongy crust, over the whole liquor. This crust is frequently raised and broken by the air as it disengages itself from the liquor, and forces its way through it. This effect continues whilst the fermentation is brisk, but at last gradually ceases. The liquor now appears tolerably clear to the eye, and has a piquant, vinous sharpness upon the tongue. If in this state the least hissing noise be heard in the fermenting liquor, the room is too warm; and atmospheric air must be let in at the doors and at the windows.

"This (continues he) is the critical moment, which the cyderist must not lose sight of; for, if he would have a strong, generous, and pleasant liquor, all further sensible fermentation must be stopped. This is best done by racking off the pure part into open vessels, which must be placed in a more cool situation for a day two, after which it may again be barrelled, and placed in some moderately cool situation for the winter. The Herefordshire cyder-farmers, after the cyder has perfected its vinous fermentation, place their casks of cyder in open sheds throughout the winter: and, when the spring advances, give the last racking, and then cellar it. In racking, it is advisable that the stream from the racking-cock be small, and that the receiving-tub be but a small depth below the cock: lest, by exciting a violent motion of the parts of the liquor, another fermentation be brought up.

Though in common practice the racking of the liquor is rarely much attended to, especially for some months after casking, this being the old method; there cannot, however, be much doubt but that it should be accomplished at the proper moment as shewn above: in proof of which it is found that in the management of the finer liquors, in some districts, in which the fermentation is rapid, some have servants in constant attendance to watch its progress, racking it when necessary, even in the night, as such saccharine li-

quors require timely checking to prevent their taking on the acetous state.

But though frequent rackings have, without doubt, a tendency to reduce the liquor to a quiet state, the strength is supposed to be considerably lowered by it, in consequence of the continual escape of the spirit by exposure to the atmosphere. Brandy, or any other clean spirit may likewise be employed for the same purpose as racking, if not found too dear. The same object may also be obtained in some measure by leaving the cask unfilled, with an ullage. Where the tendency to fermentation is great, the casks should not be too much filled to the bung-hole, the action of the air on the surface of the liquor being favourable to the checking of that process.

The grounds, lees, or feculence of the cyder, after racking, may be strained through filtering bags, made for the purpose, of coarse linen or hempen cloth, and the running placed among the second-rate cyders; but by no means should it, in Mr. Crocker's opinion, be returned to the prime cyder. Some find it useful in checking any farther irregular fermentation in the casks. In this situation the cyder will, in course of time, by a sort of insensible fermentation, (the same writer says) not only drop the remainder of its gross lees, but will become transparent, highly vinous and fragrant.

"But, (it is observed by Mr. Knight,) that after the fermentation has ceased, and the liquor is become clear and bright, it should instantly be drawn off, and not suffered on any account again to mingle with its lees; for these possess much the same properties as yeast, and would inevitably bring on a second fermentation. The best criterion to judge of the proper moment to rack off will be (he says) the brightness of the liquor: and this is always attended with external marks, which serve as guides to the cyder-maker. The discharge of fixed air, which always attends the progress of fermentation, has entirely ceased; and a thick crust, formed of fragments of the reduced pulp, raised by the buoyant air it contains, is collected on the surface. The clear liquor being drawn off into another cask, the lees are put, he says, into small bags, similar to those used for jellies, being made, as noticed above: through these, whatever liquor the lees contain gradually filtrates, becoming perfectly bright, and it is then returned to that in the cask, in which it has the effect, in some measure, of preventing a second fermentation, as already hinted. It appears, he says, to have undergone a considerable change in the process of filtration. The colour is remarkably deep, its taste harsh and flat, and it has a strong tendency to become acetous; probably by having given out fixed, and absorbed vital air. Should it become acetous, which it will frequently do in forty-eight hours, it must not, on any account, he says, be put into the cask. If, however, the cyder, after being racked off, remains bright and quiet, nothing more is to be done to it till the succeeding spring; but if a scum collects on the surface, it must immediately be racked off into another cask; as this would produce bad effects, if suffered to sink. If a disposition to ferment with violence again appears, it will be necessary, he thinks, to rack off from one cask to another, as often as a hissing noise is heard. The strength of cyder is much reduced, he says, as noticed above, by being frequently racked off; but this, he supposes, arises only from a large portion of sugar remaining unchanged, which adds to the sweetness, at the expence of the other quality. The juice of the fruits which produce very strong cyders, often remains muddy during the whole winter, and much attention must frequently be paid, to prevent an excess of fermentation.

The casks into which the liquor is put, whenever racked off, should always have been thoroughly scalded, and dried again; and each should want several gallons of being full, to expose a larger surface to the air of the atmosphere.

But, says he, should the cyder-maker neglect the above precautions, the inevitable consequence will be this: another fermentation will quickly succeed, and convert the fine vinous liquor he was possessed of into a sort of vinegar; and all the art he is master of will never restore it to its former richness and purity.

When, however, the acetous fermentation has been suffered to come on, the following attempts may, he says, be made to prevent the ill effects of it from running to their full extent. For this purpose several means have been tried, sometimes with a degree of success, at other times wholly unavailably; the most popular ones would, however, seem to be these: as already noticed, a bottle of French brandy, half a gallon of spirit extracted from the lees of cyder, or a pailfull of old cyder, poured into the hogshhead soon after the acetous fermentation is begun: but no wonder, continues he, if all these should fail, if the cyder be still continued in a close warm cellar. To give effect to either, it is necessary that the liquor be as much exposed to a cooler air as conveniently may be, and that for a considerable length of time. By such means it is possible fermentation may, in a great measure, be repressed; and if a cask of prime cyder cannot from thence be obtained, a cask of tolerable second-rate kind may. These remedies are innocent; but if the farmer or cyder-merchant attempt to cover the accident, occasioned by negligence or inattention, by applying any preparation of lead, let him reflect that he is about to commit an absolute and unqualified murder on those whose lot it may be to drink his poisonous draught. Such means should, therefore, on no account be ever had recourse to.

The practice which is provincially termed *flumming*, and which signifies the fuming a cask with burning sulphur, may sometimes be advantageous. It is thus performed: take a stripe of canvas cloth, about twelve inches long and two broad; let it be dipped into melted brimstone: when this match is dry, let it be lighted, and suspended from the bung of a cask (in which there are a few gallons of cyder) until it be burnt out. The cask must remain stopped for an hour or more, and then rolled to and fro, to incorporate the fumes of the match with the cyder; after which it may be filled. If the *flumming* be designed only to suppress some slight improper fermentation, the brimstone match is sufficient; but if it be required to give any additional flavour to the cyder, some powdered ginger, cloves, or cinnamon, &c. may be brewed on the match when it is made. The burning of these ingredients with the sulphur will convey somewhat of their fragrance to the whole cask of cyder; but to do it to the best advantage, it must be performed as soon as the vinous fermentation is fully perfected.

It is stated by Mr. Crocker, that when the cyderist has succeeded in obtaining a favourable vinous fermentation, and by a well-timed racking and attention he has prevented the acetous and other succeeding fermentations from rising, his cyder will require very little further attention, more than filling up the vessels every two or three weeks, to supply the waste by the insensible fermentation, until the beginning of the succeeding March; at which time it may be reasonably expected he will find his cyder bright, pure, and in a fit state for its final racking. This should be done in fair weather; and, if necessary, a commixture should now be made of the high-coloured cyder, made from the Jersey,

or the luscious sweet apples, with that of the pale-coloured cyder from the poorer four apples: by which means a general regular colouring may be obtained with the least trouble, and without expence in any way.

Though it may be expected that the cyderist will now find his liquor to his mind, both in point of brightness and colour, yet should he be disappointed, this is the time for applying some innocent remedy to remove the disorder. He does not recommend to him either of the *forces* commonly used for fining liquors, namely, bullock's blood, singlafs, eggs, &c. as they as frequently spoil a cask of cyder as improve it; but if he put two pounds of lump sugar into a hogshhead of cyder, he will receive all the benefit which may be expected from the most nauseous *force* which nastiness can employ. If higher colour in cyder be desired than what his fruit naturally gives under the foregoing management, the cyderist will do well, he says, to melt a pound of lump-sugar in a stewpan, over a clear fire, stirring it frequently, until it comes to a very dark brown colour; then to take it off the fire, and, as it cools, add some cyder thereto by little and little, and continue stirring it until it becomes a thin uniform fluid. This colouring, in the quantity of about a pint, more or less as occasion may require, to a hogshhead, is very cheap and wholesome, tinges to perfection, gives no luscious sweetness, but rather an agreeable bitterness, and thus recommends itself to the nicer palates. Soon after this spring racking, but not till then, the casks may be gradually stopped, by first laying the cork on the bung-hole, and in a few days forcing it very tightly into it, covering it over with a layer of melted rosin, or other similar substance.

Bottling the Liquor.—This is the next business to be attended to in the management of cyder; and it is stated by the writer just mentioned, that in the month following, that which is named above, the cyder, in general, will be in a fit state for this operation; but that the critical time for this process is when the liquor has acquired in the cask its highest degree of perfection: then, when the weather is fair, the barometer high, and the wind in some northerly point, let the bottles be filled, setting them by uncorked until the morning; then let the corks be driven very tightly into the necks of the bottles, tied down with small strong twine or wire, and well secured with melted rosin, or other material of the same nature.

It is stated by Mr. Knight, that cyders which have been made from good fruits, and have been properly manufactured, will retain a considerable portion of sweetness, in the cask, to the end of three or four years; but that the saccharine part, on which alone their sweetness depends, gradually disappears, probably by a decomposition and discharge of fixed air, similar to that which takes place in the earlier stages of their fermentation. Cyder is generally in the best state to be put into the bottle at two years old, where it will soon become brisk and sparkling; and if it possesses much richness, it will remain with scarcely any sensible change during twenty or thirty years, or as long as the cork duly performs its office, or resists decay.

But in making cyder for the common use of the farmhouse, the same writer says, few of the foregoing rules are or ought to be attended to. The flavour of the liquor is here a secondary consideration with the farmer, whose first object must be to obtain a large quantity at a small expence. The common practice of the country is sufficiently well calculated to answer this purpose; the apples are usually gathered and ground as soon as they become moderately ripe; and the juice is either racked off at once, as soon as it becomes bright, or more frequently conveyed

from the prefs immediately to the cellar. A violent fermentation soon commences, and continues until nearly the whole of the saccharine part is decomposed. The casks are filled up and stopped early in the succeeding spring, and no further attention is either paid or required. The liquor thus prepared may be kept from two to five or six years in the cask, according to its strength. It is generally harsh and rough, but rarely acetous; and in this state, the writer believes, it is usually supposed to be preferred by the farmers and peasantry. When it has become extremely thin and harsh by excess of fermentation, the addition of a small quantity of bruised wheat, or slices of toasted bread, or any other farinaceous substance, will, he says, much diminish its disposition to become sour. But the above opinion is not, he thinks, well founded; they like it best when it possesses much strength with moderate richness, and when it is without anything harsh or sour in its flavour; but they will drink it, and to a most extraordinary excess, even when it is really in the acetous state.

And, as has been seen above, an inferior kind of liquor is made, the writer says, by macerating the reduced pulp, from which the cyder has been pressed, in a small quantity of water, and regrinding it. This may be kept till the next autumn, and usually supplies the place of cyder in the farm-house for all purposes, except for the labourers in the harvest. It is generally fit to drink very soon after it is made; and though no attention is ever paid to it during its fermentation, it often remains, till near the end of the succeeding summer, more palatable than the cyder pressed from the same fruit, which is a fortunate circumstance for the farmer.

In the business of making perry, which is a liquor of a somewhat similar nature, there is but little which is materially different in the process. See PERRY.

Produce and application of Cyder.—The produce of this liquor is a matter which is extremely difficult to ascertain, whether the quantity be taken by the acre, or in any other way. It has been stated by the author of the “Present State of Husbandry,” in this country, that the quantity of cyder and perry made for sale in the fruit districts is very great; but that, that used by the inhabitants is by various accounts much more considerable. These liquors are, he says, sold by the farmers in different states of preparation for market. Sometimes they are sold immediately from the prefs, sometimes after the first racking, and frequently, not until ready for use. The price of cyder and perry always advances according as these liquors are in a prepared state for the consumer’s use, as well as according to the quantity on hand, and the quality of the fruit whence it was made. Stire cyder and squash-perry, for instance, says he, always give much higher prices than what is made from any other sorts of fruit. The price of common cyder liquor from the prefs, for a course of seven years, may, he thinks, be rated at from 15s. to 30s. the hoghead of 110 gallons; and common perry from 12s. to 15s. Stire-cyder, in the same state, sells for 5l., 10l., and sometimes 15l. the hoghead; and squash perry, in ordinary seasons, from 4l. to 8l. the hoghead.

But the produce of cyder or perry by the acre can only, he says, be guessed at by first ascertaining the number of trees. From an orchard of trees, in full bearing, half a hoghead of cyder may, in seasons ordinarily favourable, he thinks, be expected from the fruit of each tree. As the number of trees on the acre varies from ten to forty, the quantity of cyder must vary in the same proportion; that is, from five to twenty hogheads. Pear trees, in equally good bearing, yield fully one-third more liquor; therefore, although the liquor extracted from pears sells at a lower price

than that produced from apples, yet the value by the acre, when the number of trees is the same, is nearly on a par.

Mr. Vancouver, in his Survey of the County of Devonshire, has remarked, that the great uncertainty of this sort of crops renders it a matter of great difficulty, to state any thing like an average produce of that district. He has found, however, that the mean, of several statements taken upon a period of seven years, which varied from two and a half to five hogheads per acre, will be found to equal that of three hogheads and two-fifths for the acre. And that the average price of the liquor at the *pond’s* mouth, or prefs, was, in 1807, fifty shillings the hoghead.

And the intelligent writer of the Report of the County of Gloucester, has offered a statement of the expence, produce, and profit of this kind of crop, in a different way on the extent of twenty acres.

Supposing the distance of planting the trees to be sixteen yards, the acre will admit sixteen stocks, which, with the original cost, planting, and fencing, may be estimated at 5s. each, or in the whole 4l.

Grafting, protecting, and keeping up fences till the trees are out of danger, may be stated at 2s. 6d. each.

It is suggested, that the return to the landlord will be very small for the first twenty years; and that he will not be able to put an additional rent on his lands, in less than thirty years, for the plantation.

The cost of erecting a cyder-house and mill stated at eighty pounds.

<i>General Estimate.</i>		£.	s.	d.
Planting 20 acres	-	80	0	0
Grafting, protecting, repairing, &c.	-	40	0	0
Interest for 30 years on 80l.	-	120	0	0
Building cyder-house, &c.	-	80	0	0
Total expence		320	0	0
		£.	s.	d.
Interest of 320l.	-	16	0	0
Profit	-	14	0	0
		30	0	0
Advance of rent on 20 acres	-	30	0	0

Consequently the landholder has the distant prospect, he says, of increasing his income 14l. per annum, or of receiving nearly 10 per cent. for money laid out, but subject to the deductions of repairs, &c.

But that, with the tenant the advantages are still less certain. Suppose the ground to be so well planted and grown as to contain sixteen trees capable of affording in a good season sixteen barrels, or 800 gallons of cyder, which is a large average allowance; and suppose the liquor to be sold from the mill at 4d. the gallon, the produce will be 13l. 6s. 8d. per acre, subject to the deductions of 20s. for tyres, 2l. for making, 10s. for gathering; in the whole 3l. 10s.: the remainder, 9l. 16s. 8d. will be clear profit; which, if it occurred every year, it would be considered highly beneficial; but a good crop rarely happens oftener than once in four years, while the damage done to the grafts under the trees is continued, as well as the increased parochial rates from the increased rent; it does not seem, therefore, the writer says, that the additional rent on account of the trees, is returned with much interest.

Though there are many individuals in the cyder districts who evince much care and attention in the management of their

their orchard-grounds, trees, fruit, liquor, &c.: Yet this is by no means, he says, the common case; on the contrary, such general negligence prevails, and so imperfect are the modes in which this branch of husbandry is for the most part conducted, that many are of opinion, so much valuable land being occupied as orchards, is, in a national view, extremely unprofitable; and that owing to the same causes, want of attention, and adopting improper modes of management, the farmers at large are also injured, rather than benefited. While, says he, orchards continue to be considered as secondary objects only of the farmer's attention, as is the case at present, it can hardly be expected that the produce will be abundant, or the quality such as to recommend it to more general notice. In place, however, of condemning orchard husbandry at large, it appears much more correct, he thinks, to recommend a general reform in the management; whereby liquors, that are both wholesome and agreeable, when well made, may be introduced into more general use, and so large an importation of foreign vinous liquors be rendered unnecessary. In place of planting only ten or a dozen of trees on the acre over an extensive tract of land, it would, he supposes, be more for the interest, and certainly much more convenient for the cydermen, were they to allot a few acres adjoining to their places of residence, for the sole purpose of growing fruit-trees. The loss and inconvenience of having fruit trees scattered over an arable field, are considerable. When the trees are full grown, they overshadow, and consequently greatly injure the crop below; the roots also spread to a great distance, and besides impeding the ploughing of the ground, extract a great share of the nourishment that would otherwise go to support the crop of corn. The additional expence in gathering and carrying home a crop of fruit from an extensive fruit-ground, beyond what is incurred when four trees stand on the same space of ground which in the other case is occupied by one, also merits attention. Inconveniences as great and numerous result from having fruit-trees thinly scattered over a pasture field. The grass under the shadow of the trees is very inferior to that in the open part of the field. The cattle must, says he, be excluded when the fruit-trees begin to ripen, especially during and immediately after high winds, otherwise they would eat the fruit. The falling of leaves in autumn is very destructive to pastures of all descriptions; and the same additional expence and trouble of gathering and carrying home the crop are also incurred. For these reasons, a close planted cyder-orchard must, he thinks, be preferable to fields; and where the soil and situation are proper, the grounds stocked with full-bearing trees of the best sorts; and when the trees, the fruit, and the liquor, are judiciously managed, it is impossible but, according to the produce and prices above-stated, such grounds must turn out profitable, even supposing they produce but one crop equal to that above-mentioned, every third year. On the other hand, if the slovenly manner of conducting the various operations of cyder-making be persisted in, it would be in favour of the nation, and of the individuals concerned in that branch of husbandry, he supposes, that there were not a cyder-orchard in the island. Perhaps, on another account also, it might be for the interest of the farmers in the fruit districts that orchards were abolished: the quantity of cyder annually used by the servants and labourers is so immense, that considering the injury which the crops of grain and grass sustain from the land's being incumbered with trees, the labour of collecting and carting home the fruit, and the trouble attending the

manufacturing it into liquors, this beverage must be a more serious article of expence than the generality of cyder farmers are disposed to allow.

It is, however, stated by Mr. Rudge, that where the management of these sorts of liquors is perfectly known and attended to, and there is a capital sufficient to prevent the necessity of immediate sale, as well as plenty of casks in the farmer's own cellar, he may be enabled to take the advantage of the most favourable circumstances of bringing it to the market, as when there is a scarcity from early sales, and no supplies expected from crops of succeeding years; when the price is frequently increased to 8*d.* or 1*s.* the gallon.

It is added, that old cyder is always valuable, and pays for keeping; which is suggested as the best means of countervailing the uncertainty of crops, though it oftener benefits the dealer than the grower of the fruit.

The same able writer also states, that farmers who live contiguous to canals or navigable rivers, have peculiar advantages from their situations, often turning long keeping fruits to a better account than grinding them for cyder, by sending them into the interior districts of the kingdom for the purpose of the table, at the price of 16*s.* per team: "for," says he, "supposing that eleven teams of nine pecks each, are required for 100 gallons, the cyder should be sold at 8*l.* 16*s.* to equalize the profit of their sale unground; but cyder, in its early state, seldom averages more than 9*d.* per gallon, which would be only 3*l.* 15*s.*; so that even supposing all the cyder to turn out well, the former method is far the more advantageous. It is therefore conceived, that in this way alone, the profits of a fruit estate can be satisfactorily made out in favour of the tenant of it. See ORCHARD, and APPLE-tree.

CYDER-Cask, in *Rural Economy*, a vessel of the barrel kind, made use of for the purpose of keeping the liquor. They are of various sizes or dimensions, according to the extent of the fruit grounds, and the fancy and circumstances of the farmer, in so far as capital is concerned. It is, however, commonly supposed that the strength of the liquor is better preserved, if not increased, by a large quantity or body of it being kept together. Though casks of this sort are made to hold from 400 to 500 gallons, the most general size is 110 gallons, which is alone employed in sending out the cyder for sale. The usual price of this kind of casks is about five-pence the gallon.

It is observed that the choice of proper vessels for keeping the liquor in after it has been fermented, is a very material point to be regarded, as none is so liable as this to take the taste or twang of the cask: new vessels, though the wood be ever so well seasoned, are apt to give a disagreeable relish to all liquors, and remarkably so to cyder, unless due caution be used beforehand. Frequent scalding with hot water, into which some handfuls of salt have been first thrown, or with water in which some of the pommage has been boiled, and washing afterwards with cyder, are the usual remedies against this evil, and seldom fail of removing it effectually. Of all sorts of old casks, beer vessels are the worst, as they always spoil cyder; and in return cyder casks infallibly spoil beer. Wine and brandy casks do very well, provided the tartar adhering to their sides be carefully scraped off, and they are well scalded. These different circumstances should always be carefully attended to, in cleaning and preparing casks of this kind for the reception of the liquor.

CYDER-Cloths, are such cloths as are manufactured for the purpose of the cyder-maker, being made use of for

C Y D E R.

containing the pommage, in order to its undergoing the operation of the prefs. They are usually formed of common hair-cloth, but which is of the more close and compact nature or texture.

The size is generally about four feet square; and they hold about two or three bushels, or as much as the mill can grind at once; and these are, as has been seen, heaped over each other until the prefs is full, being kept to an uniform size by a wooden frame or gauge. The larger presses are capable of holding from eight to fifteen bags or cloths, which yield from one to two hundred gallons of liquor, according to the largeness of what is termed the *cheefe*. To perform the work neatly, it is necessary to have two sets of these cloths or bags, as they are apt to clog and fur in pressing, and consequently become unfit for use again till they have been washed and dried; so that while this is doing, either the prefs must stand still, or another set be ready to employ it. But some, instead of cloths or hair-bags, lay dry straw under the pommage, the ends of which they turn up over it; then cover the pommage entirely with fresh clean sweet-smelling straw, upon which they spread another layer of pommage; and so on alternately, until the prefs is full. Either of the methods will answer the purpose; but those who are desirous of doing the work in the neatest and best manner, generally use hair bags or cloths in performing the business. See CYDER.

CYDER-Kin, an inferior sort of fruit liquor, which is made after the better kind has been prepared, in the manner which has been noticed in speaking of cyder. (See CYDER.) It is mostly used for domestic purposes.

CYDER-Mill is that sort of machine or contrivance, which is constructed for the purpose of crushing, grinding, and reducing apples, or other similar fruits, into the state of a fine pulp or pommage, in order that the juice or liquor may be drawn from it, by means of pressure. In different districts there are variations in the manner of constructing these mills; but they chiefly consist of two kinds, the horse and the hand mills; the former being principally in use where the extent of fruit ground is considerable, but the latter mostly where the farms of this kind are small, and insufficient to repay the expence of such large machinery.

The first sort, or *horse-mill*, which is that by much the most generally met with, is commonly constructed somewhat on the same principles as those in use for the purpose of grinding bark for the tanners, and consists of the following distinct parts, namely, the cistern-chase, or trough, the runner or bruising-stone, and the cog-wheel and upright axle-tree, with the stirrer, the reever, and the shovel employed in the process.

It is stated by Mr. Rudge, in his "Agricultural Survey of Gloucestershire," that the cistern is circular, and formed of stone, being hollowed out in such a manner as to fit and receive the runner, commonly to the depth of about nine inches. On the inner side, or that which is next, what is usually termed the "nut" or central space, it is cut out in a perpendicular form, but on the exterior or outside somewhat in a sloping direction, being left wider across at the top than at the bottom; and the outside upper edge is left two or three inches in width, in order to receive what is denominated a "curbing," which is made of wood, and raises it four inches higher, being finished with nearly a sharp edge. The design of this wood-work is not merely to prevent the pulp or pommage from being carried over, as the stone rolls or turns round, but likewise to correspond with a four-inch plank or planks, which cover the nut, or

circular vacant space in the centre. It is usual for the cisterns to be delivered from the quarries in three or four separate parts, which are afterwards fitted and cramped together by the mill-wright. A cistern of thirty feet in circumference will be requisite for a mill of the ordinary size; and the price is regulated by the number of gallons which it is capable of containing, or at the rate of one guinea the foot in diameter.

In regard to the runner or bruising stone, it is seldom less than three feet and a half, or more than four feet in diameter, being made perfectly flat on the side next the nut, but a little convex on the other, nearly fitting the bottom of the cistern. In the middle, a strong axle of wood is fastened through it, which is connected with an upright or standard axle-tree in the centre, which extends sufficiently far from the exterior side of the runner to connect by means of an iron rod with a wooden bar, which is also linked to the upright axle, and to which the horse is fastened. This wooden bar or pole is so fixed as to be before the runner, and keep the horse clear of it. The height is regulated by a substructure of stone work under the cistern or chase.

To the horizontal axle is fitted a cog-wheel of from eighteen inches to two feet in diameter, which runs on the wood-work that covers the whole space; from the interior edge of the cistern to the perpendicular axle, and which is denominated the nut. The exact height of this wheel must consequently be determined by that of the centre of the runner above the nut. The cogs of this wheel catch upon upright teeth, fixed in the nut, as it rolls upon the surface, and by this means force the stone into a rotatory motion, which under other circumstances it would not always keep; as when the apples are first introduced, or when the bottom of the cistern has become smooth from the pulp, it might slide along rather than roll, was it not for some machinery of this nature; though some mills are without it notwithstanding.

The perpendicular axle-tree has an iron pin at each end as pivots, which runs in a sunk iron centre; the wood of the axle, which is bound with an iron ring or hoop, forming the shoulder of it.

The runner, or stone for grinding, is commonly sold at the quarry at the rate of one guinea the foot, or as many guineas as the stone measures feet in diameter; being, in the district mentioned above, procured from the forest of Dean. They are a sort of dark reddish kind of grit stone, not calcareous, but of sufficient hardness.

It is suggested by Mr. Marshall that much depends upon the quality of the stone. It should not be calcareous, either in the whole or any part, as the acid of the liquor would, in that case, corrode and decompose it. Some of the stones in Herefordshire have, he says, calcareous pebbles in them, which being dissolved as above, of course leave holes in them. Nor should the stone be of such a kind as to communicate a disagreeable tinge to the liquor.

The same writer remarks likewise that there are some mills of this kind which have two runners, one opposite the other. And he thinks that the situation of these mills should be such as to have a horse-path, of about three feet in width, between the bed and the walls; consequently, a moderate sized mill, with its horse-path, takes up a space of fourteen or fifteen feet in every direction.

At Fig. 1. in Plate XI. on *Agriculture*, an improved mill of this sort is represented, in which A is the runner or stone, B C D the cistern-chase or trough, in which the
stone

stone moves and reduces the apples; EFG the horse-path; and HI the manner in which the moving power is attached.

The other appendages of the cyder-mill noticed above may be thus described:

The *stirrer* consists of a strong round stick, with which the fruit is constantly kept to the stone, and removed from the sides to the bottom, during the process of grinding; for which purpose, a woman or boy usually walks either before or behind the horse. Some horse-mills have two stirrers, so attached to the axle-tree of the runner as to execute the work effectually without manual assistance.

The *reever* is a small piece of board securely fastened to a wooden handle, and so formed as to fit the shape of the cistern; by means of which, when the pommage or pulp is sufficiently ground, it is drawn together in order to be conveyed to the prefs by the shovel.

The *shovel* is a tool somewhat of the spade kind, mostly made of wood, being a sort of scoop, by which the above operation is readily performed. Iron shovels are, however, sometimes made use of; but a portion of the iron is supposed to be dissolved by the acid of the liquor, which may possibly contribute to the black tinge frequently noticed in cyder, after exposure to the air. Wooden implements should therefore, of course, be preferred, as being more cleanly, and, at the same time, free from this sort of danger.

The second sort, or *hand cyder-mill*, is constituted of two toothed or indented wooden cylinders of about nine inches in diameter, each being inclosed in the manner of other mills, having a feeder at the top, and being made so as to be turned by the hand. By this sort of mill, the work of bruising the rind, kernel, and stalk, as well as that of reducing the fleshy parts to a perfect pulp, is well performed. From the circumstance of the cylinders being so arranged as to be capable of being removed to a greater or less distance from each other, the business advances in a regular progressive manner, from the first cutting of the fruit until the cylinders are brought so close together that a kernel cannot pass without being bruised; and where another pair of finer toothed cylinders are had recourse to, to work under these, so as to bring the pulp into a perfect state of fineness, the business is still more effectually executed. But though by this means much time is saved, more strength is required in the operation. It is with difficulty that the same degree of fineness can be effected by the horse-mill, as in spite of the incessant attention of the labourer who has the care of stirring the fruit while under the operation of grinding, and of keeping it to the runner, a large portion is conveyed to the prefs without having been fully reduced. A mill of this description is shown at *fig. 2.* in the same plate.

It is observed by the intelligent author of the Report noticed above, that "two disadvantages attach to the hand-mill in its present state, loss of time and increase of manual labour;" it being "difficult, with the assistance of three men, to grind a hoghead in a day;" while "with a horse-mill, from two to three hogheads may be made by a man and woman, or younger person, and one horse;" consequently, its superiority on a large fruit farm is conceived to be decided. It is, however, added, that the hand-mill is capable of being greatly improved in the point of expedition, by the attachment of a large horizontal wheel and horse, as has been done in some manufactories.

It has been remarked by the author of the Rural Economy of Gloucestershire, that from observing the great simplicity and high degree of perfection with which the sugar

mills grind the canes or rather prefs out their juice between two plain iron rollers, the imperfections of cyder-mills appear more striking. It is however noticed that the sugar cane is a long fibrous body; and readily passes through between the rollers: whereas fruit being globular, and of a cellular substance, is not easily laid hold of, or, if caught, has no lengthened fibres to induce it to pass, like the cane, between plain rollers. It has, however, been found, that between fluted rollers it may be made to pass; and in consequence, these rollers are in use, though not common. They are of cast iron, hollow, about nine inches diameter, with flutes or teeth, about an inch wide, and nearly as much deep. In general they are worked by hand, two men working against each other. Between these the fruit passes twice: the rollers being first set wide, to break it into fragments, and afterwards closer, to reduce the fragments. But even this is not, he says, a perfect engine: in the residuum from the prefs many kernels are found. Besides, the acid of the fruit is liable to corrode the iron, and this, in return, to tinge the liquor, though neither of these inconveniences is acknowledged. In a country, however, where stone is not easily to be had, this may, perhaps, be found the most eligible cyder-mill. But in this district, where stone is sufficiently plentiful, the stone runner and trough seem to be the most eligible mill at present known: though it appears to him highly probable, that, with attention and perseverance, a more perfect machine might be invented. Be this, says the writer, as it may, the present mill appears to be capable of improvement. It is at present an unfinished machine: he means when it is first turned out of the workman's hands: time and constant wear do that, in part at least, which the workman leaves undone. The acting parts of the machine, those which are to bruise the rind, and crush the kernels, are the face of the roller and the bottom of the trough. But instead of their being adapted to each other, in such a manner as to effect these purposes with a degree of certainty, they are left in such rough unfinished state as in a great measure prevents them, during the first fifty years at least, from performing that which is their principal intention. Instead of being worked over, and fitted nicely to each other, with the square and chisel, they are hewn over with the stone-mason's peck only, leaving holes and protuberances which would have even horse-beans from the pressure, much more the kernels of fruit. A runner which has been worn two and twenty years has often holes left in it which would lodge half a dozen kernels with safety. To account for this absurdity seems, he says, impossible: perhaps the roughness was intended to prevent the runner from sliding; but the use of the cogged wheels has superseded this intention. Perhaps it was left to gather up the fruits with greater effect; but surely, deep chisel marks, left in the form of flutes across the face, would have answered this purpose better, and would perhaps have laid hold of and fixed the kernels, so as to serve their being effectually broken, preferable to any other equally simple expedient. Or, perhaps, the custom was established when the uses of the rind and kernel were not known, and time has not yet corrected the error. He has been told, that the roughness is left to cut the fruit the better on its being first put into the trough: and that on this ingenious principle, some will pick their runners over as often as they wear smooth. To such cyder-makers, he would recommend the horse-mill, which would come much cheaper, and work still faster, and save the expence of pecking. Be the origin of folly what it may, says he, it is painful to observe its effect. In this case, however, the folly, and, of course, its effect may be easily removed. Having made the face of the roller as true as the square

and the chissel can render it, work, says he, the bottom of the trough to it, until not a mustard-seed can escape them. The kernels of fruit are hard, slippery, and singularly difficult to fix, escaping pressure in a peculiar manner; and with singular alertness.

It is remarked in addition, that another improvement of the common cyder-mill appears to be much wanted; namely, a method of preventing the materials in the last stage of grinding from rising before the runner; and further, a more mechanical way of stirring up and adjusting them in the chafe. Until these improvements be made, cyder-mills, says he, must remain, what most of them evidently are at present, imperfect machines.

It has been noticed by the same writer, that a mill-house, on an orchard farm, is as necessary as a barn on those of other kinds. It is in general found to be one end of an out-building, or frequently an open shed, under which straw or small implements are laid up when not in use. The smallest dimensions possible to render it in any degree convenient and useful are, he thinks, twenty-four feet by twenty; having a floor thrown over it at the height of seven feet; and a door in the middle of the front with a window opposite; the mill being fixed up on one side of it, and the press on the other; as much room as is possible being left towards the door, in the front part, for the reception of fruit and the different necessary utensils.

Mr. Rudge considers the "arrangement of the buildings for the convenience of making and storing fruit liquors as a matter of great importance," though it seems to have been but little attended to on old farms. The mill and press being often found in an insulated building at a distance from the cellars; which occasions the employing of a man and boy, with a horse and dray to convey the liquor to the place where it is to be casked, which is a labour that would be unnecessary were the mill-house and cellars attached. In some of the more recent erections of this description, the spout of the vat is so contrived as to discharge the liquor through an opening in the wall, into a receiver in the cellar, from which it is distributed with facility to the different casks which are to be filled.

The rest of the utensils belonging to a mill-house are few: the fruit being simply brought in casks or large baskets, and the liquor carried out in pails, or by means of spouts as noticed above. The hair-cloths, mentioned above, are the principal addition to the mill and press. The expence of fitting up a cyder-mill house depends, Mr. Marshall says, on the size and quality of the mill and press. One of a moderate size, for a farm, may be furnished completely for from twenty to twenty-five pounds. One on a small scale might be furnished for from ten to fifteen pounds: much depending on the distance of carriage of the stone. This expence is usually borne by the landlord. A mill-house substantially fitted up will last many years. He has observed a mill and press which, by the date upon them, have been set up more than twenty years, yet they appeared almost as fresh as new. Many of the old mills and presses, which are seen, may, compared with those, seem to be a century old; or the mills more particularly a greater age, and were probably the original mills of the farms they are upon.

These observations shew that considerable attention should be bestowed by the fruit farmer in fitting up and completing his buildings and machinery for the management of this sort of liquor.

CYDER-PRESS, a machine of the press kind, contrived for the purpose of forcing the juice from different sorts of fruits after their substance has been reduced to the state

of pulp by means of grinding. They are mostly constructed on the same principles as those of other kinds which are intended to afford a strong or powerful pressure, as the packing and oil-press.

It is constituted, according to Mr. Rudge, of the following parts, a cistern-still, vat, cheeks, or "sifters," cap and screw, lanthorn, bridge, press-blocks, shooter, lever, windlas, and rope.

The cheeks, or sifters, are two strong upright pieces of oak, which are preserved in their situations, by being let into the ground first, and then by the cistern-still, which is a thick piece of timber, extending from one cheek to the other, near to the ground, being open mortised at each end, resting upon a shoulder, and clipping the upright: through these open mortises, and the upright, a strong iron pin is passed, which prevents the cheeks from spreading or giving way in the operation of pressing. A corresponding piece is fixed near the top, which is mortised and fastened in the same manner to the cheeks, through the centre of which the female screw or nut is made, in that case denominated the cap.

What is termed the vat, is a wide plank, with a groove running round it near the edge, or what is preferable, a raised levelled border coinciding with the edge, about an inch in thickness, to prevent the liquor from running off at the sides, and conduct it to the sluice or spout from which it is discharged into the receiver. This vat is firmly fixed on the cistern-still.

The screw, when made of wood, is mostly nine or ten inches in diameter, and which passing through the cap, rises three or four feet to the lower end, which is square; the bridge is hung, by means of a rounded pin, which is a plank reaching from one cheek to the other, being freely moveable up and down, but kept to a regular situation or position by open mortises. The lower end of the screw is left of a larger diameter, when the lever is intended to work in it, being in this case perforated and hooped with iron, but the lanthorn is more frequently fixed upon it. This is made of two circular pieces of wood, less than two feet in diameter, being kept eight inches apart by ten strong pillars, between which a piece of ash or elm timber is occasionally placed, which is termed the lever. There are two of these belonging to the press, being used according to the extent of power required, one being shorter and less strong than the other, being capable of being worked by the strength of one man, during the commencement of the pressing; but as the liquor becomes more expressed and when nearly exhausted, another lever of greater length and strength is applied to the lanthorn, and worked by means of the windlas, which is an upright post, turning with an iron pivot in a socket on the ground, and passing through a beam in a rather free manner at the top, being removeable when not wanted. A rope coiled round this windlas, is hung by a loop to the end of the lever, being there secured from springing off, by a wooden pin. The windlas has likewise at proper heights, from two to four bars of wood passing through for the purpose of handles, to which the strength of four men may be applied with much effect. The press-blocks are pieces of oak, about two feet in length, and six inches square, placed one above the other, crossing in alternate pairs, under the bridge, for the purpose of keeping the lanthorn, lever, and rope above the heads of the workmen at the windlas.

It is suggested that iron screws have of late been coming much into use, being either cast or wrought; the price of the former being about 2*l.* 15*s.*; and of the latter nearly 10*l.* The power is supposed by some to be increased by the

the fineness of the threads in the iron screw, while others admit of no other superiority but that of durability.

The price of a good press with wooden screw is usually about ten guineas.

It has been suggested by the author of the Rural Economy of Gloucestershire that the situation of the press should be as near the horse path of the mill as conveniency and the nature of the building will permit, in order to the more ready conveyance of the ground pommage or pulp from the mill to it. The size of the cyder-press may be different according to the extent of the apple orchard.

An improved *Large Cyder-press* is shewn at *fig. 3*, in which A A is the base or foundation with its supporting parts: B, B, the cheeks or filters: D D the cross piece at top, through which the screw passes, and which consequently contains the nut or female screw: E the screw with its appendages: F F the bridge or cross piece which acts on the pommage: G G is the wide plank or vat on which the pulp rests in the hair bags; in which the mode of the liquor's passing off is seen: H H (*fig. 4.*) is the windlass, with its handles, wheel, rope, &c.

At *fig. 5*, is seen a small *Cyder-press* of a different kind, which acts by means of a heavy stone or block of wood made of a conical form, moving round the centre by a lever which is inserted into its base, as shewn at A and B: C is the bed of the press, notched for letting off the liquor into the cask or vessel, D, placed below: E, E, E, are the feet or blocks on which the whole rests.

CYDER-SPIRIT, a spirituous liquor drawn from *cyder* by distillation, in the same manner as brandy from wine. The particular flavour of this spirit is not the most agreeable, but it may, with care, be divested wholly of it, and rendered a perfectly pure and insipid spirit, upon rectification. The traders in spirituous liquors are well enough acquainted with the value of such a spirit as this: they can give it the flavours of some other kinds, and sell it under their names, or mix it in large proportion with the foreign brandy, rum, and arack, in the sale, without danger of a discovery of the cheat.

CYDER-VAT, is a term applied to that part of the cyder-press which first receives the liquor as it is forced out from the pulp, and by which it is conveyed into the receiver. See *CYDER-PRESS*.

It is likewise a name often given to the vessels which receive the cyder before it is racked off into the store casks.

It is remarked in the Survey of the County of Gloucester, that the vat is still, in some cases, covered with lead, although the pernicious effects of its being corroded by the acid of the liquor have been frequently experienced. It should on this account be always made of some sort of hard wood.

CYDER-VINEGAR. See *VINEGAR*.

CYDER-WINE, is the name of a sort of family wine made by concentrating the juice or liquor of apples, by evaporating it to nearly one half, and afterwards, when it becomes cold, fermenting it, in a suitable cask in the usual way. By this means a very pleasant and cooling wine is said to be prepared.

CYDISES MOUNTAINS, in *Ancient Geography*, a mountain of Asia, towards Armenia. Strabo.

CYDNA, a town of Macedonia, the same with *Pydna*.

CYDNUS. See *CIDNUS*.

CYDNUS, a river of Asia Minor, in Bithynia.

CYDOESSA, a fortified village of Phœnicia, at a small distance from the sea, which belonged to the Tyrians.

CYDONEA, an island of the Mediterranean sea;

opposite to that of Lesbos; one of the five islands comprehended under the denomination of *Leuce*.

CYDONIA, in *Botany*. Tournefort. Juss. Vent. See *PYRUS Cydonia*.

CYDONIA, or *CYDONIS*, in *Ancient Geography*, *la Canée*, the most ancient city in the island of Crete, said to have been built by Minos, and enlarged by the Samians. It stood according to Strabo, Pliny, and Diodorus Siculus, on the coast opposite to the Laedæmonian territory in the Peloponnesus, and it was the most powerful and wealthy city of the whole island; since in the civil wars it withstood the united forces of Gnoffus and Gortyna, after they had reduced the greater part of the island. Its strength was such that, though it was often besieged; it was never taken till the time of Metellus, to whom its gates were opened after the defeat of Lathenes and Panares. On account of its antiquity, it was called by the Greeks "the mother of cities." From Cydonia the quince-tree was first brought into Italy, and thence the fruit was called *malum Cydonium*, or *Cydonian apple*.

CYDONIS, or *ACYDONIS*, a river of Greece, in the Peloponnesus. Strabo.

CYDONITES VINUM. See *VINUM*.

CYDRANA, in *Ancient Geography*, a town of Asia Minor, situated on the confines of Phrygia and Lydia; W. of Colossæ, S. of the Meander.

CYDRIÆ, a town placed by Strabo on the frontiers of Epirus and Macedonia, belonging to a people, called *Byrsi*.

CYDRUS, or *CYDRINA*, a town of Asia, in Armenia. Steph. Byz.

CYENIUM, a place of Ethiopia, which, according to Arrian, was situated between the Nile, and the town of Adule.

CYGNUS, or *CYGNUM*, a town built by the Greeks at the lower part of the Euxine sea, near the banks of the Phasis.—Also, another town in the same country at a great distance from the Phasis. Pliny.

CYGNUS, or *Cygnus*, *Gallina*, the *SWAN*, in *Astronomy*, a constellation of the northern hemisphere, between *Lyra* and *Cepheus*. See *CONSTELLATION*.

The stars in the constellation *Cygnus*, in Ptolemy's Catalogue, are 19; in Tycho's, 18; in Hevelius's, 47; in the Britannic Catalogue, 81. For an account of the variable stars in this constellation by Edward Pigott, esq. see *Phil. Mag.* vol. lxxvi. p. 198, &c. For observations on the comparative lustre of its stars by Dr. Herschel, see *Phil. Trans.* vol. lxxxvi. p. 201. 217. vol. lxxxvii. p. 307.

CYGNUS, *swan*, in *Ornithology*, a species of *ANAS*, which see. See also *SWAN*.

CYGNUS cucullatus, the *hooded swan*, a name very improperly given by some authors to the *dodo*, a very large bird, rather approaching to the cassowary kind, but not so long legged, or long necked. Ray. See *DIDUS Neptus*.

CYIZA PORTUS, in *Ancient Geography*, a sea-port on the coast of Carmania, between the promontories *Bagia* and *Alabater*.

CYLANDUS, an ancient town of Asia Minor, in *Caria*. Steph. Byz.

CYLARABIS, a place in the Peloponnesus, in *Laconia*, about 300 paces from Sparta, where the youth exercised.

CYLICES, a people of Illyria, according to Athenæus, called by others, *Enchelæ*.

CYLICRANI, a people of Greece, in the Phthiotide territory, between the *Sperchius* and *Asopus*. Ortelius, says that they were the inhabitants of the town of *Heraclæa*, situated at the foot of Mount *Cæta*.

CYLINDER. If a right-angled parallelogram be made

CYLINDER.

made to revolve about one of its sides which remains fixed, the solid figure thus described is called a cylinder. The axis of the cylinder is that side of the parallelogram which remains fixed. This solid is terminated by three surfaces: a convex surface, and two plane circles, which are the ends, or bases, of the cylinder.

The above is Euclid's definition (Def. 21. 11. E.): it may be rendered more general. Let there be a plane circle, and a right line drawn from the centre, whether perpendicular, or inclined in any manner to the plane of the circle; and let another right line, indefinitely produced, be carried completely round in the periphery of the circle so as to be always parallel to the right line drawn from the centre; thus the surface described by the revolving line is called a cylindrical surface, of which the plane circle is the base, and the line drawn from the centre the axis. A cylinder may now be defined to be a solid figure bounded by a cylindrical surface, and two plane circles equal and parallel to the base of the cylindrical surface. This definition will coincide with Euclid's, when the axis of the cylindrical surface is perpendicular to the plane of the base. In this case the solid is called a right cylinder; in all other cases it is called an oblique cylinder.

From these definitions the following consequences may be described in a manner too obvious to require to be formally demonstrated. If a plane, parallel to another plane, drawn through the axis of a cylinder, cut the plane of the base of the cylinder in a right line that is a tangent of the base; that plane will touch the cylindrical surface, and will meet it in a right line parallel to the axis: but if such a plane cut the plane of the base in a right line that passes within the base, it will cut the cylindrical surface in two parallel right lines, and the common section of the plane and cylinder will be a parallelogram. And, again, the common section of a cylindrical surface, and a plane parallel to the base, is a circle having its centre in the axis.

Let us now consider the section of a cylinder by any other plane. Suppose a plane (*Plate IV. Geometry, fig. 3.*) to cut a cylinder in the common section PQ: let the cutting plane produced meet the plane of the base in the line MN, and from E, the centre of the base, draw the diameter CD, perpendicular to MN, and let a plane drawn through CD, and the axis of the cylinder, EF, meet the cutting plane, in the line PQR, and the cylinder in the parallelogram ABCD: let the axis of the cylinder, EF, meet the line PQO in, (which is plainly the middle of PQ), and through O, and any other point of PQ, as I, draw GH and ST parallel to MN: let a plane, STZX, be drawn through ST parallel to the plane, GHJK, that passes through GH, and the axis EF; because GH is parallel to MN, the common section of any two planes drawn through these lines will be parallel to both of them: therefore, KL is parallel to GH: and in like manner XZ is shewn to be parallel to ST and MN. Therefore the figures, GHJK, STZX, are parallelograms; and GH = KL = CD, also ST = XZ. Because XZ is parallel to MN, it is perpendicular to CD, and consequently it is bisected by CD: hence it is plain that ST is bisected by PQ. Now

$$PQ : CD, \text{ or } GH :: PI : CY$$

$$PQ : CD, \text{ or } GH :: IQ : DY$$

Therefore, because $CY \times YD = XY^2 = SI^2$,

$$PQ^2 : GH^2 :: PI \times IQ : SI^2$$

Therefore the section is, in general, an ellipse, of which PQ and GH are two conjugate diameters.

Two conditions are necessary to make the section PQ a circle: the conjugate diameters PQ and GH must be equal; and they must cut one another at right angles.

The first of these conditions will take place when the triangle, ROE, is isosceles, or when the line, PQ, is so inclined to the axis of the cylinder, as to make the angle FOP = the angle AFO, and the angle POE = CEO. The second condition requires that GH be perpendicular to PQ, or MN perpendicular to FR; which cannot be the case unless the plane, ΔPCD , be perpendicular to the ends of the cylinder as well as to the plane of the section PQ. Hence, then, we are to conclude that, if a cylinder be cut through the axis, by a plane, ABCD, perpendicular to the two ends, and likewise by another plane, PQ, perpendicular to the former, in such a manner that the second plane, PQ, is equally inclined to the axis of the cylinder as the two ends, but in a contrary position; the section of the cylinder by the second plane will be a circle equal to the ends of the cylinder. Such a section of a cylinder is usually called a subcontrary section. In a right cylinder the section parallel to the base, and the subcontrary section, are confounded together, and make only one section. Every other section of a cylinder, excepting those mentioned, is an ellipse.

The solidity of a figure, of which all the parallel sections are equal, such as a prism or cylinder, is measured by the product of the surface of one section by the perpendicular distance of the extreme sections. Hence all cylinders are equal in solid content, that stand on equal bases, and have equal perpendicular heights, however they may differ from one another in degrees of obliquity. If a cone and cylinder have equal bases and equal perpendicular heights, the solidity of the former will be one-third part of the solidity of the latter. Euclid has demonstrated this proposition in the case of the right cone and cylinder (10. 12. E.), and the same demonstration will equally apply when the solids are oblique.

The convex surface of a right cylinder is measured by the product of the altitude multiplied by the periphery of the base. If a rectangle be constructed, having its length equal to the altitude of a right cylinder and its breadth equal to the periphery of its base; it is plain that such a rectangle, being lapped round the convex surface of the cylinder, will completely cover it. From this we may derive the solution of the problem (*fig. 4.*) which requires to trace the line of shortest distance between two points (as A and B) on the surface of a right cylinder. Through one of the points, as A, draw a plane, MAN, parallel to the ends of the cylinder, and through the other point, B, draw BG in the cylindrical surface parallel to the axis, EF: take $cd, cd, \&c.$, in the same surface, parallel to BG, and of such lengths that they may bear to the arcs, $cA, cA, \&c.$ the same proportion that BG bears to the arc GA: then will the points, $d, d, \&c.$ mark out the line of shortest distance between A and B. For if the surface of the cylinder be rolled off into a plane, the arcs AG, $Ac, Ac, \&c.$ as well as the lines BG, $cd, cd, \&c.$ will be right lines, and therefore the points, $d, d, \&c.$ will be in the right line between A B, which is the shortest distance between these points.

If an oblique cylinder be cut by a plane perpendicular to the axis, then, according to what has already been shewn, the section will be an ellipse, the periphery of which will be at right angles to all the right lines drawn in the surface of the cylinder parallel to the axis; and because these right lines are all of the same length, equal to the axis, it readily follows that the convex surface of the cylinder is measured by the product of the axis into the periphery of the ellipse.

It is demonstrated in mechanics, that the solidity of a cylinder

cylinder is the factum of the generating rectangle ABCD, *Plate IV. Geometry, fig. 5.*) into the periphery of the circle described by the radius E G, which is subtiple of E F, or the semidiameter of the cylinder. See CENTRO-BARYC method.

CYLINDERS, for the ratio of. As all cylinders, cones, &c. are in a ratio composed of their bases and altitude: hence, if their bases be equal, they will be in the ratio of their heights; if their altitudes be equal, in the ratio of their bases.

Hence, also, the bases of cylinders and cones being circles; and circles being in a duplicate ratio of their diameters; all cylinders and cones are in a ratio compounded of the direct ratio of the altitude, and the duplicate one of their diameters: and, if they be equally high, as the squares of the diameters.

Hence, again, if in cylinders the altitude be equal to the diameter of the bases, they will be in a triplicate ratio of the diameters of the base. All cylinders, cones, &c. are in a triplicate ratio of their homologous sides; as also of their altitudes.

Again, equal cylinders, cones, &c. reciprocate their base and altitudes. See CONE, &c.

Lastly, a cylinder, whose altitude is equal to the diameter of the base, is to the cube of its diameter, as 785 to 1000.

To find a circle equal to the surface of a given cylinder, we have this theorem: the surface of a cylinder is equal to a circle, whose radius is a mean proportional between the diameter and height of the cylinder.

The diameter of a sphere, and altitude of a cylinder equal thereto, being given, to find the diameter of the cylinder: the theorem is, the square of the diameter of the sphere is to the square of the diameter of the cylinder equal to it, nearly, as triple the altitude of the cylinder to double the diameter of the sphere. See SPHERE.

To find a rete, or cage, whence a cylinder may be formed, or where-with any cylinder may be covered. With the diameter of the base describe two circles; find their peripheries: and, upon a line equal to the altitude of the cylinder, form a rectangle, whose other dimension is equal to the found periphery. Thus may the cylinder required be formed, or covered.

When the cylinder is oblique, the estimate of its superficies depends upon the rectification of the ellipse; for a plane cutting the cylinder at right angles to the axis will produce an ellipse, and the superficies will be equal to the product of this elliptic periphery by the side of the cylinder.

CYLINDER, resistance of a. See RESISTANCE.

CYLINDER, scenography of a. See SCENOGRAPHY.

CYLINDER, in Zoology, the VOLUTA *Oliva*; which see.

CYLINDER, concave, of a gun is the inward cavity or bore of the gun, which receives the powder and shot. See CANNON.

CYLINDER, charged, is the chamber and that part of the concave cylinder, which is filled or occupied by the powder and ball. See CANNON.

CYLINDER, vacant, is that part of the bore which remains empty after the gun or other piece of ordnance is loaded.

CYLINDER, rolling, in Mechanics, a cylinder which rolls up an inclined plane.

The phenomena of the rolling cylinder may be easily accounted for from what we have observed under centre of gravity.

For let ABED (*Plate XXII. Mechanics, fig. 1.*) repre-

sent the section of a cylinder of wood, biased on one side by a cylindrical piece of lead, as B, which will bring the centre of gravity out of the centre of magnitude, C, to some point, G, between C and B. Let F H be an inclined plane, whose base is F L. It is evident the cylinder laid upon the plane will no where rest but there, where a perpendicular to the horizon, F L, passes through the centre of gravity G, and that point of the plane E, in which the cylinder touches it; and this, in all angles of inclination of the plane less than that whose sine is equal to C G, the radius being C D, will be in two situations ABED, and abed: because when the cylinder moves, the centre of gravity describing a circle round the centre of magnitude C, this circle will meet the perpendicular in two points G and g, in each of which the centre of gravity being supposed, the cylinder will rest. Therefore the cylinder moves from E to e by the descent of the centre of gravity from G to g, in the arc of the cycloid G l g.

If the cylinder ABED, *fig. 2.* insiding on the horizontal line E L, in the point E, has the centre of gravity G in the horizontal diameter D B, it will gravitate in the perpendicular G: if therefore the plane F H touch the cylinder in the point e, it is evident the cylinder cannot either ascend or descend on such a plane. Because G in any situation between e and H, or e and F, will gravitate to the left or right from the point in which the cylinder touches the plane; and so will in either case bring it back to the point e. And as the angle E C e is equal to H F L, it follows, that a cylinder cannot ascend on a plane whose inclination is greater than that angle.

CYLINDER-Boring, is the method of boring out and smoothing cylinders of brass, iron, or other metals, for pump-barrels, steam-engines, &c. &c.

Plate XXIII. Mechanics, is appropriated to the description of a machine for this purpose, designed by Mr. John Dixon, Maid-lane, Southwark, and erected by him at the Falcon iron-foundery.

Fig. 1. is an elevation of the machine, in the operation of boring a cylinder for a steam-engine. *Fig. 2.* is a plan. *Figs. 3, 4, 5,* parts of the machine. *Fig. 6.* an end elevation. *Fig. 7.* a section.

The machine is turned by a steam-engine, which communicates motion by means of a coupling-box, a, to a long iron shaft A B, turning in brass bearings, supported on iron standards C, D, bolted to the two ground hills E, F; this shaft (called the boring bar) is perforated from end to end, as is shewn in the section, *fig. 3,* and has also a slit, b b, *fig. 1,* through it nearly its whole length; it is turned in a lathe, and thus made a perfect cylinder. Another short cylinder, D D (in the section, *figs. 3.* and *fig. 5.*), slides easily upon the boring bar without shake, and is made to turn round with the bar, by two short iron bars, d, d, which pass through the slit, b b, made in the boring bar, and fit in their ends into two notches made in the ends of the short cylinder D D. E is a long screw going with in the boring bar, and of the same length; the end which enters the boring bar, and which is not cut into a thread for some length, passes through holes made in the middle of the short bar d, d, and is held in by wedges, as in *fig. 3.*

The knife or cutters, c, c, *fig. 1,* are fixed in wedges which touch round the circumference of a cast-iron ring, *fig. 4,* called the cutter block; the inner circle, *fig. 5,* is of the same line as the outside of D D, upon which *fig. 6,* *plate 3,* and made to turn round with it, by two small wedges driven into notches, *fig. 7,* made in the inside of the ring, and entering similar notches in the outside of D D.

The cylinder, *II H*, to be bored, is fixed firmly concentric with the boring-bar upon a frame of cast iron, consisting of several pieces, which are moveable, and can be set to hold a cylinder of any length or diameter. The first are four cast iron bars, *I, I, I, I*, with slits through them nearly their whole length; they are firmly bolted down to the ground fills, and support two cross bars *K, K*, which can be fixed at any place along the bars *I, I, I, I*, by screws passing through the grooves. The cross bars, *K, K*, have grooves through them in the direction of their length, to receive screws which fix upon each bar two uprights, *L, L*, at any place.

By this sliding of the two cross bars *K, K*, the fixtures are adapted to the length of the cylinder, and by moving the uprights *L, L*, nearer to or farther from each other, the cylinder is fitted in its diameter, horizontal; the weight of the cylinder is supported by blocks and wedges driven under it upon the cross bars *K, K*, and it is kept down by two strong wrought iron-bands, *r, r*, put over it, and drawn down by screws on the top of the uprights *L, L*.

A cross beam is fixed upon the end of the ground fills, into which an upright beam, *M*, is mortised, and its upper end is supported by the beams of the ceiling; the upright has a socket fixed to it, in which a nut for the screw *E* turns, in such a manner that it cannot move backwards or forwards, though it is at liberty to turn round freely; an iron cross, *m m*, is fixed on the nut to turn it by. The end of the screw, *E*, is square, and has a short cross bar, *n*, pinned on it, which has wheels at its ends, and runs upon a thick plank, *N*, supported on iron legs, *o, o*; at one edge of the plank, a piece of iron plate, *p*, is screwed and turned over at top, to form a groove in which one of the wheels run; the cross bar and plank prevent the screw from turning while it can be moved endways along the plank.

In the working of the machine, the first thing is to fix the cylinder; for which purpose the plank, *N*, must be removed, the screw, *E*, drawn out of the boring bar, the upright, *M*, and iron standard, *D*, taken away, the weight of the boring bar being supported by blocks put under the middle of it; the cutter block, and the short cylinder *D D*, *fig. 3*, is now put upon the boring bar, the bars, *d, d*, *fig. 3*, being first put through the slit, *bb*, in *fig. 1*, in the bar at its end towards *D*, where it is enlarged for the purpose; the cutters are fixed in the block by wedges, and adjusted, that they may all be at the same distance from the centre, and that they may bore the cylinder of the proper size. The cylinder is now put over the boring bar, and when the end of the bar comes through the cylinder, the standard, *D*, is replaced; the weight of the bar is now supported, and the blocks in the middle can be taken away, to get the cylinder in its place, and fix it fast, as before described. The screw, *E*, is next introduced into the boring-bar, and pinned into the two cross bars *d, d*, as in *fig. 3*, the upright *M*, is fixed, and the nut of the cross, *m m*, screwed upon the screw *E*; the plank, *N*, is set up, and the whole put in the situation represented in the plate, except that the cutter block is seen on the boring bar towards *A*.

The steam-engine is now set to work, and the boring bar thereby turned; a workman turns the cross, *m m*, and with it the nut of the screw *E*; as the screw is prevented from turning by the cross bar, *n*, on its end, the screw is drawn endways, and consequently the cutter block with it, until it meets the end of the cylinder, when the cutters begin to bore, forming a new smooth cylinder, somewhat larger than the old one left by the casting of the cylinder; as the cutters clear the metal before them, they are drawn further into the cylinder by turning the cross, *m m*, until they

come completely through. The operation is now finished, and the cylinder is removed in the same manner as it was put in, the machine being left in pieces ready to put in another cylinder to be bored.

A great number of cutter blocks, *fig. 4*, are cast, of different sizes for various cylinders, and they all fit upon the same sliding cylinder, *D D*, *fig. 3*.

CYLINDRELLA, in *Entomology*, a species of *PHALENA Tinea*, found at *Hamburgh*.

CYLINDRI, in *Conchology*. A fossil shell, which has been referred to this genus by Mr. Walcott, has been figured in his "Petrefactions found near Bath," *fig. 46*; it has four spires or turns at one end, and is rounded at the other. They are found in the free-stone quarries near Bath.

CYLINDRIA, in *Botany*, (so called because the segments of the border of the corolla are, by their juxtaposition, a continuation of the cylinder of the tube.) *Lour. Cochin. 69*. Class and order, *tetrandria monogynia*.

Gen. Ch. *Cal.* Perianth inferior, tubular, short, permanent, four-cleft; segments acute, coloured, spreading. *Cor.* tubular, four-cleft; segments linear, acute, fleshy, extended jointly into a cylindrical tube, cowed at the tip. *Stam.* Filaments scarcely any; anthers four, two-celled, roundish, compressed, included in the cowls of the segments. *Pist.* Germ egg-shaped; style very short; stigma four-cleft. *Peric.* Berry small, roundish, dry.

Seed solitary, globular, lanuginous.

Eff. Ch. Calyx four-cleft, inferior. Corolla tubular, four-cleft. Berry with one seed.

Sp. C. rubra. (*Blimbingum sylvestre*; *Rumph. Amb. 6. 79. tab. 73.*) A moderate-sized tree. *Branches* ascending. *Leaves* opposite, lanceolate, somewhat serrated, smooth. *Flowers* red, small; peduncles nearly terminal, many-flowered. *Berry* black. A native of woods in *Cochinchina*. *Bosc* observes, that it is very nearly allied to *Protea*.

CYLINDRICAL *Column, Compasses, Mirrors, Wax-candles.* See the several substantives.

CYLINDROID, formed of *κυλινδρος, cylinder*, and *ειδος, form*, in *Geometry*, a solid body, approaching the figure of a cylinder; but differing from it in some respect, e. gr. as having its bases elliptical, but parallel, and equal. The solidity and curve superficies of this solid are found in the same manner with those of the cylinder; *viz.* by multiplying the circumference of the base by the length or axis, for the surface; and the area of the base by the altitude, for the solidity.

CYLINDROID, *hyperbolic.* See *HYPERBOLIC*.

CYLINDROIDEÆ, in *Zoology*, a section or division of the *VOLUTA* in the class of *Vermes Testacea*.

CYLIPENUS SINUS, in *Ancient Geography*, a gulf of the Baltic sea; supposed by *Cellarius* to be the gulf of *Livonia*.

CYLISTA, in *Botany* (*κυλιστος, twining*). *Hort. Kew. 3. 512. Schreb. 1759. Willd. 1351.* Class and order, *diadelphia decandria*. *Nat. Ord. Papilionaceæ, Linn. Leguminosæ, Juss.*

Gen. Ch. *Cal.* Perianth one-leaved, four-parted, very large, permanent; upper division reflexed, bifid at the tip; the rest erect, oblong, acute. *Cor.* papilionaceous, a little longer than the calyx, permanent; standard roundish, emarginate, with a small lobe on each side at the base; wings oblong, obtuse, shorter than the standard, with a process on each side at the base; keel oblong, cloven at the tip and the base, longer than the wings. *Stam.* Filaments, one single; nine united, ascending; anthers roundish.

Pist.

Pist. Germ superior, egg-shaped, compressed; style awl-shaped, ascending; stigma somewhat capitate. *Peric.* Legume ovate-oblong, compressed, one-celled. *Seeds* two, oval.

Eff. Ch. Calyx very large, four-parted; upper division bifid at the tip. Corolla permanent.

Sp. 1. *C. villosa*. Hort. Kew. 3. 36. Introduced into Kew garden in 1776. Native country unknown. It is a shrub, and requires the heat of a stove. 2. *C. scariosa*. Willd. Roxb. Corom. 1.-64. tab. 92. A shrub. *Stem* twining. *Leaves* ternate, with the pubescence of phaseolus; stipules small, lanceolate-awl-shaped. *Flowers* in axillary racemes the length of the leaves; calyx green, veined; corolla yellow. A native of mountains on the coast of Coromandel. As there is no description of *C. villosa* in the Hortus Kewensis, we cannot determine the specific difference of the two plants.

CYLISTANOS, in *Ancient Geography*, a town of Italy, called also *Parthas*.

CYLISTARAUS, a river of Italy, mentioned by Lycophron.

CYLISTI, formed of *κύλιω*, to roll, or tumble, in *Antiquity*, a designation given to the *pancratiaste*; because when the weaker found himself fore pressed by his adversary, he fell down, and fought, rolling on the ground. See PANCRATIUM.

CYLLA, in *Ancient Geography*, a town of the Chersonesus of Thrace, situated on the Hellespont, which had been episcopal; called Cælos by Mela.—Also, a town of Asia Minor, in the Troade. Herodotus.

CYLLANTICUS, or CYLLANICUS, *Traçtus*, a particular country of Asia, in Pisidia. Pliny.

CYLLENA, or CYLLENE, a town situated on the western coast of the Peloponnesus, near Elæa, of which it was the port; supposed to be the present *Chiarenza*. It had two temples: one of Æsculapius, with a fine statue of ivory, and another of Venus, in which was a naked statue of Mercury.—Also, a town of Asia Minor, in the Æolide, furnished, according to Xenophon, *Egyptian*.

CYLLENE, a mountain of the Peloponnesus, in Arcadia, which, according to Pausanias, was the highest in this country. It was situated to the north-east, between the territory of Pellene in Sicyonia and that of Pheneos in Arcadia. On the top of the mountain was a temple of the Cyllenian Mercury, in which was a wooden statue of this god. Near this mountain, according to Homer, was the tomb of Epytus, consisting of a mound of earth encompassed by a balustrade of stones. Epytus, it is said, died of a wound inflicted by a serpent.

CYLOPERA, a place of Greece, in Attica, near mount Hymettus, in which, as Suidas says, was a temple consecrated to Venus.

CYLLOSIS, or CYLLUM, from *κύλλος*, lame, in *Medical Writers*, is used to signify a leg put out of joint outwardly;—also one that is lame and crooked.

CYLONGO, in *Geography*. See CHYLONGO.

CYMA, in *Architecture*. See CYMATIUM.

CYMA, in *Botany*. See CYMF.

CYMA, in *Ancient Geography*, an island in the Mediterranean sea, near Sicily, according to Steph. Byz; but placed by Lycophron near Italy.—Also, a very high mountain of Italy.

CYMATITES, in *Natural History*, a name given by some writers to a species of *ASTROITES*, the lineations of which are indented and represent waves.

CYMATIUM, CYMA, or CYMA, an architectural moulding of an undulated form, being concave at top and con-

vex at bottom. (See *Plate of Mouldings*.) It is also called *doucine* and *gola diritta*. Some write the word *smaise*, from *smus*, *canus*, *flat-nosed*, but this etymology is improbable: the beauty of the moulding consists in its having its projection equal to its height. M. Felibien, therefore, rejects this origin; contending, that the moulding is not so denominated from its being the uppermost member of the cornice, but, according to the sentiments of Vitruvius, from its being waved, from the Greek *κυματός*, *undula*, of *κύμα*, *wave*. This is certain, that Vitruvius sometimes uses the word *unda* for cymatium; and sometimes *lysis*, i. e. *solution*, *separation*; because corniches, where the *cymaises* are found, separate one piece of architecture from another; as the pedestal from the column, and the frieze from the cornice. But it must be observed, that Vitruvius appears to use the term cymatium for any subordinate moulding which terminates a principal member without regarding its particular form. Thus he mentions the Doric cymatium, which, from the authority of ancient examples, we should pronounce to be an ovolo, and the Lesbian cymatium which Newton supposes to be an ogee.

Felibien makes two kinds of cymatiums; the one *right*, the other *inverted*: in the first, that part which projects the furthest is concave, and is otherwise called *gula recta*, and *DOUCINE*. In the other, the part that projects furthest is convex, called *gula inversa*, or *TALON*.

Our architects do not chuse to give the name cymatium to these mouldings, except when found on the tops of corniches, but the workmen apply the name indifferently, wherever they find them. Palladio distinguishes the cymatium of the *corniche* by the name *intavolata*.

CYMATIUM, *Tuscan*, consists of an ovolo, or quarter round. Philander makes two Doric cymatiums, whereof this is one: Baldus calls this the Lesbian *astragal*.

CYMATIUM, *Doric*, is a cavetto; or a cavity less than a semicircle, having its projection subduple its height.

CYMATIUM, *Lesbian*, according to Vitruvius, is what we otherwise call *talon*; viz. a concavo-convex member, having its projection subduple its height.

CYMBACHNE, in *Botany*, (from *κύμα*, a boat, and *αχνη*, a glume or chaff.) Mart. Mill. Retz. Obs. 6. 36. Class and order, *polygamia monœcia*. Nat. Ord. *Gramina*.

Gen. Ch. Hermaphrodite flowers. *Cal.* Glume two-valved, one-flowered, so placed that each valve is pressed close to the rachis and parallel, not one hidden by the other; outer valve linear, blunt, ciliated at the back; inner equal in length, semiovate, acute, boat-shaped, very much compressed, striated, coloured, ciliated at the back, enclosing the corolla. *Cor.* Glumes two, hyaline, smaller than the calyx. *Stam.* Filaments three; anthers black. *Pist.* Germ minute; style simple; stigmas two, black-bearded. Female flowers. *Cal.* one valved, egg-shaped, slightly bifid at the tip, ciliated at the edge, opposite to the rachis, pressed close. *Cor.* none. *Pist.* as in the hermaphrodite, but with longer stigmas.

Eff. Ch. Inflorescence half-spiked. *Herm. Calyx* two-glumed, one-flowered, parallel to the rachis; outer valve linear; inner boat-shaped. *Fem.* Calyx one-glumed, egg-shaped, opposite to the rachis.

Sp. *C. ciliata*. Mart. Retz. *Culms* several, slender, a foot high, simple or branched, with a single leaf, or leaflets. *Leaf* short, slender, ciliated on the edge above the sheath with long separate hairs; sheath truncate, with a pale brown mouth and ciliated. *Spikes* two, terminal, linear, an inch and a half long, a line broad, some hermaphrodite, others female. *Rachis* linear, membranous, flat behind with three longitudinal streaks alternately and flexuously hollowed out in front. A native of Bengal.

CYMBAL, a musical instrument, used among the ancients; called by the Greeks *κυμαλον*, and by the Latins *cymbalum*.

Sylburgius derives the word from three several roots, *viz.* from *κυρος*, *crooked*; from *κυμαλον*, *cup*; and from *φωνη*, *voice*. Isidore derives it from *cum*, and *ballematica*, an immolated dance used to accompany this instrument. The real etymology appears to be from *κυμαλον*, *cavity*.

The cymbal was of brass, like our kettle-drums; and as some think, resembling them in their form, but smaller, and applied to a different use.

Cassiodorus and Isidore call it *acetabulum*, the name of a cup or cavity of a bone wherein another is articulated; and Xenophon compares it to a horse's hoof; whence it must have been hollow; which appears, too, from the figure of several other things denominated from it: as a basin, caldron, goblet, casque; and even a shoe, such as those of Empedocles, which were of brass.

In reality, the ancient cymbals appear to have been very different from our kettle-drums, and their use of another kind: to their exterior cavity was fastened a handle; whence Pliny compares them to the upper part of the thigh, *coxendicibus*; and Rabanus to phials.

They were struck against one another, in cadence, and made a very acie found. Their invention was attributed to Cybele; whence their use in feasts and sacrifices; setting aside this occasion, they were seldom used but by dissolute and effeminate people. M. Lampe, who has written expressly on the subject, attributes the invention to the Curetes or inhabitants of mount Ida, in Crete; it is certain these, as well as the Corybantes, or guards of the kings of Crete, and those of Rhodes and Samothracia, were reputed to excel in the music of the cymbal. See CORYBANTES.

The cymbals of Bacchus were two small brass vessels, somewhat in the form of a shield, which being struck together by the hands, gave a sound. The well-known statue of the dancing fawn has one of these in each hand. An instrument of this kind is frequently to be seen in the Bacchanalian sacrifices or processions represented in ancient sculpture. It is still in general use in eastern countries, and has lately been introduced among the troops of almost all the princes of Europe, on account of its utility in marking the steps of the soldiers, with force and precision during their march. *Crotalo* is the modern Italian name for this instrument; but *κροταλον* in Greek, and *crotalum* in Latin, implies one that was different from the cymbalum; a kind of castanet.

The Jews, too, had their *cymbals*, which they called *צלצלים*, or *תצללים*; or, at least, instruments which the Greek, Latin, and English translators render cymbals; for as to their matter, form, &c. the critics are wholly in the dark.

Le Clerc has taken some pains to prove, that the *tzilzelim*, which our version, after the septuagint, renders cymbals, were only a couple of hollow demiglobes of brass, or some other tinkling metal, about 6 inches in diameter, which they used to shake one against another like a pair of castanets, because we find some such instruments to have been in use among the ancients, and because the root *tzalzal* often signifies *to tinkle*.

The modern cymbal is a mean instrument, chiefly in use among vagrants, gypsies, &c. It consists of steel wire, in a triangular form, whereon are passed five rings, which are touched and struck along the triangle with an iron rod held in the left hand, while it is supported in the right by a ring, to give it the free motion. Durandus says that the monks

used the word cymbal for the cloister-bell, used to call them to the refectory. See BELL.

CYMBALARIA, in Botany. Bauh. Pin. See ANTIRRHINUM *Cymbalaria*.

CYMBARIA, (from *κυβη*, a *boat*, alluding to the shape of the fruit.) Linn. Gen. 751. Schreb. 1008. Willd. 1146. Gært. 312. Juss. 119. Clafs and order, *ydli namia angiospermia*. Nat. Ord. *Perfonata*; Linn. *Scrophularia*; Juss.

Gen. Ch. *Cal.* Perianth ten-toothed, erect, permanent; two opposite teeth stronger and more spreading; the rest erect, linear. *Cor.* monopetalous, ringent; tube oblong, bellied; border two-lipped: upper lip two-parted, reflexed, obtuse; lower lip three-cleft, obtuse. *Stam.* Filaments four, the length of the tube; anthers bifid, prominent. *Pyl.* Germ superior, egg-shaped; style difform, the length of the stamens, incurved at the tip; stigma obtuse. *Peric.* Capsule elliptic-heart-shaped, two celled, two-valved; partition contrary to the valves. *Seeds* several, oblong, compress'd.

Eff. Ch. Calyx ten-toothed. Capsule heart-shaped, two-celled. Nearly allied to antirrhinum.

Sp. C. *laurica*. Linn. Sp. Pl. Mart. Lam. Willd. Amm. Ruth. 47. tab. 1. fig. 2. Gmel. Sib. 3. 198. n. 8. Gært. tab. 53. fig. 12. Lam. Ill. Pl. 530. Whole plant slightly pubescent and hoary. *Root* perennial, fibrous. *Stems* several, six or seven inches high; branches few, opposite, barren. *Leaves* opposite, lanceolate-linear, acute. *Flowers* large, yellow, tinged with purple on the inside, lateral, almost sessile. *Capsule* membranous, slender, brown bay, marked with a deep groove on each side, dehiscent only at the edge; valves finally narrower than the receptacle; receptacles large, fungous, white, kidney-shaped, connected with the partition on each side by an intermediate flat substance. *Seeds* from twelve to fifteen in each cell, surrounded by an irregular membranous edge, pendulous from a nearly terminal umbilicus, imbricated downwards, bay-coloured. A native of mountainous rocky places in Siberia. This genus is distinguished from all the rest of its natural family by the calyx.

CYMBIDIUM, (from *κυβη*, a *boat*, alluding to the shape of the tip of the flower.) Willd. v. 4. 94. Swartz. Act. Holm. 1800 p. 236. Tracls on Botany, 167. Schrad. Journal, 1799. 213. t. 1. Sco. Orchid. in Schr. Neues Journ. v. 1. 72. Clafs and order, *gynandria monandria*. Nat. Ord. *Orchideae*, Linn. Juss.

Gen. Ch. reformed. *Cal.* three leaved. *Cor.* Petals two, generally smaller than the calyx-leaves; nectary a lip, concave at the base, without any spur, separate from the style at its edges, its termination spreading, either upward or downward, undivided or lobed. *Stam.* Anther an hemispherical deciduous terminal lid, of two or four cells; masses of pollen pedicled, in pairs. *Pyl.* Germen inferior, oblong or ovate, erect, furrowed; style semi-cylindrical, often gibbous, concave in front; stigma either concave or convex, in the fore-part of the style near the top. *Peric.* Capsule oblong or ovate, with three or six ribs, with one cell and three valves, opening by clefts between the ribs. *Seeds* numerous, minute, each clothed with a chaffy tunic, inserted into the downy internal ridges of the valves.

Eff. Ch. reformed. Calyx-leaves upright. Lip concave at the base, without a spur, with a spreading border. Anther a terminal lid, deciduous. Pollen gibbous.

Obf. Very rarely the two lowermost leaves of the calyx are united into one. For the reasons of our thus denominating the three outer petals of Linnæus, or outer calyx-

leaves of Swartz and Jussieu; see Sm. *Introd. to Botany*, p. 461.

This genus was founded by Dr. Swartz, and consists in his last work on the subject (*Genera et species orchidearum*, the first article in Schrader's *New Journal of Botany*, publ. 1805), of 43 species, 29 of which are said to be parasitical and 14 to grow on the ground. Among the former are *Cymbidium coccineum*, (*Epidendrum coccineum*, Linn.)—*C. tripterum*. (*E. tripterum*, Sm. *Icon. Pit. t. 14.*) a native of Jamaica, which flowered several years ago in the collection of the Hon. Mrs. Barrington, and also at Kew, but has rarely been seen in our gardens. Its numerous green bulbs, resembling a dish of green-gage plums, bear long narrow leaves, and elegant spikes of white flowers. Many beautiful species of *Epidendrum*, or *Limnorum* in Linnæus, Roxburgh, &c. are referred to this section by Dr. Swartz, which do not all well agree togeth'er. Among the *terrestrial* species is *C. pubellum*, (*Limnorum tuberosum*, Linn. *Curt. Mag. t. 116.*) and others allied to it.—*C. hyacinthinum*, Sm. *Exot. Bot. t. 60.*—*C. giganteum*, (*satyrium giganteum*, Linn.) with several other Linnæ in *Satyria* from Africa.—*C. corallorhizon*. (*Ophrys corallorhiza*, Linn. *Engl. Bot. t. 1547.*) is the only British *Cymbidium*. This has lately been found, much more plentifully than heretofore, by Mr. Edward Maughan, in boggy shady ground not many miles from Edinburgh. It grows also in the more northern parts of Europe and America. The fleshy roots, branched like a coral, and fragrant like *Vanilla*, even long after drying, are very remarkable. The flowers are small, greenish, and inconspicuous. Leaves none, except a few sheathing scales.

The genus of *Cymbidium* is not one of the most natural, its species having no very striking habit or aspect in common, and there being some Indian *Orchideæ*, lately discovered, in which the absence or presence of a spur appears of no moment as to generic distinction. See LIMNORUM.

CYMBIUM, in *Natural History*, a name given by many authors to a kind of sea-shell, commonly called the gondola shell. It is of the genus of the concha globosa, or dolium, and there are several species of it.

CYMBURUS, in *Botany*, (from *κύβος*, *cavus recessus*, and *οὐρα*, *cauda*) Salisb. *Parad. Lond.* 49 (Sherardia; Vahl. *Stachytarpheta*; Vahl) Class and order, *diandria monogynia*. Nat. Ord. *Personata*, Linn. *Vitices*, Juss. *Pyrenaceæ*, Vent.

Gen. Ch. Cal compressed, seated in a lateral hollow of the common peduncle. Cor. monopetalous; tube crooked; border rather funnel shaped, unequally quinquefid. Stam. Filaments four; two barren; anthers two, long, two-lobed; one lobe placed perpendicularly upon the other. Pist. Germ superior; style bifurcated, the length of the tube; stigma cap-shaped. Seeds two, naked. Linn. Juss. Gerit. Almost naked. Vent. Peric. a thin pellicle adhering to the seeds, but continuous with the style, two-seeded. Salisb.

Ess. Ch. Calyx compressed, seated in a hollow of the common peduncle. Anthers long; one lobe placed perpendicularly upon the other. Stigma cap-shaped.

Sp. 1. *C. mutabilis*. Salisb. *Parad.* 49. (*Stachytarpheta*; Vahl. *Sp. Pl.* 1. 205. *Zephania mutabilis*; Lam. *Ill.* 257. *Verbena mutabilis*; Jard. *Malm.* 36. *Jaqc. Ic. Coll.* 2. 334. *V. Orubica tenuifolia*; Herm. *Prod.* 258. *V. americana flore coccineo*; Breyer. *Prod.* 2. 103. *Sherardia tenuifolia*; Vahl. *Sex.* 49.) "Leaves egg-shaped, tomentous underneath; bractes spreading and bristle-shaped at the tip; back of the calyx scarcely toothed; corolla externally vivid-purplish; stigma entire." Stem becoming somewhat woody,

with widely spreading branches, sharply four-cornered, hairy. Leaves from two and a half to four inches long, yellowish-green, egg-shaped, serrated, obtuse, hairy, paler and more nappy underneath, wrinkled; petioles half an inch long or more, convex on the upper side, bordered almost to the bottom with the decurrent leaf. Flowers in a long spike; common peduncle hollowed out for each flower as in some of the grasses; bractes shorter than the calyx; calyx half an inch long, exceedingly compressed, with two deep furrows next the peduncle, hairy on the outside; corolla an inch long or more; tube dark red, with a whitish bottom, cylindrical, thickly bearded within on one side with erect hairs; border deep scarlet, gradually changing to a lilac tinge, more than twice as long as the tube, its lower part only a little wider than the tube, somewhat compressed with two furrows in front, where it is internally bearded up to its mouth; upper part horizontal, with a deep purple heart-shaped mark about the mouth, divided into five short rounded unequal segments; filaments whitish, short, bearded on one side; barren ones very narrow; anthers pale yellow; pollen consisting of three or four globular bodies confluent with a still larger central one; style pale yellow, smooth; stigma green, smooth, Salisb. A native of the island of Oruba and the adjacent continent of North America. 2. *C. orubica*. (*Verbena orubica*; Linn. *Sp. Pl. Pluk. Alm.* 383. tab. 228. fig. 4. and tab. 327. fig. 7. *Sherardia urticae folio*; Ehret. *Pict.* tab. 5. fig. 1.) "Spikes very long, leafy." A native of the island of Oruba. 3. *C. jamaicensis*. (*C. urticifolia*; Salisb. *Parad. Lond.* 53. *Stachytarpheta jamaicensis*; Vahl. *Sp. Pl.* 1. 207. *Verbena jamaicensis*; Linn. *Sp. Pl.* 3. *Jaqc. Obs. Fasc.* 4. p. 6. tab. 85. *V. erecta divisa*; Brown. *Jam.* 115. *V. folio subrotundo*; Sloan. *Hist.* 171. tab. 107. fig. 1. *Sherardia tenuifolia*, flore purpuro; Vaill. *Sex.* 49. *Valerianoides*; Boerh. *Hort. Lugdb.* 2. 270.) "Leaves oval-lanceolate, smooth; middle nerve somewhat hairy underneath; bractes close pressed their whole length, ovate-acuminate; back of the calyx not toothed; stigma entire." Stem becoming woody, hairy when young. Leaves bright green, sharply serrated; petioles long. Flowers in a very long slender spike, scented; common peduncle with a deep shining cavity; bractes membranous towards the base, slightly torn or crenulate; calyx only about two lines and a half long, exceedingly compressed, four-toothed, the dorsal nerve terminating below the top; corolla violet-blue, internally bearded as in *C. mirabilis*; filaments white; anthers sulphur coloured; stigma greenish, smooth. Salisb. A native of the island of Barbadoes. 4. *C. indica*. (*Verbena indica*; Linn. *Sp. Pl.* 2.) "Spikes very long, fleshy, naked; leaves lanceolate-egg-shaped, obliquely toothed; stem smooth and even." Similar to the preceding, but differs in having the stem entirely smooth, the leaves more lineate, not serrated, gradually narrowed at the base, with petioles not margined. Linn. Flowers blue. A native of the island of Ceylon.

CYME, *СУМА*, is a form or mode of inflorescence, consisting of several flower-stalks, all springing from one centre or point, but each stalk is variously subdivided, and in this last respect, the cyme differs essentially from an umbel, the subdivisions of the latter being formed like its primary division, of several stalks springing from one point. This difference, however slight it may appear in description, is of great importance in nature. Examples of a cyme are found in the genus *viburnum*, of which the common *launimus* is a species. In several of these the subdivisions are numerous or often repeated, and some of them are umbellate like the primary division; but this is of no moment, provided any

of them be irregular or dispersed. In an umbel, which mode of flowering chiefly belongs to a natural order of plants thence called umbellate or umbelliferous, the inflorescence is never more than twice compounded, consisting of a general umbel formed of several partial ones.

Linnæus considered the cyme, as well the umbel, kinds of aggregate flowers. See AGGREGATE and COMPOUND. Their stalks he reckoned as a branched receptacle, their *bractææ* or floral leaves, as a kind of calyx remote from the flower, for which he invented the term *involucrum*. Hence the flowers became florets, *fosculi*. Many arguments may be found in favour of this hypothesis, especially what are derived from the analogy between such aggregate flowers and the proper compound or syngenesious ones, both having frequently radiant, female, or even neuter, marginal flowers or florets. In the marigold, *calendula*, a true compound flower with united anthers, the central florets are entirely male, the marginal ones female, exactly as in the umbelliferous flower *oenanthe*; and there are many similar instances in both families. In the cyme of *viburnum opulus*, and various species of *hydrangea*, the flowers of the circumference are very often dilated or radiant, and in that case neuter. Such flowers become double, as it is called, not by multiplication of their petals, or a change of stamens or styles into the latter; but by a strange dilatation of their petals, attended with obliteration of the organs of impregnation. It seems to us, nevertheless, most natural and convenient to esteem both the cyme and the umbel modes of inflorescence, as they so insensibly, in some instances, slide into a *corymbus*, a *capitulum*, or a *spica*; or at least evince a common generical affinity, if we may so express it, with those. We would therefore follow the example of those who characterize the genera of umbellate, as well as cymose, plants by the real parts of fructification alone, being well convinced that to depend on such only, is one of the foundation of the Linnæan maxims. See GENUS and INFLORESCENCE. S.

CYME, called also incorrectly *Cuma*, in *Ancient Geography*, a very handsome town of Asia Minor, in *Æolia*, at the lower part of a small gulf of the same name, north-east of Phocæa. It was also called *Phiririconites*, from mount Phiricius, in the Locride, above Thermopylæ. Some vestiges of this town are discernible in a place called *Nemour*.

CYMEUS SINUS, the gulf of Cyme, was formed by the sea of the Archipelago, and extended eastward along the coast of Etolia, between a peninsula which advanced to the north-west, towards the city of Lesbos, and another which advanced to the south-west, towards the entrance of the gulf of Smyrna.

CYMENE, in *Botany*, a name given by the ancient Greeks to a plant with which they used to dye woollen things yellow, and with which the women also used to tinge the hair yellow. The *cymene* of the Greeks is evidently the same plant with the *lutum* or *lutea herba* of the Latins; and this is described to have leaves like the *linum*, or flax, and flowers like the *genista*. It is plain from this, that the *lutum* of the Romans, is the *genista tinctoria* of Linnæus, or dyer's weed, still used to dye yellow, and which answers to all the characters of the Roman description.

CYMINALIS, a name used by some authors for the *gentian*, the plant whose root is the fine bitter drug of that name.

CYMINO, *Cataplasm* δ . See CATAPLASM.

CYMINOSMA, in *Botany*, Gært. See LAXMANNIA.

CYMINUM. See CUMINUM.

CYMODŒEA. Konig. *Annals of Botany*, 296.

Class and order, *diœcia? tetrandria*. Nat. Ord. *Innudata*, Linn. *Naiades*, Juss.

Gen. Ch. *Cal.* and *Cor.* none. Barren flowers. *Stam.* Filaments none; anthers four, lanceolate-acuminate, erect, connivent; fixed to a scape or peduncle, (filament, Cassin) which is bifid or quadrifid at the top; containing a solid mass of pollen, which, when mature, becomes filamentous. Fertile flowers. *Pist.* Germens two, nearly sessile, convex-plane, approximate; style to each germen one, filiform; stigmas awl-shaped. *Peric.* Capsules two, approximate, compressed, two-valved; valves united by an ambient ring.

Sp. C. *æquorea*. Konig. ubi supra, Pl. (Plucagrostis Theophrasti major; Caulini Monog. cum. tab.) Stem (root?) perennial, rather woody, creeping, zig-zag, jointed, throwing out filiform radicles at each joint; branches (shoots?) rising from each joint, annulated towards the base. *Leaves* linear, obtuse, membranous, sheathing; sheaths flat, closely covering each other. *Scape* or peduncle from the sheaths of the leaves, long, attenuated, nearly the length of the leaves; anthers attached lengthwise so as to leave a space at the two opposite sides, opening longitudinally, and discharging a white capillary pollen; styles about an inch long; stigmas two to each style, longer than the style, dark yellow at the upper part, tubular when viewed through a microscope. *Fruit* roundish, compressed, with elevated margins, terminated by the remains of the style, rather woody, with a thin pulp. A native of the bay of Naples, totally immersed in the sea.

CYMOTHÆ, in *Ancient Geography*, a fountain of the Peloponnesus, in Circædia; placed by Pliny near the mountain *Scioessa*.

CYNA, a town of Asia Minor, in Lydia.

CYNADRA, a fountain of the Peloponnesus, in the Argolide.

CYNÆDUS, in *Ichthyology*, a species of LABRUS, which see.—Also, a name given by Gronovius to the SPARUS *Sargus*, and SPARUS *Dentex* of Gmelin.

CYNÆTHA, a town of Thrace, situated at the foot of mount Nerife. Steph. Byz.—Also, a town of Peloponnesus, in Arcædia, on the river Crathis. Pausanias says, that, in his time, many altars, consecrated to different deities, and a statue of the emperor Adrian, remained on the site of this town. Bacchus had a temple here, in which, in the winter season, the feast of this god was celebrated with peculiar ceremonies.

CYNAMOLGI, a name given by the Greeks to a people seated in the southern parts of Ethiopia. They had long beards, and kept very fierce dogs, in order to hunt Indian oxen, of which prodigious herds came amongst them every year.

CYNANCHE, in *Medicine*, $\kappa\upsilon\upsilon\acute{\alpha}\nu\chi\eta$, from $\kappa\upsilon\upsilon\acute{\alpha}$, a dog, and $\acute{\alpha}\nu\chi\eta$, I strangle; hence probably the French *esquinancie*, and our own *quinansy* or *quinsy*. This term is applied by nosological writers to inflammations of the throat in general. It is synonymous with the Latin, *angina*. See ANGINA.

Sauvages has described a number of species of cynanche; but Dr. Cullen reduced them to five, setting aside all those which were only symptomatic, or mere varieties of the same disease. Dr. Cullen's species are, 1. *Cynanche tonsillaris*; 2. *C. maligna*; 3. *C. trachealis*; 4. *C. pharyngea*; 5. *C. parotidea*.

1. *Cynanche tonsillaris*, is an inflammation of the mucous membrane lining the throat, and affecting especially the tonsils, and spreading from thence along the velum and uvula.

The

CYNANCHUM.

The disease is marked by a redness of the parts, accompanied by swelling, which is sometimes considerable, so as to render the act of swallowing painful and difficult, or even to impede it almost entirely. There is also a troublesome clamminess of the mouth and throat, with a frequent but difficult excretion of mucus; there is often a pain shooting into the ear: the voice is altered, and articulation rendered indistinct. A degree of fever is generally present.

This species of quinry is never contagious. It terminates frequently by resolution, sometimes by suppuration, but hardly ever by gangrene. The progress of this inflammation to suppuration, is sometimes, indeed, very rapid; at other times there are several small abscesses, which break one after another, and the disease is tedious. Occasionally the tonsils become enlarged and hard after this inflammation, and remain so for years. When a large imposthume breaks, there is generally sudden relief from the pain, difficulty of breathing, swallowing, and speaking; although often no matter is thrown up, but passes down the œsophagus.

The disease is commonly traced to exposure to cold. It affects the young and sanguine, and is very liable to return, in some constitutions, upon the application of cold to any part of the body, so as to become almost habitual. It occurs, especially in spring and autumn, when vicissitudes of heat and cold frequently take place. The inflammation and swelling often begin most violently in one tonsil, and afterwards, abating in that, increase in the other.

The remedies for inflammation and the antiphlogistic regimen are to be employed for the cure of this complaint. It is greatly aggravated by heating diet and stimulating medicines. General blood-letting is seldom necessary, but leeches to the neck and external fauces are very useful. Blisters, when early applied to the same parts, are also highly beneficial, and have often had the effect of curing by resolution a violent inflammation of the throat. When suppuration is begun, they can be of little use. Purgatives, repeated occasionally, are of essential benefit; and gentle diaphoretics are useful, whether in the shape of diluents, or saline medicines. The inflammation is often relieved by moderate astringents, and particularly acids, applied to the inflamed parts; hence the use of gargles, containing vinegar, lemon juice, or the mineral acids, and rendered palatable by means of honey or syrup. The acids coagulate the mucus, which adheres about the parts, and cleanse the passages. In many cases, however, no application has afforded more relief, than the vapour of warm water, received into the fauces by means of Mudge's inhaler.

The external applications of oil and volatile alkali, of vinegar, &c. by means of flannel, have little or no efficacy, unless employed so as to excite some inflammation externally.

II. *Cynanche maligna*, is the contagious ulcerated sore throat, which accompanies scarlet-fever. See FEVER, *scarlet*.

III. *Cynanche trachealis*, or inflammation of the wind-pipe, is the technical name which Dr. Cullen, and after him, some other physicians have applied to the disease, popularly termed croup. See CROUP.

IV. *Cynanche pharyngea*, appears to be the same disease as the first species, except that it is seated lower down in the throat.

V. *Cynanche parotidea* is a disease known to the vulgar, among whom it has obtained a peculiar appellation, in every country of Europe, but has been little taken notice of by medical writers. In England it is called the *mumps*; in Scotland, the *branks*; in France, *oreillons* and *ourles*.

It is often epidemic, and manifestly contagious. It comes on with the usual symptoms of pyrexia, which is soon after attended with a considerable tumour of the external fauces, and neck. This appears first as a glandular moveable tumour at the corner of the lower jaw; but the swelling soon becomes uniformly diffused over a great part of the neck, sometimes on one side only, but more commonly on both. The swelling continues to increase till the fourth day; but from that period it declines, and in a few days more passes off entirely. As the swelling of the fauces recedes, some tumour affects the testicles in the male sex, or the breasts in the female. These tumours are sometimes large, hard, and somewhat painful; but, in this climate, are seldom either very painful or of long continuance. The pyrexia attending this disease is commonly slight, and recedes with the swelling of the fauces; but sometimes when the swelling of the testicle does not succeed to that of the fauces, or when the one or the other has been suddenly repressed, the pyrexia becomes more considerable, is often attended with delirium, and has sometimes proved fatal.

As this disease commonly runs its course without either dangerous or troublesome symptoms, so it hardly requires any remedies. An antiphlogistic regimen, and avoiding cold, are all that will be commonly necessary. But when, upon the receding of the swellings of the testicles in males, or of the breasts in females, the pyrexia comes to be considerable and threatens an affection of the brain, it will be proper, by warm fomentations, to bring back the swelling; and by vomiting, bleeding, or blistering, to obviate the consequences of its absence. See Cullen, *First Lines*, § 332.

CYNANCHUM, in *Botany*, *strangle-dog* (from *κυν*, *canis*, and *ανχων*, *strangulo*.) Linn. gen. 304. Schreb. 430. Willd. 408. Gart. 685. Juss. 147. Vent. 2. 429. Class and order, *pentandria digynia*; Linn. *Decandria*; Jacq. *Gynandria pentandria*; Dr. Smith. *Nat. Oid. Contortæ*; Linn. *Apocinea*; Juss.

Gen. Ch. *Cal.* Perianth one-leaved, five-toothed, or five-parted, or five-leaved, small, permanent. *Cor.* monopetalous; tube generally very short; border nearly flat, five-parted; divisions long, oblong, acute. *Nect.* surrounding the organs of impregnation, nearly cylindrical, five-parted, furnished with five membranous appendices which have a kind of two-celled bag destined to receive the protruding pollen-masses. *Pist.* Germen superior, oblong, two-cleft; styles two, sometimes only one, or none, short; stigma single, common to both styles, or both germs, abrupt, very thick, pentangular. *Stam.* Five two-lobed glands seated on the angles of the stigma, and producing in each of their cells a mass of glutinous pollen, which finally protrudes with a very slender pedicel, and is received into one of the cells of the appendices to the nectary. *Peric.* Follicles two, oblong, acuminate, one-celled, opening lengthwise. *Seeds* numerous, oblong, crowned with a down, imbricated on a free receptacle.

Ess. Ch. Corolla contorted. Nectary cylindrical, divided upwards into five segments, and furnished with five membranous appendices, which receive the pollen masses of the anthers, into as many two-celled bags.

Obs. The complex and peculiar structure of the flower in this genus, and some others nearly allied to it, has occasioned much perplexity to the best botanists, and has been differently understood by different authors. The appendices to the nectary bear a great resemblance to filaments, they have accordingly been so called by Linnæus and others, and their two celled bags have in consequence been considered as real anthers. But Dr. Smith observes, that the pollen

is neither attached to, nor secreted by these cells, but is produced in five pair of glutinous masses, exactly like the pollen of the orchidæ, from five glands inserted upon the stigma, so that no plants can be more certainly gynoandrous. See his Introduction to Botany, p. 495.

Sp. 1. *C. cymbat.* Lam. Mant. 92. Mart. 1. Lam. 1. Willd. 1. (*Euphorbia viminalis*; Linn. Sp. Pl. 9. Apocynum vineale; Bass. Act. bonon. A. guineen.; Herm. parad. 51. Felsel Tavil. Alp. Fig. tab. 190?) "Stem twining, perennial, leafless." Whole plant milky. *Stems* several, from three to six feet high, about the thickness of a goose-quill, greenish, smooth, twining about each other, or any neighbouring support, and then sometimes rising to the height of ten or twelve feet, with opposite branches on their upper part. A native of the Cape of Good Hope; and of Egypt if the reference to Aipinus be correct, but La Marck thinks it dubious. 2. *C. pyratechnicum.* Lam. Forst. Æg. 53. n. 79. "Stem shrubby, naked; peduncles solitary, axillary, tubercled; flowers pedicelled, in heads." La Marck thinks it distinct from the preceding. A native of the Cape of Good Hope. 3. *C. verticillare.* Lam. Enc.* (*C. filiforme*; Mart. 15. Willd. 2. Linn. jun. Supp. 169.) "Stem erect, quite simple; leaves linear; flowers axillary, whorled." A native of the Cape of Good Hope. 4. *C. hastatum.* Lam. Enc.* "Stem twining, shrubby, much branched; branches nearly filiform; leaves hastate-linear, acute, smooth. Brought from the Levant by Dr. André, and cultivated at Paris. 5. *C. crispum.* Willd. 3. Thunb. prod. 46. "Stem erect, herbaceous; leaves lanceolate, curled; flowers lateral." A native of the Cape of Good Hope. 6. *C. mauritianum.* Lam. Enc.* Commers. Herb. (Funis papus; Rumph. Amœ. 5, 14. tab. 10 and 11?) "Stem twining, shrubby; leaves ovate-lanceolate, smooth on both sides." *Follicles* cylindrical, awl-shaped, spreading horizontally. 7. *C. tenellum.* Linn. jun. Supp. 168. Mart. 13. Lam. 14. Willd. 4. "Stem herbaceous, somewhat twining; leaves ovate-oblong." *Stem* filiform, with alternate branches. *Leaves* about the size of those of common chickweed, opposite, petioled, smooth, mucronate. *Umbels* lateral, irregular, shorter than the leaves, sessile. *Flowers* small. *Follicles* awl-shaped, the length of a finger. Found by Mutis in New Granada. 8. *C. filiforme.* Mart. 26. Lam. Enc.* Jacq. Amer. 86. tab. 60. fig. 1. pict. tab. 86. "Stem twining; leaves ovate-acuminate, flat shining; umbels globular." Milky. *Stems* very numerous, cylindrical, filiform, shining, branched. *Leaves* scarcely an inch and half long, quite entire, petioled. *Umbels* small, erect, lateral, alternate; common peduncle filiform, twice the length of the petioles. *Flowers* without scent, small; petals and nectary snow-white. A native of New Spain about Carthagea. 9. *C. clausum.* Mart. 27. Lam. Enc.* Jacq. Amer. 87. tab. 60. fig. 2. pict. 1. 87. "Stem twining; leaves acuminate-oblong, rolled back at the edge; flowers umbelled." Milky. *Stems* numerous, cylindrical, smooth. *Leaves* from two to three inches long, quite entire, veined, shining. *Umbels* lateral, solitary. *Flowers* without scent; petals and nectary snow-white. A native of New Spain. 10. *C. undulatum.* Linn. Syst. Nat. 9. Mant. 54. Mart. 10. Lam. 5. Willd. 23. Jacq. Amer. 85. tab. 58. pict. 45. tab. 84. "Stem twining; leaves lanceolate-ovate, smooth; umbels globular." A milky plant, entirely smooth. *Stems* cylindrical. *Leaves* four inches long, on very short petioles, quite entire, thick. *Umbel* small, solitary, close; common peduncle lateral, cylindrical, thickish, usually shorter than the petiole. *Flowers* small, without scent, firm; calyxes ash-coloured,

five-leaved; leaflets ovate, concave, spreading; corollas nearly the colour of the calyx on the outside, dirty purple within; tube globular dehiscent, a little longer than the calyx; border five-cleft; segments flat, very blunt spreading much, half the length of the tube; throat spreading very wide. A native of New Spain about Carthagea. 11. *C. reticulatum.* Mart. 17. Willd. 22. Retz. Obs. 2. 15. "Stem twining; leaves egg-shaped, acuminate, smooth, flat umbels axillary." *Stem* woody; with a thick, whitish, corky bark; branches twining, striated, smooth. *Leaves* distant, petioled, smooth; upper ones lanceolate. *Flowers* small, hairy on the outside, unequally pedicelled; in peduncled, axillary umbels. *Follicles* egg-shaped, smooth. A native of the East Indies. 12. *C. obtusifolium.* Mart. 12. Lam. 12. Linn. jun. Supp. 169? Willd. 5. "Stem twining, herbaceous, smooth; leaves oblong-lanceolate, obtuse at the tip with a point; umbels peduncled, lateral." Lam. "Stem twining, herbaceous, leaves oblong, rounded at the tip, ending in a point; umbels lateral." Linn. jun. Smooth in all its parts. *Stems* a foot and half long, slender, cylindrical. *Leaves* opposite, petioled, somewhat nerved underneath. *Flowers* small, from twelve to fifteen in an umbel, on unequal pedicels. Lam. A native of the Cape of Good Hope. La Marck's plant was communicated by Sonnerat; Linnæus's by Thunberg. 13. *C. pedunculare.* Lam. Enc.* (Apocynum scandens, foliis lauri, flore albo umbellato; Plum. Cat. 2. Burm. Amer. tab. 27. fig. 2. Aubl. Guian. 273.) "Stem twining; leaves egg-shaped, smooth on both sides, peduncles axillary, very long, solitary, umbelliferous." *Flowers* pure white; peduncles a foot long. A native of Guiana. 14. *C. longiflorum.* Mart. 25. Jacq. Amer. 85. tab. 59. pict. 85. "Stem twining; leaves oblong, acute, shaggy; flowers umbelled." Milky. *Stems* fifteen feet high, cylindrical, hairy. *Leaves* half a foot long, cordate at the base, quite entire, thickish, with hairy veins and nerves, on short and hairy petioles. *Umbels* lateral, solitary, at most seven-flowered; common peduncle, hairy, thick, cylindrical, the length of the petiole; involucre many-leaved, unequal. *Flowers* without smell or beauty; calyxes pale greenish; corolla pale without, fuliginous within, beset with numerous silvery hairs; tube elongated. A native of New Spain about Carthagea. 15. *C. parviflorum.* Mart. 20. Willd. 24. Swartzprod. 53. Fl. ind. occ. 1. 537. (Periploca scandens; Plum. ic. 215. fig. 1. "Stem twining, filiform; leaves ovate, awl-shaped at the tip; umbels nearly sessile." A native of the West Indies. 16. *C. capense.* Linn. jun. Supp. 168. Mart. 11. Lam. 13. Willd. 6. Thunb. prod. 47. "Stem twining closely on every side; leaves somewhat cordate-ovate; peduncles many-flowered." *Stem* lofty, scarcely pubescent, even surfaced at the top, not at all cork-barked. *Leaves* opposite, petioled, mucronate, smooth and even; younger ones ovate; more advanced ones emarginate, with a point; peduncles axillary, shorter than the leaves, finely toothed, simple; pedicels alternate, capillary, longer than the peduncle; calyx very short. A native of the Cape of Good Hope. 17. *C. acutum.* Linn. Sp. Pl. 1. Mart. 2. Willd. 6. Jacq. Musc. 1. 16. tab. 1. fig. 4. Gært. tab. 117. (*C. monspeliacum* β. Lam. Scammoniz monspeliacæ affinis; Bauh. pin. 294. Apocynum 3-latifolium; Clus. hist. 1. 125.) "Stem twining, herbaceous; leaves cordate-oblong, smooth." *Root* perennial, creeping. *Stems* annual, six or eight feet high. *Leaves* ending in acute points, in pairs, on long petioles. *Flowers* in small axillary bunches, of a pale flesh-colour; with lanceolate, bluntnish, much-spreading, flat segments; nectary ascending from the tube of the corolla, bel-

bell-shaped, shorter than the corolla, divided about two-thirds of its length into five lanceolate, acute segments, so far removed from each other as to admit five other very small rounded segments, sometimes quite entire, sometimes lacerated or bifid; sheath conical and narrow at the base, thence widening and divided into five two-celled, oblong appendices ending in as many rounded scales, and embracing the mouths of the stigma. Jacq. *Follicles* diverging horizontally as they approach to maturity, cylindrical, acuminate, smooth; receptacle linear, membranous, free. *Seeds* several, imbricated downwards, ovate-oblong, somewhat compressed, with a narrow membranous edge and a lateral umbilicus, reddish-ferruginous, crowned with a tuft of silky-white hairs five times the length of the seed. Gært. The silky glofs may be easily cleared from its seeds by confusion, and affords an excellent flock, which may be adapted to various purposes. The more this flock is carded the finer and more fleecy it becomes, yielding a good warm down, and by its lightness and elasticity, particularly fit for linings or wadding to fur-touts and cloaks against the frost. In carding it will not easily mix with cotton, but it thus acquires a greater consistence and might perhaps be capable of being spun. Tooke's View of Russia, vol. iii. A native of Spain, Sicily, and the neighbourhood of Atrachan. 18. *C. planiflorum*. Linn. Syst. Nat. 6. Mant. 50. Mart. 3. Lam. 2. Willd. 8. Jac. Am. 82. tab. 55. pict. 44. tab. 81. "Stem twining; leaves cordate, smooth, downy underneath; peduncles somewhat racemed, milky." *Root* perennial. *Stems* cylindrical, smooth. *Leaves* oblong-cordate, acuminate, quite entire, very soft; bearded at the origin of the petiole with very short, stiff, ferruginous hairs. *Flowers* without scent, half an inch in diameter, very flat; common peduncles smooth, lateral, solitary; with about five flowers on elongated pedicels; calyx five-leaved; leaflets lanceolate, acuminate, flat, widely spreading, slightly coloured, generally longer than the corolla; tube of the corolla very short, spreading; border with five ovate-roundish, widely-spreading, flat divisions; nectaries five, connected at the base, so as to form one body of the same form and size as the tube of the corolla; producing from their base in the centre of the flower five blunt, upright little appendices, twice as long as the tube of the corolla, furnished at the top with cowed, two-celled, little membranes; pollen-masses in pairs, on short capillary pedicels, inversely egg-shaped, obtuse, columnar, upright, concealed by the cowl; germens the length of the tube of the corolla; styles short, upright; stigma very large, cloven in the centre, funnel-shaped. A native of New Spain about Carthagenæ. 19. *C. rostratum*. Mart. 19. Willd. 9. Vahl. Symb. 3 45. "Stem and petioles bristly; leaves cordate-oblong; divisions of the corolla lanceolate, flat." *Stem* twining, rough with reversed bristles. *Leaves* two or three inches long, opposite, acuminate, beset with thinly scattered hairs on the upper surface, paler underneath, studded with numerous raised dots visible only through a lens, with a sinus open, not closed as in *C. crispiflorum*. *Peduncles* axillary, shorter than the petiole, smoothish; pedicels four or five, somewhat umbelled, unequal, filiform, bristly, often twice the length of the peduncle, shorter than the leaves; segments of the calyx ovate, beset with thinly scattered hairs; corolla, before it expands, ovate, acuminate-beaked; when open, three times the length of the calyx, with a few hairs on the outside. 20. *C. tomentosum*. Lam. 11. "Stem twining, downy; flowers somewhat cordate-oval, mucronate, downy underneath; umbels with about five flowers." *Stems* woody, cylindrical, cottony, whitish. *Leaves* opposite, on short petioles. *Um-*

bels lateral, peduncled; pedicels at least as long as the peduncle. A native of the East Indies, found by Sonnerat. 21. *C. grandiflorum*. Mart. 22. Willd. 10. Cavan. ic. 1. 14. tab. 21. "Stem twining; leaves cordate, ovate-cuspidate, glaucous underneath; corollas coriaceous." *Stem* very long, cylindrical, with a rufous nap at the joints. *Leaves* with one branching nerve; petiole shorter than the leaves, thicker at the base, rather shaggy, often twisted. *Flowers* in short racemes; common peduncle thick, between the two petioles; pedicels in alternate pairs, an inch long; calyx deeply divided into five acute segments; corolla, before it expands, rolled up in a spiral, afterwards much-spreading, deep green on both sides; with five lanceolate, acute divisions near an inch long; nectary yellow, the size of a pea, with five hollows at the base, and as many claws arched inwards; appendices yellow, ovate, concave; attached to the sides of a green pentagon, which terminates a very short prism, rising from the centre of the nectary. anther-glands red; pollen-masses in pairs, on diverging pedicels thinner than the finest hair, club-shaped, transparent, yellow, concealed between the sides of the pentagon, and the appendices almost in a horizontal situation; germens two, approximating, ending in conical styles; stigma common, fungous, large. A native of South America. 22. *C. racemosum*. Linn. Syst. Nat. 7. Mart. 4. Lam. 3. Willd. 12. Jacq. Amer. 81. tab. 54. pict. 43. tab. 80. "Stem twining; leaves ovate-cordate, smooth, acuminate; racemes simple, many-flowered." *Stems* herbaceous, milky, smooth. *Leaves* opposite, petioled, bright green on the upper surface, russet underneath, four inches long. *Flowers* small, white, in lateral racemes; calyx five-leaved; leaflets lanceolate, concave, acute, spreading; tube of the corolla bell-shaped, very short; divisions of the border lanceolate, flat, widely spreading, revolute and emarginate at the tip, a little longer than the calyx; nectary in the centre of the flower, produced from its base, and divided into five erect, ovate, flat segments, the length of the calyx, three jagged and acuminate at the end; with as many short blunt appendices, ending in cowed, two-celled membranes; pollen-masses in pairs, on short pedicels, oval, columnar, upright, concealed in the cells of the cowl; germens two, very small; style single, filiform, upright, almost the length of the nectary; stigma very large, flat on both sides, with five sharp angles. A native of South America near Carthagenæ. 23. *C. nigrum*. Willd. 11. Cavan. ic. 2. 45. tab. 159. "Stem twining; leaves oblong-cordate, smooth, acute; racemes simple, few-flowered." Allied to the preceding, but quite distinct. *Flowers* four times the size, almost black. A native of Mexico. 24. *C. maritimum*. Linn. Syst. Nat. 8. Mant. 54. Mart. 5. Lam. 4. Willd. 13. Jacq. Amer. 83. tab. 56. pict. 44. tab. 82. "Stem twining; leaves cordate, bristly, downy underneath; peduncles aggregate." Milky. *Stems* cylindrical, bristly. *Leaves* acuminate, quite entire, from two to four inches long, petioled. *Flowers* without scent, dark purple; peduncles shortish, one-flowered, springing from a tubercle among the leaves; calyx with five lanceolate, acute, small, spreading segments; tube of the corolla very short, spreading; segments of the border ovate, acute, flat, large, bristly within, spreading; nectary bell-shaped; leaflets inversely cordate, three-toothed, spreading, connected at the sides into one body, of the same colour with the corolla, and of the same length with the calyx; appendices furnished with membranous, cowed, two-celled scales; style cloven at the base; at the height of the scales spread out into a wide and sharply five cornered, body flat on both sides; from the centre of which it again emerges single, filiform, erect, bifid at the tip, the length of

- the corolla. A native of South America, in Tierra Bomba, on the coast. 25. *C. altissimum*. Mart. 24. Lam. * Jacq. Amer. 84. tab. 57. Piët. tab. 83. "Stem twining; leaves cordate, downy on both sides; flowers umbelled." Milky. *Stems* cylindrical; when old, woody, climbing trees to the height of fifty feet, smooth, ash-coloured, leafless; when young, green, downy, leafy. *Leaves* at first two inches, afterwards half a foot long, quite entire, thickish. *Umbels* lateral, solitary, close, hemispherical; common peduncle very thick, cylindrical, downy, scarcely the length of the petioles; involucre many-leaved, unequal. *Flowers* thick, firm, without scent; calyxes greenish ash colour; corollas dirty purple. *Follicles* one abortive. A native of New Spain, about Carthage. 26. *C. radians*. Lam. * (Aclepias; Forsk. Ægypt. 49. 67.) "Stem erect, shaggy; leaves cordate, acute, undulated; umbels terminal." A native of Ægypt. 27. *C. suberosum*. Linn. Sp. Pl. 2. Mart. 6. Lam. 6. Willd. 14. (Periploca carolinensis; Dill. alth. 300. tab. 229. fig. 226.) "Stem twining, rough with hairs; leaves ovate-cordate, acuminate; corymbs axillary; segments of the corolla lanceolate." *Root* perennial. *Stems* slender, covered on the lower part with a thick fungous bark resembling cork, full of fissures; twining above, and, if supported, rising to the height of six or seven feet. *Leaves* two at each joint; on long hairy petioles. *Flowers* green at first, afterwards dusky purple. A native of Carolina. 28. *C. carolinense*. Willd. 15. Jacq. ic. 2. tab. 342. Collec. 2. 288. "Stem climbing, rough with hairs; leaves oblong-cordate, acuminate; corymbs axillary; segments of the corolla oblong, obtuse." A native of Carolina. 29. *C. obliquum*. Willd. 16. Jacq. ic. 2. tab. 341. Collec. 1. tab. 148. "Stem twining, rough with hairs; leaves ovate-cordate, acute; corymbs axillary; segments of the corolla ovate, acuminate." *Leaves* shaggy. Segments of the corolla oblique, revolute at the edges. A native of Carolina. 30. *C. birtum*. Linn. Sp. Pl. 3. Mart. 7. Lam. 7. Willd. 17. (Periploca scandens; Plum. Sp. 2. Apocynum scandens virginianum rugosum; Morif. Hist. 3. 611. § 15. tab. 3. fig. 61?) "Stem twining, shrubby, cork-barked and chinked towards the bottom; leaves ovate-cordate." *Stem* rising to the height of twenty feet or more, if supported. *Leaves* on long, smooth, petioles. *Flowers* yellowish-green. Sent to Miller by Houlton from Jamaica. 31. *C. crispiflorum*. Ait. Hort. Kew. 1. 302. Mart. 16. Willd. 18. Swartz Prod. 52. (Periploca florum divifuris crispis; Plum. ic. 210. tab. 216. fig. 1.) "Stem twining; leaves shaggy underneath, oblong-cordate; sinus closed; petals curled at the tip." A native of South America and the West Indies. 32. *C. prostratum*. Mart. 21. Willd. 19. Cavan. Hist. 5. n. 7. tab. 7. "Stem prostrate, somewhat herbaceous; leaves reniform-cordate, acute, downy underneath." *Stems* a foot high, cylindrical, filiform, branched, knotted, downy. *Leaves* nearly equal to the petioles, quite entire, soft, with an unpleasant smell. *Flowers* in solitary umbels; common peduncles half an inch long, between the two petioles; rays four, one-flowered, surrounded at the base by three little bractes; calyx small, divided half way down into five ovate shaggy segments; corolla deep green, deeply divided into five spreading divisions, with a revolute border; nectary whitish, pitcher-shaped, with five deeply two-horned segments; appendices two from the centre of each horn; one arched towards the stigma; the other very small, opposite to the former, verging outwards. A native of Mexico. 33. *C. monspeliacum*. Linn. Sp. Pl. 4. Mart. 8. Lam. 8. Willd. 20. Cavan. Hist. 44. tab. 50. (Periploca monspeliaca, foliis rotundioribus; Tournef. 93. Scammonea monspeliaca; Bauh. Pin. 294. Apocynum. / 4-latifolium; Clus. Hist. 1. 126.) "Stem twining, herbaceous; leaves reniform-cordate, acute, smooth." *Stems* very long, swelling at the joints, green, smooth. *Leaves* about the length of the petioles, glaucous. *Flowers* on solitary peduncled racemes, between two petioles; calyx small, five-cleft; corolla deeply five-parted; segments linear, white above, pale rose-coloured underneath; nectary whitish, pitcher-shaped, ten-cleft, with five broad shorter segments and five acute longer ones, furnished internally with as many acute appendices, which are raised upwards; sheath in the middle of the nectary, obscurely five-cornered, with five pendulous two-celled appressed little bags, ending at the top in as many orbicular scales, converging towards the top of the sheath; pollen masses in pairs, globular, on very short capillary pedicels; stigma crowned by two little teeth, approximating at the base, afterwards divaricating. Cav. The milky juice of this species thickens when dry, becomes blackish, and resembles the true scammony in its purgative qualities; but it is not equally strong. A native of the south of France and Spain. 34. *C. extensum*. Ait. Hort. Kew. 1. 303. Mart. 9. Willd. 21. Jacq. ic. 1. tab. 54. Misc. 2. 353. (*C. cordifolium*; Retz. Obs. 2. 15.) "Stem twining, shrubby; leaves cordate, acute; peduncles elongated; pedicels filiform; corollas bristly at the edge; follicles ramentaceous." *Root* annual, divided into whitish fibres a foot and half long, and not so thick as a quill, milky. *Stem* twelve feet high, cylindrical, shaggy, with longer hairs thinly interspersed, rough, glaucous, finely tinged with purple. *Leaves* quite entire, almost smooth on both sides, on a long, cylindrical, shaggy petiole. *Flowers* of a pale-greenish colour, pendulous sweet-smelling, opening about six in the evening, and closed by morning; common peduncles between the opposite petioles, generally single, but sometimes one on each side, from half a foot to a foot long, cylindrical, rugged, shaggy, spreading; pedicels an inch and half long, coming out aggregately at intervals; calyx small, somewhat shaggy; with five lanceolate, acute, erect divisions; corolla wheel-shaped; tube somewhat five-angular, longer than the calyx; divisions of the border three times the length of the tube, lanceolate, acute, flat, but rolled back at the sides, spreading; nectary a sheath attached to the tube of the corolla, elevated into a pentagon five-grooved white cone, shorter than the corolla, which consists of five erect obtuse scales, three-lobed at the tip, the middle lobe longer and lying on the vertex of the stigma, with a small two-celled bag for the lodgment of the pollen masses; and on the back at the base of the bag, a lanceolate convex appendix, bent both ways, acute, erecting itself from the middle of the sheath beyond the stigma; pollen-masses in pairs, inversely egg-shaped, compressed, yellow, pendulous, on short pedicels. Stigma capitate, globular, with an obtusely five-cornered rim about the edge. *Follicles* lanceolate, acuminate, mucicated, turgid, glaucous, coriaceous, diverging or reflexed. A native of the East Indies. 35. *C. asperum*. Mart. 18. "Stem twining, shrubby; leaves cordate, acute, rough; flowers lateral." *Stem* twenty feet high or more, very slender, armed with small stinging hairs. *Leaves* in distant pairs at each joint, on slender petioles. *Flowers* in small clusters, sitting close to the stalks, rather large, yellow, star-shaped, spreading open to the bottom. *Follicles* long, swelling. A native of La Vera Cruz, in New Spain; raised by Miller from seeds sent by Dr. Houlton. 36. *C. odoratissimum*. Mart. 23. Lour. Cochinch. 166. (Flos Siamicus, five flos Tunkini; Rumph. Amb. tab. 26. fig. 1.) "Stem twining, cork-barked, and chinked towards the bottom; leaves heart-shaped, acuminate, wrinkled; cymes reflexed."

flexed." *Root* perennial. *Stem* very long, cylindrical, and smooth in the upper part. *Leaves* undulated, smooth, opposite, on long petioles. *Flowers* yellow, very sweet-scented; cymes large, hemispherical, axillary, reclined; calyx five-leaved; leaves ovate-lanceolate, undulated, nearly erect; corolla salver-shaped; tube thick, short, inflated at the base; border large, with five oblong somewhat reflexed divisions; nectary cylindrical, thick, erect, with five connivent segments; appendices five, membranous, adhering to the outside of the nectary, and terminated by compressed, acute, two-celled bags incumbent on the stigma; stigma sessile, ovate, emarginate. A native of Siam and Cochinchina, cultivated about Canton. In fragrance it does not yield to jasmium sambac, and though very common is not less used by women of the higher rank as an ornament to their hair. 37. *C. indorum*. Lour. Cochinch. 166. "Stem twining, cork-barked, and chinked towards the bottom; leaves ovate-acuminate; peduncles subdivided." *Root* perennial. *Stem* long, branched. *Leaves* smooth, opposite. *Flowers* numerous, small, yellow, scentless; peduncles short, axillary; corolla rather salver-shaped; segments linear, longer than the tube, spreading; stigma large, sessile, ovate-oblong. *Follicles* oblong, acuminate, downy, curved inwards. A native of Cochinchina. 38. *C. erectum*. Linn. Sp. 5. Mart. 14. Lam. 9. Willd. 25. Jacq. Hort. 1. tab. 38. Misc. 1. 20. tab. 2. fig. 1. (*Apocynum folio subrotundo*; Bauh. Pin. 302. Tourn. 92. A. 1. latifolium. Clus. Hist. 1. 124.) "Stem erect, divaricated; leaves cordate, smooth." *Root* perennial. *Stems* several, about three feet high, slender, somewhat branched. *Leaves* opposite, petioled, ending in a point, inclining to glaucous. *Flowers* small, white; in lateral, lax, branched corymbs; calyx green, small, ciliated, five-cleft; segments lanceolate, acute, erect; corolla white, divided almost to the base into five, oblong, obtuse, flat segments, forming at the bottom an almost bell-shaped corolla, but spreading much at the top; nectary a sheath placed immediately on the pedicel of the flower, cylindrical, green, two-grooved near the bottom; putting out from the back, about the level of the germ, five, small, white, petal-shaped, somewhat linear, upright leaflets; dividing afterwards into five oblong, concave, yellowish segments, ending in a roundish scale, applied to the stigma, and about half its length, not furnished with two-celled bags, but having instead of them two roundish, yellow, small plates, situated above the base in a parallel position, and extended forward; germens two, obtuse, pale; style very short, thick, single, and undivided, common to both germens; stigma very large, elongate-conical, thick, erect, pale yellow, bifid and obtuse at the end, very long; anther-glands five, at the sides of the stigma about the middle, from each of which protrudes a pair of yellow, obovate, flat, pollen masses, almost without pedicels, hanging forward between adjoining plates of the nectary. A native of Syria. 39. *C. arborcum*, Lam.* Forsk. Egypt. 53. n. 80. "Stem twining; corolla rotate." A lofty tree, not milky. *Flowers* green. A native of Egypt.

C. vomitoria; Lam. See ASCLEPIAS *Asthmatica*.

Propagation and Culture.—*C. acutum* and *C. monspeliacum*, being natives of the south of Europe, are hardy, and propagate too fast by their creeping roots; they may be transplanted any time after the stems decay, till they begin to shoot in the spring. *C. erectum* and *C. suberosum* will live in the open air in England, if planted in a dry soil and warm situation. The former may be increased by parting the roots in the spring; the latter by laying down the

young shoots about Midsummer, which may be transplanted in the autumn. The natives of the Cape must be preserved in the dry stove, and may be increased by layers, cuttings, &c. Those of the tropical climates require a bark stove all the year, and must be allowed only a little water in winter; they may be propagated by laying down the young shoots, which, in three or four months, may be transplanted into pots filled with light sandy earth, and plunged into the tan-bed.

CYNANTHEMUM, a name given by some authors to the ANTHEMIS *Cotula*, or stinking May-weed. Ger. Emac. Ind. 2.

CYNANTHROPIA, from *κυνν*, *dog*, and *ανθρωπος*, *man*, a term used for madness given by a dog, wherein the patient avoids light, or any thing bright, fears water, and trembles at the sight and remembrance of it. It proceeds usually from a poisonous bite, or the like, of some mad creature, as a dog, a wolf, &c.

CYNAPIUM, in *Botany*. See ÆTHUSA.

CYNARA, (according to Linnæus, from *κυνν*, *canis*; but the derivation is altogether uncertain. The French botanists spell it cinara, as it is found in some Latin authors.) Linn. Gen. 928. Schreb. 1257. Willd. 1436. Juss. 173. Vent. 2. 498. Class and order, *syngenesia polygama equalis*. Nat. Ord. *Compositæ capitatæ*; Linn. *Cinarocephalæ*; Juss.

Gen. Ch. *Cal.* common, very large, dilated towards the base, imbricated; scales numerous, large, fleshy at the base, ending in a more or less prickly point. *Cor.* Florets all perfect, nearly equal, funnel-shaped; tube very slender; border erect, ovate, five-cleft; divisions linear, one of them more deeply separated. *Stam.* Filaments five, capillary, very short; anthers united into a tubular cylinder, the length of the floret, five-toothed. *Pist.* Germ somewhat ovate; style filiform, longer than the stamens; stigma simple, oblong, emarginate. *Peric.* The permanent common calyx a little converging. *Seeds* solitary, oblong-ovate, four-cornered, compressed; down sessile, long. *Recept.* bristly, more or less thick and fleshy.

Eff. Ch. Calyx dilated at the base, imbricated with somewhat fleshy scales; receptacle more or less thick and fleshy.

La Marck observes that this genus really differs from *carduus* only in the fleshiness of the scales of the calyx, and the thickness of the receptacle; since the emarginate termination of the scales with a point in the middle, though inserted by Linnæus, occurs only in the first species, and must therefore be excluded from the generic character.

Sp. 1. *C. scolymus*. Common artichoke. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 2. Blackw. tab. 458. Woodv. Med. Bot. tab. 199. (*C. sylvestris*; Park. Parad. tab. 519. fig. 4. Ger. 992. 3. emac. 1153. 3.) "Leaves somewhat spinous, pinnated and undivided; calyx-scales ovate." β Mill. Dict. 1. French artichoke. *C. hortensis aculeata*; Bauh. Pin. 383. *C. maxima alba*; Ger. 991. emac. 1153. 2. *C. patula*; Par. parad. tab. 519. fig. 3. γ . *C. hortensis*; Mill. Dict. 2. Globe artichoke. *C. hort. foliis non aculeatis*; Bauh. Pin. 383. *C. maxima anglica*; Ger. 991. fig. 1. emac. 1153. 1; Bauh. Pin. 383. *C. fativa rubra et alba*; Par. parad. tab. 519. fig. 1. 2. *Root* perennial, large, fibrous. *Stem* from three to six feet high, thick, strong, striated, somewhat branched. *Root-leaves* from two to four feet long, petioled, irregularly pinnatifid, deeply cut, more or less spinous; ash-coloured, smooth and veined above, hoary, downy and reticulated underneath. *Stem-leaves* simple, serrated or jagged, sometimes almost quite entire.

entire. *Flowers* terminating the stem and branches, on thick fleshy peduncles; common calyx globular, three or four inches in diameter; scales thick and fleshy at the base; tough, membranous, and shining above; deeply and widely notched at the tip, with a strong point between the segments; florets purple or blue. A native of the south of Europe. In its wild state it is said to be taller, more downy, and more spinous, than it appears in our kitchen gardens, but to have smaller heads. It has long been cultivated in almost every part of Europe; but in England, at least, rather as a luxury than as a profitable esculent. With us the heads, in their immature state and before the flowers open, are boiled in salted water, till all such parts of them are soft as are capable of becoming so. The scales of the calyx are then plucked off one by one, the lower part of them dipped in a mixture of melted butter and pepper, and the fleshy substance sucked from the rest. But there is generally so little to be obtained, as almost to justify the observation of a raw country servant, who having waited at supper when artichokes made one of the dishes, was eager, on his return into the kitchen, to taste a kind of food which he had never seen before; but, to his great disappointment, finding little more than a kind of horny substance, which equally defied his tongue and his teeth, declared with great *naïveté*, that gentlefolks seemed to him to have strange fancies, for as far as he could discover, one leaf would do as well to lick up the butter as a thousand. It was fortunate for him that he did not encounter what is emphatically styled by Englishmen the choke, from a not ill-founded persuasion that any unlucky wight who should happen to get it into his throat would certainly be choked. This consists of the unopened florets and bristles which stand upon the receptacle of the compound flower, and must be carefully cleared away before the epicure can arrive at the receptacle itself, the *bottom*, as we call it, or *le cul*, as it is more elegantly termed by our polished and refined neighbours on the other side of the channel, which is undeniably the most plentiful, as well as the most delicate part of the viand. On the continent, artichokes are more generally used, and are also eaten raw with salt and pepper. It is moreover esteemed a branch of good housewifery, to preserve them as a valuable part of the family winter-store.

For this purpose various methods have been devised; but the best is said by Parmentier to be that which is practised at Laon and in its neighbourhood. The heads are first half boiled and stripped of the calyx-leaves and the choke; the bottoms while they are still warm, are then plunged into cold water, which gives them a consistence, or as it is there expressed, *blanches* them. They are afterwards laid upon flat pieces of wicker work, and put four times successively into an oven in which bread has been baked, where they are kept till it has gradually cooled. By this process they become thin, hard, and transparent as horn, and do not resume their primitive appearance till they have been steeped in warm water. When they are once thoroughly dried in the oven, nothing farther is necessary than to keep them in a dry place, that that they may not grow mouldy. To obtain a pound of these preserved bottoms about forty heads of a moderate size must be expended.

Mr. Miller has mentioned two kinds, which he thought distinct species, but which appear to be only permanent varieties. 1. *C. Scolymus*, the green or French artichoke. 2. *C. hortensis*, the globe artichoke. The first has the scales of the calyx remarkably open; its head draws up rather to a point in the middle; the leaves are larger, much wider, of a paler colour, and inclining to yellow on the under surface

terminated by short spines; the bottoms are not so thick of flesh, and have a perfumed taste, which is not generally agreeable, so that it is not much cultivated by our gardeners. The second, which is our common artichoke, has its calyx-leaves turned inwards at the top, and its head rather flat; its leaves are of a bluer cast, and are more deeply cut, with no, or only small and scarcely perceptible prickles. John Bauhin had long before observed that the presence or absence, the abundance or the rarity of spines are merely characters of seminal varieties which are often produced indiscriminately from the same seeds. In France, where artichokes are in more general use, there is a greater number of varieties. Parmentier mentions five principal ones. 1. The white, distinguished by the strong spines of its calyx leaves, is the earliest and the smallest kind; but as it is also the most tender, and is with difficulty kept alive through the winter in the most favourable situation and soil, it is but little propagated. 2. The green, which is most in request in the French green markets, grows to a great size. Its form is more flat, and its scales more open than in the other varieties; its bottom is sometimes five inches in diameter, and the flesh very tender and well tasted, when it has been boiled in a good deal of water. 3. The violet, which has a more pointed head than the preceding, and scales with a small sharp spine, and a tinge of violet at their extremity, is as good and as tender as the green, but being smaller, is not so profitable to the grower. The French artichoke of Miller seems to be an intermediate variety of these two. 4. The red, which has entirely a red-purple exterior, with a yellow and more delicate flesh than any of the former kinds. It is always eaten raw, and that only when it is very young, as it soon becomes hard and stringy. 5. The sugary artichoke of Genoa, so called from its remarkably sweet taste. It is eaten raw like the red, and is even thought more delicate, but as it degenerates in the second year, and must therefore be annually renewed by fresh sets brought from Genoa, it is found in but few of the French gardens.

This species has obtained a place in the *Materia Medica*, and has been recommended for its diuretic qualities, but is now little used. The whole plant has a strong bitter taste and a peculiar smell. The flowers are used to curdle milk, and have lately been found to possess so much of the tanning principle as not to be inferior to white galls. 2. *C. horrida*. Aiton. Hort. Kew. 3. 148. Mart. 2. Willd. 3. "Leaves pinnatifid, downy underneath, spinous; spines at the base of the leaves, and of the pinnæ connate at the base." Found by Masson in the island of Porto Santo, near Madeira; and introduced at Kew in 1778. 3. *C. cardunculus*. Cardoon, Linn. Sp. Pl. 2. Mart. 3. Willd. 4. (*C. sylvestris* β . Lam. *C. spinosa*, cujus pediculi, esitantur; Bauh. Pin. 385.) "Leaves spinous; all pinnatifid; calyx-scales ovate." J. Bauhin asserts that this is either a hybrid plant, or a seminal variety of the first species. La Marek makes it a variety of his *sylvestris*, to which he refers Caspar. Bauhin's *C. sylvestris latifolia*, quoted by Linnæus and other authors as a synonym to *C. scolymus*. He gives the following description of the wild plant, which he says is a native of the south of France, Spain, Italy, and Sicily. "Very spinous; leaves somewhat hoary, finely cut; spines long, flavescens." *Stem* four or five feet high, upright, thick, cottony, a little branched, spinous near the top by means of the upper leaves, which are slightly decurrent and very spinous at the base. *Leaves* large, winged; pinnules decurrent; narrower than those of the first species, furnished with a long yellowish spire at the extremity of each segment, pale green above, very white and cottony underneath. *Flowers* blue, terminal, smaller than those of the common artichoke; calyx-scales somewhat fleshy,

C Y N A R A.

fleshy, terminated by a very sharp and rather long spine. It is much cultivated for the table in many parts of the continent, but is not much esteemed in England, and not often raised. The roots, and the stalks with the midribs of the leaves are the only parts that are eaten, and chiefly the latter, which are thick and crisp, and though naturally bitter, are rendered mild and pleasant by being blanched like celery. They are eaten either alone, or as a sauce to animal food, and especially roast meat, and are often introduced as a dish in the second course. But the cultivation of them is so troublesome, and after all so much depends upon the skill of the cook to render them very palatable, that they are almost confined to the upper ranks. In France the flowers carefully dried in the shade, are used by the country people as well as those of the common artichoke, to coagulate milk for the purpose of making cheese. 4. *C. integrifolia*. Mart. 6. Willd. 1. Vahl. Symb. 1. Vahl. Symb. 1. 68. "Leaves lanceolate, finely toothed; calyx scales lanceolate-acuminate." A low smooth plant with a simple, striated stem. Leaves an inch and half long, petioled, mucronate, toothed with remote small spines. Flower blue, terminal, solitary, peduncled, only half the size of that of *C. scolymus*; lower calyx-scales terminated by a weak spine. A native of the mountains near Toledo in New Castile. 5. *C. humilis*. Linn. Sp. Pl. 3. Mart. 4. Lam. 3. Willd. 5. Desfont. Atl. 2. 248. (*C. sylvestris bœtica*; Clus. Curf. 35. *Carduus tingitanus*; Pluk. Alm. 85. tab. 81. fig. 2. *C. humilis tingitanus*; Morif. Hist. 3. 158. § 7. tab. 33. fig. 9.) "Leaves spinous, pinnatifid, downy underneath; calyx-scales awl-shaped." β. *Carduus andelusiacus*; Pluk. Alm. 85. tab. 19? Lower leaves a foot long or more, three or four inches broad, stretched on the ground, cut on each side to the midrib into pinnatifid, rather narrow, pointed pinnules, with each of their segments ending in a short spine. Stem erect, scarcely longer than the root-leaves. Flower terminal, large, blue; calyx-scales oval-lanceolate, terminated by a sharp point. A native of Spain and Barbary. 6. *C. acaulis*. Linn. Sp. Pl. 4. Mart. 5. Lam. 4. Willd. 6. Desfont. Atl. 2. 249. tab. 223. Lam. Ill. Pl. 663. fig. 2. (*C. acaulos tunetana fasga-dicta*; Til. Pis. 41. tab. 20. *C. orientalis moschata*; Tourn. Cor. 51.) "Stemless; leaves pinnated, without spines, smooth above." Linn. "Stemless; leaves without spines, downy underneath, pinnatifid; segments incise-toothed; calyx-scales lanceolate, scarious and toothed at the tip. Willd. A native of the coast of Barbary near Tunis, and of the Levant. Obs. Jussieu has observed that *C. humilis*, having a radical flower, and calyx-scales not spinous, but ciliate-palmate at the tip, like the jaceæ, ought to be referred to another genus. But did he not mean this species? 7. *C. glomerata*. Willd. 7. Thunb. Prod. 141. "Stemless; leaves pinnatifid, spinous." A native of the Cape of Good Hope. 8. *C. pygmaea*. Willd. 8. "Stemless; leaves pinnated, nearly smooth; segments toothed, spinous; inner calyx-scales scarious at the tip." Leaves an inch and half or two inches long, green on both sides, unequally pinnated, bristly on the midrib. Flowers an inch and half long, sessile; calyx cylindrical; outer scales ovate, toothed at the tip; teeth terminated by a spine; inner ones ovate, quite entire, furnished with a single spine at the tip; innermost oblong, scarious and without a spine at the tip. A native of Spain.

CYNARA, in Gardening, comprehends plants of the hardy perennial and biennial kinds; of which the species cultivated are, the common artichoke (*C. scolymus*); and the cardoon-artichoke, or cardoon, (*C. cardunculus*).

Method of Culture.—These different plants are increased without much difficulty, if proper care be taken to preserve

them from the frosts in winter season, by some protecting material.

Method of Culture in the Artichoke Kind.—These are a sort of plants which succeed best in a soil of the light, deep, friable, loamy kind, well enriched by stable dung, or some other manure. Where the soil is stiff and wet, they are liable to be destroyed in the winter season by the stagnation of moisture about their roots.

Their propagation is most commonly effected by planting the offsets, or suckers produced from the old stools or roots, in the early spring months, as about the latter end of March, in an open situation, in rows four or five feet apart, and the same distances in the rows. The ground should be previously prepared by trenching in the dung to a good spade's depth or more.

In the business of planting out the offsets, after being separated from the old plants, they should be trimmed in their leaves and other parts, and be then put in by means of a line and dibble to the depth of three or four inches. Some plant two or three plants in one place, but others only one. The latter is probably the better method, as the plants spread very much. Whichever mode is practised, the earth should be well clofed about the sets, and a good watering immediately given, especially if the weather be dry; repeating it as there may be occasion afterwards.

After this they only require to be kept free from weeds during the summer, which is best performed by hoeing between the rows with a large sharp hoe; and to be protected from frost in the winter months.

Whenever large heads are wanted, all the small lateral ones should be removed as soon as they are formed to any size. In some situations, the small lateral crooked heads are, however, held in much esteem, consequently must not be rubbed off. The maturity of the heads of the artichoke is shewn by the plates or scales separating from each other considerably, and appearing of a brownish call.

In separating or cutting the heads, six inches of the stem should be preserved to them, and in many cases, when for market, a foot or more. And care should be taken, that as the heads are cut, the stalks be broken down to the bottom and removed, in order to promote the growth of new suckers for offsets.

With the view of protecting the plants during the winter from being injured by frost, it is the practice of some gardeners to earth or mould up the rows of the plants, so as to cover their crowns, forming the earth into a ridge. This is usually done about the latter end of November, or beginning of the following month, the lower leaves being cut and removed before the work is attempted. The author of the "Scotch Forcing Gardener," however, instead of ridging up the plants, advises that they should be carefully covered with stable-dung or other litter in the beginning of winter, which he considers as much better than digging trenches and moulding up with the earth from them, as the roots in that way are, he supposes, doubly exposed. Many instances have occurred where the plants managed in that method have been destroyed, while those well covered by litter have not sustained the least injury.

About the middle of March, or beginning of the following month, when the plants have begun to shoot, the ridges where that method has been employed, should be levelled down, removing all the unnecessary shoots, only leaving one or two on each plant. This work should be performed when the weather is dry, and the mould be well cleared and removed from the crowns of the plants.

But where they have been covered with litter, the coarse parts should be removed about the same time, and the more reduced.

reduced and rotten parts dug in; previously removing the shoots, as in the former case, to prevent their being too much crowded and producing small imperfect heads.

This is a sort of culture which must be repeated every year, for the old roots or stools, which should not be suffered to continue more than seven or eight years in the same situation, as they then begin to produce heads that are smaller in size; and where successions of this sort of crop are wanted, a few of the best offsets should be planted every year as soon as possible, after being taken off, in the manner that has been directed above. This practice not only keeps up the stock of plants, but continues the season of having the produce, as the young plants afford their heads much later than the old ones.

When it is necessary that the offsets should be conveyed to a distance, they should be carefully packed, eight or ten together, when dry, and bound round with a hay-band, the whole being then placed in a hamper or mat. In this case, some advise moistening the roots before planting them out in the garden.

The globular-headed sort is, in general, found the largest and most fleshy, but the green conical-headed the most hardy, and best capable of resisting the effects of severe seasons.

Method of Culture in the Cardoon Kind.—This is readily accomplished, in this sort of plants, by sowing the seeds in the latter end of April or beginning of May, or later, in the places where the plants are to remain. It is best done by forming trenches at the distance of about five feet from each other, in the manner directed for celery, to the depth of a good spade, placing the mould on the sides or interspaces; then to point in with a spade a little well-rotted compost manure in the bottoms, and make a small drill in the centre, to the depth of an inch, dropping in the seeds two or three inches apart, covering them with the fine mould: a little water should be given at the same time, when the season is dry and hot.

When the young plants have advanced two or three inches in their growth, they should be thinned out to the distance of ten or twelve inches, and gradually to much greater distances. And as they proceed in their growth, they should be gradually moulded up when dry, in order to be blanched and rendered tender, in the same manner as practised for celery; only the leaves being carefully gathered, and tied together each time with a little old matting, in order to prevent the mould from getting between them and causing their decay.

It is likewise the practice with some gardeners to raise the plants on beds, and afterwards transplant them into drills, or holes, where they are to remain and be earthed up for blanching; but it is probable that the former is, in most cases, the preferable practice.

With the view of having a longer succession of these plants, the moulding up should be performed at different times, from about the beginning of September, at the distance of a fortnight or three weeks.

These plants are found to succeed best on such soils as are of the more deep sandy loam kinds, which have not been much enriched by manure from long cultivation.

With the view of saving seed, some of the best plants should be suffered to remain without being blanched, and be protected by litter during the winter; and in the spring they will shoot up into flower, and produce ripe seed in the autumn, which should be carefully preserved.

The fleshy parts and roots of the cardoon are capable of being preserved in the winter season, in the same manner as

the carrot, celery, and other similar plants, which have large thick roots.

CYNARA, in *Ancient Geography*, a name given by Pliny to an island of the Ægean sea.

CYNCHRAMUS, in *Ornithology*, a name given by Al-drovand and Brisson to the *EMBERIZA Miliaria*, which see.

CYNDONIS, a river of the Hellespont. Hesychius.—Also, a river of Greece, in the Peloponnesus.

CYNEAS, or CINEAS, in *Biography*, a minister of Pyrrhus, king of Epirus, more distinguished by his talents than by birth. He had been instructed in oratory by Demosthenes, and in military tactics by the most celebrated officers in Alexander's army. So remarkable was he for the arts of persuasion that his sovereign used to compliment him with having gained more towns by his eloquence, than he could ever have conquered by force of arms. He was indeed an enemy to war, as the curse of mankind, when undertaken for the gratification of ambitious projects: he was of the Epicurean sect, and was perpetually urging upon the mind of his king the maxim, "That no addition to his territory; no augmentation of his power, could add one ingredient to the happiness already within his reach." Pyrrhus, however, was a warrior and a king, and not a philosopher; he determined on conquest, and forced upon his minister a chief command. After a decisive victory over the Romans in the year B. C. 280, Cyneas proposed to negotiate, the king consented, and sent him to Rome for the purpose. In this he was unsuccessful, and on his return, he told Pyrrhus that the Roman senate seemed to him an assembly of kings. Cyneas made a second attempt but with no better success than before. He was afterwards dispatched to Sicily, and prepared the way for his master's reception in that island. From this period no more is heard of Cyneas: he is recorded by Pliny and others as a most extraordinary instance of the powers of memory: he is said to have been able, the day after his arrival in Rome, to salute all the senators and knights by their names. As an author, he is mentioned by Cicero, as having in conjunction with the king, his master, composed a treatise on the military art. He abridged also the "Tactics" of Æneas. Univer. Hist. Moreri.

CYNEBOTE, the same with Cenegild.

CYNEGETICA, in *Ancient Geography*, a name given by the Greeks to a mountain of Africa, on the straits of Hercules, opposite to that of Europe; and both together were called the *Columns of Hercules*.

CYNEGETICS, from κυνηγετης, *hunter*, of κυνη, *dog*, and αγω, *I lead out*, books treating of the art of hunting. Gratus Faliscus has written a *Cynegetica* with applause.

CYNEGICA REGIO, in *Ancient Geography*, a country of Asia, in Syria, placed near the town of Antioch.

CYNESII, a people of Iberia, or Spain, called also *Cynete*; supposed to be that part of Lusitania which is now denominated Algarve.

CYNETIA, a town of the Peloponnesus in the Argolide.

CYNETICUM JUGUM, a mountain of Spain on the coast of the Mediterranean sea, and near the river Ana.

CYNIA, a town of Epirus, in Acarnania. Strabo.

CYNICS, a sect of ancient philosophers, who valued themselves on their contempt of every thing, especially riches and state, arts and sciences; all excepting morality.

The founder of this sect is said to have been Antisthenes, a disciple of Socrates; who, after his master's death, quitting the Pyreum, retired to Cynofarges, a kind of academy not far from the gates of Athens. See ANTISTHENES.

Hence, some will have it, came the name κυνικος, *cynicus*, viz. from *cynofarges*. But others, with more probability, derive

CYNICS.

derive it from *κυνν*, *dog*, because of their severity and importunity in reprehending vice. Thus Aristotle observes, *ὅτι δὲ κύνικος*, &c. *the Cynics were so called from their free way of rebuking, &c.* Hence Diogenes the Cynic said of himself, *I bite the evil*; and Antisthenes himself was called *ἀπλὸς κύνν*, *an ingenious and sincere dog*: it being the distinguished character of the Cynics to attack and bark at the ill, and to defend and fawn on the good.

Arrian very much extols the Cynical genius: "A Cynic (says he) is a messenger sent from Jupiter to overlook human affairs; a public doctor, and tutor of mankind; who instructs and chastises at the same time; an Æsculapius; a lord and king, adorned with a sceptre and diadem, who governs the people; and this voluntarily, without trembling, without guards, &c. but by a good conscience." The ground of this encomium may be owing, in some measure, to the affinity between the *Stoics* and *Cynics*: the chief difference between them consisted in this, that the former were more modest and reserved than the latter; who were said to have banished all shame, and were able to practise any obscenity without blushing.

Hence Laertius observes of Diogenes, that he did every thing openly, whether it belonged to Ceres or to Venus: though the same Laertius adds, that he did it in imitation of the choridifascali, *i. e.* he only ran to an excess of impudence, to put others out of conceit with it.

The sect of the Cynics is to be regarded more as an institution of manners than as a school of philosophy: as it was formed rather for the purpose of providing a remedy for the moral disorders of luxury, ambition, and avarice, than with a view to establish any new theory of speculative opinions. Antisthenes, and the other leaders of this sect, were considered by their disciples not so much as the authors of a new doctrine, as inflexible patterns of virtue, and rather as examples for their imitation in the conduct of life, than as preceptors to guide them in the search after truth. The sole end of the Cynic philosophy was to subdue the passions and produce simplicity of manners: and the characteristic peculiarities of the sect were an indignant contempt of effeminate vices, and a vigorous adherence to the rules of moral discipline. According to the original spirit of the sect, a Cynic was one who appeared in a coarse garb, and carried a wallet and staff, as external symbols of severity, and who regarded every thing with indifference, except that kind of virtue which consists in a haughty contempt of external good, and a hardy endurance of external ill. Simplicity and moderation were, indeed, in this sect, carried to the extreme of austerity, and at last produced the stoical system of apathy: but the real design of both these sects seem to have been to establish virtuous manners. The vigorous discipline of the Cynics, which had for its primary object the laudable purpose of exhibiting an example of moderation and virtuous self-command, degenerated by degrees into the most absurd severity: but candour will suggest an apology for the errors of this extreme. In order to be at perfect liberty to apply themselves to the cultivation of virtuous habits and manners without interruption from the noisy contents of speculative philosophy; the Cynics renounced every kind of scientific pursuit: accordingly they discarded all dialectic, physical, and mathematical speculations, and confined themselves to the study, or rather to the practice, of virtue. In this respect they formed themselves upon the model of Socrates: and it may be pleaded in their excuse, that the learning which chiefly prevailed in Greece at that time consisted very much in futile speculations and an illegitimate kind of eloquence, which contributed little towards the happiness of society, or the real improvement of the human mind. As an apo-

logy for the singularities of this sect, it may be further alleged, that the manners of the Greeks were at this time verging much towards the extreme of effeminacy. Luxury and vanity infected even the philosophers, as we may justly infer from the accounts that are transmitted to us concerning the dress and manners of Aristippus, Arcefilaus, Aristotle, Stilpo, and others. Socrates made an attempt to correct the public taste; and Antisthenes, without possessing his judgment and moderation, adopted the same plan, but pursued it to an extreme that passed beyond the limits of decorum. Regarding attention to external appearance as unfavourable to virtue, he deviated into the simplicity of nature farther than was consistent with the decorum of civilized life. His followers, seduced by his example, and by the reputation and influence which he acquired, as a pattern of wisdom and fortitude, adopted his peculiarities and carried them to a ridiculous and absurd extreme. Thus the Cynic philosopher, being at first merely a severe public monitor:—

"Virtutis vere custos, rigidusque fasces—"

Hor. ep. i. 1. 17.

"The stern defender of pure virtue's cause—"

commanded attention and respect; but when, in process of time, the freedom of censure degenerated into scurrility, the boldness of the philosophers was admired by the vulgar, but their imprudence excited the wonder of the more judicious: and the whole order gradually sunk into disesteem and contempt. Hence we may account for the disgraceful tales which have been industriously propagated concerning this sect; inasmuch, that the singularity of the early Cynics, and their gross violations of decorum, rendered the sect, at a later period, not only ridiculous but infamous, and furnished occasion for those, who did not properly distinguish between the first design of this institution and its subsequent abuses, to declaim against the Cynical philosophy in general, as a compound of vulgarity, spleen, and malignity.

The sum of the moral doctrine of Antisthenes, and the Cynic sect, is this: virtue alone is a sufficient foundation for a happy life. Virtue consists, not in a vain ostentation of learning, or an idle display of words, but in a steady course of right conduct. Wisdom and virtue are the same. A wise man will always be contented with his condition, and will live rather according to the precepts of virtue, than according to the laws or customs of his country. Wisdom is a secure and impregnable fortress: virtue, armour which cannot be taken away. Whatever is honourable is good; whatever is disgraceful is evil. Virtue is the only bond of friendship. It is better to associate with a few good men against a vicious multitude, than to join the vicious, however numerous, against the good. The love of pleasure is a temporary madness." Laertius, Julian. Orat. Maxim. Tyr. Diss. Arrian. Diss. Epict. Fabr. Bib. Grec. v. ii. Brucker's Hist. Philos. by Enfield, vol. i.

CYNIC Period. See *Egyptian Year*.

CYNIC Spasm, spasms CYNICUS, a sort of convulsion, whereby the patient is brought to imitate the gestures, snarlings, howlings, &c. of a dog. See SPASM.

Dr. Freind, in the Philosophical Transactions, gives us an account of a very extraordinary *spasmus* of this kind, wherewith two families, at Blackthorn in Oxfordshire, were seized.

The novelty of the thing drew abundance of visitors to the village, and among the rest Dr. Willis; who, a good while before he reached the place, heard a terrible noise of barking and howling: upon his entering the house, he was immediately saluted by five girls, bawling, and answering each other by turns, with violent motions of the head. In

their face there was no convulsion seen, beside cyclic dilations, and oscillations of the mouth: their pulse was pretty regular; their noise was rather like that of the howling, than of the barking of dogs; though its returns were more frequent, with deep sighings between.

The *spasmus* had seized all equally: whereof the youngest was but six, and the eldest fifteen years of age: at intervals they had their reason and senses entire; but not long before one of them, returning to her ye'ling, set on the rest: till at length, all fainting, they fell like epileptics on a bed laid in the middle of the room to receive them.

A little while they would lie quietly and decently together; but upon a new orgasm of the spirits, they began to heat and bruise each other. Two of the youngest awaked while the doctor slayed, and list their sisters on the bed: but the *spasmus* soon had hold on them again.

In July 1700, Dr. Friend visited another family, in the same village; where one boy and three girls had been seized ten weeks, without any apparent preceding cause. A girl had had it first; and the rest, as the mother informed him, were so struck with their sister's disorder, that they too were seized. At his arrival, they were all at play, very briskly, and unconcernedly, before the doors; at length the eldest girl, about fourteen years of age, was seized as usual.

The only symptom of its approach, was a swelling of the stomach; which rising gradually up to the throat, set the muscles of the larynx and the head upon their usual convulsions: this rising was a certain symptom of an approaching paroxysm in them all; and if they endeavoured to stop it, it burst out with the greater violence, and held the longer.

The noise they made was incessant, and disagreeable; yet not so much like the barking or howling of dogs, as had been given out, as a quaint kind of a song, consisting of three notes, or tones, repeated twice over; and closed by deep sighs, &c. accompanied with extraordinary gestures and nutations of the head.

This disease the doctor takes to be natural; and to rise from the common cause of all convulsions, viz. from the animal spirits growing unruly in the nerves, and driving the muscles into various contractions, according to the circumstances of the indispotion.

CYNIPS, in *Entomology*, a genus of hymenoptera in the Linnæan system, and of the piezata in that of Fabricius. The mouth is furnished with a short unidentate membranaceous jaw, the mandibles vaulted, horny and cleft, and the lip entire; feelers four, short, unequal, and capitated; antennæ moniliform; sting spiral, and often concealed within the body. The Fabrician character consists in having four unequal and somewhat capitated feelers, the lip horny and entire, and the antennæ moniliform.

Many of the excrescences found on the leaves, stems, branches, and roots of trees, are occasioned by the puncture of these insects; their larvæ are soft, without feet, of a cylindrical form, and inhabit within the gall, where they subsist on the juices of the tree; the pupa differs from the complete insect only in being destitute of wings, but the rudiments of the wings are perceptible even in this state of the creature. Most of the species appear to be peculiar to certain plants; the oak and willow in particular are much infested with insects of this kind.

Species.

ADSCENDENS. Brassy; abdomen petiolate, conic and ascending. Fabr.

The largest species in this genus, and is found in Saxony.

The antennæ are short and black; scutal pointed; legs pale, thighs black at the base.

ROSÆ. Black; abdomen ferruginous, black behind; legs ferruginous. Linn.

Inhabits the rosa hispida in Europe.

COMPRESSA. Glossy-black; abdomen compressed; shanks ferruginous. Fabr. Append. Native of Italy.

GLECHOMÆ. Fuscous; thorax villous. Fabr. *Cynips glechomæ hederaceæ*, Linn.

Inhabits Europe, and forms rough globular galls on the glechoma hederacea.

QUERCUS BACCARUM. Black, base of the antennæ and legs yellowish. Linn.

Forms roundish pellucid galls about the size of a pea on the under surface of the oak leaves. Found in Sweden, France, and other parts of Europe.

QUERCUS FOLII. Black; thorax lineated; legs grey; thighs beneath black. Linn. *Diplolepis fuscus*, Geoffr.

This species forms galls about the size of a nut on the under surface of the leaves of the oak.

QUERCUS INFERUS. Deep black; antennæ and legs pale. Linn.

Forms globular opaque red galls on the under surface of the leaves of the oak.

QUERCUS PETIOLI. Black; legs white; thighs fuscous; Linn.

Forms convex galls on the footstalk of oak leaves.

QUERCUS PEDUNCULI. Grey; wings with a linear cross. Linn.

Occasions by its puncture the granulated connected galls on the male flowers of the oak.

QUERCUS RAMULI. Pale; abdomen and wings black. Linn.

QUERCUS TOJÆ. Grey; abdomen shining-ferruginous. Fabr.

One of the largest species of the genus, and is found in France on the quercus toja. Bosc.

FAGI. Deep black and without spots. Linn.

Forms pear-shaped galls on the under surface of the leaves of the beech.

VIMINALIS. Yellow; thorax black. Linn.

Forms galls on the leaves of the willow, salix viminalis.

CAPREAE. Green, and shining; legs pale. Linn.

Forms ferruginous galls, resembling grains of barley, on the leaves and branches of the willow.

SALICIS STROBILI. Deep black; thorax greenish on the back. Linn.

In the extremities of the branches of the salix glabra, which it dilates into a strobile-shaped excrescence.

AMERICANÆ. Black; legs pale. Linn.

Forms unequal galls at the ends of the branches of salix pentandria.

RUFICORNIS. Black; abdomen azure; antennæ rufous. Fabr.

Found in France by Bosc.

ACERIS. Body brown; thorax black, and longer than the abdomen. Gmel.

Forms glabrous subturbinated galls on the leaves of acer pseudoplatanus. Act. Boh.

MEGACEPHALA. Deep black; head large and retuse; abdomen truncated. Fabr.

A small species, found on rotten wood in Denmark.

ITALICA. Deep black and shining; thorax golden. Fabr. Native of Italy.

PSEVES. In protuberances of the *ficus carica*. Linn.
SYCOMORI. In protuberances of the *ficus sycomorus*.
 Hassel.

The body is black; the sting weak and exerted.

LONGIPENNIS. Black; abdomen compressed; wings long, white, and marked with two black dots. Fabr.

Inhabits France, and is found in a small flat gall. Bosc.

APTERA. Without wings, ferruginous with compressed abdomen marked with a broad black band.

A large species, found in France.

ROSMARINI. On the *rosmarinus chilensis*. Molin. Chili.

Forms white galls about the size of a nut, and of a globular form, which are full of clear oil, on the branches of *rosmarinus chilensis*.

ATERRIMA. Black, with raised dots; tarsi pale. Schrank.

Inhabits Austria, and forms a very large excrescence on the stems of plants.

RUBI. Silky green-gold punctured; bristles at the end of the tail shorter than the body. Schrank.

Forms protuberances on the stems and branches of the *rubus caesius*.

PHRAGMITIS. Black; base of the antennæ and legs testaceous; abdomen elongated into a broad projecting tail. Schrank.

Found in the inflated stalk of the *arundo phragmitis*.

LUGDUNEA. Black, spotted with yellow; posterior thighs globular, and dentated at the inner margin; flag triple, turned back over the abdomen. Tourette. Act. Par.

A large species, found on various plants.

TESTACEA. Testaceous; head and legs yellowish; eyes black. Gmel. Native of Europe.

NIGRA. Black; base of the abdomen and legs pale. Gmel. Inhabits Europe.

INANITA. Black; abdomen of one segment; the anterior part with a diaphanous spot each side; legs ferruginous. Gmel.

Size of *formica rufa*, and inhabits Upsal.

CYNNA, in *Ancient Geography*, a town of Asia, in the vicinity of Heraclea; the same with the episcopal town of *Ceniva*, placed by Hierocles in Galatia.

CYNO, a place of Egypt, in the Delta, between Tmuis and Tava, according to the Itinerary of Antonine.

CYNOCEPHALÆ, eminences of Greece, in Thesaly, before Scotussa, mentioned by Strabo; who adds, that the Romans under the command of T. Quintius Flaminius, gained here a victory.—Also, the most western promontory of the isle of Corcyra or Corfu.

CYNOCEPHALI, a section of the simia, with short tail, including the baboons. See **SIMIA**.

CYNOCEPHALI, in *Mythology*, a kind of baboons, or animals with heads like dogs, which were wonderfully endowed and revered in many temples of Egypt. See **CUNOCEPHALI**.

CYNOCEPHALUS, in *Ichthyology*, a name given to some species of the *Squalus*, which see.

CYNOCRAMBE, in *Botany*, *Dioscoridis*; Bauh. pin. 122. *Alfines foliis*; Barrel. ic. 335. *Prostrata*; Gært. tab. 75. fig. 9. See **THELYGONUM**. *C. mas* and *fœmina*; Cam. epit. 999. See **MERCURIALIS perennis**.

CYNOCTONON. See **ACONITE**.

CYNODESMUS, or **CYNODESMION**, among *Anatomists*, the band, or ligament, which ties the prepuce of the yard to the nut or glans.

CYNODON, in *Ichthyology*, the name given to the *SPARUS Dentex*, which see.

VOZ. X.

CYNOGLOSSA, in *Botany*, *minor montana*. Col. Ephr. See **MYOSOTIS Lappala**.

CYNOGLOSSA montana media et maxima. See **CYNOGLOSSUM officinale et apenninum**.

CYNOGLOSSOIDES, Isard. See **BORAGO Indica et Africana**.

CYNOGLOSSUM (*κυνόγλωσσον*, from the shape of the leaves). Hounds-tongue. Linn. Gen. 183. Schreb. 243. Willd. 278. Tourn. cl. 2. § 4. gen. 9. Gært. 416. Juss. 131. Vent. 2. 393. Class and order, *pentandria monogynia*. Nat. Ord. *Asperifolia*, Linn. *Borraginea*, Juss.

Gen. Ch. *Cal.* Perianth one-leaved, inferior, with five divisions, permanent. *Cor.* monopetalous, funnel-shaped, the length of the calyx; tube cylindrical, shorter than the border, closed at the mouth by five convex, prominent, converging scales; border cleft half way down into five obtuse segments. *Stam.* Filaments five, very short, in the mouth of the tube; anthers roundish. *Pist.* Germs four; style awl-shaped, permanent. *Peric.* Nuts four, compressed or concave, attached to the style by their interior side.

Eff. Ch. Corolla funnel-shaped; the throat closed with arched scales. Nuts flat, attached to the style by their interior side.

Sp. 1. *C. officinale*. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Pluk. Ic. tab. 78. Curt. Lond. Fasc. 4. tab. 16. Eng. bot. 921. Woody. Med. Bot. Supp. tab. 216. Lam. Ill. Pl. 92. fig. 1 (*C. majus vulgare*; Bauh. pin. 257. Tourn. 139. Lob. ic. 580.) "Stamens shorter than the corolla; leaves broad-lanceolate, downy sessile." Root biennial, spindle-shaped, a little branched, with a blackish bark. Whole herb downy and soft to the touch, with a strong fetid smell resembling that of mice, or the urine of dogs. *Stem* about two feet high, erect, cylindrical, often furrowed, branched, leafy. *Leaves* scattered, entire, undulated, veined, of a dullish green colour, seven or eight inches long; lowermost petioled, upper ones half embracing the stem, almost heart-shaped. *Flowers* in recurved naked racemes, forming a panicle, small, dull purplish red; lobes of the corolla rounded; stigma acute. *Seeds* inversely ovate, attached by their points, rough with numerous hooked prickles. A native of England and most parts of Europe, by road sides and in waste places, chiefly in a calcareous soil. Like most plants of its natural family, it is mucilaginous, astringent and narcotic, and is supposed to be deleterious, when taken internally in any considerable quantity. A decoction of the roots taken inwardly, and cataplasms of them applied externally, have been recommended in stumous and serophalous cases; but no preparation of the plant is much used in the present practice.

2. *C. sylvaticum*. Smith Fl. Brit. 2. Jacq. Coll. 2. 77. Eng. Bot. 1642. (*C. officinale* γ Linn. Sp. Pl. β. Hudf. Fl. Aug. β. Willd. *C. montanum*; Lam. 2. *C. fœmper-virens*; Bauh. pin. 257. *C. folio virenti*; Rai. Syn. *C. montanum virenti folio flore minore*; Tourn. 140. *Cynoglossa montana media*; Colum. ephr. 176. tab. 15.) "Stamens shorter than the corolla; leaves lanceolate, somewhat spatulate, shining, nearly naked, rather scabrous, with small tubercles." Root annual or biennial. *Stem* about a foot and half high, but little branched, beset with loose hairs. *Leaves* green, not downy, roughish with short separate hairs; root ones petioled, a little nerved; stem ones sessile, oblong, rather distant. *Flowers* at first reddish, afterwards assuming a bluish hue. The whole plant is almost free from any fetid smell. A native of Switzerland, France, and some parts of England, especially Essex. 3. *C. pitum*. Ait. Hort. Kew. 1. 179. Mart. 10. Willd. 2. Vahl. Symb. 2. 34. (*C. amplexicaule*; Lam. Ill. 1794. *C. charifolium*;

CYNOGLOSSUM.

cherifolium; Jacq. Collect. 3. 30. Scop. Carn. n. 193. *C. creticum*; Vill. delph. 2. 457. *C. creticum* 2. Cluf. Hist. 2. 162. Bauh. Hist. 3. 600. *C. creticum latifolium fetidum*; Bauh. pin. 257. Tourn. 140. *C. flore cœruleo striis rubris*; Moris. Blas. 258. Hist. 3. 449). "Corollas about the length of the calyx; lobes roundish-dilated; leaves lanceolate, downy; upper ones cordate at the base." Ait. "Border of the corolla dilated, variegated; leaves oblong, embracing the stem, pubescent; upper ones somewhat cordate." Lam. *Root* perennial. Resembling *C. officinale* in habit and size. *Stems* a foot and a half high, more branched. *Leaves* shorter, softer, and more hoary. *Flowers* pale blue or purplish, beautifully pencilled with deeper coloured veins. A native of the south of Europe, Barbary, and Madeira. 4. *C. lanceolatum*. Mart. 11. Willd. 3. Vahl Symb. 2. 34. Forfk. Ægypt. 41. "Leaves lanceolate, attenuated at both ends, rugged, with pointed tubercles above; upper ones sessile." *Stem* herbaceous, upright, angular, rough with hairs, hoary at the top. A native of Ægypt and Arabia. 5. *C. virginicum*. Linn. Sp. Pl. 2. Mart. 2. Lam. 4. Willd. 4. (*C. amplexicaule*; Gron. virg. 19. Moris. Hist. 3. 449. § 11. tab. 30. fig. 9?) "Leaves spatulate-lanceolate, shining, three-nerved at the base; bracte of the peduncles embracing the stem." *Root* annual. *Stem* four feet high, erect, branched, covered with rough hairs. *Leaves* from three to four inches long, embracing the stem, gradually lessening at both ends, rough with hairs, shining on the upper surface. *Flowers* small, white, scattered, near the ends of the branches. A native of Virginia and other parts of North America. 6. *C. limense*. Willd. 5. Feuille. Peruv. 1. 71. tab. 49. "Leaves oblong, acuminate; sessile, smooth, a native of Lima. 7. *C. cherifolium*. Linn. "Calyxes downy, shorter than the corolla; stamens included; leaves narrow-spatulate, very soft, tomentous-silky." Lam. *Root* biennial, spindle-shaped, and a little branched. *Stems* several, erect, pubescent, striated, leafy, branched. *Leaves* half embracing the stem, not rough with tubercles. *Flowers* in naked racemes, white with red, blue or purple veins. A native of the south of Europe. 8. *C. apenninum*. Linn. Sp. Pl. 4. Mart. 4. Lam. 3. Willd. 7. Gært. tab. 67. (*C. montanum maximum*; Tourn. 139. *Cynoglossia montana maxima*; Col. Eepr. 178. tab. 175. Rai. Hist. 490.) "Stamens equalling the corolla." Linn. "Stamens rather longer than the corolla; calyxes shaggy; root-leaves ovate, petioled, very large." *Root* biennial, stem two feet high or more, very thick, almost covered with leaves, which give it a pyramidal form. *Leaves* soft, pubescent, greenish white. *Flowers* in a terminal, branched panicle, at first dull red, afterwards bluish. Lam. *Nuts* four, with a leathery shell, fixed to a pyramidal receptacle, ovate-acuminate; flattish above, (depressed when old,) and muricated with small erect prickles; gibbous and scabrous with acute points underneath and at the sides; pale straw-coloured, one-celled. *Seed* large, inversely egg-shaped, beaked, umbilicated under the beak, brown. Gært. A native of the Apennines. 9. *C. hispidum*. Willd. 8. Thunb. prod. 34. "Leaves oblong, obtuse, rough with bristles; stamens shorter than the corolla." *Root* annual. 10. *C. kirjutum*. Willd. 9. Thunb. prod. 34. "Leaves lanceolate, shaggy; prickles of the seeds hooked." *Root* annual. 11. *C. echinatum*. Willd. 10. Thunb. prod. 34. "Leaves lanceolate, obtuse, covered with soft tubercles; seeds somewhat conical, beset with hooked prickles." *Root* perennial. 12. *C. muricatum*. Willd. 11. Thunb. prod. 34. "Leaves ovate, shaggy, scabrous; seeds callous-muricated." *Root* perenn. "The last four are natives of the Cape of Good Hope. 13. *C. angustifolium*. Willd. 12. (*C. emarginatum*; Lam. Ill. 1799. *C. orientale minus*, flore campanulato cœruleo; Tourn. Cor. 7.) "Leaves linear, bristly; style longer than the campanulate corolla; seeds even-surfaced." Willd. "Corolla longer than the calyx; border obtuse, emarginate; leaves narrow-lanceolate, shaggy." Lam. *Root* perennial. *Stem* half a foot high, erect, hairy. *Root-leaves* petioled, obtuse, hairy; stem ones sessile. *Flowers* in a naked, terminal, trichotomous raceme, blue. Willd. A native of Armenia. 14. *C. levigatum*. Mart. 5. Lam. 2. Willd. 13. Gært. tab. 67. fig. 4. Lam. Ill. Pl. 96. fig. 3. (*C. rindera*; Linn. jun. Supp. 130. *Rindera tetralps*; Pallas it. 1. 486. tab. 1. fig. 1, 2.) "Leaves lanceolate-ovate, smoothish; calyxes downy; seeds even-surfaced." *Root* perennial. *Stem* a foot high, erect, striated, paniced at the top. *Root-leaves* narrowed into a petiole, soft, smooth; stem ones small, sessile. *Flowers* white; calyx five-leaved; leaves linear; tube of the corolla the length of the calyx; anthers almost sessile, between the divisions of the border; style bristle-shaped; stigma globular, scarcely conspicuous. *Nuts* four, coriaceous membranous, shield-shaped on the outside; shield ovate, large, membranous at the edge, radiated with ferruginous lines; nut itself placed in the concave part of the shield, ovate-globular, acuminate at the top, marked in the middle with an oblong umbilical space, one-celled: receptacle tetragonous-awl-shaped, ending in the style. *Seeds* solitary, ovate, beaked, somewhat compressed, dark bay-coloured. A native of Siberia and the Levant. 15. *C. glaberrimum*, Willd. 14. (*C. orientale glaberrimum*; Tourn. Cor. 7.) "Leaves lanceolate, smooth, covered with soft tubercles underneath: seeds membranous, somewhat muricated in the centre." *Stem* erect, angular, smooth, branched; *Leaves* smooth, scabrous at the edge. *Flowers* in racemes; peduncles after flowering near two inches long. *Seeds* furnished with two or three solitary prickles at the centre. A native of Armenia. 16. *C. cristatum*. Lam. 7. Willd. 15. (*C. orientale buglossifolium*; Tourn. Cor. 7.) "Leaves linear-lanceolate, bristly; seeds membranous, muricated at the centre and on the margin." β. *C. fructu umbilicato*; Bauh. pin. 257. Tourn. 140. Rai. hist. 491. Moris. 5. 449. § 11. tab. 30. fig. 7. *Cynoglossia altera media*; Colum. Eepr. 1. 177. tab. 178. *Stem* a foot high or more, cylindrical, shaggy, leafy, with two or three branches near the top. *Leaves* sessile, attenuated at the base, rough with hairs proceeding from white callous points. *Flowers* in naked terminal racemes, small, red; calyx divided to the base, shaggy; corolla not larger than the calyx. *Nuts* toothed on the membranous edge. Found by Tournefort in the Levant. The variety has narrower, smoother leaves, and is a native of Italy. 17. *C. lusitanicum* Linn. Sp. Pl. 6. Mart. 6. Lam. 12. Willd. 16. (*Omphalodes lusitanica elatior*; Tourn. 140.) "Leaves cordate embracing the stem, smooth, even at the edge." Vahl. "Leaves lanceolate, nearly even-surfaced; racemes few-flowered, very short." Lam. Whole plant smooth. *Root* annual. *Stem* a foot high, erect, branched. *Leaves* glaucous green, obtuse, veinless. *Flowers* red or violet, remote, in naked terminal racemes; pedicels an inch long, spreading; calyx deeply cleft; segments lanceolate. A native of Portugal. 18. *C. linifolium* Linn. Sp. 5. Mart. 7. Lam. 13. Willd. 17. Gært. tab. 67. (*Omphalodes lusitanica lini folio*, smooth, toothed, scabrous at the edge." Vahl. "Leaves lanceolate," Tourn. *Linum umbilicatum*; Park. Theat. 1687. Barrel. c. 1234. *Cynoglossium minus album*; Moris. 3. 449. § 11. tab. 30. fig. 11.) "Leaves linear-lanceolate, glaucous, scabrous at the edge; racemes long, erect, somewhat paniced."

clad." Lam. *Root* annual. *Stems* a foot high, smooth, leafy, branched at the top. *Leaves* smooth above, rough, with short stiffish hairs at the edges and underneath. *Flowers* white, peduncled. *Nuts* four, small, incumbent on an awl-shaped receptacle which becomes incurved as the seeds ripen, somewhat membranous, compressed, ovate-acuminate, attenuated at the edge into a pellucid whitish membrane, deeply striated, with a large toothed hole at the top, whence this and some other species have been called navelwort. A native of Portugal. 19. *C. latatum*, Lam. 8. Willd. 18. (*C. orientale* flore roseo; Tourn. Cor. 7.) "Calyxes tomentous-woolly; border of the corolla with five deep acute divisions; racemes drooping." *Stem* a foot high, striated, pubescent towards the top, leafy, somewhat branched. *Root-leaves* seven or eight inches long, nine or ten lines broad, petioled, narrow-lanceolate, pubescent; stem ones small, oval-acute, embracing the stem. *Flowers* in short, clustered, woolly, terminal racemes; calyx pitcher-shaped, very woolly; style longer than the flower. A native of the Levant. 20. *C. japonicum*, Mart. 9. Lam. 9. Willd. 19. Thunb. Flor. jap. 81. "Leaves oblong, shaggy; stems prostrate." *Root* annual. *Stems* four or five, cylindrical, shaggy, decumbent, afterwards flexuose-erect, unequal, four or five inches long. *Leaves* embracing the stem, oblong, acute, finely serrated, shaggy on both sides, spreading. *Flowers* in a terminal raceme, purple. A native of Japan. 21. *C. lateriflorum*, Lam. 10. Ill. Pl. 92. fig. 2. Willd. 20. "Leaves linear, acute, narrow, hairy; flowers lateral, solitary, nearly sessile." A small shaggy plant, of a whitish colour. *Stems* three or four inches long, slender, leafy, branched. *Leaves* nearly an inch long, a line broad. *Flowers* small; corolla scarcely longer than the calyx. *Seeds* small, elliptical, rough at the edge with radiant points. Found near Lima by Dombe. 22. *C. scorpioides*. Lam. Ill. Willd. 21. Jacq. Collec. 2. 3. Schmidt Bohem. 1. n. 220. "Stem prostrate; leaves lanceolate, scabrous; peduncles axillary, one-flowered; seeds umbilicated, smooth." *Root* annual. *Stem* somewhat four-cornered, dichotomous; lower leaves opposite. A native of moist shady places in Bohemia. 23. *C. omphalodes*. Linn. Sp. Pl. 7. Mart. 8. Lam. 11. Willd. 22. Bot. Mag. tab. 7. (*Symphytum minus*, borraginis facie. Bauh. pin. 259. *Borrago minor*; Moris. 3. 437. § 11. tab. 26. fig. 3. *Omphalodes pumilaverna*; Tourn. 140.) "Creeping root-leaves ovate-cordate; stem ones ovate, petioled." Willd. "Root perennial. *Stems* slender, leafy, from four to six inches long; some barren, others bearing flowers. *Flowers* blue with a white star in the middle. A native of the south of Europe, where it is said to flower about Christmas. In our gardens it flowers from March to May. 24. *C. cappadocicum*, Willd. 23. (*C. omphalodes* β. Lam. *Omphalodes orientalis corni folio*; Tourn. cor. 7.) "Root-leaves cordate; lowest stem ones lanceolate, petioled; uppermost cordate, sessile." *Root-leaves* on long petioles, acuminate, quite entire, marked with prominent veins underneath, three or four inches long, two or three inches broad; petioles the length of the leaf or more. *Flowers* in a terminal raceme. A native of Cappadocia. 25. *C. myofotoides*, Willd. 24. Billard. ic. pl. fyr. 2. 6. tab. 2. (*C. lithospermifolium*; Lam. 14.) "Root-leaves spatulate-lanceolate; stem ones linear, sessile; seeds membranous, even-surfaced, ciliate-toothed at the edge." *Root* perennial. *Stems* four or five inches high, slender, branched, clothed with short hairs. *Leaves* scabrous and shaggy. *Flowers* in naked terminal racemes, small, alternate. *Nuts* four, smooth, wrinkled, striated, resembling those of *C. omphalodes*, but smaller. The whole plant has the habit

of *myofotis arvensis*. Found on the summit of Mount Lebanon.

CYNOGLOSSUM boraginifolium; Pluk. See *BORAGO africana*.

CYNOGLOSSUM glandulis faucium glabris; Hall. See *MYOLOTIS Lappula*.

CYNOGLOSSUM minus; C. Baul. See *MYOLOTIS Lappula*.

CYNOGLOSSUM perenne maritimum; Moris. See *PULMONARIA marina*.

CYNOGLOSSUM procumbens maritimum; Pluk. See *PULMONARIA maritima*.

CYNOGLOSSUM virginianum flore & fructu minimo; Moris. See *MYOLOTIS Virginiana*.

Preparation and Culture.—*C. lusitanicum* and *C. linifolium*, called Venus' navelwort by our gardeners, are annuals commonly sown to adorn the borders of the flower garden. They succeed best when sown in autumn, and flower earlier, but do not well bear transplanting. *C. omphalodes* should be planted in a moist cool situation; it then readily propagates itself by its trailers, but seldom produces seeds.

CYNOGLOSSUM, in *Gardening*, comprises plants of the herbaceous annual and perennial ornamental kinds. Of which the species cultivated are the flat-leaved hound's-tongue, or Venus's navelwort (*C. linifolium*); the Portugal hound's-tongue, or Venus's navelwort (*C. lusitanicum*); the comfrey-leaved hound's-tongue (*C. omphaloides*).

Method of Culture.—The two first or annual sorts, are usually increased by sowing the seeds in the early spring months, in patches, in the borders, clumps, or other places where the plants are to remain and flower, covering them in a light manner. When the plants appear, they only stand in need of being kept clean from weeds, and having a little water occasionally given them.

But in order to protract the time of flowering, two or three different sowings should be made, at proper intervals, in these sorts of plants.

With regard to the third or perennial sort, it may be easily propagated by taking off the rooted stalks, and planting them out in the situations where they are to remain, either in the spring, summer, or autumnal seasons.

These are a sort of plants which afford much ornament and variety to the garden, as well as the borders, clumps, and other compartments of grounds of the pleasure kind.

CYNOGLOSSUS, in *Ichthyology*, a species of *Pleuronectes*, which see.

CYNOGLUCOS, from *κυνος*, dog, and *λύκος*, wolf, in *Natural History*, a name given by the ancient writers to a creature which had the shape partly of a dog, and partly of a wolf, and was generated, according to their accounts, by a mixture of those two species of animals in copulation, as the *Leucocotta* was, between the hyena and lionsess.

CYNOMETRA, in *Botany* (*κυνος*: *αίτη*, canis matrix, a foolish allusion to a fancied resemblance in the form of the fruit), Linn. Gen. 519. Schreb. 710. Willd. 320. Gært. 898. Juss. 350. Vent. 3379. Class and order, *decandria monogynia*. Nat. Ord. *Leguminosae*, Linn. *Leguminosae*; Juss.

Gen. Ch. *Cal.* Perianth four-leaved; leaflets oblong, reflexed. *Cor.* Petals five, lanceolate, equal, nearly erect. *Stam.* Filaments ten, longer than the petals; anthers oval, bifid at the tip. *Pist.* Germ superior, boatshaped; style filiform, the length of the stamens; stigma simple. *Peric.* Legume somewhat fleshy, short, lunate, or nearly hemispherical, slightly compressed laterally, containing one or two large, elliptical, slightly compressed seeds.

Eff. Ch. Calyx four-leaved. Anthers bifid at the tip. Legume somewhat fleshy, shaped like a half-moon, with one or two seeds.

Sp. *C. caudiflora*, Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Ill. Pl. 331. fig. 2. Willd. 1. Gært. tab. 156. (Cynomorium; Rumph. amb. 1. 163. tab. 62. Burm. Ind. 100.) "Trunk floriferous." Roots knotty and large, appearing above ground, interspersed with curled smaller ones. Trunk seldom two feet high, very irregular, knotty, covered with a thick, rugged, dark-coloured bark; the head not large, but dense, consisting of thick long branches, subdivided into many others. Leaves only near the end of the smaller branches, in alternate conjugate pairs, each pair on a short common petiole, three or four inches long, an inch and half broad, entire, smooth, firm, flexible, sharp-pointed; with a straight rib prominent on both surfaces, and dividing the leaf into two very unequal parts. Flowers proceeding from the trunk, the large branches, and those roots which are above ground, Rumph. Legume large, the size of half the palm of the hand, or more, compressed like a lens, with a groove, like a future, along its whole circuit, tubercled on the sides and rough to the touch like a woollen cloth, one-celled, not dehiscent. Seed nearly filling the cavity of the legume, attached to it by a short thick chord at the middle of the future, smooth, marked with curved capillary vessels proceeding from the umbilicus, of a red ferruginous colour; with a simple, coriaceous, thin integument, which, in old seeds, is scarcely separable from the kernel in boiling water; albumen none, nor any vestige of it; embryo the shape of the seed, white; cotyledons plano-convex, hollowed within into a small chamber to contain the radicle; plume slender, two-horned, surrounded about its base by short, soft, matted hairs, by which it is separated from the cotyledons to the distance of half a line; radicle conical, immersed, centrifugal. A native of the East Indies. Obs. Lamarck is in possession of specimens of fruit and leaves, received from Sonnerat, which do not appear to differ from this species, except that the legumes have two seeds. 2. *C. ramiflora*, Linn. Sp. 2. Mart. 2. Lam. 2. Ill. Pl. 331. fig. 1. Willd. 2. (Cynomorium sylvestre; Rumph. amb. 1. 164. tab. 63. Iripa; Rheed. Mal. 4. 65. tab. 31. Burm. Ind. 100. Rai. Hist. 1675.) "Branches floriferous." A lofty evergreen tree, about sixty feet high. Trunk thick, solid, cinereous, reddish within; branches numerous, not forming so dense a head as in the preceding species. Leaves conjugate, nearly sessile, roundish, emarginate, smooth, dark green and shining above, paler underneath, unequally divided by the midrib, nerved. Flowers small, white, scentless. Legumes oblong-roundish, compressed, tubercled, furrowed, dehiscent on both sides. Seed solitary. A native of the coast of Malabar, and other parts of the East Indies.

CYNOMOLGUS, in *Zoology*, a species of *Simia*, which see.

CYNOMORIUM, in *Botany* (*κυνος μοριον*, another indelicate foolish comparison), Linn. Gen. 1033. Schreb. 1594. Willd. 1620. Juss. 445. Class and order, *monœcia monandria*. Nat. Ord. *Amentaceæ*; Linn. *Undetermined*; Juss.

Gen. Ch. Barren and fertile flowers in the same, erect, club-shaped, imbricated catkin. Barren ones. Cal. Perianth four scales of the catkin. Cor. none. Stam. Filament single; anther two-celled. Fertile ones. Cal. Perianth four-leaved (superior; Linn.) or none. Cor. none. Pijl. Germ ovate; style single; stigma obtuse. Peric. none. Seed single, roundish.

Eff. Ch. Barren flowers. Perianth four-leaved. Corolla none. Fertile flowers. Perianth four-leaved, or none. Corolla none. Seed one, naked.

Sp. 1. *C. coccineum*. Linn. Sp. Pl. Mart. 1. Lam. Enc. Ill. Pl. 742. Willd. 1. (Fungus typhoides, Bocc. Mus. 2. 69. Sic. 80. tab. 81. Till. Pis. 64. tab. 25. *F. mauritanicus ruber*; Pet. Gaz. tab. 39. fig. 8. *Cynomorium purpureum*; Mich. Gen. 17. tab. 12.) "Stem scaly; catkin cylindrical; scales imbricated, ovate, retuse." A parasitical, leafless plant, appearing somewhat like a fungus. Stem about a foot high, as thick as the human finger, erect, solid, becoming woody when dry; entirely covered, when young, with imbricated, oval, acute, white scales, most of which fall off when the flowers begin to appear. The whole plant is then of a purple or scarlet colour. Flowers in a catkin about the length of the stem, and twice its thickness, terminal, consisting of barren and fertile imperfect flowers closely intermixed, sometimes accompanied by a few perfect ones; three of the calyx-scales of the barren flower club-shaped; the other inferior, larger, very obtuse, channelled; filament firm, straight, longer than the scales; calyx-scales of the fertile flower club-shaped, tubercled, equal, permanent. A native of the south of Europe, and of the coast of Barbary, on the roots of trees and shrubs near the sea. 2. *C. jamaicensis*. Mart. 2. Willd. 2. Swartz Prod. 12. Fl. Ind. Occ. 1. 11. "Stem scaly; catkin elongated; scales imbricated, halved, rhomboidal." Stem three, four, or five inches high, commonly smallest towards the bottom, succulent, fleshy, at first thickly covered with cordate scales, which gradually fall off, and leave it thickly beset with transparent denticles, intermixed with a few tubular trifid flowers. A native of Jamaica in shady inland woods. 3. *C. cayanensis*. Mart. 3. Willd. 4. Swartz Prod. 12. Fl. Ind. Occ. 1. 13. "Stem naked; catkin somewhat globular; scales roundish, peltate." A native of Cayenne. 4. *C. balanophora*. Willd. 3. (*Balanophora fungosa*; Forst. Prod. n. 333. Lam. Enc. and Ill. Pl. 742.) "Stem scaly; catkin oblong; scales spreading, oblong-lanceolate." Willd. Barren flowers in two or three rows on the lower part of the catkin, larger, distinct; calyx-scales (petals; Forst.), lanceolate, rather thick, spreading; stamen the length of the scales, erect, cylindrical; anther large, oval-oblong, erect, channelled. Fertile flowers above them, much more numerous, extremely small, disposed several together on very minute, distinct, but close-set receptacles, without a calyx or a corolla. A native of the island of Tanna, in the South Sea. All the species are parasitical and perennial.

Obs. We have followed Willdenow in adding the *Balanophora* of Forster to this genus, an union suggested by Jussieu, and which La Marck seemed inclined to approve, though he did not adopt. We have accordingly ventured to make some alteration in the generic character; but the fructification of all the species stands in need of a more accurate investigation.

CYNOMORIUM; Rumph. See CYNOMETRA.

CYNONTODIUM, Hedw. See TRICHOSTOMUM.

CYNOPHALLOPHORUS. Plum. See CAPPARIS *Cynophallophora*, n. 37.

CYNOPHONTIS, in *Antiquity*, a festival observed in the dog-days at Argos, and so called *απο της κυνης φωνης*, i. e. from killing dogs; because it was usual on this day to kill all the dogs they met with.

CYNOPOLIS, or CYNOSPOLIS, "city of dogs," in *Ancient Geography*, a town of Upper Egypt, supposed, by some ruins of columns and ancient edifices, to be the present *Mi-*

net. The inhabitants of this city held the dogs in great veneration. The priests nourished this animal with sacred meat, in honour of Anubis, the companion and guardian of Osiris.—Also, a town of Asia in Haïria.

CYNOPOLITES *Nomon*, a name of Egypt, extending on both sides of the Nile; the capital of which, according to Strabo, was *Cynopolis*.

CYNOREXY, or **CYNODES OREXIS**, an immoderate appetite to the degree of a disease; called also *fames canina*, and *bulimy*.

CYNORRHODON, in *Botany*, the *dog-rose*, as the Greek term signifies; the common wild briar, or wild white rose, so common in our hedges.

CYNORTION, in *Ancient Geography*, a mountain of Greece in the Peloponnesus, where was a temple of Apollo, according to Pausanias.

CYNORYNCHIUM, in *Botany*, Pluk. See **CHELONE pubescens**.

CYNOSARGES, a place of Greece in Attica, near Athens; where were the gymnasium and a temple consecrated to Apollo. The Cynic philosophers had their school here.

CYNOSBATOS, from *κυνων* and *βατος*, *bush*, in *Botany*, a word used as the name of different shrubs by different authors. It is now generally used as the name of the wild, or dog-rose; but some authors have applied it to the common bramble; others to the *oxycanthus*, and others to the *caper-bush*.

The fruit of the wild rose is the *hip*, used in conserve, and said to be good in disorders of the breast, &c. See **CONSERVE**.

CYNOSORCHIS, in *Botany*, C. Bauh. See **ORCHIS pyramidalis**, *usulata* & *militaris*.

CYNOSSEMA, in *Ancient Geography*, a promontory of the Thracian Chersonesus.—Also, a promontory of the Doride, placed by Strabo between the towns of Lorimus and Cnidus.—Also, a maritime place of Egypt, in the vicinity of Taposiris. Strabo.—Also, a place of Africa in Libya. Steph. Byz.—Also, a place of Greece, in Calydonia. Id.—Also, a place of Thrace, in the environs of Maronea. Strabo.

CYNOSURA, in *Astronomy*, a denomination given by the Greeks to *Ursa minor*, or the little bear.

The word is formed of *κυνος*, *q. d.* the *dog's tail*.

This is the constellation next our pole, consisting of seven stars; four whereof are disposed like the four wheels of a chariot; and three lengthwise, representing the beam: whence some give it the name of the *chariot*, or Charles's *wain*: a name now more commonly given to the seven principal stars forming the same kind of figure in the Great Bear.

From these seven stars it is the pole takes its name, *Septentrionalis*; and the rest of the hemisphere, as far as the line, *Septentriones*.

CYNOSURA, in *Ancient Geography*, a promontory of Greece, in Attica, formed by a small chain of mountains, being the continuation of mount Hymettus towards the east.—Also, a place of the Peloponnesus, in Arcadia.—Also, a place of the Peloponnesus in Laconia.

CYNOSUROS, in *Zoology*, a species of **SIMIA**; which see.

CYNOSURUS, in *Botany, (*κυνος ουρα*) dog's-tail grass. Linn. Gen. 87. Schreb. 118. Willd. 138. Gært. 8. Juss. 31. Vent. 2. 105. Class and order, *triandria digynia*. Nat. Ord. *Gramina*, Linn. *Gramineæ*, Juss.*

Gen. Ch. Receptacle common unilateral, with or without bractes. *Cal.* Glume two-valved, two or many-

flowered. *Cor.* two-valved; the outer concave, longer; the inner flat, awnless; nectary two-leaved; leaflets ovate, acute, gibbous at the base. *Stam.* Filaments three, capillary; anthers oblong. *Pist.* Germ top-shaped; styles two, villous, reflexed; stigmas simple. *Peric.* only the permanent corolla closely investing the seed. *Seed* single, oblong, acuminate at each end.

Eff. Ch. Calyx two-valved, chaffy, bearded, two or many-flowered, on a unilateral receptacle.

Obs. It has often been observed that this genus, as it was established by Linnæus, consists of species differing from each other in general habit, and other characters. Gærtner has divided it into two, *cynosurus* and *cleusine*, with the following characters. 1. *Cynosurus*. *Involucres* pectinated or pinnated, under the flowers. *Calyx* two-valved, two or four-flowered. *Cor.* two-glumed, longer than the calyx. *Seed* free, covered, furrowed on one side. 2. *Eleusine*. *Cal.* two-valved, four-flowered. *Cor.* two-glumed, with unequal valves. *Capsule* membranous, one-celled, valveless, one-seeded. *Seed* globular. It is by this pericarp, which he calls a capsule, but which seems more properly an aril, that this genus, according to him, is distinguished from all the other known grasses. La Marck, when he wrote the alphabetical part of the French Encyclopedie Methodique, adhered to the Linnæan arrangement; but afterwards in his "Illustration des Genres," adopted that of Gærtner, retaining under *cynosurus* only cristatus, echinatus, and aurcus, which Dr. Stokes, in Withering's arrangements, had some time before pronounced to be the only legitimate species. After considerable deliberation, we have judged it most expedient, at least for the present, to keep the original genus entire.

* *With Bractes.*

Sp. 1. *C. cristatus*. Linn. 1. Mart. 1. Lam. 1. Willd. 1. Schreb. Gram. 69. tab. 8. fig. 1. Flor. Dan. tab. 238. Lam. Ill. tab. 47. fig. 1. Eng. Bot. 316. (Phleum cristatum; Scop. Carn. 2. n. 81. Gramen pratense cristatum; Bauh. Pin. 3.) "Bractes pinnatifid." Linn. "Bractes pinnate-distichous, awnless; spike simple, linear." Smith. *Root* perennial, fibrous, tufted. *Stems* several, a foot high, erect, stiff, leafy, naked near the top, cylindrical, striated, quite smooth. *Leaves* linear, acute, even-surfaced; sheaths cylindrical, striated, quite smooth; stipula short, obtuse, jagged. *Spike* obtuse, stiff and straight; rachis somewhat zig-zag, angular, smooth and even. *Spikelets* alternate, ovate, many-flowered, nearly sessile; calyx-glumes linear, acute, keeled; keel scabrous; florets alternate, a little tumid, scarcely keeled, scabrous towards the summit, mucronate; bractes composed of abortive flowers, which are alternate, compressed-keeled, scabrous on the back, acute, scarcely awned. Ray mentions a variety with four rows of spikelets. Smith. Common in dry pastures in England, and other parts of England. 2. *C. echinatus*. Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Willd. 3. Gært. tab. 1. Lam. Ill. Pl. 47. fig. 2. Eng. Bot. 1333. (Gramen alopecurioides spica aspera; Bauh. Pin. 4. Schench. Gram. 80. tab. 2. fig. 3. D. Barr. Rar. tab. 123.) "Bractes pinnated, spike compound, ovate. *Root* annual, fibrous, downy. *Stems* one or more, ascending, leafy, cylindrical, striated, smooth. About seven inches high. *Leaves* lanceolate, ovate at their base, acute, flat, striated, roughish on both sides; sheaths a little inflated, somewhat compressed or two-edged, furrowed, roughish; stipula lanceolate. *Spike* dense. Spikelets alternate, ovate; bractes consisting of alternate, lanceolate, membranous, ribbed, rough husks, each tipped with a straight, rough, purple

CYNOSURUS.

awn, various in length; calyx-glumes equal, thin, beardless; florets two or more; outer glume roughish, inner finely fringed. Smith. A native of a sandy soil on the southern coast of England, and other warmer parts of Europe. 3. *C. aureus*. Linn. Sp. Pl. 10. Mart. 13. Lam. 6. Willd. 2. (Gramen paniculâ pendulâ aurâ; Bauh. Pin. 3. G. barcinonense; Tournef. 523. G. sciurum, Barr. ic. 4.) "Panicle racemed; bractes resembling spikelets, pedicelled, fasciated, pendulous, awnless; spikelets about three-flowered, awned. Root annual. Stems from four to seven inches high, leafy. Leaves about two lines broad, smooth. Panicle two or three inches long, narrow, silky; bractes pinnate, chaffy, yellowish-green; pinnæ obtuse, concave, alternate. A native of the south of Europe, among rocks. 4. *C. falcatus*. Willd. 2. Thunb. Prod. 23. (Melica falk; Linn. jun. Supp. 109. Mart. Lam. Enc. & Ill.) "Bractes simple, lanceolate." Culm a foot and half high, even-surfaced. Spike the length of a finger, compressed, imbricated; bractes acuminate, three-nerved, a little longer than the spikelets, one to each spikelet; spikelets with a white edge, pubescent; calyx two-flowered, one larger, one smaller, with the rudiment of another; outer glume of the larger floret inversely egg-shaped, ciliated with white hairs, very obtuse, emarginate; inner one long, narrow, smooth, lanceolate; styles two, pubescent; smaller flower similar to the other, but without styles. Found by Sparman at the Cape of Good Hope. The younger Linnæus found no stamens in the specimens which he examined, but seems to have conjectured that the florets are imperfect, and that the smaller one is stamiferous.

** Without Bractes.

5. *C. monostachyos*. Mart. 17. Willd. 13. Vahl. Symb. 2. 20. "Spike simple; calyxes awl-shaped, about three-flowered; florets awned." Culm a foot and half high, upright, smooth. Leaves awl-shaped, narrow. Spike a span long; rachis convex and keeled on the outside; spikelets imbricated on the inner side, alternate, smooth; outer calyx-valve the length of the florets; inner one smaller; florets bearded at the base, compressed, one perfect, another imperfect and stamiferous, the third quite abortive; outer valve of all the three awned below the tip; awns straight, twice the length of the calyx. A native of the East Indies. 6. *C. filiformis*. Mart. 16. Willd. 12. Vahl. Symb. 2. 20. "Spike solitary, two-rowed; calyxes awl-shaped, three flowered; abortive floret awnless." Culms creeping, branched, filiform, compressed at the bottom; internodes an inch long. Leaves at the joints, several on each side, an inch and half long, bristle-shaped; sheaths compressed, equitant, nearly the same length with the leaves, and broader. Floriferous culms terminal, about seven inches long, quite simple, jointed, with a single awl-shaped leaf towards the middle. Spike an inch long, linear; spikelets small, alternate, compressed, smooth; calyx valves spreading, nearly equal, the length of the florets, acute; florets usually three, one perfect, sessile; another imperfect, stamiferous; the third quite abortive; the two former with an awn below the tip, a little longer than the calyx. A native of the East Indies. 7. *C. uniolæ*. Linn. jun. Supp. 110. Lam. Enc. 5. Mart. 7. Willd. 11. Thunb. Prod. 17. "Spike solitary, two-rowed; calyxes many-flowered, mucronate; corollas shaggy at the base." Quite smooth, with the habit of uniola, but its calyx is bivalved, not many-valved. Spike linear; spikelets sessile, pressed close to the rachis, alternate, spreading at the sides, oblique, quite smooth. A native of the Cape of Good Hope. 8. *C. paniculatus*. Willd. 5. Thunb. Prod. 23. "Spike compound,

ovate; calyx many-flowered; one glume mucronate; corollas hairy at the base." A native of the Cape of Good Hope. 9. *C. Lima*. Linn. Sp. Pl. 3. Mart. 3. Lam. Encyc. 3. Willd. 6. Læfl. it. 41. Cavan. ic. 1. 62. tab. 91. (Eleusine lima; Lam. Ill. 1128.) "Spike solitary; inner glume of the calyx placed below the spikelets;" Linn. "Spike rigid; spikelets sessile, in two rows, but strictly unilateral, about five flowered; glumes acute;" Lam. Root annual. Culms slender, from five to seven inches high. Leaves very narrow, shorter than the sheath, slightly rolled in at the edges so as to give them a rush-like appearance. Spike scarcely an inch long, oval, sometimes conical, glaucous; spikelets compressed, awnless, lower ones somewhat peduncled; calyx-glumes awl-shaped; outer one larger, keeled, roughish at the edges; inner one flat. A native of Spain. 10. *C. durus*. Linn. Sp. Pl. 4. Mart. 4. Lam. Enc. 4. Willd. 7. Pollich Pal. n. 100. tab. 1. fig. 1. (Eleusine dura; Lam. Ill. 1127. Gramen loliaecium majus lupinum; Bauh. Prod. 19. G. arvense poly-podii panicula; Barr. Icon. 50. Lolium; Hall. n. 1419. Poa. Scop. n. 101.) "Spikelets alternate, sessile, rigid, obtuse, adpressed;" Linn. Root annual. Culms few, about three inches high, almost procumbent, leafy. Leaves smooth and even, scarcely longer than the sheath, a line and half broad. Spike erect, branched, compressed, oval spiculate, awnless; rachis of the branches zig-zag; spikelets sessile, alternate, two-rowed, three-flowered, linear, striated, smooth. A native of the south of Europe. Linnæus thought its true genus doubtful; according to La Marek, it is more nearly allied to lolium than to poa. 11. *C. retroflexus*. Mart. 13. Willd. 8. Vahl. Symb. 2. 20. "Spike compound, spikelets aggregate; calyx two-flowered, armed; florets awnless." Stems cylindrical, smooth. Leaves about seven inches long, awl-shaped, smooth. Common rachis grooved, angular; spikelets in threes at each tooth of the rachis, an inch long, linear, spreading; lateral ones sessile; middle one on a short pedicel, all bent back when old; there is sometimes a fourth sessile spikelet a little above the others: partial rachis zig-zag; florets compressed, smooth. A native of the East Indies. 12. *C. coracanus*. Linn. Sp. Pl. 9. Mart. 8. Lam. Enc. 7. Willd. 14. (Eleusine; Gært. tab. 1. 11. Lam. Ill. Pl. 48. fig. 1. Gramen dactylon orientale; Pluk. Alm. 274. tab. 95. fig. 1. Panicum gramineum, five Naatsjoni; Rumph. Amb. 5. 203. tab. 76. fig. 2. Tsjitti-pullu; Rheed. Mal. 12. 149. tab. 78.) "Spikes digitate, incurved; culm compressed, erect; leaves nearly opposite." Root annual. Culms four or five feet high, leafy, compressed, sometimes a little branched. Leaves long, three lines broad, with a few long distant hairs just above the sheath. Spikes from four to six, an inch and half long, about five lines broad, thick, somewhat compressed, at first erect; spikelets numerous, short, sessile, four-flowered, closely imbricated in several ranks on the same side of the rachis. A native of the East Indies. The seeds are eaten in a scarcity of rice. 13. *C. floccifolius*. Mart. 20. Willd. 15. Vahl. Symb. 1. 10. Forst. Ægypt. 21. n. 73. "Spikes linear, straight; leaves folded together, alternately bearded at the edges." In habit resembling the preceding species. Spikes alternate, upper ones in pairs. Leaves alternate, smooth on the surface; sheaths not ciliated. A native of Ægypt. 14. *C. tristachyos*. Lam. Encyc. 10. (Eleusine; Illust. 11. 23.) "Spikes ternate, thick, obtuse, erect; spikelets sessile, adpressed, about four-flowered." Culms three inches high, compressed, leafy. Leaves alternate, in two opposite rows, often longer than the culms, a line and half broad. Spikes six or seven lines long, four or five broad, sessile; spikelets clove. Found by Commerçon near Monte Video. 15. *C. penicillatus*. Mart. 18. Willd.

Willd. 16. Vahl. Symb. 2. 21. "Spikes digitate; calyx four-flowered, awned at the back; outer petals of the perfect flowers awned, with bearded pencils." *Culm* cylindrical, finely streaked, pubescent at the top. *Spikes* in threes, sometimes solitary, on very short pedicels, four or five inches long, bearded at the base, sometimes a little recurved at the end; rachis somewhat convex on the outside, channelled within; spikelets from the inner side only, sessile, alternate, much crowded, awl-shaped, slightly compressed, spreading; inner valve of the calyx lower, ovate acuminate, almost transparent; outer one three times longer, lanceolate, attenuated, compressed, keeled, grooved at the back, ciliated in a raised line on each side of the groove; awn on the middle of the valve, upright, the length of the valve; florets bearded at the base, two of them perfect, outer petal bearded at the top with two pencils, ciliated with long, very soft, white hairs; two smaller, probably only stamiferous; one of them awnless. A native of the East Indies. 16. *C. pappaloides*. Mart. 19. Willd. 17. Vahl. Symb. 2. 21. tab. 27. (*Chloris petraea*; Thunb. but not of Swartz.) "Spikes digitate; calyx two-flowered, somewhat globular; exterior valve awned; florets awnless." *Culm* a foot high, almost leafless. *Root-leaves* two inches long, sheathing, linear-lanceolate, sharpish; sheaths compressed, equitant, twice the breadth of the leaves. *Spikes* five, an inch and half long, sessile, woolly at the base, linear, narrow, ferruginous, shining; spikelets the size of millet seed, alternate, crowded, very obtuse; outer valve of the calyx shorter than the corolla, ovate, awned a little below the tip, emarginate, keeled; inner ones smaller; outer glumes of the corolla keeled, ciliated at the edges and on the keel. A native of the Cape of Good Hope. 17. *C. ægyptius*. Linn. Sp. Pl. 7. Mart. 9. Lam. Enc. 8. Willd. 18. (Eleu. sine cruciata; Lam. Ill. 1125. Pl. 48. fig. 2. Gramen dactylon ægyptiacum; Bauh. Pin. 7. Theat. 110. Tourn. 521. Morf. Hist. 3. 184. § 8. tab. 3. fig. 7. Schench. Gram. 109. *G. ischænum*; Pluk. Aim. 175. tab. 300. fig. 8. Neiem el Sahb. Alp. Ægyp. 56. tab. 43. Gramen; Rumph. Amb. 6. tab. 4. fig. 1. Cavara-pulla; Rheed. Mal. 12. tab. 69.) "Spikes digitate, in fours, obtuse, widely spreading, mucronate; calyx mucronate; stem creeping." *Root* annual. *Culm* from six to nine inches long, ascending, bent at the joints, leafy. *Leaves* two or three lines broad, rough at the edges. *Spikes* generally four, sometimes five, scarcely an inch long, thick, compressed, obtuse, with a small point; spikelets short, close, mucronate, two-flowered. A native of Asia, Africa, and America. Obs. La Marek considers this species as an eleusine, in opposition to Gærtner, who asserts that, notwithstanding the similarity of its habit, it must be referred to another genus. May it not be justly doubted whether the pericarp on which Gærtner lay so much stress, be in this case a sufficient generic distinction? 18. *C. indicus*. Linn. Sp. Pl. 8. Mart. 10. Lam. Encyc. 10. Willd. 19. (Eleusine; Gært. Lam. Ill. Pl. 48. fig. 3. Panicum compressum; Forsk. Decl. 18. Gramen dactyloides; Burm. Zeyl. 106. tab. 47. fig. 1. *G. vaccinum*; Rumph. Amb. 6. 10. tab. 4. fig. 2. Ranara-pullu; Rheed. Mal. 12. 131. tab. 16.) "Spikes digitate, linear; culm compressed, declined, with a knot at the base." *Root* annual. *Culm* sometimes only four or five inches, sometimes more than a foot long, leafy, commonly with a branch springing from the knot. *Leaves* about two lines broad, in two rows, beset with loose hairs, especially about the sheath. *Spikes* from three to seven, in an open fascicle two or three inches long, generally with a solitary spike below the fascicle; spikelets three or four-flowered, short, close, awnless, in two or three longitudinal rows. A native of the East Indies.

19. *C. pectinatus*. (Lam. Encyc. 12. C. Eleusine; Ill. 1126.) "Spikes linear, somewhat pectinate, alternate, in a kind of raceme; spikelets three-flowered, shorter than the mucronate calyx." *Leaves* three lines broad or more, smooth. *Spikes* from forty to fifty, in an erect raceme five or six inches long, sessile, alternate, solitary or in pairs; smooth, compressed, diminishing in length from the bottom to the top, lower ones from twelve to fifteen lines long; spikelets sessile, in two rows, alternate, compressed, smooth, with one of their edges to the rachis as in lolium, two or three-flowered. Found in the East Indies by Sonnerat. 20. *C. virgatus*. Linn. Sp. Pl. 6. Mart. 11. Lam. Enc. 13. Willd. 20. (*Festuca virgata*; Lam. Ill. Gramen loliaceum paniculae specis simplicibus; Brown. Jam. 137. *G. dactylon*; Sloan. Jam. 34. Hist. 1. 113. tab. 70. fig. 2.) "Panicle with simple branches; spikelets sessile, about six-flowered; uppermost floret barren; the lower ones somewhat awned." β *Domingensis*. "All the florets armed." Mart. 12. Jacq. Mif. 2. 363. Ic. Rar. 1. tab. 22. (*Bromus capillaris*; Mœneh. Meth. 194.) "Culms about a foot and half high, erect, leafy. *Leaves* from two to four lines broad, with loose hairs on their upper surface towards the base, and a little upon the sheath. *Panicle* from five to seven inches long, pale green, sometimes purplish. *Spikes* from twenty to thirty, two or three inches long, linear, slender, some alternate, others fascicled or whorled, two or three together at intervals; spikelets sessile, alternate, almost two-rowed, but truly unilateral, very small, smooth; calyx-glumes lanceolate, keeled, compressed, rough at the back. A native of the East and West Indies.

CYNOSURUS eruciformis; Ait. Mart. Willd. See PHALARIS *eruciformis*.

CYNOSURUS caruleus; Linn. & *C. sphærocephalus* Jacq. &c. See SESLERIA.

CYNOSURUS scoparius; Lam. Enc. See ANDROPOGON *polydactylon*.

CYNOXYLON, *Americanum folia crassifusculo*; Pluk. See NYSSA *aquatica*.

CYNOZOLOS, a name given by some of the old Greek writers, and, from them, copied by Pliny, and the Latins, to express the black *chamæleon thistle*, a poisonous plant, which it was very necessary to distinguish perfectly from the plant called the white *chamæleon thistle*, which was a safe and esculent plant.

CYNTHIUS, or *CYNTHUS*, in *Ancient Geography*, a mountain near the sea, towards the middle of the eastern coast of the island of Delos. The city of Delos was at the foot of this mountain, between which and the sea, over-against the isle of Rhénia, was a theatre of marble. This mountain was said to be so high, that the shadow of it covered the whole island; but modern travellers represent it as a hill of very moderate height. Here Latona is said to have been delivered of Apollo and Diana; whence it derived its peculiar sanctity. It is one block of ordinary granite; cut on the side that faces the city in regular steps, enclosed with a wall. On the top of the mountain are the remains of a stately building, with a Mosaic pavement, broken pillars, and other monuments of antiquity. This mountain, as well as the whole island, was consecrated to Apollo; and hence he, and also Diana, derived the appellation of Cynthian.

CYNURA, a town of Greece, in the Peloponnesus, the territory of which was always a subject of dispute between the kings of Lacedæmon and those of Argos.

CYNURIA, a town of the Argolide, in that part which belonged to Laconia. The inhabitants of this town were called *Cynurii*.

CYNUS, a place of Greece on the sea-coast, N.E. of Opuntia, of which it was the port.

CYLOCK, in *Zoology*, a name given to the Orang-Utang, or *Simia Satyrus*; which see.

CYON, or CION, a graft, spring, or sucker.

CYON, in *Ancient Geography*, a town of Asia Minor, in Caria. Steph. Byz.

CYPÆRA, a town of Greece, in Thessaly.

CYPÆTA, a town of Africa, in Libya.

CYPARISSA, a town of various orthography, situated in that part of Messenia which, extending itself towards the north-west, formed with the territory of Elis a gulf, called the "gulf of Cyparissa." In the time of Pausanias, it had two temples, one of Apollo and another of Diana *Cyparissia*. It has been conjectured, that this town took its name from the great quantity of cypress which grew near it. The *Cyparissa* of Homer is thought by some persons, in deference to Strabo, to have been the burgh of Lycorea, situated on a mountain near Parnassus. According to Pausanias, it was the same town with Anticyra, situated on an isthmus, which united with the continent a small peninsula, that extended to the gulf of Corinth. Anticyra was celebrated among the ancients for the hellebore which was supplied by its vicinity. This place is now called *Asprospitia*.

CYPARISSIS, a river of the Peloponnesus in Messenia, near the town of Cyparissa. Both the river and town are called *Arcadia*.

CYPARISSIA, a town on the isthmus of a peninsula in Laconia, N.W. of Hypercentatum, which had a port in the lower part of a small bay. It was destroyed in the time of Pausanias. Near its ruins was a temple of Minerva *Cyparissian*.—Also, one of the names given to the isle of Samos.

CYPARISSIUM PROMONTORIUM, a promontory of the Peloponnesus in Messenia; which took its name from that of the town Cyparissia. Strabo.

CYPARISSIUS, a small river of Messenia, south of Aulon, west of Eleetra; which received the *Cocus*. The river discharged itself into a small gulf, called the gulf of Cyparissus, or Cyparissa. The gulf is now called the gulf of *Ronchio*.

CYPARISSUS, an ancient town of Greece, in the Phocide, placed by Steph. Byz. and Eustathius near mount Parnassus and the town of Delphi.

CYPASIS, a town situated towards the Hellespont.

CYPERELLA, in *Botany*, Mich. See SCHÆNUS.

CYPERI *Genus Indianum*; Pluk. See *SCIRPUS retrofractus*.

CYPEROIDES, the third natural order of monocotyledonous, hypogynous plants in the system of Jussieu, with the following character. *Flowers* perfect, or monoicous, very rarely dioicous, each furnished with a chaffy glume, which sustains the office of a calyx; glumes one-flowered, crowded, variously disposed so as to form either spikes or fascicles; sometimes empty, probably owing to the flowers having become abortive. *Stamens* generally three, inserted under the pistil. *Germ* one, superior; style one; stigmas most frequently three, sometimes two. *Seed* one, naked, or ariled, *i. e.* covered with a tunic; in some furrowed by bristles or soft hairs springing from the base. *Coraculum* and germination as in the graminæ. *Stems* or culms cylindrical, or triquetrous; in most without knots, in a few jointed. *Floral leaves* sessile; root and stem one sheathing; sheath entire. It contains the following genera. I. Flowers monoicous. Carex. II. Flowers perfect. Fuirena, schænus, galinia, eriophorum, scirpus, cyperus, thryocephalum, kil-

lingie, mapania, elryfitrix. Ventenat has admitted only carex, schænus, eriophorum, scirpus, and cyperus.

CYPEROIDES; Tourn. Mich. Schænel. See CAREX.

CYPERUS, (κυπερος; Hippoc. Theophras. Dioscor.) Linn. Gen. 66. Schieb. 93. Willd. 112. Gært. 13. Juss. 27. Vent. 2. 92. Clats and order, *triandria monogynia*. Nat. Ord. *Calamaria*, Linn. *Cyperoides*, Juss.

Gen. Ch. *Cal.* a single scale to each flower, keeled, convex, permanent, composing part of an imbricated two-rowed spike, with the rows opposite to each other. *Cor.* none. *Stam.* Filaments generally three, sometimes two or one; anthers oblong, furrowed. *Pist.* Germen superior, very small; style filiform, long; stigmas three, capillary. *Styl.* single, naked, generally somewhat triangular, acuminate, without any hairs at the base.

Ess. Ch. Flowers imbricated in two rows, perfect. Corolla none. Seed single, naked, beardless.

This vast genus is divided into two principal sections, the first consisting of species with a round stem, the others having a triangular one. The latter, by far the most numerous, are subdivided according as their spikelets are one or more, and sessile, or very numerous in branched or compound umbel-like panicles. Willdenow reckons 76 species of *Cyperus* in all, but this is perhaps scarcely half the true number.

In the first section we find *C. minimus*, Linn. of which *C. tenellus* L. Suppl. 103. (*Scirpus setaceus* α Rottb. tab. 15. f. 4.) is a variety, and the very remarkable *C. articulatus*, Linn. *Sp. Pl.* whose naked and jointed stems are two or three feet high. It grows in Jamaica, as well as in Egypt and the East Indies. See its figure in Sloane's Jamaica, t. 81. f. 1.

In the second section are *C. longus*, Linn. *Sp. Pl.* 67. Engl. Bot. t. 1309. whose long creeping roots are highly aromatic and agreeable.—*C. rotundus*, an oriental species, whose round tuberous knobs have a similar fragrance, and are used in Greece, where they are still called *κύπερον*, to keep insects away from clothes.—*C. esculentus*, whose radical tubers taste like very sweet filberds, and are sold in the markets of Italy and the Levant. The plant has been cultivated in our green-houses, where its roots increase, but never bear flowers. This is Dulcichinum of Dodonæus, p. 340; *C. esculentus* of Gerarde em. 32. The Italians call it *Trafis*.—Above all the *C. Papyrus* is most remarkable, the celebrated Papyrus of the ancients, so called perhaps from the Syrian name *Babcer*, whence also our word *paper*. This grows in Egypt, Syria, Sicily, and Madagascar, in watery places. It has flowered finely in England, having been but lately brought hither from the south of Europe. The stem is many feet in height, and terminated by a very large and compound umbel, or rather cyme, of innumerable flowers. The root is very large and creeping. Leaves sword-shaped, sheathing the lower part of the stem. The ancient paper, it must be confessed of a very rude kind, was made of the inner rind of the stem cut into strips, and laid together in parallel and transverse rows, which being pressed with weights adhered together. An ancient manuscript, composed of such paper, may be seen in the British Museum. The floral *thyrsus* or tuft of the *Papyrus* was used to adorn the temples and statues of the gods. Two new species of *Cyperus*, found by Dr. Sibthorp, are figured in the *Flora Græca*, and described by Dr. Smith; *viz.* *C. comosus*, t. 44. "Stem triangular, naked. Umbel leafy. Spikelets linear, very long. Knobs of the root ovate, obscurely zoned."—This grows in marshes near Patras, and has a fragrant root, a large and handsome umbel, with remarkably long linear spikelets of a deep shining brown. *C. radicosus*, t. 45. "Stem

“Stem triangular, naked. Umbel leafy. Spikelets lan-
ceolate. Leaves widely spreading, rigid, recurved.”—
Found on the sandy banks of the Ryndacus, between Smyrna
and Brusa, as well as in some of the Greek islands. The
roots are very long, perpendicular, creeping, beset with
frequent knobs. Stems a span high. Umbel small, twice
compound, with reddish-brown spikelets. Leaves remark-
ably spreading, rigid, recurved at their points.

CYPERUS *Root*, in the *Materia Medica*, the name of a
root used in medicine, of which there are two kinds, the
long and the round; the long cyperus is of our own growth;
the round, when genuine, we have from the East Indies;
but what is usually sold is the root of a bastard kind, com-
mon about our own ditches, and called by authors, by
way of distinction from the Indian kind, *cyperus rotundus*
nostras.

The Indian round cyperus is a knobbed root, full of small
specks and tubercles, brown on the outside, and greyish
within, of a slightly sweet smell, and of an acrid taste. The
long cyperus is an oblong root, covered with a great number
of fibres, not easily broke, of a dusky brown without, and
a pale bright grey within, of an acrid taste, and very agree-
able smell, when fresh and good. The plants which pro-
duce them both grow in watery places, and have leaves and
flowers in some measure resembling the water-grasses, which,
from their resemblance to these, are called cyperus grasses.
They are possessed of the same virtues, cure ill-scented
breaths, are good in nephritic disorders, in colics, and in
disorders of the womb. They are taken in powder, or de-
coction.

The roots of cyperus are attenuants, and deobstruents,
promote urine, and the menses, are good stomachics, and
serviceable in the first stages of the dropsy.

CYPHANTA, in *Ancient Geography*, a town of the
Peloponnesus, in the interior of Laconia; 10 stadia from
the sea, according to Pausanias.—Also, a port of Laconia,
in the Argolic gulf, south of Prusæ. Although the town
was destroyed in the time of Pausanias, there remained a
temple of Æsculapius, with a statue of this god in marble.

CYPHARA, the name of a strong place in Theffaly,
mentioned by Livy.

CYPHER. See CIPHER.

CYPHI, a term in the *Arabian Pharmacy*, signifying a
kind of cordial perfume.

Mithridates gave the appellation cyphi to the troches
wherewith the Egyptian priests used to sweeten their gods,
to make them grant what they requested. He used the
same in the composition of mithridate, on account of their
efficacy against poisons, defluxions, &c.

The cyphi are composed of raisins, or dried grapes, tur-
pentine, myrrh, bdellium, spica nardi, cassia lignea, aspa-
lathum, saffron, &c. tempered into a mass with honey and
a little wine.

CYPHIA, in *Botany*, a genus separated by Bergius and
Jussieu from *Lobelia*, on account of its anthers being all dis-
tinct and unconnected; but that character proving of no
importance in simple flowers, this alteration has not been
generally adopted. See *LOBELIA*.

CYPHOMA, CYPHOS, and CYPHOSIS, in *Medical*
Writers, an incurvation of the spine, forming a crookedness
of the back.

CYPHON, in *Antiquity*, a kind of punishment used by
the Athenians; it was a collar made of wood, so called, be-
cause it constrained the criminal, who had this punishment
inflicted on him, to bow down his head.

CYPHONISM, CYPHONISMUS, from κυφω, which has
VOL. X.

various significations, derived from κυφος, *crooked*, a kind of
torture, or punishment, in use among the ancients.

The learned are at a loss to determine what it was: some
will have it to be that mentioned by St. Jerom, in his *Life*
of Paul the Hermit, chap. 2. which consisted in smearing
the body over with honey; and thus exposing the party,
with his hands tied, to the warm sun, to invite the flies and
other vermin to persecute him.

CYPHOS, in *Ancient Geography*, a town of Greece,
mentioned by Homer as furnishing 22 ships for the siege of
Troy. Steph. Byz. refers to two places under this name,
one in Theffaly, and another in Perrhæbia. He also men-
tions a river of this name.

CYPHUS, a mountain of Greece, in Perrhæbia. Strabo
and Steph. Byz.

CYPHUS, a village of Greece, in Perrhæbia. Strabo.

CYPRÆA, in *Conchology*, a genus of univalves. The
shells of this kind are involuted, subovate, smooth and ob-
tuse at each end; aperture effuse at each extremity, extend-
ing the whole length of the shell, and dentated each side.
Animal a slug. These are the cowry or gowry of English
collectors.

Species.

EXANTHEMA. Shell subturbinated, ferruginous, with
whitish round spots and ocellations; and dorsal line some-
what ramose. Linn. &c.

Native of the American and Atlantic seas.

MAPPA. Shell subturbinated, and marked with irregular
characters; dorsal line ramose. Linn. *Porcellana montosa*,
Rumpf. *Carte géographique*, Argenv.

Inhabits the Indian and African seas, and is not a common
species.

ARABICA. Shell slightly turbinated with irregular cha-
racters; dorsal stripe simple. Linn. *Porcellana literata*,
Rumpf.

Length about three inches; general colour whitish, with
irregular brown marks resembling Arabic characters. In-
habits India.

ARGUS. Shell slightly turbinated, subcylindrical, sprin-
kled with ocellated spots; beneath four brown spots. Linn.
Argus, Rumpf. *Argus magnus*, Argenv.

Native of the Indian and Atlantic seas.

TESTUDINARIA. Shell obtuse and subcylindrical, with
the extremities depressed. Linn. *Testudinaria*, Rumpf.

Inhabits the Persian gulph.

STERCORARIA. Shell somewhat turbinated, gibbous,
with livid and testaceous spots; emarginate each side, and
flat beneath.

Native of Guinea.

CARNEOLA. Shell slightly turbinated, pale with flesh-
coloured bands; mouth violet. Linn.

Inhabits the Asiatic ocean. This shell is sometimes white,
with brown bands.

ZEBRA. Shell turbinated, cinereous with brown bands.
Gmel.

Native of India.

TALPA. Shell slightly turbinated, subcylindrical, testa-
ceous with pale bands; beneath thickened and brown.
Linn. *Talpa*, Argenv.

Length from two to three inches. Native of India.

AMPHYSTEA. Shell subturbinated; sides gibbous and
decorticate; back violet. Linn. *Achatina*, Rumpf.

Native of Madagascar.

LURIDA. Shell slightly turbinated, lurid, and slightly;

the extremities pale yellow, with two black spots. Gmel. *Souris*, Argenv.

Inhabits the Mediterranean, Atlantic, and American seas.

VENELLI. Shell slightly turbinated, spotted and marked with yellowish dots; the extremities spotted with brown; throat rufous. Linn.

Native country unknown.

LOTA. Shell slightly turbinated and white, with subulate denticles. Linn.

Found in the Sicilian seas.

FRAGILIS. Shell turbinated, ovate, glaucous, with testaceous waves, and pale bands. Linn.

Inhabits the Mediterranean sea. Gualt.

GUTTATA. Shell thin gibbous, fulvous dotted with white; line in the middle horizontal; beneath white; teeth yellow. Gmel.

Described and figured by Lister. The native place not ascertained.

CINEREA. Shell thin, ventricose, reddish-grey with paler bands; mouth white. Gmel.

PLUMBÆA. Shell slightly turbinated, thin; back lead colour, with four bands varied with blue and brown, undulated with brownish at the margin, and marked with blue and brown lines. Gmel.

A rare species, found on the coast of Guinea.

OCULATA. Shell slightly turbinated; russet-brown with white ocellations, and three paler bands on the back. Linn.

Inhabits the American seas.

HISTRIO. Shell ovate, slightly turbinated, with sub-livid ocellations; beneath flat and white; sides thickened, black, spotted with brown; dorsal line livid; throat violet. Gmel.

Native of the Indian seas.

AURANTIUM. Shell somewhat turbinated; orange with white immaculate margin. Gmel.

One of the most beautiful and elegant species of its genus, and well known to English collectors under the title of *Cypræa aurora*, or morning-dawn cowry. This species was first discovered by captain Cook at the Friendly Islands, where they were observed to constitute part of the finery and ornaments of the dresses worn by the chiefs and principal natives. Only a few shells of this species have hitherto been brought to Europe, and of course bear a high price.

FERRUGINOSA. Shell thin, elongated, yellowish or blueish, with ferruginous spots; within blue. Gmel.

The native places of this and several of the following species have not been hitherto ascertained.

LIVIDA. Shell thin, elongated, uniformly straw-colour, pale yellow or reddish; beneath dotted with brown; teeth subulate. Gmel.

GIBBA. Shell thin and gibbous; back clouded and banded transversely. Gmel.

TURBINATA. Shell turbinated, ovate, and glaucous, with pale angulated spots. Gmel.

VENEREA. Shell oblong and fuscous, with striped golden spots; within blue. Bonann.

PURPURASCENS. Shell oblong, purplish; beneath furrowed with a white line. Gualt.

ALBIDA. Shell oblong, whitish; ends of the lips spotted with fulvous. Gualt.

RUFESCENS. Shell oblong, reddish-brown, beneath whitish. Gualt.

TRANSLUCENS. Shell cylindrical, cinereous, with pelucid bands. Gualt.

PUNCTULATA. Shell cylindrical, fragile, white, with transverse bands of reddish dots. Gualt.

TIGRINA. Shell obtuse, ovate, slightly turbinated, with a longitudinal testaceous line. Seba.

DUBIA. Shell oblong, ferruginous, with paler bands. Seba.

TRIFASCIATA. Shell turbinated, thin, blueish-brown, with three yellowish bands varied with brown at each end. Knorr.

A very rare species.

CONSPURCATA. Shell turbinated, blueish-white, dotted and clouded with brown. Born.

BIFASCIATA. Shell oblong, shaded with purplish, with a straw-coloured band, and another narrower white one, and a brown border. Born.

Length four inches.

CYLINDRICA. Shell cylindrical, above pale violet, and spotted with brown at the sides, and marked at each end with two brown spots. Born.

TERES. Shell cylindrical, milk-white, one side bordered and varied with a few pale yellow narrow marks; back with three brownish waved bands. Schroet.

OVATA. Shell ovate, a little depressed, one side slightly bordered; back whitish, with crowded yellowish-brown dots and waves, and three obsolete darker bands. Schroet.

MINUTA. Shell oblong, above tinged with bloom; beneath dotted with white; border on one side and teeth of the lip white; above yellow at each end; spire black at the tip. Schroet.

SANGUIOLENTA. Shell thin, oblong, barred with brown, and dotted at the sides with red. Martini.

FASCIATA. Shell turbinated, glaucous margined, above gibbous, with transverse brownish bands; throat glaucous. Chemn.

REGINA. Shell gibbous, glaucous brown, with triangular testaceous and whitish spots, and three transverse bands; throat blackish. Seba.

UNDULATA. Shell turbinated, undulated with brownish, clouded with pale ochre, and marked with deeper bands.

* *Obtuse, and without distinct Spire.*

CAPUT SERPENTIS. Shell triangularly gibbous, and rather obtuse behind. List.

Inhabits Mauritius, and Nuffatella islands. Length an inch and half.

RETICULATUM. Shell roundish, gibbous, brown, with white confluent reticulated eyes, and a white horizontal line in the middle of the back; beneath white. List.

MAURITIANA. Shell triangularly gibbous, behind depressed and acute, beneath black. Rumpf.

Native of the Asiatic isles.

VITELLUS. Shell livid, with small white spots. Rumpf. Inhabits the Indian ocean.

MUS. Shell retuse, gibbous, cinereous, with a longitudinal brown band; teeth of the aperture blackish. Rumpf.

Native of the American and Mediterranean seas. This shell is solid and slightly gibbous.

TIGRIS. Shell ovate, obtuse behind and rounded before, ferruginous, with deep brown spots, and a yellowish longitudinal dorsal line. List.

Inhabits the Indian and Asiatic ocean.

FLAMMÆA. Shell ovate, obtuse behind, and rounded before with waved yellow spots. Valenti.

A rare species; the native place unknown.

OLIVACEA. Shell ovate, olive, clouded with yellow, and spotted

C Y P R Æ A.

spotted with brown; beneath flat, pale brown; within blueish; teeth of the lip white. Martini.

FÆMINEA. Shell ovate, very thin, white, with greenish-yellow dots disposed in rows; within violet. List.

LYNX. Shell oblong-ovate with brown dots and a yellowish line; the hind part rather acute, with a rufous mouth. List.

ISABELLA. Shell subcylindrical, with pale yellow extremities. List.

Native of Madagascar.

AMBIGUA. Shell pyriform, dusky with paler clouds and spots. Seba.

SCURRA. Shell ovate-oblong, beneath flat, yellowish with greenish and livid confluent drops; the sides varied with scattered brown dots. Martini.

Native of India.

** Umbilicate, or perforated.

ONYX. Shell beneath brown, above whitish. Rumpf.

A small shell found in the Asiatic seas.

CLANDESTINA. Shell with very fine transverse lines, some concurrent. Gmel.

Native of India.

SUCCINCTA. Interior lip rounded at each extremity. Linn.

ZIZAC. Shell beneath pale yellow with brown dots, and two spots of the same at the extremities. List.

HIRUNDO. Shell above blueish, the extremities marked with two brown spots. Linn.

Inhabits the Maldiva islands.

ASELLUS. Shell white, with three fuscous bands. Linn. *Afellus*, Rumpf.

ERRONEA. Shell with an equal testaceous spot. Linn.

URSELLUS. Shell oblong white, above smooth varied with brown, and marked with two brown dots at the umbilicus or perforation. Linn.

PYRUM. Shell pale brown with paler bands and ochraceous spots, beneath and at the sides fulvous, within blue. Gualt.

MACULOSA. Shell narrow, long, with flesh-coloured spots, above varied with pale fulvous and glaucous spots, the sides chestnut. Bonan.

PULLA. Shell thin, with the sides rufous-brown; above white or pale brown with transverse bands or a paler horizontal line. Martini.

INDICA. Shell cylindrical, marked above with characters, ocellations, and a pale horizontal line; the sides bloom coloured, dotted with black; teeth of the lip brown. Rumpf.

OVUM. Shell thin, oblong, olivaceous, with scattered ferruginous spots; beneath white. Mart.

FELINA. Shell oblong, narrow, plumbeous with ferruginous dots and spots, and paler bands marked at each end with two brown spots. Seba.

ATOMARIA. Shell oblong, snowy dotted with brown; each end marked with two dusky dots. Martini.

NEBULOSA. Shell oblong, gibbous, brown with chestnut spots. Lister.

OCHROLEUCA. Shell thin, ochraceous with paler spots. Bonan.

STELLATA. Shell thin, cinereous dotted with brown, and marked with transverse elevated striæ. Bonan.

FULVA. Shell solid, oblong, fulvous with brown spots disposed in rows, and two dusky bands; the sides and under surface saffron. Gualt.

LEUCOSTOMA. Shell oblong, gibbous, clouded with

brown and blue, the sides spotted with black; mouth white. Gualt.

LUTEA. Shell brownish with two white bands, beneath pale yellow dotted with brown. Gronov.

ZONARIA. Shell ovate, smoothish, yellowish with four brown lunules. Chemn.

Inhabits the shores of Guinea, and is very rare.

*** Margined.

CRIBRARIA. Shell umbilicate, pale yellow with round white spots. Linn.—*Argus minor*. Argenv.

MONETA. Shell whitish, with nodulous margin. Linn. *Moneta Congo*, Argenv. *Moneta nigritarum*, List. *Thoracicum vulgare*, Rumpf.

Inhabits the Mediterranean, Atlantic, Ethiopic, and Indian seas. This is the species which is fished up in vast numbers by the negro females, three days before or after the full moon, and is used by the native blacks in many parts instead of money.

ANNULUS. Shell surrounded on the back with a yellow ring. Rumpf.

Inhabits Asia.

CAURICA. Shell with gibbous, unequal, whitish margin, dotted with brown, the back marked with testaceous clouds. List.

EROSA. Shell with a jagged margin, yellow dotted with white, the sides with a brownish spot. List.

Found in the Mauritius and Ascension islands.

DEROSA. Shell with a jagged margin; flesh colour, with a greenish back marked with fulvous dots, the sides dotted with brown. Gmel.

Inhabits the Mediterranean.

FLAVEOLA. Shell with a jagged margin, yellow dotted with white; the sides marked with scattered obsolete brown dots. Linn.

SPURCA. Shell slightly margined; yellow, with deeper specks, the sides dotted with brown. Linn.

Native of the Mediterranean sea.

OBLONGA. Shell oblong ovate, above blueish dotted, and spotted with brown; beneath, and at the sides white. Born.

STOLIDA. Shell cinereous, variegated with testaceous. Linn.

Length an inch and a half. This species inhabits Amboyna.

HELVEOLA. Shell triangularly gibbous, dotted with white, jagged behind, beneath yellow and immaculate. Lister.

OCELLATA. Shell slightly margined, pale yellow, with black eyes. List.

PORARIA. Shell pale violet dotted with white. Born.

PEDICULUS. Shell with numerous transverse furrows, some furcated. Linn. *Donov. Brit. Shells, &c.*

A small shell found on most sea coasts.

NUCLEUS. Shell margined each side, slightly produced and rugged, with raised tubercles above. List.

MADAGASCARIENSIS. Shell whitish, and produced each side; the back tuberculated and marked transversely with waved striæ. List.

STAPHYLÆA. Shell somewhat produced, with elevated dots, and without striæ; the extremities pale yellow. Argenv.

CICERCULA. Shell produced each side, and sprinkled with raised dots. List.

Native of the Mediterranean and Indian seas.

GLOBULUS. Shell produced each side and smooth. Rumpf.

Inhabits Amboyna.

AFFINIS. Shell oblong, slightly produced, smooth, yellow, ocellate each side below. Knorr.

Resembles the last, but is more oblong.

SQUALINA. Shell thin, oblong, white, with ferruginous dots and spots. Lill.

FIMBRIATA. Shell white, or grey, with obsolete ferruginous spots, and transverse bands; lips of the mouth marked with violet spots. Martini.

CRUENTA. Shell gibbous, above blueish, with rufous dots; beneath and at the sides white; lips citron. Gualt.

RUBIGINOSA. Shell oblong, white, within violet; back with a ferruginous blotch; each end marked with two pale yellow spots; teeth of the lips yellowish. Martini.

MILIARIS. Shell thin, short, yellowish green, with milk-white ocellations, and a lateral horizontal line. Lill.

ACICULARIS. Shell solid, above yellowish, dotted with brown, and marked with a pale horizontal line; beneath milk-white, with impressed dots at the margin. Martini.

CRASSA. Shell thick, yellowish, with three whitish bands; mouth blueish. Lill.

VINOSA. Shell above white, with a claret stain, and marked with purple eyes, surrounded with a black circle, and an horizontal white line; within blue. Bonan.

Native of the Mediterranean.

ANGUSTATA. Shell narrow, brown, with reddish spots at the sides. Gualt.

SIMILIS. Shell oblong, gibbous, yellowish, dotted with white, and marked at the margin with a black spot. Gualt.

STRIATA. Shell convex, blueish-white, dotted with brown; beneath yellow, striated on one side. Gualt.

CHINENSIS. Shell oblong, solid, variegated, with orange lips. Argenv.

PUSILLA. Shell blueish, spotted with brown, and trifasciated. Argenv.

CYPRESS. See **CUPRESSUS.**

CYPRESS. *Summer.* See **CHENOPODIUM.**

CYPRESSETA, in *Ancient Geography*, a place of Gaul, between Avelio and Arausio, according to the Itinerary of Antonine. M. d'Anville suggests that it was situated towards the bridge of Sorgue.

CYPRIÆ INSULÆ, three barren islands mentioned by Ptolemy, and placed near the island of Cyprus.

CYPRIAN, ABRAHAM, in *Biography*, born at Amsterdam about the year 1656, received the rudiments of his knowledge in medicine from his father, who practised surgery in that city. At a proper age he went to Utrecht, where he was created doctor in medicine in 1680. Having practised medicine and surgery for twelve years at Amsterdam, he was called thence to take the chair of anatomy at Franeker. In 1700 he published an account of an extra-uterine fetus, taken from one of the Fallopian tubes, where it had lain, before the parts aposthemated, twenty-one months. The woman recovered, but dying some years after, and opportunity being given to Cyprian to dissect the body, he discovered the part in which the fetus had been detained. Cyprian is said to have been very skilful and successful in cutting for the stone, having performed the operation, it is said, on no fewer than 1400 persons. In 1724 was published, in quarto, *Cystitomia Hypogastrica*, in which he gives an account of his method of operating. Haller *Bib. Anat. Eloy Dict.* Hist.

CYPRIANUS, THASCIUS CÆCILIUS, was a native of

Africa, and as some say of Carthage, where he was bishop in the third century. He was born, probably, before the end of the second century, and in the former part of his life taught rhetoric at Carthage with great applause. Such was his reputation in the exercise of his profession, that his school was frequented by a great number of young persons, who had any fortune, and who intended to be magistrates and judges, or to appear as pleaders at the bar. He was not only well acquainted with the principles and rules of eloquence, but he was also eloquent himself: and very probably composed for others arguments or pleadings, harangues or panegyrics, or such other discourses, for which he received an adequate recompence; and he thus acquired not only a competence, but a considerable degree of affluence. Upon his conversion to Christianity about the year 246, in consequence of the instruction of Cæcilius, a presbyter of Carthage, whose name he afterwards assumed, he sold his estate and distributed the produce of it among the poor. Soon after his conversion, probably in the year 247, he was made presbyter, and in the following year bishop, of Carthage. Such are the dates assigned to these events by bishop Pearson. Others, however, are of opinion, that he was baptized in the year 244 or 245, and advanced to the episcopate in 248 or 249. His advancement, whatever was the period at which it took place, was an honour which he accepted with great reluctance, at the general and earnest desire of the people of Carthage, though his election was opposed by several presbyters of that church, who afterwards gave him great uneasiness. Soon after the commencement of the Decian persecution, A. D. 250, he became extremely obnoxious to the heathen people; and they often clamorously demanded in the theatre, and other public places, that he should be thrown to the lions. This treatment constrained him to retire to some place of safety, where he continued about 14 months, and where he was diligently employed in writing those epistles, many of which are still extant. As the place of his abode was unknown, so that the hostile government was not able to find him, he was proscribed, and proclamation was made at Carthage, that if any one had any goods of Cæcilius Cyprian, bishop of the Christians, he should discover them. When the heat of the persecution abated, in the year 251, Cyprian returned to Carthage; and resuming the exercise of his episcopal office, he held several councils, two of which regulated the treatment of those who had lapsed in the persecution; and others were engaged in settling the question concerning the baptism of heretics; with regard to which Cyprian was of opinion, that all baptism out of the catholic church was null and void, and that they who had received such baptism only, ought to be baptized when they came over from heretics to the church. In one of these councils there were present 85 or 87 bishops, besides presbyters and others. It was held in 256, and its acts are still extant. About this time a pestilential distemper wasted the Roman empire, and extended its destructive ravages to Carthage. During the prevalence of this calamity, Cyprian was indefatigable in the duties of his function; and exerted himself by his discourses and influence in recommending compassion and liberality to those who were distressed. On another occasion, the virtue of Cyprian and of the people under his care, was eminently conspicuous. Several Christians were carried captives by some barbarous people of Africa, who made inroads into Numidia; for whose relief and redemption Cyprian promoted a collection, and raised a considerable sum of money, which was distributed for this purpose. His distinguished character, however, was no security against the violence of his enemies.

When the emperor Valerian became a persecutor of the Christians, Cyprian was apprehended; and having made an undisguised confession of the Christian faith before the proconsul Paternus, avouching himself, upon examination, to be a Christian and a bishop, and declaring that he knew no other gods, besides the one true God, who made the heavens, and the earth, and the sea, and all things therein; he was banished to Curubis in the year 257. On this occasion he had many fellow-sufferers, several of whom were sent to the mines, as we learn from a letter of Cyprian, written during his exile. When Galerius Maximus succeeded Paternus as proconsul of Africa, Cyprian was recalled from banishment; and restored to the possession of his gardens, or country-house, near Carthage, which he had previously sold for a sum of money that had been distributed by him among the poor. Soon after his arrival, he was ordered to appear before the proconsul at Utica, about 40 miles distant from Carthage; but having reason to apprehend a sentence of condemnation, and being desirous of dying in the presence of his own people, he absented himself from his country residence, and retired into some place of concealment. Upon the proconsul's return to Carthage, Cyprian came back to his gardens, where he was visited by several citizens of rank, who advised him to seek some retreat, in which he might be secure from the malignity of his enemies. Cyprian, however, was fully prepared for the event that awaited him; and being apprehended by a band of soldiers commissioned by the proconsul for this purpose, he attended them to the palace at Sextii, about 6 miles from Carthage. Refusing to sacrifice at the command of Galerius, the proconsul, with the advice of his council, charged him with being an enemy to the gods, and a seducer of the people, and then pronounced sentence that he should be beheaded; upon which Cyprian said "God be thanked," and he was then led away to an adjacent field, encompassed with trees, the boughs of which were loaded with spectators, where he calmly submitted to the execution of the proconsul's sentence, September 14, A. D. 258. The whole tenor of Cyprian's life after his conversion, which was peaceable, charitable, and beneficial to men of every character in distress, and the manner of his death, in which he appeared to be undaunted, ready, and willing, without seeking it, afford a very valuable testimony in behalf of the truth and excellence of the principles of the Christian religion. His character was held in such high estimation by his contemporaries and by posterity, that the day of his martyrdom was observed as a festival not only at Carthage, but also in other places both in and out of Africa. His works consist of treatises on a variety of subjects, and of Epistles. Cave. Le Clerc. Lardner.

CYPRIANUS, in *Ichthyology*, a name given by Aristotle to the carp. He also called it *cyprinus*; and Athenæus, Oppian, and many other writers, use indifferently the one or the other of the words.

CYPRINE, in *Mythology*, a surname of Venus, because the island of Cyprus was consecrated to her.

CYPRINOIDES, in *Ichthyology*, a species of *Clupea*; which see.

CYPRINUS, a genus of the abdominal kind, distinguished by having the mouth small and destitute of teeth: the gill membrane with about three rays; the body smooth and generally whitish: ventral fins often containing nine rays.

Most of the species feed on worms, insects, smaller fish, seeds, and earth, usually spawn about April or May, and are generally considered as palatable and wholesome food. Some are of the migratory kind, inhabiting both the fresh

and salt waters, while others remain in fresh waters throughout the year.

Species.

BARBUS. Anal fin with seven rays: beards of the mouth four; second ray of the first dorsal fin serrated both sides. Linn. Donovan. Brit. fishes.

A common inhabitant of most fresh waters in Europe, and easily distinguished from the other species of carp by the upper jaw being advanced far beyond the lower, and in having four appendant beards from which the appropriate name of barbus, *Angl.* Barbel, is derived. This fish during summer prefers the rapid currents and shallows of rivers, and retires at the approach of winter to the more still and deeper places. They subsist chiefly on worms, small fishes, and aquatic insects, and live in societies. Sometimes these fishes grow to the length of two or three feet, and we have instances on record of their attaining to a much larger size in some rivers in the south of Europe. Vide Donovan. Brit. fishes.

CARPIO. Anal fin nine-rayed; beards four: second ray of the dorsal fin serrated behind. Linn. Carp, Willugh. Donovan. Brit. fishes, &c.

There are two principal varieties of this fish, one having half the body covered with scales, four times as large as those of the common sort, and the other having the body destitute of scales. These fish inhabit the slow and stagnant waters of Europe and Persia, and according to popular report were introduced into England in the year 1514. The usual length of the carp in our own country is from 12 to 18 inches, but in warmer climates it often arrives at the length of two or three feet or even more. Its general colour is yellowish olive, much deeper, or browner on the back, and accompanied with a slightly gilded tinge on the sides; the fins violet brown, except the anal which is tinged with reddish.

The usual food of the carp consist of worms and aquatic insects, or when in a course of fattening for the table, bread and milk. It is an extremely prolific fish, and the quantity of roe is so great, that it is said sometimes to exceed the weight of the emptied fish itself. This fish is known to be extremely tenacious of life, and to live to a vast age, even to that of 100 or 150 years, and some writers scruple not to affirm to the age of 200 years.

The sale of carp constitutes a part of the revenue of the nobility and gentry in Prussia, Pomerania, Brandenburg, Saxony, Bohemia, Mecklenburgh, and Holstein, in all which countries the cultivation of the carp is for this reason regarded with particular attention.

GOBIO. Anal fin 11-rayed; cirri two. Linn. Gudgeon, Will. Penn. Donovan. Brit. fishes, &c.

Inhabits gentle streams and lakes of northern Europe: is tenacious of life and remarkably fertile. The length of this fish is about 10 inches at the utmost, or rarely exceeding seven or eight, and its principal food consists of herbs, worms, insects, and the fry of other fish. The colours vary according to its age, or the nature of the waters in which it lives.

TINCA. Anal fin, with about 11 rays; tail entire; body mucous; cirri two. Linn. Tench. Penn. Donovan. Brit. fishes, &c.

This fish appears to be a native of most parts of the globe, inhabiting chiefly large stagnant waters with a muddy bottom, and varying much in the tinge of its colours according to the situation in which it resides. Its general length is about 12 or 14 inches, but grows sometimes to the length of two or three feet. The usual colour is a deep blackish olive glossed with gold, the sides and abdomen yellow, belly white, and the fins dirty violaceous. The scales are very small

C Y P R I N U S.

small and closely affixed to the skin. The head is rather large, the eyes small, and on each side the mouth is situated a small beard. The flesh is white and soft, though well flavoured.

The supposed variety *Cyprinus Tinca auratus* of Bloch is a very beautiful fish, and is cultivated in some parts of Germany. The colour is a rich orange yellow variegated with small black spots; fins thin, transparent, and of a bright red colour; and the head rather smaller than the common tench. It is found in a state of nature in Silesia and Bohemia, and is from thence transplanted into other parts of Europe, and kept as an ornamental fish in the waters of gardens and pleasure-grounds. Like the common carp this fish delights in warmth, and is very tenacious of life.

BYNNI. Dorsal fin with 13 rays, the third thick and horny; tail linear and bifid, cirri four. Linn. Forst.

Length about 12 inches; shape oblong, with the head rather compressed; back and abdomen sloping; colour silvery; lateral line curving upwards; anal and dorsal fin red, with the base white; the rest whitish with a thickish dull-red margin. This species is a native of the Nile. The Egyptians know it by the name of Bynni, and esteem it an excellent fish for the table.

BULATMAI. Anal fin eight-rayed; second ray of the dorsal fin very large, and not serrated; cirri four. Gmel.

Inhabits the Caspian sea, and is a rare species. Its size is that of a common carp; the colour steel blue with a gloss of gold beneath, inclining to a silvery cast; scales middle size; head oblong, brownish above; lateral line straight; dorsal fin blackish; pectoral greyish with reddish tips; ventral white at the base, and red at the tip; anal red, with whitish base; tail reddish brown and furcated.

CAPOETA. Anal fin nine-rayed: third ray of the dorsal and anal fin very long, the former serrated downwards; cirri two. Gmel.

Inhabits the Caspian sea, and ascends rivers in the winter; its length is about 12 inches, the body compressed and oblong, scales rounded, moderate, smooth, striated, silvery dotted with brown, those on the belly smaller and white.

MURSA. Anal fin seven-rayed, the first very long; third ray of the dorsal fin long, thick serrated backwards beyond the middle; cirri four. Guldensit.

About 12 inches long; its habit resembles that of a pike; colour olive gilded, shaded above with dusky: abdomen white; anal and ventral fins white, spotted on the upper part with brown; the rest of the fins brown. Inhabits the Caspian sea.

CAPITO. Cirri four; third ray of the dorsal fin serrated behind; sides and lower fins whitish. Guldensit.

Much allied to the barbel, but rather more compressed, and with a longer and broader head in proportion; snout more obtuse; beards longer, and eyes larger; and the dorsal fin situated lower than in the barbel. Found in rivers running into the Caspian sea, particularly the Cyrus.

* *Tail nearly even at the end.*

CARASSIUS. Anal fin 10-rayed; lateral line straight. Linn. Crucian carp.

Length from eight to ten inches, of a deep form, very thick, colour deep olivaceous yellow with a slight silvery tinge on the abdomen; fins dull violet; the tail slightly lunated with obtuse lobes. This is a native of many parts of Europe, and inhabits ponds and large stagnant waters. The Crucian carp is considered as a coarse fish for the table in this country.

CEPHALUS. Anal fin eleven-rayed; body nearly cylindrical. Gmel.

Inhabits fresh waters of Europe, frequents deep holes of rivers, and is very shy; its principal food consists of worms and insects. Grows to the weight of five or six pounds.

GIBELIO. Dorsal fin with twenty rays: tail lunulate. Bloch.

Native of Germany and other midland parts of Europe, inhabiting lakes and rivers, and seldom exceeding eight or ten ounces in weight. The body is broad, and elongated, above blueish, the sides dull, beneath silvery, and the scales large; it is very fertile, and tenacious of life, and from its habits is an easy prey to ducks and water-fowl.

SERICIUS. Dorsal fin with ten rays; anal eleven; tail reddish brown. Gmel.

Found in great abundance in the slow and stagnant waters of Dauria. This is a small species measuring an inch and a half in length: the body shaped like the Crucian carp; the colour silvery blueish or pale violet, with a broad greenish-blue stripe each side, and pale rosy abdomen.

*** *Tail quadripartite.*

QUADRILOBUS. Sanguineous; fins rosy; tail four-lobed. Cedepe.

Described and figured by Cedepe as a species; this kind may however prove to be only a variety of the following.

**** *Tail tripartite.*

AURATUS. Anal-fin double. Gmel., &c.

This beautiful fish is a native of the southern parts of China, and is particularly found in the province of Kiang, where it exists in a natural state in a large lake situated near a mountain at a small distance from the town of Tchanghou. From this spot it is dispersed into all parts of that extensive empire, and is considered as one of the most elegant ornaments which can be introduced into the gardens and houses of persons of distinction. The Chinese ladies in particular are said to spare no pains in the cultivation of this beautiful animal.

No fish is subject to so many variations in its domestic or cultivated state as the gold fish. The most general colour is a rich and splendid golden hue, tinged with scarlet above and silvery beneath; in some the back is marked with large patches of black or blue, or sometimes the whole back is uniformly tinged with a dusky hue. The back fin is occasionally wanting, or consisting only of a few rays, and the tail varies extremely in its general form.

The gold fish has long been a favourite in this country, and breeds in our climate with almost equal facility with the carp. In a domesticated state it is fed with bread crumbs, small worms, and aquatic snails, or the yolk of eggs dried and powdered. These fishes ought not to be exposed to severe cold; they must also be supplied with a change of water, and should be kept in vessels of sufficient width to permit a free access of air, and yet so formed by curving inwards at the edges as to prevent the fish from escaping.

The gold fish is said to have been first introduced into England about the year 1691, though it was not generally known till the year 1728, when a number were brought over and presented to Sir Matthew Decker, by whom they were distributed into various parts of the kingdom.

MACROPHthalmus. Scarlet; eyes protuberant; fins half white. Bloch. Telescope carp. Shaw, Nat. Misc.

Allied to the gold fish and equally beautiful; its general colour sanguineous red; head short; eyes extremely protuberant, and appearing in some degree extensile; body covered with very large scales. This is a native of China, where it is kept in a similar manner with the gold fish, and may perhaps

C Y P R I N U S.

perhaps with propriety be considered as a variety of that fish.

***** *Tail bifid.*

REGIUS. Anal fin eleven-rayed; dorsal fin extending the whole length of the back. Gmel.

About the size of a herring, the body cylindrical; scales above golden, sides silvery. Inhabits the sea round Chili.

CAUCUS. Anal fin thirteen-rayed; body tuberoso, and a little silvery. Gmel.

Inhabits the fresh waters of Chili, and measures about eighteen inches in length.

MALCHUS. Anal fin eight-rayed; body conic and blueish. Gmel.

Length twelve inches. Inhabits same waters as the last.

RIVULARIS. Anal and dorsal fins eight-rayed; body spotted with brown. Gmel.

Found in small streams running down the Altaic mountains. The length of this fish is two inches; the body rather compressed and silvery; scales scarcely visible.

LABEO. Anal fin seven-rayed, dorsal eight-rayed, and pectoral nineteen. Gmel.

Inhabits the rapid and stony rivers round Dauria which discharge themselves into the Eastern sea. This fish swims rapidly and is highly prolific; its usual length rarely exceeds three feet. The body is roundish, somewhat compressed, and coated with large scales. Flesh excellent.

LEPTOCEPHALUS. Anal fin nine-rayed; dorsal eight-rayed. Gmel.

Found in the same rivers as the last, and is about the same size as the last.

CHALCOIDES. Anal fin nineteen-rayed; dorsal twelve. Gmel.

Native of the Caspian sea; about twelve inches in length; the body of a compressed form, and oblong; scales rounded and striated; colour above greyish and silvery-green, spotted with brown; the sides shining silvery, beneath milk-white.

GALIAN. Anal fin with seven, dorsal eight, and pectoral fourteen rays. Gmel.

Length three inches; body olive, spotted with brown; beneath bright red; flesh good when fried. This inhabits the stony rivers in Siberia.

NILOTUS. Anal fin with seven, dorsal eighteen rays. Gmel.

This kind inhabits the Nile; body reddish.

GONORYNCHUS. Anal fin eight-rayed; body cylindrical. Gmel.

Inhabits the Cape of Good Hope.

PHOXINUS. Anal fin with eight rays; body pellucid; tail with a dusky spot near the base. Gmel.

Found in gravelly streams in Europe and Siberia, and keeps in shoals near the surface. The species is small, scarcely ever exceeding the length of three inches; it feeds on herbs and worms, grows slowly, is very fertile, and is the favourite food of pikes.

APHYA. Anal fin with nine rays; iris red; body pellucid. Gmel.

Inhabits the northern seas of Europe; length from about two inches to four inches and a half.

LEUCISCUS. Anal fin with ten, dorsal fin with nine rays. Linn. Dace. Penn.

Lives in still deep rivers of England, France, the south of Germany, Italy, and Siberia. The casual length is about six or eight inches, but it sometimes grows to the length of eighteen inches. It feeds on worms and insects, is very fertile, and the prey of more rapacious fishes. The flesh is white, and in some estimation.

DOBULA. Dorsal and anal fins ten-rayed. Gmel.

Inhabits the fresh-water lakes of Denmark, Germany, and France; and in the spring ascends rivers, and feeds on leeches, as well as herbs. The body is narrow, oblong, above greenish, beneath silvery-blueish; the young males in milting-time spotted with black; scales moderate, and dotted at the edges with black. Length ten inches.

GRISLAGINE. Anal fin eleven-rayed; fins whitish. Gmel.

Inhabits European lakes.

IDBARUS. Anal fin twelve-rayed; ventral fins deep red. Gmel.

Found in lakes in Sweden.

RUTILUS. Anal fin twelve-rayed and reddish. Gmel., Rosch, Penn., &c.

Inhabits deep still rivers with a sandy bottom, in Europe, and adjacent parts of Asia. This fish seldom exceeds the weight of a pound and a half. It spawns in May, is very fertile, and feeds on worms and herbs; the eggs are greenish, and become red by boiling. The body is greenish-black, beneath paler; scales large and easily deciduous; flesh white and well-flavoured.

IDUS. Anal fin thirteen-rayed and red. Gmel.

Inhabits clear fresh waters in northern Europe, chiefly the larger lakes, from whence it migrates up rivers in the spring, and is sometimes found in the Caspian sea. Length from eighteen inches to two feet.

ORFUS. Anal fin thirteen-rayed; gill covers spotted with red. Gmel.

Lives in clear streams of England, Russia, and Germany; feeds on worms, insects, fat earth, and the spawn of other fishes; body above saffron; sides and belly golden-yellow, with red marks.

BUGGENHAGIA. Anal fin with nineteen rays. Gmel.

Inhabits lakes of Germany and Sweden. The body above blackish, sides compressed; scales large and silvery; flesh white. Length from twelve to fourteen inches.

ERYTHROPHthalmus. Anal fin fifteen-rayed; fins red. Gmel.

Native of northern Europe and the Caspian sea; length about twelve inches; the back greenish-black, sides greenish above the line, beneath silvery. This species is fertile, and feeds on worms, insects, and aquatic herbs. Scales large, thin, and silvery.

JESUS. Anal fin with fourteen rays; snout rounded. Gmel.

Inhabits the most rapid parts in France, Germany, Hungary, and Russia; it swims with great swiftness, and is exceedingly fertile. The body is blue above, the sides paler; the scales large, and blue at the lower edge.

NASUS. Anal fin with fourteen rays; snout prominent. Gmel.

Found in the larger lakes of Prussia, Germany, Italy, and the Caspian sea; ascends rivers in shoals in the spring; and weighs from one to two pounds. The body is oblong; blackish above, beneath silvery; the belly black within.

ASPIUS. Anal fin sixteen-rayed; lower jaw longer and incurved. Gmel.

Native of Europe and the Caspian sea; it delights in fresh and gentle streams, and grows to the weight of about twelve pounds. The flesh is white, soft, fat, and well-tasted.

BIFUNCTATUS. Anal fin with sixteen rays; lateral line red, with black spots in a double row. Gmel.

Inhabits stony rivers of Germany. This species is small, and feeds on worms and herbs; the upper part of the body is dusky-green, the sides greenish-white; scales small, and dotted with black.

AMARUS.

AMARUS. Pectoral and ventral fins with seven bony rays. Gmel.

This inhabits the same country as the preceding; the body is pellucid, silvery, above greenish-yellow, the sides above the lateral line yellow; scales dotted with black. The flesh of this fish is bitter.

AMERICANUS. Anal fin with eighteen rays. Gmel.

Native of Carolina. The body blue and silvery; lateral line arched towards the belly; tail bifid.

ALBURNUS. Anal fin with twenty rays. Linn. Bleak, Penn. Donov. Brit. Fishes.

The bleak is abundant in many of our rivers, and in those of the north of Europe in general; the flesh is in some esteem, but it is chiefly taken for the sake of its beautiful silvery scales, which artists make use of in the manufactory of artificial pearl.

This fish grows to the length of five or six inches, or sometimes even more. At certain times in the summer it is infested with a species of gordius, which increases in a short time to a vast size, and oftentimes destroys it. Fishes so infested rise to the surface of the water, where they leap and tumble about in the greatest agonies, and are known in this state to the fishermen by the name of mad bleaks.

The small fish called the white bait, and which appears in immense numbers, during the month of July, in the Thames, near Blackwall, is generally believed to be the fry of this fish; but has been lately ascertained by Mr. Donovan to be the young of the common shad. Vide Donov. Brit. Fishes. See article **CLUPEA**.

VIMBA. Anal fin with twenty-four rays; snout truncated and prominent. Gmel.

Inhabits the Baltic seas, and migrates in summer into the rivers of northern Europe. The body is silvery, above blueish, beneath tinged with green.

BRAMA. Anal fin twenty-seven-rayed; fins brown. Linn. Bream.

Inhabits lakes and still rivers in Europe and the vicinity of the Caspian sea. This fish feeds on worms and aquatic plants. In spring it approaches the shores, and ascends rivers in vast shoals with a rushing kind of noise. The body is blackish, tinged more or less with green on the upper part, the sides yellowish, belly white. The flesh is insipid, and not therefore in request.

CULTRATUS. Anal fin with thirty rays; lateral line sloping; belly very sharp. Bloch.

Native of Sweden, Prussia, and Germany. Its length is eighteen inches; the colour above grey, beneath silvery; flesh white. The species is rather scarce.

BJÖRKNA. Anal fin with thirty-five rays. Gmel.

Inhabits the lakes of Sweden, and grows to the length of five inches.

FARENUS. Anal fin with thirty-seven rays; iris yellow. Gmel.

BALLERUS. Anal fin with forty rays. Gmel.

The body of this species is thin; above dusky-blue; sides yellow, beneath silvery; belly reddish. Inhabits the lakes of Europe, and the Caspian sea.

LATUS. Very broad; anal fin with twenty-five rays. Gmel.

Inhabits in vast shoals the lakes and still rivers of northern Europe. This species is very fertile, and feeds on worms and herbs; the body thin, white, above blueish; weight about a pound; the back is arched and carinated at the anterior part.

CYPRINUS Murenula, a name given to the **SALMO Murenula**; which see.

CYPRIPEDIUM, in *Botany*, (from *Κυπρίς*, *Venus*, and

πόδιον, a *shoe*.) Ladies' slipper. Linn. Gen. 464. Schreb. 606. Willd. Sp. Pl. v. 4. 142. Juss. 65. Swartz. Orchid. 101. Class and order, *gynandria diandria*. Nat. Ord. *Orchideæ*.

Gen. Ch. *Cal.* Perianth of two leaves, one of which is erect, the other dependent; the latter often cloven. *Cor.* Petals two, alternate, with the calyx declining, often twisted; lip large, inflated, hollow, ventricose, obtuse. *Stam.* Filaments two, very short, inserted into the style, under two opposite lobes; anthers two-celled, roundish. *Pist.* Germen inferior, obovate, gibbous, twisted, with six angles; style cylindrical, with a terminal lobe, variously shaped, covering the hollow triangular stigma. *Peric.* Capsule obovate, obtusely triangular, of one cell, and three valves. *Seeds* numerous, minute, ranged along three linear receptacles.

Ess. Ch. Calyx two-leaved, spreading; lip large, inflated, hollow.

The most magnificent and admired genus of the orchis family, and distinguished from all the rest by being truly diandrous, as well as by its inflated bladder-like lip. Eight species are now enumerated by Swartz. *C. calceolus*, Engl. Bot. t. 1, is the only English one. This grows sparingly in the counties of Durham and Yorkshire; more frequently in Switzerland, in rocky, mountainous, rather shady places. *C. parviflorum*, an American kind, *Redoutè Liliac*, t. 20, is nearly related to it. The last-mentioned country probably affords several species, besides *C. spectabile* so often figured in botanical works. *C. acaule*. Curt. Mag. t. 192, is another American species, distinguished by a cleft in its lip. *C. ventricosum* of Swartz. Gmel. Sib. t. 1. f. 2, and *C. macranthos* of the same author; *Amm. Ruth. t. 21*, both natives of Siberia, have been confounded with *C. calceolus*, but very improperly, as has his *C. guttatum*. *Amm. Ruth. t. 22*, of which we have never seen specimens, except in Pallas's rich Siberian herbarium, now in the possession of A. B. Lambert, esq. V.P. L.S. *C. japonicum* is known only by Thunberg's description and figure in his *Ik. Plant. Jap.*

Such species of this beautiful genus as have been introduced into our gardens succeed tolerably well in a mixture of bog-earth with much loam, in a shady moist situation. *C. spectabile* will bear more sun, and even artificial warmth, than the rest.

CYPRIUS, or **COLBERTINUS** *Codex*, in *Biblical History*, a copy of the four gospels, brought from the island of Cyprus, and referred by Simon to the 10th century. He collated it, and his extracts were inserted in Mill's edition. Wettstein, who notes it K, in the first part of his *New Testament*, says, that it is a latinizing MS.; but Michaelis denies the charge. Montfaucon has described this MS. in his "*Palæographia Græca*," and has given a fac-simile of its characters. He refers it to the 8th century. It is written in uncial letters, with certain marks over them. It is at present in the royal library at Paris, where it is marked 63. Michaelis's *Introd.* by Marsh, vol. ii. and iii.

CYPRIUS Lapis, a kind of adamant brought from Cyprus, with which the ancients used to perforate other gems.

CYPRON, in *Ancient Geography*, a place of Judæa, in the tribe of Benjamin, built by Herod in honour of his mother, and situated in the plain of Jericho, near that city. *Joseph. Antiq. l. lxi. c. 9.*

CYPRUS, in *Geography*, an island of the Mediterranean sea, situated in the great gulf which terminates this sea to the East. N. lat. 35°. E. long. 33°. The length of this island is about 70 leagues from East to West; its greatest breadth from N. to S. is 30 leagues; and its circumference

is nearly 180. Towards the north, and at no considerable distance, are the winding coasts of Caramania, formerly Cilicia; those of Egypt, more remote, face it to the south; and the shores of Syria, on which the Mediterranean flops, are not far from it to the west. Some of the ancients thought that it formed a part of the latter continent, from which it was detached by some violent commotion of the globe, similar to that which separated Sicily from Italy, and several other islands from different parts of the continent. Dr. Woodward, however, considers this to have been an island ever since the deluge of Noah. (Nat. Hist. of the Earth, p. 112.) Pliny (H. N. l. v. c. 31.) enumerates several of the many names by which this island was distinguished. It was called *Acamis*, from one of its promontories; *Amathus*, *Paphia*, and *Salamina*, from three of its ancient cities; *Macaria*, or the fortunate island, from the fertility of its soil, the mildness of its climate, the inexpressible beauty of its plains, and the richness of its productions; *Colinia*, or *Collinia*, from its many hills; *Sphæcia*, from its ancient inhabitants, the *Sphæces*; *Ærofa*, or *Copper island*, from its copper-mines; *Ceraftis*, or *Ceraftia*, horn island, from the multitude of narrow capes or points, by which its coasts are surrounded, and which bear some resemblance to long horns projecting into the sea; and *Cyprus*, known to the Greeks under the appellation of *Kupros* and *Kupris*, which they gave to *Venus*, indicating that the worship of this goddess came to them from this island. This latter name has been derived by some from the Greek *cryptos*, signifying hidden, because the island was often concealed by the waves of the sea from the eye of the sailor; by others it is supposed to have been formed from *Cyrus*, who is said to have founded here the city of *Aphrodisia*; but 600 years before the age of *Cyrus*, in the age of *Homer*, it was known by the name of *Cyprus*. Some are of opinion, that the abundance and beauty of the copper contained in the bosom of this island occasioned its receiving the name of a metal, which, being found formerly in metallic masses, and less difficult to melt than iron, was employed, long before, for fabricating weapons and implements of agriculture. Others have discovered the origin of *Kupros*, in the name of a shrub, celebrated by the ancients, still much used among the modern Orientals, and in which the island of *Cyprus* carried on a considerable traffic. This tall shrub, called *kopher* by the Hebrews, and by the Greeks *kupros*, is the *benne*, or *hanna*, of the Arabs, and the *kanna* of the Turks; the *Lacæsonia inermis, foliis subsessilibus ovatis, utrinque acutis* of the *Linnaean* system. This shrub embellishes and perfumes with its blossoms the gardens of the island of *Cyprus*, like those of *Upper Egypt*. See the above-mentioned articles.

The principal cities of *Cyprus* were, according to *Ptolemy* and *Strabo*, on the north side of the island, *Arfinoe*, deriving the name from a queen of *Egypt*, to which country *Cyprus* had been long subject; *Solæ* or *Soli*, so called, from respect to *Solon*, the famous Athenian law-giver, in which was a famous temple consecrated to *Venus* and *Isis*; *Lapithus*, or *Lapathus*; *Aphrodisias*, *Carpæta*, *Cerines* or *Cerdunia*, and *Tremitus*:—on the eastern coast were *Salamis*, afterwards called *Constantia*, supposed to be the site of the present *Famagosta*, and the small islands *Clides*—two, according to *Strabo*, and three, according to *Pliny*;—on the south coast were *Throni*, *Citium*, *Malun*, and *Amathus*, consecrated to *Venus*, and having in its vicinity copper-mines, and a famous temple consecrated to *Venus* and *Adonis*;—on the west side of the island were *Palæpaphos*, or *Old Paphos*, where *Venus* is said to have first appeared after she was formed out of the froth of the sea,

peculiarly sacred to this goddess, and where the young women prostituted themselves to strangers that came on shore, in order to raise money for their portions, and *Neapaphos*, or *New Paphos*, famous for its harbour, and a stately temple dedicated to *Venus*, ruined by an earthquake, but re-built by *Augustus*, and called *Augusta*. The inland towns mentioned by *Ptolemy* are three; *viz.* *Chybrus*, *Tronethus*, and *Tamathus*, or *Tamafus*, to which *Strabo* adds *Lamenia*. The following cities, whose precise situation is now unknown, are mentioned by *Pliny*, *Diodorus Siculus*, *Pausanias*, *Stephanus*, and others; *viz.* *Cingria*, *Marium*, having a king of its own, *Golgi*, where *Venus* was worshipped, *Epidarum*, *Cresum*, *Erylthen*, *Lacedæmonia*, *Tegefus*, *Mefina*, *Hyle*, *Tembro*, *Le'rum*, or *Leuteon*.

By the ancient geographers, *Cyprus* was divided into four districts, or provinces; *viz.* *Paphia* to the west, *Amathæsa* to the south, *Lapitha* to the north, and *Salamina* to the east. It was afterwards divided into 12 provinces by the princes of the *Lusignan* family, who were put in possession of it by *Richard I.* of *England*, and held it for 17 generations. These twelve divisions were denominated *Nicosia*, *Famagosta*, *Paphia*, *Audima*, *Limissa*, *Maforum*, *Salines*, *Messoria*, *Crusocus*, *Pentalia*, *Carpallus*, and *Cerines*; so called from the chief cities of each district; besides which cities, and several other towns of less note, the island contained no fewer than 800 villages.

This island was first discovered by the *Phœnicians*, as we learn from *Eratosthenes* (apud *Strabonem*, lib. xiv.) about two or three generations, according to *Isaac Newton's* computation, (*Chronology* apud *Oper.* vol. v.) before the time of *Asterius* and *Minos*, kings of *Crete*; or about the year 1045. B. C. When the island was first discovered, it was, as *Eratosthenes* represents it, so overgrown with wood, that it could not be tilled; and the *Phœnicians* first cut down the wood for melting copper; but afterwards, when they began to navigate the *Mediterranean* without fear, they applied this wood to the construction of ships, and even large fleets. *Herodotus* also supposes that this island was first peopled by the *Phœnicians*. But *Josephus* says, that the descendants of *Cittim*, the son of *Javan*, and grandson of *Japhet*, were the original inhabitants of *Cyprus*, and that they laid the foundations of the city of *Citium*, the most ancient in the island. The learned *Bryant*, likewise, intimates, that the *Cnthites* (see *CYTH*) were among the first settlers in this island. *Sir Isaac Newton* also intimates, that the *Phœnicians* were accompanied in their migration by a sort of men who were skilled in the religious mysteries, arts, and sciences of *Phœnicia*, and who settled in several places under the names of *Curetes*, *Corybantes*, *Telchines*, and *Idæi Dactyli*, about the period above-mentioned. In process of time, other nations, invited by the fertility of the soil, came and settled here, *viz.* the *Phœnicians*, *Athenians*, *Salaminians*, *Arcadians*, and *Ethiopians*; for *Herodotus* says (lib. vii.) that *Cyprus* was inhabited by colonies from these different countries. The government of *Cyprus* was, without doubt, monarchical; for we find that kings reigned here in the earliest ages. The first monarch mentioned in history is *Cinyras*. (See his article.) However, *Cinyras*, and his successors, whose names are unknown, were not kings of the whole country, but only of *Paphos*, and the adjoining province. At an early period, the realm of *Salamis* was the most powerful in *Cyprus*; the *Salaminian* princes having, in process of time, subdued the whole island. Till the time of *Cyrus the Great*, the island was parcelled out among several petty kings, each of whom reigned with an uncontrolled authority. *Cyrus* subdued them by his lieutenants, and leaving them in possession of their

C Y P R U S.

their respective dominions, imposed upon them an annual tribute, and obliged them to supply him and his successor, with men, money, and ships, whenever they were required. The Cyprians continued in subjection to the Persians till the reign of Darius, the son of Hytaspes, when they made an attempt to throw off the yoke; being instigated to this revolt by a king of Salamis, about the year 460 B. C. Cimon (see his article) received a commission from the Athenians to drive the Persians from the island of Cyprus, and, in pursuance of his victories and of the articles stipulated between Artaxerxes and the Athenians, the Persians withdrew all their garrisons from the island, leaving the several kings, among whom it was parcelled out, to govern their respective kingdoms, without any dependence on the kings of Persia. Accordingly Cyprus remained free from any foreign yoke till the 18th year of Artaxerxes Mneumon, king of Persia; when it was again subjected to the Persians, together with all the Greek cities in Asia. In the year 387 B. C. Euagoras II. son of Nicoteles, who had been raised to the throne of Salamis, eminently distinguished by his natural and acquired talents, recovered the throne from which his father had been driven by a treacherous usurper; and by his valour and activity, made himself master of the greater part of the island. This prince having been assassinated by one of his eunuchs, was succeeded by his son Nicoteles; and Nicoteles again by his son Euagoras, who was expelled from the throne by his uncle Protagoras. On this occasion Euagoras joined the Persians, in hopes of recovering his crown. Cyprus had at this time nine kings, subject and tributary to the king of Persia, who all joined in the confederacy for shaking off the Persian yoke, and making themselves independent, each of them in his own city. Protagoras made a vigorous defence, and by a compromise with Ochus, the king of Persia, was confirmed in the throne of Salamis. From this time, to the reign of Ptolemy I., no mention of the Cyprian kings occurs. They all, without doubt, submitted to Alexander, upon the same terms which had been granted them by the Persian monarchs, as Arrian (*De Exped. Alex.*) seems to insinuate. Upon the death of that conqueror, and the partition of his conquests, Cyprus fell to Antigonus. But, during his absence, Ptolemy, the son of Lagus, having invaded the island with a powerful fleet, reduced the greatest part of it, and obliged the kings, who reigned there, to do him homage. From this time, 311 B. C. the kings of Cyprus should rather be called governors than sovereigns, being subjects and mere vassals to the Egyptian monarchs. Ptolemy was not long in possession of Cyprus, before Antigonus, apprized of its fertility and value, commissioned his son Demetrius to attempt the recovery of it. Accordingly, Demetrius, having raised a considerable army, and equipped a numerous fleet, invaded the island; and, after gaining several advantages, he totally defeated Ptolemy in a naval engagement, so that he was compelled to return to Egypt with the small and shattered remnant of his fleet. Upon his retreat, the whole island of Cyprus, with all the forces, shipping, and magazines, belonging to Ptolemy, fell into the hands of Demetrius. As soon as Antigonus received the news of his son's success, he assumed the title of king, and conferred it likewise on his son.

After an interval of eleven years, Ptolemy again recovered the island of Cyprus; and from this time, 293 B. C., it continued subject to Egypt, and for a short interval to Syria, till it was unjustly seized by the Romans in the year 58, B. C. Founding their pretended claim to the island on a testament of Alexander, late king of Egypt, who died at Tyre, and made the Roman people his heirs, but really wishing to gratify the private revenge of Clodius and to indulge their own insatiable avarice; the senate passed a decree for seizing Cy-

prus; and Cato was deputed to execute it by dethroning the king, who had been declared a friend and ally of Rome, and had never done any thing to incur the displeasure of the haughty and imperious republic. Cato, on his arrival, took unopposed possession of the island in the name of the republic, and seized the treasury which he found amounting to 7000 talents, or about 1,356,250*l.* sterling, which were carried to Rome, and lodged in the public treasury. From the emperors of the west, this island passed to those of the east, and became a part of the Byzantine empire. From them it was taken by the Arabs, under the reign of Heraclius. Isaac, a prince of the Comneni family, who governed it with the title of duke, fired with ambition, seized on the whole island, and established himself as its sovereign, assuming the magnificent title of emperor. The weakness of the empire for a long time favoured the views of the usurper; but in 1191, Richard I., king of England, expelled him from the sovereignty, threw him into prison, where he was confined with silver fetters, and, as some say, deprived him of his life. Being afterwards sold by this monarch to the templars, difference of religion caused the inhabitants to revolt and take up arms against their new sovereigns; upon which the knights apprehending that they should not be able to retain possession of it, surrendered it back to Richard, who conferred it on the house of Lusignan, as a compensation for the loss of Jerusalem. In 1460, Charlotte, the last heiress of Guy de Lusignan, was expelled from it by James, her natural brother. She married Louis of Savoy; and on this account the dukes of that country assume the title of king of Cyprus. After the death of James, Catharine Cornaro, his widow, having no male children, transferred the kingdom in 1480 to the republic of Venice. But the Venetians did not long enjoy their acquisition; for Sultan Selim wrested it from them in 1570; and since that epoch it has made a part of the Ottoman empire. This change of proprietors and rulers was accomplished on the part of the Ottoman forces with an attendant circumstance of savage cruelty. After having sustained six assaults and experienced the ravages of 500,000 shells, the valiant Bregadino, commander of the Venetian army, being forced to yield, capitulated Aug. 1. 1571. The conditions, previously settled, were honourable to the besieged, and worthy of their prolonged and brave resistance; but at the moment when the European general went into the tent of Mustapha, the general of Selim, in order to announce his departure, and take leave of him, the barbarian caused him to be seized, and delivered up to the most cruel tortures. He was skinned alive; then impaled; and his skin, stuffed with straw, was hung to the yard-arm of a galley, as an eternal testimony of the horrible inhumanity of the Turks, and a signal of vengeance to civilized nations.

This beautiful and productive island is divided lengthwise by a chain of mountains, the most remarkable of which is mount Olympus, or as it is called by the Greeks, Trogodos, Trobodos, or Trobos. The principal towns are Famagusta and Nicosia, the latter of which is its capital and the residence of its governor. Other towns of some note are Larnica, where the consuls and merchants of European nations fix their residence, and near which are Chiti, the ancient Citium, and the hamlet of Salterna, so called from a large lake near the sea in which salt is made; Limassol, formerly Nemofia, frequented merely on account of its harbour, in the environs of which the best wines are made, and which is the emporium of all those in the island who are concerned in trade; and Bassa or Baso, the ancient Paphos; Cerines, the ancient Ceraunia, with a bad harbour which serves, however, for the trade of the island with Caramania. On a survey of the present state of this island, and on comparing it with the accounts

C Y P R U S.

of former times, one cannot forbear regretting the pernicious and desolating influence of a despotic government. Soncini very justly observes, that the riches which are contained in its bosom, are more deeply buried by despotism than by the earth with which they are covered. The search after mines is strictly prohibited; and copper, of which it was formerly so productive, remains useless in the bowels of the mountains that contain it, as well as zinc, tin, iron, and other minerals, to the abundance of which it owed its celebrity. The mines of this island in ancient times afforded gold, but they have been for ages abandoned, and tradition can scarcely assign the places where they were found. The copper of Cyprus was in former ages the finest in the world, and its rich and primordial mines furnished the first blocks of that metal which were brought into use. The blue or azure vitriol, which still retains the name of Cyprus vitriol, was found in abundance in the copper mines. The ancient Tamassus furnished a great quantity of it, but the best was drawn from Chermesse, a village near a gulf of the same name occupying the site of Acamantis; the vitriol mines of which were wrought towards the end of the 17th century. The iron mines lie scattered, and in a quantity sufficient for the supply of the Cypriots themselves and the trade of the neighbouring countries. In the rocks is also found a very fine rock-crystal called the Bassa or Paphian diamond, from the place where it is procured. But the place is always surrounded by Turkish guards, who prevent its being carried away. Some of this crystal is likewise found in the mountains that lie in the vicinity of cape Chromachiti and of cape Alexandretta. The bowels of the high mountains contain also emeralds, amethysts, peridots, opals, &c. The Seythian jasper was deemed the best among the ancients, next to that was the Cyprian, and last of all the Egyptian. The river Pedicous, which has its source in the mountains near Nicosia, rolls down, with its limpid waters, fragments of very fine red jasper. The quarry which furnishes asbestos lies in the mountain of Acamantis, near cape Chromachiti, and it is still as plentiful as ever. Tale is common, especially near Larnica; and there are numerous quarries of plaiter. The quarries of marble afford it in quantity sufficient for building; but scarcely any are now worked but those which yield a common white marble, of little consistence. The Turk allows the unfortunate islander to trade in none of the treasures which the earth conceals but yellow ochre, umbre, and terre verte, substances common in Cyprus, and which are employed in coach-painting. The trade of coarse felt was formerly a source of considerable revenues. The salt-marsh, near the hamlet called Salterna, where it is found, was formerly three leagues in circumference; but the trade being diminished, the lake is reduced by drainage and culture to about a league in circuit. Some few country barke suffice for the conveyance of the quantity which enters into the export-trade, whereas the Venetians annually farmed it the cargo of 70 large ships. The effects of despotism are no less apparent in the productions of the surface than those of the bowels of the earth. Olive trees, in consequence of languishing culture, are much less common than they were in former times, their fruits no longer afford sufficient oil for the supply of the inhabitants, whereas it was formerly a very considerable branch of commerce. Immense reservoirs, in the form of cisterns, and coated with an impervious cement, still subsist in the environs of Larnica. Mulberry trees still form small woods in certain quarters of the island; but in several others the culture of them is utterly abandoned. The silk trade, however, though less flourishing than it was before the invasion of the Turks, is still of some importance. At Famagusta, where the market for this commodity is held,

there are annually sold about 25,000 bales, of 300lbs. each, including white silk, gold, yellow, sulphur-yellow, and orange-coloured. The floss is likewise thrown into trade, and like the silk itself, it is dispatched to the ports of Turkey or Europe. The carob, or St. John's bread-tree, furnishes pods, which are an article of considerable commerce to Syria and Alexandria. These trees are cultivated in great abundance in the environs of Limassol. Most of the plains, of which cotton constituted the wealth, still preserve some traces of that culture; the whole island now affords to commerce about 3, 4, or 5000 bales of cotton, according to the goodness of the season; whereas under the government of the Venetians, the annual quantity of these bales amounted to 30,000. Cyprus cotton is the most esteemed, as the finest of the whole Levant, and bearing a higher price. In Cyprus, the seeds of the cotton tree are sown in the month of April; when the plants appear above ground, they are thinned and weeded, and the earth is loosened about them in the course of the summer; towards the month of October the pods ripen, and the silky down which they afford is then separated from the seeds which it surrounds. A moist atmosphere, and frequent or long continued rains, are unfavourable to the cotton-tree; whereas a strong heat is very suitable to it; serving to promote the dazzling whiteness of the down, and contributing to the fineness, and substance of the silk.

At the time when the Venetians possessed the island of Cyprus, they made large plantations of sugar-canes, which succeeded as well as in Egypt, in the best districts of the island, such as that of Pincopia, on the road from Limassol to Bassa, where the best cotton in the country also grows, and near Lafca in the gulf of Pantala. Proper buildings were erected on the same spots for refining the sugar, and great advantages must have been derived from these plantations, and these sugar-refineries, in a situation so near Europe. The soil of Cyprus in various parts of it is also favourable to the vegetation of the coffee-tree, and Soncini thinks it might be here cultivated with success. The goodness of the soil is evinced by various circumstances. The gardens are full of pot herbs of a very good quality; cauliflowers are excellent, and vegetables are so abundant as to supply ships with an ample stock. Orange-trees, lemon-trees, pomegranate, and other fruit trees abound, and form groves round the habitations. Wheat and barley were formerly some of the principal articles of exportation; but now they hardly suffice for the subsistence of the inhabitants, even when they escape the destructive ravages of the grasshoppers which flock in thick clouds over the fields and dart on their produce. On their approach every kind of verdure disappears, and they even gnaw the very bark of the trees. It is therefore partly to the oppression of the government and partly to the desolating ravages of these insects, the destruction of which the Turks forbid, because they regard them as sent by the Almighty, that we are to ascribe the state of languor and almost decay of the agriculture of Cyprus. These swarms of grasshoppers, says Soncini, arrive from the continent, where, according to the opinion of M. Hessewitz, they must be formed in the midst of the deserts of Arabia, whence they depart supported and impelled by the winds. The Strait which they have to cross from the coast of Syria to cape Saint Andrea, the most eastern point of the island of Cyprus, is not more than from 20 to 25 leagues; and a gale of wind may easily carry light insects, assisting themselves with their wings, and possessing much strength and agility.

In the island of Cyprus they also gather madder, called in the Levant *al-sary*, with which cottons are there dyed red; coloquintida, which covers many fields without culture; a small quantity of cinnamon; and opium, cultivated at the

C Y P R U S.

foot of mount Olympus, and purified and packed up at Nicosia. The sandy soil of Cape Cromachiti is covered with soda, which is burnt in summer, in order to send the ashes to Europe, where it is employed in soap-manufactories. The forests also afford a fine wood for building and for planks; thence are likewise drawn tar and pitch; and the turpentine of Cyprus is more esteemed than that of any other country.

The flocks of Cyprus, that might be more numerous, afford to commerce a tolerably large quantity of wool, which passes into Italy and France. One of the productions which the Cypriots rear with the greatest attention, and which has been a beneficial branch of trade, is the famous wine which is yielded them by vines with twisting and creeping stems, and large delicious fruit. The best vines, which supply the yellowish fruits, and perfumed wine that is so much valued, occupy a district called the "Commandery," because it made a part of the great commandery of the templars, and of the knights of Malta. It is comprised between mount Olympus and the towns of Limassol and Paphos. Among the Greeks of Cyprus, there subsists a very ancient custom, which is, that when a child is born, they bury large vessels filled with wine, and closely stopped; these are not taken out of the ground but on occasion of the marriage of that same child. Part of this which remains unconsumed, is sold to Europeans, and admired for its peculiarly excellent quality. Cyprus wine is conveyed to Europe either in casks, or in those large glass bottles covered with rush or wicker, which are called *dames-jeannes*. When Cyprus wine is shipped in casks, and the price is not considered, in order to have that of the best quality, the purchaser procures casks in which has been left a certain quantity of lees, which have the property of improving the wine. Accordingly, the casks, thus provided with lees, fetch four times the price of those which are destitute of them. The wines yearly made in this island amount to near 40,000 gallons. The arts, both liberal and mechanical, find little encouragement in Cyprus. With the exception of the preparation of the leather called "Turkey-leather, or Morocco," there are scarcely any that deserve attention. This leather is prepared at Nicosia, and in the neighbouring villages: the workmen pretend to have a particular process, which they keep secret; however this be, it is certain that the leather which has passed through their hands is more lively and more brilliant in colour, and is, in general, better dressed than in other parts of Turkey. The workmen of Nicosia and its environs know how to apply dyes that are equally brilliant and durable. They also manufacture printed calicoes, the colours of which become brighter by wear and bleaching. Other cloths, half silk and half cotton, are likewise manufactured in the same places; but they fetch a high price, and are of little importance as articles of trade. In return for these productions of nature and art, the Cypriots receive woollen cloths, satins, light stuffs, laces, some metals, Indian spices, and commodities from European colonies, &c. &c. These articles of the import trade are not so numerous as they would be, if the worst of governments had not singularly diminished the population and resources of one of the finest countries of the East. Cyprus was formerly stocked with deer, roebucks, asses, wild boars, and a great number of very beautiful pheasants; but they are now all destroyed. No wild animals are seen here but foxes and hares; the odoriferous herbs on which the latter feed give their flesh an agreeable flavour. The most common of the winged tribe are rails, partridges, snipes, quails, and thrushes. Of water-fowl there is great plenty. The beccaficos and ortolans are remarkably fat, and so numerous that

they may be procured at the rate of a penny for a dozen. The oxen are lean and small; the mutton is tender and juicy; Cyprus has serpents, harmless and noxious, and also a kind of spider called tarantula.

The climate of Cyprus has been reckoned insalubrious on account of its heat and long continued drought and infrequency of rain. The heat, partly owing to the vicinity of Syria, is in summer excessive; but it is different in different parts of the island, which, being intersected from east to west by a chain of mountains, affords two different regions as well as temperatures. To the north, the winds that blow from the high mountains of Caramania, checked and repelled by those with which the island is crossed in its length, temper the heat of the summer, produce piercing colds during the winter, and preserve frozen snow on the most lofty spots, through the greater part of the year. This northern region is also, generally speaking, the most hilly, the most wooded, the most rural, and the least fertile. In the plains of the south, on the contrary, the heat of the sun, reflected by the shelves of rocks, which, in a great measure, form on this side the back of the mountains, there acts at full liberty. The north winds not being able to clear the natural barrier which the middle of the island opposes to them, do not cool the atmosphere; and without the light sea breeze which occasionally springs up and moderates the heat, it would be insupportable in certain days of the summer. Rain here is also very rare in this season, and long droughts sometimes banish an agreeable verdure, destroy the plants, attract close and innumerable columns of grasshoppers, and with the avidity thus occasioned, introduce a distressing scarcity. The irrigation of the lands is neglected by the oppressed and spiritless inhabitants, while, in some districts, stagnant waters render them an unwholesome abode. Running streams are scarce, and most rivers that flow here are mere torrents, formed by the winter rains, and the melting of the snow on the mountains, and whose beds are dry during warm weather. The abbé Mariti, who seems unwilling to acknowledge the insalubrity of Cyprus, allows that the inhabitants are very subject to intermittent fevers; but these, he observes, are easily avoided by care and temperance. In order to cure them, the Greeks take a draught of their oldest wine when they feel the access of the cold fit; and many of the Cypriots live to a very advanced age.

The Greeks, who inhabit this island, are tall and well made; their countenances and their manners are equally noble and agreeable. But their moral character is not thought to correspond with these external good qualities. They are said to be the most cunning and knavish of all the Greeks; qualities which some have ascribed to the oppressed and slavish state to which they are reduced; and even these obliquities of disposition and character are said to be counterbalanced by the hospitality, for which they are distinguished. The Cypriot is gay, says Sonnini, and a great friend to show and pleasure; but he is not the only slave whom we have seen dancing in his fetters. The women have fine eyes, but, in other respects, as Mariti informs us, are far from being beautiful:—they do not, however, degenerate from their ancestors, as votaries of that goddess, whose favourite habitation this isle was supposed to have been. In their attire they are choice; being excessively fond of flowers, as the most natural and elegant accompaniment of their other attractions; they do not dissemble their wish to please, but they manifest it with an amiable frankness. Although enjoying, perhaps, less liberty than they formerly possessed, the restrictions to which custom, or the caprice of the men subjects them, does not amount to constraint; and at least they no longer compose the disgraceful

tribute

tribute which their ancestors paid to the queens of Persia, of 50 among them, whose duty, in a haughty and despotic court, consisted in throwing themselves between the wheels of the cars, and presenting their backs to the queen, who made use of them as a footstool.

Like most places in the Levant, Cyprus is ruined by the oppressive despotism of the Turks, which counteracts the bounty of nature, and the productions of the soil, and which extends its baneful influence over fields, arts, and men; so that the curious traveller every day sees commerce fail, industry decay, lands dry up, and agriculture restrained and impoverished. Vallies, once fertile and productive, are either marked by traces of sterility, or, for want of culture, overrun with brambles and other useless or noxious plants. Population declines, and men quit a desolated country, and seek other abodes. This island was formerly governed by a *basbaev*; but the poor inhabitants, weary of his extortions, which, as they delusively imagined, were increased in order to maintain the splendour of his station, petitioned the Ottoman court to send them a *mubassil*, or governor of inferior rank:—their request was granted; but they soon found that the change of title made no alteration in the rapacity of their plunderer. The revenues are enjoyed by the grand vizir, but he farms them to the governor, who, of course, is always the highest bidder. When the island was first taken by the Turks, it contained, beside women and children, above 70,000 men, subject to annual capitation, which produced a revenue of 400,000 pialtres; the sum now exacted is much greater, though the number of contributors is scarcely a sixth part of what it then was. When a new tax is to be raised, the governor does not immediately call on the people, but sends his order by his interpreter to the archbishop, who communicates it to the bishops, and these must obtain the sum demanded from the inhabitants of their several dioceses. These taxes are often of the most absurd kind; sometimes they are laid on Christian names. The poor people are treated with the most unfeeling insolence by the governors, who do not even condescend to give their exactions a decent appearance of equity. This violence in the year 1764, occasioned an insurrection, in which the governor met with the death which he deserved from the fury of the injured people. The consequence of this was a civil war which lasted two years; but the people, being at length obliged to submit to those whom the sulan sent to succeed the deceased, their attempt to shake off the yoke only served to exasperate their tyrants, and to render their own servitude more severe. In this island there are several resident consuls; among these we find, from Mariti's account, that the British consul is invested with authority to banish any of his countrymen who shall embrace the Mahometan religion. Sonnini's Travels in Greece. Abbe Mariti's Travels in the Island of Cyprus, &c.

CYPRUS, an order of knights, called also knights of *Silence*, and knights of *the Sword*; instituted by Guy de Lusignan, king of Jerusalem and Cyprus, in 1192.

The ensign of this order was a coliar interwoven in manner of true lovers' knots, garnished with precious stones, and intermixed with the letters S and R; pendant to which was a medal of gold enamelled, with a sword, the blade environed with the letter S; round the medal was this motto, "Securitas Regni," expressing the design of the institution, which was to oppose the inroads and irruptions of the mischiefs in that island.

CYPRUS Bird, in Ornithology, a common name for the *atricapilla*, or *black-cap*, a very small bird, well known in England, and much more plentiful in the island of Cyprus,

where it is esteemed a very delicate bird at table. See *MOTACILLA*.

CYPRUS *Vitriol*. See *CYPRUS* and *VITRIOL*.

CYPRUS *Wood*, in the *Materia Medica*, a name given by some authors to the *rose wood*, because much of it is brought from the island of Cyprus.

CYPSELA, or *CYPSELLA*, in *Ancient Geography*, a town of Thrace, in the province of Rhodope, according to Thucydides, Appian, Livy, Mela, and Steph. Byz.; the last of whom places it near the river Hebrus. In the Itinerary of Antonine, it is marked between Trajanopolis and Syracella. It had been episcopal. Bellonius describes alum-works at a place called *Cypleia* or *Chypilar*; and he says, that the alum in commerce was called *alumen Lesbium*, or *di metelin*. "In some maps," says Beckmann (Hist. Inv. v. i.), "I find the names *Tysala* and *Chippilar* on the western side of the river Mariza, Maris, or Marichch, which was the Hebrus of the ancients; in others stands the name *Scapsiler* on the west bank of the sea Bouron; and it is not improbable that these may be all derived from the old *Scaptasyle* or *Scaptia Hyla*, where, according to the account of Theophrastus, Pliny, and others, there were considerable ruins."

CYPSELA, a place of the Peloponnesus, in Arcadia. Thucyd. Steph. Byz.—Also, a town of Spain, near the Mediterranean sea, and a mountain named *Celebanticum jugum*.

CYPTASIA, a town of Asia Minor, in Galatia. Ptol.

CYRA, an island of the Persian gulf. Steph. Byz.—Also, a mountain of Africa, in the Cyrenaic territory.

CYRACTICA, a name given by Strabo to an island of the Adriatic gulf, called by Ptolemy, Pliny, and others, *Curida*.

CYRANO DE BERGERAC, SAVINIEN, in *Biography*, a French author, born at Bergerac, in Perigord, in 1620. He was initiated in the art of war, and displayed a daring temper, in the number of duels which he fought. He obtained, by his general conduct, the name of "The Intrepid." At the sieges of Moulson and Arras he was wounded, which, together with his passion for literature, induced him to quit the army, for the study of philosophy and the belles lettres. Gassendi, Chapelle, and Moliere, were his instructors; and he became an author, distinguished, however, rather for the peculiarity of his works, than for those qualities which give a man distinction. He published a tragedy and a comedy, which were well received; but he is known chiefly for his "Comic History of the States and Empires of the Moon:" a burlesque piece, in which philosophy is blended with satire. In a similar style he wrote "A comic History of the States and Empires of the Sun." He left behind him, likewise, "Letters," "Discourses," and a small piece on "Physics." In his youth his conduct was licentious, and his opinions seemed to accord with his manners. An accident led him to reflection, and to a reformation of his life; but its consequences were the cause of his death, which happened in the year 1655. Moreri.

CYRASSENSIS, in *Ancient Geography*, an episcopal see of Asia Minor, in Lydia; mentioned in the Council of Chalcedon.

CYRAUNIS, a name by which Herodotus (l. iv. c. 195.) mentions an island situated on the coast of Libya, near the country of the Gyzantes; it was very narrow, and 200 stadia in length, and covered with olives and vines: it had also a lake, concerning which some fabulous stories are related.

CYRBA,

CYRBA, a town of Asia, in Pamphylia. An episcopal see of this name is mentioned in the Acts of the Council of Nice.

CYRBASIA, Κυρβασία, among the Greeks, a kind of caps with high tops, in form of a cone, which were worn by the priests.

CYRE, in *Ancient Geography*, a fountain consecrated to Apollo, in Africa, on the spot where the town of Cyrene was built, to which it gave its name.

CYRENAICA, a country of Africa, bounded on the east by Marmarica, on the west by the Regio Syrtica, on the north by the Mediterranean, and on the south by the Sahara. The ancient geographers are somewhat divided in opinion as to the extent of this country. Ptolemy says, that it extended from the promontory of Cherfontus Magnus to the gulf of the greater Syrtis; but Pliny makes its extent more considerable, bounding it by mount Catabathenos, and on the west by the Smaller Syrtis, and making it 500 miles broad. Strabo also asserts it to have extended as far as Egypt, and maintains that Marmarica lay between these two regions. This country has also been called *Pentapolis*, from its having included the five cities, Cyrene, Arsinoe or Teuchira, Berenice, Ptolemais, and Apollonia; however, this canton was only a part of Cyrenaica. Its metropolis was *Cyrene*, which see. Berenice, Teuchira, Ptolemais, Apollonia, and Adriane or Hadrianopolis, lay along the coast of the Mediterranean; and their inhabitants carried on a considerable trade.

Although a great part of Cyrenaica and the Regio Syrtica was a perfect desert, yet in both countries there were some fruitful plains. The inhabitants were subject to fevers, which have been ascribed to the insalubrity of the air. The Lathon, placed by some in Mauritania, was the only considerable river of Cyrenaica. The Montes Valsi and Anagombri are the only mountains of note; and the Palus Pahuri is the only fountain or lake. Some parts of the Cyrenaica and Regio Syrtica were famous for the production of the silphium, a plant or shrub much celebrated by the ancients. Great quantities of this vegetable were imported into Greece, and many other countries. The ancients had various modes of preparing it, both for food and for physic, as we learn from Athenæus and Hippocrates. Cyrenaica also abounded with a rich oil, as we are informed by Theophrastus. Athenæus relates, that the roses, violets, and all other flowers growing in this country, except saffron, were famous for the fragrant odours they emitted; and that, in the time of Berenice, a most valuable ointment was made of the Cyrenean roses.

The principal nations inhabiting this tract, or contiguous to it, were the Barcæi, so called from Barce or Barca, their capital, the Pphyli, and the Nasamones. The first occupiers of this country, as we learn from Herodotus, consisted of a colony brought by Battus, the Theraean, from his own country, the isle of Thera, to Platæa, an island on the coast of Libya. Hence they removed to that part of the continent that was opposite to this island, and took possession of a delightful province, watered by two rivers, and called Azirisus. By the Libyans they were conducted to Irafra, a charming country to the west of Azirisus, and here it is said, by Eusebius, they built Cyrene, about the third year of the 37th Olympiad, 650 years B. C. Aristotle says, that in his time Cyrene was a republic; and we learn from Sallust, that the people were free, and the contention took place between them and the Carthaginians about their respective limits; and that they were governed by their own laws, till the Macedonians subdued Egypt, we find asserted

by Strabo. After several conflicts with invaders, Cyrenaica was ceded to Ptolemy, and it remained subject to the kings of Egypt, till Ptolemy Physcon transferred it to his natural son, surnamed Apion, who, in the year of Rome 657, the 97th year B. C., left it by will to the Romans. The senate, instead of accepting it, permitted all the cities to be governed by their own laws; a permission which filled the country with a number of petty tyrants, who contended for power, and threw the country into confusion: but Lucullus in a great measure restored the public tranquillity, on his arrival, during the first Mithridatic war, 89 years B. C. The descendants of those Jews who had been settled here by the first Ptolemy, are said to have greatly contributed to these disturbances. The troubles of the country, however, did not terminate till it was reduced to the form of a Roman province, about 20 years after the death of Apion, and 77 B. C. Strabo says, that in his time Crete and Cyrenaica formed one Roman province. Upon a revolt, Cyrene was destroyed by the Romans; but they afterwards rebuilt it. In process of time it fell to the Arabs, and afterwards to the Turks, who are the present possessors of it.

CYRENAICI, a sect of ancient philosophers; so called from the native city of their chief, Aristippus of Cyrene, a disciple of Socrates. See ARISTIPPUS.

The distinguishing tenets of the Cyrenaic system, as far as they can be collected from the casual, and perhaps unfair, representations of prejudiced contemporaries, and from the adulterated and vague reports of later writers, are as follow:

“Perceptions alone are certain; of the external objects which produce them we know nothing. No one can be assured, that the perception excited in his mind by any external object is similar to that which is excited by the same object in the mind of another person. Human nature is subject to two contrary affections, pain and pleasure; the one a harsh, the other a gentle emotion. The emotions of pleasure, though they may differ in degree, or in the object which excites them, are the same in all animals, and universally create desire. Those of pain are, in like manner, essentially the same, and universally create aversion. Happiness consists not in tranquillity or indolence, but in a pleasing agitation of the mind, or active enjoyment. Pleasure is the ultimate object of human pursuit; it is only in subserviency to this that fame, friendship, and even virtue, are to be desired. All crimes are venial, because never committed but through the immediate impulse of passion. Nothing is just or unjust by nature, but by custom and law. The business of philosophy is to regulate the senses, in that manner which will render them most productive of pleasure. Since pleasure is to be derived, not from the past or the future, but the present, a wise man will take care to enjoy the present time, and will be indifferent to life or death.” Such a system, we may naturally suppose, would engage temporary admirers and votaries; but we may no less reasonably conclude, that, whilst it provided merely for the gratification of the senses and passions, and left human nature destitute of its noblest ornaments and highest pleasures, it would soon fall into the contempt which it deserved.

Cicero makes frequent mention of Aristippus's school; and speaks of it as yielding debauchees.

Three disciples of Aristippus, after his death, divided the sect, the doctrine of which was for some time taught by his daughter *Arete*, into three branches; under which division it languished and sunk: the first called the *Hegesiac* school; the second the *Anticarian*, and the third the *Theodoran*; from the names of their authors.

Hegesias, gloomy in his temper, and deriving from his principles no sufficient sources of happiness, became to thoroughly dissatisfied with life, that he thought it the only concern of man to avoid misery; and wrote a book to prove, that death, as the cure of all evil, is the greatest good; hence he obtained the appellation of *παραθνήσκων*, the advocate for death. *Anicerris* receded from the doctrine of his master so far as to a knowledge the merit of liberal piety, friendship, and patriotism, and to allow that a wise man might retain the possession of himself in the midst of external troubles; but he inherited so much of his frivolous taste, as to value himself upon the most trivial accomplishments, particularly upon his dexterity in being able to drive a chariot twice round a course in the same ring. *Theodorus* was a disciple of *Anicerris*, and, for the freedom with which he spoke concerning the gods, was stigmatized with the name of atheist, and banished from Cyrene. At Athens, where he took refuge, his impiety would have terminated fatally to him, if *Demetrius Phalereus* had not interposed in his favour, and introduced him to the court of *Ptolemy Lagus*. After a long interval he returned to Athens, and is said to have suffered death by hemlock; but it has been much disputed whether his offence was atheism or contempt of the Grecian superstitions. *Sextus Empiricus* (*Adv. Math.* l. ix. c. 57.) joins him to those who maintained, that the reputed gods were men, who had possessed great power on earth; and *Clemens Alexandrianus* (*Protrept.* p. 24.) expresses his surprise, that *Eumencus*, *Nicanor*, *Diagoras*, *Theodorus*, and others, who had lived virtuously, should be pronounced atheists for their opposition to Gentile polytheism. *Laert.* lib. ii. *Brueker's Hist. Philos.* by *Enfield*, vol. i.

CYRENE, now called *Cairoan*, or *Corone*, in *Ancient Geography*, a town of Africa, and capital of the country called Cyrenaica. It derived its name from the fountain Cyre, near which it stood; at the distance of 11 miles from the sea, according to *Pury*, 24 *Stadia* from *Apolonia*, which was its port. It was large and populous, and abounded with all the elegancies as well as necessaries of life. Its territory produced a great number of excellent horses; a circumstance which probably induced the Cyreneans, whether Libyans or Greeks, to apply themselves to the study and practice of every thing that related to those animals. The inhabitants of Cyrene worshipped their king, *Battus*, the founder of their kingdom. *Herod.* l. iv. c. 161. See CYRENAICA.

CYRESCHATA, a name given by *Ptolemy* to two towns of *Cyropolis*, in *Media*, and in *Sogdiana*.

CYRETLE, a town of *Macedonia*, in *Perrhæbia*; so called by *Livy*, and named *Chyretie* by *Ptolemy*.

CYRIA, an episcopal town of *Asia*, in *Syria*.

CYRIL, bishop of *Jerusalem*, was born about the year 315, ordained presbyter in 344 or 345, and bishop in 350 or 351, and died in 386. Whilst Cyril was bishop of *Jerusalem*, the emperor *Julian* is said to have proposed to the Jews the rebuilding of their temple, and as some writers have asserted, made preparations for this purpose: but the bishop, as we learn from *Rufinus* (l. i. c. 37), considering the prophecies of *Daniel*, and the words of our Lord recorded in the gospels, confidently asserted, that it could not be, that the Jews should be able to lay there, one stone upon another.

His works, now extant, are his "Epistle to the emperor *Constantinus*," mentioned by *Sozomen*, with "18 Catechetical Discourses," in which he treats of the principal subjects of the christian faith, compiled in 347 or 348, and his "5 Mystagogic Catecheses," in which he discourses con-

cerning the two sacraments of the church. *Cave's H. L.* vol. i. *Lardner's works*, vol. iv.

CYRIL, bishop of *Alexandria*, was a native of this city, and succeeded *Theophilus* as bishop of it in the year 412. The authority which had been usurped by this see, was enlarged and confirmed by Cyril; for as soon as he obtained the episcopate, he banished the *Novatians*, shut up their churches, and took away all their sacred vessels and ornaments, and deprived their bishop *Theopemptos* of his whole property. Soon after, when the Jews committed some outrages in the city, the bishop put himself at the head of the people, assaulted them in their synagogues, drove them out of the city, and permitted the christians to plunder their ellates. This conduct of Cyril displeased *Orestes* the governor, whose authority was thus invaded, and occasioned frequent skirmishes in the city. Cyril was also charged with having been accessory to a sedition, in which *Hypatia*, a famous heathen philosopher, respected and consulted by *Orestes*, was cruelly murdered; but this charge has been repelled by the advocates of the bishop. However, Cyril owed his chief fame to his dispute with *Nestorius*, against whom he maintained, that the virgin *Mary* ought to be called the mother of God. This dispute, trivial and uninteresting in its origin, terminated in a severe contest, and a general council was summoned at *Ephesus* in order to decide it. Cyril distinguished himself by a defence of the christian religion against the emperor *Julian*, consisting of 10 books, and dedicated to *Theodosius* the younger. He died in the year 444. His works are very numerous; they have been collected together and printed in Greek and Latin at *Paris* in 1538, in 6 large volumes fol. They consist of the commentaries upon the *Pentateuch*, called "Glossæ, &c." *Isaiah*, the 12 lesser prophets, and *St. John's* gospel; 17 books on the adoration and worship of God in spirit and truth, composed in form of a dialogue; dialogues on the holy and consubstantial trinity, and on the incarnation; a discourse of the orthodox faith; homilies, letters, and apologies. *Cave's H. L.* vol. i. *Dupin's E. H.* vol. iv. *Lardner's works*, vol. iii. iv. viii.

CYRILLA, in *Botany*, (named by *L'heritier* in honour of *Domenico Cyrillo M. D.* Professor of botany at *Naples*, and a very eminent physician there, who sold a sacrifice in the stormy times of the French revolution. *Linnaeus* had previously named a *cyrilla*, which proves a species of *Itea*. See *ITEA*.) *L'herit.* *Sturp.* 147. t. 71. *Willd.* *Sp. Pl.* v. 3. 229. Class and order, *didynamia angiospermia*. *Nat. Ord.* *Personate*, *Lin.*

Gen. Ch. *Cal.* Perianth superior, of five narrow leaves, permanent. *Cor.* monopetalous, funnel-shaped; tube cylindrical, curved, slightly compressed; limb spreading, five-cleft, rounded, the three lower lobes largest. *Stam.* Filaments four, inserted into the tube and included in it; the two lowermost longest, at length spiral; the others with a barren filament between them; anthers ovate, two-celled, at length confluent, whitish. *Pist.* Germen inferior, turbinate, downy; style thread-shaped, shorter than the tube; stigma two-lobed. *Peric.* Capsule imperfectly two-celled. *Seeds* numerous, minute.

Eff. Ch. Calyx five-leaved. Corolla funnel-shaped, with a spreading, five-cleft, unequal border. Anthers confluent. Capsule inferior, imperfectly two-celled, with many seeds.

Only one species is known, *C. pulchella*, *Curt. Mug.* t. 374. (*Achimenes* *Brown. Jam.* t. 30. f. 1.) a native of moist hilly places in *Jamaica*. It is herbaceous and perennial. Roots granulated and scaly. Flowers of a most vivid scarlet, extremely beautiful. Leaves ovate, serrated; named

stained with purple beneath, as well as pale and polished, like those of *Fuchsia coccinea*. It requires great stove heat, and flowers late in autumn.

CYRIUS, in *Ancient Geography*, town of Macedonia, in Emathia, inhabited by a people called Cyrrhestæ. Ptolemy.

CYRMIARÆ, a people of Thrace, mentioned by Herodotus.

CYRNABA, a gulf of Asia, placed by Pliny in Serica.

CYRNUM, an island of Greece, placed by Pliny in the vicinity of Etolia.

CYROCEPHALUS, in *Botany*, the name given by some authors to the *antirrhinum*, the calves-snout, or snap-dragon.

CYROPOLIS, in *Ancient Geography*, a town of Asia in that part of Media, called Atropatene; between the Cyrus and the Amardus; ascribed by Ptolemy to the Cadusians.—Also a town of India, mentioned by Ælian and said to have been built by Alexander.—Also, a town of Asia, in Sogdiana. Arrian says that it was built by Cyrus on the banks of the Jaxartes, and that it was taken by Alexander. He adds, that it was very large, and that its walls were very high; but that it was utterly destroyed to its very foundations. It is called *Cyra* by Strabo, and *Cyresebata* by Ptolemy.

CYRRHA, a port belonging to Crissa, a town of the Loerians, near a gulf of the same name.

CYRRHADÆ, a people of Asia in Sogdiana, who inhabited the banks of the Oxus. Ptolemy.

CYRRHÆUS, a people of Æthiopia, placed by Claudian on the banks of the Nile.

CYRRHÆSTICA, a small country of Asia, being one of the divisions of Syria; which lay between Seleucia, Commagene, and the Euphrates. It was so called from its metropolis Cyrrhus; and had 20 towns according to Ptolemy.

CYRRHUS, or *Cyrus*, a town of Asia in Syria, and capital of Cyrrhestica. Procopius says, that it was founded by the Jews, and called by its name Cyrus, in honour of Cyrus their deliverer from the captivity in Assyria. It was re-established and adorned by Justinian.—Also, a town of Greece, in Macedonia, near Pella—Thucydides.

CYRTA, a river of Gallia Narbonensis, in the territory of the Massilians.

CYRTÆA or CYRTÆ, a town situated on the banks of the Red Sea.

CYRTANTHUS, in *Botany*, (from *κυρτος*, curved, and *ανθος*, a flower), Ait. H. Kew. v. 3. 510. Willd. Sp. Pl. v. 2. 48. Class and order, *hexandria monogynia*. Nat. Ord. *Narcissi*, Juss.

Gen. Ch. *Cal.* none. *Cor.* monopetalous, club-shaped, curved; its border in six smallish, ovate-oblong, segments, of which the three outermost are rather the largest, and each tipped with a point. *Stam.* Filaments six, inserted into the tube, shorter than the corolla; anthers oblong, erect. *Pist.* Germen inferior, ovate, obtusely triangular; style thread-shaped, as long as the corolla; stigma three-cleft. *Peric.* Capsule of three cells. *Seeds* numerous.

Eff. Ch. Corolla tubular, club-shaped, curved, its limb in six ovate-oblong segments. Stamens inserted into the tube, approximated at the top.

C. angustifolius, Curt. Mag. t. 271. (*Crinum angustifolium*, Linn. Suppl. 195); and *C. obliquus*, Ait. H. Kew. v. 1. 414, Andr. Repos. t. 178. (*Crinum obliquum*, Linn. Suppl. 195, *Amaryllis Umbrella*, L'herit. Sert. t. 16.), are beautiful bulbous-rooted plants found at the Cape of Good

Hope. The former has drooping slender scarlet blossoms; the latter large pendulous ones, variegated with orange and green. Both are cultivated, either in the greenhouse or stove, like other Cape bulbs, and flower in the summer.

CYRTANTHUS, in *Gardening*, comprises plants of the bulbous rooted perennial kind; of which the species mostly cultivated are, the narrow leaved cyrtanthus, (*C. angustifolius*;) and the oblique leaved cyrtanthus.

Method of Culture.—These are a sort of plants which are capable of being multiplied either by off-sets from the roots, or by seeds; but the former is much the best method.

In the off-set method, they should be separated from the roots at the time the stems begin to decay, and be planted out in separate pots, being then put under the protection of a greenhouse or garden frame.

In the seed method, they should be sown in pots in the spring season, being immediately plunged in a moderate hot bed. And when the plants appear, and have attained sufficient growth, they should be removed into separate pots.

The plants afterwards require similar management in the different methods of raising them to other bulbous rooted kinds from the same place.

They afford a pleasing variety in greenhouse collections.

CYRTII, a people of Asia, in Media, mentioned by Strabo and Livy.

CYRTOMA, a bunch or curvity of the back. See *GIBBOUS*.

CYRTONE, in *Ancient Geography*, a town of Greece, in Bœotia, built on a mountain, according to Pausanias, who says that it had a temple of Apollo, and a wood consecrated to that deity, and also a statue to Diana.

CYRTUS, a town situated in the interior of Egypt.

CYRUS, in *Biography*, the famous founder of the Persian monarchy, and the restorer of the Jews to their country, their temple, and their former state, was the son of Cambyses, and was born about 600 years before the Christian era. It is agreed by all writers, that the mother of Cyrus was Mandana, the daughter of Astyages, the Median king; but historians are not unanimous as to the quality and description of his father. Herodotus considers him only as a private person of high rank; but Xenophon makes him sovereign of Persia, subject however to the Medes. Dr. Prideaux, who has examined with much attention the two accounts of Herodotus and Xenophon, and who is well qualified to appreciate their different merits, follows decidedly the facts detailed by the latter, because he not only wrote at all times, and on all subjects with much consideration, and a clear judgment, but having lived at the court of the younger Cyrus, was well qualified for the task which he undertook. Rollin also concurs with Xenophon in his history of this illustrious prince. Cyrus, beautiful in his person, and more amiable for the qualities of his mind, lived with his father during the first twelve years of his life, and was educated after the Persian manner in hardship and toil, and all such laborious exercises, as would tend to fit him for the fatigues of war in which he unquestionably excelled all his contemporaries. At this early period he surpassed all of his age, not only in aptness to learn, but in the courage and address with which he executed whatever he undertook. After this he was sent to Media to the court of Astyages, his grandfather, with whom he lived about five years. Here his conduct was so excellent and amiable, notwithstanding the pride, luxury, and magnificence which prevailed in the court of Media, that he was general-ly

C Y R U S.

ly beloved, and laid the foundation of that attachment to his person which enabled him afterwards to perform the exploits which are recorded of him. He was gentle, affable, beneficent and generous. Whenever the young lords had any favour to ask of the king, Cyrus was their solicitor. If the king had any subject of complaint against them, Cyrus was their mediator; and he always managed their affairs so well, that he never failed of obtaining what he desired. When he was sixteen years of age, he accompanied Astyages in an attack upon the Assyrians, who had made inroads upon the Persian territories; his behaviour on this occasion was such, that the victory obtained was imputed to his energy and superior prowess. Soon after this he returned to his father, with whom he resided till he had attained the age of forty, when he was called forth to the assistance of his uncle Cyaxares, by whom he was appointed generalissimo of the Medes and Persians. This led to the establishment of that vast empire, of which he was the founder, and which he erected upon principles of so much wisdom, that it existed, in spite of the weakness, and the wickedness of his successors, for a period of 200 years. In this sketch we shall not attempt to follow the hero in all his contests; we have already viewed him in his conduct with regard to Cræsus, and in every instance, where valour and wisdom were required, he was found possessed of all those qualities that can render a man and a prince truly great. After a signal victory obtained by Cyrus over the Assyrians, aided by Cræsus, a young princess of exquisite beauty was found among the prisoners of war; and in the division of the spoil, she was reserved for Cyrus. Her name was Panthea, the wife of Abradates, king of Susiana. Upon the report made to Cyrus of her extraordinary beauty, he refused to see her; fearing (as he said) that such an object might engage his affection more than he desired, and divert him from the prosecution of the real design which he had in view.

When he had dethroned the Lydian king, he completed the reduction of all Lesser Asia, and Syria, and then turning his arms against the king of Assyria, he invested Babylon, which he took after a siege of two years, and thus put an end to that great and powerful monarchy, B. C. 538. See **BABYLON.**

The destruction of Babylon forms a very interesting event both in profane and sacred history; and, more particularly, in its reference to the predictions of Scripture and the subsequent state of the Jews. To the particulars that have been recited under the article **BABYLON**, we shall here subjoin some other facts that serve to ascertain the precise accomplishment of the prophecies, pertaining to this event, both as to the causes that produced it, and the consequences that resulted from it. Isaiah, who began to deliver his predictions in the year 757 B. C., and who was put to death about the year 696 B. C., and Jeremiah, who died about the year 577 B. C. expressly foretold the destruction of this city, together with several circumstances that attended it, and that marked it as a very important era in the history of the world. Both these prophets speak with such assurance of its destruction, and of the manner in which it would be brought about, that they seem to describe a future event as if it had already occurred, and they had been witnesses of the catastrophe. "Babylon," says Isaiah (xxi. 9.), "is fallen; and all the graven images of her gods he hath broken unto the ground." "Babylon," says Jeremiah (li. S.) "is suddenly fallen and destroyed, howl for her, take balm for her pain, if so she may be healed." (See *Is.* xiii. 6, 9, 15, 18, 19, 22; xiv. 23, 24. *Jer.* l. 18, 29, &c.) Cyrus, who was the destined conqueror of Babylon, and who transferred the empire from the Babylonians

to the Medes and Persians, was foretold by name above an hundred years before he was born; and that the world might not be surpris'd at the prodigious rapidity of his conquests, God condescended to declare, that he himself would be his guide, and that in all his expeditions he would lead him by the hand, and would subdue all the princes of the earth before him. It was promised that he should be a great conqueror, subduing nations before him, &c.; and accordingly he subdued kings and took several cities, extending his conquests over the whole of Asia, from the river Indus to the Ægean sea. It was also promised that he should find rich spoil among the conquered nations; and according to Pliny's account (*H. N.* l. xxxiii. c. 15.) the treasure he found in his conquests amounted to a prodigious value; nor is this surpris'ing when we consider that those parts of Asia at that time abounded in wealth and luxury; that Babylon had been heaping up treasures for many years; and that the riches of Cræsus, king of Lydia, conquered and taken prisoner by Cyrus, were in a manner proverbial. "Thus saith the Lord to his anointed, to Cyrus," &c. &c. *Is.* xlv. 1—4. The time of the reduction of Babylon was specifically marked out by the prophet Jeremiah (xxv. 11, 12.) "These nations," says he, referring to the Jews and neighbouring nations, "shall serve the king of Babylon 70 years; and it shall come to pass, when 70 years are accomplished, that I will punish the king of Babylon, and that nation, saith the Lord." This prophecy was delivered, as appears from the 1st verse of the chapter, "in the 4th year of Jehoiakim, the son of Josiah king of Judah; that was the first year of Nebuchadnezzar king of Babylon," and from that time 70 years elapsed to the taking of Babylon and the restoration of the Jews. Several circumstances relating to the siege and taking of Babylon are likewise prefigured by the prophets. It was foretold that God would stir up the Medes and Persians against it (*Is.* xxi. 2. *Jer.* l. 11); and accordingly it was besieged by the united forces of the Medes and Persians under the command of Cyrus the Persian, the nephew and son-in-law of the king of the Medes. It was foretold that various nations should unite against Babylon (*Is.* xiii. 4. *Jer.* li. 27.); and accordingly Cyrus's army consisted of various nations. Moreover it was predicted that the Babylonians should be terrified, and hide themselves within their walls (*Jer.* li. 30.), which was actually the case, both at his first and second summons. It was also foretold, that the river should be dried up before the city should be taken, an event very unlikely to happen, because it was more than 2 furlongs broad, and deeper than the height of 2 men, standing upon one another. (*Is.* xlv. 27. *Jer.* l. 38. li. 36.); and it is well known that Cyrus turned the course of the river Euphrates, which ran through the midst of the city, as we have already stated under the article **BABYLON.** It was foretold, that this city should be taken by surpris'e during a feast, (*Jer.* l. 24. li. 39. 57.) and accordingly the city was taken in the night of a great annual festival. It was predicted that the king would be instantaneously seized with horror and perturbation of mind (*Is.* xxi. 3, 4) and this, we know, was the state of Baltazar or Belsazzar, when the event occurred. (*Dan.* v. 6.) The prophecies above cited were delivered by Isaiah and Jeremiah, and the facts are related by no less historians than Herodotus and Xenophon; and Isaiah lived above 250 years before Herodotus, and near 350 before Xenophon; and Jeremiah lived above 150 years before the one, and near 250 before the other. As Cyrus took Babylon in the year 538 B. C. Isaiah delivered his prophecies at least 160 years before the taking of Babylon; and Jeremiah sent his prophecies concerning Babylon to Babylon by the hands of Seraiah,

C Y R U S.

“in the 4th year of the reign of Zedekiah,” (Jer. li. 59.) which was 56 years before the taking of Babylon, for the 4th year of Zedekiah coincides with the year 594 B.C. That the destruction of Babylon was complete and final is no less expressly foretold and minutely described than other circumstances attending this event. For the prophecies see II. xiii. 19, &c. xiv. 22, 23, Jer. l. 13, 23, 39, 40. li. 13, 26, 29, 37, 42, 43; and for the manner in which they were accomplished, see the article B A B Y L O N.

After Cyrus had settled his affairs at Babylon, he went into Persia to make a visit to his parents who were still living, and on his way thither through Media, he there married the daughter of Cyaxares, (called in Scripture Darius the Mede) having with her as a dower the kingdom of Media in reversion, and then with his wife went to Babylon. He now (*viz.* in the year 536 B. C.) issued an edict, which has given celebrity to his name, permitting such of the Jews as were remaining from the Babylonish captivity, to return to Jerusalem and rebuild their temple. This decree was certainly obtained by the intercession of the prophet Daniel, who was already highly famed for his wisdom and integrity, in a licentious and truly infamous court. In Daniel, Cyrus seems to have placed the highest degree of confidence; which the prophet turned to the advantage of his oppressed countrymen. From concurring testimony, he no doubt pointed out to the prince the prophecies of Isaiah, in which himself was pointed out by the finger of heaven, as destined for the most important purposes; as designated to be a great conqueror, and the restorer of the Jews to their native land.

The learned Prideaux offers many reasons that might have concurred to induce the conqueror to comply with the urgent solicitations of the prophet, his friend and principal minister. Nor does the form of the edict, mentioned in the first book of Esdras, appear to us liable to the objection framed against it by an excellent biographer. Though Cyrus was born and brought up as an idolater, the interposition of providence must occasionally have made an impression on his mind, which Daniel seems to have converted to the best ends.

He speaks in his decree in the name of the lord of Israel; he was too wise to believe in the gods which his countrymen and the world in general were accustomed to worship, and was probably too much enlightened to refer the passing events of life, and the revolutions of empires, to what the ignorant would denominate chance. He had heard of the hand-writing on the wall, which none but Daniel could explain, and he only, according to his own profession, by the interposition of his God. He had been informed of the deliverance of the same excellent man from the lion's jaws, and he might be almost, if not altogether persuaded, that the God of Israel was the God that had made him “king of the whole world.”

Cyrus not only permitted and encouraged the Jews to return to their own country, but readily restored all the sacred vessels and furniture which Nebuchadnezzar had brought from Jerusalem, and deposited in the temple of Baal. Having established his empire, which was bounded on the east by the river Indus, on the north by the Caspian and Euxine seas, on the west by the Ægean sea, and on the south by Ethiopia and the sea of Arabia, upon a foundation not easily shaken; he fixed his residence in the midst of all these countries, spending generally 7 months of the year at Babylon in the winter season, on account of the warmth of that climate, 3 months at Susa, in the spring of the year, and 2 months at Ecbatana during the heat of the summer. Seven years being spent in a state of tranquillity, as he was equally beloved by his own natural

subjects, and by those of the conquered nations, he returned into Persia, which was the seventh time from his accession to the whole monarchy. At this time he was about 70 years of age; 30 of which had elapsed since his having been first made general of the Persian forces, and from the capture of Babylon, and 7 from his beginning to reign alone after the death of Cyaxares. His life had been uniformly sober and temperate, and he therefore enjoyed to the last a vigorous state of health. When he perceived that the time of his death was drawing near, he ordered his children and the chief officers of the state to be assembled near him; and, after having thanked the gods for all their favours to him during the course of his life, and implored similar protection and favour on behalf of his children, his country, and his friends, he declared his eldest son, Cambyses, his successor, and left the other, whose name was Tanaoxares, several very considerable governments. He gave them both excellent instructions, and represented to them that the main strength and support of the throne were neither the vast extent of countries, nor the number of forces, nor immense riches; but a due respect for the gods, a good understanding between brethren, and the art of acquiring and preserving true and faithful friends. After having given his hand to be kissed by all who were present, finding himself at the point of death, he added these last words: “Adieu, dear children, may your lives be happy; carry my last remembrance to your mother. And for you, my faithful friends, as well absent as present, receive this last farewell, and may you live in peace!” Having closed this address, he covered his face, and died, according to Xenophon, quietly in his bed; but if Herodotus is to be credited it was in battle, occasioned by the invasion of the Scythians. To the former opinion Dr. Prideaux, Rollin, and the writers of the Universal History, are decidedly inclined, and by this account he was at his death seventy years of age. Xenophon says that he was buried at Pasargarda, and that his monument was to be seen in the time of Alexander the Great.

Cyrus, says M. Rollin, may be justly considered as the wisest conqueror, and the most accomplished prince whose name occurs in prophane history. He possessed all the qualities requisite to form a great man; wisdom, moderation, courage, magnanimity, noble sentiments, a wonderful ability in managing men's tempers and gaining their affections, a thorough knowledge of all the branches of the military art, as far as that age had carried it, a vast extent of genius and capacity for forming, and an equal steadiness and prudence for executing the greatest projects. As real merit was the foundation and support of his greatness, he affected no self-importance and haughtiness of demeanour, but studied to render himself affable and easy of access; and he was amply compensated by the cordial affection and respect of his people. He was beloved, and had many friends, because his sentiments were kind and liberal, and he was friendly in his disposition and conduct. Cicero observes (lib. i. epist. 2. ad Q. fratrem), that during the whole time of Cyrus's government he was never heard to speak one rough or angry word; and this shewed a very singular degree of self-command. It was his invariable persuasion, that all his purposes and labours should tend to the happiness of his people. Whilst he was one day discoursing with his courtiers upon the duties of a king, he observed that a prince ought to consider himself as a shepherd; and that he ought to have the same vigilance, care, and goodness. Many great and good characters have been formed by adversity and affliction; but Cyrus was great and good without this kind of discipline. He himself informs us, that during the whole course of his life, the happiness of it was never interrupted by any unfortunate accident, and that in all his designs the success had answered

his utmost expectations. He adds, however, that in the midst of his uninterrupted prosperity, he still reserved in his heart a secret fear, proceeding from the changes and misfortunes that might happen; and this prudent fear was not only a preservative against insolence, but even against intemperate joy. As to the nature and motives of his wars and victories, M. Rollin considers Cyrus as having maintained a very different character from those conquerors who are influenced by ambition and avarice, and who are chargeable with violence and injustice. Although Cyrus was not in every respect justifiable, yet he revered the laws, and well knew that there are unjust wars, which being undertaken without just foundation, render the person concerned in exciting and producing them accountable for the blood that is shed. Cyrus's conquests were the consequences of the victories he obtained over Croesus, king of Lydia, who was master of the greatest part of Lesser Asia, and over the king of Babylon, who was master of all Upper Asia, and many other countries; both which princes were the aggressors. With good occasion, therefore, is Cyrus represented as one of the greatest princes recorded in history; and his reign justly proposed as the model of a perfect government, which it would not be, unless justice had been the basis and foundation of it; "Cyrus à Xenophonte scriptus ad justitiam imperii." Cic. l. i. epit. 1. ad Q. fratrem. Prideaux's Connection. Universal Hist. Rollin's Anc. Hist.

CYRUS, second son of Darius Nothus, king of Persia, was born about the year 423 before Christ. He was sent at the age of sixteen to govern the provinces of Asia Minor. In this situation he assumed all the haughtiness of royal birth, and inflicted the punishment of death on some of his own relations, who approached him without a due regard to the customs and ceremonies of the times. For this he was called severely to account by his father, who, on the present, and on some other occasions, was with difficulty reconciled to him. He engaged in a conspiracy against his elder brother, for which he was condemned to death, but the sentence was commuted into banishment to the provinces; being, however, of a restless disposition, as well as cruel and ambitious, he raised an immense army, under false pretences, but really with a view of attacking his brother. On the plains of Cunaxa, in the province of Babylon, he came in fight of Artaxerxes at the head of 100,000 men. Cyrus was attended by Clearchus, who advised the prince to remain in the rear; but prudence and fear were not among his qualities; he posted himself in the van; and so great was his success at the outset of the business that he was saluted king by those around him. Rushing, however, too far into danger, he was slain, at the moment when victory appeared to be deciding the fate of the day. This battle is supposed to have been fought B. C. 400. Universal History. Prideaux and Plutarch.

CYRUS, in *Ancient Geography*, one of the largest rivers in Asia. Strabo says, that it had its source in Armenia, that it ran through this country, Iberia, and Albania, and that after having received the waters of the Araxes, and of several other rivers, it discharged itself by two mouths into the Caspian sea. Ptolemy calls it *Cyrrhus*, and Plutarch *Cyrnus*. The former says that it was only a branch of the Araxes that flowed into this river, and that the other branch ran into the Hyrcanian sea. Strabo, Plutarch, and Appian say that it had two mouths; but Herodotus gives it 40.—Also, a river of Asia, in Media. Ptolemy places its mouth between the Cambyfes and the Amardus.—Also, a river of Asia, which ran through the valleys of Persia, near the Paspargadæ, according to Strabo; who adds that the king had

given it the name of Cyrus instead of its ancient appellation of Agradate. It discharged itself into the Persian gulf.—Also, an ancient town of Syria, called *CYRRHUS*; which see.—Also, a town of Greece, in the island of Eubœa.

CYSSUS, a town and port of Asia, opposite to and eastward of the town of Chios, in an island of the same name. This port is known by the victory which the Romans gained here over the fleet of Antiochus, in the year of Rome, 561. Livy, l. xxxvi. c. 44.

CYST, in *Surgery*, the bag, or membrane, in which an encysted tumor of the scirrhus, atheromatous, or sarcomatous kind, is included. In extirpating these tumors, if, by neglect, or accident, the cyst, or any considerable part of it be left behind, the tumor will not fail to return. Indeed, if the tumor be a scirrhus, the contents are hard enough to make a clear extirpation of it, notwithstanding its including coats be wounded; but when the matter of the tumor is soft, or fluid, by its escaping the tumor will become flaccid; so that it will be hardly possible to make a clear extirpation of the cyst without leaving some fragments of it behind, which must, in that case, be brought away afterwards by suppurations, digestives, and a proper treatment; and when the sinus is, by this means, cleared, the wound may be safely healed, without any danger of the return of the complaint.

CYSTICA ARTERIA; is a branch of the hepatic artery, which supplies the gall-bladder. See ARTERY.

CYSTICAPNOS, in *Botany*. See FUMARIA.

CYSTICS, denote medicines against distempers of the bladder. See STONE, LITHONTRIPTIC, &c.

CYSTICUS DUCTUS, in *Anatomy*, is the tube of communication between the gall-bladder and the hepatic duct. See LIVER.

CYSTIRRHŒA. See CATARRHUS vesicæ.

CYSTIS FELLEA, a Latin term for the gall-bladder.

CYSTIS, in *Botany*, a name by which many authors have called the *alkekengi*, or *winter-cherry*. It had this name cystis, from the remarkable character of its fruits being contained in a skinny bladder, or bag. It was generally, however, called *halicacabum*.

CYSTIS, the same with vesica or bladder.

The word is *κυστις*, which signifies the same.

CYSTIS *choleodocha*, the same with felleculus, or vesicula fellis.

CYTA, CUTATIS, in *Ancient Geography*, a town of Asia, in the kingdom of Colchis (now Mingrelia) situated at the mouth of the river Cyaneus, N. E. of Tynderis. It is said to have been the birth-place of the famous Medea, denominated from thence, by the poets, Cytzis.

CYTA, or *Cytea*, an ancient town of Scythia. Steph. Byz.

CYTEUM, SONDAG, a town of the Tauric Chersonesus, near the sea, N. E. of the promontory.—Also, a town situated on the northern coast of the isle of Crete; now called *Corax Settia*. It had been episcopal.

CYTAIS, a country of Asia, in Carmania.

CYTHARA, in *Music*. See CITHARA.

CYTHEORUM, in *Ancient Geography*, a town of Asia, in the Pontus Polemoniacus; the *Colyorum* of Pliny, and *Colyora* of Xenophon.

CYTHERA, now CERIGO, one of the Greek islands, situated in the Laconic gulf, opposite to Malca, or promontory of Laconia, from which it is distant, according to Strabo, 40 furlongs. Stephanus says, that it derived its name Cythera, from a Phœnician, called Cytherus, who settled here. Before his arrival it was called Porphyris, or Porphyrisa, as some say, because it abounded with porphy-

ry; or, as others affirm, on the authority of Aristotle, because the best scarlet was dyed here. It is about 60 miles in compass, blessed with a fruitful soil, and has several havens, one of them very safe and spacious, called anciently Scandea, about ten furlongs from the city of Cythera, situated on the southern coast of the island, and once famous for the temple of Venus, surnamed Urania, or heavenly; the most ancient and most respected temple in Greece. See CYTHEREA.

CYTHERA, a town of the island of Cyprus, supposed by some to be the present village, *Conucha*.—Also, a town of Greece, in Thessaly.

CYTHEREA, in *Mythology*, the surname of Venus, so called from the island Cythera, into which her worship was brought by the Pœnicians, and where she had a temple esteemed the most ancient in Greece. In this temple was a statue of the goddess, in complete armour, holding, like Pallas, a javelin in her hand. Upon her first springing out of the froth of the sea, for such was her origin, she is said to have been borne to the shores of this island by the Zephyrs, surrounded by the Loves, the Tritons, and Nereides, reclining in a languishing posture, in a sea-shell. They give the name of *Cytheriades* to the Graces which attended her on the shore without quitting her, except on those occasions, when she rather chiose to be waited on by the Pleasures. From this island she was carried to Cyprus; and this island, as well as Cythera, was in a peculiar manner sacred to her.

CYTHERIUM, in *Ancient Geography*, a town of Italy, situated in the interior of Oenotria; supposed to be the present *Cyrisano*.

CYTHERON, a mountain of Greece, in Bœotia, consecrated to Jupiter Cytheronius. (Pausan. l. ix. Bœotic.) In a defile of this mountain Oedipus is said to have slain his father Laius.

CYTHERUS, a river of the Peloponnesus, in the Elide, where it watered the town of Heraclea.—Pausanias says that at the source of this river there was a temple consecrated to the nymphs called *Ionides*. This river is called *Cytherius* by Strabo.

CYTHINON, in *Botany*, a name given by the ancient Greeks to the yellow wood, called also thapsum and chrysoxylon, a wood used in dyeing cloths, &c. See CYMENE. It was also called *Scythicum lignum*, Scythian wood, from the country whence it was brought; and from this last name it is easy to deduce the name cythinon. The old Greeks often wrote cythinon for scythion, and the leaving out the initial s, which was a common practice among them, reduces this word to cythinon. Familiar instances of this practice occur to us in the words milax for smilax, maragdas for fmaragdas, &c.

CYTHIUM, in *Ancient Geography*, a town of the island of Cyprus, in which Cimon died.

CYTHNUS, one of the Greek islands, distant about 12 miles E. of Ceos, and esteemed by Strabo to be one of the most fruitful islands of the Ægean sea. It was the birth-place of Cydias, an eminent painter, mentioned by Dionysius, and his commentator Eustathius. The cheese of Cythnus was, according to Stephanus and Julius Pollux, in great estimation among the ancients. This island is now called THERMIA; which see. On the southern coast there are some remains of an ancient and very magnificent city. Cythnus was also called *Ophiussa* and *Dryopis*.

CYTINA, a town of Greece, in Thessaly. Steph. Byz.

CYTINIUM, a town of Greece, in the Doride, according to Strabo, who adds, that it was one of the cities

which caused the country in which they were situated to be called *Tetrapolis*.

CYTINUS, in *Botany*, (perhaps, as Martyn suggests, “from *κύβωτος*, a name given by Theophrastus to the blossoms of the pomgranate,” whose calyx the flower in question resembles in shape.) Linn. Gen. 878. Schreb. 609. Willd. Sp. Pl. v. 4. 589. Juss. 73. Class and order, *gynandria octandria*. Nat. Ord. *Arifolochia*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, tubular, somewhat bell-shaped, coloured, permanent; its border four-cleft. *Cor.* none. *Stam.* 8; anthers sessile on the style under the stigma, oblong, 2-celled. *Pist.* Germen inferior, roundish; style cylindrical, thick, rather shorter than the calyx; stigma in 8 lobes. *Peric.* Berry globose, crowned with the calyx of 8 cells. *Seeds* numerous, minute.

Ess. Ch. Style 1. Calyx superior, 4-cleft. *Cor.* none. Anthers 8. Berry of 8 cells. *Seeds* many.

The only known species is *C. hypocistis*, Rape of Cistus, a fleshy pale-yellowish plant, parasitical on the roots of several species of *Cistus* in the south of Europe. It is figured in the wooden cuts of many old authors, also in *Cavan. Ic. t. 171*. Its qualities are said to be of an astringent nature.

CYTIS, in *Ancient Geography*, the name given by Pliny to an island which he places at the entrance of the Red sea.

CYTISO GENISTA, in *Botany*. See GENISTA.

CYTISUS, (*κύβωτος* of the ancient Greeks.) Linn. Gen. 378. Schreb. 499. Willd. Sp. Pl. v. 3. 1118. Juss. 354. Class and order, *diadelphia decandria*. Nat. Ord. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* of 1 leaf, bell-shaped, obtuse at the base; upper lip of 2, lower of 3 teeth. *Cor.* papilionaceous; standard ovate, erect, reflexed at the sides; wings as long as the standard, straight, obtuse; keel swelling, pointed, of 2 petals. *Stam.* Filaments in 2 sets (single and nine-cleft), ascending; anthers roundish. *Pist.* Germen oblong, compressed; style ascending; stigma obtuse. *Peric.* Legume oblong, taper at the base, of 1 cell. *Seeds* several, kidney-shaped, compressed.

Ess. Ch. Calyx 2-lipped; the upper of 2, lower of 3; teeth. Legume of 1 cell, with several seeds, taper at the base.

The species are very numerous, shrubby, without thorns; their leaves ternate; their flowers copious, generally yellow; except *C. purpureus*, an elegant Austrian species, frequent in our gardens. *C. Laburnum*, so commonly cultivated, even in towns, is a native of Austria, Switzerland, &c. Its wood is hard and valuable; its bunches of flowers most ornamental; but its seeds bitter and poisonous. Hares and rabbits are particularly fond of the leaves and bark. *C. sessilifolius* is a smaller, but very pretty and also hardy species. *C. Cujan* is a tropical shrub, which but ill accords with this genus.

CYTISUS of Virgil. See *MEDICAGO arborea*.

CYTISUS, in *Gardening*, comprehends plants of the evergreen and deciduous flowering shrubby kinds; of which the species chiefly cultivated are, the laburnum, (*C. laburnum*) the common cytissus, (*C. sessilifolius*), and the hairy evergreen cytissus, (*C. hirsutus*.)

Method of Culture.—These are plants which are all capable of being increased by seeds, and many of them by cuttings and layers likewise.

In the first mode the seeds should be sown, either on beds, or, where the plants are to remain, in the spring, as about March, being in this way, when of sufficient growth, transplanted into nursery-rows, to remain till of a proper
size

size for being planted out in the situations where they are to grow. When sown where they are to remain, they only require to be kept perfectly free from weeds, and trimmed to one good plant in a place, giving the tender forts the protection of mats during the severity of the winter-season.

The trees of most of the forts affords seeds in abundance in the autumnal season. In the cuttings method, they should be made from the young shoots, ten or twelve inches in length, and planted out in a rather moist, shaded situation, either in the early autumn or spring months, in rows twelve or eighteen inches apart, and eight or ten in the rows. They mostly become well rooted in the course of twelve months; and would then be kept perfectly clear of seeds till removed.

The layers may be laid down either in the summer, autumn, or spring seasons; and when the plants are well rooted, they should be taken off, and planted out in nursery-rows, as described above, for the other methods.

In the management in the nursery they only require to be preserved from the injury of weeds, and to have the land dug well between the rows annually in the autumn, till they are removed; being suffered to take their natural growth in a great measure while there.

Most of the forts are hardy, and succeed well in almost any soil or situation. The third fort should have a dry soil, and sheltered situation, as it is liable to be injured by frost. It may also be planted in pots, and placed in the greenhouse, during the winter-season, when necessary.

They are all plants which are very ornamental for the borders, clumps, and other parts of ornamented grounds; affording much variety by their numerous beautiful bunches of flowers. The large forts should be placed towards the back parts, and those of less growth towards the fronts and more conspicuous parts of such situations.

CYTNI, in *Ancient Geography*, a people placed by Ptolemy in the eastern part of the Upper Pannonia.

CYTONIUM, a town of Asia Minor, on the confines of Lydia and Mysia.

CYTORUS, or CYTORUM, a town situated on a part of the coast of Paphlagonia, which is inclined from the south-west to the north-east, between the promontory Carambis and Amastris. It is thought to have been founded by a colony of Milesians. According to Strabo, it had been a port of the inhabitants of Sinope. In its vicinity was a mountain, which produced a beautifully-veined box-tree. Its foundation is ascribed to Cytor, son of Phryxus; and it was one of the four towns which formed the estate of Amastris, sister of Darius, and wife of Dionysius, tyrant of Heraclea, at the time of the destruction of the Persian empire. It is mentioned by Pliny, Virgil, Suidas, and Xenophon, the latter of whom says that it was a sea-port, where the Greeks embarked; and after having navigated a day and night, they arrived at Sinope.

CYTTIUM, a town situated on the southern part of the island of Cyprus; called by Pliny and Ptolemy *Cittium*.

CYULES, a name given by William of Malmesbury, Gildas, and others, to the long galleys in which the Saxons, under the command of Cerdic, were transported to Britain. Of these galleys there were five, and the number of men conveyed by them was 15,800; and therefore they must have been very capacious, and the barbarians must have been satisfied with very inconvenient accommodations.

CYZICENE ÆCUS, or hall: a name given to apartments of a particular construction in the ancient villas, and

thus explained by Vitruvius. "They are situated towards the north, generally have a view of the garden, and have valved doors in the middle. They are of such a length and breadth, that two trichmia, with their surrounding appendages, may be placed opposite to each other. They have also valved windows on the right and left, that the garden may be seen through their openings, and their height is equal to one and a half their breadth. These Cyzicenses, or Cyzicena, were, among the ancient Greeks, what the *trichinia* and *conacula* were among the Romans.

CYZICUM MARMOR, a species of marble, so called by the ancients from the great use made of it by a statuary called Cyzicus. It was white, with fine narrow veins of black, and was called also *PROCONNESIUM marmor*.

CYZICUS, or CYZICUM, in *Ancient Geography*, a town in that part of Asia Minor which lay on the Propontis, seated on an island of the Propontis, bearing the same name, but joined to the continent with two bridges by Alexander the Great. It had two ports, which were formed so as to close themselves: one of them, called *Panormus*, was the work of nature, the other, the production of art, was called *Chytus*, from the Greek *κλύω*, denoting a work formed by digging; somewhat similar to the oriental *Cothon*. One part of this city was on a plain, another towards mount Arctos. According to Pliny, it consisted of a colony of Milesians. It is said to have borrowed its name from Cyzicus, king of that island and the adjacent continent, who is said to have been killed through mistake by Jason, the Argonaut. When this city became first known to the Romans, it was one of the richest and largest in Asia: and hence was styled by Florus, the Rome of Asia, and celebrated for its walls, bulwarks, haven, marble towers, &c. Among its magnificent buildings, the chief temple is particularly celebrated by the ancients;—the whole structure was of polished marble, and the joinings covered with lines of gold; the pillars were four cubits thick, and fifty high, each of one piece. The statue of Jupiter, which stood in the temple, was of ivory, and most exquisite workmanship. In subsequent ages, this city made a glorious stand against Mithridates, who lost under its walls no fewer than 300,000 men, and after all failed to reduce it. At this time it was distinguished by wise laws, a naval power of 200 gallees, and three arsenals of arms, of military engines, and of corn. (Strabo, l. xii.) But in the year 365, the city and island of Cyzicus were constrained after an honourable defence, to yield to the power of Procopius, aided by the Gothic princes. However, the ancient inhabitants of this city and island were generally deemed a cowardly and effeminate race; inasmuch that a man of a timorous disposition was contemptuously called a "Cyzican." Cicero represents them as a quiet and inoffensive people, unaccustomed to ambitious machinations against the neighbouring nations, and willing to sacrifice every thing to the enjoyment of the sweets of peace.

The current coins of this island, called stater, weighing 18 drams, were engraved with such exactness, nicety, and skill, that they were looked upon in ancient times as a miracle of art. Thence originated the Greek proverb *Κιζικονια σαφαις*, an expression used in commending any eminent performance in the art of engraving; as if the Cyzican statues were the utmost effort of that art. This coin represented on one side Cybele, the great mother of the gods, and a lion on the other; which has induced some to think that the above-mentioned proverb was a taunt on those who boast of their prowess, and affect to appear like lions, though they be in reality as timid and fearful as women. (Erasm. *Cilind.*)

The

The inhabitants of Cyzicus made pretensions to very high antiquity; and believed that their city had been given by Jupiter to Proserpine for her dowry, on which account they worshipped her as their chief deity. Appian (in Mithrid.) has particularly described the beauty, magnitude, riches and laws of this city. It was ruined by an earthquake; and the fallen marbles and pillars were conveyed to Constantinople, for the embellishment of that city. Under the Romans it was the metropolis of the consular Hellefpont, and a metropolitan see under the patriarchate of Constantinople; but it is now little better than a village, known under the names of Chizico, Spiga, and Palormi.

CZACHEC, in *Geography*, a town of Lithuania, in the palatinate of Brzesc: 25 miles E.N.E. of Brzesc.

CZACSANICH, a town of Poland, in the palatinate of Braclaw, 38 miles S. of Braclaw.

CZAR, a title of honour assumed by the grand-dukes, or, as they are now styled, emperors of Russia.

The natives pronounce it *tzar*, or *zaar*; and this, as some have supposed, by corruption from Cæsar, emperor; from some fancied relation to the Roman emperors; on account of which they also bear the eagle as a symbol of their empire.

When the czar, Peter I., required his imperial title to be acknowledged by the court of Vienna, there was great difficulty made about it: but the czar shewing them, by his ambassador, an original letter of Maximilian I. to the czar John Basilowitz, the count Zinzendorff, grand chancellor of the court of Vienna, caused the archives of the house of Austria to be searched for the original of that letter; but no such letter was found: however, the hand-writing of the secretary, and the signature of Maximilian, being known and acknowledged, the title of emperor was allowed to Peter and his successors, which they continue to enjoy. This anecdote, M. l'Abbé Langlet acknowledges to have received from count Zinzendorff himself, 1722. Encycl.

It is generally affirmed, that John Basilowitz, or Iwan Vassilievitch, declared himself czar in the year 1547; though this title is expressly attributed in history to Russian sovereigns of a period far more remote; whether it was actually borne by them, or whether the old annalists added it merely to signify, indiscriminately, a monarchical dignity, or modern historians have arbitrarily applied it to them without sufficient reason. We are told by Lomonosof, in his ancient Russian history, that Vladimir, the Saint, who died in 1015, on his marriage with the Greek princess, took upon him the title of czar. The same author says, in his abridged chronicle, that not only Vladimir Vsevolodovitch Monomachus, who began his reign in 1114, was crowned czar of all Russia; but also that Vassilly Ivanovitch, who died in 1535, first wrote himself in the last year of his reign, czar and self-holder of all Russia. With regard to the derivation of the term czar or tzar, it has been alleged, that, in the Russian bible, it denotes a king; yet the ancient Russian writers make use of it also when speaking of the Greek emperors. Moreover, the derivative *tzarstvo* means kingdom; thus, in the pater-noster, *tzarstvoe tvoe*, thy kingdom; but also, in general, it signifies empire; and it is even used in the kingdoms of nature.

M. Sperlingius, in his dissertation on the majesty of the name *konning*, observes, that the Russian princes never bore the name *czar*, till their people had embraced the Greek faith: before that time, he says, they were called *konger*, KING.

The Russians are the only persons who by czar denote a sovereign; and Mr. Tooke, as to the etymology of the word, thinks it scarcely imaginable that it has been formed by an abbreviation of Cæsar and Tzesar; for, throughout

the New Testament, where the word occurs, it was rendered by *kesar*, perhaps from the Greek Bible, which came into Russia with the Christian religion; this was afterwards changed into *tzesar*, and that again has been altered into *imperator*. Mr. Tooke farther observes, that, in the old Russian year-books, mention is frequently made of Tartarian and Siberian tzars, and *tzarevitches* (tzar's sons); thus we find, among many other instances, the tzar of the golden horde, the tzar of the krim, the tzar of Kazan. This title has not been negligently introduced, and appropriated by the Russian historians; for the sovereigns of Russia have borne it since the conquest of those kingdoms, to this day, as it stands in the imperial title; "tzarina of Kazan, tzarina of Siberia, &c." We may, therefore, suppose, says Mr. Tooke, with the highest probability, that the Russian nation, on finding these tzars among the neighbouring people, borrowed the title from them, and adopted it into the Russian language, to which it is entirely foreign. Tooke's Life of Catharine II. vol. iii.

CZARLAKOW, in *Geography*, a town of Poland, in the palatinate of Kaminiac; 34 miles W.N.W. of Kaminiac.

CZARNAKI, a town of Poland, in the palatinate of Podolia; 60 miles N.N.E. of Kaminiac.

CZARNEWECYZE, a town of Lithuania, in the palatinate of Brzesc; 10 miles N.E. of Brzesc.

CZARNKOW, a small town of the grand duchy of Warsaw, which, since the peace of Tilsit, belongs to the kingdom of Saxony. It is situated in the palatinate of Posen; 26 miles N. of Posen.

CZARNOKOZYNECZIE, a town of Poland, in the palatinate of Kaminiac; 12 miles W. of Kaminiac.

CZARSKOEZELO, the famous summer residence of the sovereigns of Russia, about 30 miles from Petersburg, is situated in an open pleasant country, diversified by little hills, meadows, and woodlands. The versts, or distances, are marked on the side of the road by columns of marble, jasper, and granite; and there are 1100 globular lamps, which are lighted when the court is there.

Czarskozele owes its origin to the empress Catherine I. its embellishments to Elizabeth, and its present tasteful magnificence to Catherine II., grand mother to the emperor Alexander. The gardens are laid out in the English manner. Their principal curiosities are a small temple, containing an exquisite collection of antique and modern statues, a magnificent bath, picturesque artificial ruins, and a small town in commemoration of the acquisition of the Taurida. Storch's Picture of St. Petersburg.

CZARTORYSK, a small town of Austria, in the kingdom of Galicia and Lodomeria, or that part of Poland, which, at the final partition of the country, was allotted to the house of Austria. It has an old castle, and is situated in Volhinia, in the district of Luck, or Luceorien.

CZASLAU, a small town of Austria, situated in Bothnia, on the river Crudimka; 51 miles S.E. of Prague. It is the capital of the circle of the same name, and was built in 796. The principal church has the highest steeple in Bohemia; it contains the ashes of John Zisca, the founder of the Hussites, who was buried here in 1424.

CZASNIKI, a small town of Russia, in Lithuanian Russia, which formerly was part of Poland, in the district of Polock.

CZASTAWSK, a town of Bohemia, in the circle of Czaslau; 12 miles S.W. of Ledetsch.

CZATORISKO, a town of Poland, in the palatinate of Volhynia; 42 miles N.N.E. of Lucka.

CZATZA, a town of Hungary, on the river Kuffutsha; 10 $\frac{1}{2}$ miles N.N.E. of Vienna, and 48 N. of Cremnitz.

CZAY-KOWKA, a town of Poland, in the palatinate of Volhynia; 38 miles N.E. of Zytomiers.

CZAZIN, a town of Croatia; 20 miles S.S.W. of Novi.

CZCRAZAN, a town of Poland, in the palatinate of Braclaw; 64 miles N.W. of Braclaw.

CZCZANOW, a town of Poland, in the palatinate of Belz; 36 miles S.W. of Belz.

CZEBRYN, a town of Poland, in the palatinate of Kiow; 44 miles S.S.E. of Czerkafy.

CZECHTITZ, a town of Bohemia, in the circle of Czaflau; 10 miles S.W. of Ledetsch.

CZECZORA, a town of European Turkey, in the province of Moldavia; 14 miles E. of Jaffy.

CZEILTÉ, a town of Hungary; 20 miles W. of Topoltzan.

CZEMER, in *Medicine*, a name given by the people of Hungary, and some of the neighbouring nations, to a very troublesome distemper of the wrists, and lower part of the arms, to which the people of this part of the world are very subject. It consists of a tumour not hard, but very painful to the touch. The general method of cure is, by giving first a strong emetic, and then confining the patient to his bed, and to the use of sudorifics, which in some days carry it off. *Phil. Transf.* N^o 243.

CZENSTOCHAU, or **CZENSTOCHOW**, *Czenstokowa*, in *Geography*, a small town of the grand duchy of Warsaw, which, from the last partition of Poland, until the peace of Tilsit, belonged to Prussia, and is a province of the kingdom of Saxony. It is situated on the river Warta; 90 miles S.E. of Breslau, and 60 N.W. of Cracow. Near this place, on the Clarenberg, is a small fortress, with a convent of monks, of the order of St. Paul, the Hermit, celebrated for a picture of the Virgin Mary, which, it is pretended, was painted by the evangelist St. Luke, and which is styled the "Treasure of the Virgin," because it draws pilgrims from all quarters. Czenstochau was considered as the *Loretto* of Poland.

CZERNETZ, or **TSCHERINCK**, a town of Walachia, near the north side of the Danube; 44 miles E. of Belgrad, and 106 W. of Buchoreft.

CZERNIKOW, **CZERNIKOF**, or **TSHERNIGOW**, *Tshernigof*, a town of Russia, in Europe, formerly in the government of Kiew, but which, since the year 1781, constitutes a separate government. It is situated on the river Desna; 90 miles N.E. of Kiew, and is the see of an archbishop. N. lat. 51^o 20.

CZERNITZ, a small town of Walachia, in that part of the country which belongs to the empire of Austria.

CZERNOMITZ, a town of Hungary, on the river Gran; 11 miles N.N.W. of Bakan.

CZERNOWITZ, a town of Austria, in the kingdom of Galicia and Lodomeria, and chief place of that part of the country called the Buckowina, which became an Austrian province in 1777. It is situated on the river Pruth.

CZERNVODA, a town of European Turkey, in the province of Bulgaria; 42 miles N. of Ternovo.

CZERSKO, or **CZERSK**, a handsome town of the grand duchy of Warsaw, which, since the peace of Tilsit, is a province of the kingdom of Saxony. It is the chief place of a district of the same name, and situated on the Vistula; 24 miles S.E. of Warsaw. N. lat. 51^o 58'.

CZERWENITZA, a poor miserable village of Austria, in upper Hungary, a short day's journey from Caschau, re-

markable only for its opal mines. The rocks are formed of decomposed porphyry and trafs. The hill is some miles in extent, and has been opened in several places, and most successfully in three particular spots, where guards are stationed to prevent strangers from digging. These mines yield several different kinds of opal, some of no value to the jeweller. It is, however, supposed, that the most valuable opals which pass in commerce under the name of oriental opals are really from the mines of Czerwenitza. Tavernier, part ii. p. 293, says; "Pour ce qui est de la Hongrie, il y a une mine d'où l'on tire des Opals, et il ne s'en trouve en aucun lieu de la terre qu'en celui là." Mr. Fichtel, in his "Mineralogische Bemerkungen von den Carpathien," that is to say, mineralogical observations on the Carpathian mountains, page 595, is of the same opinion, and assures us there are papers in the archives at Caschau, which shew that, about four centuries ago, 300 men were engaged in these mines, which circumstance would account for the quantity of opals that has been for so long a time in the market.

The mines of Czerwenitza produced, perhaps, that very opal, to obtain which Anthony could proscribè a Roman senator, and to keep which a Roman senator could suffer banishment. Townson's Travels in Hungary.

CZESTIN, a town of Bohemia, in the circle of Czaflau; 13 miles from Czaflau.

CZETEZUTA, a town of European Turkey, in the province of Moldavia; 6 miles S. of Jaffy.

CZETNEK, a town of Hungary; 26 miles W. of Caschau.

CZETWERNIA, a town of Poland, in the palatinate of Volhynia; 16 miles N. of Lucko.

CZIEZER, a town of Hungary; 21 miles E. of Caschau.

CZIFFEN, a small town of Austria, in Lower Hungary, situated on an extensive plain, and formerly a place of some consequence.

CZIGLED, a town of Austria in Lower Hungary, in the district of Ketskemet. It is situated in a very fertile country, and belongs to the nuns of St. Clara at Buda. After the battle of Sicambria, it became the residence of the Zuklers, who were among the principal leaders or chiefs of the Transylvanians.

CZIGLIN, a town of Sclavonia; 7 miles N.W. of Brod.

CZIRKNITZ. See **CIRKNITZ**.

CZIRNIECHOW, a town of Poland, in the palatinate of Volhynia; 12 miles W. of Zytomiers.

CZIROKOGRODNA, a town of Poland, in the palatinate of Braclaw; 54 miles N.N.W. of Braclaw.

CZNICLOW, a town of Poland, in the palatinate of Sandomirz; 24 miles N.W. of Sandomirz.

CZOCHWIACE, a town of Poland, in the palatinate of Kiow; 4 miles S. of Bialacerkiev.

CZONGRAD, or **CZONGRODT**. See **CSONGRAD**.

CZORNOW, a town of Lithuania, in the palatinate of Brzesc; 18 miles S.S.W. of Brzesc.

CZUCKERMANDEL, a small town of Austria, in Lower Hungary, in the district of Presburg, not far from Presburg castle, inhabited chiefly by Jews.

CZUDNATZ, a town of Poland, in the palatinate of Lublin; 40 miles N.W. of Lublin.

CZUDNO, a small town of Turkey, in Europe, in Upper Moldavia, on the river Pruth.

CZUGUR, a river of European Turkey, in the province of Moldavia; which runs into the Pruth, near Stephanowze.

CZUWACHIANS,

C Z U

CZUWACHIANS, a tribe of Tartars dispersed over the right bank of the Wolga, in the government of Kafan, and extending as far as Ufa, in that of Orenburg; and, on this account, denominated Ufian Tartars. They are a very laborious people; and their number is said to amount to upwards of 100 thousand persons, inhabiting small towns, and a great number of villages. Their two chief places are Silisgorod and Kobshatsk. They acknowledge the god, named Tor, but pay almost an equal worship to the sun. They have no temples; but, in the midst of forests, pay their homage to Tor, and offer sacrifices, consisting of black lambs, which, in the lamb-season, they slaughter in such numbers as their jumak, or high priest, has ordered. The yumaski, who are priests subordinate to the jumak, possess the greatest authority among the Ufian Tartars. These are their only physicians, when any are ill; the only judges

C Z Y

to whom they appeal for deciding their disputes; and the only counsellors to whom they apply for advice in affairs of moment. Like the other Tartars, they abstain from hog's flesh, and from working on Friday. They annually celebrate a kind of Easter, at a place, and on the day determined by the grand jumak. Every family repairs thither with the most profound meditation, carrying their lamb, which is killed in the name of Tor, and after the sacrifice it is eaten by those who brought it. All of them use nearly the same kind of dress, and the same kind of food with the Barshkirians, whom they also resemble in their manners. *Chontrean's Travels.*

CZYRCASSY, CZYRKASSY, or *Czircaffi*, in Latin *Czircaffia*, a small town of Russia, in Europe, in the Ukraine, situated on the Dnieper, in the government of Kiew, or Kiow; 105 miles S.E. of Kiow. It has an old castle.
